Title: Maternally controlled length of the neurogenic period determines the number of produced neocortical neurons

Authors: *B. K. STEPIEN[1], S. VAID[2], R. NAUMANN[2], A. HOLTZ[2], W. B. HUTTNER[2]

Abstract: Mammalian species exhibit an enormous variability in the size of their neocortex and the number of neurons therein, which are generated during a relatively short developmental window. The number of neurons produced in a given species is determined by the pool sizes of the various neural stem and progenitor cells, their proliferative capacity and the various progenitor lineages, as well as by the length of the neurogenic period. Mathematical modelling has suggested that distinct classes of mammals can be distinguished that differ in their progenitor lineages and modes of progenitor cell division (Lewitus et al., 2014 PLoS Biology 12, e1002000). Remarkably, within each of these classes, the final neuronal output was found to be directly correlated to the length of the neurogenic period.
In the present study we have explored, in a mouse model system, the previously proposed link between the neurogenic period and gestation length on the one hand and neuron production on the other hand, and have aimed at the identification of cell-extrinsic and/or maternal factors that link these two parameters. We have used mouse inbred strains with genetically determined, different gestation lengths to determine the number of neocortical pyramidal neurons produced in relation to the length of the neurogenic period. Given the difference between gestation lengths of up to 10% between the strains with shortest and longest gestation, we observe that the long-gestation strain produces more upper-layer, but not deep-layer, neurons than the short-gestation strain. Moreover, the onset of gliogenesis, which in mouse follows neurogenesis, appears later in the long-gestation strain, consistent with a lengthening of the neurogenic period. The increased neuron production upon lengthening of the neurogenic period depends on the maternal environment as embryo transfer between the short- and long-gestation strains results in a neuron production that is consistent with maternal phenotype.
Taken together our results point to a common developmental mechanism synchronizing gestation with neurogenic period and suggest an important role of maternally-derived factors in determining neocortex size. Our data open the door for further investigation of the maternal-fetal communication and its effect on organ growth.

Title: The effects of apolipoprotein E (APOE) polymorphism on human hippocampal neurogenesis

Authors: *H. LEE[1], S. THURET[2]
[1]Inst. of Psychiatry, Psychology, and Neurosci., King's Col. London, LONDON, United Kingdom; [2]Dept. of Basic and Clin. Neurosci., King's Col. London, London, United Kingdom

Abstract: Apolipoprotein E (APOE) polymorphism is the most common genetic risk factor for Alzheimer's disease (AD), the ε4 allele of which is known to both increase the overall onset of the disease and also decrease the age of onset. Growing body of evidence suggests that APOE polymorphism may differentially affect adult hippocampal neurogenesis in the dentate gyrus, which has been implicated in AD progression in its own right. However, the impact of APOE isoforms on hippocampal neurogenesis at a cellular/molecular level is yet to be fully understood. We have performed a time-course characterization for neurogenic properties in isogenic human induced pluripotent stem cell lines that differ only in APOE genotype by differentiating them into hippocampal neural progenitor cells (NPC) and then dentate gyrus granule cell (DGC)-like neurons. We found that APOE4/4 cells showed significantly different patterns of expression for hippocampal NPC markers and PROX1, the marker for mature DGCs, compared to APOE3/3 cells. The gene expression pattern of APOE and immunolabeling of MAP2 and DCX did not significantly differ between APOE3/3 and APOE4/4 cells. The isogenic lines exhibited differential phenotypes in the expression of Ki-67, a marker for cell proliferation, during DGC differentiation. Taken together, our findings suggest that APOE genotype can impact the course of hippocampal neurogenesis, and that sustaining normal levels/pattern of hippocampal neurogenesis can be a potential target for early intervention against AD for APOE4-carriers. We are now aiming to investigate whether APOE genotype interacts with environmental factors to either exacerbate or ameliorate the phenotypes we have characterized thus far in our model system.

Title: Role of Meis1 in the cerebellar development

Authors: *T. OWA
Natl. Inst. of Neurosci., Tokyo, Japan

Abstract: Cerebellar granule cell precursors (GCPs) and granule cells (GCs) represent good models to study neuronal development. Here, we report that the transcription factor myeloid ectopic viral integration site 1 homolog (Meis1) plays pivotal roles in the regulation of mouse GC development. We found that Meis1 is expressed in GC lineage cells and astrocytes in the cerebellum during development. Targeted disruption of the Meis1 gene specifically in the GC lineage resulted in smaller cerebella with disorganized lobules. Knock-down/knock-out (KO) experiments for Meis1 and *in vitro* assays showed that Meis1 binds to an upstream sequence of Pax6 to enhance its transcription in GCPs/GCs and also suggested that the Meis1-Pax6 cascade regulates morphology of GCPs/GCs during development. In the conditional KO (cKO) cerebella, many Atoh1-positive GCPs were observed ectopically in the inner external granule layer (EGL) and a similar phenomenon was observed in cultured cerebellar slices treated with a bone morphogenic protein (BMP) inhibitor. Furthermore, expression of Smad proteins and Smad phosphorylation were severely reduced in the cKO cerebella and Meis1-knock-down GCPs cerebella. Reduction of phosphorylated Smad was also observed in cerebellar slices electroporated with a Pax6 knock-down vector. Because it is known that BMP signaling induces Atoh1 degradation in GCPs, these findings suggest that the Meis1-Pax6 pathway increases the expression of Smad proteins to upregulate BMP signaling, leading to degradation of Atoh1 in the inner EGL, which contributes to differentiation from GCPs to GCs. Therefore, this work reveals crucial functions of Meis1 in GC development and gives insights into the general understanding of the molecular machinery underlying neural differentiation from neural progenitors.

Abstract: Neurodevelopmental disorders are due to an abnormal brain development commonly associated to cognitive impairment, motor disorders and communication problems. Recent work suggests that neural precursor cells (NPCs) are important cellular substrates for neurodevelopmental disorders, since disruption of genes associated to neurodevelopmental disorders in NPCs perturb the numbers and types of neurons that are generated. We have focused on PTPRD, a protein tyrosine phosphatase receptor that is genetically associated with neurodevelopmental disorders such as autism spectrum disorder, restless leg syndrome, and ADHD. Here, we asked whether PTPRD mutations cause aberrant neural development by perturbing neurogenesis, focusing on the embryonic murine cortex. Using embryonic cortical precursors from E12.5 $Ptprd^{-/-}$ mice, we evaluated whether PTPRD regulates NPCs *in vitro*. Furthermore, we used embryonic brains at different embryonic ages from $Ptprd^{-/-}$ mice to evaluate the role of PTPRD in self-renewal, proliferation, and differentiation of NPCs during embryonic neurogenesis. Here, we show that loss of one or both alleles of PTPRD caused decreased proliferation and self-renewal of cortical neural precursor cells and aberrantly increased neurogenesis. These effects were intrinsic to neural precursor cells since acute PTPRD in vitro and in vivo knockdown caused similar perturbations. PTPRD mediated these effects by dephosphorylating receptor tyrosine kinases since it interacted with TrkB and PDGFRβ, and loss of PTPRD caused hyperactivation of TrkB, PDGFRβ and the downstream MEK-ERK signaling pathway in neural precursor cells. Moreover, inhibition of aberrant MEK activation by Trametinib and PD98059 MEK inhibitors rescued the increased neurogenesis caused by knockdown or homozygous loss of PTPRD in cortical precursor cells in culture. These results

suggest that PTPRD regulates receptor tyrosine kinases to ensure appropriate developmental neurogenesis, providing a mechanism for its genetic association with neurodevelopmental disorders.

Title: Synergistic effects of a plasma fraction and exercise on neurogenesis

Authors: *I. D. GALLAGER, R. ALCANTARA-LEE, M. CASTRO, R. ESTRADA, S. P. BRAITHWAITE, V. KHEIFETS
Behavioral Neurosci., Alkahest Inc., San Carlos, CA

Abstract: Exercise has long been considered the gold standard for increasing neurogenesis in animal models of aging. It is widely promoted clinically as a method to stave off the deleterious effects of increased inflammation, decreased neurogenesis and cognitive deficits observed in age-related disorders. We have identified a human plasma fraction that has beneficial effects on neurogenesis and cognition and explored whether it acts through similar pathways to exercise. The plasma fraction or vehicle was delivered intravenously to aged immunodeficient, NOD.Cg-*Prkdc*^{scid}*Il2rg*^{tm1Wjl}/SzJ (NSG), mice. Following administration, a subset of mice were provided home-cage running wheels for 6 weeks to assess the effects of voluntary exercise. Significant increases in terminal histological measures of cell survival (BrdU) and neurogenesis (doublecortin, DCX) within the dentate gyrus of the hippocampus were confirmed for both the animals treated with the bioactive plasma fraction and those exposed only to exercise. Unexpectedly, animals provided with both a home-cage running wheel and treated with the plasma fraction showed dramatic synergy in stimulating neurogenesis through both markers of new neurons (DCX) and cell proliferation (Ki67). This synergy was observed in both young (3 month old) and middle-aged (6 month old) mice. We also demonstrate that cellular proliferation is directed towards neuronal cell fate. This finding suggests that orthogonal biological processes are involved in the neuroregenerative mechanisms of the plasma fraction and those induced by voluntary exercise. The therapeutic application of plasma fractions together with exercise may provide synergistic benefit to aging populations with cognitive disorders.

Abstract: Leukemia inhibitory factor (LIF) from fetal erythroblasts promotes the proliferation of cortical neural progenitors in the fetal brain (Hatta, T., et al., 2002); however, the exact mechanism of its contribution to cerebral cortex development remains unclear. To identify the molecular mechanism underlying this phenomenon, we examined the effects of maternal LIF administration on fetal gene expression using DNA microarray analysis and qPCR. Our findings demonstrate that maternal LIF induces the expression of placental ACTH, which subsequently induces LIF expression in fetal erythroblasts (Shimamura et al., 2010). This LIF-ACTH-LIF signal relay plays a vital role in proper cerebral cortex development in mice. Pregnant mice (C57BL/6J) received an intraperitoneal injection of LIF (5μg/kg) at 13.5 days post coitum. After 30 min or 3 h of LIF administration, the placenta, and fetal cerebrum, choroid plexus, liver, and blood cells were collected, and RNA was purified from each tissue. DNA microarray analysis revealed that maternal LIF administration increased the expression of genes associated with proliferation and differentiation of interneurons, including *Dlx-1*, *Dlx-2*, *Nkx2.1*, *Lhx6*, and *Gad2*—in the fetal cerebral cortex 3 h after LIF administration. In addition, an increase in the expression of these genes were quantitatively determined by qPCR. Maternal LIF administration increased the expression of *Nkx2.1* in the fetal ventral cerebrum, including the medial ganglionic eminences (MGE), 3 h after LIF administration. In MGE, *Nkx2.1* induces *Lhx6*, which is involved in the differentiation and migration of cortical GABAergic interneurons. Considering

the sequential expression of GABAergic neuron-associated genes, our results suggest that the differentiation and migration of interneurons in the cerebral cortex may be promoted by maternal LIF administration via induction of *Nkx2.1* expression.

Title: GSK3 beta inhibition restores impaired neurogenesis in premature infants with intraventricular hemorrhage

Authors: *P. BALLABH[1], P. DOHARE[2]
[1]Pediatrics and Neurosci., [2]Albert Einstein Col. of Med., Bronx, NY

Abstract: Intraventricular hemorrhage (IVH) is a common complication of extreme prematurity in infants born at 23-28 weeks of gestational age. Survivors exhibit impaired growth of the cerebral cortex and suffer from cognitive deficits, intellectual disabilities, and neurobehavioral disorders. However, the underlying mechanism(s) are obscure. Previously, we have shown that neocortical neurogenesis continues until at least 28 gestational weeks. This renders the extremely prematurely born infants vulnerable to impaired neurogenesis. Here, we hypothesized that IVH would disrupt neurogenesis in the dorsal telencephalon and thus, might reduce the neuronal populations in the upper cortical layers. We also postulated that signaling through GSK3β, a critical intracellular kinase regulated by Wnt and other pathways, would mediate this effect. These hypotheses were tested observationally in autopsy specimens from premature infants, and experimentally in a premature rabbit IVH model. Significantly, in premature infants with IVH, the number of neurogenic $Tbr2^+$ cortical progenitor cells was reduced compared to infants without IVH, indicating acutely decreased neurogenesis. Accordingly, in rabbits with IVH, total and cycling $Tbr2^+$ progenitor cells and $Sox2^+$ radial glia were reduced in the dorsal ventricular and subventricular zone. The occurrence of IVH in rabbit kits also diminished the density of $Cux1^+$ and $Satb2^+$ neurons in the upper cortical layers after longer survival. Additionally, Pax6 expression and phosphorylation of retinoblastoma protein were elevated in rabbits with IVH, suggesting inhibition of the G1-to-S phase transition. Both the acute reduction of $Tbr2^+$ and

$Sox2^+$ neurogenic progenitors, and the subsequent decrease of $Cux1^+$ upper layer neurons, were reversed by treatment with AR-A014418, a specific inhibitor of GSK3β. These results indicate that IVH impairs late stages of cortical neurogenesis, and suggest that treatment with GSK3β inhibitors may enhance neurodevelopment in premature infants with IVH.

Title: GATA cofactor Fog1 is reguired for the development of dorsal raphe serotonergic neurons and inactivation of Fog1 causes anxiety

Authors: *L. TIKKER[1], P. CASAROTTO[2], C. BIOJONE[2], N. M. ESTARTÚS[1], J. PARTANEN[1]
[1]Mol. and Integrative Biosci. Res. Programme, [2]Neurosci. Ctr., Univ. of Helsinki, Helsinki, Finland

Abstract: Dysfunction of serotonergic neurons in the dorsal raphe nucleus can cause several psychiatric disorders, including anxiety disorders. Therefore, the correct development of dorsal raphe neurons is essential. Previously, it has been shown that GATA-family transcription factors, Gata2 and Gata3 are required for the development of the dorsal raphe neurons. These transcription factors also have multiple co-regulators with whom they form a regulatory complex to modulate the gene expression by which they influence differentiation and cell fate in several tissues. We hypothesized that these regulators also have a role in the development of serotonergic neurons in the dorsal raphe. Here we have studied one of these regulators, the GATA cofactor Fog1 (Friend of GATA-1) that is also expressed in the developing serotonergic neurons. We show, how inactivation of Fog1 does not prevent early serotonergic neuron differentiation, but leads to a loss of one of its subgroups, the lateral wing serotonergic neurons of the dorsal raphe. Interestingly, these neurons have been implicated in panic disorder. Analyses of the behaviour of the Fog1 mutant mice showed neophobia and increased anxiety. Our results demonstrate that the GATA cofactor Fog1 is required for the development of serotonergic neuron diversity and differentiation of a functionally important serotonergic neuron subgroup in the dorsal raphe.

Title: Large-scale parallel tracing of cell-type specific transcriptional trajectories in the developing mouse neocortex

Authors: *D. JABAUDON[1], L. TELLEY[2], G. AGIRMAN[1], J. PRADOS[1], P. OBERST[1], L. NGUYEN[3], A. DAYER[1]
[1]Univ. of Geneva, Geneva, Switzerland; [2]Univ. of Lausanne, Lausanne, Switzerland; [3]Univ. of Liege, Liege, Belgium

Abstract: The cerebral cortex is a cellularly heterogeneous structure, whose circuits underlie our high-order cognitive and sensorimotor abilities. During development, distinct subtypes of glutamatergic neurons are sequentially born and differentiate from dynamic populations of progenitors located below the cortex, in the ventricular zone. The aggregate competence state of these progenitors progresses as corticogenesis proceeds; likewise, newborn neurons transit through sequential transcriptional states as they differentiate. Little is known on the orthogonal molecular mechanisms driving on the one hand the developmental progression of progenitors through competence states, and on the other hand the differentiation of newborn neurons through cell-type specific differentiation states. To address these questions, we used FlashTag (Telley et al., Science 2016) to trace the developmental trajectories of successive waves of isochronic neurons and progenitors throughout corticogenesis and performed a large-scale, parallel single cell transcriptional profiling of these time-locked populations. Our results identify chronotopic transcriptional maps defining the type-specific organization of transitions through cellular states, and highlight principles allowing emergence and consolidation of type-specific neuronal identities in the developing cerebral cortex.

Abstract: GABAergic interneuron subtype identities are established early in the developing embryo (day 13.5 in mice) in ganglionic eminences (GEs). Gene networks that contribute to interneuron identity are fundamentally based on enhancer-mediated selective regulation of genes during this time. Here, we show that the *Evf2* lncRNA is a master regulator of interneuron subtype genes in E13.5GEs, acting through both antisense *Dlx6* repression and selective targeting of enhancer-gene superloops (at distances greater than 2Mb). *Evf2* is required for *Dlx5/6* ultraconserved enhancer (UCE) interaction with the repressed target gene aldo-ketoreductase 1b8 (*Akr1b8*), at a 27Mb distance. Genetic and gain-of-function experiments support that *Evf2* loss increases *Akr1b8*, a repressor of *5Htr3a* in caudal GE, and activator of *5Htr3a* in medial GE. *Akr1b8* spatial dependence is explained by *Akr1b8* regulated enhancers (*AkrRE1* and *AkrRE2*) located ~63kb downstream of *5Htr3a*, in the *5'*-end of the *Zbtbt16* gene. Metabolites of the mevalonate pathway differentially regulate *AkrRE1/2*, linking epigenetic and lipid mechanisms with serotonin receptor regulation. These studies support a role for an lncRNA-dependent enhancer-gene superloop that contributes to interneuron development, identifying a novel mechanism of serotonin receptor regulation in developing mouse brain.

Title: Systemic administration of antihistamines in pregnant rats impairs offspring motor cortical cytoarchitecture and pyramidal intrinsic electrophysiological properties

Authors: *R. VALLE-BAUTISTA[1], E. GRIEGO-MELO[2], G. HERRERA-LÓPEZ[2], E. GALVÁN[2], N. DÍAZ[3], J. ARIAS-MONTAÑO[1], A. MOLINA-HERNÁNDEZ[3]
[1]Fisiología, Biofisica y Neurociencias, [2]Farmacobiología, Cinvestav, Mexico City, Mexico; [3]Inst. Nacional de Perinatología, Mexico City, Mexico

Abstract: In rat cortical neuroepithelium, histamine H_1-receptor (H_1R) is expressed at embryo day (E) 12, when deep cortical layer neuron differentiation begins. Interestingly, *in vitro* through H_1-receptor activation histamine (HA) promotes neuron differentiation of cortical neural stem cells to deep layer forkhead box protein 2-positive neurons ($FOXP2^+$). And, the *in utero* administration of chlorpheniramine (H_1R antagonist/inverse agonist) at E12 decreases the number of microtubule associated protein 2-positive ($MAP2^+$) and $FOXP2^+$ neurons at E14. The above suggests that early treatment with chlorpheniramine decreases cortical neuron differentiation, event that could lead to postnatal changes on cortical lamination and function.The aim of this study was to evaluate the pharmacological effect of two antihistamines drugs during deep cortical layer development and its implications in the motor cortex. To achieve this goal, pregnant rats were daily injected (ip) from E12 to E14 with chlorpheniramine, mepyramine or vehicle (control), and their offspring was sacrificed at postnatal days (P) 0, 5 and 21. We determined HA level (ELISA, P0 and P21), H_1R density (binding assay), expression and layer position of H_1R and FOXP2 (qRT-PCR and immunofluorescence, respectively), cortical cytoarchitecture (Golgi-Cox stain) and the intrinsic electrophysiological properties of pyramidal neurons in primary motor cortex from P21 control and treated litters. Our results showed a significant increase in H_1R density and a decrease in both dendritic tree arborization, as well as orientation changes, and in the amplitude of the action potential evoked by current injection at P21 in the chlorpheniramine group as compared with the other groups. These data suggest that only chlorpheniramine treatment during the establishment of the deep cortical layers affects postnatal motor cortex cytoarchitecture and suggests alterations in the intrinsic electrophysiological properties of pyramidal neurons in pregnant rats offspring; insult that could

have consequences in both early and late postnatal cortical processes. As chlorpheniramine is a drug classified into B category for pregnancy by the FDA, is important to perform more studies and begin to reconsider the use of this specific drug during pregnancy.

Title: Pannexin1 plays a prominent role in promoting axonal growth during neuroblastoma cell differentiation

Authors: Q. XING[1], P. DOHARE[1], Q. LI[1,3], F. GUAN[3], *D. C. SPRAY[2]
[1]Neuronscience, [2]Albert Einstein Col. Med., Bronx, NY; [3]Sch. of Life Sci., Zhengzhou Univ., Zhengzhou, China

Abstract: Pannexin1 (Panx1) is a protein found in vertebrates that is related to invertebrate gap junction proteins. Rather than forming gap junction channels between cells, Panx1 forms large conductance pores that allow exchange of moderately large signaling molecules such as ATP from inside to outside the cell. Functions of Panx1 channels include signaling through purinergic receptors that are activated by released ATP and likely play major roles in such processes as neuronal myelination and maturation. We have performed studies on a neuroblastoma cell line (Neuro2a) to determine mechanisms underlying this phenomenon. For this, we knocked out Panx1 in Neuro2a cells using CRISPR/Cas9, obtaining modified Neuro2a cell lines that were Panx1 deficient and did not exhibit compensatory upregulation of Panx2, Panx3 or other proteins forming large conductance channels (Cx36, Cx43, CAHLM).To determine the extent to which neurite extension was affected by Panx1 deletion, we compared fraction of neurite bearing WT and Panx1 null Neuro2a cells up to day 5 after plating in medium alone or with supplementation by two agents known to stimulate neuronal outgrowth [40μM retinoic acid (RA), 50ng/ml nerve growth factor (NGF), 5% FBS as control]. The results show that the percentage of neurite bearing WT Neuro2a cells increased at day 3, day 4 and day 5 after RA induction, compared

with the control group (P<0.001); similar extent of differentiation was seen with NGF at day 3 (P<0.05) and day 4 (P<0.001). In contrast, neurite outgrowth in Neuro2a cells lacking Panx1 was markedly suppressed at day 3-5 after treatment both with RA and NGF (P<0.05). Our findings that Panx1 deletion decreases the differentiation of Neuro2a cells and diminishes the maturational effects of NGF and RA provides evidence that Panx1 plays a major role in controlling axonal growth in the peripheral nervous system.

Title: Impaired interneuron density in the human preterm prefrontal cortex

Authors: *H. LACAILLE[1], C. M. VACHER[1], D. BAKALAR[1], J. J. O'REILLY[1,2], J. SALZBANK[1], A. A. PENN[1,2,3]

Abstract: Preterm birth is a significant risk factor for neuropsychiatric disease development, particularly schizophrenia and autism spectrum disorder. A common feature of these disorders is an imbalance between neuronal excitation and inhibition in the prefrontal cortex (PFC), mediated by developmental alterations of Gamma-Aminobutyric Acid (GABA) interneurons. Specifically, alterations in Brodmann area 9 (BA9), a region involved in working memory and social cognition, may account for some of the characteristic cognitive deficits of these disorders. Histological evidence of decreased GABA levels has been seen in rodent models and humans with major psychiatric disorders. Similarly, in preterm birth survivors, a decrease is also seen in right frontal GABA concentration and connectivity, suggesting similar deficits. To elucidate the cellular changes underlying these alterations, we have investigated GABA interneurons in human PFC from both preterm and term infants. Interneurons continue to be generated through late

pregnancy (35 weeks) and keep migrating and integrating into the frontal lobe during infancy, leaving them highly susceptible to perinatal insults. We examined interneuron numbers and subtypes in BA9, from 7 term (> 37 weeks of gestation) and 6 preterm (< 29 weeks of gestation) infants who survived until ~4 months of age (NIH Neurobiobank University of Maryland, Baltimore, MD; ID #709). Sex, gestational age and cause of death varied, but were not attributed to CNS abnormalities. Tissues were sectioned and stained for four interneuron markers. Positive cells were counted in two bins of equal width corresponding to the upper and lower layers of the frontal cortex. A significant decrease was observed in the number of somatostatin and calretinin positive interneurons in the upper but not the lower section of the cortex of preterm infants. However, no change was observed in the number of calbindin or neuropeptide Y expressing cells. To further investigate the effect of preterm birth on human interneuron maturation, the density, and the position of interneurons in the cortical layers is being assessed by total GABA expression and co-staining with interneuron subtype markers to determine whether there is a maturational delay and whether the cell loss is specific to a ganglionic eminence. Taken together, these data will lead to a better understanding of the impact of preterm birth on interneuron development; and will potentially lead to new avenues for treatment to reduce offspring's neuropsychiatric risk after compromised pregnancies.

Title: Expression of NCAM, PSA-NCAM, GFAP, and S100 in subgranular zone of dentate in developing hippocampus

Authors: *S. CHOMPOOPONG[1], C. TURBPAIBOON[1], B. TASSANEETRITHEP[2], W. WIRIYARAT[3], P. NIMNOI[1], W. SIRIPAN[1]

Abstract: In mammals, neurogenesis presents in the subgranular zone (SGZ) of dentate in hippocampus throughout life. Currently, various protein markers expressed during the progressions of adult hippocampal neurogenesis have been reported. The expression of these

biomarkers during brain development are also promising and has been widely studied but not yet fully appreciated because of the difference in rodent species. In this study, the expression of the neural cell adhesion molecule (NCAM), the polysialylated (PSA)-NCAM, the glial fibrillary acidic protein (GFAP), and the neurotrophic protein S100 were determined in fetus (E17), postnatal (P3, P5, P7 and P14) and adult ICR mice by using immunoperoxidase staining in dorsal hippocampus and Western blot analysis of brain tissue homogenate. NCAM mediates adhesion, guidance, synaptic plasticity and differentiation during neuronal growth, NCAM expression was localized on the cell surface of neurons, glia. In SGZ, NCAM found highly in adult and postnatal mice than embryonic mice. PSA-NCAM plays role in the modulation of cell-cell adhesive interactions for the migration and proliferation including the differentiation of neural stem cells. PSA-NCAM was found in cytoplasm, cell surface and some nucleus of neural cells, more densely staining in SGZ in early postnatal mice P3 than late stage P14 and adult mice but no staining found in embryonic mice E17. The amount of GFAP increased with increasing mice age reflecting general supporting of the cytoskeleton in astrocytes, GFAP expression was increased gradually from P3 to P14 and adult mice. More early expression of S100 is associated with its proliferative potential and migration of undifferentiated neuroblasts and astrocytes. The amount of the neuro- and gliotrophic protein S100 increased from young E17 due to secretion for proliferative phase then decreased and S100 expression increased again in P14 and adult mic, therefore S100 expression is also related to mature astrocytes. In conclusion, this finding provides valuable information on the developmental processes, the different up and down regulation of NCAM/PSA-NCAM, GFAP and S100 in various stages of developing mice are useful to understand not only brain functions but also brain developmental defects in offspring mice.

Abstract: We have identified a fractionated plasma product that enhances neurogenesis within the dentate gyrus of the hippocampus in 12month old NOD.Cg-*Prkdc*^{scid}*Il2rg*^{tm1Wjl}/SzJ (NSG) immunodeficient mice. Here we examined NSG mice at various ages treated intravenously with the plasma fraction and compared the extent of their age-dependent decline in new-born neurons (doublecortin, DCX) and cell survival of BrdU labeled dividing cells six weeks post treatment compared to naïve animals. We identified a precipitous decline in total DCX positive cells in 6-month-old compared to 3-month-old animals concomitant with significant deterioration in spatial cognitive behavior. In all ages, the plasma fraction inhibited the decline in neurogenesis and cell survival occurring over 6 weeks post-dosing. We demonstrate that the increase in neurogenesis is likely due to increased precursor cell proliferation that occurs during the dosing of the plasma fraction and demonstrate that the proliferation increase is maintained for at least 1 week following cessation of dosing. Six-month-old animals were selected to be used for examination of an extended dosing paradigm to guide treatment methodology for clinical trials with plasma fractions.

Abstract: Somatic megabase scale copy number variations (CNVs) are present in adult neurons of the brain, however, little is known about the genesis, prevalence, and consequences of this phenomenon. We characterized mosaic CNVs in the developing cerebral cortex of *Mus musculus* using a novel wetlab approach. We also developed informatic tools to confidently identify somatic CNVs in the data generated by low depth single-cell whole-genome sequencing (scWGS). Using immune system recombination as a known locus for naturally occurring CNVs, we applied machine learning to create filters to remove unreliable CNVs. This resulted in removal of >90% of false positive CNV calls while maintaining identification of sub-megabase alterations smaller than previously reported brain CNVs identified through scWGS. Thousands of CNVs were identified in cells isolated during cortical neurogenesis and adulthood, allowing us to identify periods of CNV formation in brain development. These data support prenatal origins for the majority of mosaic CNVs present in adult neurons.

Title: Differential expression of GRIM-19 (gene associated with retinoid-interferon induced mortality-19) in the adult mouse dentate gyrus: A regulator in adult neurogenesis

Authors: J.-C. KIM[1,2,3], S.-N. HWANG[1,2,3], *S. KIM[1,2,3]

Abstract: Gene associated with retinoid-interferon-induced mortality-19 (GRIM-19), a subunit of mitochondrial respiratory chain complex I, is a multifunctional gene involved in cell death, proliferation, migration and metabolic balance between aerobic glycolysis and mitochondrial oxidative phosphorylation (OXPHOS). Although such functions of GRIM-19 are also closely related with adult neurogenesis, the role of GRIM-19 in adult neurogenesis is unknown. Thus, the present study investigated the expression pattern of GRIM-19 and analyzed cell types expressing GRIM-19 in the adult mouse hippocampal dentate gyrus, one of the regions where adult neurogenesis takes place. We performed double immunofluorescence staining on hippocampal sections of adult C57BL/6 mice (11 weeks old) using various specific markers related to adult neurogenesis stages (type-1, type-2a, type2-b, type-3, immature granule cell and mature granule cell; stage 1-6). Interestingly, GRIM-19-positive cells were prominently expressed in the dentate gyrus cell layer, but barely observed in the subgranular zone (SGZ) where neural stem and progenitor cells (NSPCs) are active. Further analysis revealed that GRIM-19 was nearly not expressed in GFAP-positive cells (type-1), Nestin-positive cells (type-1, 2a and 2b) and Ki-67-positive cells (type 2a, 2b and 3). Further, a few GRIM-19-positive cells were merged with DCX-positive cells (type 2b, 3 and immature), Prox1-positive cells (type 2b, 3, immature and mature), PSA-NCAM-positive cells (type 3, immature and mature). Furthermore, Most GRIM-19-expressing were co-labeled with Calretinin-positive cells (immature), NeuN-positive cells (immature and mature), Calbindin-positive cells (mature). These results indicate that GRIM-19 was not expressed at early neurogenesis stages including NSPCs, but at later stages including immature and mature granule cells.

Abstract: In the mammalian brain adult-born granule cells (abGCs) are continously integrated into established hippocampal circuits throughout life. Whereas the evolution of in- and output connectivity on abGCs and GCs has already been studied in detail on the population level little is known about the per-cell connectivity, its development and the cellular output specifity of DG input axons in general. We used serial block-face scanning EM to acquire a large-scale 3D EM dataset from mouse (P28) dentate gyrus and densely reconstructed GCs and their synaptic input axons. The cellular organization of younger GCs towards deeper layers allowes the analysis of temporally different stages of GC maturation in the same dataset, aimed at uncovering the connectomic patterns of neurons newly integrated into an existing neuronal circuit.

Title: Pattern of expression of the transcription factor Ebf2 in the lateral hypothalamus of the mouse brain

Authors: *R. VIDALTAMAYO[1], X. A. ACOSTA-VILLALOBOS[2], V. C. ZOMOSA-SIGNORET[2]
[1]Univ. of Monterrey, San Pedro, Mexico; [2]Biochem. and Mol. Med., Univ. Autónoma de Nuevo León, Monterrey, Mexico

Abstract: Neuron populations in the lateral hypothalamic area (LHA) regulate motivated behaviors such as food intake and metabolic energy balance through integrating internal and external sensory cues and modulating the output of arousal and reward systems. The cellular and molecular mechanisms responsible of these regulatory processes are not completely understood, due to the complex architecture and heterogeneity of the cell populations in the LHA. Three major populations of neurons have been described within the LHA, that participate in the formation of circuits regulating motivated behavior. These populations appear to express distinct neuropeptides in an exclusive manner, and each population is characterized by the expression of either orexin A and B, melanin concentrating hormone (MCH), or neurotensin. This latter population also expresses the large version of the leptin receptor (LepRb) as a distinct marker. EBF2 is a transcription factor involved in the development and maintenance of different neuron populations across the nervous system. Several studies have suggested a relationship between EBF2 and orexin neurons: *Ebf2* expression is decreased in hypothalamus samples from transgenic mice where orexinergic neurons are depleted by the targeted expression of a neurotoxin, and there is a corresponding decrease (roughly by 80%) in orexin- expressing neurons in *Ebf2* knockout mice, which leads to a narcoleptic phenotype. However, it is presently unknown if EBF2 is expressed by the orexinergic neurons of the LHA.
Here, we analyzed EBF2 expression in the LHA by immunofluorescence in the brains of female and male wild-type C57BL/6 at embryonic stages E14.5, E15.5, and young (7- to 9-week old) and senescent adult mice. We performed double stainings to evaluate coexpression of EBF2 and any of the characteristic markers of the neuron populations of the LHA: orexin-B, MCH, NPY, CART, neurotensin and LepRb.
A subpopulation of the LHA expressed EBF2, which is also expressed in other areas participating in the integration of motivated behavior such as the VTA, preoptical hypothalamic area and the insular cortex. The EBF2+ neurons of the LHA were located in close proximity to ORXB+ axons, but no colocalization of EBF2 and ORXB, MCH, CART or NPY could be detected in the somas expressing either one of these neuropeptides in the LH and ventral hypothalamic (arcuate nucleus) areas. Labeling with anti-neurotensin antibodies suggests that neurons belonging to this subpopulation of the LHA coexpress EBF2. The interaction between the neurotensin+ and ORX+ populations could lead to reciprocal regulation of gene expression.

Title: Lead (Pb^{2+}) exposure alters cellular and behavioral neurodevelopment in a planarian model

Authors: *S. ABDALLAH[1], R. CANDIA[2], M. SCOTTO[2], N. MAGNAVITA[2], S. R. GUARIGLIA[3]
[1]CUNY Col. of Staten Island, Staten Island, NY; [2]St. Joseph by the Sea High Sch., Staten Island, NY; [3]New York State Inst. for Basic Res., Staten Island, NY

Abstract: Lead is a well-characterized toxicant with known deleterious effects on nervous system function. How Pb^{2+} influences the critical period of early neurodevelopment is less understood. Here, we utilize *Dugesia Dorotocephala,* a planarian, to model the effects of lead on early nervous system development. To accomplish this task, we amputated the heads of adult planarians and allowed the tails to regenerate heads and brain in 0.01 ppm, 0.1 ppm, and 0.5 ppm Pb^{2+}. The duration of Pb^{2+} exposure was seven days, as entire head and brain regeneration occurs within seven days of amputation. We examined (1) the effect of varying concentrations of Pb2+ on regenerating blastema and the (2) impact of Pb^{2+} on CNS neuronal cell number at a 24h, 48h, 72h, 120h, 168h (during exposure) and two weeks post-amputation (after exposure) using a combination of immunohistochemistry, Western Blot, and qRT-PCR. We have found that Pb^{2+} exposure attenuated blastema formation and that Pb^{2+} exposure reduced the neuronal cell number in Pb^{2+} exposed planaria. Furthermore, we found that exposure to Pb^{2+} during brain development had persistent effects on behavior. Planaria exposed to all concentrations of Pb^{2+} showed hyperactive locomotor activity and increased body rotations. In an active avoidance fear conditioning assay, planaria exposed to all concentrations of Pb^{2+} demonstrated significant and persistent cognitive impairments. The sum of this data suggests that Pb^{2+} has deleterious effects on early neuronal patterning and lasting behavioral effects. Furthermore, we describe assays that are high throughput and may be useful for others in evaluating potential toxicological consequences of exposure during early neurodevelopment.

Title: Corpus callosum formation requires FOXG1 action in cortical projection neurons

Authors: *F. CARGNIN[1], J.-S. KWON[2], B. CHEN[3], J. W. LEE[2], S.-K. LEE[4]
[1]Papé Family Pediatric Res. Inst., Oregon Health&Science Univ., Portland, OR; [2]Papé Family Pediatric Res. Inst., Oregon Hlth. & Sci. Univ., Portland, OR; [3]Molecular, Cell & Developmental Biol., UC Santa Cruz, Santa Cruz, CA; [4]Papé Family Pediatric Res. Inst., Oregon Hlth. and Sci. Univ., Portland, OR

Abstract: Cerebral hemispheres exchange and coordinate information derived from motor and somatosensory inputs via the major axonal transit that defines the corpus callosum. Awry neocortex maturation and agenesis of the corpus callosum are hallmarks of neurodevelopmental disorders, like FOXG1 syndrome, that emerge from mutations in genes pivotal to the organization of brain architecture. However, there are no prior evidences that mutations in a single neuronal gene may directly hijack both cortical lamination and corpus callosum formation. We discovered that FOXG1 gene, aside from its known function in neural progenitors, is strictly necessary for axon trajectory of callosal projection neurons (CPN). The neuron-specific actions of Foxg1 are achieved by forming a transcription complex with Rp58. The Foxg1-Rp58 complex directly binds and represses proneural and axon guidance genes, coordinating the laminar position of cortical neurons and the acquisition of CPN-defining traits. As FOXG1 syndrome results from mutations in a single *FOXG1* allele, we also found that deletion of one *Foxg1* allele specifically in cortical neurons was sufficient to cause cortical atrophy and corpus callosum agenesis. This study reveals a novel gene regulatory pathway that specifies neuronal characteristics during cerebral cortex development and sheds light on the etiology of FOXG1 syndrome.

Title: Role of Fezf2 in maintaining corticospinal motor neuron identity in the mammalian cerebral cortex

Authors: *A. ZHANG[1], S. LODATO[2], J. L. SHERWOOD[1], J. R. BROWN[1], H.-H. CHEN[3], R. AMAMOTO[1], S. SIMMONS[4], J. LEVIN[4], P. ARLOTTA[1]
[1]Stem Cell and Regenerative Biol., Harvard Univ., Cambridge, MA; [2]Dept. of Biol. Sci., Humanitas Univ., Milan, Italy; [3]Genentech, South San Francisco, CA; [4]Broad Inst., Cambridge, MA

Abstract: In the mammalian cerebral cortex, distinct classes of neurons are generated embryonically and maintain their subtype-specific identities throughout the lifetime of the organism. While the developmental programs that control the generation of this heterogeneous neuronal output have begun to be elucidated, much less is known about the molecular mechanisms that preserve their identity through time. A potential mechanism to actively maintain subtype-specific neuronal identity is through the continuous expression of powerful, fate-determining transcription factors. We have previously shown that the transcription factor *Fezf2* as the first selector gene known for any class of projection neurons in the cortex (Lodato et al., 2014). Fezf2 is necessary for the birth and specification of corticospinal motor neurons (CSMNs), and it is sufficient to instruct corticofugal (CFuPN) neuronal identity (Molyneaux et al., 2005, Chen et al., 2005, Rouaux et al., 2010, 2013; De la Rossa et al., 2013; Ye et al., 2017), of which CSMNs are a subset. Here, we hypothesize that *Fezf2* is a *terminal* selector gene and is therefore needed to maintain CSMN identity throughout the life of the animal. To test this hypothesis, we employed a genetic strategy, which allowed for conditional inactivation of *Fezf2* specifically from CSMNs at distinct postnatal timepoints (P3 and P30), when CSMN fate specification and connectivity have already been established. This approach enabled us to test whether aspects of CSMN identity, such as their distinctive molecular signature and somatodendritic morphology, are affected upon Fezf2 deletion. By combining transcriptomic and morphological analysis, we assessed whether *Fezf2* deletion in in post-mitotic CSMNs, at different stages of their maturation, causes the neurons to *lose* their CSMN molecular identity. Transcriptional data suggests that, at least during early postnatal development, Fezf2 is needed to maintain distinctive CSMN traits, as well as repress those of closely related neuronal lineages. Whether *Fezf2* is also needed in the adult to maintain CSMN identity is still unknown, and we are currently pursuing this question by integrating our genetic approach with single cell transcriptomics. By exploiting *Fezf2* function in mature CSMNs as a model system to understand

class-specific identity maintenance, our work aims at illuminating a potential active molecular mechanism for CNS neurons to maintain their identity and function in the mature cerebral cortex.

Title: Essential role of RLS-associated MEIS homeobox proteins revealed by modeling human forebrain development

Authors: *V. R. KITTKE, D. D. LAM, C. ZHAO, J. WINKELMANN
Inst. of Neurogenomics, Helmholtz Zentrum München, Neuherberg, Germany

Abstract: The genes encoding the highly homologous homeobox transcription factors MEIS1 and MEIS2 are strongly associated with risk of restless legs syndrome (RLS). However, the functional role of MEIS proteins in RLS pathogenesis remains elusive. Since RLS-associated variants selectively affect expression of MEIS1 in the developing forebrain, we aimed to model human forebrain development *in vitro* in the context of engineered MEIS deficiency. We first generated *MEIS1* and *MEIS2* homozygous loss-of-function induced pluripotent stem cell (iPSC) lines through CRISPR/Cas9-mediated genome editing. We subsequently differentiated these cell lines to forebrain-like neurons of mixed excitatory and inhibitory types via a neural progenitor intermediate. Surprisingly, given the high homology of MEIS proteins and their functional redundancy in other contexts, homozygous deletion of single *MEIS* genes severely disrupted cell type composition. We also employed three-dimensional in vitro models of forebrain development, which develop greater complexity including neurogenic zones adjacent to ventricle-like structures. We examined the effects of MEIS1 and MEIS2 inactivation on the thickness of neurogenic zones and the formation of mature neurons.
In order to identify genomic binding targets of MEIS1 and MEIS2, we performed ChIP-seq on human neural stem cells. As in other tissues and cell types, MEIS bound both promoters and distal regulatory elements. Binding patterns in neural cells were highly distinct from other cell types, showing enrichment for genes involved in neural development. Among the direct MEIS targets we found other RLS-associated genes, suggesting a functional gene network in RLS pathogenesis. Together, these findings show the critical role of MEIS1 and MEIS2 in human

forebrain development and support aberrant neural development as a key factor in RLS pathophysiology.

Title: Differential mode of Hes-1 activation maintains neural stem cells and promotes its transition into radial glial cells during neocortical development

Authors: *J. JAMES, R. ANN PAUL, L. SOUNDARARAJAN, S. PARVATHY, S. SURYA, V. MEERA, S. DHANESH, B. BUDHADITYA
Neuro Stem Cell Biol., Rajiv Gandhi Ctr. for Biotech., Trivandrum, India

Abstract: It is known that the neural progenitors in the ventricular zone of neocortex are maintained through canonical Notch signaling. Recently, we have shown that the non-canonical mode of activation of Hes-1 (NIHes-1) maintains a subset of neural stem cells which later attain Notch dependency (NDHes-1) and transit into neural progenitor/Radial Glial Cells (RGCs) that eventually differentiate into neurons and glia populating the upper layers of neocortex. Even though we have demonstrated a differential activation of Hes-1 and its presence in different populations of stem cells/progenitors, we currently do not have any understanding regarding the functional significance of existence of such a differential activation of Hes-1 in neural stem cells/progenitors. Also, it is intriguing to know how the neural stem cells expressing NIHes-1 transit to a NDHes-1 expressing neural progenitor state. To address this, we transfected ES cells with reporter vector that is able to differentiate between the NIHes-1 and NDHes-1 expressing cells. These clones were further transfected with NIHes-$1^{f/f}$ plasmid to generate NIHes-$1^{f/f}$ sub clones. The NIHes-$1^{f/f}$ ES cells were transfected with Cre-recombinase expressing plasmid to generate NIHes-$1^{-/-}$ ES cell line. Cortical organoids were generated from the NDHes-$1^{f/f}$ and NIHes-$1^{-/-}$ ES cells. Organoids generated from NIHes-$1^{-/-}$ ES cells showed a drastic reduction in NDHes-1 expressing progenitors accompanied with cortical layer patterning. These results clearly showed that NIHes-1 expression is required for maintaining the subset of neural stem cells throughout early development of the neocortex. We also carried out transcriptomic analysis

between differentiating ES cell derived NIHes-1 and NDHes-1 expressing cells. Our results showed the involvement of stem cell maintenance pathways activated in NIHes-1 cells.To understand the mechanism of transition from NIHes-1 expressing neural stem cells to NDHes-1 expressing neural progenitors *in vivo*, we have developed NIHes-$1^{f/f}$ mice and also generated a reporter mice that can report all the NIHes-1 expressing cells as green and NDHes-1 expressing cells as red. Immuno fluorescence analysis with reporter transgenic mice showed that one of the reasons for the transition from NIHes-1 to NDHes-1 expression state is due to differential expression of Notch ligand DLL1 and Notch receptor in NIHes-1 and NDHes-1 expressing cells respectively. Overall, our results demonstrated a novel mechanism by which the neural stem cells are maintained in their niche in ventricular zone of developing neocortex and can have implication in treating neuro degenerative disorders.

Title: Molecular controls over corticospinal neuron axonal segmental targeting

Authors: *V. V. SAHNI[1,2], S. J. SHNIDER[2], D. JABAUDON[2], J. SONG[2], F. DING[2], J. D. MACKLIS[2]
[1]Burke Neurolog. Inst., Weill Cornell Med., White Plains, NY; [2]Stem Cell and Regenerative Biol., Harvard Univ., Cambridge, MA

Abstract: For execution of precise motor control, distinct corticospinal neurons (CSN) extend axons to, and innervate, distinct target spinal cord segments – from rostral targets in the brainstem and cervical cord to caudal targets in the thoracic and lumbar cord. The molecular basis for this segmentally specific connectivity is unknown.
Using anterograde and retrograde labeling and intersectional viral mapping, we identified that distinct CSN subpopulations, residing in distinct locations in sensorimotor cortex, exhibit striking axon targeting specificity during development. These developmental axon-extension decisions are maintained in adult mice, and correlate with their distinct spinal segmental collateralization, suggesting that early developmental axon extension decisions critically control

segmentally specific corticospinal connectivity.
Based on their distinct neocortical locations, correlated with anterograde and retrograde connectivity analyses, we isolated segmentally distinct CSN subpopulations during development, and identified differentially expressed genes between them at critical developmental times. Our data indicate that segmentally distinct CSN subpopulations are molecularly distinct from the earliest stages of corticospinal axon extension into the spinal cord, with these molecular identities beginning by the time of neuronal birth.
We next utilized stringent statistical criteria in our differential gene expression analysis, as well as the temporality of these differences, to further define molecular distinctions between CSN subpopulations that exhibit differential axon extension between bulbo-cervical and thoraco-lumbar spinal segments, beyond their spatial separation in the cortex. Collectively, these data enable the molecular delineation and prospective identification of developing CSN subpopulations well before their eventual axon-targeting decisions are evident in the spinal cord.
Finally, we functionally investigate a subset of these molecular controls, and identify their critical roles in directing CSN axons to appropriate spinal levels. These molecularly-controlled axon extension decisions occur prior to axonal collateralization, and, therefore, further indicate that mechanisms controlling CSN axon targeting to specific spinal segments are independent of mechanisms controlling spinal segment-specific axonal collateralization.
This work provides foundation for further investigation of mechanisms directing the development, evolution, and potential regeneration of specific corticospinal circuitry, and the roles of distinct CSN populations in execution of motor control.

Title: R-loops as mechanisms governing neural differentiation and cell-type specific transcription

Authors: *L. LAMARCA[1], S. ESPESO-GIL[2], E. FLAHERTY[2], P. RAJARAJAN[2], N. BARRETTO[2], N. TSANKOVA[2], K. BRENNAND[2], S. AKBARIAN[2]

Abstract: Schizophrenia, bipolar disorder, and major depression together affect over 16% of the worldwide population, but their etiologies are poorly understood. Gene expression variation is a common attribute of these disorders, so research to identify and target aberrant mRNA regulation may provide novel therapeutic benefit. mRNA can anneal to template DNA during transcription, forming a DNA/RNA hybrid known as an R-loop. New genome-wide mapping strategies have identified a connection between R-loops and transcriptional regulation, suggesting a role for R-loops in gene expression variation. However, R-loops have never been characterized on a genome-wide scale in human brain cells, precluding research exploring their role in neuropsychiatric illnesses. Here, using DNA/RNA immunoprecipitation followed by deep sequencing (DRIP-seq), we show that R-loops are abundant in human neural cells and display a distinctive distribution relative to non-neural cells. We find evidence that R-loops may be poising genes for transcription, particularly those genes involved in neural differentiation and cell type-specific function. We predict that aberrant R-loop regulation may be involved in the pathophysiology of neuropsychiatric illness, and our future studies will test this hypothesis by directly manipulating R-loop formation and examining the phenotypic consequences in neural cells both in vitro and in vivo.

Title: Knee joint inflammation: A new trigger for adult neurogenesis in the hippocampus and spinal cord of rats

Authors: *E. D. AL-CHAER[1], M. FOUANI[2], W. ABOU-KHEIR[2], N. LAWAND[3]
[1]Dept. of Anatomy, Cell Biol. & Physiological Sci., [2]Anatomy, Cell Biol. and Physiological Sci., [3]Dept. of Neurol., American Univ. of Beirut, Beirut, Lebanon

Abstract: Knee joint inflammation causes pain and hypersensitivity to mechanical and thermal stimulation, and triggers a prolonged increase in the excitability and synaptic efficacy of central nociceptive neurons. In this study, we explored whether knee joint inflammation enhances neurogenesis in the dentate gyrus of the hippocampus, and induces proliferation of neural progenitor cells in the dorsal horn of the spinal cord. Male Sprague-Dawley rats were injected with kaolin and carrageenan in the synovial cavity of the knee joint. Rats received intra-articular

injection of saline served as control. Nociceptive tests including mechanical allodynia and heat hyperalgesia were performed prior to, and at 4, 8, 24 and 48hrs post induction. In addition, motor changes were assessed using the rotarod test. The knee joint circumference was also measured to evaluate the severity of inflammation. All rats received intraperitoneal injections of 5'-Bromo-2'-deoxyuridine (BrdU) (200 mg/kg) before induction of inflammation and were then perfused transcardially at 8, 24, or 48 hours' post-injection. Brain and spinal cord tissues were collected for immunofluorescence staining. Newly born neurons that are immunopositive for BrdU and neuronal nuclear antigen (NeuN), a mature neuronal marker, were identified using confocal microscopy.
Injection of K/C into the knee joint of adult rats produced swelling of the knee, increased paw sensitivity to innocuous mechanical and noxious heat stimulation, and decreased motor activity. The brain and spinal cord sections stained with anti-BrdU revealed an increase in BrdU-positive neurons both in the dorsal horn of the spinal cord and the dentate gyrus. This increase was correlated with the severity of the inflammation. Our results suggest that knee joint inflammation can induce the proliferation of neural progenitor cells at different levels of the central nervous system. These new cells may account for the changes in central nociceptive neurons and the enhanced pain sensitivity associated with inflammation.

Abstract: Key questions about the fundamental building blocks of the human brain, including the number, proportion, and lineage relationships of its distinct cell types remain unanswered.

We used multiple single-cell RNA-seq technologies to obtain and compare profiles for 40,000 cells from PCW15-17 human neocortex to define cell types and generate an unbiased molecular taxonomy. We identified expression profiles corresponding to all known major cell types at this developmental period including radial glia, intermediate progenitors, migrating and cortical plate excitatory neurons, interneurons, microglia, and oligodendrocyte precursors. We identified multiple transcription factors and co-factors expressed in specific cell types which provide a rich resource for understanding human neocortical developmental programs. We characterize the major developmental trajectories during early neurogenesis, showing that human neocortical cell type differentiation is on a gradual continuum and involves transcriptomic transitions tied to cell cycle progression with early cell fate decisions. Finally, we use this catalog to map neuropsychiatric disease genes to specific cell types, implicating dysregulation of specific cell types as the mechanistic underpinnings of several neurodevelopmental disorders. Together these results provide an extensive catalog of cell types in human neocortex, and extend our understanding of early cortical development and the cellular basis neuropsychiatric disease.

Title: The role of lactate in neuronal differentiation

Authors: *M. M. DARWISH[1], N. TUERSUNJIANG[2], H. FIUMELLI[2], P. J. MAGISTRETTI[2]
[1]BESE, King Abdullah Univ. of Sci. and Technol., Thuwal, Saudi Arabia; [2]Biol. and Envrn. Sci. and Engin. Div. (BESE), King Abdullah Univ. of Sci. and Technol. (KAUST), Thuwal, Saudi Arabia

Abstract: During neuronal differentiation, cellular energetics is leveraged and undergoes profound remodeling. Although neuronal differentiation has been extensively studied, the exact role of metabolic reprogramming/shift in regulating neuronal differentiation has not been clearly elucidated. Here, by differentiating neuroblastoma SH-SY5Y cells with retinoic acid, we found that the glycolysis rate and L-lactate levels increased during the early stages of neuronal differentiation. The mRNA expression levels of key glycolytic enzymes such as 6-phosphofructo-2-kinase/fructose-2,6-biphosphatase 3 (PFKFB3), pyruvate dehydrogenase kinase 4 (PDK4), and lactate dehydrogenase A (LDHA) were upregulated upon retinoic acid treatment by 5, 3.3, and 2.3 fold, respectively. Moreover, the release of L-lactate was doubled over 48

hours. To investigate the significance of lactate elevation during neuronal differentiation, we treated SH-SY5Y cells with lactate (in addition to retinoic acid). We found at both the transcriptomic and proteomic levels that tyrosine hydroxylase, an SH-SY5Y differentiation marker, was significantly upregulated when the neuroblastoma cells were treated with either L-lactate or D-lactate. Observed increases at the mRNA levels were 2.1 and 5.8 fold ($p < 0.05$), respectively. Interestingly, when cells were treated with either of the enantiomers alone or in combination with retinoic acid, the effects of D-lactate were stronger than those of L-lactate, suggesting a possible signaling role of the lactate enantiomers rather than a metabolic effect in the differentiation of SH-SY5Y. This work gives an insight on the role of lactate in regulating neuronal differentiation.

Title: Generation of maternal UBE3A knock-out pluripotent stem cell lines for a practical verification of Angelman syndrome pathogenesis

Authors: *R. OKOCHI[1], M. ISHIKAWA[2], T. SONE[2], H. OKUNO[2], H. OKANO[2]
[1]Physiol., Keio Univ. Sch. of Med., Tokyo, Japan; [2]Dept. of Physiology, Keio Univ. Sch. of Med., Tokyo, Japan

Abstract: Angelman syndrome (AS) is a neurodevelopmental disorder whose main features include intellectual disability, mental retardation, and epileptic seizures. AS is caused by deficient expression of the ubiquitin protein ligase E3A (UBE3A) gene, which displays paternal imprinting in neurons. Previous studies showed the gene expression of paternal UBE3A is suppressed by lncRNA whose transcription initiation site is within the imprinting center far upstream of UBE3A gene locus. Approximately 70% of all cases involve a large maternal deletion of the chromosome 15q11-q13 region, which includes UBE3A gene. The remaining known causes of AS include mutations within UBE3A, uniparental disomy (UPD), and imprinting defects. About 10% of cases are caused by currently unknown genetic or epigenetic mechanisms. There is a number of reports of UBE3A knock-out (KO) mice, and also UBE3A

homozygous KO induced-pluripotent stem cells (iPSCs). However, the expression level of UBE3A in neurons of AS patients is probably different from homo KO iPSCs-derived neurons, since imprinting effect are canceled in homozygous KO cell lines. Using genome editing, maternally specific KO in human iPSCs can be generated, although there are not any convenient method to discriminate whether gene mutation has occur in either maternal or paternal allele. Here, we produced maternal allele-specific UBE3A KO iPSCs lines. Establishing the highly efficient excitatory or inhibitory neuronal induction methods by tet-inducible ovexpression of Ngn2 or Ascl1+Dlx1/2, respectively, we measured expression level of UBE3A gene and 15q11-13 region-specific lncRNAs in the purified neurons, and tried to examine in which allele the mutation occur. The maternal KO iPS cell lines made AS studies more practical. Now we are investigating the reproducibility of AS-related phenotypes in purified excitatory or inhibitory neurons-derived from patients iPSCs of 15q11-13 deletion syndrome, UPD and UBE3A KO. AS phenotypes depend on genome imprint level. The maternally inherited UBE3A KO iPSCs provide crucial material for clarifying the AS pathogenesis.

Title: Using iPSC-derived neurons to uncover cellular phenotypes associated with NGLY1 deficiency

Authors: *A. A. MANOLE[1], S. STERN[1], R. MARES[2], X. CHENG[2], G. WANG[2], K. J. LEE[3], C. MARCHETTO[1], F. H. GAGE[1]
[1]Salk Inst. For Biol. Studies, La Jolla, CA; [2]Stanford Univ., Palo Alto, CA; [3]Grace Sci. Fndn., New York, NY

Abstract: Biallelic mutations in the gene that encodes for the N-glycanase 1 (NGLY1) protein cause a rare disease with multi-symptomatic features including developmental delay, neuropathy, seizures, axonal loss and hypotonia. NGLY1 is a deglycosylase involved in the endoplasmic reticulum-associated degradation pathway and its role is to deglycosylate misfolded proteins that are further degraded by the cytoplasmic ubiquitin-proteasome system. In the absence of NGLY1,

the initial deglycosylation cannot take place, disabling proteasomal breakdown of the misfolded protein. It is currently thought that this leads to an accumulation of misfolded proteins and proteotoxic stress but an increase in misfolded protein has not yet been directly observed. Neurons are one of the most vulnerable cell types in the face of disease-related aggregate formation. This is thought to lead to synaptic dysfunction, neuronal apoptosis and brain damage. Our aim was to evaluate the phenotypical changes in neural cells derived from NGLY1 deficient patients. For this we employed a rapid single-step induction of functional neurons from induced pluripotent stem cells. This conversion strategy gives rise to a major fraction of functional glutamatergic neurons and a very minor fraction of GABAergic cells in a short period of time. We observed an increase in the number of bead-like swellings in neuronal processes in the patients. Neuritic beading is an early hallmark of neuronal toxicity induced in a variety of pathological conditions including mitochondrial disease. Earlier in the differentiation process we observed lower mitochondrial membrane potential, abnormal morphology and distribution. We used whole-cell patch-clamp recordings to characterize single neuron properties from control individuals and NGLY1 patients. We found a lower rate and amplitude of excitatory postsynaptic currents in the patients compared to the controls. Using a rotor fluorescent dye we then looked for the presence of protein aggregates with and without proteasome inhibitor. We observed an increase in the number of cells that stained positively with this dye in basal conditions in the NGLY1 deficient patients but not in the controls. We then confirmed the presence of these aggregates using ultrastructural examination of neurons (including axons, dendrites and synaptic domains) in the NGLY1 deficient patients. Future studies will develop more robust, highly predictive and quantitative systems to explore the role of proteostasis networks in the regulation of aggregate formation and degradation, and would harness this knowledge for therapeutic development.

Title: Modeling benign adult familial myoclonic epilepsy (BAFME) using patient specific induced pluripotent stem cells (iPSCs)- derived neurons

Authors: *Y. NAGASAKO[1,2], S. MAEDA[2], H. TANABE[2], M. ISHIKAWA[2], H. ISHIURA[1], T. TODA[1], S. TSUJI[1], H. OKANO[2]
[1]Neurol., The Univ. of Tokyo, Tokyo, Japan; [2]Physiol., Keio Univ. Sch. of Med., Tokyo, Japan

Abstract: Benign adult familial myoclonic epilepsy (BAFME) is an autosomal dominant disorder characterized by myoclonic tremor and infrequent epilepsy with a benign clinical course. Recently, we have discovered that noncoding TTTCA and TTTTA pentanucleotide repeat expansions in introns of three different genes, *SAMD12*, *TNRC6A* and *RAPGEF2*, as causative mutations in BAFME families (Ishiura et al. Nat Genet, 2018), indicating that these pentanucleotide repeat expansions have key roles in the pathogenesis presumably through RNA-mediated toxicity mechanisms. This is also supported by the findings that RNA foci were observed in cortical neurons. Due to the lack of obvious neuropathological alterations in the brains of patients with heterozygous mutations, aberrant neural network rather than neurodegeneration appears to underlie the phenotype. To elucidate the mechanism by which these pentanucleotide repeat expansions become neurotoxic, we used human induced pluripotent stem cells (iPSCs)-derived neurons to model BAFME-associated pathophysiology *in vitro*. We have successfully generated integration-free iPSCs derived from the fibroblasts of two donors of BAFME using five non-integrative episomal plasmids (pCE-hOCT3/4, pCE-hSK, pCE-hUL, pCE-mp53DD and pCXB-EBNA1), encoding reprogramming factors of Oct3/4, dominant negative p53, Sox2, Klf4, L-Myc, Lin28, and EBNA1, under feeder free conditions. Recent studies suggested that the altered balance between inhibitory and excitatory neurons leads to the over-excitation of neural network and epileptic phenotypes. To elucidate the balance between inhibitory and excitatory neurons in BAFME, we employed the temporal over-expression method using *Neurogenin2 (Ngn2)* or *Ascl1/Dlx2* that can induce the neuronal differentiation toward excitatory and inhibitory neurons, respectively. First, we introduced the transgenes, that can drive the expression in DOX dependent manner, using PiggyBac transposon-mediated gene transfer and established stable cell lines. We differentiated the stable cell lines to excitatory neurons and found that iPSC derived from BAFME patients could be differentiated to excitatory neurons as well as that from normal controls, which is consistent with the assumption that BAFME is caused by neuronal impairment in adulthood but not in developmental stages. These neurons maintaining the patient's genetic background will provide a model allowing exploration of the downstream effects of the expansion as well as therapeutic interventions, such as drug screening and dual sgRNA-guided excision of the (TTTCA)n tract by CRISPR/Cas9 technology.

Title: Subset of genes spanning chromosome 16p11.2 deletion contribute to a hyperproliferation phenotype observed in patient derived neural stem cells

Authors: *M. MEHTA[1], R. CONNACHER[1], P. G. MATTESON[2], S. PREM[1], M. WILLIAMS[1], M. AYALA[2], E. DICICCO-BLOOM[1], J. H. MILLONIG[1,2]

Abstract: Current research supports the idea of multiple forms of autism: idiopathic with no known cause, as well as syndromic forms associated with single gene mutations, or copy number variations. Here we are studying a form of autism caused by a 28-gene deletion on Chromosome 16, known as Chromosome 16p11.2 deletion syndrome. The deletion is associated with speech and/or developmental delays in 85% of carriers, and autism spectrum disorders in 19-28% of carriers. For the present study, iPSCs were obtained from 2 individuals with the deletion syndrome, along with 6 unrelated sex matched controls. 3 clones from each individual were picked to serve as biological replicates, and were differentiated into neural stem cells (NSCs). Initial proliferation experiments comparing DNA synthesis via thymidine incorporation uncovered a hyperproliferation phenotype in NSCs derived from patients carrying the deletion. To determine which of the 28 genes spanning the deletion were contributing to the phenotype, a 28 gene multiplex Luminex assay was employed to measure gene expression. Of the 28 genes, only 11 were found to be expressed during the NSC time point. A significant reduction ($p < 0.01$) in gene expression was found for all 11 genes for the two 16p11.2 affected individuals when compared to 6 unique controls. We have hypothesized that these 11 genes, or a subset of the 11, are contributing to the hyperproliferation phenotype. As of now we have obtained 3 shRNAs per gene, 33 total, and have generated lentivirus in order to perform knockdown experiments in control NSCs to test if any of the knock-downs can phenocopy the 16p11.2 hyperproliferation effect. Future studies will involve overexpression experiments in the 16p11.2-affected NSCs in attempts to correct the phenotype. Uncovering the molecular basis of the Chr16p11.2 hyperproliferation phenotype will allow us to further identify subgroups of autism, which will lead to a more personalized treatment approach for the disorder in the future.

Title: Modeling an epilepsy-associated cortical malformation using hiPSC-derived organoids

Authors: *S. SONG, R. DHINDSA, D. WILLIAMS, E. HEINZEN COX, D. GOLDSTEIN, M. BOLAND
Columbia Univ., New York, NY

Abstract: Periventricular nodular heterotopia (PVNH, OMIM #300049) is a malformation of cortical development that often presents with epilepsy, and currently no effective treatment exists. While a number of genes have been implicated in PVNH, it is most often caused by mutations in genes involved in cytoskeletal (i.e. *FLNA*) or cytoskeleton-associated pathways. Our group recently performed a trio-based whole-exome sequencing analysis of individuals with PVNH and discovered several heterozygous protein-truncating variants in *MAP1B*; a gene not previously implicated in PVNH. Interestingly, we identified both *de novo* and familial MAP1B mutations, and 2 out of 4 *MAP1B* PVNH cases also presented with polymicrogyria. MAP1B is a microtubule-associated protein that has known roles in growth cone dynamics, migration, and axon elongation and guidance in the nervous system. To date, PVNH causative genes have not been developmentally or functionally evaluated in human neurons or neural networks. Given that several proteins associated with the cytoskeleton are implicated in neuronal migration disorders (lissencephaly, polymicrogyria, heterotopias), and MAP1B's functions in microtubule and actin cytoskeleton dynamics, we hypothesize that *MAP1B mutations affect cellular polarity and migration, and result in morphological abnormalities and aberrant neuronal activity.* CRISPR/Cas9 was used to create a patient-specific *MAP1B* mutation (R303X) into an hiPSC line derived from a healthy female. In the process, we were also able to derive heterozygous ($^{+/-}$) and homozygous ($^{-/-}$) *MAP1B* knock-out hiPSC lines. Similar methods were used to generate *FLNA*$^{+/-}$ and *FLNA*$^{-/-}$ hiPSC lines. *FLNA* encodes the cytoskeletal protein Filamin-A; the most commonly mutated gene in PVNH. Together, these MAP1B and FLNA hiPSC lines were used to develop a cortical organoid (hCO) model to study the etiology of PVNH in human neural networks. We have identified striking morphological phenotypes related to neuronal progenitor polarity and migration defects in mutant hCOs relative to isogenic control hCOs. Furthermore, single-cell RNA-seq has begun to identify molecular network and cellular signatures of PVNH in MAP1B and FLNA hCOs. Taken together, this study will significantly enhance our understanding of the molecular machinery controlling neuronal migration and cortical development in humans, which may thereby improve the health of individuals with PVNH-related epilepsy.

Title: Ultrastructural analysis of motor neurons derived from induced pluripotent stem cells (iPSCs) of patients with Brown-Vialetto-Van Laere (BVVL) syndrome

Authors: *F. COLASUONNO[1], A. NICEFORO[1,2], A. FRACASSI[1,3], C. COMPAGNUCCI[2], E. BERTINI[2], S. MORENO[1]

Abstract: Brown-Vialetto-Van Laere syndrome (BVVL) is a rare, childhood-onset neurological disorder characterized by hearing loss, sensory ataxia and spinal motor neuron (MN) neurodegeneration[1]. The disease is caused by loss-of-function mutations in two riboflavin transporters (RFT2 and RFT3). Riboflavin is the precursor for FMN and FAD, i.e., cofactors of flavoproteins, which are involved in several energy metabolism pathways. Particularly, redox reactions, such as mitochondrial electron transport chain, depend on flavoproteins, so that impaired mitochondrial functionality is likely to contribute to the disease. However, the role of oxidative stress and, more generally, the pathogenic mechanisms underlying BVVL syndrome are still unclear. Even morphological studies aiming at characterizing mitochondrial population in BVVL cells are lacking, encouraging research addressing this specific issue. On the other hand, the cellular effects of riboflavin, empirically used in systemic therapeutic treatment of patients, are so far unexplored[2]. In the present work, we took advantage of induced pluripotent stem cells (iPSCs) technology to perform ultrastructural analyses of BVVL cells, before and after treatment with riboflavin and the antioxidant N-acetyl-cysteine (NAC). Patient-specific iPSCs and iPSCs-derived MNs were analyzed by Focused Ion Beam/Scanning Electron Microscopy (FIB/SEM)[3], and compared with their counterparts, obtained from healthy individuals. BVVL iPSCs and derived MNs displayed aberrant mitochondrial ultrastructural features compared to control cells, compatible with the concept that riboflavin deficiency affects energy metabolism. Treatment with riboflavin in combination with NAC resulted in partial rescue of iPSCs-mitochondrial morphology in patients' cells. Consistent with ultrastructural results, molecular data obtained by a sensitive technique employing MitoSOX^{TM}Red probe, demonstrate significantly higher levels of superoxide anion in diseased cells *vs.* controls. Also in agreement with FIB/SEM observations, riboflavin and/or NAC supplementation restored normal $O_2^{-\cdot}$ levels. Our data support the use of iPSCs for *in vitro* modeling of BVVL syndrome, highlighting the pathogenic role of oxidative stress generated by mitochondrial dysfunction. Restoring redox balance by riboflavin/NAC treatment opens the way to future antioxidants-based therapeutic strategies aimed at ameliorating and/or preventing symptoms of BVVL syndrome. *1. Title: Reduced neuronal complexity and -activity in human inducible pluripotent stem cell derived excitatory cortical neurons carrying the MELAS 3243A>G mitochondrial mutation

Authors: *T. M. KLEIN GUNNEWIEK[1], M. FREGA[2], D. CASSIMAN[3], E. MORAVA-KOZICZ[3], N. NADIF KASRI[4], T. L. KOZICZ[5]
[1]Dept. of Anat., [2]Radboudumc, Nijmegen, Netherlands; [3]Univ. Hosp. Leuven, Leuven, Belgium; [4]Radboud UMC, Nijmegen, Netherlands; [5]Anat., Radboud Univ. Med. Ctr., Nijmegen, Netherlands

Abstract: Most individuals diagnosed with the most common mitochondrial disorder MELAS (Mitochondrial encephalomyopathy, lactic acidosis, and stroke-like episodes), carry the pathogenic variant m.3243A>G in their mitochondrial DNA (mtDNA). Patients show a broad range of symptoms, involving mainly the skeletal muscle and the central nervous system. In order to increase our understanding on the neuropathobiology, we generated human excitatory cortical neurons, derived from human inducible pluripotent stem cells (hiPSCs) and studied the impact of mt.3243A>G on mitochondrial- and neuronal function. Patient-derived fibroblasts were reprogrammed to hiPSCs, during which the mitochondrial bottleneck induced biphasic mitochondrial segregation. Two clones from the same patient, with different heteroplasmy levels (0%, and 83%) were expanded, as well as an external, commercial control cell line. These hiPSCs, one external control line, one isogenic control line, and one line containing the 3243A>G mutation, were differentiated into excitatory neurons by lentiviral rtTa- and Neurogenin 2 (Ngn2) expression.
We compared neurons of all three cell lines using a Seahorse Mito Stress test, and found that the presence of the m.3243A>G mutation in the neurons was accompanied by lower basal-, ATP-linked-, and maximal mitochondrial respiration ($P<0.05$). Using DsRed2-Mito7 transfection, we found a significantly lower abundance of axonal mitochondria in the neurons with the m.3243A>G mutation, whilst a MAP2/Synapsin immunohistochemical staining revealed a lower post-synaptic density ($P<0.05$). We also found a decreased sEPSC frequency in the m.3243A>G neurons ($P<0.05$) using single-cell voltage clamp recording. In addition, using micro-electrode arrays (MEAs), we observed a similar phenotype on the network level, with a reduced mean firing rate ($P<0.05$) as well lower synchronous network bursts ($P<0.005$), in the neurons carrying the 3243A>G mutation.
Our study illustrates for the first time, the potential role of a synaptic deficit in the neurological manifestations of MELAS, and highlights the relevance of a patient-specific in vitro

neurophysiologic model of MELAS disease. Our future goal is to employ our MEA system in validation of current forms of therapy, as well as a tool for the screening of new treatments.

Title: Investigation of the role of CHD8 in human brain development at single-cell resolution

Authors: *G. QUADRATO[1,2], B. PAULSEN[2], T. NGUYEN[1,2], S. SIMMONS[3], S. VELASCO[3,2], J. SHERWOOD[4,2], J. PAN[3], F. ZHANG[3], A. REGEV[3], J. LEVIN[3], P. ARLOTTA[2]

Abstract: The ATP-dependent chromatin-remodeling factor CHD8 is one of the most commonly mutated genes in sporadic autism spectrum disorder (ASD), and results in an ASD subtype associated with a high prevalence of macrocephaly. Although this gene has been shown to regulate other ASD risk genes the study of its functional relationship to autism phenotypes has so far focused primarily on low-complexity cell culture models. To date, limited information is available on the cell-type specific cellular and molecular defects induced by CHD8 mutation in human brain cells. To address this question, we have used pluripotent stem cell (PSC) lines heterozygous for a CHD8 loss of function mutation and isogenic control lines. We have demonstrated that these lines can be used to generate different 3D brain organoids models, which can be grown over extended time periods. We have used these models to investigate developmental processes and cellular and molecular changes associated with the CHD8 mutation. These organoids can recapitulate the macrocephaly phenotype observed in several of the ASD patients carrying this mutation. In order to gain information on specific cell types affected we have performed single-cell analysis of CHD8 mutant and control organoids. We have profiled the RNA of a total of 128,000 single cells from both 4 and 6 month old organoids (n=4 per age and genotype) using the 10X Genomics Chromium system, and have performed clustering and differential gene expression analysis. Upon clustering of single cells we find that most clusters are populated by cell types of both genotypes. This indicates that most cell types are reliably made, and that comparisons can be performed even with a relatively small number of samples (n=4 organoids per age and genotype). Furthermore, preliminary analysis has identified

sets of genes that are differentially expressed between the CHD8-/+ and control organoids. Within specific clusters and subclusters we find that both the type and degree of molecular phenotypes differ between cell types. Altogether, these data provide first insight into cellular and molecular abnormalities associated with ASD genetics validate the use of organoids to model human cortical development and cell type specific changes in neurodevelopmental disorders.

Sch., Boston, MA; [6]Yale Univ., New Haven, CT; [7]Univ. of Texas Southwestern Med. Ctr. at Dallas, Dallas, TX

Abstract: Disease heterogeneity in psychotic illness presents a significant challenge. The BSNIP consortium has demonstrated that a battery of measures of cognition and brain activity collected from individuals with diverse psychosis diagnoses identified no diagnosis-specific biomarker, but rather suggested three distinct psychosis subgroups called Biotypes. We hypothesize that neural progenitor cells (NPCs) and neurons differentiated from patient-derived induced pluripotent stem cells (iPSCs) may uncover synaptic mechanisms and divergent cellular traits in these novel Biotypes. A panel of cognitive, neuropsychological and neuroimaging measures were previously collected for individuals with psychosis (schizophrenia, schizoaffective disorder, psychotic bipolar disorder) (N=711), relatives (N=883) and healthy comparison subjects (N=278). A subset of these individuals provided dermal biopsies for additional study, which were cultured to establish patient-derived fibroblast lines. The BSNIP phenotyping was used to define three Biotypes, each with divergent cognitive control and sensorimotor reactivity scores. Fibroblasts representing all three Biotypes and healthy comparisons (N=16) were reprogrammed into iPSCs. These iPSC lines were then validated and differentiated into neural progenitor cells (NPCs) and cortical-like neurons. Cellular adhesion and migration is being measured in NPCs. In mature neurons and cortical-like organoids, cellular morphology and

organization are being examined. Data on cellular migration and morphology from the cells will be presented, along-side of the human phenotypes from psychosis individuals. Biotype-1(B-1) shows significant cognitive impairment and EEG hypoactivity in basal and evoked conditions, therefore we hypothesize that B-1 NPCs will show impaired adhesion/migration and B-1 neurons will demonstrate reduced connectivity and dendritic arborizations. Since Biotype-2(B-2) shows EEG hyperactivity, we hypothesize that B-2 neurons will demonstrate cellular integration and connectivity. Since Biotype-3(B-3) are most similar to healthy, we expect B-3 neurons to have healthy developmental and morphological profiles. We are testing these outcomes to explore the biological bases for the BSNIP Biotypes, and test further stratification of psychosis subgroups The use of patient-derived iPSCs is a potential method for investigating cellular mechanisms of human disease, and may offer a novel translational platform for novel drug discovery.

Title: Optimization and characterization of protocols for 3D human brain models: Cerebral organoids and spheroids

Authors: *S. VELASCO[1], G. QUADRATO[2,3], T. NGUYEN[2,3], S. SIMMONS[1], A. NASH[1,3], M. ROCHA[1,3], J. LEVIN[1], A. REGEV[1], P. ARLOTTA[3,1]
[1]Stanley Ctr. for Psychiatric Res., Broad Inst., Cambridge, MA; [2]Dept. of Stem Cell and Regenerative Biol., USC, Los Angeles, CA; [3]Dept. of Stem Cell and Regenerative Biol., Harvard Univ., Cambridge, MA

Abstract: Many 3D human brain models have been described in recent years: some of them rely on inducing early patterning of specific brain regions (patterned-brain organoids and spheroids), while others omit exogenous morphogenetic and fate-specifying cues and rely largely on self-organization and self-patterning (whole-brain organoids). Brain organoids and spheroids offer great promise for the study of the development and function of the human brain and provide an invaluable tool to model neurological disease. However, the utility of these model systems has been hampered by the limited characterization and comparison of the cell types and features produced by distinct protocols and their inherent reproducibility. In order to address these issues, we generated and optimized different 3D brain model systems and performed extensive comparison of the cell types produced in each, using large-scale single-cell molecular profiling. This type of systematic comparison, across stem cell lines and within sufficient resolution, is

necessary to be able to standardize and cross- compare these models. Single-cell transcriptomic atlases from the endogenous human brain, both existing and those that are currently being generated, will be used to compare and define the similarities and differences of the various cell types produced in 3D cellular models and their endogenous counterparts. The results of this study will pave the way for the future development and optimization of 3D brain models and will be crucial to inform the choice of models for distinct experimental applications.

Abstract: Disorders of the central nervous system (CNS) result in one of the largest economic burdens on society. While research has made enormous contributions in the identification of CNS disease-related genes, the underlying molecular mechanisms associated with disease pathology in human neuronal cells remain unclear. Developing a method to recapitulate disease pathology in human neurons grown *ex vivo* is critical for furthering understanding on CNS disorders and advancing therapeutic development. Our research uses CRISPR guide RNAs (gRNA) with a nuclease-deficient Cas9 (dCas9) fused with a transcriptional activator to upregulate endogenous neuronal-fate determining genes in adult somatic cells to facilitate transdifferentiation to induced neurons (iN). We have successfully upregulated endogenous

BRN2, *ASCL1*, *MYT1L* and *NEUROD1* (*BAMN*) in human adult fibroblasts following delivery of a CRISPR-dCas9 activation complex and gRNAs targeted to *BAMN*. Our time course studies show downregulation of fibroblast markers and upregulation of immature, developing and mature neuronal markers via qPCR. Immunocytochemistry revealed subpopulations of cells that are positive for neuronal markers, suggesting transdifferentation. We are currently investigating methods to increase transdifferentiation efficiency that will enable *in vitro* disease modeling of genetic neurological disorders in patient-specific iNs. Our group is creating iN to advance understanding on neuronal dysfunction in patients with Jordan's Syndrome, a rare neurodevelopmental disorder arising from *de novo* mutations in protein phosphatase PP2A regulatory B56δ subunit gene (*PPP2R5D*). Our research is also focused on implementing the CRISPR/Cas9 nuclease to correct *PPP2R5D* mutations, thereby enabling disease-associated phenotypic analysis. We are currently characterizing Jordan's Syndrome patient-derived fibroblasts and employing CRISPR/Cas9 targeted correction of *PPP2R5D* with Homology Directed Repair (HDR), Homology-mediated End Joining (HMEJ) and Microhomology-mediated End Joining (MMEJ). To our knowledge we are the first to demonstrate endogenous upregulation of *BAMN* in human somatic cells with dCas9-VP64 and begin studies towards Cas9 gene-editing in patient somatic cells transdifferentiated with dCas9-VP64 and gRNAs. These studies support the potential of the CRISPR/dCas9 and Cas9 systems as alternative methods for creating disease models and advancing personalized medicine for individuals with neurological disorders.

Title: Three-dimensional cellular model of hypoxic brain injury of prematurity

Authors: *A. M. PASCA[1], J.-Y. PARK[2], H.-W. SHIN[2], Q. QI[4], O. REVAH[2], R. KRASNOFF[4], R. O'HARA[2], J. WILLSEY[2], T. PALMER[2], S. P. PASCA[3]
[1]Pediatrics, [3]Psychiatry & Behavioral Sci., [2]Stanford Univ., Palo Alto, CA; [4]UCSF, San Francisco, CA

Abstract: Progress in critical care has significantly improved the survival of extremely premature infants born before 28 weeks of gestation. However, extreme prematurity is associated with devastating consequences, particularly for brain development. Up to 70% of patients have significant life-long impairments, including intellectual disability, autism or ADHD. Little is

known about the cellular mechanisms leading to brain injury in this vulnerable population, but it is thought that low oxygen levels in the brain play a critical role. Here, we used human stem cells derived 3D brain region-specific organoids or spheroids that resemble the developing cerebral cortex to study the effect of oxygen deprivation at mid-gestation. We found defects in specific progenitor populations that are associated with the expansion of the human cerebral cortex. Moreover, we demonstrate that this effect is mediated through the unfolded protein response (UPR) and leads to cell cycle changes. We validate these findings in human fetal tissue and show that modulation of the UPR pathway can prevent the cell specific defects during oxygen deprivation. We anticipate this human cellular platform will serve as a powerful tool to study the effects of environmental insults and genetic susceptibilities underlying brain injury in premature infants and that it may facilitate drug discovery for preventing long-term neuropsychiatric conditions in premature infants.

Abstract: Bipolar disorder (BD) is neuropsychiatric mood disorder which is among the most disabling conditions worldwide. Since no suitable animal models exist for BD, revealing the etiology and pathophysiological mechanisms still represents a challenging task. In vitro cultivated human induced pluripotent stem cell (iPSC)-derived neural cells are emerging and

might hold promise to investigate the etiology, disease mechanisms and treatment options. However, *in vitro* human neurons that can faithfully reflect the basic principle of human brain functionality, i.e. synchronous network activity has not been achieved in solely person specific human iPSC-based in vitro models. In this study six BD and four control iPSC lines were established from abdominal fat samples of patients with bipolar disorder type 1 and healthy volunteers. We combined isogenic human iPSC-neural aggregates with microelectrode array (MEA) technology and demonstrate the development of functional human neuronal circuits *in vitro*, i. e. neuronal populations with autonomously generated synchronous network activity. We successfully mimic drug-overdose induced seizures in *in vitro* human neuronal networks. Moreover, we apply an anti-epileptic drug, Perampanel, and counteract pathophysiological neuronal network activity of human cortical circuits exposed to intoxicating concentrations of currently prescribed drugs, e.g. lithium salts. Our presented platform allows drug screening and the evaluation of drug repurposing approaches in the context of human specific neuropsychiatric disorders. Thereby, we close a conceptual gap between preclinical animal-based CNS disease modelling and human clinical trials.

Title: Modeling prenatal environmental challenges in placental cells derived from schizophrenic patients

Authors: *E. TIETZE[1], G. URSINI[1], D. R. WEINBERGER[1], J. VAN DE LEEMPUT[1], J. ERWIN[1,2]
[1]Lieber Inst. for Brain Develop., Baltimore, MD; [2]Neurol., Johns Hopkins, Baltimore, MD

Abstract: Schizophrenia (SZ) is a devastating neuropsychiatric disorder affecting around 1.1% of the population. While it is well established that underlying genetic vulnerability interacts with environmental factors to cause SZ, the specific mechanisms contributing to risk are poorly understood. Epidemiological evidence suggests that perturbations to the intrauterine environment play a critical role in SZ etiology. A history of maternal respiratory infections increases the risk of SZ in offspring 3-7 fold. More broadly, pregnancy, labor and delivery, or early neonatal complications termed early life complications (ELCs) increases the risk of SZ by two fold.

Recent genomic analysis using a polygenic risk score model of SZ risk have found that ELCs interact with genomic risk to increase SZ liability by more than 5 fold. Interestingly, loci associated with placental genes that are highly expressed or differentially expressed in preeclampsia or intrauterine growth restriction mediate this effect. Emerging evidence support the idea that placental function plays a key role in brain development. The placenta acts as a dynamic interface that conveys changes between the maternal environment and the fetus. In the case of maternal infection, the placenta acts as a barrier to the infectious agent, while allowing pro-inflammatory cytokines such as IL-6 to enter the fetal circulation. The placenta also produces various compounds including serotonin, BDNF, IGF1/IGF2, and prostaglandins that play important roles in neurodevelopment. In order to investigate the role of the placenta in neuronal development we established iPS cell model of placental differentiation using SZ patient cells. We characterized the differentiation of these cells by single-cell RNAseq and the endophenotypes of these cells both with and without simulated intrauterine environmental challenges.

Title: Using forebrain assembloids to study the role of L-type calcium channels in human cortical interneuron function and dysfunction

Authors: *F. BIREY[1], R. M. AGOGLIA[2], S. P. PASCA[3]
[1]Psychiatry and Behavioral Sci., [2]Genet., [3]Psychiatry & Behavioral Sci., Stanford Univ., Palo Alto, CA

Abstract: Voltage-gated L-type calcium channels (LTCCs) variants are among the most replicable risk factors in genetic studies of neuropsychiatric disease. The mechanisms by which these genetic events lead to disease are not currently known. Previous work has indicated that LTCCs play a critical role in cortical interneuron migration and functional integration into cortical circuits. We have developed a tridimensional (3D) neural differentiation platform derived from human induced pluripotent stem cells (hiPSCs), termed forebrain assembloids, to study the migration and circuit integration of human cortical interneurons. Using this modular, region-specific organoid system, we identified migration defects in interneurons generated from Timothy syndrome, a monogenic form of autism caused by mutations in a LTCC subunit encoded by *CACNA1C*. Using transcriptional profiling, functional live imaging and

pharmacology in patient and control hiPSC-derived forebrain assembloids, we investigated the specific contributions of LTCCs to interneuron migration and underlying molecular mechanisms that are disturbed in interneurons derived from Timothy syndrome. Our results show that the forebrain assembloid system can be used to study the molecular underpinnings of dynamic cellular processes that take place in late human brain gestation towards revealing novel disease signatures.

Abstract: The corticospinal tract plays a central role in controlling muscle activity by mediating voluntary movements. In primates, this circuit possesses unique monosynaptic projections from corticospinal fibers to spinal motor neurons that are thought to be involved in fine distal motor control. Damage or degeneration of this circuit in spinal cord injuries, amyotrophic lateral sclerosis or autoimmune disorders results in severe motor dysfunction. We developed a novel approach to study human cortico-spinal development and neuromuscular function using 3D brain region-specific organoid or spheroid cultures generated from pluripotent stem cells (hPSCs). We first generated hPSC-derived ventral spinal cord spheres (hSCs), which include functional motor neurons able to promote muscle contraction when co-cultured with 2D and 3D human skeletal muscle (hSkM). Assembly of human cortical spheroids (hCSs), which include pyramidal neurons of all layers, with hSC-hSkM in cortico-spinal assembloids results in the formation of corticospinal projections. Using a combination of viral tracing, calcium imaging and electrophysiological methods we present evidence of the formation of the first in vitro model of the human cortico-spinal-muscular assembly that could be used to study the development and disorders affecting this circuit.

Title: Evaluation of redox dysregulation in schizophrenia using induced pluripotent stem cells

Authors: *B. GIANGRECO[1], D. DWIR[1], S. SACHCHITHANATHAM[1], J. KOCHER-BRAISSANT[1], L. BARTESAGHI[2], P. STEULLET[1], J.-H. CABUNGCAL[1], R. CHRAST[2], N. TONI[1], K. Q. DO[1]
[1]Ctr. for Psychiatric Neurosciences, Prilly-Lausanne, Switzerland; [2]Neuorscience, Karolinska Institutet, Solna, Sweden

Abstract: Schizophrenia (SZ) is a psychiatric disorder that involves genetic and environmental factors. A decrease of glutathione (GSH), a major cellular antioxidant, was shown in patient's brain and CSF. Furthermore, polymorphisms in the key synthetizing enzyme for GSH were found associated with the disease. These observations lead to the hypothesis that redox dysregulation is a main hub in this disorder. In this study, we aim to investigate the role of the redox state on neuronal development using induced pluripotent stem cells (iPSC)-derived neuronal precursor cells (NPCs) from SZ patients and healthy controls. iPSC-derived NPCs were generated from one patient from a well-characterized cohort of SZ patients at the early stage of the disease and two aged-matched healthy controls. Here, we examined the role of redox dysregulation in iPSC differentiation. We found that a redox dysregulation led to a delay in the differentiation of iPSCs-derived NPCs into neurons. Differences of neuronal maturation between patients and controls are under investigation. This method, together with other approaches, will allow assessing whether the redox balance is endogenously altered in iPSC-derived neurons from patients compared to controls.

Title: Stem cell and genome engineering technologies to advance the understanding of neurological diseases

Authors: *R. VEGA, J. DIZON, J. WEBB, D. PIPER
Thermo Fisher Scientific Inc Carlsbad, Carlsbad, CA

Abstract: Neurological disorders are a health concern since a large percent of the population suffers from it. The chronic disorders comprise a spectrum of symptoms that current therapies only partially ameliorate. Familial and mouse models have been valuable tools to gain insight into the diseases but do not completely support preclinical efforts needed for drug development. More effective and predictive models are needed to develop new therapies more reliably and economically. Recent advancements in the genome editing and stem cell field make it possible to establish disease-relevant in vitro models. Human induced pluripotent stem cells (iPSCs) can be differentiated into numerous cell types and in combination with CRISPR/Cas9 genome editing can provide new ways to study the pathophysiology of the brain in vitro. In this study, we utilize an iPSC line that stably expresses the Cas9 nuclease protein to efficiently introduce the disease-linked mutations. We derived neuronal progenitors and neurons from the normal and mutant lines to perform functional and High Content phenotypic assays. We demonstrate the cellular phenotypes of iPSC-derived neurons can be translated into disease models to accelerate the finding of new therapeutic targets for drug discovery.

Title: Alpha-tocopherol and polyunsaturated fatty acids treatment effects on quality and maturation of cultured human neurons derived from induced pluripotent stem (hIPS) cells

Authors: *K. M. GLANOWSKA[1], G. G. MURPHY[2], K. S. O'SHEA[3], C. J. DELONG[4]
[1]Dept. of Neurol., [2]Mol. and Behavioral Neurosci. Inst., [3]Dept. of Cell and Developmental Biology, Dept. of Psychiatry, [4]Dept. of Cell and Developmental Biol., Univ. of Michigan, Ann Arbor, MI

Abstract: Utilization of hIPS cells derived neurons as models of neurological and neuropsychiatric disorders has been growing rapidly in recent years. Existing differentiation protocols generate, at least in terms of expression of appropriate neuronal markers, neurons that appear to be relatively mature. However, mature electrophysiological properties of those neurons and their ability to reproduce firing behavior observed in tissue from both rodent or human brains have been difficult to obtain. Both passive and firing active properties of IPS cells derived neurons e.g.: high input resistance, depolarized resting membrane potential, and wide action potentials (APs) suggest immature developmental state. The relatively low fraction of mature IPS cells derived neurons in 2D cultures likely contributes to the high variability and low reproducibility of electrophysiological studies performed in these model systems. To overcome these challenges, we have begun to test the impact of factors known to be crucial for proper brain development and which can be easily incorporated into established cell culture protocols. Here we present data using tocopherol, a potent antioxidant demonstrated to enhance efficiency of neural stem cell differentiation in rodent cultures, and polyunsaturated fatty acids (FAs) critical for the fetal brain development. Human NPCs were derived from IPS cells via dual inhibition of BMP and TGFβ signaling using Dorsomorphin and SB431542. Neuronal differentiation was induced by culturing NPCs in complete BrainPhys supplemented weekly with α-tocopherol (α-t) and various FAs. Electrophysiological recordings were made after 8 weeks of differentiation. We have tested the following treatments: cont + α-t; + α-t + docosahexaenoic acid (DHA); + α-t +eicosapentaenoic acid; + α-t +arachidonic acid, and + α-t +oleic acid. To minimize bias, the experimenter performing recordings was blind to the culture conditions. We examined both passive properties and ability of neurons to fire evoked individual as well as repetitive APs and the presence of synaptic activity. The success rate defined as the fraction of recorded cells with stable seals over time and ability to fire repetitive APs was highest in the cont + α-t and lowest under control conditions. Most treatments with FAs appear to improve quality of recordings in comparison to controls with addition of DHA resulting in the highest proportion of spontaneously active neurons. Interestingly, the consistent synaptic activity was the highest in α-t alone. Our results provide a strong evidence that culture enrichment with α-t improves the quality of electrophysiological data from IPS cells derived neurons.

Title: Post-translational tubulin modifications in differentiated human neural stem cells

Authors: V. B. KNIGHT, M. P. JOGALEKAR, *E. E. SERRANO
Biol., New Mexico State Univ., Las Cruces, NM

Abstract: The protein tubulin is assigned diverse cellular functions that range from chromosomal separation to locomotion. The functional diversity of tubulin is achieved through the expression of specific tubulin isotypes in different cell types or developmental time periods. Post-translational modifications (PTMs) of tubulin are also critical for specific intracellular objectives, such as binding and recruiting motor proteins. In neurons, the isotypic expression profile for tubulin is well characterized, and the importance of PTMs for proper neuronal function has gained recent attention due to their implication in neurodegenerative disorders. There are relatively fewer studies of tubulin PTMs and isotypes in astrocytes. It is well established that tubulin isotypes and specific PTMs are crucial for distinct cellular functions. However, the role of tubulin specializations in the specification of neural cell fate has not been evaluated. Therefore, we undertook an analysis of PTMs in basal and differentiated human neural stem cells (hNSCs) derived from the federally approved H9 embryonic stem cell line. Immunocytochemical methods, fluorescent antibody probes, and confocal microscopy facilitated image acquisition of fluorescent signals from class III β- tubulin (βIII-tubulin), acetylated tubulin, and polyglutamylated tubulin. Fluorescent probe intensities were assessed with the 'EBImage' package for the statistical programming language R, and compared using Student's t-tests. Qualitative analysis indicated that βIII-tubulin, acetylated tubulin, and polyglutamylated tubulin were expressed to some degree in all basal and differentiated hNSCs. Quantification and statistical analysis of fluorescence intensity demonstrated that the fluorescence probe intensity ratio for acetylated tubulin/ βIII-tubulin was greater than the ratio for polyglutamylated tubulin/ βIII-tubulin in differentiated astrocytes. These findings represent a snapshot of the tubulin expression profile during the specification of neural cell fate. Furthermore, these results imply that investigations of tubulin PTMs have the potential to advance our understanding of the generation and regeneration of nervous tissue.

Title: A novel approach for efficient dissociation of distinct adult mouse brain regions and subsequent sorting of neurons and neural stem cells using the MACSQuant® Tyto®

Authors: *A. BOSIO, S. REIß, C. WITTWER, J. GAISER, M. JUNGBLUT
Miltenyi Biotec, Bergisch Gladbach, Germany

Abstract: Careful tissue dissociation and preparation of single-cell suspensions with high cell viability and a minimum of cell debris are prerequisites for reliable cellular analysis. In case of adult rodent brain, sophisticated mechanical and enzymatic treatments are required to successfully disaggregate the tightly connected neural cells. The process becomes even more challenging when only small brain regions serve as starting material for generation of single cell suspensions and highest possible viability, recovery and functionality are crucial for successful down-stream processing. In the past, we have set up elaborated technologies for the automated dissociation of adult rodent brain by combining mechanical dissociation using the gentleMACS™ Octo Dissociator with an optimized enzymatic treatment, followed by an efficient clearing procedure to eliminate debris and erythrocytes. The protocol was now further refined for highly effective generation of single cell suspensions from small brain regions with highest possible viability and neural cell yield and a minimum of contaminating debris. Dissociation of one cerebellum yielded 1.3x10E6 ± 6x10E5 cells (n=5), whereas 6.3x10E5 ± 2.8x10E5 cells were obtained one cortical hemisphere, 4.3x10E5 ± 7.6x10E4 cells from the SVZ tissue of one mouse (n=9), and 3.3x10E5 ± 9.5x10E4 cells (n=9) from 2 hippocampi (n=9). Viability rates were between 70 and 97%, depending on the brain region. Subsequently, cell isolation of neurons or Neural Stem Cells (NSCs) was carried out with the MACSQuant Tyto, a new multi-parameter cell sorting device that uses a micro-chip based sorting technology for sterile and gentle cell isolation. Unlike conventional droplet sorters, cells do not experience high pressures and no charge is applied, ensuring high viability and functionality. Neurons were indirectly identified by a combination of markers specific for non-neuronal cell populations. A number of 1.2x10E4 neurons with a viability of 97% was obtained from one cerebellum and a number of 4.4x10E3 neurons with a viability of 95% from one cortical hemisphere. NSCs were identified by labeling the positive markers GLAST and PlexinB2 and the negative markers CD24, TER119, and CD45 before subjected to the MACSQuant Tyto sorting. This protocol resulted in highly pure (>95%) and viable NSCs (>90%), which formed a high number of neurospheres, that differentiated into different neural cell types. In summary, we present a novel approach for isolation of neurons from various brain regions and NSCs from the SVZ by

combining an elaborated method for gentle and efficient dissociation of small brain regions with a sophisticated cell sorting Technology.

Title: Examining the role of sex hormones in postnatal depression and major depressive disorder: Polygenic risk scores and hippocampal neurogenesis

Authors: *D. SMEETH[1], I. KOUROUZIDOU[1], T. POWELL[2], S. THURET[1]
[1]Basic and Clin. Neurosci., [2]MRC Social, Genet. & Developmental Psychiatry Ctr., King's Col. London, London, United Kingdom

Abstract: Background: Genetic variation accounts for up to 54% of postnatal depression (PND) liability and 40% of major depressive disorder (MDD) liability. Alterations to sex hormones have been associated with the pathophysiology of depressive disorders and may partly explain the higher rates of MDD amongst females. However, few studies have considered whether genetic variants associated with sex hormone levels directly increase risk for depressive disorders. This risk may be mediated by alterations in adult hippocampal neurogenesis (HN), a cellular process which has been associated with mood regulation. Here we consider: i. the effects of oestradiol, testosterone and prolactin on human HN, and ii. whether polygenic risk for higher sex hormone levels directly affect risk for MDD or PND. Methods: To better understand how sex hormones affect HN, human female hippocampal progenitor cells (HPCs) were cultured with biologically relevant concentrations of each hormone. Immunocytochemistry and high-throughput analysis were used to quantify a range of markers of cell fate. To understand how polygenic risk scores (PRS) for sex hormones moderate risk, we used the PRSice software and sex hormone genome-wide summary statistics from the Twins UK cohort (n=2913). Our target dataset was the European RADIANT cohort consisting of 176 PND, 2772 MDD and 1588 control subjects. Sex and seven ancestry principal components were included as covariates in all logistic regressions. Results: When examining the effect of sex hormones on HPC fate, prolactin increased the proportion of Map2-positive cells ($N=4$, $F(6,21) = 7.04$, $p = 0.0003$) indicating an increase in neuronal differentiation, but had no effect on HPCs maintained in a proliferative

state. Conversely, oestradiol and testosterone had no effect on HPC differentiation, but increased cell number (N=3, $F(6,14) = 3.42$, $p = 0.027$ & $F(5,11) = 5.378$, $p = 0.0096$). Only the best-fit PRS for oestradiol levels was associated with a depressive disorder, specifically PND case-control status ($\beta = -1156.4$, SE = 423.7, uncorrected $p = 0.006$), where genetic risk for lower levels predicted higher risk for PND. Conclusions: Here we provide evidence that genetic risk for higher plasma oestradiol may explain a small amount of the variance in risk for PND, potentially lowering risk via its ability to increase HPC number. Furthermore, we provide evidence that prolactin possesses neurogenic properties, but that genetic risk for higher prolactin does not influence risk for depressive disorders. This work suggests that the relationship between sex hormones, HN and depression is complex, and that there may not be a clear-cut pathway for aetiology or risk moderation.

Title: Inhibition of the thrombin receptor promotes subventricular zone neural stem cell expansion and differentiation towards the oligodendrocyte lineage

Authors: *C. CHOI[1,2,3], H. YOON[1,2,3], M. LANGLEY[1,2,3], L. KLEPPE[1,2], I. A. SCARISBRICK[1,2,3]
[1]Dept. of Physical Med. and Rehabil., [2]Rehabil. Med. Res. Ctr., [3]Dept. of Physiol., Mayo Clin., Rochester, MN

Abstract: Protease activated receptor 1 (PAR1) is a G-protein coupled receptor (GPCR) family that is widely expressed in the central nervous system and activated by proteolytic cleavage within its extracellular domain to elicit intracellular signaling. Thrombin activates PAR1 with high affinity and is frequently elevated in the context of neural injury. Although over activation of PAR1 has been linked to neural injury, little is currently understood regarding the mechanisms involved or whether PAR1 can be targeted to limit injury and foster repair. In this study, we investigate the regulatory role of PAR1 in the production and differentiation of adult subventricular zone (SVZ)-derived neural stem cells (NSCs) towards the oligodendrocyte lineage. First, we established that PAR1 is expressed by Sox2+ NSCs and by Nestin+ neural progenitors within the SVZ of the adult mouse brain. We then demonstrated that thrombin gates

Ca^{2+} signaling in SVZ NSC monolayer cultures in a PAR1-dependent manner. SVZ NSCs derived from PAR1 knockout mice showed an enhanced capacity for self-renewal in cell culture, including increases in neurosphere formation and in BrdU incorporation, and these effects were mimicked by a PAR1 small molecule inhibitor SCH79797. Monolayer cultures from the SVZ of PAR1-knockout mice contained more Nestin, NG2+ and Olig2+ cells indicative of enhancements in expansion and differentiation along the oligodendrocyte lineage. Also, cultures of NSCs lacking PAR1 expressed higher levels of myelin basic and proteolipid protein upon differentiation induced by growth factor withdrawal. Reflecting a potentially suppressive role for PAR1 in SVZ NSC production and differentiation, the SVZ of PAR1-knockout mice contained more Sox2+ and Ki-67+ self-renewing NSCs, in addition to Olig2+ oligodendrocyte progenitors. Furthermore, the corpus callosum and anterior commissure of adult PAR1-knockout mice contained greater numbers of Olig2+ progenitors and CC1+ mature oligodendrocytes. Altogether, these findings point to PAR1 as a novel target to foster the expansion of SVZ neural stem cells and their differentiation towards mature myelinating oligodendrocytes that may be of particular benefit in the context of neural injury in which PAR1 agonists such as thrombin are increased.

Title: Electrophysiological characterization of sensory neurons derived from human induced pluripotent stem cells (hIPSCs) using a small molecule inhibition protocol

Authors: *L. S. LESPERANCE[1], S. S. SHARMIN[3], J. ELLIS[2], S. A. PRESCOTT[4], A. PIEKNA[3], W. WEI[3]
[1]Neurosci. and Mental Hlth., [2]Developmental & Stem Cell Biol., The Hosp. For Sick Children, Toronto, ON, Canada; [3]Developmental & Stem Cell Biol., The Hosp. for Sick Children, Toronto, ON, Canada; [4]Neurosciences and Mental Hlth., Hosp. For Sick Children, Toronto, ON, Canada

Abstract: The use of human induced pluripotent stem cells (hIPSCs) is rapidly proving to be a valuable tool in the characterization of human disease and represents the forefront of patient-specific medicine. Through modulation of specific developmental pathways using small molecule inhibitors, differentiations can be guided to produce an array of neuronal types. Using

this approach, nociceptor-like neurons can be generated at an accelerated pace compared with previous differentiation methods (Chambers et al. 2012). One of the main limitations surrounding the use of hIPSC-derived neurons, however, is the substantial functional heterogeneity within a differentiated population. Here we report a detailed electrophysiological characterization of hIPSC-derived sensory neuron (hIPSC-PSN) cultures. Our results highlight the heterogeneous physiological profiles of the cells, suggesting that while repetitive spiking nociceptors represent the majority of the population, they are not the only type of neuron present. While certain electrophysiological properties of these neurons such as resting membrane potential and action potential half-width are consistent with values measured from human cadaveric dorsal root ganglion (DRG) neurons, other properties such as rheobase and soma diameter are markedly different, which may hint at differences (e.g. ion channel expression patterns) between regular and hIPSC-derived sensory neurons. Attempts to better direct hIPSC differentiation to achieve a more homogeneous neuron population using varying growth factor combinations reveal a substantial difference in the spiking patterns at 3 weeks post induction but, by 5 weeks, approximately 85% of cells exhibit a repetitive spiking pattern (during sustained somatic current injection) as well as AMPA receptor-mediated excitatory post synaptic currents. Future work will focus on further optimization of the differentiation protocol and the validation of these neurons as model systems with which to elucidate underlying mechanisms of neuropathic pain and human disease using electrophysiology, pharmacological blocking, imaging based approaches and gene expression studies. These findings suggest that careful attention should be taken when interpreting the physiology of hIPSC derived sensory neurons and advocates for methods with which to purify these populations and the need for cell-specific characterizations. Funded through the CHIR and SPOR (Chronic Pain Network).

Title: Elevated MeCP2 in starved neural stem cells

Authors: *X.-B. HE, F. GUO
Shanghai Univ. of Med. & Hlth. Sci., Shanghai City, China

Abstract: This study aims at exploring potential epigenetic regulation of autophagy in neural stem cells. Neural stem cells extracted from mouse embryonic day 14 cortex were challenged with PBS-induced starvation for 10 minutes, half, one, three and six hours respectively. Autophagy was induced from one hour starvation evidenced by increased ratio of LC3II/LC3I protein level, and accumulation of LC3 puncta in cytoplasm. Interestingly elevated MeCP2 protein expression was observed mainly in LC3-weakly expressed cells. Inhibition of autophagy with Bafilomycin A1 or 3-methyladenine further increased the proportion of high MeCP2 expressing cells. Knockdown of MeCP2 in neural stem cells altered their autophagic performance in response to starvation. We also found that DNA methylation pattern of autophagy-related genes was differentially regulated in normal and starved neural stem cells. Taken together, these results suggest that MeCP2 is a negative regulator to autophagic response of neural stem cells.

Title: Sex differences in the proteome of exosomes secreted by fetal neural stem cells

Authors: *D. CHUNG[1], M. PINSON[1], S. KOO[1], L. DANGOTT[2], R. MIRANDA[1]
[1]Neurosci. and Exptl. Therapeut., Texas A&M Hlth. Sci. Ctr., Bryan, TX; [2]Texas A&M Univ., College Station, TX

Abstract: Cells release nano-sized membrane vesicles termed exosomes, that may serve as a mode of intercellular communication by transferring biological information between cells. Neural stem cells (NSCs) reside in a complex microenvironment rich in exosomes. However, the roles of exosomes in mediating interactions between NSCs and their surrounding environment are largely unknown. Using fetal mouse derived cortical neuroepithelium, cultured ex-vivo as non-adherent neurosphere cultures, we found that exosomes could transfer information between donor and recipient cells, serving as a novel means for communication within the fetal NSC niche. While many studies have focused on NSCs in the fetal brain, it has long been assumed that the genetic sex-of-origin of NSCs do not have a significant role in the behavior of NSCs. We therefore initiated an investigation into the impact of genetic sex on the proteome of exosomes secreted by NSCs. Exosomes were isolated by ultracentrifugation from male and female derived NSCs, maintained as neurosphere cultures, and their proteome was assessed by liquid

chromatography-tandem mass spectrometry (LC-MS/MS). Sample data were analyzed using Mascot (Matrix Science, London, UK; version 2.6.0). Scaffold (version 4.8.5, Proteome Software Inc., Portland, OR) was used to validate MS/MS based peptide and protein identifications. Preliminary analysis identified 348 proteins in exosomes that were expressed at approximately equal levels in exosomes derived from both male and female NSCs. However, a number of proteins were expressed uniquely in male or female-derived exosomes. These data suggest that exosomes from male and female-derived NSCs may exert sex-specific control over the behavior of the neurogenic niche during early fetal development.

Title: Investigating the promyelinating properties of the quinolone GSA-10

Authors: L. TIROU[1], C. DEMONGIN[1], H. FAURE[1], A. DEL GIOVANE[2], E. NOCITA[2], A. RAGNINI-WILSON[2], *M. RUAT[1]
[1]NeuroPSI, UMR9197, CNRS, Gif Sur Yvette, France; [2]Univ. of Roma "Tor Vergata", Roma, Italy

Abstract: Adult subventricular zone (SVZ) neural stem cells (NSCs) of the lateral ventricles and parenchymal oligodendrocyte progenitor cells (OPCs) are proposed as the main sources of remyelinating oligodendrocytes (OLs). Various remyelination strategies have been developed to mobilize these cells and to stimulate their differentiation into OLs in animal models of demyelination (Juarez et al, *Brain Res*, 2016). Several small molecules, including the antifungal agent miconazole, the corticosteroid clobetasol, the muscarinic agents benztropine and clemastine, have been shown to promote differentiation of neural progenitors into OPCs and to promote functional remyelination *in vivo* (Deshmukh et al, *Nature*, 2013; Najm et al, *Nature*, 2013; Porcu et al, *PlosOne*, 2015). Interestingly, pharmacological inhibition of Gli1, a transcription factor associated to the Hedgehog (Hh) pathway, using GANT61 increased both SVZ-derived NSCs progeny recruitment to the corpus callosum and their differentiation into OLs, enhancing remyelination (Samanta et al, *Nature*, 2015). Thus, modulators of Smoothened (Smo), the main transducer of Hh, by acting either on NSCs or OPCs to stimulate the rebuilding of the damaged tissue, may have therapeutic value for demyelinating diseases (Ruat et al, *Top Med Chem*, 2015). To further identify active molecules promoting remyelination, we have now investigated the pro-myelinating properties of the quinolinone GSA-10, a Smo agonist acting

through an AMPK non-canonical pathway associated to inhibition of Gli1 transcription (Manetti et al, *EJMC*, 2016; Fleury et al, *Sci Rep*, 2016). We have determined its efficacy to induce the expression of Myelin Basic Protein (MBP) in the mouse immortalized oligodendrocyte precursor cell line (Oli-neuM) expressing the Myelin Regulatory Factor (Porcu et al, *PlosOne*, 2015). Preliminary data indicate that this quinolinone promotes high expression of MBP in an increased number of cells compared to the non-selective Smo agonist clobetasol and relative to Vehicle. These data suggest that GSA-10 is a potent myelin gene inducer. Experiments are underway for evaluating its potency to induce the expression of oligodendrocyte markers and to identify Hh signaling implicated in these effects. We are further characterizing Hh signals regulating the plasticity of the SVZ neurogenic niche using GLAST^{CreERT2}-Ptc$^{+/+}$-YFP and GLAST^{CreERT2}-Ptc$^{-/-}$-YFP mouse reporter lines (Daynac et al, *Stem Cell Reports*, 2016) during remyelination. Altogether, these experiments should bring novel strategies and tools for developing active drugs for demyelinating diseases.

Title: Nanocellulose surfaces promote neural differentiation

Authors: *S. C. PANDANABOINA[1], A. B. RANGU MAGAR[2], K. D. SHARMA[1], B. CHHETRI[2], A. GHOSH[2]
[1]Biol. Sci., Arkansas State Univ., State University, AR; [2]Chem., Univ. of Arkansas at Little Rock, Little Rock, AR

Abstract: Injury or diseases of the nervous system results in permanent loss of function as neurons cannot divide and replace the dead neurons. A possible treatment for restoring normalcy to those patients will be transplantation of functional neurons, prompting our efforts to significantly increase population of neurons differentiating from neural stem cells (NSCs). Of late, matrices fabricated from natural or biocompatible polymers have been tested for neural stem cell differentiation. Cells can grow and differentiate on scaffolds formed by various combinations of polymers and biocompatible materials. In addition, conductive polymers such as polypyrrole (ppy), coupled with natural materials are being tested to check if they are capable of enhancing the differentiation of stem cells into neurons. The use of natural materials such as

nanocellulose (NC) used as cell culture surface has been receiving attention as cellulose is widely available, biocompatible and non-corrosive. Therefore, we differentiated rNSCs on (i) poly-D-lysine (PDL) (ii) NC+polypyrrole (NCPPy) (iii) quaternized NC+polypyrrole (QNCPPy). After differentiation for two weeks, we determined the percentage of cells positive for the neuronal marker βIII tubulin and the glial marker GFAP relative to the total cell count. The highest percentage of rNSCs differentiated into neurons was on NCPPy (69±9.4%) in comparison to the PDL (51±1.04%). Interestingly, astrocyte differentiation was least on NCPPy (12±4.6%) compared to the other surfaces (17±5.2% on QNCPPy and 26±0.8% on PDL). Based on these results, we plan to optimize the surfaces in an effort to further test and check at different time periods if they can promote higher neuronal differentiation.

Title: *In vitro* system to dissect the molecular basis of vanilloid/TRPV1 mediated anti-tumoral activity of human neural progenitor cells in glioblastoma multiforme

Authors: *L. AZMITIA, SR[1], R. UYAR[2], R. KÄLIN[2], B. BRÄNDL[3], F. MÜLLER[3], R. GLASS[2], M. SYNOWITZ[4]

Abstract: Malignant gliomas are the most frequent primary brain tumor in adults, with no curative therapy (Curado *et al.* 2007). Endogenous vanilloids secreted by neural progenitor cells (NPCs) induce cytotoxicity in GBM cells. Thus appears to be mediated by stimulation of the Transient Receptor Potential Vanilloid 1 (TRPV1,) specifically of GBM. We turned to neural progenitors differentiated from human induced pluripotent stem cells as well as directly induced from fibroblasts as in vitro model (Fig. 1 and 2).
Human induced pluripotent stem cells (iPSCs) were differentiated into long-term expandable neural stem cells (lt-NSCs) (Koch *et al*. 2009) and directly reprogrammed fibroblasts into induced NPCs (iNSCs). Both cell lines were expandable, expressed NPCs markers, differentiated into mature neurons and glial cells, showed a stable karyotype and had active membrane potentials (Fig 3).
Human GBM cells were exposed to conditioned media from lt-NSC and iNSCs. We observed an increased cell death in GBM. Exposure of TRPV1-deficient GBM to the same conditioned media

preparations resulted in an attenuated cytotoxic response, suggesting an involvement of endogenous vannilloids secreted by lt-NSC and iNSC in the observed GBM cell death (Fig 4). We have established a model with two different source for human neural progenitors in order to molecularly dissect vanilloid -mediated GBM cytotoxicity. This system may be either exploited via transplanted, isogenic neural progenitors in GBM patients or to identify metabolic pathways leading to the synthesis of individual vanilloids as chemotherapeutic agents.

Title: Zika Virus E protein modulates proliferation and differentiation of human fetal neural stem cells by modulating of microRNA circuitry

Authors: *R. BHAGAT[1], B. PRAJAPATI[2], S. NARWAL[2], Y. K. ADLAKHA[2], P. SETH[2]
[1]Cell. and Mol. Neurosci., [2]Natl. Brain Res. Ctr., Gurgaon, India

Abstract: Zika Virus (ZV) infection has gained worldwide attention following large outbreaks in Brazil during 2015-2016 epidemics and has been linked to severe clinical condition called microcephaly where fetuses are born with abnormally small brain. Emerging literature demonstrate that ZV infection causes death and quiescence in neural stem cells hence reducing overall pool of cells leading to microcephaly. However to date molecular mechanisms of ZV induced microcephaly are poorly understood. We have employed well characterized in-vitro model system of primary human fetal neural stem cells (fNSCs) for understanding the molecular mechanisms of ZV induced microcephaly. We delineated ZV E protein over expression hampers proliferation of fNSCs and reduces growth of neurospheres. Moreover there was induction of proneural gene post E protein expression in fNSCs cultured in proliferating medium, suggesting pre-mature differentiation of cells. Differentiation of fNSCs into neuronal lineage in the presence of E protein induces apoptosis at day-3 of differentiation and migration from differentiating neurospheres is also disrupted. Further we analyzed the global miRNA expression (miRNA Seq) which shows disrupted miRNA circuitry in fNSCs post E protein expression. Among differentially expressed miRNAs (DEM), we validated miR-204-3p, miR-1306-5p, miR-6087, miR-23c and miR-676 using qPCR. These miRNAs are also reported to play role in other viral infections. GO analysis for biological process of targets of differentially expressed miRNAs revealed particular enrichment of DEM targets in cell cycle and cell cycle processes which further substantiates our findings that E protein alters cell cycle dynamics. PANTHER pathway analysis of targets of DEM showed enrichment of crucial developmental pathways including WNT, CCKR, PDGF, EGF, p53, FGF and notch signaling pathways. Our study not only provides novel insights into the mechanisms of ZV induced complications but also function as valuable resource to the field for further understanding of mechanisms.

Title: The neural stem/glioblastoma cell marker GlioStem associates with GOLGA2/GM130, a golgi apparatus protein

Authors: *O. HERMANSON, B. MIGLIORI
Dept. of Neuroscience, Karolinska Institutet, Stockholm, Sweden

Abstract: Certain polymers, such as oligothiophenes (LCOs), can function as single molecule LEDs. LCOs are able to cross physiological cell membranes without additional reagents and to illuminate when interacting with certain biological structures, such as insulin. We have with our collaborators generated and characterized an LCO called p-HTMI or GlioStem that specifically detects embryonic cortical stem cells and subpopulations of cells derived from glioblastoma (GB), including stem cell-like cells and rapidly migrating cells. GlioStem is at least as sensitive and specific than previous methods to detect these cell types (e.g., CD133 or CD44).
We have previously made a thorough verification and validation of the molecule, and found that i) GlioStem passes the cell membrane without any additional reagent or modification, and within a maximum of 10 minutes specifically detects subpopulations of patient-derived GB cells *in vitro* by omitting fluorescence at a wavelength similar to GFP just by simple dispersion in the existing media, ii) GlioStem-positive human GB cells can efficiently be sorted out from mixed cell populations by cell sorting techniques (FACS), iii) the specificity of GlioStem is dependent on a methylation modification of two imidazole rings making the molecule similar in structure to histidine/histamine, iv) GlioStem labels the same GB cells as CD271 (NGF receptor p75) which in turn labels stem cell-like cells and rapidly migrating cells in GB, and v) pilot studies have shown that GlioStem indeed detects patient-derived GB cells also *in vivo* in a rodent model.
We have now pursued a thorough screen for putative intracellular structures GlioStem may interact with, and we have found that the main intracellular target for GlioStem is GOLGA2/GM130, a protein of the Golgi apparatus. GlioStem was found to be in close proximity and sharing pixels with around 80% of GOLGA2 immunoreactivity and GOLGA2 in turn occupied around 60% of GlioStem-positive pixels. We conclude that GOLGA2, or a protein very closely associated with it, is the major intracellular target of GlioStem. Current investigations focus on elucidating the structure of GOLGA2 as well as similarities and differences in the Golgi apparatus between GB cells, embryonic neural stem cells, and other - GlioStem-negative - cell types.

Title: High-throughput screening of induced pluripotent stem cell derived motor neurons on qube and qpatch

Authors: K. R. ROSHOLM[1], *D. SAUTER[2], M. SCHUPP[1], R. B. JACOBSEN[1]
[1]Sophion Biosci., Ballerup, Denmark; [2]Sophion Biosci., Woburn, MA

Abstract: Human induced pluripotent stem cells (hiPSCs) can be differentiated into many cell types, including neurons and cardiomyocytes, and therefore constitute a novel way to model human diseases for drug-testing *in vitro*[1]. Ion channels represent highly attractive therapeutic targets in the nervous and cardiovascular systems[2], rendering electrophysiological studies of hiPSCs critical for their usage in drug-discovery. However, such studies have traditionally been limited by the labour-intensive and low-throughput nature of patch-clamp electrophysiology[2]. Here we present the electrophysiological characterization of hiPSC derived motor neurons using our Automated Patch Clamp (APC) platforms, Qube 384 and QPatch. Our results include a measure of channel expression versus time in culture, the pharmacological dissection of endogenous ion channels (e.g. Na_v and K_v), identification of ligand-gated receptors, and recordings of action potentials using current clamp. The major challenge when investigating neurons using APC platforms is the requirement to dissociate the cells from their neuronal network while maintaining cell viability and membrane integrity[3]. By optimization of the harvest- and whole-cell protocols we have overcome this obstacle resulting in success rates of up to 60% using our 384 well system. Our results demonstrate the feasibility of conducting electrophysiological characterization and drug-screening on hiPSC derived neurons on APC platforms like Qube 384 and QPatch, thus paving the way for high-throughput ion channel-targeted screening of drugs for neurological disorders.

Title: The role of Elk-1 transcription factor in tumoursphere formation of brain tumour cells

Authors: *M. SAVASAN SOGUT[1,2], B. YILMAZ[3], I. KURNAZ[1]
[1]Biotech. Inst., Gebze Tech. Univ., Kocaeli, Turkey; [3], Med. Faculty, Dept. of Physiol., [2]Yeditepe Univ., Istanbul, Turkey

Abstract: ELK-1 transcription factor, a member of ETS oncogene superfamily, is responsible for many crucial processes within the cell through its phosphorylation via MAPK/ERK pathway. However, little is known about its biological significance in the formation of brain tumours, especially glioblastoma and neuroblastoma. Over-expression or down-expression of ELK-1 through transfection has been shown to be related with the expression of certain stemness factors. In this study, we aimed to investigate the functions of ELK-1 in tumoursphere formation of both glioblastoma and neuroblastoma cell lines. We assessed the effects of ELK-1 over-expression and its knock-down via short hairpin RNA (shRNA) on glioblastoma and neuroblastoma cell lines *in vitro*. Tumoursphere formation was provided by sphere formation medium and CD133(+)-cell enrichment was conducted by magnetic separation with MACS CD133 microbeads. The change in gene expression pattern and protein levels of certain stemness genes and tumoursphere markers were evaluated with qPCR and Western blot analysis, respectively. The interaction on the chromatin level was checked with chromatin immunoprecipitation (ChIP) experiments. Brain tumour cell lines, incubated in sphere formation medium that was supported with EGF and bFGF, formed distinct tumourspheres, depending on whether they were stemmed from glia or neurons. The results show ELK-1 is effective in the regulation of stemness gene expressions. This study may pave the way for the biological triangle of brain tumour cell lines: tumourigenesis, survival and ELK-1.

Phildelphia, PA; [3]Univ. of Pennsylvania, Philadelphia, PA; [4]Univ. of Pennsyvania, Philadelphia, PA; [5]Mt. Sinai, New York, NY

Abstract: The paradigms of induced pluripotent stem cell (iPSC) and induced neurons (iNs) offer an opportunity to study neurons derived from patients with neuropsychiatric illnesses. A critical question remains, however, to what extent neurobiological characteristics of donors, epigenomic markings in particular, are maintained in neurons derived via these paradigms. Increasing evidence suggests that reprogrammed cells reflect molecular characteristics of source cells. It follows that it will be preferable to use source cells that are more likely to harbor neural characteristics and to convert them with least modification of epigenetic landscape. Presently, skin fibroblasts or blood cells are most often used as source cells for genomic reprogramming. Here we examined olfactory neuroepithelial (OE) cells derived from human subjects for their neurogenic potential and changes in chromatin conformation following transduction of miR-9/-124. Upon transduction with miR9/124, OE cells showed significantly decreased cell proliferation. In addition, 20 to 25% of OE cells showed neuron-like morphology within 5 to 7 days of culture in differentiation condition. Neuronal morphology of these cells were maintained or further elaborated over the next 21 days, during which time these neuronal cells changed their morphology, their positions and contacts with other cells. OE cells transduced with mir9/124 or with mirSS were analyzed by quantitative polymerase reaction for expression of molecular markers specific for exiting the proliferative cell cycle (BM88), cellular commitment to the neuroprogenitors (Doublecortin) and neuronal markers (Map 2, Map 1b, Tuj-1). A critical question is the extent to which the chromatin conformation of OE cells is accessible to the genes that have been implicated for neuropsychiatric illnesses. ATAC seq results from OE cells before and after neuronal conversion will be presented compared to those of human skin fibroblasts with respect to chromatin accessibility in genes that have been implicated for neuropsychiatric illnesses.

Title: Calcium dynamics identify neural progenitor populations altered by ethanol exposure and withdrawal

Authors: *A. H. MAHNKE, R. C. MIRANDA
Neurosci. and Exptl. Therapeut., Texas A&M Univ. Hlth. Sci. Ctr., Bryan, TX

Abstract: Aberrant cortical development is one of the hallmarks of Fetal Alcohol Spectrum Disorders. While prenatal ethanol exposure can activate cell death pathways in developing neurons, the neural stem and progenitor cell populations are largely spared. Instead, our data suggests these cells are reprogrammed to favor premature maturation and decrease self-renewal capacity. Calcium dynamics are known to affect cell cycle progression and differentiation as well as coordinate behavior across neural progenitors. Here, we examined how chronic ethanol exposure and withdrawal affect calcium dynamics in a model of the neural stem and progenitor cell niche. Neurosphere cultures, derived from GD12.5 mouse dorsal neuroepithelium and maintained in mitogenic media, were exposed to ethanol for 5 days at levels reflecting control (0 mg/dL), low (60 mg/dL), binge (120 mg/dL), and chronic (320 mg/dL) drinking behavior. Subsequently, these neurospheres were then either loaded with Fluo-4 AM for calcium dynamic imaging or allowed to withdraw from ethanol for an additional two days prior to imaging. We found that some baseline calcium attributes were affected by low levels of ethanol, such as elevation of resting calcium, while others were altered in a dose-dependent manner, such as calcium event frequency. We also found that there were dose-specific effects on the calcium response to subsequent exposure to acute ethanol and nicotine. These effects may be mediated directly following chronic exposure through alterations to ryanodine receptor composition and after withdrawal by alterations to inositol-3-phosphate receptor composition. Principal component analysis identified three distinct sub-populations of neural progenitors which define the diversity of observed calcium signaling behaviors observed. Moreover, these three sub-populations exhibited varying sensitivity to ethanol exposure and withdrawal as well as to subsequent acute drug exposure. These data show that ethanol perturbs calcium dynamics within the neural progenitor cells in a dose-dependent manner and that some alterations are enhanced only after withdrawal. These data indicate that ethanol's effect on reprogramming cells may be mediated by calcium signaling mechanisms, and that intracellular calcium dynamics are robust indicators of both ethanol exposure and withdrawal.

Title: Let-7 MicroRNA inhibits adult ciliary epithelium cells neurosphere formation

Authors: *C. B. DEL DEBBIO, L. T. FRASSON
Cell Biol. and Develop., Univ. of Sao Paulo, Sao Paulo, Brazil

Abstract: The Ciliary Epithelium (CE) of adult mammalian eyes contains a quiescent population of retinal progenitor/stem cells that are able to proliferate and generate neurospheres in vitro. These cells express retinal progenitor genes and proteins and are known to generate different and functional retinal neurons after induction. Despite this regenerative capacity, the reprogramming efficiency is low due to the presence of unknown mechanisms and regeneration inhibitory factors such as microRNAs (miRNAs), small non-coding RNAs responsible to regulate a variety of progenitor and pluripotent genes expression. Here, we investigated the expression of Let-7 family of miRNAs and its regulatory protein Lin28 in CE cells from rodents, and its influence on neurospheres formation. CE cells from normal newborn and adult animals (Wistar) were carefully separated from retina and the expression of Let-7 miRNA family, as well as Lin28 transcripts and protein levels were analyzed. We found that Lin28 was highly expressed in newborn CE tissues while Let-7 family indicated low expression levels at this age. Adult CE tissues expressed an inverted pattern, with Let-7 family 10-fold higher and Lin28 6-fold lower in comparison to newborns. This shows that Let-7 miRNA are highly expressed in adult CE cells. We induced adult CE neurospheres formation by culturing these cells with growth factors (EGF and FGF) for 7 days and found higher levels of Lin28 in comparison to Let-7 miRNAs, similar to newborn tissues, indicating that neurospheres and newborn CE cells share similar Let-7-Lin28 expression patterns. Latter we added chemically modified single-stranded oligonucleotides designed to bind to and inhibit endogenous Let-7 or to mimic endogenous mature Let-7 in CE cells culture at early neurosphere formation stage. The overexpression of Let-7 in CE cells gradually decreased neurospheres formation (Let-7 mimic 10nM, 20nM and 30nM, decreased 70%, 90% and 100% neurospheres respectively), with complete inhibition of neurospheres formation at 30nM. No differences in neurospheres numbers were observed with Let-7 inhibition. Our results suggest that up-regulation of Let-7 miRNAs are sufficient to prevent the mechanisms involved in stem cells activation. However, down-regulation of Let-7 expression alone is not capable to improve CE cells stem/progenitor cells reprogramming efficiency. The information gleaned from this study may provide valuable insight into the cellular and molecular events that underlie the reprogramming response of CE cells and the mechanism of retinal recovery.

Title: Development and characterization of an *in vitro* human iPSC-derived neurospheroid model

Authors: *J. L. MOHN, M. KLAUSNER, P. J. HAYDEN
MatTek Corp, Ashland, MA

Abstract: Objective and Rationale: Multiple approaches have recently been described to generate *in vitro* neural organoid models from human induced pluripotent stem cells (iPSC). While these models are effective at recapitulating many features of human fetal brain development, the processes used to generate them are not amenable to large-scale production and high-throughput applications. The goal of this exploratory research is to develop a scalable and reproducible *in vitro*, 3-dimensional neurospheroid model that may be used for high-throughput applications assessing neurodevelopmental toxicology and drug development.
Methods: iPSCs (male, 68 years old) were differentiated to neural progenitor cells (NPCs) by blocking TGF-β/BMP-dependent SMAD signaling. Differentiation was assessed by immunofluorescent staining for NPC markers nestin and SOX2. An additional NPC line was commercially obtained. To generate neurospheroids, NPCs were seeded in ultra-low adhesion multi-well plates at various cell densities, and neuronal differentiation was induced with BNDF and GDNF. Neurospheroids were maintained in culture for up to 8 weeks. Immunofluorescent analysis of neurospheroids was performed on frozen sections.
Results: NPCs differentiated from iPSCs expressed NPC markers SOX2 and nestin. The size of neurospheroids grown in ultra-low adhesion plates steadily increased up to 8 weeks in culture at all cell seeding densities tested. Neurospheroid size was very consistent over time, both within and across batches. Immunofluorescent analysis of frozen neurospheroid sections revealed widespread expression of neuronal markers MAP2 and βIII-tubulin, as well as VGLUT1, indicating presence of presynaptic glutamatergic specializations.
Conclusions: Neurospheroids of consistent size containing mature neurons were successfully generated using this approach. The model is easily scalable and can be adapted to either 96- or 384-well plate formats, allowing use in high-throughput applications. Further efforts will continue to characterize the cell types present in neurospheroids and assess the maturity of synaptic connections, and this characterization will be expanded to include neurospheroids generated from iPSCs representing an array of ages, gender and disease conditions.

Title: Quantification of functional network electrophysiology from stem cell derived neurons with multiwell microelectrode array technology

Authors: *D. C. MILLARD, H. B. HAYES, A. M. NICOLINI, C. A. ARROWOOD, M. CLEMENTS
Axion Biosystems, Atlanta, GA

Abstract: The flexibility and accessibility of induced pluripotent stem cell technology has allowed complex human biology to be reproduced in vitro at high throughput scales. Indeed, rapid advances in stem cell technology have led to widespread adoption for the development of in vitro models of neural disease and for screening applications in drug discovery and safety. However, to effectively characterize stem cell derived models, or to extract meaningful and predictive information from these models, new technology is required for evaluating functional cellular and network responses. For electro-active cells, like stem cell derived neurons, measurements of electrophysiological activity across a networked population of cells provide a comprehensive view of function. Microelectrode array (MEA) technology offers such a platform by directly connecting key biological variables, such as gene expression or ion channel distributions, to measures of cellular and network function in stem cell derived neurons. A planar grid of microelectrodes interfaces with cultured neural networks, modeling complex, human systems in a dish, such that the electrodes detect the raw electrical activity of nearby neurons in the population. Furthermore, the advent of multiwell MEA platforms has enabled high throughput capacity for applications including drug discovery, toxicological and safety screening, disease models, and stem cell characterization and optimization. Here, we present results from evaluation of stem cell derived neural cultures on the Maestro Pro multiwell MEA platform. The stem cell derived neurons were cultured on 48- and 96-well MEA plates and monitored throughout maturation of the network connections. To characterize the cultured networks, advanced metrics describing the burst, synchrony, and evoked aspects of the functional population activity were computed in response to ion channel blockers and compounds altering synaptic activity. In comparing across wells, the stem cell derived networks displayed reliable and expected functional responses. These results support the continued development and use of stem cell derived neural network assays on multiwell MEA technology for high throughput drug discovery and evaluation of phenotypic disease-in-a-dish models of neural disease.

Title: An improved cell culture system to recapitulate endogenous neural stem cell behavior

Authors: *N. ZHANG, T. OUGHOURLIAN, L. PENG, J. SHEPPARD, M. BAY, M. BONAGUIDI

Abstract: Adult neural stem cells (NSC) were first isolated and characterized using cell culture over 25 years ago. However, recent advances in lineage tracing have elucidated that NSC properties *in vitro* do not mimic their native behavior *in vivo*. Using adult hippocampus, we developed a simple and scalable culture approach to recapitulate endogenous NSC fate choices. We determined that commonly used growth factor concentrations promote NSC symmetric divisions while suppressing neuronal fate, and amplify glial-committed progenitors. Instead, low growth factor application during an ‘expansion phase’ balances NSC symmetric, neurogenic and astrogenic fate choices akin to multipotential NSC behavior *in vivo*. Further, we show that NSC fate choices are reversible, which permits both amplification of NSC number and proper cell fate outcome. Our study provides a new system to study new cell generation, neural circuit formation, mechanistic regulation, and perform drug screening with high throughput capacity.

Abstract: The advent of the CRISPR/Cas9 system complexed with induced pluripotent stem cells (iPSCs) provides a powerful tool to support *in vitro* disease modeling and drug discovery efforts. CRISPR/Cas9 mediated genome editing in iPSCs coupled with the ability to differentiate into numerous cell types, either Neural Stem Cells (NSCs) or neurons, can be used to study disease-specific genetic defects in physiologically-relevant cellular models. Here, we demonstrate the ability to use our CRISPR tools to edit the genome efficiently in iPSCs to create disease-relevant genetic changes to relate to neurological disease primarily in the cortical region of the brain. We subsequently differentiated these edited iPSCs into NSCs and further into cortical neurons as *in vitro* neurobiological disease models that manifest cellular phenotypes commonly observed in human disease. Furthermore, we developed several scalable assays to screen the isogenic iPSC-derived NSCs and cortical neurons generated using the above method. These assays can measure cell health and viability, neurite outgrowth, synaptogenesis, calcium influx and variations in channel activity, and electrophysiological changes. By combining genome editing of iPSCs and subsequent differentiation to relevant cortical cell types followed by downstream phenotypic identification using these assays, we have created a system that enables deeper understanding of neurobiological diseases, thereby enabling the potential identification new drug targets, and advancement in the development of personalized medicine.

Abstract: Dental tissue contains dental pulp stem cells (DPSCs), that are mesenchymal stem cells, capable to differentiate into multiple linages including neuronal. The study of the differentiation potential of the DPSCs has implications on the development of therapeutic applications for neurodegenerative diseases and has been applied for cell therapy and tissue engineering. The aim of this study was to explore the differentiation potential of the DPSCs to the neuronal phenotype. For this purpose, we culture the mesenchymal stem cells in a chemical defined medium (with Insulin, Transferrin and Selenium, ITS), supplemented with or without growth factors (BDNF and GDNF). We isolated DPSCs from a healthy 46 years old female first molar. The cells were expanded in a growing medium (DMEM/F12) containing 10 % FBS. By Western blotting, Confocal imaging of Immunofluorescence, RT-PCR and FACS of several phenotype markers, we demonstrate in the DPCs cultured in growing medium, the expression of the mesenchymal and stem cells markers: CD105, CD90, CD73, SOX2, Oct3/4, NANOG and the absence of the expression of hematopoietic markers CD45, CD34, CD14. Furthermore, when the DPSCS were cultured in the ITS medium with or without growth factors, we were able to detect the expression of neuronal markers, such as NF-M, MAP-2 and Neu at 35 days in vitro. At this long culture time point, the mesenchymal markers were no longer expressed. To validate the maturation the Neuronal cells differentiated from DPSCs, we evaluate the passive membrane properties by hole cell recording (Rin, RMP and Cm).

Abstract: Silver nanoparticles (Ag-NPs) are one of the most popular nanotechnologies because of their unique antibacterial and antifungal properties. Given their increasing use in a wide range of commercial, biomedical and food products, exposure to Ag-NPs is now a reality in people's lives. However, there is a serious lack of information regarding their potential toxic effects in the central nervous system. In this study, we investigated the biocompatibility of "homemade" Ag-NPs in an *in vitro* model of human neurons derived from dental pulp mesenchymal stem cells. Our results, showed that acute exposure to Ag-NPs cause cytotoxicity, by triggering cell apoptosis, damaging neuronal connections, affecting the mitochondrial activity and changing the mRNA expression level of *MT3* and *OSGIN2*, two genes involved in heavy metals metabolism and cellular growth during oxidative stress conditions. Further studies are needed to understand the molecular mechanisms and the physiological consequences underlying Ag-NPs exposure.

Abstract: Determining the functional cellular and network mechanisms of the human cortex is an important step in understanding human brain function and investigating deficits underlying dysfunction. A major impediment to studying these processes has been a lack of available tissue. However, innovations in the field of human induced pluripotent stem cell (hiPSCs) are now providing efficient differentiation protocols of cortical neuronal and glial subtypes to enable this research in interrogatable *in vitro* cultures. An important feature of neuronal networks that is absent in traditional planar 2D cultures is however their 3D structure and connections. A possible way forward would be to produce different non-planar cell-supporting structures using two-photon polymerization (2PP), part of our aim in the MESO-BRAIN project. An important first step is the identification of 2P-polymerizable materials which are biocompatible, and have the capacity to allow electrophysiological and fluorescence calcium imaging monitoring of network activity. Biomaterials chosen from a panel of commonly utilized polymers were tested against prerequisites: amenability to the 2PP printing process at μm resolutions, biocompatibility to promote healthy long-term neural cultures, and ability to optically interrogate for dynamic network imaging and fluorescence-sensitive identification of cell populations. HiPSC-derived neural progenitors (Axol Bioscience Ltd., UK) were initially cultured upon planar 2PP-polymerized candidate biomaterials: Organically-modified silica (Ormosil), Polyethylene glycol diacrylate (PEG-DA), Polylactic acid (PLA). Culture development was quantified using phase-contrast microscopy, nuclei-counting, live/dead viability staining, and fluorescence immunocytochemistry. All materials tested displayed no overt toxicity to hiPSC-derived cultures in CellTitre-Blue® viability assays. All materials displayed some degree of auto-fluorescence, with Ormosil and PLA being excluded from further investigation due to their incompatibility with fluorescent probes. Neural progenitors ($PAX6^+$ / $SOX2^+$ / $NESTIN^+$) cultured on PEG-DA differentiated into mature neuronal populations ($MAP2^+$ / $TBR1^+$ / $CTIP2^+$) as assessed via immunocytochemistry using Alexa Fluor® 488, 561 and 633 fluorescent probes. PEG-DA cultures were also calcium imaged with Fluo-4 acetoxymethyl ester, exhibiting increased responses to 25 μM glutamate, and subsequent block of activity with addition of 1μM tetrodotoxin. Our data currently determines PEG-DA to be a suitable polymer for 2PP-fabrication of 3D biocompatible scaffolds for growing hiPSC-derived neuronal networks.

Abstract: In this work we study how functional connectivity between neurons can be influenced by the structure of the substrate they grow on. We study the connectivity of neurons in three-dimensional (3D) cultures to understand how neurons connect in developing tissue.
We report the evolution of functional 3D neuronal networks over several days. We have applied network inference methods to recordings of calcium fluorescence imaging at a resolution allowing the segmentation of individual neurons into Regions of Interest (ROI), and the extraction of their activity time series. ROIs with identical dynamics occurring at overlapping coordinates in adjacent volumes have been grouped as representing a single neuron.
Networks are inferred using Generalised Transfer Entropy and Time Delays methods. These methods yield the direction and relative weight of connections. A surrogate method has been applied to the activity traces to eliminate spurious connections.
Functional connections persistent in a given culture during development are identified. The evolution of local network properties such as degree and clustering coefficient of given nodes are compared along development of the culture over several days. Additionally, we compared the network patterns obtained for rat primary cortical cultures to those of human induced pluripotent stem cell derived cultures.

Abstract: Three-dimensional (3D) *in vitro* neuronal cultures mimic extracellular conditions more accurately than standard 2D networks. Cells remain healthy for longer periods, develop richer connectivity architectures, and show much more complex activity patterns. These 3D networks have become a valuable tool for tissue engineering, with promising applications for the modeling of brain functions and the study of neuropathologies.
In the present study we investigate 3D networks grown in a semisynthetic hydrogel termed 'PEGylated Fibrinogen', which allows for a biocompatible yet mechanically tunable environment. We monitored spontaneous activity using fluorescence calcium imaging with GCaMP6s, a genetically encoded calcium indicator, that allows the observation of network development and behavior along several days. We used light-sheet microscopy to image neurons in the entire 3D volume of the network. This imaging technology grants a sufficiently fast recording speed and image quality to capture the details of neuronal dynamics and render functional connectivity maps. In our setup, we considered a 1 mm^3 volume, and imaged activity in 10 planes of the volume at 200 frames per second.
Tests with primary embryonic cortical neurons demonstrate the capacity of 3D networks to show

rich spontaneous activity already from day in vitro 7. Neuronal cultures derived from human induced pluripotent stem cells (HiPSC, provided by AXOL Bioscience) were also tested, with the goal to compare both culture conditions and characterize their functional connectivity. This research is part of MESOBRAIN.

Title: Patterned spontaneous network activity accompanies synapse development in the *Drosophila* visual system

Authors: *B. T. BAJAR[1], O. AKIN[1], M. F. KELES[2], M. A. FRYE[2], S. L. ZIPURSKY[1]
[1]Dept. of Biol. Chem., HHMI / Univ. of California Los Angeles, Los Angeles, CA; [2]Dept. of Integrative Biol. and Physiol., Univ. of California Los Angeles, Los Angeles, CA

Abstract: Stereotyped synaptic connections define the neural circuits of the brain. In vertebrates, synapse development is accompanied by a sustained period of spontaneous network activity. The mechanisms driving this activity and its contribution to establishing synaptic specificity remain poorly understood. Using two-photon microscopy in live, intact animals, we report that patterned spontaneous network activity (SNA) accompanies synapse development in the *Drosophila* visual system. SNA begins halfway through metamorphosis, shortly after synapses begin to form. This activity is oscillatory, in which each cycle exhibits an “active phase”, where all neurons in the optic lobe exhibit multiple bouts of activity, and a shared “silent phase”. SNA lasts for about 50 hours, during which activity evolves from an initial periodic stage, characterized by cycles of regular frequency, to a later chaotic stage, in which this consistent periodicity is lost. Using a combination of calcium imaging, voltage imaging, and pharmacology, we showed that SNA is dependent on voltage-gated sodium channels, independent of visual stimuli, and accompanies neurotransmitter release. Next, we investigated activity patterns at the level of individual cell types using cell-type specific expression systems. We analyzed the spatiotemporal structure of SNA for 14 different neuronal cell types, based on the degree of participation of cells in the active phases, and the relative timing of their activity. These two metrics, termed “coordination” and “coherence”, provided distinct activity signatures for different cell types and revealed

similarities between cell types that are synaptically coupled in the adult. Indeed, pairwise imaging showed that such cells have more correlated activity relative to uncoupled pairs. However, neither the proximity in coordination-coherence values nor direct correlation between pairs of cell types strictly follow the relative strength of the synaptic coupling observed in the adult. Together, these results suggest that the early connectome of the developing brain reflects that of the adult, but synaptic weights may continue to be modulated throughout development. Our observations indicate that SNA is a shared feature of both vertebrate and invertebrate brain development, and its discovery in *Drosophila* offers a complementary track to studying its contribution to synaptogenesis.

Title: Target-dependent signaling mediates synaptic plasticity at the *Drosophila* neuromuscular junction

Authors: *H. S. KESHISHIAN[1], B. A. BERKE[2,1], L. LE[2]
[1]MCDB Dept., Yale Univ., New Haven, CT; [2]Biol. Sci. Dept., Truman State Univ., Kirksville, MO

Abstract: Drosophila motoneurons undergo activity-dependent expansion of their neuromuscular junctions (NMJs). This form of synaptic plasticity requires a TGF-β growth factor, Glass bottom boat (Gbb), which is released by the muscle fiber to activate a BMP receptor complex at the presynaptic bouton. This retrograde, trans-synaptic signal results in the local phosphorylation of the R-Smad transcription factor pMad, and leads to pMad-dependent transcription that is required for NMJ growth and plasticity. Since transcription occurs at the cell body, distant from the NMJs, it raises the question as to how a neuron that innervates multiple cells can control activity-dependent plasticity at specific subsets of its targets. To test this, we examined the ventral Common Exciter motoneuron (vCE), a cell that innervates multiple ventral muscle fibers. Using GAL4 driver lines specific to subsets of the vCE muscle fiber targets, we expressed transgenes postsynaptically, opposite specific branches of the neuron, leaving the

other branches to serve as controls. RNAi knockdown of the dGluRC or dGluRA subunits of glutamate receptors, in just one of the vCE target muscles, resulted in reduced presynaptic quantal release at that contact, and also blocked the ability of that vCE branch to undergo activity-dependent expansion. The adjacent branches of the vCE on unaltered muscles showed normal synaptic function and plasticity. Loss of postsynaptic glutamate receptors at a single muscle fiber target of the vCE also resulted in the loss of local presynaptic pMAD accumulation at the corresponding branch's boutons, with normal pMAD accumulation at adjacent, unaffected vCE contacts. This indicates that branch-specific pMAD accumulation is under the direct local control of the corresponding postsynaptic cell. To address a role for trans-synaptic signaling, a wild-type Gbb transgene was driven in a subset of the vCE targets of a *gbb* mutant, which rescued the functional and plasticity phenotypes, but only in the branch opposite the Gbb-rescued muscle fiber. Conversely, growth and plasticity of specific vCE branches was locally suppressed by RNAi knockdown of Gbb in the corresponding muscle fiber, with the other branches of the vCE remaining unaffected. We propose that presynaptic pMad accumulation in synaptic boutons plays a key role in locally determining the potential for activity-dependent plasticity through an unknown non-canonical mechanism. This may be an example of "synaptic tagging", governing the capture of molecules transported from the soma that are essential for synaptic growth and plasticity.

Title: Alterations in MHCI subclass expression in neurally restricted IKK2 conditional knockout mice

Authors: *J. OGAWA
Salk Inst. LOG-V, La Jolla, CA

Abstract: The Rel homology NFkB transcription factors are well known to have nearly ubiquitous expression and are mostly associated with innate immune functions in many metazoans and are especially well represented in mammalian organisms. The critical regulator in most cases is the I kappa B kinase (IKK) complex which regulates the pathway by regulation of protein stability of the IkB inhibitors are well as the activation of transactivation by phosphorylating the transcription factors themselves. Although ubiquitously expressed, a function for the IKK2 or the NFkB function in the brain has remained elusive. Here, in the

present study we show that the expression of Major histocompatibility complex (MHC I) proteins is altered when the IKK2 kinase is conditionally deleted in the CNS. Transcriptome data derived from RNA-seq of P0 pup brains, reveals an alteration of MHC class I subtype levels in IKK2 KO brains. This alteration however, was not observable in cultured neural progenitor cells. No visible structural alterations in neuroanatomy were observed. Similarly, no overt immune or inflammatory changes were observed in postnatal mice up into adulthood. The preliminary results suggest that unlikley previously assumed, there is a possible function of IKK2 in the brain through its regulation of MHC class I that has recently been shown to play a role in synaptogenesis, pruning and postnatal neurodevelopmental maturation pathways.

Title: Synaptic acetylcholinesterase in the mouse brain increases following administration of donepezil or galantamine

Authors: *R. L. ROTUNDO, S. G. ROSSI
Dept. of Cell Biol. (R-124), Univ. of Miami Sch. of Med., Miami, FL

Abstract: The predominant form of acetylcholinesterase (AChE), the enzyme responsible for terminating cholinergic neurotransmission, expressed in neurons is the globular G4 form consisting of four catalytic subunits anchored by a 125 amino acid transmembrane peptide called PRiMA. This AChE form is synthesized and assembled in the endoplasmic reticulum and subsequently transported through the secretory pathway for externalization at the plasma membrane. In neurons this includes transport down the axons via rapid axoplasmic transport and deposition at cholinergic synapses. Many cholinesterase inhibitors can stabilize the protein to thermal denaturation. However active site directed inhibitors have a unique ability to enhance AChE expression in tissue cultured cells. When HEK 293 cells expressing mouse AChE are incubated with either Donepezil (Don) or Galantamine (Gal), the two most common drugs used to treat Alzheimer's patients, there is a large 200-300% increase in AChE expression due to enhanced protein folding and stabilization. This increase in catalytically active AChE occurs without changes in total AChE protein indicating that the source of active enzyme is the

intracellular pool of inactive enzyme molecules. When these drugs are injected into mice at the same relative concentrations used to treat humans there is a large increase in total brain AChE within several hours. The increased AChE consists almost exclusively of the synaptic G4 AChE form, and occurs without apparent changes in total AChE protein as well. At a transport rate of 200 mm/day it would only take a couple hours for the newly-synthesized AChE to reach most cholinergic synapses in the mouse brain. Moreover, an increase in synaptic AChE could possible reduce the efficiency of cholinergic transmission in the brain thereby reducing the effectiveness of the very drugs designed to enhance cholinergic transmission. Future behavioral studies are planned to test this hypothesis.

Title: Development and activity-dependence of spinules in primary sensory cortex

Authors: *M. NAHMANI[1], A. ERISIR[2], C. CAMPBELL[1], S. KIM[1], A. KNYAZ[1], W. SONG[1]
[1]Div. of Sci. & Mathematics, Univ. of Washington | Tacoma, Tacoma, WA; [2]Psychology, Univ. of Virginia, Charlottesville, VA

Abstract: Spinules are thin projections that emanate from one neurite and protrude into an adjacent (often pre- or postsynaptic) neurite. Increased prevalence of these evolutionarily conserved features of neuronal anatomy has been correlated with experimental regimes that induce high frequency neuronal activation (e.g. long-term potentiation, KCl application) within particular microcircuits (e.g. stratum radiatum of CA1 in hippocampus), suggesting a role for spinules in neuronal circuit remodeling (Toni et al, 1999; Tao-Cheng et al, 2009). In addition, the appearance of spinules at a synapse is correlated with ‘perforations’ in the postsynaptic density and coated endocytic pits at spinule tips in the developing and adult brain, indicating a role for spinules in neuronal communication (Jones and Calverley, 1991; Spacek & Harris, 2004). Yet, the developmental profile, activity-dependence, and possible functions of spinules at cortical synapses remain unknown. Here, we have determined the developmental prevalence and ultrastructural features of spinules within presynaptic terminals forming excitatory cortical synapses in layer 4 of primary visual cortex (V1) from developing and adult ferrets. Furthermore, we present preliminary evidence exploring whether perturbations of in vivo activity (i.e.

monocular deprivation and early eye opening) are correlated with altered spinule prevalence at excitatory synapses in layer 4 of V1. In analyzing > 100 randomly collected synapses per age group (n=2-3 male & female animals/age) with experimenters blinded to condition, we find that the percentage of spinules within excitatory synapses remain largely unaltered from the age of eye opening around postnatal day 35 (p35) through the end of the critical period for ocular dominance plasticity (p60). However, the percentage of spinules within excitatory synapses in V1 rapidly peaks near the age of sexual maturity (> p90). These data suggest that spinules within excitatory synapses of primary sensory cortex may serve as ultrastructural 'anchors' that aid in stabilizing mature synapses, rather than purely filopodial-like structures that participate in circuit remodeling.

Title: Synapse elimination triggered by BMP4 exocytosis and presynaptic BMP receptor activation

Authors: *T. HIGASHI, S. TANAKA, T. IIDA, S. OKABE
Dept. of Neurobio., Univ. of Tokyo, Tokyo, Japan

Abstract: The process of synapse turnover is regulated by specific signaling mechanisms. Various molecules that promote formation and differentiation of synapses have been identified. Some of these molecules were classified as synapse organizers, because they were shown to initiate differentiation of hemi-synapses when they were expressed in non-neuronal cells and co-cultured with neurons. That said, little is known about the mechanisms underlying destabilization and elimination of unnecessary synapses. Here, we report that bone morphogenetic protein (BMP) 4 released from axons has the ability to eliminate synapses. BMPs are members of the transforming growth factor β(TGF-β) superfamily. Multiple members of the TGF-β superfamily are expressed in hippocampal neurons, but neuronal activity dependent regulation of the genes encoding this group has not been systematically analyzed. we investigated the expression profiles of genes related to TGF-βsuperfamily signaling in response to downregulation of neuronal activity in hippocampal neurons. Blocking neuronal activity using a sodium channel blocker induced *Bmp4* upregulation.At the synaptic level, molecular mechanisms and significance of BMP signaling have not been fully investigated. There has been no direct

evidence of BMP release at synapses. Whether BMP regulates synaptogenesis positively or negatively is still an open debate. These questions should be answered by direct monitoring of BMP release, its binding to receptors, and subsequent effects on synaptic structure and function. BMP4 transported into axons was secreted and accumulated on the axonal surface close to synaptic sites via type I receptors. BMP4 overexpression or knockout in culture reduced or increased presynaptic structures, respectively. *In vivo* single-cell knockout of BMP4 and subsequent two-photon imaging of synaptic dynamics confirmed the importance of BMP4 in the regulation of appropriate synaptic density. These results suggest an active role of BMP4 on the axonal surface in eliminating inappropriate synapses during neural circuit development.

Title: Brain-specific actinfilin that is associated with infantile spasms modulates dendrite arborization and spine formation

Authors: *H.-T. HU, Y.-P. HSUEH
Inst. of Mol. Biology, Academia Sinica, Taipei, Taiwan

Abstract: Dendritic spines, the actin-enrich protrusions emerged from dendrites, are subcellular locations of excitatory synapses in the mammalian brain. Many actin-regulating molecules modulate dendritic spine morphology and synapse plasticity in response to neuronal activity. Actinfilin (AF), an actin-binding protein, is predominantly expressed in brain. It contains N-terminal Broad-Complex, Tramtrack and Bric a brac (BTB) domain, which is involved in CUL3-dependent ubiquitination, and C-terminal kelch domain, which interacts with F-actin. Human genetic study indicated the association of AF with infantile spasms, a rare childhood epilepsies and related to mental retardation, suggesting that AF plays a role in brain development and function. Here, we used cultured hippocampal neurons to explore the role of AF in neuronal morphogenesis and synaptic plasticity. We found that AF is presented in dendrites, including dendritic branching site and dendritic spines. Its expression was regulated by neuronal activity. Using miRNA knockdown approach, we found that loss of AF influenced dendritic arborization, spinogenesis and functional synapse formation. We further suggested that AF regulates F-actin intensity at dendritic spine and alters activity-induced spine enlargement. In addition to knockdown of AF expression, overexpression of AF fragments was also performed to disrupt the function of endogenous AF in neurons. Both AF-N terminal and AF-C terminal truncated

mutants had impact on F-actin rearrangement and synapse formation. In addition to morphology change, loss of AF also altered surface AMPAR expression, suggesting that AF may modulate synaptic strength. Furthermore, CRISPR-Cas9 AF knockout mice also show alteration of dendrite arborization, dendritic spine formation and activity-induced spine enlargement. In conclusion, our results provide the evidence that AF, a gene associating with infantile spasms, contributes to neuronal morphogenesis and synapse plasticity.

Title: Role of histone deacetylase 2 (Hdac2) in PV cell circuit development

Authors: *M. LAVERTU JOLIN, B. CHATTOPADHYAYA, F. DUMOUCHEL, P. CHEHRAZI, G. DI CRISTO
Ctr. de recherche du CHU Sainte-Justine, Montreal, QC, Canada

Abstract: Cortical parvalbumin-positive basket cells (PV cells), the major source of GABAergic inhibition in the brain, innervate hundreds of postsynaptic targets with multiple synapses clustered around the cell body and proximal dendrites. These cells are particularly important for the regulation of multiple cognitive functions and developmental cortical plasticity. Although PV cell function is being explored extensively, the mechanisms that control their development and plasticity have not been entirely resolved.
Molecular mechanisms involved in synapse formation and strengthening include the activation/repression of specific subsets of genes by epigenetic modifications. In particular, Histone Deacetylase 2 (HDAC2) regulates excitatory synapse plasticity and memory formation, however, whether and how HDAC2 affects PV cell synapse development is unknown. Here, we first show that HDAC2 is expressed by PV neurons. In order to dissect the role of HDAC2 in PV cell development *in vivo*, we used the conditional KO mice (PV_Cre;HDAC2$^{lox/lox}$), which express Cre selectively in PV cells after P14. We observed that PV expression levels and putative perisomatic synapses density formed by PV cells are significantly reduced in both the

prefrontal cortex (PFC) and basolateral amygdala (BLA) by P60. We also found a reduction in both the number and intensity of perineural nets (PNN) around PV cells somas of the BLA. Behaviorally, we found that adult PV_Cre;Hdac2$^{lox/lox}$ mice extinguish fear memories more efficiently than control littermates. The reduced fear memory retrieval and renewal is accompanied with an increase in putative perisomatic PV synapse remodeling during fear memory extinction. Moreover, we used a new specific Hdac2 inhibitor which reduced fear memory retrieval in wildtype adult mice. Finally, in order to directly prove that Hdac2 in PV cells is important for fear memory extinction, we will rescue extinction behavior following viral-induction of Hdac2 protein expression specifically in PV cells of the BLA in PV_Cre;Hdac2lox/lox mice.
Globally, our work supports the model in which PV cells play a pivotal role in fear extinction and suggests that modulation of Hdac2 activity in combination with behavioral therapy can increase plasticity during the treatment of post-traumatic stress disorder (PTSD).

Title: A unique tyrosine in the intracellular domain of neuroligin-1 regulates the recruitment of AMPA receptors during synapse differentiation and potentiation

Authors: *O. THOUMINE[1], Z. SZIBER[1], I. CHAMMA[1], C. SAPHY[1], I. PAPASIDERI[1], B. TESSIER[1], H. JANOVJAK[2], M. SAINLOS[1], K. CZONDOR[1], M. LETELLIER[1]
[1]UMR CNRS 5297, Interdisciplinary Inst. for Neurosci., Bordeaux Cedex, France; [2]Inst. of Sci. and Technol. Austria, Klosterneuburg, Austria

Abstract: The molecular mechanisms by which early neuronal connections mature into excitatory or inhibitory synapses are still debated. We examined here the impact of neuroligin-1 (Nlg1) tyrosine phosphorylation on synapse differentiation in hippocampal neurons, focusing on

a unique intracellular residue (Y782) which differentially regulates Nlg1 binding to PSD-95 and gephyrin. By expressing two Nlg1 point mutants (Y782A/F) in hippocampal neurons, we show using imaging and electrophysiology that the Nlg1 phosphorylation state modulates the recruitment of functional AMPA versus GABA-A receptors. Nlg1-Y782F impaired both dendritic spine formation and AMPA receptor diffusional trapping, but not NMDA receptor recruitment, suggesting that this mutant assembles silent synapses. Furthermore, replacing endogenous Nlg1 by either Nlg1-Y782A or Nlg1-Y782F impaired LTP, indicating that these Nlg1 mutants differently retain AMPA receptors. A screening of candidate tyrosine kinases points to Trk family members as major regulators of endogenous Nlg1 phosphorylation and synaptogenic function in neurons. Finally, optogenetic stimulation of endogenous Nlg1 tyrosine phosphorylation using a photoactivatable receptor tyrosine kinase selectively increased the number of dendritic spines and AMPA- (but not NMDA-) receptor mediated synaptic responses in hippocampal neurons. Thus, Nlg1 tyrosine phosphorylation critically regulates excitatory synapse differentiation and function.

Title: Functional changes in connectivity induced by differential silencing or ablation of tonic versus phasic motoneurons in *Drosophila*

Authors: *N. A. APONTE-SANTIAGO[1], J. T. LITTLETON[2]
[1]Biol., MIT, Cambridge, MA; [2]Dept. of Biol. and Dept. of Brain and Cognitive Sci., The Picower Inst. for Learning and Memory, Massachusetts Inst. of Technol., Cambridge, MA

Abstract: Structural plasticity induced by neuronal competition is a common feature of developing nervous systems, and alterations in this process may contribute to neurodevelopmental disorders. The Drosophila larval neuromuscular junction (NMJ) provides a glutamatergic model synapse to study synaptic competition and compensation. Most larval muscle fibers are innervated by at least two motor neurons, a type Ib “tonic” motor neuron and a type Is “phasic” motor neuron. The Ib neuron innervates a single muscle, while Is neurons

innervate a subset of muscles to coordinate contraction of distinct muscle groups. If and how the postsynaptic muscle can differentiate between these two inputs, and how it might preferentially regulate them, is unknown. We are examining if Ib and Is motor neurons compete for synaptic drive to the postsynaptic cell by creating an input imbalance through genetic manipulation of one of the two neurons. We identified cell-type specific motor neuron drivers to genetically increase or decrease synaptic activity at either the Ib or Is motor neuron of muscle 1 (M1). Overexpression of Reaper in MN1-Ib to induce early cell death causes developmental changes in the synapses at M1. No type I motorneurons (Ib or Is) are present in M1 following MN1-Ib ablation, indicating synapse formation or retention may require early Ib function. Ablation of the Is neuron by Reaper expression did not disrupt the MN1-Ib connection at M1. Decreasing the activity of MN1-Ib or MNIs neuron (rather than ablating it) by expressing tetanus toxin light chain (TeTXLC) resulted in structural changes of synaptic boutons at muscle 1. In non-perturbed animals, Ib boutons are bigger than Is boutons. When release of MN1-Ib or MNIs is perturbed, Ib and Is boutons onto M1 are indistinguishable. Furthermore, the morphological changes observed are muscle specific, with the Is bouton increasing in size only at M1 due to MN1-Ib silencing. Additional studies are underway to test molecular pathways that control synaptic balance of tonic and phasic input at Drosophila NMJs.

Title: Mechanisms regulating the alternative splicing of synaptic adhesion molecules in somatosensory neurons

Authors: *J. YOO, R. W. GEREAU, B. COPITS
Anesthesiol., Washington Univ. Sch. of Med., St Louis, MO

Abstract: Processing external information from distinct sensory modalities is vital for generating the diversity of somatic sensations that we perceive. However, altered communication within these pathways can result in chronic pain states. While the plasticity of nociceptive circuits is well established, we possess a limited understanding of the molecular mechanisms that

establish the wiring of sensory circuitry, and how this connectivity may be altered in chronic pain. Neurexins (*Nrxn*s) are presynaptic cell-adhesion molecules that are essential in coordinating synapse formation through trans-synaptic interactions with myriad post-synaptic ligands. Extensive alternative splicing of neurexins generates thousands of unique isoforms which has been proposed to impart a combinatorial "splice-code" for connectivity. In the central nervous system, *Nrxns* have been shown to regulate synaptic properties critical to coordinating neuronal circuitry, yet the role of *Nrxns* in somatosensory circuits remains largely unexplored. Here we tested whether peripheral sensory neurons regulate *Nrxn* alternative splicing in response to changes in activity or injury to alter somatosensory circuit connectivity. We found that both mouse and human sensory neurons dynamically regulate exon inclusion at SS4, a site known to regulate synaptic connectivity. Additionally, we found that *Nrxn* alternative splicing at SS4 is highly conserved in human sensory neurons despite variation in age, sex, and race, suggesting a critical role for this splice-site in peripheral somatosensation. However, we observed significant changes in *Nrxn* splicing in sensory neurons from donors in which spinal neurons had degraded, suggesting that these changes can be regulated by a lack of activity or connectivity. To test the effects of activity on splicing, we treated cultured mouse sensory neurons with KCl, glutamate, and prostaglandin E2 to stimulate activity *in vitro*. We found in preliminary experiments that each treatment resulted in differential splicing changes. We are currently testing how *Nrxn* alternative splicing is differentially regulated by activity or synaptic connectivity to understand the mechanisms underlying these dynamic changes, and how they might influence somatosensory circuit rewiring in chronic pain.

Title: IL-33/ST2 signaling enhances the formation of excitatory synapses in the hippocampus

Authors: *Y. WANG[1,2,3], K.-W. HUNG[1,2,3], C.-Y. CHUANG[1,2,3], W.-Y. FU[1,2,3], A.-Y. FU[1,2,3], N. Y. IP[1,2,3]

Abstract: Emerging evidence suggests that immune molecules play important roles in modulating neuronal functions. Interleukin 33 (IL-33), originally identified as an alarmin, is a crucial mediator in the regulation of both innate and adaptive immunity during tissue injury. Upon tissue damage, IL-33 initiates immune responses by binding to the ST2/IL-1RAcP receptor complex. We recently reported that IL-33 rescues synaptic plasticity deficits and cognitive impairment in an Alzheimer's disease transgenic mouse model. We further investigated whether IL-33 has a physiological role in synapse formation and/or maintenance. We found that IL-33 enhances the formation of excitatory synapses in hippocampal neurons, as revealed by increased excitatory synaptic transmission. Deletion of ST2 or IL-1RAcP in hippocampal neurons abolished the IL-33-induced increase of excitatory synaptic transmission, suggesting that IL-33 promotes synaptogenesis through the activation of the ST2/IL-1RAcP-dependent signaling pathway. Thus, our findings collectively demonstrate a novel role of IL-33/ST2 signaling in excitatory synapse formation and function in the hippocampus.

Title: SIRPα: An activity-dependent regulator of synaptic refinement

Authors: *S. NAGAPPAN CHETTIAR, E. M. JOHNSON-VENKATESH[1], H. UMEMORI[2]
[1]Neurobio., Boston Children's Hosp., Boston, MA; [2]FM Kirby Neurobio. Center, Dept. of Neurol., Boston Children's Hospital, Harvard Med. Sch., Boston, MA

Abstract: Synapses are the sites of information transfer that are central to brain function. Synapses develop through distinct stages beginning with synaptic differentiation, followed by the neural activity-dependent stage of synaptic refinement. During synapse refinement, active

synapses are preferentially strengthened and stabilized, while inactive synapses are eliminated. Defects in this process of refinement are implicated in various neuropsychiatric disorders. Therefore, it is important to understand the molecular mechanisms that detect synaptic activity and determine which synapses to stabilize and which to eliminate. Our previous work has identified the postsynaptically-expressed transmembrane protein, Signal Regulatory Protein-α (SIRPα) as a critical regulator of activity-dependent synaptic maturation. At active synapses, the ectodomain of SIRPα is cleaved and released to retrogradely signal presynaptic maturation. However, how SIRPα senses synaptic activity such that it releases its ectodomain in an activity-dependent manner is not known. Furthermore, whether SIRPα serves as a stabilization signal for active synapses and prevents them from elimination is unknown. Here, we demonstrate that the activity-dependent tyrosine phosphorylation of SIRPα is critical for SIRPα ectodomain cleavage and synaptogenic function. We further show that SIRPα is critical to prevent aberrant synaptic elimination during refinement. We biochemically establish that SIRPα is highly tyrosine phosphorylated in the mouse hippocampus at the start of synapse maturation and that this tyrosine phosphorylation of SIRPα is driven by neuronal activity. Using immunochemistry and electrophysiology in combination with a phosphorylation-deficient mutant of SIRPα, we determine that the tyrosine phosphorylation of SIRPα drives presynaptic maturation and SIRPα ectodomain cleavage in neurons. Finally, we electrophysiologically demonstrate that in the absence of SIRPα signaling, synapses undergo greater elimination during synapse refinement *in vivo*. Together, these results support a model where SIRPα tyrosine phosphorylation detects synaptic activity and directs activity-dependent synapse maturation by driving SIRPα ectodomain cleavage. This SIRPα signaling serves as a stabilization signal to prevent the elimination of active synapses in the brain. This work sheds light on the molecular mechanisms by which synapses are precisely refined in response to neural activity to ensure proper brain function.

Title: Amyloid-β(25-35) peptide administration into the CA1 subfield decreases dendritic spines number but not their morphology in the hippocampus of rats with spatial memory

Authors: *C. SÁNCHEZ MALDONADO, E. RAMÍREZ HERNÁNDEZ, I. D. LIMÓN PÉREZ DE LEÓN
Lab. of Neuropharm., Benemérita Univ. Autónoma De Puebla, Puebla, Mexico

Abstract: It has been shown that the administration of the $A\beta_{25-35}$ into cognitive regions of the brain reproduces some of the neurotoxic mechanisms described in Alzheimer's disease, some of which decrease dendritic spines density. Dendritic spines morphological changes are associated to their function: stubby and branched spines are immature forms that express predominantly in the post-natal days; thin spines are highly dynamic mature forms associated to learning, and mushroom spines are stable mature forms linked to memory. The effect of $A\beta_{25-35}$ administration on dendritic spines morphological changes and its association with cognitive impairment is still unknown. The aim of this study was to typify dendritic spines in the hippocampus and dentate gyrus of rats administrated with $A\beta_{25-35}$ peptide into the CA1 subfield. Twenty four male Wistar rats (4 months old, 350-400 g) were divided in two groups for stereotaxic surgery (n=12 each). One group was anesthetized and bilaterally injected 1 μL of $A\beta_{25-35}$ solution [0.1 μg/μL] into the CA1 subfield of the hippocampus (AP -4.0, LM ±2.6, DV -2.3 mm, from Bregma). Six rats from each group (Intact+LM, $A\beta_{25-35}$+LM) performed learning on days 6 to 10 post-surgery and memory tests on days seventeen and thirty-eight post-surgery in the Morris water maze. Next day all animals were euthanized, brains were obtained and processed for Golgi-Cox staining. Dendritic spines were evaluated in distal dendrites randomly chosen in 5 neurons per region and in both hemispheres. Typing was done according to spines morphology in mushroom, thin, stubby or branched. Total spines decreased in $A\beta_{25-35}$ group, compared to Intact group. Similarly, total spines decreased in $A\beta_{25-35}$+LM group, compared to Intact+LM group. Proportion of mushroom spines increased in the $A\beta_{25-35}$, Intact+LM and $A\beta_{25-35}$+LM groups, compared to Intact group. Proportion of stubby and thin spines decreased in $A\beta_{25-35}$ and Intact+LM groups, compared to Intact. Results indicate that $A\beta_{25-35}$ decreases dendritic spines number in the hippocampus but does not modify their morphology, which could be associated to extinction, as shown in memory evaluation.

Title: Functional maturation of mossy fiber terminals from adult-generated hippocampal dentate granule cells

Authors: *N. P. VYLETA, D. R. SEIB, J. S. SNYDER
Psychology, The Univ. of British Columbia, Vancouver, BC, Canada

Abstract: The dentate gyrus of the hippocampus is one of few regions in the mammalian brain to exhibit continued neurogenesis throughout adulthood, and these neurons may be uniquely suited to contribute to information transfer through hippocampal circuits. Understanding the mechanisms of how these new neurons signal in the mature network—both receiving inputs and transmitting output signals—is fundamentally important to understanding their roles in hippocampal function. It is well established that adult-generated granule neurons experience a period of enhanced excitability of the somato-dendritic compartment, as well as greater plasticity at the input synapses coming from the entorhinal cortex (Schmidt-Hieber et al., 2004; Ge et al., 2007). However, the time course of the development of output synapses from these neurons into the CA3 region of the hippocampus remains far less clear. Because the shape and dynamics of the action potential waveform at a presynaptic bouton determines calcium entry and ultimately the efficacy of release of neurotransmitter (Geiger and Jonas, 2000), how the electrical impulse at output mossy fiber terminals from adult-generated granule neurons develops with cell age could have important time-dependent effects on synaptic plasticity. Here, we have systematically characterized electrical properties of output mossy fiber terminals from adult-generated granule neurons using direct patch clamp recordings (Geiger and Jonas, 2000; Vyleta and Jonas, 2014). Recordings were made at various time points after induction of a fluorescent reporter in granule neurons in $Ascl1^{CreERT2}$;$CAG^{floxstopTom}$ mice. Neurons were labeled during adulthood (6- to 8-weeks of animal age) and during early development (postnatal day 0-3). The size and kinetics of action potentials, dynamics of the action potential waveform during trains of stimuli, excitability threshold, input resistance and resting capacitance were evaluated as a function of cell age, and compared between adult-born and early development-born groups.

Abstract: In mammals, olfactory sensory neurons (OSNs) located in the nasal epithelium gather odor information from the environment, and relays it to the olfactory bulb (OB). Within the OB, this olfactory information is received by mitral and tufted cells, and further shaped by local inhibitory interneurons. Uncovering contributions of diverse interneuron subtypes towards OB circuit processing is essential to fully understand olfaction. Interneuron diversity in the OB is heavily influenced by ongoing adult neurogenesis. Additionally, survival and integration of adult-born neurons is known to be influenced in an activity-dependent manner. To investigate cellular heterogeneity in the mouse OB and query the developmental program of adult-born neurons, we utilized single cell RNA sequencing (scRNA-seq) and computational modeling. Our data reveal 38 transcriptionally distinct neuronal and non-neuronal cell types, and suggest novel markers for each. Additionally, we analyzed molecular changes throughout the development of adult-born interneurons, and uncovered changes in their patterns of gene expression that are differentially regulated throughout their development. Finally, we investigated changes in tissue composition upon sensory deprivation and enrichment, and discovered distinct mechanisms that differentially affect the development of adult-born neurons. Together, we provide a transcriptome-based foundation for studying subtype specific neuronal function in the OB, a map of molecular changes throughout maturation and integration of adult-born neurons, and document activity-dependent changes in the cellular composition of the olfactory system. These data provide a valuable resource of cell type specific markers that allow for the investigation of cell type-specific functions in the olfactory bulb. Furthermore, the associated list of genes that are differentially regulated in adult-born neurons throughout development can be utilized in ongoing work towards better understanding synapse formation and maintenance in adult brain tissue.

Title: The protein arginine methyltransferase PRMT8 regulates dendritic spine maturation and localization of excitatory synapses

Authors: *K.-O. LAI, L. H. Y. LO, R. DONG, A. CHAI, Q. LYU
Sch. of Biomed. Sci., The Univ. of Hong Kong, Hong Kong, Hong Kong

Abstract: Most excitatory synapses are located in the dendritic spines, which exist as various morphologies. The formation of mature mushroom spines is crucial for long-term storage of memory, while higher abundance of the immature thin spines and filopodia is associated with autism and Fragile-X syndrome. Spine maturation is influenced by neuronal activity and requires dendritic translation of specific mRNAs. Characterizing dendritically localized transcripts might therefore identify key molecules and signaling pathways that control spine maturation. PRMT8 (protein arginine methyltransferase 8) belongs to a family of enzymes that catalyze arginine methylation, a form of post-translational modification (PTM) that is most-studied as a regulatory mechanism during transcription and splicing in the nucleus. Among the nine PRMTs, PRMT8 is unique because of its anchorage to the plasma membrane via myristoylation. Here we found that PRMT8 was localized in dendritic spines of dissociated hippocampal neuron. The PRMT8 mRNA was present in the dendrites, and the expression of PRMT8 protein was regulated by neuronal activity. Depletion of PRMT8 resulted in the loss of mushroom spines and an increase in the number of immature filopodia. This change in spine morphology was coupled with a shift of excitatory synapses from dendritic spines to the dendritic shaft without affecting the number of functional synapses. Our findings have identified PRMT8-mediated arginine methylation as a novel regulatory PTM at the synapse that is crucial for dendritic spine maturation.

Title: Non-redundant functions of different kinesin I motor proteins in dendritic mRNA transport and synapse development

Authors: *J. ZHAO, R. FAN, H. K. FOK, H.-L. CHAN, L. H. Y. LO, J. D. HUANG, C. S. W. LAI, K.-O. LAI

Abstract: Most excitatory synapses are located on dendritic spines, which exist in heterogeneous shapes. Mushroom spines are believed to contribute to long-term memory storage, and their formation depends on local dendritic protein synthesis. Dendritically localized mRNAs are transported in the form of RNA granules by the motor proteins kinesin and dynein along microtubule. There are 45 kinesin genes in the mammalian genome, and different classes of kinesin proteins may exhibit functional specificity by transporting distinct cargos to different subcellular localization. The conventional kinesin, Kinesin I, consists of three homologous members (KIF5A, KIF5B and KIF5C), which form complexes with RNA granules in the brain. Whether the three highly homologous Kinesin I motor proteins have redundant or non-overlapping roles in RNA transport and dendritic spine development have not been explored. Here we found that specific depletion of individual Kinesin I family member in dissociated hippocampal neurons led to distinct dendritic spine phenotypes. By labeling RNA with SYTO 14 or expression of GFP-FMRP followed by time-lapse confocal imaging, we demonstrated that KIF5B regulates dendritic mRNA transport. Transcriptome analysis of synaptoneurosomes isolated from wild-type and *kif5b* knockout mice was performed to identify putative mRNA transcripts that showed differential synaptic localization. Our findings have shed new light on the non-redundant roles of different kinesin motor proteins in regulating intracellular transport, synapse development and function.

Title: Functional diversity between splice variants of the neurodevelopmental disorder gene Kirrel3

Authors: *M. TAYLOR, E. A. MARTIN, M. E. WILLIAMS
Neurobio. and Anat., Univ. of Utah, Salt Lake City, UT

Abstract: Cell adhesion molecules (CAMs) play critical roles in synapse development. The diversity of CAMs at individual synapses and the fact that different classes of synapses use different CAMs suggests that these proteins are not simple glues holding synaptic membranes together. Rather, different CAMs provide specificity for synaptic structure and function. We previously found that Kirrel3 is a homophilic CAM expressed only in specific subsets of hippocampal neurons. Loss of Kirrel3 leads to loss of synapses between Kirrel3 expressing neurons, ultimately creating an excitation/inhibition imbalance within the hippocampus. Interestingly, Kirrel3 is alternatively spliced, but the function of these alternative splice forms in synapse development is unknown. Potentially, alternative splicing at the Kirrel3 locus creates variants that work together, separately, or in opposition to build specific synapses. Here we determine the functional differences of two Kirrel3 splice forms with respect to cell adhesion, subcellular localization and synapse formation.

Title: The functional impact to synapse formation of Kirrel3 variants associated with neurodevelopmental disorders

Authors: *E. A. MARTIN[1], M. R. TAYLOR[2], M. E. WILLIAMS[3]
[1]Dept of Neurobio. and Anat., [3]Neurobio. and Anat., [2]Univ. of Utah, Salt Lake City, UT

Abstract: Neurodevelopmental disorders are often diseases of the synapse, yet few molecules are identified that link specific mutations to impaired synapse function. Kirrel3 is a homophilic transmembrane cell adhesion protein expressed within hippocampal DG and GABA neurons. We showed that structurally, loss of Kirrel3 reduces mossy fiber DG-to-GABA synapses and functionally, loss of Kirrel3 significantly increases the excitation/inhibition ratio of CA3 neurons. These defects may underlie neurodevelopmental disorders associated with Kirrel3 in humans. Currently, many Kirrel3 protein coding variants have been identified as potentially damaging in patients with autism spectrum disorders and mild to severe intellectual disability. Yet to date, no study has examined the functional relevance of these Kirrel3 variants in synapse formation. Here we examine the function of several Kirrel3 variants in cell adhesion, subcellular localization, and synapse formation. These results are necessary to determine if specific Kirrel3 variants may be pathogenic and lead to synaptic defects relevant to neurodevelopmental disorders.

Title: The role of Kirrel3 in presynaptic structural plasticity

Authors: *R. L. RAWSON, D. WOODRUFF, T. TUIFA, M. WILLIAMS
Univ. Utah, Dept. of Neurobio. & Anat, Salt Lake Cty, UT

Abstract: All behaviors, from simple reflexes to complex cognitive tasks, require neuron communication via synapses. Consequently, many neurological disorders are linked to impairments in synapse form and function. Synapses must be correctly established during development, yet they must also be flexible to accommodate future adaptations. Synapse flexibility is critical for learning and memory and includes altering synapse architecture, known as structural plasticity. Very little is known about mechanisms mediating structural plasticity, and even less still about the structural plasticity of presynaptic structures. In the hippocampal mossy fiber system, DG neurons make elaborate presynaptic structures that are physically altered during learning and memory. They form large boutons that connect with CA3 neurons and filopodia-like extensions that synapse with both GABA and CA3 neurons. The Williams lab has recently demonstrated that the cell adhesion molecule Kirrel3 is required for mossy fiber filopdia number, as well as their synapses onto GABA neurons. Preliminary data also show that Kirrel3 is regulated by neuronal activity. To test the model that Kirrel3 is a potential mechanism behind presynaptic structural plasticity during learning and memory, we are investigating *in vivo* if Kirrel3 is required for altering filopodia number in response to changes in neuronal activity and during learning and memory. This is likely to have clinical relevance as mutations in Kirrel3 have been repeatedly associated with Autism and intellectual disability.

Title: Heterogeneous expression of glutamatergic receptor genes in normally developing human cortex and adult schizophrenia

Authors: *S. MANCINI[1], D. G. JONES[3], K. M. MURPHY[2]
[1]MiNDS, [2]Dept Psychol Neurosci & Behaviour, McMaster Univ., Hamilton, ON, Canada; [3]Pairwise Affinity Inc., Dundas, ON, Canada

Abstract: Biological heterogeneity of the human brain is a common finding in studies of neurological or neuropsychiatric disease. These disease-related heterogeneities are found at many levels from behaviour to molecular mechanisms. We have been studying heterogeneity in normal brain development and found a wave of high inter-individual variability in expression of glutamatergic proteins in visual cortex in young children but relatively homogeneous expression

at other ages.
We chose to look at glutamatergic mechanisms because they are involved with both adaptive and maladaptive experience-dependent plasticity. Here we asked if: glutamatergic gene expression has a similar wave of heterogeneity; other cortical areas have waves of heterogeneity in childhood, and adult heterogeneity in diseases like schizophrenia (SZ) is similar to the heterogeneity found during normal development?
We analyzed transcriptome data for glutamatergic receptor subunit expression in human cortex during normal development and in adults with SZ. We used two databases one with developmental data (Allen BrainSpan) (n=41), age range 8pcw-40yrs, 9 cortical areas, and 19 glutamatergic receptors. The other database (GDS4523[ACCN] accessed through Gene Expression Omnibus) contained data from the anterior prefrontal cortex of adults (age range 25-88 yrs) with SZ (n=28) or control cases (n=23). We plotted gene expression by age and calculated heterogeneity (variance-to-mean ratio, VMR) for a sliding window of 5 adjacent ages. During normal development several cortical areas and genes including GRIN2A, GRIN3A, GRIN3B, GRIA1, GRIA2, and GRIA3 showed a wave of heterogeneity in young childhood, peaking at ~1-2 years of age, with relatively homogeneous expression at other ages. We compared heterogeneity at the peak in childhood with young adults by calculating a contrast index using the VMRs and found as much as 80% greater heterogeneity in young children. We then applied the same approach to compare heterogeneity in glutamate gene expression between adult SZ and control cases. Here we found that GRIN2A, GRIN3A, GRIN3B, GRIA1, GRIA2, and GRIA3 had ~25-50% greater heterogeneity in SZ cases.
Thus, glutamatergic genes, like proteins, have a wave of heightened heterogeneity in childhood and this pattern is part of normal development for many areas of the human cortex. Also, in adults with SZ, there is heightened heterogeneity for some glutamatergic genes suggesting that these regulators of experience-dependent plasticity may maintain or re-entered that wave of childhood heterogeneity.

Abstract: Age is an important variable in a number of psychological and biological models, including those predicting antisocial behavior. However, individual variation in biological processes assures that chronological age may not be the best proxy for capturing important neurodevelopmental differences in such models. Neuroimaging-based quantifications of brain-age have been previously developed, and these models have demonstrated high accuracy in predicting chronological age and psychological outcomes related to aging, cognitive development, and cognitive decline. While age is also highly relevant to antisocial outcomes, brain-age measures have not yet been applied to models predicting antisocial behavior. Here we utilize independent component analysis (ICA) of structural MRI data to identify intrinsic networks of gray matter (GM) that are discriminative of age among a large incarcerated sample (n = 1332). We then carry these age-related components forward in models predicting re-arrest in a separate sample of offenders recently released from prison (n = 93). After an average of four years follow-up, 54% of the sample was re-arrested. Feature selection in a support vector machine framework identified two components of GM volume and five components of GM density that were predictive of re-arrest. These components were included with a number of other relevant variables in a series of Cox proportional hazards analyses, examining time to re-arrest. Model comparisons indicated that brain-age consistently outperformed chronological age in predicting re-arrest when examined alone or in conjunction with other variables including psychopathic traits, drug and alcohol dependence, behavioral performance on an inhibition task, and neural activity in the anterior cingulate cortex. These findings support the relative value of examining more precise neural indicators of brain maturity compared with chronological age, suggesting certain neural indices are promisingly more sensitive to some important behavioral and psychological outcomes.

Title: Race, violence exposure, and the psychosocial stress response

Authors: *E. DAVIS[1], A. M. GOODMAN[1], T. R. OREM[1], N. G. HARNETT[1], M. D. WHEELOCK[1], S. MRUG[1], M. A. SCHUSTER[2], M. N. ELLIOTT[3], S. R. TORTOLERO[4], D. C. KNIGHT[1]
[1]Univ. of Alabama At Birmingham, Birmingham, AL; [2]Harvard Univ., Cambridge, MA; [3]RAND, Santa Monica, CA; [4]Univ. of Texas at Houston, Houston, TX

Abstract: African American, in comparison to European American, individuals have higher rates of violence exposure throughout their lifetimes (Roberts et al., 2010). Violence exposure in adolescence has been linked to changes in brain structure and function, and appears to alter the way people respond to stress (Teicher et al., 2016; Teicher & Samson, 2016). However, it remains unclear whether race and prior violence exposure interact to affect the stress response. Therefore, the present study investigated the relationship between prospectively measured adolescent violence exposure (ages 11-19 years) and the neural response to psychosocial stress as young adults (age = 19.54 ± 1.31). In the present study, 262 African American and European American participants completed the Montreal Imaging Stress Task (MIST). Violence exposure was greater in African American than European American participants, and self-reported stress ratings to the MIST were higher in European American than African American participants. Further, a significant interaction was observed between race and cumulative violence exposure on self-reported stress ratings ($p < 0.01$). Specifically, stress ratings decreased as violence exposure increased among African American but not European American participants. Functional magnetic resonance imaging (fMRI) results showed differences in prefrontal cortex activity that varied with violence exposure, race, and the interaction of race and violence exposure ($p < 0.05$). These findings demonstrate racial differences in stress reactivity that vary with violence exposure.

Title: The effects of early childhood trauma and gender on brain structure

Authors: *S. MCQUINN
Univ. of Utah, Salt Lake City, UT

Abstract: Background
Early childhood stress or trauma has many lasting psychological and physiological effects. Stress in early development can lead to changes in brain structure and function. Little is known as to whether early life stress (ELS) may affect men and women differently. The aim of this study was to examine the differential effects of ELS on cortical thickness in a group of healthy men and women.
Methods
48 healthy participants between the ages 18-45 were asked to complete the Family Life Experience Questionnaire to determine the extent to which they had experienced early life stress. Each participant was scanned and T1-weighted MRI scans were collected. The Computational Anatomy Toolbox (CAT12) for SPM was used to measure cortical thickness and determine whether there were significant cortical thickness differences between groups (i.e., Men vs Women, ELS vs no ELS) and test for interactions between ELS and sex.
Results
Females exhibited greater cortical thickness than males within visual and auditory association areas (XYZ = -15, -101, 13, T=5.06, p_{FWE}=0.011, XYZ = 67, -34, 6, T=3.89, $p<0.001_{uncorrected}$), the ventral temporal cortex (XYZ = 36, -6, -37, T=4.31, $p<0.001_{uncorrected}$), the premotor cortex (XYZ = -41, 6, 50, T=3.93, p<0.001, uncorrected), and the superior parietal lobule (XYZ = 36, -47, 50, T=3.59, $p<0.001_{uncorrected}$). Males had thicker cortices than females within the middle occipital gyrus (XYZ = -46, -79, 3, T=4.51, p_{FWE}=0.041), the extrastriate cortex (XYZ = 25, -54, 2, T=3.89, $p<0.001_{uncorrected}$) and the dorsal temporal cortex (XYZ = 44, -20, -3, T=3.84, $p<0.001_{uncorrected}$). Those who experienced ELS showed greater cortical thickness on the middle occipital gyrus (XYZ = -5, -90, -3, T=5.06, $p<0.001_{uncorrected}$). When testing the interaction between sex and trauma, we found a difference in a small region of the orbitofrontal cortex (XYZ = 41, 29, -16, Z=3.64, $p<0.001_{uncorrected}$).
Discussion
Our findings suggest that early life stress does indeed have an effect on cortical thickness and

that sex may play a role in that effect.

Title: Associations between socioeconomic factors and brain structure in preadolescence

Authors: M. R. GONZALEZ[1], K. A. UBAN[1], M. M. HERTING[2], E. KAN[1], *E. R. SOWELL[3]
[1]Children's Hosp. Los Angeles, Los Angeles, CA; [2]USC, Los Angeles, CA; [3]Pediatrics, USC/CHLA, Los Angeles, CA

Abstract: Previous findings from our group (Noble et. al., 2015) suggest that indices of socioeconomic status (SES), such as family income and parental education, are associated with brain development. These effects are particularly notable among the most disadvantaged individuals. Importantly, differences in SES predict differences in brain structure during a time when youth are at-risk for substance use. Here, associations between SES and brain structure were examined in a cross-sectional sample of 4,500 preadolescent children ages 9 - 10 years of age participating in the Adolescent Brain Cognitive Development (ABCD) study. The Data Analytics Exploration Portal (DEAP) was used to run multilevel regression models (gamm4) to test the effects of SES on cortical surface area. We examined FreeSurfer measures of total cortical surface area (SA), as well as SA in regions of interest in brain structure related to executive function and language. Measures of SES examined were household income and highest parental education. All models included age, sex, and ethnicity/race as fixed effect covariates and family relationship and site as random effects. Higher parental income predicted larger total cortical SA ($F = 17.48$, $p < 0.001$) and accounted for an additional 0.87% of variance (Null model: AIC=87,745.45; BIC=87,820.95; Full model: AIC=87,805.71; BIC= 87,868.62). Similar associations were found for higher income and larger SA in the left superior frontal ($F = 14.00$, $p < 0.001$), right superior frontal ($F = 15.49$, $p < 0.001$), left pars orbitalis ($F = 9.81$, $p < 0.001$), and right pars orbitalis ($F = 14.75$, $p < 0.001$). In a separate model, higher parental education predicted larger total cortical SA ($F = 8.49$, $p < 0.001$) and accounted for an additional 0.78% of variance (Null model AIC=94,958.88; BIC: 95,048.08; Full model: AIC=95,045.32; BIC=95,109.03). Similar associations were found for higher parental education and larger SA in

the left superior frontal (F = 8.96, p <0.001), right superior frontal (F = 6.98, p <0.001), left pars orbitalis (F = 4.92, p <0.001), and right pars orbitalis (F = 7.17, p <0.001). Factors such as environmental toxins and physiological measures will be examined as potential underlying mechanisms influencing the impact of SES on brain structure using a model of mediation. These preliminary results confirm and extend findings from Noble et. al., (2015) to a larger sample with a narrower age range.

Title: The influence of neighborhood disadvantage during adolescence on volume of the adult amygdala, hippocampus, and thalamus

Authors: *K. BELL[1], N. G. HARNETT[2], S. MRUG[2], M. A. SCHUSTER[3], M. N. ELLIOTT[4], S. R. TORTOLERO[5], D. C. KNIGHT[2]
[1]Psychology, Univ. of Alabama at Birmingham, Homewood, AL; [2]Psychology, Univ. of Alabama at Birmingham, Birmingham, AL; [3]Boston Children's Hosp., Boston, MA; [4]RAND Corp., Santa Monica, CA; [5]Hlth. Sci. Ctr., Univ. of Texas, Houston, TX

Abstract: Depression and anxiety have been linked to changes in the gray matter volume of the amygdala, hippocampus, and thalamus (Mervaala et al., 2000; Merz, Tottenham, and Noble, 2018). Additionally, children that live in disadvantaged neighborhoods are at increased risk for depression and anxiety (Xue, Leventhal, brooks-Gunn, and Earls, 2005). Prior research has linked household socioeconomic status (SES) to amygdala and hippocampal volume, however, studies of the impact neighborhood environment has on the gray matter of these structures have been inconsistent. Determining the impact neighborhood disadvantage has on amygdala, hippocampus, and thalamus volume may offer new insight into mechanisms by which adverse life experiences impact developing neural systems. The current study investigated the impact of living in a disadvantaged neighborhood during childhood on the gray matter volume of the amygdala, hippocampus, and thalamus in young adults. Using geocoded addresses for each participant at age 11, multiple indicators of neighborhood disadvantage from the U.S. Census were combined. Magnetic resonance imaging (MRI) was used to collect anatomical images from these individuals in young adulthood (N=249; Mean age 19.53 years; SD = 1.11). Results

demonstrate a positive correlation between neighborhood disadvantage and right amygdala volume ($r(241) = .196$, $p < .002$). Likewise, a positive correlation between neighborhood disadvantage and left ($r(241) = .178$, $p = .006$) and right ($r(241) = .178$, $p = .005$) thalamus volume was observed. There were no significant correlations between neighborhood disadvantage and hippocampal volume. These findings suggest neighborhood disadvantage can impact brain structures that are important for healthy emotional function.

Title: Differential brain response between OPRM1 genotypes to reward feedback during early adolescence

Authors: *V. C. MUCCIARONE[1], R. A. SCHROEDER[1], B. W. STEVENS[1], D. H. FISHBEIN[2], J. W. VANMETER[1]
[1]Dept. of Neurol., Georgetown Univ., Washington, DC; [2]Human Develop. and Family Studies, Pennsylvania State Univ., University Park, PA

Abstract: Adolescence is a developmental period characterized by greater risk-taking and reward-seeking behaviors, influenced by both environmental and genetic factors. The single nucleotide polymorphism (SNP) rs1799971 in the μ-opioid receptor (OPRM1) gene has been implicated in reward processing (Ray et al., 2014) and substance use disorders (Miranda et al., 2010), where the minor G-allele is implicated in higher risk. Few studies have investigated the effects of this SNP on adolescent reward processing, and no studies have examined a substance-naïve population. To assess the effect of this allelic variation on reward processing before exposure to drugs and alcohol, we analyzed blood oxygen level-dependent (BOLD) response during a Wheel of Fortune (WoF) functional MRI task, as well as moderation by family history of alcohol use/abuse and beliefs about substance use.
Participants were typically developing, alcohol and drug naïve youth aged 11-13, N = 115 (25 AG; 63 F), enrolled in the Adolescent Development Study, a prospective longitudinal neuroimaging study of substance use in adolescents. BOLD signal was acquired during the WoF task on a Siemens 3T scanner. Image preprocessing and analysis were conducted in SPM8. Adolescents completed a survey querying beliefs about alcohol use. Parents reported on family

history of alcohol use/abuse via a family tree questionnaire.
A whole brain analysis of activation patterns during feedback for winning versus losing trials in the WoF task revealed a significant cluster of activation (466 voxels, p = 0.019 FWE cluster-corrected) in the right middle frontal gyrus (MFG; peak 24, 28, 44) for AA homozygotes greater than AG heterozygotes. This region is involved in goal planning (Fincham et al., 2002) and attention to positive emotions (Kerestes et a., 2012), possibly implying greater reflection on positive reward feedback in the AA homozygotes compared to G-allele carriers. The reduced MFG response to reward in the G-allele carriers suggests that they are less stimulated by natural reward.
No significant difference was found in family history of alcohol use/abuse. However, a significant difference (p = 0.002) was found in the adolescents' beliefs about parental alcohol consumption, such that G-allele carriers believed their parents drank more alcohol than AA homozygotes believed of their parents. Taken together, results showing a heightened awareness of parental alcohol consumption and decreased brain response to reward, suggest G-allele carriers may be at increased risk for substance use disorders.

Title: fMRI activation predicts depressive episodes in highly -comorbid adolescents

Authors: *I. FROSCH[1], N. A. HUBBARD[1], M. GONCALVES[1], V. SILESS[2], J. WANG[2], G. VERGARA[3], K. CONROY[4], C. BAUER[1], F. VAZ DE SOUZA[5], J. R. KACZMARZYK[1], I. ROSSO[3], D. Abstract: Depression is one of the most common psychiatric illnesses among adolescents. There is a high rate of comorbidity with depression and anxiety in adolescence, and often overlapping symptomatology between these disorders. Heterogeneity within depressive samples is a likely contributor to the current lack of reliable neural markers of depression during adolescence. Here,

we assessed the degree to which activation information from task fMRI can accurately predict a current major depressive episode (MDE) in a sample of anxious and depressed adolescents (ages 14-15). We recruited two comorbid patient groups: (1) all participants had a current MDE, but also many had comorbid anxiety disorders (e.g., generalized anxiety disorder); (2) all participants had an anxiety disorder, and many also had previous diagnoses of MDEs. Participant diagnoses were classified in a diagnostic interview. Targeting overlapping and comorbid groups of adolescents allowed our sample to closely resemble typical adolescent psychiatric populations and to differentially predict MDEs from two diagnostically-similar groups. Single-layer neural networks were trained to predict (1) whether adolescents had a current MDE; or (2) a continuous variable of depressive symptom severity (via the Mood and Feelings Questionnaire [MAFQ]). Blood-oxygen-level dependent (BOLD) activation data from voxels in three regions-of-interest (amygdalae, striatum, and middle frontal gyrus) were gathered from three tasks targeted to elicit activation in one of these regions. Neural networks modeling BOLD data showed exceptional accuracy in predicting MDEs (*K*-fold out-of-sample Accuracy = 93.3%) and depressive symptom severity (*K*-fold out-of-sample R^2 = .564). The neural network using BOLD data showed greater predictive accuracy for MDEs compared to models using the MAFQ (*K*-fold out-of-sample Accuracy = 71.4%), and models using additional anxiety and depression self-report measures (*K*-fold out-of-sample Accuracy = 85.7%). These preliminary results (*N* = 43) demonstrated that task fMRI can provide a useful tool, beyond that of standard diagnostic rating scales, to identify current depression in adolescents.

Title: Alterations in gray matter volume of the prefrontal cortex, hippocampus, and amygdala persist into adulthood following alcohol, tobacco, and cannabis use during adolescence

Authors: *J. B. PURCELL[1], N. G. HARNETT[1], S. MRUG[1], M. N. ELLIOTT[2], S. TORTOLERO EMERY[3], M. A. SCHUSTER[4], D. C. KNIGHT[1]

Abstract: Alcohol, tobacco, & cannabis are the most commonly used substances during adolescence (Johnston, O'Malley, Miech, Bachman, & Schulenberg, 2017). In fact, approximately 61%, 28%, and 45% of adolescents report using alcohol, tobacco, & cannabis, respectively, by grade 12. Given the relatively rapid brain development occuring at this age, (Toga, Thompson, & Sowell, 2011), adolescence may represent a particularly sensitive period to the deleterious effects of alcohol, tobacco, & cannabis use. Evaluating gray matter volume in young adulthood can provide indirect information about whether substance use disrupts brain development and maturation (Jacobus & Tapert, 2014). Therefore, the present study investigated whether adolescent alcohol, tobacco, or cannabis use varies with gray matter volume within the prefrontal cortex, hippocampus, and amygdala as young adults. A community sample of adolescents were interviewed prospectively (at ages 11, 13, 16 & 19) regarding their use of alcohol, tobacco, & cannabis. Following the final assessment, participants completed a single magnetic resonance imaging (MRI) scanning session. Anatomical images were obtained using a 3T Siemens Allegra MRI scanner. Analyses were completed using AFNI (Cox, 1996) and FreeSurfer software packages (Fischl, 2012). Anatomical information about cortical and subcortical structures was obtained from FreeSurfer and was output into SPSS for further analysis. Frequency of binge drinking was associated with increased volume of the left hippocampus and amygdala ($r = 0.168$, $p < 0.05$; $r = 0.195$, $p < 0.05$, respectively) in males, but not females. Within the right hemisphere, frequency of binge drinking was negatively correlated with ventromedial prefrontal cortex volume (vmPFC; $r = -0.231$, $p < 0.01$). Sex differences in neural development may account for the observed differences in the effects of binge drinking. Further, there was a significant negative correlation between the number of cigarettes smoked and bilateral hippocampal and amygdala volume (L hippocampus: $r = -0.137$, $p < 0.05$; R hippocampus: $r = -0.128$, $p < 0.05$; L amygdala: $r = -0.158$, $p < 0.05$; and R amygdala: $r = -0.145$, $p < 0.05$). Similarly, there was a significant negative correlation between the number of cigarettes smoked and bilateral vmPFC volume (left hemisphere: $r = -0.158$, $p < 0.01$; right hemisphere: $r = -0.114$, $p < 0.05$). There were no associations between frequency of cannabis use and cortical or subcortical volume. These findings suggest substance use during adolescence, particularly alcohol and tobacco use, influence the neural development of the amygdala, hippocampus, and ventromedial prefrontal cortex.

Title: Parental involvement predicts posterior ínsula hemodynamic activation in response to child's costly error

Authors: *E. L. RATLIFF[1,2], K. T. COSGROVE[2,3], K. L. KERR[1,2], D. C. DEVILLE[2,3], K. BURROWS[2], A. MOORE[2,1], J. BODURKA[2,4], W. K. SIMMONS[5], A. S. MORRIS[2,1]

Abstract: Parental involvement, including attention, awareness, and supervision, strongly influences connectedness and trust in the parent-child relationship. Parental involvement has been implicated in studies of parental emotional responsiveness and warmth, with higher levels related to greater parental responsiveness to a child's emotional distress. Additionally, neuroimaging studies have found that activation in the insular cortices of mothers is associated with levels of maternal responsiveness and empathetic reactions to their infant's expressions of emotional distress (Lenzi et al., 2008). This association has yet to be examined in adolescents; therefore, we sought to assess the association between adolescent reports of parental involvement and empathy-related activation in the insular cortices of parents. The current study examined this association in the context of parent-adolescent interactions using fMRI hyperscanning (e.g., simultaneous fMRI scanning of two interacting participants using identical MRI scanners). Twenty-one psychiatrically healthy, control parents (*Mean* age = 43 years, 90% female) and their adolescent children (*Mean* age = 15 years, 62% female) were included in this study. Prior to the scan, parents and adolescents completed a battery of measures assessing parent-adolescent relationship quality, emotion awareness, and parenting styles and techniques. During the scan, parents and adolescents participated in the Testing Emotional Attachment and Mutuality (TEAM) task, which is a collaborative game intended to examine brain activity when either member of the dyad makes a costly error. The TEAM task includes several fixed trials in which each member of the dyad believes the other member has made an error, costing the dyad $5. A one-sample t-test with parental involvement scores (as rated by their adolescent) entered as a covariate in AFNI's 3dttest++ program was used to examine the relationship between parental involvement and parent's brain responses to their child's costly error. Adolescent reports of lower levels of parental involvement were found to be associated with bilaterally decreased hemodynamic activation in the posterior insula of parents ($p < .005$). Activity in the posterior insula has been associated with perceptions of other's pain, suggesting a role in empathetic reactions. The findings provide initial evidence for the neural basis of parents' empathetic reactions to their adolescents' costly errors and reveal how activity in the recruited regions relates to their child's perceptions of parental involvement.

Title: The relationship between brain activation during parent-child fMRI hyperscanning and symptoms of anxiety and depression

Authors: *K. T. COSGROVE[1,2], D. C. DEVILLE[1,2], K. L. KERR[3,1], E. L. RATLIFF[3,1], K. BURROWS[1], A. J. MOORE[1], S. F. TAPERT[4], M. MISAKI[1], J. BODURKA[1,5], R. L. AUPPERLE[1,2], W. K. SIMMONS[1,6], A. S. MORRIS[1,3]

Abstract: A reciprocal relationship exists between children's emotion regulation (ER) abilities and those of their parents. A parent's ER and mental health symptoms can alter how a child learns to modulate their own distress. Conversely, children's mental health symptoms may lead to parent ER difficulties. The medial prefrontal cortex (mPFC) has been implicated in ER processes, including the appraisal of errors and receipt of negative feedback. However, it remains largely unknown how mPFC activity within parent-child dyads may relate to one another's mental health.

In an ongoing study, we use hyperscanning fMRI with parents (N = 22, mean age = 43, 91% female) and their adolescent children (N = 25, mean age = 15, 64% female). All subjects are psychiatrically healthy and right-handed. While undergoing simultaneous fMRI scans, the parent-adolescent dyads play the Testing Emotional Attachment and Mutuality task. In this task, subjects experience feigned error conditions in which it appears the other person made a mistake, costing the dyad five dollars. AFNI's 3dttest++ was used to examine adolescents' and parents' mPFC BOLD activation during feigned error conditions and how this related to the other dyad-member's mental health symptoms (voxelwise $p < 0.005$).

Decreased parent mPFC activity was associated with higher anxiety in adolescents. Greater adolescent mPFC activity was associated with higher depression in parents. Furthermore, measures of parent and adolescent mental health symptoms were not related. However, there was a significant negative correlation between parent and adolescent mPFC percent signal change during the feigned error condition.

These findings provide neurobiological support for the idea that ER is developed within a dyadic parent-child context. Parent ability to recruit mPFC regions when confronted with their child's

error may represent an adaptive brain response that contributes to decreased adolescent anxiety. Adolescents with more depressed parents exhibit increased mPFC activation when confronted with their parents' errors, potentially as a compensatory response to parent ER disruptions. Future longitudinal investigations could be used to identify causal relationships between parent-child neural responsivity and ER.

Title: Developmental, cognitive, and gender correlates of dynamic functional brain connectivity

Authors: *B. ROSENBERG, E. MENNIGEN, R. KAISER
UCLA, Los Angeles, CA

Abstract: BACKGROUND: Resting-state functional connectivity (rsFC) has traditionally identified *static* properties of brain networks over long periods of time. Prior research has showed that magnitude or spatial extent of static networks correspond with individual differences in development or cognitive functioning. Recently, scientists have become interested in how patterns of network connectivity exhibit *dynamic* changes on a shorter timescale. As these measures have a unique capacity to highlight network integration and coordination, they may provide novel insights into brain network functioning. Given that individuals consistently exhibit differences in static rsFC as a function of age, gender, and task performance, the present study assessed if these variables also relate to dynamic rsFC. METHODS: This study used resting-state data on 26 subjects (ages 8-75) from the Human Connectome Project. Data were analyzed using the Group ICA of fMRI Toolbox. This approach yielded spatially distinct components that covaried in their levels of activation over time. Next, the timeseries was separated into sliding windows, and patterns of rsFC among these components for each sliding window were estimated. Finally, patterns were clustered into network states and mean dwell time (MDT; average time in each state before switching to another state) was estimated. Group-level analyses were performed on all five states to explore differences in MDT based on gender, age, and working memory (WM) task performance. RESULTS: Analysis yielded five brain connectivity states; group-level analyses revealed significant effects for States 2 and 5. State 2 was defined by

positive rsFC among regions of the prototypical default network, including the precuneus and angular gyrus, and negative rsFC between bilateral insula and both the precuneus and angular gyrus. State 5 was defined by positive rsFC among regions involved in visual processing, including occipital regions, bilateral lingual gyrus, and bilateral fusiform gyrus; positive rsFC between occipital regions and areas of superior parietal lobule; and negative rsFC between occipital regions and inferior frontal gyrus. Group-level analyses revealed a main effect of gender on MDT for State 2 (male > female), which was moderated by both age and WM task performance. Analyses did not detect gender or age differences in State 5 MDT, but there was a main effect of task performance in which greater N-Back accuracy predicted lower MDT. DISCUSSION: These results suggest that dynamic rsFC may underlie or reflect individual differences in cognitive functioning, as well as sex-specific differences in the development of functional brain networks.

Abstract: Boys and girls exhibit different trajectories of brain development especially during adolescence. Prior studies have mainly examined sex-related differences in intrinsic functional

connections (FCs) and its interaction with age. Although the child-parent relationship plays critical roles in the child's brain development, no studies have investigated how the child-parent relationships influence on boy's and girl's brain differentially in adolescence. Furthermore, relationships with father and mother may impact on the child's brain differently. To investigate sex-dependent effects of mother- and father-child relationship on child's FCs we analyzed a cohort dataset of early adolescence that included resting-state fMRI data and questionnaires. For the evaluation of child-parent relationship, we used part of the Network Relationships of Inventory (NRI) that assessed child's positive relationships with his/her father and mother separately. In addition, the Child Behavior Checklist (CBCL) was used to assess child's behavioral symptoms. After data quality control, we used 93 children (52 girls; age [mean ± SD]: 11.96 ± 0.79). For each child, FC matrix was created using a 273 whole brain atlas. To examine the effect of NRI and its interaction effect with sex separately for father and mother, we fitted a general linear model that included NRI score, sex, interaction term of NRI and sex, and other nuisance covariates. Statistical analyses revealed that the child-father relationship was associated with FCs between right fronto-parietal (FP) and default mode networks (DMN), while the child-mother relationship was associated with FCs between the limbic and primary sensorimotor networks (P &lt 0.05, corrected). Furthermore, the interaction effects were observed mainly in FCs between right FP and other networks such as DMN and orbitofrontal network.Using the identified FCs, we built a connectome-based predictive model (CPM) with leave-one-out cross validation for the severity of behavioral symptoms. CPM revealed a separate pattern of correlations with subscales of CBCL for boys and girls: boy-specific correlations were found in rule-breaking behavior ($r = 0.36$, $P = 0.01$), aggressive behavior ($r = 0.43$, $P = 0.002$), and externalizing problems ($r = 0.41$, $P = 0.004$), whereas girl-specific correlations were found in anxious/depressed ($r = 0.32$, $P = 0.01$) and internalizing problems ($r = 0.32$, $P = 0.01$). These results suggest that the father- and mother-child relationships differentially affect FCs and identified FCs have a potential for predicting the severity of externalizing problems for boys and that of internalizing problems for girls differentially.

Title: Differential effects of pubertal development on changes in white matter microstructure in adolescent boys and girls

Authors: *T. C. HO[1], K. OSKIRKO[1], N. L. COLICH[3], J. K. LEONG[2], I. H. GOTLIB[1]
[1]Psychology, [2]Stanford Univ., Stanford, CA; [3]Psychology, Univ. of Washington, Seattle, WA

Abstract: Adolescence is the transition between childhood and adulthood; it is a key developmental window during which significant psychosocial and biological changes occur. There is rapid brain development during adolescence that is attributed, in part, to surges in gonadal hormones (Dahl & Spear, 2004; Spear, 2010). Data from animal studies suggest that these hormones affect axonal myelination and the growth of astrocytes (Yates & Juraska, 2008; Chowen et al., 2000). Further, recent work has documented sex-specific effects in long-range white matter tracts terminating in frontal cortex (Herting, 2011; Tamnes, 2017). To date, however, there have been no longitudinal investigations of the effects of sex hormones and white matter tract development. Here, we acquired T1-weighted MRI, diffusion-weighted MRI (60 directions) at two timepoints from 52 females (11.05±1.03 years at Time 1; 12.77±1.31 years at Time 2) and 31 males (ages 12.01±0.87 years at Time 1; 13.9±0.92 years at Time 2) who were matched on pubertal development at Time 1. On the morning of each participants' scans, we also collected saliva samples to assay levels of testosterone (in males) and estradiol (in feamles). All data were preprocessed according to standard protocols (Ho et al., 2017). We used Automated Fiber Quantification (AFQ) to segment 8 major white matter tracts and to estimate diffusivity metrics for each tract (Yeatman et al., 2012). We conducted separate linear regressions to predict the rate of change in fractional anisotropy (FA) of each white matter tract from the rate of change in gonadal hormone levels and age at Time 1. We found, in females only, that increases in estradiol were significantly associated with changes in FA of tracts terminating in frontal cortex (all t's>1.78, p's<0.01); changes in estradiol were not significantly associated with FA of posterior tracts (all t's<0.79, p's>0.44). There were no associations between changes in testosterone and changes in FA of any of the 8 tracts (all t's<0.10, p's>0.9). Our findings suggest that there are sex-specific effects of FA on white matter development in tracts terminating in frontal cortex during adolescence that may be explained by changes in levels of estradiol.

Effects of change in estradiol (accounting for age and Tanner) on FA in females

Title: Representational differentiation in the amygdala to faces relates to trustworthy judgments in adolescents

Authors: *S. M. TASHJIAN, J. F. GUASSI MOREIRA, A. GALVÁN
UCLA, Los Angeles, CA

Abstract: Judgments of trustworthiness are a common aspect of social interaction and are important for determining approach and avoidance behavior. During adolescence, socioemotional skills undergo significant development due to structural and functional changes in the brain. Although prior human neuroimaging work identifies the amygdala as an important neural region underpinning the evaluation of facial expressions, less is known about the evaluation of trustworthiness during the developmental period of adolescence. Prior work suggests impaired trust learning may be associated with risk of assault in adolescents (Lenow et al., 2014), highlighting the importance of understanding neural systems that contribute to trustworthy judgments.

Using representational similarity analyses (RSA; Kriegeskorte et al., 2008; Lee et al., 2017), we assessed individual differences in amygdala differentiation of faces at poles of a trustworthy continuum and examined how this differentiation related to judgments of trustworthiness for ambiguous faces at the middle of the continuum. During functional magnetic resonance imaging, 46 adolescents (M_{age} = 15.85, 26 female) made binary judgments (trustworthy, not trustworthy) for each face image presented in a randomized series. Faces varied along established dimensions of trust (Todorov et al., 2008) yielding stimuli ranging in trustworthy valence from 1-7 (least to most trustworthy).

Behavioral discrimination index scores were calculated for each participant representing one's tendency to classify faces as trustworthy or not during the task. Higher scores indicated a greater propensity to judge faces as trustworthy. Discrimination scores for faces at the low end of the continuum were significantly lower than scores at the high end of the continuum, $p < .001$.

We examined individual differences in amygdala sensitivity during evaluation of diametric faces and subsequently related those differences to discrimination scores of ambiguous faces. RSA was conducted for voxel-wise bilateral amygdala (anatomically defined) activation to faces at the poles of the trustworthy continuum using CoSMoMVPA (Oosterhof et al., 2016). Participants with greater similarity (e.g., less differentiation) to faces ranked as low and high on the trustworthy continuum rated ambiguous faces in the middle of the continuum as more trustworthy, $p < .05$. These findings indicate that a lack of amygdala differentiation to subtle changes in trustworthiness is associated with more positively biased judgments in response to social ambiguity during adolescence.

Abstract: Electroacupuncture (EA) affects the neurophysiology in overweight/obese populations, curbing appetite and decreasing cravings. Our study evaluated overweight/obese Chinese patients' responses to a food-cue functional-magnetic-resonance-imaging (fMRI) task after receiving standard weight-loss EA (n = 15, 5M/10F) and Sham stimulation (n = 7, 3M/4F) using clinical measures (YFAS, SDS, SAS, STAI (SAI, TAI)) and high-calorie (HC)/low-calorie (LC) food-cue stimuli which consisted of 88 unique HC, 88 LC food pictures and 88 neutral pictures selected from IAPS and others. The stimulation consisted of 3 HC, 3 LC and 3 neutral pictures blocks presented in a pseudorandom order. Each block lasted 30 seconds, during which 10 pictures were presented for 3 seconds each without inter-trial interval. There were 30 seconds between blocks. At baseline, there were no significant differences in these demographic/clinical measures between EA/Sham groups. ANOVA showed significant time effect only for HC food-craving ($F = 8.89$, $P = 0.007$) (Fig 1). There was only significant reduction in HC food-craving in EA group ($t = -2.25$, $P = 0.041$). There were significant interaction effects (group × time) on brain responses to food vs. neutral (NC) cues in the ventral anterior cingulate cortex (vACC) (*P*

< 0.001) due to significant increased activation in EA group (t = 5.31, *P* < 0.001), and HC vs. LC food cues in the left DLPFC (*P* < 0.001) due to significant increased activation in EA group (t = 2.83, *P* < 0.05) and reduction in Sham group (t = -3.49, *P* < 0.05). At baseline, there were significant negative correlations between DLPFC activation and BMI (*P* = 0.044, r = -0.53), and soreness (*De-qi*) was negatively correlated with changes in DLPFC activation (*P* = 0.026, r = -0.58) in EA group. Psycho-physiological interaction analysis was further employed to depict the regional connectivity, but we did not obtain any significant results. Most importantly, this study revealed the neuromechanism how EA is associated with food craving via the fronto-limbic system.

Title: Acute electroacupuncture modulates the somatosensory and mesocorticolimbic dopamine systems in overweight/obese patients during resting state

Authors: *M. XU[1], Y. REN†[2], W. ZHANG[2], X. LI[2], Y. ZHANG[1], K. VON DENEEN*[1]
[1]Sch. of Life Sci. and Technol., Xidian Univ., Shaanxi, China; [2]Xi'an Traditional Chinese Med. Hosp., Shaanxi Univ. of Chinese Med., Xi'an, China

Abstract: Obesity is a worldwide epidemic with few alternative treatment methods, but electroacupuncture (EA) is effective in managing it. We compared acute effects during resting-state functional magnetic resonance imaging (fMRI) between overweight/obese patients who received weight-loss EA (n=15, 5M) and Sham stimulation (n=7, 3M) using amplitude of low-frequency fluctuation (ALFF) and clinical measures (YFAS, SDS, SAS, STAI). At baseline, there were no differences in these clinical measures between EA/Sham groups. De-qi sensations were all significant between EA/Sham groups (P<0.05) except for coolness/sharp pain (P>0.05). Hunger was not significant between EA/Sham groups (P=0.18). Significant difference existed in food craving in response to high-calorie (HC) food cues post-EA (t=-2.26, P=0.041) (Fig 1). Significant interaction effects (group × time) for ALFF were in left precentral gyrus, thalamus and insula (P<0.001). EA increased and sham decreased ALFF in these three regions. At baseline, BMI correlated with ALFF in thalamus (P=0.029, r=0.56); same for waist circumference (WC) and ALFF in left insula (P<0.001, r=0.80); and soreness (*De-qi*) was negatively correlated with change in ALFF in left insula (P=0.035, r=-0.55). Significant (group × time) interaction effects on resting-state functional connectivity (RSFC) existed between left thalamus seed and ventral tegmental area (VTA), and between left insula seed and postcentral/dorsolateral prefrontal cortex (DLPFC) (P<0.001). Post-hoc test showed EA increased thalamus-VTA and insula-postcentral gyrus connectivity and decreased the insula-DLPFC connection. At baseline, BMI was significantly negatively correlated with thalamus-VTA connectivity (P=0.010, r=-0.64) and insula-postcentral gyrus connectivity (P=0.022, r=-0.59), and changes in craving for HC food were negatively correlated with insula-DLPFC (P=0.038, r=-0.54). These results depict the neuromechanism that EA modulates the insula/thalamus via somatosensory connections along with VTA via the mesocorticolimbic dopamine system.

Title: Physical health and active lifestyle in 12-year-old children is linked with brain measures

Authors: *P. SALVAN[1], T. WASSENAAR[1], C. WHEATLEY[1], N. BEALE[2], H. DAWES[2], H. JOHANSEN-BERG[1]
[1]Univ. of Oxford, Oxford, United Kingdom; [2]Oxford Brookes Univ., Oxford, United Kingdom

Abstract: Current research suggests that regular physical activity (PA) and aerobic fitness are associated with better cognitive performance and variation in brain measures. However, in children the cross-sectional brain correlates of physical activity and fitness are still poorly characterized. Here we tested the hypothesis that physical activity and fitness in 12-years-old children co-vary with white-matter (WM) microstructure. In 50 pupils, we acquired measures of fitness (via VO2max testing); objective week-day PA (via wrist-worn accelerometers); reported number of days performing at least 60min of moderate-to-vigorous PA; body mass index (BMI); heart rate (HR) at rest; together with multimodal-MRI. We performed automatic probabilistic tractography to reconstruct 29 major WM tracts and quantified distinct microstructural parameters. WM parameters and lifestyle measures were adjusted for age; sex; pubertal developmental level; socioeconomic score; whole-brain volume. Model comparison of the association between each WM parameter and lifestyle/health measures was carried out using cross-validated canonical correlation analysis (CV-CCA) and Monte Carlo repetitions (MCR). The model with lowest mean squared prediction error (MSPE; median value across MCR) was then selected (Fig. 1A) and tested against permutations in order to assess statistical significance (Fig. 1B). We found that the best model significantly linked WM microstructure with a positive lifestyle/health phenotype (CV-CCA results: rho = 0.64; p-value = 0.0115; MSPE = 1.0146; p-value = 0.0080; median values across MCR and compared against 1,000 permutations). In this covariation mode, higher fitness, regular exercise, lower BMI and lower HR at rest (Fig. 1C), were associated with greater WM extra-neurite density (Fig. 1D). These findings provide novel insight into the relationship between variation in lifestyle and physical health and measures of WM microstructure. This work may inform future intervention and rehabilitation studies aimed to foster healthy neurodevelopment throughout the life-span.

Title: Typical total sleep time is associated with intra- and inter- resting-state network functional connectivity in 9-10 year olds

Authors: *A. GOLDSTONE[1], S. A. CLAUDATOS[1], L. ROSAS[1], V. ALSCHULER[1], Y. LIM[1], M. GIL[1], M. DE ZAMBOTTI[1], D. B. CLARK[2], B. P. HASLER[2], D. E. PROUTY[1], I. M. COLRAIN[1,3], F. C. BAKER[1,4]

Abstract: The brain undergoes substantial developmental changes during childhood and adolescence, the full extent of which remains unknown. Sleep has been associated with waking resting-state network (RSN) functional connectivity (FC) strength in adults, but it remains to be seen how sleep may affect RSN FC in youth. Here we used data from the first year of The Adolescent Brain Cognitive Development (ABCD) study, which is the largest multi-site, longitudinal study of brain development to date. Baseline data from 3947 participants (1892 female, aged 9-10 years) are included in this analysis. All participants underwent an MRI session, using either a GE, Siemens or Philips scanner (depending on study site). The scanning protocol was the same across sites and included up to four ~5-minute resting-state fMRI scans, from which FC measures were derived. A seed-based approach calculated FC between each region-of-interest pair, derived from a number of cortical networks. FC was then averaged across pairs within (intra) and between (inter) networks to create average network FC measures. A measure of 'typical' total sleep time (TST) (i.e. number of hours slept on most nights in the past six months) was obtained from the Parent Sleep Disturbance Scale. We identified that shorter sleepers (<7 h sleep per night) had significantly weaker intra-RSN FC for default-mode (DMN), cingulo-opercular (CO), dorsal attention (DAN), retrosplenial temporal (RST), ventral attention (VA), visual and motor networks compared to longer sleepers (9-11 h sleep per night). Similarly, shorter sleepers exhibited weaker salience (SN)-DMN and SN-fronto-parietal (FPN) inter-network FC. Follow-up regression models identified that shorter TST significantly predicted

lower RSN FC, after controlling for ethnicity, sex, race, scanner, and parent's highest level of education. Models accounted for 2-17% of the variance in RSN FC, depending on the network investigated. We provide evidence that typical night-time TST, assessed by parent-report, predicts RSN FC in 9-10 year olds, with shorter TST associated with weaker FC. Notably, the association between TST and RSN FC was network-specific, rather than brain wide, suggesting that sleep is important for maintaining connectivity within specific cortical networks. Furthermore, sleep may be particularly important for maintaining coherence between the SN and other cortical regions. Future longitudinal analysis of ABCD data will allow investigation of whether TST and other sleep characteristics mediate RSN development across adolescence.

Title: Inverse relationship between homotopic and intra-hemispheric asymmetry of intrinsic brain functional connectivity in school-age children

Authors: *Z. GRACIA TABUENCA[1], M. B. MORENO[2], F. A. BARRIOS[2], S. ALCAUTER[2]
[1]Dept. of Behavioral and Cognitive Neurobio., Univ. Nacional Autónoma de México, Queretaro, Mexico; [2]Univ. Nacional Autónoma de México, Querétaro, Mexico

Abstract: Hemispheric specialization is a dynamic process along age and unbalanced functional asymmetries are related with developmental disorders such as dyslexia. In order to improve the better understanding of normal and atypical development, this study focuses on characterizing the relationship between inter-hemispheric and intra-hemispheric functional connectivity in healthy school-age children.The sample consisted in 60 typically developing children (6-10 years old, 35 girls; mean age = 8.46, sd = 0.77 years old) with resting state functional MRI scans (TR=2s; 150 volumes). After standard preprocessing, five noise-based components (aCompCor) and movement-affected volumes (relative RMS &gt 0.25mm) were regressed out, and corregistered to a symmetric standard space.Functional connectivity (FC) was defined as the the Pearson correlation (R) between two voxels fMRI timeseries. For each subject, inter-hemispheric connectivity was computed as the FC between all possible pairs of ipsilateral voxels (i.e., homotopic FC). While intra-hemispheric asymmetry was calculated as the absolute asymmetry

index (ASI) of intra-hemispheric weighted degree (WD) for every pair of mirrored voxels. WD is a basic graph theory measure that computes the sum of connections above a threshold (R &gt 0.3 in this case), and ASI was computed as: (rWD-lWD)/(rWD+lWD); where rWD accounts for WD in right hemisphere and lWD for the left hemisphere. The relationship between both measures was assessed by the voxelwise correlation and the slope of the linear fit between asymmetry and homotopy, in both cases regressing out average head motion. Significance was defined as p-value &lt 0.05 after correction for multiple comparison, estimated with a permutation test with 5000 permutations.A widespread significant negative correlation was found between homotopy and asymmetry covering every area of the brain. Moreover, the averaged linear slope of this relationship was -1.00 (sd = 0.56).This study showed an inverse and significant relationship between inter-hemispheric and intra-hemispheric asymmetry of brain FC in the rest condition. These results emphasize that homotopic and inter-hemisperic asymmetry of FC interact in an opposite direction, suggesting that both processes may consolidate hemispheric specialization during development, and even work as a compensatory mechanism for any developmental disruption. These results will contribute to the better understanding of typical development.This research was supported by CONACyT 619683/330142.

Title: Preliminary evidence of the maturation of cortical inhibition from a TMS-evoked potential study

Authors: *C. P. WALKER[1], N. MURPHY[2], N. RAMAKRISHNAN[2], D. FRAHER[2], R. Y. CHO[3]
[1]Grad. Sch. of Biomed. Sci., Univ. Of Texas Hlth. Sci. Ctr. At Houst, Houston, TX; [3]Psychiatry, [2]Baylor Col. of Med., Houston, TX

Abstract: Background: Adolescence is a distinct developmental period marked by rapid changes in affective and motivational systems and comparatively slower maturation of higher-order cognition with adult levels reached around 25 years. Much of this slower development is attributed to the protracted course of inhibitory maturation in the prefrontal cortex. To measure this trajectory *in vivo*, we recorded electroencephalography (EEG) data from children and adolescents during transcranial magnetic stimulation (TMS) of the left prefrontal (PFC) and motor (MT) cortices. **Methods:** High density 64-channel EEG recordings were collected from a

sample of healthy children (n=2; 10-11 yrs) and adolescents (n=3; 15-17 yrs) during biphasic single pulse TMS. The stimulation intensity was set to 120% of resting motor threshold, determined by motor evoked potentials recorded from the first dorsal interosseous. This scalp location was set as the MT stimulation site. PFC stimulation was applied to the left dorsolateral prefrontal cortex by co-registering an MNI template to fiducial head locations. For both sites, the TMS coil was oriented tangential to the scalp at ~45 degrees from the mid-sagittal line. Artifacts were removed via 2-stage independent component analysis. Artifact free TMS-evoked potentials (TEP) were extracted from the cluster of electrodes immediately surrounding the stimulation sites. **Results:** Preliminary evidence suggests a fundamental restructuring of early TEP components with age. As recently reported (Määttä, et al., 2017), the N100 to MT was substantially reduced in adolescents compared to children. Nevertheless, the morphology of the TEP was largely intact. In the PFC, the N45 was found to be absent in children and present in adolescents. Furthermore, the latency of the N120 was found to peak later in children (~140ms) and a positive frontal potential with a peak at 100 ms was present when compared to adolescents. **Conclusions:** The emergence of the classic PFC TEP component structure is notable in this sample. The N45 and N100/N120 are associated with GABA-A and GABA-B neurotransmission, respectively (Premoli et al., 2014). In non-human primates, GABA-A receptors have been shown to shift from a predominance of α2 to α1 subunit compositions which supports faster inhibitory kinetics and high-frequency cortical oscillations. The N45 has been shown to be particularly sensitive to GABA-A agonists selective for the α1 subunit suggesting the a similar subunit shift may be occurring in humans. To our knowledge, this is the first study of its kind to investigate the EEG response to prefrontal TMS in children or adolescents.

Title: Developmental trajectories of MR diffusion parameters in major brain fiber tracts: A longitudinal study with multiple measurements from ages 5 to 12

Authors: *W. ZHAO[1], W. K. THOMPSON[3], N. AKSHOOMOFF[4], T. T. BROWN[2], A. M. DALE[5], T. L. JERNIGAN[2]

Abstract: Strong age dependence of diffusion MRI parameters in brain fiber tracts during postnatal development is well established in previous research. Tamnes et al (2017) reviewed longitudinal studies measuring white matter microstructure in pediatric samples. Among these, only two studies followed young school-aged children, one which included only 2 observations for each participant (Krogsrud et al., 2016), and the other included more observations in a only a handful of children (Lebel & Beaulieu et al., 2011), limiting the ability to model the nonlinearity of developmental trajectories. In this study, we examined the within-subject, nonparametric, age-related trajectories in white matter FA and MD in children studied at approximately 1-year intervals.

Longitudinal DTI data were acquired in the Pediatric Longitudinal Imaging, Neurocognition, and Genetics (PLING) study from 126 participants aged 5-12 years old, who were scanned annually between 2 and 5 times. Repeated measure of white matter diffusion parameters allows the identification of any curvilinear pattern of maturation in these tracts. FA and MD measures were computed for major white matter tracts that may exhibit different maturation rates during development, including the corticospinal tract, anterior thalamic radiations, corpus callosum, superior and inferior longitudinal fasciculi, inferior frontal-occipital fasciculus, uncinate, and cingulum.

Nonparametric statistical analyses of age effects on FA and MD of white matter tracts were performed with generalized additive mixed models (GAMM4) with a smooth age term (with sex and scanner as covariates) to allow different shapes of curvilinear age trends for different white matter tracts. GAMM4 results of smooth and linear age models for FA and MD were compared with model selection statistics. The results of these comparisons and the best fitting age function will be presented, illustrating the tract variability in the apparent underlying developmental trajectories. Results will be compared with previous observations and possible explanations for apparent differences will be discussed.

Title: White matter microstructure relates to reward-seeking behavior under stress in adolescents and adults

Authors: *J. P. UY[1], A. GALVAN[2]
[1]Psychology, UCLA, Northridge, CA; [2]Psychology, UCLA, Los Angeles, CA

Abstract: Adolescence is characterized by increases in risky behavior, heightened physiological response to stress relative to other age groups, and ongoing white matter development in long-range association tracts that connect the prefrontal cortex (PFC) to other cortical and subcortical regions. Previous research suggests that protracted development of the PFC during adolescence renders the PFC susceptible to the effects of stress, potentially amplifying adolescents' proclivity toward reward-motivated risky behavior. Research relating white matter microstructure and risky decision-making during adolescence has been limited, and no study has examined the associations between white matter microstructure and risky decision-making in the context of stress in adolescents. In the current study, daily self-reports of stress were documented in adolescents (n=19, 12 females; ages 15-17 years) and adults (n=19, 12 females; ages 25-30 years). Participants completed two visits - once each when they endorsed a high and low level of stress - during which they completed a risky decision-making task about monetary gains and losses with varying expected values (EV). DTI scans were acquired from participants at one of the visits and fractional anisotropy (FA) values were used as an index of white matter coherence. Results revealed that adults evinced greater FA in long-range association tracts (e.g., inferior fronto-occipital fasciculus) compared to adolescents. Controlling for age and gender, greater FA in long-range association tracts were associated with fewer gain-related risks with EV that was equal to and/or disadvantageous to the certain decision under high stress, but not low stress. FA was not associated with gain-related risks with advantageous EV or loss-related risks across levels of EV. These findings suggest that, rather than relating to general increases in risky decisions across contexts, developing white matter tracts might specifically underlie increases in gain-motivated risky decisions under stress during adolescence.

Title: Focal abnormalities in white matter microstructure correspond to neuropsychological comorbidities in BECTS

Authors: *L. OSTROWSKI[1,2], D. Y. SONG[2], E. L. THORN[2], S. M. STOYELL[2], G. XIAO[2], M. PARNES[2], M. A. KRAMER[3], S. M. STUFFLEBEAM[4], A. K. MORGAN[5], B. C. EMERTON[5], C. J. CHU[2,6]
[1]Brown Univ., Providence, RI; [2]Neurol., Massachusetts Gen. Hosp., Boston, MA; [3]Dept. of Mathematics and Statistics, Boston Univ., Boston, MA; [4]MGH NMR Ctr., Charlestown, MA; [5]Psychological Assessment Center, Massachusetts Gen. Hosp., Boston, MA; [6]Harvard Med. Sch., Boston, MA

Abstract: Benign epilepsy with centrotemporal spikes (BECTS) is a common childhood epilepsy syndrome with a male-predominance, characterized by seizures arising from the sensorimotor and temporal cortices and neurocognitive difficulties associated with these anatomic regions. The coincident maturation of association fibers during childhood provides a structural substrate that could contribute to the neurodevelopmental aspects of this disease. To investigate this relationship, we use an *a priori* region of interest (ROI) based approach to evaluate specifically for focal white matter abnormalities contiguous to the seizure onset zone (SOZ) in children with BECTS compared to healthy control (HC) children. We analyze the characteristics of the peri-rolandic u-fibers and termination zones of the superior longitudinal fasciculus (SLF) in relation to fine motor performance and phonological awareness, respectively. We also evaluate the relationship of white matter features in these regions to gender. Children with BECTS (n=22) and age-matched HCs (n=18) underwent multimodal testing with high resolution MRI including DTI sequences and targeted neuropsychological assessment. In the peri-rolandic region, children with BECTS had increased FA ($p=0.017$). Consistent with abnormal crossing u-fiber development, increased FA correlate with inferior fine motor performance ($p=0.029$). As with the peri-rolandic SOZ, children with BECTS had increased FA in the terminal zones of the SLF($p=0.044$). Phonological awareness was found to be impaired in BECTS subjects ($p=0.041$), though this did not directly correspond with FA. In the peri-rolandic region, we found gender-specific differences in white matter microstructure such that all BECTS subjects and HC males have higher FA values than HC females ($p\leq0.035$ for all measures), suggesting that the typical male pattern of white matter development may predispose boys to BECTS. Global exploration revealed that the FA abnormalities we observed were specific to the superficial white matter and the SOZ. These data provide evidence that focal atypical maturation of white matter microstructure is a basic feature in BECTS and may contribute to the neurodevelopmental comorbidities observed in this disorder.

Title: Chemical neuroanatomy of the olfactory system of the nocturnal tree pangolin (Manis tricuspis)

Authors: *A. IMAM[1,3], M. S. AJAO[3], A. BHAGWANDIN[2], M. A. SPOCTER[4], I. O. AMADI[2], P. R. MANGER[2]
[2]Sch. of Anatom. Sci., [1]Univ. of the Witwatersrand, Johannesburg, South Africa; [3]Dept. of Anat., Univ. of Ilorn, Ilorin, Nigeria; [4]Dept. of Anat., Des Moines Univ., Des Moines, IA

Abstract: The tree pangolin is one of the eight extant species of Pholidota, with conflicting phylogeny. Despite the expanded olfactory gene family, it is unknown if the structural and neurochemical architecture of the pangolin olfactory system support its behavioural preference for olfactory cues. We used a range of neuroanatomical stains (Nissl; Myeline; Anti-NeuN, PV, CR, CB, ChAT, vGlut2, SMI-32, TH and DCX) to determine the organization of the main and accessory olfactory systems within the brain of the tree pangolin. The tree pangolin has a typically mammalian olfactory system, but minor variations were observed. The main olfactory system is comprised of the layered main olfactory bulb (MOB), the anterior olfactory nucleus (AON), the rostral olfactory cortex (including the taenia tecta, anterior hippocampal continuation and induseum griseum), the olfactory tubercle (Tu), the lateral olfactory tract (lot) and the olfactory limb of the anterior commissure, the nucleus of the lateral olfactory tract (NLOT), the piriform cortex (PIR) and a typically mammalian rostral migratory stream (RMS). The accessory olfactory system included the layered accessory olfactory bulb (AOB), the bed nucleus of the stria terminalis (BNST), and the nucleus of the accessory olfactory tract (NAOT). Volumetric analysis of the relative size of the MOB and PIR indicate that the tree pangolin has an olfactory system that occupies a proportion of the brain typical for the majority of mammals. Within the MOB, the glomeruli of the tree pangolin, at 200 µm diameter are larger than observed in most other mammalian species, and the MOB lacks a distinct internal plexiform layer. In addition, the laminate appearance of the NLOT was not observed in the tree pangolin. The accessory olfactory system appears to lack the posterior compartment of the accessory olfactory bulb. These observations are contextualized in relation to olfactory-mediated behaviours in pangolins.

Abstract: Chimpanzees have the closest evolutionary kinship with humans. Their brain sizes are about three times smaller than the brain sizes of humans. However, the brain sizes of chimpanzees are almost same as the ancient hominoid *Australopithecus africanus*. The macro-anatomical structures and shapes are similar between chimpanzees and humans. Thus, in order to reveal the evolutional progress of human brains, it must be helpful to comprehend the brain development in chimpanzee and to compare this with the brain development in human. We used magnetic resonance imaging (MRI) technique to study the brains of four chimpanzees (one male and three females), whose ages (ranged from 1.8 to 60 months) were longitudinally evaluated during development from infancy to the juvenile stage. Ages of adult chimpanzees (3 males and 7 females) were ranged 23 to 42 years old. All subjects lived within a social group of 14 individuals in an enriched environment at the Primate Research Institute, Kyoto University (KUPRI). The brain size almost doubled from 1.8 to 36 months after birth. Among 4 lobes of cortices, volume increase in the frontal cortex was largest. These developmental processes were similar to those of the humans although the relative sizes of human brains were about 3 times

larger than those of chimpanzees. In the initial 36 months of infancy, the relative volume of the high intensity portion that corresponds to the mielinated white matter was smaller compared with the adult level. These data resemble the age-related volumetric changes of the mielinated white matter in human. To facilitate scientific discoveries in the field of primate comparative neuroanatomy, we launched a collaborative project to develop a database of growing chimpanzee brain images as an open resource. As an initial attempt, we will release a collection of structural MRI obtained from all 14 chimpanzees including growing chimpanzees at KUPRI in near future. The expected significant contributions of this database include (1) resources for comparative neuroscience research and (2) preservation of chimpanzee brains as endangered species, in a permanent digital form. User-initiated research projects beyond these contributions are also anticipated.

Title: Organization of telencephalic inputs to the medial spiriform nucleus, a pretectal cerebellar relay nucleus in birds

Authors: *C. GUTIERREZ-IBANEZ[1], M. D. FERNÁNDEZ[2], G. J. MARÍN[2], D. R. WYLIE[1]
[1]Neurosci. and Mental Hlth. Inst., Univ. of Alberta, Edmonton, AB, Canada; [2]Biologia, Facultad de Ciencias, Univ. de Chile, Santiago, Chile

Abstract: Birds, like mammals, have relatively large telencephala and cerebella. In mammals, one of the largest circuits in the brain involves a projection from the cerebral cortex to the cerebellum through the pontine nuclei, a group of neurons in the base of the caudal brainstem. Inputs to the pontine nuclei arise from all parts of the cortex, and these inputs are organized in discrete, non-overlapping areas. As in mammals, the telencephalon of birds sends descending projections to several nuclei that in turn project to the cerebellum, but the organization of these efferents has not been studied extensively. Birds possess a medial and lateral pontine nuclei at the base of the brainstem that receive projections from the telencephalon and project to the cerebellum and are thought to be homologous to the pontine nuclei of mammals. Additionally,

birds are unique in that they have a pretectal nucleus, the medial spiriform nucleus (SpM), that receives projections from the telencephalon and projects to the cerebellum. Here we used injections of anterograde tracers in the two main output regions of the pallium of birds, the Wulst and the arcopallium, to show the organization of these inputs to the SpM. We found that the anterior somatomotor and more posterior visual wulst project upon two separate and non-overlapping regions of the medial SpM. Additionally, we show that the visual arcopallium projects to more lateral regions of the SpM. Our results suggest that the organization of telencephalic inputs to SpM in birds parallels that of the projection to the pontine nuclei in mammals, and supports the notion that SpM can be considered a "displaced" pontine nuclei. Combined with our previous work, showing segregated projections from different regions of SpM to different zones of the cerebellum, this study helps to understand the organization of telencephalo-cerebellar pathways in birds.

Title: The role of grp and grpr in the extinction of cued fear memory in zebrafish

Authors: *L. L. BRUCE[1], E. A. DORCHUCK[2], B. N. HASSMAN[2], A. W. MEZHER[1], O. OCHUBA[1], K. L. KRAMER[1]
[1]Biomed. Sci., [2]Biol., Creighton Univ., Omaha, NE

Abstract: The amygdala is the anatomical core of an emotional learning circuit. In particular, the amygdalar basolateral complex (BLC) is a critical site for sensory convergence for conditioned stimuli (e.g., light), unconditioned stimuli (e.g., shock), and for extinction retention and learning. Gastrin-releasing peptide (Grp or bombesin) is a neurotransmitter that is highly expressed in excitatory pyramidal neurons in the rodent BLC and may be co-released with glutamate. Gastrin-releasing peptide receptor (Grpr) is expressed in GABAergic inhibitory interneurons, which then exert negative feedback on BLC pyramidal neurons. Studies in mice have shown that Grp and Grpr regulate memory formation and retention related to behavioral and stress responses to emotional stimuli. We have previously demonstrated that *grp* mRNA is highly expressed in the dorsomedial region of the zebrafish *(Danio rerio*) forebrain, the proposed homologue of the mammalian BLC that contains *grp*- and *grpr*-expressing neurons. To determine if Grp and Grpr

function is conserved across species, we examined chronic anxiety, cued fear conditioning, and extinction of conditioning using *grp* and *grpr* mutant zebrafish.
Measures of chronic anxiety behavior in young fish aged 12-15 days post-fertilization showed no significant differences between zebrafish with wildtype (TL) and *grp*- or *grpr*-mutant genotypes. A second task, a cued fear conditioning assay that tested amygdalar memory, used freezing as an index of fear. Adult *grp*-mutant, *grp*-heterozygote, and wildtype fish rarely froze after exposure to an 8 sec red light stimulus in adaptation trials. When the last second of the red light was paired with a shock (learning trials), all groups responded similarly with increased average freezing ratios. During the subsequent retention and extinction trials, the red light was presented without shock. Wildtype and *grp*-heterozygote fish approached normal freezing times after 6 trials, whereas the mutant *grp* fish reached normal freezing times after only 1 trial. Trials using *grpr*-mutant fish are underway.
Our results suggest that *grp*- and *grpr*-mutant zebrafish responded and adapted to chronic anxiety situations similar to wildtype fish. Although mutation of *grp* had little effect on chronic anxiety, the *grp*-mutant zebrafish exhibited selective impairment of cued fear memory retention, consistent with most previous studies in mice. Furthermore, our data support the observations that a region homologous to the mammalian BLC has a similar role in the formation and expression of emotional memories in zebrafish.

Title: Carnivores and rodents evolved different patterns of proportional brain structures than other taxa

Authors: S. GRETA[1], W. TOMITA[2], A. BURRE[4], D. ROSTAMIAN[3], N. SCHOTTLER[3], *W. E. GRISHAM[3]
[1]Univ. of Chicago, Chicago, IL; [2]Undergraduate Interdepartmental Program for Neurosci., [3]Dept Psychol, UCLA, Los Angeles, CA; [4]Keck Neurosci. Program, Claremont McKenna Col., Claremont, CA

Abstract: Examining the proportion of brain devoted to various neuroanatomical structures across taxa provides an interesting lens into how mammalian orders diverged through evolution. By using proportions, all brain regions are on the same scale, which allows us to compare the pattern of relationships across various taxa. This will enable us to determine whether the same

pattern of brain evolution occurred across taxa or if they have diverged. We examined each of the following regions as proportions of the whole brain: isocortex, subcortical structures (striatum, thalamus and hippocampus), and cerebellum. Images were obtained from the Comparative Mammalian Brain Collection (http://neurosciencelibrary.org/).
Considering all of the animals together, the proportional subcortical structures were all positively and significantly correlated with each other. The proportional isocortex, however, was significantly inversely correlated with all other structures. The proportional cerebellum was significantly correlated with the proportional hippocampus and thalamus but inversely correlated with the isocortex. We then sought to see if this pattern was uniformly present in the various taxa. We examined these brain regions across primates (n =11), carnivores (n=17), artiodactyls (n = 8), rodents (n = 7) and "others" (n=18).
Some notable exceptions to the overall pattern appeared. Given that the proportional isocortices are fairly large are in carnivores, we expected an inverse relationship between proportional isocortex and subcortical structures. However, this inverse relationship was largely lost, although the proportional subcortical structures stayed fairly well correlated in carnivores. The pattern of relationships in carnivores suggest that the subcortical features evolved in concert but independent of proportion of brain devoted to isocortex.
The relationships among the proportional subcortical structures among rodents are essentially absent. Rodents have a relatively large proportional hippocampus, striatum, and thalamus compared to other taxa. Whereas these structures seem to evolve in concert in other taxa, they don't seem to do so in rodents.
Finally, the relationships between the proportional cerebellum and any other structure are largely lost when we examine the individual taxa. The cerebellum appears to be subject to very different sets of evolutionary pressures both across and within taxa than are the other structures.
Clearly brains evolve in different patterns across taxa—most particularly carnivores and rodents, which are on very different paths in brain evolution.

Title: An overview of adult neurogenesis in the forebrain of domestic pigeons

Authors: *J. MEHLHORN[1], E. SCHREIVOGEL[2], K. AMUNTS[2,3], C. HEROLD[2]
[1]Inst. of Anat. I, Univ. of Düsseldorf, Duesseldorf, Germany; [2]C. & O. Vogt Inst. of Brain Res.,

Abstract: Adult neurogenesis in the avian brain has been detected in the telencephalon of several species of song birds, food caching birds and poultry. Only a few studies reported on generation and proliferation of neurons in the domestic pigeon and up to now there is no overall overview about adult neurogenesis particularly in pigeons or birds in general that includes different stages of cell proliferation in the telencephalon. Here, the comparison between pallial and subpallial structures will give new insights in functional consequences of adult neurogenesis and brain plasticity in general. In this study, free flying homing pigeons (*Columba livia* f.d.) were treated with 5-bromo-deoxyuridine (BrdU) to label dividing cells and sacrificed about three months after injection. Brains were dissected and immunohistochemically processed with several markers to examine different stages of cell proliferation in a quantitative and qualitative way. We used SOX2, GFAP and PCNA for precursor cell stages, doublecortin (DCX), Prox1, Tbr2, NeuN, S100β and Calbindin for intermediate progenitor cells and postmitotic stages. BrdU-positive (BrdU-ir) and DCX-positive (DCX-ir) neurons were widely distributed in the telencephalon. The number of DCX-ir cells was higher compared to BrdU-ir cells and comparable to SOX2-positive cells. Next to the olfactory bulb and the ventricular zone, the ventrolateral part of the V-complex and the ventral dorsolateral subdivision of the hippocampal formation exhibit high numbers of proliferating cells. Pallial, most of the proliferating cells are detected in the intercalated hyperpallium, while subpallial the highest numbers were found in the basal ganglia. The used markers allowed a differentiation between the different cell stages and cell types, revealing a highly plastic nature of structures in the pigeon's telencephalon. Our findings provide detailed insights into adult neurogenesis in pigeons and complete the knowledge about this dynamic process in birds. The high number of immature neurons indicate a wide range in plasticity. Now, it is possible to link our knowledge about brain structure and function under the influence of brain plasticity.

Abstract: Advances in magnetic resonance imaging (MRI) and computational analysis technology enable comparisons among various primate brains in a three-dimensional electronic format. Results from comparative studies provide information about common features across primates and species-specific features of neuroanatomy. Investigation of various species of non-human primates is important for understanding such features, but the majority of comparative MRI studies are based on experimental primates, such as common marmoset, macaques, and chimpanzee. A major obstacle has been the lack of a database that includes non-experimental primates' brain MRIs. To facilitate scientific discoveries in the field of comparative neuroanatomy and brain evolution, we launched a collaborative project to develop a repository of non-human primate brain images using *ex vivo* MRI as an open resource. As an initial attempt, we released a collection of structural MRI and diffusion tensor imaging obtained from 12 species: pygmy marmoset (*Cebuella pygmaea*), owl monkey (*Aotus trivirgatus*), white-fronted capuchin (*Cebus albifrons*), long-tail macaque (*Macaca fascicularis*), Japanese macaque (*Macaca fuscata*), bonnet macaque (*Macaca radiata*), toque macaque (*Macaca sinica*), Sykes's monkey (*Cercopithecus albogularis*), red-tailed monkeyt (*Cercopithecus ascanius*), Schmidt's monkey (*Cercopithecus ascanius schmidti*), de Brazza's guenon (*Cercopithecus neglectus*), and lar gibbon (*Hylobates lar*), 16 postmortem brain samples from the 12 species, stored in the Japan Monkey Centre (JMC), were scanned using a 9.4 T MRI scanner and made available through the JMC collaborative research program. The expected significant contributions of the JMC Primates Brain Imaging Repository include (1) resources for comparative neuroscience research, (2) preservation of various primate brains, including those of endangered species, in a permanent digital form, (3) resources for optimizing methods of scanning large fixed brains, and (4) references for veterinary neuroradiology. User-initiated research projects beyond these contributions are also anticipated. We encourage its use by not only neuroscientists but also

researchers that belong to research fields outside traditional neuroscience, such as computer science, mathematical modeling, and medicine.

Title: Differential serotonergic innervation at the amygdala among macaque species that differ in social style

Authors: *D. N. JONES[1], C. C. SHERWOOD[2], P. R. HOF[3], J. M. ERWIN[2], M. RAGHANTI[1]
[1]Kent State Univ., Kent, OH; [2]The George Washington Univ., Washington, DC; [3]Icahn Sch. of Med. at Mount Sinai, New York, NY

Abstract: Among the 23 macaque species that constitute the genus *Macaca*, a high level of behavioral diversity has been observed, particularly related to aggressiveness. To investigate the neural underpinnings of variation in aggressiveness among species, we compared serotonergic innervation of the amygdala among four species. The amygdala plays a prominent role in emotional processing and social intelligence. Additionally, central serotonin (5HT) availability and aggressive behavior have been found to be inversely related in humans and nonhuman primates. Our study sample included left hemisphere brain sections containing the amygdala from 19 individuals of the following species: rhesus (*M. mulatta*) n = 6, Japanese (*M. fuscata*) n = 2, pigtailed (*M. nemestrina*) n = 6, and moor (*M. maura*) n = 5. Four amygdaloid nuclei were examined: the lateral, basal, accessory basal, and central nuclei. We used immunohistochemical methods to stain for the 5HT transporter (SERT) and quantified SERT-immunoreactive axon density using a stereological approach. Based on evidence that suggests increased central serotonergic signaling functions to inhibit aggressive behavior, we hypothesized that the greatest amount of innervation would exist in the least aggressive, most egalitarian species, the moor macaque. However, in contrast to this prediction, our results reveled a significantly greater amount of innervation in the more aggressive, hierarchical species, the Japanese and pigtailed macaques, relative to the moor macaque. These findings suggest that, unlike what has been

reported in a similar comparative study on the more aggressive chimpanzee and the relatively tolerant bonobo, increased serotonergic innervation of the amygdala in macaques may not be associated with more affiliative, egalitarian social styles. The implications of our findings are discussed in a larger evolutionary framework.

Title: Neural scaling of auditory nuclei with overall brain size in passeriformes

Authors: *P. MILLER[1], J. CORFIELD, 21804[2]
[1]Biol. Sci., [2]Salisbury Univ., Salisbury, MD

Abstract: Generally, neural scaling follows the rule that the larger the brain is, the larger individual brain regions are. Although, after more detailed analyses, we know that exceptions to this rule are frequent. Auditory regions in Galliformes, for example, do not scale in the same way that mammals do. In Galliformes, as brain size increases neuron density decreases. Whether this applies to other avian orders or to other brain regions is not known. Passeriformes (songbirds) are a highly derived order of birds that have a well-developed auditory system, complex communication system and vary in body sizes, making them excellent candidates for examining neural scaling relationships. This study investigated neural properties in two auditory nuclei, nucleus magnocellularis and nucleus laminaris, in ~20 different species of songbird. Neuronal sizes, neuronal number and the volume of each region was measured using stereological techniques. Regression models were used to assess how the volumes of auditory nuclei scaled in songbirds and how this compared to other species of birds. Interestingly, results suggests that the relative size of auditory regions in songbirds scale differently to that of other birds, and were significantly smaller than that predicted based on their brain size. This decrease in size in these auditory regions appears to be associated with an increase in neuronal density, rather than a reduction in the relative number of neurons or neuronal size. Neuronal size showed a strong correlation with overall brain size, with the largest species having the largest neurons and also the largest range of neuronal sizes. This research will help us better understand the general rules that determine how neural structures scale across vertebrates.

Title: A white matter atlas of the chimpanzee brain and quantitative comparison with the human and macaque

Authors: *K. L. BRYANT[1], L. LI[2], R. B. MARS[3]
[1]Radboud Univ., Donders Inst. for Brain, Cognition, and Behavi, Nijmegen, Netherlands; [2]Children's Healthcare of Atlanta, Marcus Autism Ctr., Atlanta, GA; [3]Radboud Univ., Donders Inst. for Brain, Cognition & Behaviour, Nijmegen, Netherlands

Abstract: Determining the unique specializations of the human brain requires an anatomically informed understanding of how the neocortex has been modified and reorganized since our evolutionary divergence from other primates. The chimpanzee brain is arguably the least understood of the three. Therefore, in this project we create a comprehensive atlas of the major white matter fibers of the chimpanzee brain, based on diffusion MRI tractography data, similar to maps created previously for the human and macaque (Mars et al., 2018; Thiebaut de Schotten et al., 2012). In addition to comparing fascicular anatomy, we also produce cortical projection maps in chimpanzees. We can then use these projection maps with similar maps in the other species to create a formal comparison between the organization of the three different brains, following techniques recently developed in a direct human/macaque comparison (cf. Mars et al., 2018). We produced the chimpanzee white matter atlas using probabilistic diffusion tractography on *in vivo* HARDI scans of 29 chimpanzees from Yerkes Primate Center available through the US-based National Chimpanzee Brain Resource. Protocols seeding in the bodies of over 20 major white matter tracts, derived from protocols designed for human and macaque tractography (De Groot et al., 2013; Mars et al., 2018), were adapted and in some cases refined using additional information from previous investigations in chimpanzee (Hecht et al., 2015), human (Dejerine and Dejerine-Klumpke, 1895; Catani and Thiebaut de Schotten, 2008), and macaque (Schmahmann and Pandya 2006) fascicular anatomy. Tractography was carried out in native space for each individual chimpanzee and then averaged and thresholded to produce a

chimpanzee fascicular atlas. Next, tracts were projected to the surface by multiplying the tracts with a matrix describing the tractography of cortical grey/white matter boundary to the whole brain (O'Muircheartaigh & Jbabdi, 2017), allowing us to create a map of each tract's cortical termination points. Our results suggest modifications to the organization of the superior longitudinal fasciculi (SLF), middle longitudinal fasciculus, and inferior longitudinal fasciculus (ILF) have occurred in the hominoid lineage. The second branch of the SLF seems to project more ventrally than expected based on the human brain, while the ILF contains a branch in the human and chimpanzee that is not observed in the macaque.

Title: Expansion of primary areas occurs without a change in the relative distribution of cortical neurons

Authors: *M. GABI[1], E. C. TURNER[2], J. KAAS[1]
[1]Vanderbilt Univ., Nashville, TN; [2]The Biodesign Inst., ASU-Banner Neurodegenerative Res. Ctr., Tempe, AZ

Abstract: Across primate species, the cerebral cortex shows a similar neuronal distribution along the anterior-posterior axis, with lower densities in the frontal areas that increases towards the occipital areas. Previous studies have shown that the primary motor cortex, primary visual cortex, and primary auditory cortex, occupy a similar percentage of the cortical surface and also contains a similar percentage of all neurons across nonhuman primates. However, these studies did not address how these areas scale in relative number of neurons with the cerebral cortex. Here we aim to understand what are the cellular scaling rules of the primary motor cortex(M1), primary visual cortex (V1), primary auditory cortex (A1) and primary somatosensory cortex (S1) of 44 individuals from 10 primate species (*Aotus trivirgatus, Saimiri sciureus, Callicebus moloch, Otolemur garnettii*, *Macaca mulatta*, *Macaca radiata, Pan troglodytes*, *Papio cynocephalus, Callitrix jacchus*, *Macaca nemestrina).* In all species, the neocortex was separated from the underlying white matter, manually flattened and then the locations of primary areas were estimated as seen previously. Each area had its number of neurons determined using the Isotropic Fractionator, a method which transforms a tissue into a nuclei suspension. Across all ten species, the surface area scales with similar power functions of the number of neurons in all

four primary areas (A1, M1, S1 and V1). The neuron density (Neurons/area) remain constant with the surface area in M1 suggesting that the relative neuron size remains the same in this region. Also, V1 scales slowly as the number of neurons in the cerebral cortex increases in all primates analyzed, while S1 and M1 have similar power functions that are close to the linearity with exponents 0.885 and 0.903 respectively. Most importantly, we find that the number of neurons in primary motor cortex and the neurons in the primary somatosensory cortex varies linearly in all species analyzed. These findings indicate that the expansion of primary areas occurred with no particular increase in the relative distribution of cortical neurons across primate species, which shows to vary in a similar manner in all four areas as seen previously. Still, primary motor cortex and primary somatosensory cortex vary proportionally in its number of neurons in all species, from the smallest New world monkey to the Chimpanzee, suggesting a functional relationship among these areas.

Title: Longevity and sexual maturity scale with number of cortical neurons across birds and mammals, and humans are no different

Authors: *S. HERCULANO-HOUZEL
Dept. of Psychology, Vanderbilt Univ., Nashville, TN

Abstract: Maximal longevity of endotherms has long been considered to increase with decreasing specific metabolic rate, and thus with increasing body mass. Using a dataset of over 700 species, here I show that maximal longevity, age at sexual maturity and post-maturity longevity across bird and mammalian species instead correlate primarily, and universally, with the number of pallial brain neurons. Correlations with metabolic rate and body mass are entirely explained by clade-specific relationships between these variables and numbers of pallial neurons across species. Importantly, humans reach sexual maturity and subsequently live just as long as expected for their number of cortical neurons. Longevity might increase together with numbers of pallial neurons through their impact on three main factors: delay of sexual maturity, which postpones the onset of aging; lengthening of the period of viable physiological integration and adaptation; and improved cognitive capabilities that benefit survival of the self and of longer-lived progeny.

Title: Analysis of astrocyte densities across the cerebral cortex of primate species

Authors: *L. GLASSBURN[1], S. E. DOS SANTOS[2], S. HERCULANO-HOUZEL[2]
[1]Psychology, [2]Dept. of Psychology, Vanderbilt Univ., Nashville, TN

Abstract: Across the evolution of mammalian brains, the scaling of neuronal size and density in the cerebral cortex varies between mammalian orders, with a clade-specific neuronal scaling rule and density for primates. In contrast, non-neuronal cell size and densities indicate that non-neuronal cells do not scale differently between mammalian orders. Mammals share a common and unique non-neuronal scaling rule and have a constant density and invariant average non-neuronal cell size across species and brain structures, including cerebral cortex. These non-neuronal cells are glial cells and vasculature-associated cells, and more research is needed to understand if each of these cell-types are themselves invariant in density across mammals. Alternatively, their densities may be inversely correlated such that variation in the cell-types is not evident in analyzing overall non-neuronal cell density. This research investigates how astrocyte density scales across the cerebral cortex of 8 primate species, including human. We used the isotropic fractionator method to quantify astrocyte numbers in the grey and white matter of coronal sections of the cerebral cortex, for which total, neuronal, and non-neuronal cell numbers were previously reported. Astrocyte nuclei were immunocytochemically labeled with the astrocyte-specific marker S100β. Astrocytes quantification was done in every fourth section (*M. fascicularis* N = 18, *M. nemestrina* N = 29, *P. cynocephalus* N = 27, *H. sapiens* N = 75), every second section (*A. trivirgatus* N = 19), or the entire cerebral cortex (*C. apella* N = 82, *S. midas* N = 22, *O. garnetti* N = 27), depending on the overall size of the brain. In total, 299 samples were analyzed. Results indicate that astrocyte densities have similar relationships to structure mass and neuronal density across species and cortical regions, where within cortex structure mass is related to astrocyte numbers by a power function with an exponent of 0.761 ± 0.028 ($p < 0.0001$). Astrocyte density varies with neuronal density within the cortex of primates ($\alpha = 0.512 \pm 0.054$, $p < 0.0001$), and the astrocyte to neuron ratio decreases with increasing neuronal density ($\alpha = -0.488 \pm 0.054$, $p < 0.0001$) in the cortical grey matter, giving interesting functional implications for neurons with varying numbers of supporting astrocytes. However, the cortex of *M. fascicularis* and the human hippocampus appear to have higher astrocyte densities than other primate cortical tissue with similar neuronal density. Overall, primates have evolved with one rule for adding astrocytes into cortical tissue, and this similar scaling rule indicates that primates of varying brain size have similar sized astrocytes.

Title: MicroRNAs associated with neurogenesis in the developing human cerebral cortex

Authors: *M. J. LAFFERTY[1], D. H. GESCHWIND[2], L. DE LA TORRE-UBIETA[2], J. L. STEIN[1]
[1]Dept of Genet. & Neurosci. Ctr., UNC-Chapel Hill, Chapel Hill, NC; [2]UCLA, Los Angeles, CA

Abstract: Gene regulation is critical to fate decisions during differentiation. Previous work has shown transcription factors, broad orchestrators of gene regulation, can guide fate decisions during neurogenesis. MicroRNAs (miRNAs) also have broad effects on transcriptional programs, yet their impact on human neurogenesis is relatively understudied. Mouse knockout models, of the key miRNA processing gene Dicer, have shown that miRNAs play a critical role in neural progenitor proliferation, neuronal differentiation, and cortical wall development. Additionally, expression of miR-124 is greatly upregulated in neurons in culture, and overexpression of this miRNA can promote differentiation of progenitors into neurons. Here, we sought to identify specific miRNAs involved in human neurogenesis. We profiled miRNA expression levels within dissected germinal zone and cortical plate fetal cortex tissue from 3 donors ranging from gestation weeks 17-19. After standard pre-processing and correcting for confounding effects, we identified 95 miRNAs that are significantly upregulated in germinal zone tissue and 76 miRNAs significantly upregulated in cortical plate tissue. Consistent with previous work in cultured neurons, miR-124 is upregulated in cortical plate. We performed miRNA target prediction analyses and assessed regulatory relationships with key neurogenesis genes to identify molecular processes driving cortical neurogenesis. Profiling miRNAs associated with human neurogenesis will lead to a more complete understanding of gene regulation influencing proliferative or neurogenic fate decisions and may lead to the development of higher fidelity neuronal trans-differentiation tools.

Title: Secretory cells in the digestive epithelium of Trichoplax adhaerens, an animal that feeds by external digestion

Authors: *T. D. MAYOROVA, C. L. SMITH, T. S. REESE
Structural Biol., NINDS, Bethesda, MD

Abstract: *Trichoplax adhaerens*, a tiny marine animal, locomotes by ciliary gliding to feed upon algae and bacteria. It has only six cell types (1) and represents an early branch of the metazoan tree (2). It lacks an internal gut but, instead, feeds by external digestion on its lower surface, which contains several cell types resembling those in the digestive epithelia of Eumetazoa. When the animal crawls over a patch of food, it ceases gliding (3). Pausing is thought to be elicited by an endomorphin-like peptide (ELP) secreted by cells that express proteins involved in regulated secretion in neurons and neuroendocrine cells (1, 4, 5). Then a different type of secretory cell secretes a large granule whose contents lyse nearby algae/bacteria (3). The lysate is endocytosed by the ciliated cells, which, like enterocytes, bear microvilli. Here we examine the structures and distributions of *Trichoplax* secretory cells in more detail and provide evidence of another type of secretory cell, mucus cells. Analysis of serial sections obtained from an ATUM microtome with backscatter SEM revealed ciliated cells with large electron dense granules (Type 1). These cells were most prevalent around the edge and correspond to the neuropeptidergic cells described previously. Another type of secretory cell (Type 2) was distributed sparsely but widely in the lower epithelium, had microvilli, but no cilium and contained smaller, clear granules. Because the granules were clear, we supposed they might contain mucus (6). We applied various fluorescent lectins and discovered that one, wheat germ agglutinin (WGA), labeled the mucus trails left by migrating animals and the rings of mucus that appear around animals during feeding. Labeling of fixed animals revealed WGA-labelled cells, including many that co-labeled for endomorphin, distributed widely in the lower epithelium and around its edge. Electron microscopic analysis of animals labeled with HRP- or nanogold-labeled lectins confirmed that the clear secretory granules of Type 2 cells contained mucins. However, we are left with a puzzle because, as yet, no lectin label has been detected by EM in Type 1 cells. The presence of mucus cells in the digestive epithelium of *Trichoplax* reinforces its similarity to digestive epithelia of more complex animals and is consistent with the idea the gut evolved by invagination of a tissue originally used for external digestion (7). 1. Title: Exploring the evolutionary origin of small-molecule neurotransmission through the Hydra nervous system

Authors: *H. MAHMOOD, Y. NORO, H. SHIMIZU, K. MINETA, P. MAGISTRETTI, T. GOJOBORI
King Abdullah Univ. of Sci. & Technol., Thuwal, Saudi Arabia

Abstract: *Hydra* is a fresh water metazoan of the phylum Cnidaria which is among the first phylum to develop a nervous system. The primitive organisms of this phylum are known to use peptides as neurotransmitters. However, the presence of neurotransmission through small molecules like glutamate and glycine in *Hydra* is debatable. The purpose of this study is to elucidate the evolutionary origin of small molecule-mediated neurotransmission in animals by studying it in *Hydra*. Using the genome sequence of *Hydra*, we performed phylogenetic tree analyses, revealing that there are genes of sequence homology to mammalian glutamate and acetylcholine receptors. We also found that there is conservation of sequences pertaining to the ligand binding domains of these receptors in *Hydra*. In order to explore whether these receptors are functional in *Hydra* and whether they are localized in neurons, we created transgenic actin-GCAMP *Hydra* to study their response to treatment with small molecular weight neurotransmitters. GCaMP6s is a calcium sensor, allowing us to monitor neuronal activity *in vivo* on stimulation with neurotransmitters. The stimulations were carried out by bath application of the small molecules into *Hydra* media and recording changes in the firing of neurons. Our initial experiments suggest that *Hydra* do not respond to stimulation by glutamate and glycine by mere bath application. Although, the other possibilities are not ruled out. For example, these receptors are localized in epithelial cells rather than neurons in *Hydra.* Including this possibility, it is of particular interest to examine, in the near future, if glutamate and other small molecules may have served merely as metabolites in Cnidarians and evolved as neuronal signaling molecules later in the animal kingdom.

Title: Comparative development of the cerebellum in reptiles reveals different strategies for morphogenesis

Authors: T. VARELA[1], *R. J. WINGATE[2]
[1]MRC Ctr. for Neurodevelopmental Disorders, [2]King's Col. London, London, United Kingdom

Abstract: The cerebellum is composed of only a few cell types whose stratification within the organ has remained fairly conserved throughout evolution. The classic image of a cerebellum is that of a highly folded structure, though in truth, the complexity of foliation various quite dramatically between species. Reptiles, for example, exhibit a wide range of cerebellar shapes ranging from the simple, relatively flat structures of snakes and turtles, to the larger, multiply folded cerebella of alligators and birds. The contoured appearance of brain tissue is due to the division of different nerve cell progenitors that combine to generate folds and bends. How these differences are generated are likely to be due to the genes that control patterns of cell division. By comparing the development of different reptile and bird cerebella, we have found that different degrees of foliation correspond to observable differences in proliferation in the transient external granule cell layer. These patterns also correlate with the maturation of Purkinje cells underlying the external granule layer, which serve as a source of signalling factors that influence the behaviour of granule cell precursors. We have also examined the expression of *Atonal1*, *NeuroD1* and *SHH* through immunohistochemistry and *in situ* hybridisation. Our results suggest that precocious expression of NeuroD1 in granule cell precursors is a key factor in attenuating cell division in unfoliated cerebella, and I have knocked down NeuroD1 in turtles by electroporation of shRNA constructs into cultured cerebellar explants to further investigate the function of this gene.

Title: Whole brain imaging of neuronal activity in ciona intestinalis, an early branching chordate

Authors: *K. KOLAR, M. CHATZIGEORGIOU
Sars Intl. Ctr. For Marine Mol. Bio, Bergen, Norway

Abstract: The vast majority of functional studies in systems neuroscience are performed in a limited number of model species. Over the past few decades these studies have provided us with a very detailed understanding of these nervous systems, but we still lack an understanding of how nervous system function is altered for adaptation and evolution.
Here we aim to incorporate an evolutionary perspective into modern neuroscience by presenting whole brain imaging in *C. intestinalis* larvae, an early branching chordate. The *C. intestinalis* CNS consists of only about 330 cells (connectome by Ryan *et al.* 2016), but possesses presumptive integration centers and specialized sensory structures. These merits and the ability to induce transgenesis in wild-caught animals are key reasons for introducing *C. intestinalis* to the broader neuroscience community.
To record spontaneous activity, larvae expressing GCaMP6 under the pan-neuronal promoter pc2 (proprotein-convertase 2) were embedded in low melting point agarose and imaged for 300 sec at 10Hz. Movies were motion corrected and calcium traces extracted using CNMFE (Giovannucci *et al.* 2017). We show diverse patterns of calcium activity in the sensory vesicle, a brain-like structure and low activity in an RTEN and Palp neuron that are presumed to be part of an olfactory system (Fig C). In order to classify and cluster neurons to interpret the diverse activity patterns, we first differentiate neuronal and non-neuronal calcium dynamics using animals that express pan-cellular GCaMP6. Our results suggest a neuronal cluster which is a subset of the pan-cellular cluster (Fig D). We will classify all neuronal subtypes to determine if their activity patterns form cluster domains, and interpret how domains in the *multidimensional calcium dynamics space* shift in response to sensory cues. We speculate that these domains may represent a language or repertoire of vocabulary that these neurons are able to employ. We will soon expand our methodology to other species to understand how they explore and utilize the *calcium dynamics space*, and examine how their languages vary.

Title: Duplicated genes and their role in human neurological development and disease

Authors: *A. SEKAR[1], J. WANG[2], E. HA[2], K. HINO[3], G. KAYA[2], S. SIMO[3], M. DENNIS[4]
[2]Genome Center, Dept. of Biochem. & Mol. Medicine, MIND Inst., [3]Dept. of Human Anat. & Cell Biology, UC Davis, Davis, CA 95616, [4]Genome Center, Dept. of Biochem. & Mol. Med., [1]Univ. of California Davis, Davis, CA

Abstract: The human brain exhibits radically different anatomical and cognitive features relative to closely ape related species. Gene duplications have long been identified as drivers of speciation. Duplications arising uniquely on the human lineage ("human-specific segmental duplications" or HSDs) are enriched for genes implicated in neurological function—relative to nonhuman great apes—and have the propensity to contribute to novel phenotypes by creating gene copies that may be truncated, fused with other genes or expressed in alternative tissues. One example is *SRGAP2C*, a HSD gene implicated in neuronal migration and synaptogenesis, that is co-expressed, translated and heterodimerizes with its ancestral paralog, *SRGAP2A*, in mammalian cell lines. In mice, expression of *SRGAP2C* was found to result in altered neuronal migration and neoteny of synaptogenesis reminiscent of human neurodevelopment. Another HSD gene, *ARHGAP11B*, has been implicated in the promotion of basal progenitor amplification and neocortex expansion in mice. Here, to further understand the roles of both *SRGAP2* and *ARHGAP11* paralogs during cortex development, we have reanalyzed RNA-seq data of human fetal tissue and embryonic stem cells and overexpressed these genes in mammalian cell lines and mice. Using two existing RNA-seq datasets, (1) distinct cortical layers of human fetal tissues and (2) differentiated embryonic stem cells (hESC)-derived cortical neurons at varied time points, we have assessed for regional differences and temporal changes between human-specific and ancestral paralogs during corticogenesis. Since actin dynamics play an important role in neuronal migration and both ancestral *SRGAP2A* and *ARHGAP11A* are implicated in signaling pathways affecting the cytoskeleton, we have overexpressed the aforementioned HSD genes in monkey kidney and rat neuronal cells (COS-7 and PC12) and assayed for changes affecting cell membrane physiology, such as outgrowth of filopodia/lamellipodia and molecular activation/inactivation of myosin phosphatase. In mice, we have expressed these HSD paralogs using in utero electroporation in developing embryos and assessed for differences in neuronal migration and polarization. We have preliminary results that suggest *SRGAP2C* expression leads to different outcomes in neuronal cell fate and *ARHGAP11B* causes alterations in neuronal migration within the developing mouse cortex, both novel findings. Overall, our results continue to support previous research that human-specific paralogs of *SRGAP2* and *ARHGAP11* have distinct impacts on cortex development relative to their ancestral paralogs.

Title: Characterization of diminished diffusion in the brain extracellular space of the naked mole-rat harboring unique high-molecular-mass hyaluronan

Authors: *D. THEVALINGAM[1,2], S. HRABETOVA[3], D. P. MCCLOSKEY[4,2]
[1]CUNY Col. of Staten Island, Staten Island, NY; [2]Biol., The Grad. Ctr. of the City Univ. of New York, New York City, NY; [3]Dept. of Cell Biol., SUNY Downstate Med. Ctr., Brooklyn, NY; [4]Dept of Psychology and Program in Developmental Neurosci., City Univ. of New York, Staten Island, NY

Abstract: Hyaluronan (HA; Hyaluronic Acid), a primary scaffolding component of the brain extracellular matrix, serves as an integral structural component to the brain extracellular space (ECS). The fossorial African naked mole-rat (Heterocephalus glaber), a mammal demonstrated to have protracted brain development and remarkable longevity, has been shown to synthesize and sustain a unique high-molecular-mass variant of hyaluronan macromolecule (HMM-HA). Thus the naked mole-rat serves as a unique model to observe the role of the extracellular matrix in maintaining brain microstructure and regulating diffusion in the brain ECS. In the present study, we utilized Integrative Optical Imaging to quantify the diffusion of fluorescently labeled dextran (~3,000 MW) in naked mole-rat cortical slices (400 μm). The average tortuosity, which is a measure of the hindrance to a diffusing molecule in the ECS, was significantly higher in naked mole-rat cortical slices than in mouse. These results are indicative of a significant role for the extracellular matrix, particularly HMM-HA, in regulating the behavior of diffusing molecules in the brain ECS of the naked mole-rat. This study provides additional insight into how the composition of the brain extracellular matrix ultimately affects brain physiology and behavior.

Title: Homology in Gyf gene maintains neuron cell homeostasis in *Drosophila melanogaster* and *Drosophila* eugracilis

Authors: *L. A. NEAL, J. LARIMORE, S. ROBIC
Agnes Scott Col., Decatur, GA

Abstract: The Drosophila 4th chromosome, the Muller F Element, or the 'Dot' Chromosome is a unique feature of the Drosophila genome (Leung et. al., 2015). This region of the genome is of particular interest due to the fact that even though it is almost entirely heterochromatic, it still contains a number of active proteins, which are not characteristic of heterochromatin (Leung et. al., 2015). The Genomics Education Partnership (GEP), based at Washington University in St. Louis, MO, has organized a study based on comparative genomics of the 'Dot' chromosome in all Drosophila. This study examines the conservation of the genes found on this chromosome across D. eugracilis and D. melanogaster species using various bioinformatics softwares such as FlyBase BLAST, NCBI BLAST, Gene Record Finder, and the UCSC Genome Browser. In particular, we focused on contig25, a 50kb stretch of DNA in the D. eugracilis genome, where the ortholog of the D. melanogaster 'Gyf' gene lies. According to FlyBase, the Gyf gene is found to be involved in three terms or groups of functions: muscle cell cellular homeostasis, neuron cellular homeostasis, and regulation of autophagy (Gramates et. al., 2017). Our results concluded that there is between 68.5% and 68.8% identity between the genes found in both species, with an E value of 0. These results indicate that there is a relatively high conservation of this gene in the various species. Further analysis of this gene reveals that it plays an important role in the reduction of protein aggregates and organelle dysfunction that have implications in the onset of Parkinson's disease (Kim et. al., 2015). In conclusion, understanding the differences in the gene in these species is important to our understanding of neurodevelopment, neurodegeneration and the use of Drosophila as a model species.

Title: The miR-183/-96/-182 cluster - A key player in the ontogeny of neuronal asymmetries?

Authors: *S. LOR[1], V. THEIS[2], D. MOSER[3], R. KUMSTA[3,4], C. THEISS[2,4], O. GUNTURKUN[1,4]
[1]Inst. of Cognitive Neuroscience, Dept. Biopsychology, [2]Dept. Cytology, Med. Fac., [3]Genet. Psychology, [4]Intl. Grad. Sch. of Neurosci., Ruhr-University Bochum, Bochum, Germany

Abstract: The asymmetrical organization of the nervous system (or *lateralization*) is a fundamental organizational principle of the brain which means that the left and the right hemisphere differ in cognition, perception, and motor control. Atypical lateralization in humans has been linked to various types of neurological disorders while lateralized brain functions in non-human animals have been shown to allow for higher cognitive capacities and therefore,

benefit survival. One of the animals, in which the ontogenesis of lateralization has been studied, are pigeons that display left/right differences in their visual system. Owing to the embryo's asymmetrical body position inside the egg, the resulting uneven light input onto the eyes shortly before hatch induces left/right differences of neural wiring in their visual system. Consequently, one side of the brain develops bigger neurons and more fibers, resulting in a higher computational system than the other. This is also observable in behavioral tasks, in which the right eye/left hemisphere excels in visual discrimination of fine patterns, whereas the left eye/right hemisphere is specialized on spatial attention. The fact that the modulation of the brain can be regulated at such a precise point in time suggests a tightly regulated mechanism. So, what are the cellular cascades triggered by this light stimulation to shape the brain into its lateralized system?
In the recent years, miRNAs have emerged as an important class of small non-coding RNAs, which are involved in a subset of biological processes such as developmental timing. They regulate gene expression on the post-transcriptional level and entire pathways, and thus, are considered as master regulators of gene expression. Therefore, our study aims to uncover the cellular mechanisms of the retino-tectal system during embryonic development via miRNA analyses. Whereas on retinal level, miRNAs were symmetrically expressed and therefore, might not be required for the ontogeny of lateralization, the cluster of miR-183/-96/-182 showed higher expression in the right tectum opticum compared to the left side. Dark incubated pigeon embryos displayed a symmetrical expression pattern of this cluster while their overall expression was significantly diminished compared to normal incubated embryos. Interestingly, other studies in humans have reported an involvement of the miR-183/-96/-182 cluster in the ontogenesis of handedness, and potentially in dyspraxia. Further investigations will unravel the anatomical localization of the miR-183/-96/-182 cluster within the tectum opticum, and to investigate their effects on the targeted mRNA and protein output.

Abstract: Cortical neurogenesis occurs prenatally, when neural progenitor cells differentiate into neurons. Neurogenic or proliferative fate decisions are determined, in part, by regulatory elements modulating the expression of proliferative or neurogenic genes. Previous work has recently identified neurogenesis-associated regulatory elements from dissected fetal tissue laminae in humans, and found that genetically mediated alterations in these elements impact risk for a variety of neuropsychiatric illnesses. This previous work was unable to dissect cell-type specific effects, however, as laminae contain heterogeneous populations of cells. Here, we extend this work by profiling chromatin accessibility in a cell-type specific manner using a large population of human neural progenitor cells. In this study, we cultured neural progenitor cells derived from 92 human fetal brain donors (61 males and 31 females, gestation weeks 14-21). We differentiated cells for 8 weeks and sorted virally labeled neurons (AAV2-hSyn1-EGFP). We then then generated open chromatin profiles for both neural progenitor cells and sorted neurons using the Assay for Transposase Accessible Chromatin followed by sequencing (ATAC-seq). We found global chromatin accessibility profiles are strongly different based on cell-type. Differential chromatin accessibility peaks at gene promoters were enriched in gene ontology terms related to neurogenesis (progenitor > neuron peaks) or synapses (neuron > progenitor peaks), as expected. A differential motif enrichment analysis identified transcription factors (TFs) driving neuronal differentiation, including NEUROG1 and CUX1/2. Similarly, well-known TFs involved in neural progenitor proliferation and maintenance including SOX2 had binding sites more often accessible in progenitors. We found common genetic variants within differentially accessible peaks are enriched in heritability explained for several human neuropsychiatric illnesses and cognitive traits, most notably IQ, neuroticism, schizophrenia, and ADHD. This provides further evidence linking functional alterations in neurogenesis to risk for these illnesses and traits. Chromatin accessibility profiles from in vitro neural progenitor differentiation show largely consistent findings to previous in vivo profiling of fetal cortical laminae, providing further validation of both our culture system and genetic risk factors for neuropsychiatric diseases impacting neurogenesis. These data may also be used to prioritize transcription factors that can be modulated to induce neurogenesis in human culture systems.

Title: Binding of noncompetitive inhibitors to the extracellular domain of neuronal nAChRs: Molecular docking with anticonvulsant α-substituted acetamides and lactams

Authors: *A. V. KRIVOSHEIN, J. L. GUEVARA, M. F. MERIANO
Physical and Applied Sci., Univ. of Houston - Clear Lake, Houston, TX

Abstract: We have recently discovered that α-substituted acetamides and lactams noncompetitively inhibit neuronal nAChRs (Krivoshein, 2016, *ACS Chem. Neurosci.* 7: 316-326). Importantly, their inhibitory affinities toward the receptor *in vitro* (in patch clamp measurements) show excellent correlation with their anticonvulsant potency *in vivo* (in MES tests in mice). We are thus interested in developing a framework for rapid *in vitro* (patch clamp) and *in silico* (molecular docking) testing of the newly synthesized derivatives. In this study, we used molecular docking simulations with AutoDock VINA and EADock DSS to pinpoint binding sites and estimate affinities for neuronal nAChRs (α2, α4β2) and the acetylcholine-binding protein (AChBP) for a series of α-substituted acetamides and lactams. Notably, despite the different algorithms employed in these two programs, the docking results were similar. However, when docking the same inhibitor to different intersubunit interfaces, substantial differences were found. Even more profound differences were found between the binding sites on the different target proteins. The predicted affinities follow about the same rank order as those observed in patch-clamp experiments with a heterologously expressed neuronal nAChR. Our results (*i*) underline the importance of conducting molecular docking simulations with multiple receptor structures and (*ii*) demonstrate the potential of molecular docking in screening of novel noncompetitive inhibitors of the nAChR *in silico*.

Abstract: Immune cells including T and B cells, dendritic cells and macrophages have the ability to synthesize acetylcholine (ACh) by choline acetyltransferase (ChAT). Activation of these immune cells up-regulates ChAT expression and ACh synthesis. Furthermore, immune cells express various subtypes of both muscarinic and nicotinic ACh receptors (mAChRs and nAChRs, respectively) including α7 nAChRs. These findings suggest that ACh synthesized and released from immune cells during antigen presentation between $CD4^+$ T cells and antigen-presenting cells (APCs) plays a role in regulation of immune function by acting on their mAChRs and nAChRs. In fact, by immunization with ovalbumin (OVA), we found a significant elevation of anti-OVA-specific IgG_1 in α7 nAChR-deficient (α7-KO) mice compared to the wild-type C57BL/6J (WT). Furthermore, OVA-activated spleen cells from α7-KO mice produced more TNF-α, IFN-γ and IL-6 than those from WT mice. These findings support a notion that α7 nAChRs in immune cells are involved in regulation of immune function.
We investigated whether α7 nAChRs play roles in $CD4^+$ T cell differentiation into $CD4^+$ $CD25^+$ $FoxP3^+$ regulatory T cells (Tregs) and effector T cells (Th1, Th2 and Th17) using spleen cells from OVA-TCR transgenic BALB/c (DO.11.10) mice. The spleen cells containing $CD4^+$ T cells were activated using OVA or OVA-peptide$_{323-339}$ (OVA-P) and cultured in the presence or absence of GTS-21 (3-30 μM), a partial α7 nAChR agonist, for 5 days in 96-well plate. For activation of $CD4^+$ T cell differentiation, OVA is required to be endocytosed into APCs and processed to OVA-P and then coupled to MHC class II before presentation on the surface of the APCs. On the other hand, OVA-P binds directly to MHC class II expressed on the surface of APCs. At the end of the culture, we performed flow cytometric analysis of the expression of a number of Treg and effector T cell markers.
GTS-21 down-regulated the OVA-activated $CD4^+$ T cell differentiation into Tregs and effector T cells significantly. However, GTS-21 up-regulated the OVA-P-activated $CD4^+$ T cell differentiation into Tregs and effector T cells significantly. The results suggest that activation of α7 nAChRs in APCs inhibits antigen presentation via suppression of antigen processing leading to down-regulation of $CD4^+$ T cell differentiation, and that activation of α7 nAChRs in $CD4^+$ T cells facilitates differentiation into Tregs and effector T cells. In conclusion, these findings demonstrate that α7 nAChRs in both APCs and $CD4^+$ T cells play roles in regulation of $CD4^+$ T cell differentiation.

Abstract: Nicotinic acetylcholine receptors (nAChRs) were described to be implicated in a series of pathological disorders in the CNS and in the PNS. Furthermore, these receptors are interesting therapeutic targets for the treatment of intoxications by organophosphorus compounds (OPCs). OPCs inhibit the enzyme acetylcholinesterase (AChE) resulting in accumulation of the transmitter acetylcholine in the synaptic cleft. Thereby, the function of postsynaptic nAChRs is impaired by desensitization. Consequently, identification of drugs acting as positive allosteric modulators (PAMs) and reducing or reversing nAChR desensitization may be regarded as rational therapeutic approach. A series of structurally-related bispyridinium non-oxime (BP) compounds was tested for their ability to prevent desensitization. For this purpose, whole-cell currents of human α7-nAChRs stably expressed in a CHO cell line (CHO/RIC-3/hα7-nAChR) were recorded under voltage-clamping conditions (-70 mV) performed with planar electrodes in an automatic setup (Patchliner®, Nanion Technologies GmbH, Munich).
Cholinergic currents of hα7-nAChRs induced by nicotine (1–100 µM) increased concentration-dependently up to approx. 500 pA at 100 µM nicotine. However, at higher concentrations (> 100 µM) currents decayed reflecting desensitization of hα7-nAChRs.
Incubation of BP compounds carrying a *tert*-butyl- methoxy- or a dimethylamino-group at both pyridinium moieties in presence of 100 µM nicotine produced an amplification of nicotine-induced peak current amplitudes and a prolonged duration of these currents. Regarding that the effect of these compounds is induced only when co-administered with nicotine, it can be considered as a positive allosteric modulation. At high concentrations of these BP compounds (≥ 30 – 70 µM), dose-response relations revealed a concentration-dependent current decay.
These results are valuable basics for the development of potent PAMs for hα7-nAChRs, allowing initial structure-activity relationships requested for predictive drug design.

Title: Functional analysis of muscle-type nicotinic acetylcholine receptors using SSM-based electrophysiology - Detection of novel "resensitizers"

Authors: *K. V. NIESSEN[1], S. RAPPENGLUECK[1], W. SCHMEISSER[1], T. WEIN[2], S. SICHLER[1], G. HOEFNER[2], K. T. WANNER[2], H. THIERMANN[1], F. WOREK[1], T. SEEGER[1]
[1]Bundeswehr Inst. of Pharmacol. and Toxicol., Muenchen, Germany; [2]Dept. of Pharm. - Ctr. for Drug Res., Ludwig-Maximilians-University, Muenchen, Germany

Abstract: Transmission in neuromuscular synapses may be impaired by various toxic substances, e.g. organophosphorus compounds (OPC). In OPC poisoning, acetylcholinesterase (AChE) is inhibited, resulting in accumulation of acetylcholine in the synaptic cleft. Thus, the desensitization of nicotinic acetylcholine receptors (nAChRs) in the postsynaptic membrane is provoked. Direct targeting of nAChRs to recover their activity from desensitization (i.e. “resensitizing”) might be a promising therapeutic approach. Screening of several novel substances interacting with the receptor needs to be performed for identifying active compounds. In addition to the affinity of such ligands towards the nAChRs[1], their functional properties have to be considered. Bilayer methods (so-called “cell-free electrophysiology“) based on solid supported membranes (SSM) are suitable for investigation of activity of electrogenic membrane proteins (e.g. ligand-gated ion channels like nAChRs) which are not accessible for patch clamp methods. Using native plasma membrane fractions prepared from *Torpedo californica* electroplax, functional measurements of muscle-type nAChRs were performed. Rapid exchange of differently composed buffers forced the receptor to shift into the conformations of resting, activated and desensitized states[2]. Especially, the interaction of ligands with the receptor in a desensitized state and their ability to “resensitize” the blocked receptor was topic of interest. To enhance the screening capacities, the recently developed method was transferred to the fully parallel 96 well-based platform SURFE^{2}R 96SE (Nanion Technologies, Munich), the first marketed instrument featuring the SSM-technology in a high-throughput manner. The upscaling allowed repetitive measurements of differently substituted bispyridinium propanes including positive and negative controls as well as multiple ligand concentrations within one single run. Depending on their substitution pattern, several bispyridinium propanes interact as positive allosteric modulatos (PAMs) and revealed “resensitizing” activity after desensitizing nAChRs by excess carbamoylcholine (> 1 mM). The results demonstrate that SSM-based electrophysiology is well suited to allow detailed functional screening of nAChR-active compounds and has great potential for drug discovery, because of its robustness und scalability.

Title: Evaluation of nicotinic acetylcholine receptor expression and plasticity following chronic nicotine exposure in alpha 4-GFP and WT C57Bl/6 mice

Authors: *J. R. PAULY[1], C. L. RICHARDS[2], P. MORAN[1]
[1]Pharmaceut. Sci., [2]Chem., Univ. of Kentucky, Lexington, KY

Abstract: Many studies have previously shown that neuronal nicotinic acetylcholine receptors (nAChRs) respond uniquely to chronic agonist treatment with a paradoxical increase in the level of receptor protein expression. The process of nAChR “up-regulation” seems to involve multiple post-translational processes that have been difficult to fully characterize. The purpose of this study was to compare the responsiveness of α4 and α7 nAChRs to chronic nicotine treatment in wild type C57BL/6 mice and mice with a green fluorescent protein expressed on the α4 subunit (α4-GFP mice). Adult male wildtype C57BL/6 and α4-GFP mice were randomized to the following treatment groups: 1) 2% saccharin (Sigma Chemical Company, St Louis, Mo., USA) in tap water for 7 days, 2) 200 µg/mL nicotine in 2% saccharin for 3 days, or 3) 200 µg/mL nicotine (free base; Sigma) in 2% saccharin for 7 days (n=5 per group). Brain sections were prepared for an autoradiographic analysis of [^{3}H]-Epibatidine and [^{125}I]-alpha bungarotoxin to alpha 4-containing and alpha 7 nAChRs respectively. In saccharin treated mice there was a 30-50% decrease in the baseline expression of [^{3}H]-Epibatidine in the α4-GFP mice in some (motor cortex, dentate gyrus of the hippocampus) but not all brain regions. The decreased α4β2 nAChR baseline expression was selective since there were no strain differences seen in α7 nAChR expression in similar brain regions. There were also no strain differences in cytisine resistant [^{3}H]-Epibatidine binding to non-β2 containing nAChR's. In spite of the decreased baseline number of α4-containing nAChRs in the GFP mice, the plasticity of the expression was similar following chronic nicotine treatment. Chronic nicotine treatment via the drinking solution increased [^{3}H]-Epibatidine binding by 20-30% in both strains of mice. These studies reveal for

the first time that tagging the α4 subunit with GFP may significantly decrease the level of α4β2 baseline receptor expression, which could have functional impacts on cellular and behavioral studies performed with these animals.

Title: Evaluating commercially-available antibodies for RIC3

Authors: *R. H. LORING, S. SUKUMARAN, J. P. THUMMAPUDI, Z. WANG
Pharmaceut. Sci., Northeastern Univ., Boston, MA

Abstract: α7 nicotinic acetylcholine receptors (nAChRs) depend on chaperone proteins that allow folding, assembly and transport to the cell surface membrane. Resistance to Inhibitors of Cholinesterase 3 (RIC3) is one known chaperone for α7 nAChRs. Antibodies validated to cross-react with human, mouse and rat RIC3 would be very useful, but currently, only antibodies raised against human RIC3 epitopes are commercially available. Also, RIC3 has alternate splice variants, including an alternate extra serine (S+) or not (S-) encoded at the boundary between exons 4 and 5. Mutations due to single nucleotide polymorphisms (SNPs) are also common. We tested existing antibodies that might cross-react between species and whether SNPs and splice variants make any difference. DNA encoding either human or S+mouse RIC3 (S+mRIC3 from Genescript) was linked to a Flag (DDK) epitope to allow detection by anti-DDK antibodies. Human RIC3 (S-hRIC3-YN) purchased from Origene had SNPs C130Y and D352N present in one version without the serine but with a DDK tag, while S-hRIC3-HF, also from Origene, had SNPs P57H and I165F and a DDK tag. Western Blotting detected anti-hRIC3 or anti-DDK antibodies that bound to protein from hRIC3 or mRIC3 constructs transiently expressed in human embryonic kidney (HEK) cells and blotted onto nitrocellulose following electrophoresis. Rat RIC3 (S-rRIC3) expressed without an extra serine or a DDK tag was also tested as an antigen. Four rabbit anti-human RIC3 antibodies (two antibodies from ThermoFisher Scientific and one each from Abcam and Santa Cruz Biotechnology) were tested. Three of these antibodies recognized only hRIC3-YN and hRIC3-HF, while one antibody strongly reacted with S+mRIC3 at a dilution of 1:5000 and showed weak reactions with both S-hRIC3 isoforms and with S-rRIC3. An antibody that recognizes mouse or rat RIC3 will allow us to evaluate whether RIC3 protein is expressed in animal tissues that expresses surface α7 nAChRs in the presence or absence of other known α7 nAChR chaperones. Further experiments are planned to evaluate the

effects of the serine splice variants in cross-reactions between species, and whether this antibody also detects Xenopus RIC3.

Title: Bupropion modulation of 5-HT_{3AB}receptors

Authors: *M. JANSEN[1], A. STUEBLER[1], F. OMORUYI[2]
[1]Ctr. for Membrane Protein Research, Cell Physiol. & Mol. Biophysics, [2]Med. Student Summer Res. Program, Ctr. for Membrane Protein Res., Sch. of Medicine, Texas Tech. Univ. Hlth. S, Lubbock, TX

Abstract: The FDA-approved drug bupropion has been prescribed as an antidepressant (Wellbutrin) for over three decades, and more recently as a smoking cessation aid (Zyban). The presumed mechanism of action of bupropion was inhibition of norephinephrine and dopamine reuptake by their respective transporters. Subsequently, its non-competitive antagonistic effect was demonstrated in nicotinic acetylcholine receptors (α1βεδ, Torpedo, α1βγδ, α3β4α5±β2, α3β2, α4β2, α7) of the Cys-loop superfamily providing an alternate pharmacological pathway. Recently, our laboratory has shown that another cation-selective member of the Cys-loop superfamily, the serotonin type 3 receptor (5-HT3-R), is modulated by bupropion at clinically relevant concentrations. Specifically, we determined that bupropion acts as a non-competitive antagonist at 5-HT_{3A}subunits. 5-HT3-Rs are found pre- and postsynaptically, and are currently targeted by anti-emetics and irritable bowel syndrome treatments. They also hold promise as potential future targets for multiple neurological disorders, such as Alzheimer's disease, schizophrenia, and bipolar disorder.The 5-HT3-R family consists of five different subunits (A-E) but the assembly of this receptor requires the 3A subunit, yielding either a homomer or heteromer with another subunit. To date, only the interaction of bupropion with the 3A subunit has been studied. Here, we extend our investigations to heteromeric 5-HT_{3AB}-Rs, which are known to frequently show different responses to non-competitive antagonists as compared to homomeric 5-HT_{3A}-Rs. 5-HT_{3AB}-Rs are found in the central and peripheral nervous system, predominantly in the amygdala, caudate nucleus, and hippocampus. The functional interaction of bupropion with 5-$HT_{3AB}$was characterized in *Xenopus*oocytes using two-electrode voltage clamp

and patch clamp techniques. Further studies, including docking studies and site-directed mutagenesis, will be used to identify the binding site/s in 5-HT_3-R.

Title: Macroscopic and microscopic activation of α7 nicotinic acetylcholine receptors by the structurally unrelated ago-PAMs B-973B and GAT107

Authors: *M. QUADRI[1], S. GARAI[3], G. A. THAKUR[3], C. STOKES[1], A. GULSEVIN[2], N. A. HORENSTEIN[2], R. L. PAPKE[1]
[1]Dept. of Pharmacol. and Therapeut., [2]Dept. of Chem., Univ. of Florida, Gainesville, FL; [3]Dept. of Pharmaceut. Sci., Northeastern Univ., Boston, MA

Abstract: We report the profiles of two α7 nicotinic acetylcholine receptor (nAChR) ago-PAMs, GAT107 and B-973B, in both two-electrode and patch-clamp experiments. α7 positive allosteric modulators (PAMs) are able to potentiate channel activation by binding to a site in the transmembrane domain (TMD). By binding to additional allosteric sites in the extracellular domain, ago-PAMs act as allosteric agonists, inducing activation in the absence of a typical orthosteric agonist. By also acting at the α7 TMD PAM site, this activation results in large macroscopic currents and protracted bursts of channel opening. Both compounds showed the typical ago-PAM profile but with several significant differences. Specifically, allosteric activation by B-973B appeared more protracted than that produced by GAT107, and B-973B responses were relatively insensitive to the noncompetitive neuronal nAChR antagonist mecamylamine compared to GAT107 responses. Detailed patch-clamp analyses indicated differences in open times, closed times, and burst durations, together with different patterns of full and subconductance states. In single-channel studies we saw that for B-973B, mecamylamine was able to completely block full conductances of the receptor, but was permissive of a single subconductance. Mecamylamine's activity for this subconductance state was consistent with sequential block of the open channels, such that, while individual openings were shorter, burst durations were longer, so that the total open time within a burst was unchanged. In the case of GAT107, however, full conductances were not completely abolished even if profoundly affected in open durations. *In silico* analyses suggested that B-973B bound in

the TMD PAM site might distort the channel, preventing mecamylamine access to binding sites deeper in the pore. Our results demonstrate that, although similar in some ways, the two agents have different balances in their activities at the two allosteric sites and subsequent coupling to the orthosteric site and the ion channel of the receptor. These differences may have further implications as to how the intracellular domains couple to the interactome and subsequent signal transduction associated with the cholinergic control of inflammation.

Title: Upregulation of α4* and α4α6* nAChRs on VTA dopamine neurons is correlated with nicotine reward-related behavior

Authors: *B. J. HENDERSON, A. T. AKERS, Z. J. BAUMGARD, A. J. AVELAR
Biomed. Sci., Joan C Edwards Sch. of Med. at Marshall Univ., Huntington, WV

Abstract: Nicotine is the primary addictive component of tobacco products. Previous reports indicate that nicotine reward is mediated through α4β2*, α6β2*, and α4α6β2* nicotinic acetylcholine receptors (nAChRs) (*, indicates that additional nAChR subunits may be present). Little is known about α4α6β2* nAChR involvement due to a lack of methods that allow the direct investigation of this particular nAChR subtype. Here we use mice that contain α4-mCherry and α6-GFP nAChR subunits to show that concentrations of nicotine sufficient to evoke reward-related behavior (in a conditioned place preference assay) robustly upregulate α4* and α4α6* nAChRs on midbrain dopamine and GABA neurons. Furthermore, the extent of α4* and α4α6* nAChR upregulation on ventral tegmental area (VTA) dopamine neurons correlates to the magnitude of nicotine reward-related behavior. We also show that the upregulation of α4α6* nAChRs in VTA dopamine neurons is accompanied by a change in nAChR stoichiometry that is dependent on the concentration of nicotine in our long-term exposure paradigms. Together, these data highlight the importance of nAChRs that contain both the α4 and α6 nAChR subunit and suggest that α4α6β2* nAChRs on VTA DA neurons play a significant role in the cellular changes that mediate the addiction to nicotine.

Title: Green apple tobacco flavorant farnesol enhances nicotine reward-related behavior

Authors: *A. J. AVELAR, A. T. AKERS, Z. J. BAUMGARD, B. J. HENDERSON
Biomed. Sci., Marshall Univ., Huntington, WV

Abstract: Previous investigations have shown that menthol, the most popular tobacco flavorant, can enhance nicotine reward and reinforcement. With the growing popularity of electronic nicotine delivery systems, more flavors are available to smokers and there is a critical need to understand how these flavorants may alter nicotine's actions. The need to know the abuse liability of flavorants is especially urgent considering that it is generally assumed that flavorants are harmless and they are, therefore, used without caution. In this study we examined the green apple flavorant and odorant farnesol for its ability to alter nicotine reward-related behavior and nicotinic acetylcholine receptor (nAChR) upregulation.
Using a conditioned place preference assay we found that farnesol enhanced nicotine reward-related behavior to a degree that is similar to menthol. We then used confocal microscopy and α4-mCherryα6-GFP mice to examine the upregulation of α4-containing (α4*), α6*, and α4α6* nAChRs in ventral tegmental area (VTA) dopamine neurons. Here, we observed that farnesol, combined with nicotine, enhanced the upregulation of α6* nAChRs but had little effect on α4* and α4α6* nAChRs.
Together, these data show that farnesol alters nicotine reward-related behavior. This is most likely accomplished by its ability to enhance α6* nAChR upregulation. These data highlight the need to study how tobacco flavorants alter nicotine reward and reinforcement.

Title: Building extracellular domain α4β2 nicotinic acetylcholine receptors on stilts for making water-soluble receptors

Authors: *G. B. WELLS, A. M. PERSON
Mol. & Cell. Med., Texas A&M Univ. Col. of Med., College Station, TX

Abstract: Background: Extracellular domain (ECD) receptors from α7, α4, α3, β2, and β3 nicotinic receptor subunits that are truncated after the first transmembrane domain (M1) have functional and structural similarity to full-length nicotinic acetylcholine receptors (nAChRs). Their smaller size and reduced transmembrane sequence might allow structural studies at higher resolution and lead to better understanding of structural and functional roles of extracellular and transmembrane domains. The conserved Cys-loop of the ECD interacts with proximal residues of M1 in crystallographic structures of full-length Cys-loop receptors. This interaction guides the design of site-specific protease sites at the ECD-M1 interface that might liberate water-soluble ECD nicotinic receptors *in vitro*. Properties of interfacially-inserted residues, figuratively called "stilts", that facilitate expression of ECD nicotinic receptors, however, are poorly understood.
Objective: Determine whether extending the ECD with proximal residues from M1 functionally unlinks the two domains and guides a strategy for inserting a site-specific protease site at the interface in ECD α4β2 nAChRs.
Methods: Human α4 and β2 cDNAs were truncated after M1 (α4M1 and β2M1). Five to 11 residues were inserted at the interface between the ECD and M1 by mutagenesis, producing an extended ECD followed by native M1. Subunits were expressed in *Xenopus laevis* oocytes. Immunoblotting and immunoisolated [^{3}H]epibatidine binding sites assessed expression of subunits and ECD α4β2 nAChRs.
Results: Excluding the conserved proline at the N-terminus of M1 from its juxtaposition with the ECD and extending the ECD with residues SGMH (from DNA restriction sites) adversely affected expression. Extending the ECD with the first six M1 residues PLFYTI maintained expression. In contrast, extending the ECD with 6 PAGSAG residues for increased interfacial flexibility adversely affected expression. Extending α4 ECD with 11 M1-derived residues PLFYTILFYTI maintained expression of ECD α4β2 nAChRs when combined with β2M1. Extending both α4 and β2 ECD with these 11 M1-derived residues, however, adversely affected expression.

Conclusions: Interaction between the Cys-loop and proximal M1 residues likely is important for expressing ECD α4β2 nAChRs. Success of functionally unlinking the ECD from M1 by inserting residues at the interface may be limited by increased orientational flexibility that inserted residues permit for the ECD of each subunit. A site-specific protease site inserted at the interface may need to include proximal residues from M1, be as short as possible, and have low overall hydrophobicity.

Abstract: Nicotinic acetylcholine receptors (nAChRs) are ligand-gated ion channels that modulate synaptic transmission throughout the brain. Accordingly, nAChR dysfunction has been implicated in a variety of neurological disorders, including Alzheimer's disease and schizophrenia, as well as drug addiction. Though neuronal nAChRs have long been considered promising targets for therapeutic compounds, relatively little was known, until recently, regarding the involvement of other, regulatory proteins in their biogenesis. Recent studies from our group have identified NACHO as an essential chaperone for the assembly of homomeric α7 nAChRs, in both recombinant expression systems and brain tissue (Gu et al., 2016; Matta et al., 2017). Additional high-throughput screening of α7 and NACHO, cotransfected with the Broad cDNA library in HEK293T cells, revealed that several anti-apoptotic members of the Bcl2 protein family further upregulated functional expression of this nAChR subtype. Though Bcl2 proteins are principally known to promote or inhibit apoptosis at the mitochondrial membrane, we found that α7 nAChRs possess a Bcl2-like binding motif that facilitates their interaction during biogenesis in the endoplasmic reticulum. Point mutations targeted to this motif strongly attenuate Bcl2-mediated effects on receptor assembly and expression, as assessed by immunostaining and patch-camp electrophysiology. Meanwhile, the same mutations did not affect receptor upregulation by NACHO and the previously reported nAChR chaperone RIC3.

Similarly, chemical inhibitors of Bcl2 proteins also diminished their ability to regulate α7 assembly. Other neuronal nAChR subtypes, including the α4β2 receptor did not appear to be regulated by Bcl2 overexpression. In summary, we characterized a subset of Bcl2 proteins as sufficient to upregulate recombinant α7 expression in HEK293T cells, through a distinct mechanism from other known nAChR protein chaperones.

Title: Characterization of murine brain region-specific ^{3}H-epibatidine binding in response to chronic exposure to nicotine, (-) menthol, and nicotine co-administered with either (-)-menthol or (±)-menthol

Authors: *M. J. MULCAHY, S. M. HUARD, J. H. WANG, H. A. LESTER
Biol. and Biol. Engin., Caltech, Pasadena, CA

Abstract: Nicotinic acetylcholine receptors (nAChRs) are pentameric cation channels that are expressed in the mammalian central nervous system, the peripheral nervous system, and the neuromuscular junction. Eleven neuronal nAChR subunits have been identified in mammals (α2-7, α9-10, β2-4), and receptors containing α4β2, α3β4, and α7 subunits are the most abundant nAChR subtypes in the mammalian CNS. Chronic nicotine exposure upregulates total neuronal nAChR levels, as measured by ^{3}H-nicotine and ^{3}H-epibatidine binding. Epibatidine is a toxin that has high affinity for nAChRs and can be used to quantify nAChR levels. Chronic exposure of menthol, a cigarette flavorant, has been shown to upregulate specific nAChR subunits in

several brain regions. A systematic characterization of changes in receptor levels in response to chronic menthol or chronic nicotine + menthol had yet to be performed prior to this study. We investigated the effect of chronic nicotine, (-)-menthol, and nicotine co-administered with either (-)-menthol or (±)-menthol in fourteen murine brain regions for changes in ^{3}H-epibatidine binding. Total ^{3}H-epibatidine binding was further resolved through characterization of cytisine sensitive (mostly α4β2 nAChRs) and cytisine resistant (mostly non-α4β2 nAChRs) fractions. C57bl/6 mice were separated into five treatment groups: vehicle (ethanol), nicotine (2 mg/kg/hr), (-)-menthol (2 mg/kg/hr), nicotine + (±)-menthol (2 mg/kg/hr), or nicotine + (-)-menthol (2 mg/kg/hr). Osmotic minipumps were used for chronic treatment administration over 10-12 days. Our investigations identified region specific upregulation and downregulation of nAChR levels in response to the different chronic drug treatments tested. This comprehensive characterization of changes in nAChR levels in specific brain regions enhances our understanding of the effects of menthol on the mammalian CNS.

Abstract: Nicotinic acetylcholine receptors (nAChRs) play crucial roles in many cellular and physiological processes. The manner by which lipid composition affects the functionality and stability of solubilized nAChR is poorly understood. Lipid-protein interactions are of crucial importance for stability and correct function of transmembrane proteins.Cholesterol, which is a key lipid for maintaining the correct functionality of membrane proteins, has been found to alter the nAChR function. Our objective of this study is to understand how cholesteryl hemisuccinate (CHS) affects the thermal stability and functionally the nAChR-detergent complex (nAChR-DC). The nAChRs was extracted from the electric organ tissue of *Torpedo californica,* using

LysoFos Choline 16 as a lipid-analogous detergent (LFC-16), followed by affinity purification, size exclusion, and ionic exchange chromatography. We used circular dichroism spectroscopy, dynamic light scattering, and a two voltage-clamp assay to examine the functionality and stability of the nAChR-DC prepared with different concentrations of CHS and LFC-16. The present results suggest that the CHS preserves the secondary structure of the nAChR making it more thermo-stable in the thermal unfolding experiment. Also, the addition of CHS increases the yields of the nAChR-DC in the affinity purification assay and preserves the functionality in oocytes. Abstract: Until the discovery of NACHO, α7 nicotinic acetylcholine receptors (nAChRs) were known to not express well in recombinant cell systems. To identify additional partners that can modulate α7 nAChR expression in the presence of NACHO, we conducted a high throughput screen of the Broad cDNA library using surface Bungarotoxin (Bgt) staining and Opera Phenix high content, high throughput imaging system. A group of Bcl2 proteins showed synergy with NACHO to further enhance surface Bgt staining. Systematic study of all Bcl2 proteins indicated that only anti-apoptotic Bcl2 proteins exert this effect. In cultured hippocampal neurons, treatment with inhibitors of Bcl-xl and MCL1 reduced surface Bgt staining, while surface GluA1 labeling was not changed. The inhibitor concentrations were optimized to cause minimal cell death. Only healthy neurons were used in quantification of the Bgt and GluA1 surface stain. Lentiviral-mediated MCL1 overexpression in cultured hippocampal neurons increased Bgt staining but didn't affect GluA1 surface labeling. These results indicate that these anti-apoptotic Bcl2 proteins regulate α7 nAChR surface expression in a manner that is not related to apoptosis.

Title: Uncovering cholinergic mechanisms of anxiety regulation through the nicotinic receptor protein modulator, lynx2, in mice and humans

Authors: *K. R. ANDERSON[1], H. WANG[1], A. HUPBACH[2], J. M. MIWA[1]
[1]Biol. Sci., [2]Psychology, Lehigh Univ., Bethlehem, PA

Abstract: Anxiety is an adaptive response to a threatening situation, but if not regulated properly can lead to the development of anxiety disorders. The exact etiology of anxiety disorders are unknown. Due to this gap in full understanding, current treatments only provide temporary symptomatic relief and are not effective in all anxiety disorder sufferers. A novel therapeutic approach is through the nicotinic acetylcholine receptors (nAChRs) of the cholinergic system. Nicotinic acetylcholine receptors (nAChRs) have been shown to regulate amygdalar activity but the discovery of their exact roles is still under investigation due to the complexity of nAChR subtypes and varied responses to antagonism. Additionally, anxiety disorders are thought to develop from a complex interaction between genetic, psychological, and environmental factors. To study the role of amygdalar nAChRs and a possible genetic underpinning of anxiety we are using the candidate gene, lynx2. The lynx2 gene is expressed in the amygdala, where the protein product binds to and suppresses nAChR activity. Additionally, heightened anxiety-like behavior have been reported in the lynx2 knockout mouse. Here we further characterize the role of lynx2 in anxiety-like behaviors and responses to different environmental conditions in the knockout

mouse model. We also identify a role of the lynx2 gene in human behavior through human gene sequence analysis and human anxiety behavior correlations.
We hypothesize that lynx2 modulators act to properly regulate amygdala nAChR activity and thus proper anxiety responses in both mice and humans. We are investigating associations between human lynx2 gene sequences and human anxiety levels. To investigate the biological and cellular mechanisms underlying behavioral differences observed in lynx2KO mice, we are pairing behavioral pharmacology assays to further characterize the extent of the anxiety phenotype with electrophysiology studies. We have found that anxiety behaviors such as fear learning are altered in lynx2 knockout mice and that deficits in fear learning could be restored with cholinergic blockade and pharmacology targeted at learning mechanisms. Further studies into the lynx2 knockout mouse model could identify biological mechanisms of anxiety and inform a pharmacogenetic approach to treatment of anxiety disorders.

Title: Effects of positive allosteric modulators on the human α4β2 receptor desensitization

Authors: *S. BERTRAND[1], T. SCHAER[1], D. BERTRAND[1], M. ACKERMAN[2], J. NAU[2]
[1]Hiqscreen, Vesenaz - GE, Switzerland; [2]Oyster Point Pharma Inc, Princeton, NJ

Abstract: Neuronal nicotinic acetylcholine receptors display a high degree of desensitization upon sustained exposure to an agonist. While onset and recovery of desensitization was characterized for acetylcholine at the human α4β2 receptors, much less is known about the effects of other agonists.
In this work, we examined the desensitization and recovery to a sustained exposure for the full agonist OC-02 (Oyster Point Pharma, Inc, formerly TC-6499) and the partial agonist varenicline at the human α4β2 receptors. Whereas almost full recovery of the response was observed for OC-02, inhibition caused by varenicline was more profound and long lasting.
The discovery that several substances such as Br-PBTC or NS-9283 act as positive allosteric modulators at neuronal nicotinic receptors offers additional possibilities to tackle the mechanisms underlying receptor desensitization. Experiments conducted at the human α4β2 receptors expressed in *Xenopus* oocytes confirmed that Br-PBTC and NS-9283 are powerful positive allosteric modulators at these receptor subtypes. A difference was, however, observed

between these two compounds when comparing their activity at the responses evoked by OC-002. Namely, while Br-PBTC significantly increase the maximal evoked currents, exposure to NS-9283 caused no increase of the current amplitude.
Effects of Br-PBTC and/or NS-9283 were next examined on the desensitization caused by sustained exposure to OC-02 or varenicline and if co-exposure with a modulator could prevent varenicline desensitization. A major difference was observed in presence of BrPBTC. Namely coexposure with this modulator was able to reverse desensitization caused by varenicline within 3 hours. Conversely, NS9283 caused no significant modification of recovery from desensitization. While these modulators had little or no effect at recovery from desensitization caused by OC-02
These data illustrate the importance of allosteric modulation on the functional properties of neuronal nicotinic acetylcholine receptors and highlight the possibility to minimize desensitization effects caused by sustained exposure to an agonist.

Title: Properties of novel alpha7 nicotinic acetylcholine receptor ligands for predicting performance as PET tracers

Authors: *M. M. LEVANDOSKI[1], A. KOZJEK[1], Y. LIU[1], W. TEAGLE[1], D. PETERS[2], W. DEUTHER-CONRAD[3], M. SCHEUNEMANN[3], P. BRUST[3]

Abstract: The nicotinic acetylcholine receptors (nAChRs), especially the α7 homomeric subtype, have been implicated in several neuropsychiatric disorders, such as Alzheimer's disease, Parkinson's disease, and schizophrenia. Although monitoring the activity of nAChRs *in vivo* can be achieved with positron emission tomography (PET), an optimal tracer for the α7 subtype with a high affinity, specificity and sensitivity has yet to be discovered. We aim to develop a correlative model to predict the *in vivo* performance of potential α7 nAChR PET ligands with *in vitro* methods. After expressing the receptor in *Xenopus* oocytes, we performed two-electrode voltage-clamp experiments to examine the pharmacological properties of six compounds (DBT-10, DBT-38, NS6784, NS10743, NS14490, and NS14492), including their potencies and efficacies, modes of modulation, and desensitization properties.
We have found that the compounds of the NS series are agonists with EC_{50}s ranging between 0.3 ± 0.1 and 2.5 ± 1.5 μM and efficacies in the range of that for acetylcholine (ACh). In contrast, the DBT compounds are weak partial agonists, but they modulate ACh responses in co-application experiments. We found a biphasic response, with the DBT compounds potentiating at low concentrations but inhibiting the response at higher concentrations. DBT-10, recently characterized as a suitable PET tracer, can achieve complete inhibition with an IC_{50} of 100 ± 25 nM, but DBT-38 only reached 40% inhibition. Modes of modulation vary, notably with DBT-10 being a non-competitive inhibitor.
Due to the importance of desensitization of α7 nAChRs, we studied the effects of the novel ligands on these properties. We studied the time course of recovery back to the control response following exposure to each compound in several ways. We found that recovery from desensitization is a function of time, frequency of receptor activation, and amount of exposure to the drug, and all vary depending on the compounds used. Responses in oocytes exposed to NS14490, DBT-10, and DBT-38 take longer to recover, whereas those for the other NS compounds recover at a rate comparable to ACh.
Future research will include the examination of the PET tracer [^{18}F]ASEM, a structural analog of DBT-10, and further derivatives in order to establish a link between function and structure. We have started developing a single-channel approach to address the complication in predicting the performance of α7 nAChR potential PET ligands regarding desensitization properties. Finally, we have begun developing an initial model correlating these parameters and ligand effectiveness *in vivo.*

Title: *In vivo* optical control of brain nicotinic acetylcholine receptors

Authors: *A. MOUROT, R. DURAND-DE CUTTOLI, S. MONDOLONI, J. JEHL, P. FAURE
Neurosci. Paris Seine, Sorbonne Univ., Paris, France

Abstract: Acetylcholine (ACh) provides a widespread and diffuse signal in the brain. It alters neurotransmitter release and affects neuronal integration and network activity, notably by acting through ionotropic nicotinic ACh receptors (nAChRs). nAChRs consist of hetero- and homo-pentameric arrangements of α and β subunits (9 and 3 genes, respectively), yielding a high combinatorial diversity of channel composition, localization and function. Nicotinic neuromodulation controls learning, memory and attention, and has been associated with the development of numerous neurological and psychiatric disorders, including epilepsy, schizophrenia, anxiety and nicotine addiction. To understand how nAChRs mediate such diverse functions, we developed an opto-chemical-genetic strategy for acutely and reversibly manipulating these receptors in the mammalian brain in vivo (1). We have notably developed light-inhibitable nAChRs (LinAChRs) of the β2 and β4 subtypes, that respond normally to ACh or nicotine in darkness, but are rapidly antagonized upon illumination with 380 nm light (2, 3). This strategy relies on the covalent attachment of a photoswitchable tethered antagonist onto a genetically-encoded, cysteine-ready receptor mutant. We used lentiviruses to demonstrate rapid and specific control of nicotinic transmission in the ventral tegmental area (VTA) and the interpeduncular nucleus (IPN), two brain regions expressing high densities of nAChRs and strongly implicated in nicotine addiction. Using in-vivo electrophysiological recordings coupled to photocontrol of specific nAChRs, we provide direct evidence that the ACh tone fine-tunes the firing properties of VTA dopamine and IPN neurons through somatic nAChRs. Furthermore, locally photo-antagonizing β2-containing receptors in the VTA was sufficient to reversibly switch nicotine reinforcement on and off. By enabling control of nicotinic transmission in targeted brain circuits, this technology will help unravel the various physiological functions of nAChRs and may assist in the design of novel therapies relevant to neuropsychiatric disorders.

Title: Screening of alpha-Conotoxins with activity at the alpha3beta2* nicotinic acetylcholine receptor subtype

Authors: *B. EATON[1], F. FISHER[3], F. HARARAH[3], C. HUIDOBRO[3], J. MCINTOSH[3,5,4], P. WHITEAKER[2]
[1]Neurobio., [2]Div. Neurobiol, Barrow Neurolog. Inst., Phoenix, AZ; [3]Dept. of Biol., [4]Dept. of Psychiatry, Univ. of Utah, Salt Lake City, UT; [5]George E. Whalen Veterans Affairs Med. Ctr., Salt Lake City, UT

Abstract: α-Conotoxin MII (α-CtxMII) selectively antagonizes α3β2*- and α6β2*-nAChR. We have previously developed α6β2*-nAChR-selective α-Ctxs to define mesolimbic α6β2*-nAChR contributions to nicotine and other drug abuse phenotypes. A lack of selective compounds, and lethality in α3-nAChR subunit-null mutant mice, means virtually no studies of native α3β2*-nAChR have been performed. The medial habenula (MH) and interpeduncular nucleus (IPN) contain the densest CNS α3β2*-nAChR populations (outnumbering MH and IPN α6β2*-nAChR). MH & IPN α3β4*- and α5*-nAChR are already known to support nicotine dependence, but ganglionic α3β4*-nAChR expression and a lack of α5 subunits in orthosteric binding sites may make these problematic anti-smoking targets. These potential difficulties motivate us to assess the contributions of additional MH and IPN subtypes such as α3β2*- and α6β2*-nAChR to nicotine abuse and addiction phenotype. Here, we describe screening of a panel of 372 α-Ctx ligands, to discover leads with α3β2*-nAChR selectivity. Preliminary screens were performed utilizing the $^{86}Rb^{+}$ efflux assay. Fifteen ligands in the panel have been found to be highly potent at α6/3β2β3-nAChR, having IC_{50} values less than 100nM. Included in those fifteen ligands are ten α-Ctxs that have multiple variants represented in the screen. Potency is highly sensitive to amino acid substitutions. Point mutations have weakened or completely eliminated activity of related α-Ctxs, and have also rendered inactive α-Ctxs highly potent at α6β2*-nAChR. As of the submission of this abstract our previously-created stably-transfected α3β2-nAChR mammalian cell line has lost function over multiple passages in cell culture. Because of this, we have been unable to screen with $^{86}Rb^{+}$ efflux assays. We are, instead, currently screening the α-Ctx panel for activity at α3β2-nAChR utilizing *Xenopus laevis* oocytes and two electrode voltage clamp

(TEVC) electrophysiology. Lead peptides will be identified as those with selectivity for α3β2- over α6β2*-nAChR. Following identification of such lead α-Ctxs, we will compare their sequences and use this information to drive a positional scanning mutagenesis approach. Our goal is to develop and validate a panel of α-Ctxs with greater than 100-fold α3β2-nAChR selectivity across human, mouse, and rat nAChR. This will be sufficient to identify and characterize the potential of α3β2*-nAChR, as well as refine our understanding of α6β2*-nAChR viability, as novel pharmacotherapeutic targets for smoking cessation.

Title: Amyloid beta-induced alterations in basal forebrain cholinergic intrinsic excitability are mediated by α7 and α7β2-containing nicotinic acetylcholine receptors (nAChRs)

Authors: *A. A. GEORGE[1], H. A. BIMONTE-NELSON[2], R. J. LUKAS[1], P. WHITEAKER[1]
[1]Neurobio., Barrow Neurolog. Inst., Phoenix, AZ; [2]Arizona State Univ., Tempe, AZ

Abstract: Alzheimer's disease (AD), a progressive neurodegenerative disorder, is one of the most common causes of mental deterioration in the elderly. Hallmarks of AD pathology include alterations in brain regions associated with higher cognitive functions. Several studies have correlated the severity of cognitive decline in early AD with a loss of basal forebrain cholinergic neurons (BFCNs). Mechanisms underlying cholinergic neurodegeneration and subsequent memory impairments remain unknown. However, interactions between amyloid-beta (Aβ), a suspected etiopathogenic agent in AD, with a nicotinic acetylcholine receptor (nAChR) subtype containing α7 subunits trigger an increase in hippocampal neuronal excitability. Heteromeric α7β2-nAChRs have similar pharmacological properties to those of homomeric α7-nAChRs and are highly sensitive to functional modulation by Aβ. Toward understanding the roles played by nAChRs in BFCN function we used single-channel electrophysiology to explore the functional relationship between Aβ and α7 and α7β2-containing nAChRs. We demonstrate that oligomeric Aβ activates both α7 and α7β2-nAChRs and preferentially enhances α7β2-nAChR single-channel open dwell-times (representing a 3.5-fold increase), effects that can be abrogated using the known nAChR antagonists MLA or mecamylamine. Using organotypic slice cultures and

whole-cell patch clamp electrophysiology we demonstrate that chronic incubation with oligomeric Aβ increases BFCN firing rates in the medial septum and horizontal diagonal band (MSDB: 64 ± 8% and HDB: 25 ± 3.5%, respectively). BFCN firing rates were mirrored by 1) reduced afterhyperpolarization (AHP) magnitude (reduction of 44 ± 6.5% and 15 ± 2.5%, respectively), 2) attenuation in action potential amplitude (38 ± 6.5% reduction), 3) reduced spike-frequency adaptation (i.e. reduced interspike interval ratio) and 4) development of a hyperpolarization-activated cationic current (I_h), when compared to controls (scrambled Aβ). These Aβ-induced alterations were absent in the nucleus basalis (NB). Interestingly, regionally-specific changes in BFCN intrinsic excitability were normalized in β2 nAChR subunit knockout, suggesting that Aβ alters cholinergic intrinsic excitability by interacting with α7 and β2-containing nAChRs. These interactions may be specific to certain cholinergic circuits within the basal forebrain and suggest novel and potentially productive therapeutic strategies to combat neurodegeneration in a brain region affected early in AD. Abstract: Dopamine (DA) release in the striatum is critical for regulation of movement and disruption of DA signaling underlie a variety of psychomotor disorders, including Parkinson's disease (PD). Pre-synaptic nicotinic acetylcholine receptors (nAChRs) are involved in the control of dopamine release and nAChRs containing the α6-subunit (α6* nAChRs) have gained interest as therapeutic targets in PD due to the restricted expression pattern of these receptors. Furthermore, parkinsonian animal models in which the nigrostriatal pathway has been selectively

damaged with dopaminergic neurotoxins such as 6-OHDA or MPTP, show a decreased α6* nAChR expression and function. Such lesions closely parallel the decline in dopaminergic terminal integrity seen in post mortem PD brains, which supports the involvement of nigrostriatal α6* nAChRs in PD.
By using a combination of fluorescence-based and electrophysiological assay techniques, we have identified small molecules acting as positive allosteric modulators (PAMs) of α6* nAChRs. Here we present data on AN6001, which has sub-micromolar potency at α6* nAChRs and demonstrates a high degree of selectivity for α6* nAChRs over other more widely expressed nAChR subtypes. When tested at native rodent receptors, AN6001 caused a significant potentiation of α6-stimulated synaptosomal DA. Furthermore, slice electrophysiological recordings on putative dopaminergic neurons from rat substantia nigra pars compacta, AN6001 displayed augmentation of cholinergic stimulated action potential firing. Additionally, we tested cell survival of dopaminergic neurons using rat primary mesencephalic cultures. By challenging the neurons with MPP+, we found that AN6001 elicited a significant enhancement of the neuroprotective effect mediated by nicotine.
These results provide the first evidence of positive allosteric modulation of α6* nAChRs and demonstrate that a nicotinic α6 PAM has the potential to strengthen acetylcholine-mediated dopaminergic signaling. An α6 PAM, as presented here, is expected to selectively enhance endogenous α6* nAChR-mediated signaling in a process that is not supposed to promote increased steady state desensitization of the receptors and thereby, is less likely to induce tolerance as compared to nicotinic receptor agonists.

Title: SUVN-911 (potent and selective nicotitinicacetylcholine α4β2 receptor antagonist) - Safety, tolerability and pharmacokinetics in healthy subjects

Authors: *G. BHYRAPUNENI, K. MUDIGONDA, R. PALACHARLA, P. JAYARAJAN, R. SUBRAMANIAN, V. GOYAL, S. PANDEY, D. AJJALA, A. MOHAMMED, S. JETTA, R. NIROGI
Suven Life Sci. Ltd., Hyderabad, India

Abstract: SUVN-911 is a potent and selective α4β2 receptor antagonist with more than 300 fold selectivity (NovaScreen selectivity panel). SUVN-911 showed good oral bioavailability in all

preclinical species. It also showed good brain penetration and receptor occupancy following oral administration. It demonstrated antidepressant like effects in animal models of depression. Faster onset of action, no sexual dysfunction and procognitive potential in animal models are the differentiating features for SUVN-911. At behaviorally effective doses, SUVN-911 produced a significant increase in cortical serotonin and norepinephrine levels. SUVN-911 showed good margin of safety in toxicity studies and is non-mutagenic. SUVN-911 was studied in a single-center, multi-faceted, Phase 1 clinical trial (US IND) to evaluate its safety, tolerability, and pharmacokinetics after single and multiple ascending doses administered orally in healthy male subjects. For single dose evaluation, healthy human volunteers were once dosed with 0.5 mg, 6 mg, 15 mg, 30 mg and 60 mg of SUVN-911 tablets. For multiple ascending dose evaluation, once daily doses of 15, 30 and 45 mg SUVN-911 were administered orally for 14 days. SUVN-911 was quantified in plasma using a validated LC-MS/MS method. Safety and tolerability was evaluated throughout the study by assessing the incidence and severity of AEs, abnormalities in vital signs, ECG and clinical parameters.SUVN-911 was well tolerated up to the highest tested dose of 60 mg single dose or 45 mg/day multiple doses in healthy male subjects. There were no clinically relevant or serious adverse events reported. During single ascending dose studies, the absorption of SUVN-911 was rapid and exposures (C_{max} and AUC) were more than dose proportional at the tested doses between 0.5 mg to 60 mg. During multiple ascending dose studies, SUVN-911 achieved the projected efficacy concentrations. Additional Phase 1 clinical study (US IND) to evaluate the effect of food, gender and age on human pharmacokinetics is in progress.

Title: The genes encoding the alpha7 nicotinic acetylcholine receptor subunit and the human truncated and duplicated form, dup alpha7, are expressed and regulated in microglia cells

Authors: *J. D. MIKKELSEN, S. ARPE, M. DINARZEHI, J. MENEZES, M. H. SØRENSEN, S. S. ARIPAKA
Univ. Copenhagen - Rigshospitalet, Copenhagen, Denmark

Abstract: The penta-homomeric alpha7 nicotinic acetylcholine receptor (nAChR) is a ligand-gated ion-channel, and activation of the receptor leads to inward flow of calcium and natrium in neurons. Previous studies carried out in THP-1 or Jurkat cell lines, shows that the alpha7 nAChR conveys anti-inflammatory properties by reducing the inflammatory cytokine releases by a mechanism not involving ion flow. It is considered that the receptor signal involve other intracellular signalling pathways in microglia cells than in neurons. While agonists have no effect, a subset of low-efficacy partial or silent agonists such as NS6740 elicit anti-inflammatory effects. In this study, we compared the pharmacology and expression of the two genes (*chrna7* and c*hrfam7a*) encoding the alpha7 nAChR and the human truncated and duplicated form, dup-alpha7 nAChR in primary microglia and the microglia cell line, BV2. In all cells, NS6740 reduced lipopolysaccharide (LPS)-induced TNF-alpha release at concentrations of 30 uM, and full effect was achieved at 100 uM. Also, in rat microglia microglia NS6740 reduced interleukin-1b and TNFalpha gene expression in LPS-stimulated cells. Expression, of alpha7 nAChR mRNA was detected in non-human microglia, and the level up-regulated by LPS. In contrast, only dup-alpha7 nAChR mRNA was detected in human microglia. These data suggest that alpha7 nAChR is expressed in microglia and may exert an important role in control of inflammation in the brain, and that duplicated form may exert a role in human that may be different from other mammalian species.

Title: Modulation of glutamate release by nicotine in the rostromedial tegmental nucleus (RMTg)

Authors: *D. E. CASTILLO-ROLON, G. ARENAS-LÓPEZ, S. MIHAILESCU, O. HERNANDEZ-GONZALEZ, S. HERNÁNDEZ-LÓPEZ
Fisiología-Facultad de Medicina UNAM, Natl. Autonomous Univ. of Mexico (UNAM), Ciudad de Mexico, Mexico

Abstract: The rostromedial tegmental nucleus (RMTg) is a bilateral structure localized in the midbrain. The RMTg is mainly constituted by GABAergic neurons which exert a strong tonic inhibition on the mesolimbic and the nigrostriatal dopamine systems (Barrot et al, 2012; Kaufling, 2009; Gonçalves, 2012). Accordingly, it has been reported that the inhibition or activation of the RMTg, increases or decreases the activity of midbrain dopamine neurons, respectively (Jhou et al, 2009b; Stamatakis & Stuber, 2012). The major excitatory input to the RMTg is glutamatergic projections from the lateral habenula (LHb). On the other hand, RMTg receives dense cholinergic inputs from the tegmental laterodorsal and pedunculopontine nuclei. Previous studies suggest the presence of nicotinic acetylcholine receptors (nAChRs) at glutamatergic terminals that establish contact with the RMTg cells (Lecca et al, 2012). The aim of this work was to investigate whether the activation of nAChRs modulates glutamate release in the RMTg nucleus. We used voltage clamp techniques in whole cell configuration to examine the effect of selective nicotinic drugs on the spontaneous glutamatergic excitatory postsynaptic currents (EPSCs) recorded from GABAergic RMTg neurons in rat midbrain slices. We found that the activation of nAChRs by nicotine or acetylcholine, increase the frequency of EPSCs in the RMTg neurons through α7 but not α4β2 nAChRs. This effect persisted for about 30-40 minutes after the washout of the drug. The effect was dependent on calcium release from intracellular calcium stores but independent on action potentials or the activation of voltage-gated calcium channels.

Title: Opposite effects of alpha7 and alpha4beta2 nicotinic acetylcholine receptors on dorsal raphe serotonergic neurons

Authors: *S. P. MIHAILESCU[1], O. HERNANDEZ[2], D. CASTILLO-ROLON[2], S. HERNANDEZ-LOPEZ[2]
[1]Fac. of Medicine, UNAM, Mexico City, Mexico; [2]Physiol., Fac. of Medicine, UNAM, Mexico, Mexico

Abstract: The dorsal raphe nucleus (DRN) provides the serotonergic input for most of forebrain structures. Alpha7 and alpha4beta2 nicotinic acetylcholine receptors (nAChRs) are present on the soma of 5-HT DRN neurons an on intra-raphe noradrenergic, glutamatergic and GABAergic terminals. Previous studies from our laboratory indicated that nicotine increases the firing activity of 5- HT DRN neurons through stimulation of both postsynaptic and presynaptic nAChRs (Mihailescu et al, 1997; Galindo et al., 2008, Garduño et al, 2012). These studies did not however establish which type of presynaptic nAChR is responsible for the increase in 5-HT DRN neuron firing rate. The purpose of this study was to determine the effects on 5-HT DRN neuron firing rate, glutamate and GABA release of specific agonists of alpha7 and alpha4beta2 nAChRs. The experiments were performed in midbrain slices obtained from young (19-21 postnatal days) Wistar rats. The electrical activity of 5-DRN neurons was recorded using the whole cell voltage- and current clamp techniques. When bath administered in a concentration of 0.1 μM, the specific agonist at alpha4beta2 nAChRs E-N-methyl-4-(3-pyridinyl)-3-butene-1-amine (RJR-2403 oxalate, 0.1 μM), produced an increase in the firing rate of 5-HT DRN neurons by 37% and an increase of the frequency of spontaneous and miniature excitatory postsynaptic currents (sESPSCs and mEPSCs respectively). Surprisingly, mecamylamine (MCM, 3 μM), a non-specific and non-competitive antagonist at nAChR, produced similar effects as RJR-2403. The specific agonist at α7 nAChRs *N*-(3*R*)-1-Azabicyclo[2.2.2]oct-3-yl-4-chlorobenzamide (PNU-282987,100 nM), induced a 64.8% decrease in 5-HT DRN neuron firing rate and an increase in the frequency of GABAergic sIPSCs and mIPSCs. These data indicate that the stimulatory effects of nicotine and mecamylamine on 5-HT DRN neurons are indirect, presynaptic, dependent on alpha4beta2 nAChRs-mediated increase of glutamate release in the DRN. The stimulation of DRN alpha7 nAChRs produces the inhibition of 5-HT DRN neurons by inducing presynaptic release of GABA from GABAergic terminals present in the DRN.

Title: Sex differences in gene expression of nicotinic acetylcholine receptor (nAChr) subunits in the interpeduncular nucleus of female and male rats experiencing nicotine withdrawal

Authors: *M. C. GARCIA ARREGUIN[1], V. L. CORREA[1], R. J. FLORES GARCIA[2], L. E. O'DELL[3]
[1]The Univ. of Texas at El Paso, El Paso, TX; [2]Psychology, Univ. of Texas at El Paso, El Paso, TX; [3]Univ. Texas at El Paso, El Paso, TX

Abstract: Withdrawal from chronic nicotine elicits negative affective states that are modulated, in large part, via nAChRs in the medial habenula-interpeduncular nucleus (MHb-IPN) pathway of the brain. Previous research using knock-out mice has demonstrated that $alpha_4beta_2$ and $alpha_5$ nAChRs in MHb-IPN pathway are necessary for the expression of negative affective states produced by nicotine withdrawal. Despite the current knowledge of the role of nAChRs in nicotine withdrawal, there is little information regarding sex differences in the expression of these receptors during withdrawal in the IPN. To address this issue, the present study compared gene expression of $alpha_4$, $beta_2$, and $alpha_5$ receptor subunits in the IPN of female and male rats during nicotine withdrawal. Female and male rats were implanted with a pump that delivered nicotine for 14 days. The following day, the rats received an injection of saline or the nAChR antagonist, mecamylamine, to precipitate withdrawal. Twenty minutes later, rats were tested for anxiety-like behavior using the elevated plus maze (EPM) test. After testing, the IPN was dissected and $alpha_4beta_2$, and $alpha_5$ mRNA expression was assessed using RT-qPCR methods. The results from the EPM revealed that female rats displayed an increase in anxiety-like behavior during withdrawal that was larger than males. The molecular results revealed that female rats displayed an increase in the expression of $alpha_5$ mRNA, an effect that was absent in male rats experiencing withdrawal. In contrast, male rats displayed an increase in the expression of $apha_4$ and $beta_2$ mRNA, and this effect was absent in female rats. These data suggest that sex differences in anxiety-like behavior produced by nicotine withdrawal is related to a differential expression of $alpha_4beta_2$ and/or $alpha_5$ nAChRs in the IPN, and future studies are needed to explore the role of various nAChRs in the MHb-IPN pathway in modulating sex differences in the expression of the nicotine withdrawal syndrome.

Title: Space clamp issues fail to confound estimates of nicotinic synaptic strength in rat sympathetic neurons

Authors: *J. P. HORN, P. H. M. KULLMANN
Dept of Neurobio., Univ. of Pittsburgh, Pittsburgh, PA

Abstract: In recent experiments, we estimated the strength of individual nicotinic synapses on sympathetic neurons by whole-cell patch recording from the isolated intact rat superior cervical ganglion (SCG) at 36°C. To estimate synaptic size, we recorded EPSCs under voltage-clamp using minimal stimulation. We calibrated the excitatory strength of individual synapses in terms of threshold synaptic conductance (thresh-g_{syn}), measured using virtual EPSPs created by dynamic clamp. Given that nicotinic synapses are distributed over the cell body and dendrites, this raises an important methodological question. Do space clamp limitations invalidate our approach? To address this question, we took advantage of the fact that the strength of some nicotinic synapses straddles threshold when activated repeatedly at 1Hz. With minimal stimulation, we recorded trains of 100 straddling EPSPs and trains of 100 EPSCs from 10 synapses in 5 SCGs. In each case, we converted the EPSCs into a train of virtual EPSPs and used it to stimulate the same cell. To test our question, we then compared the number of action potentials evoked by the real EPSPs and the virtual EPSPs. The real EPSP trains triggered 3 to 87 spikes and the virtual EPSP trains triggered 3 to 88 spikes. The real and virtual spike numbers were well fit by linear regression (slope = 0.94, r^2=0.83, 95% confidence limits of slope = 0.60 to 1.29). Importantly, we also discovered that the excitatory strength of virtual EPSPs was very sensitive to the decay time constant of the EPSC, which was 4 ms in these experiments. This suggests that converting synaptic currents into corresponding virtual EPSPs can accurately mimic the excitatory strength of real EPSPs in these neurons. Although space clamp limitations may obscure synaptic events in distal dendrites, this hypothetical effect appears not to bias the mimcry produced by virtual EPSPs. These exploratory results provide the basis for a definitive confirmatory study. The approach described here also opens the door to detailed studies of postsynaptic integration of converging nicotinic EPSPs at synapses of known strength.

Title: The elusive role of the alpha5 nicotinic receptor subunit in prefrontal responses to acetylcholine

Authors: *S. VENKATESAN[1,2], E. E. TURNER[5,6], E. K. LAMBE[2,3,4]
[2]Dept. of Physiol., [3]Dept. of Obstetrics and Gynecology, [4]Dept. of Psychiatry, [1]Univ. of Toronto, Toronto, ON, Canada; [5]Ctr. for Integrative Brain Res., Seattle Children's Res. Inst., Seattle, WA; [6]Dept. of Psychiatry and Behavioral Sci., Univ. of Washington, Seattle, WA

Abstract: Layer 6 pyramidal neurons of the medial prefrontal cortex (mPFC) are excited robustly by acetylcholine (ACh) and are thought to be involved in top down cholinergic modulation of attention. The α5 nicotinic receptor subunit encoded by *Chrna5* is an accessory subunit that is heavily expressed in layer 6 of the PFC and is thought to affect receptor conductance and desensitization properties. Previous studies show that $\alpha5^{-/-}$ mice are impaired during demanding attentional tasks. Single nucleotide polymorphisms in *Chrna5* are also associated with increased risk of schizophrenia and smoking. However, the exact function of *Chrna5* in the cellular and network response to acetylcholine (ACh) is unknown. We performed whole cell recordings of layer 6 mPFC pyramidal neurons expressing *Chrna5* to measure responses to exogenous application of ACh in brain slices. BAC transgenic mice that express Cre from the *Chrna5* locus without the overexpression of the associated nicotinic receptor genes were generated and crossed with a ZsGreen reporter line (Ai6) to record from the labeled cells. Both male and female mice of postnatal day 36-40 were used. All labeled neurons were regular spiking, with input resistance 116 ± 11 MΩ, and resting membrane potential -86 ± 2 mV (mean ± SEM; N=16). The peak inward current elicited by bath application of 1mM ACh is twofold higher in *Chrna5* positive cells (-184 ± 17 pA, N=17 cells) compared to an unlabeled population of cells (-97 ± 7 pA, mean ± SEM; N=9 cells; p= 0.002, unpaired t test). Nonstationary fluctuation analysis of whole cell ACh currents will be used next to ascertain whether the higher response in *Chrna5* positive cells is due to increased single channel conductance of the nicotinic receptors. Our results show that there is a subpopulation of cells expressing *Chrna5* in layer 6 of the mPFC that have the highest responses to ACh. Further experiments will use *Chrna5* transgenic mice crossed with mice expressing Channelrhodopsin 2 in cholinergic neurons

(ChAT-ChR2 mice), to achieve optogenetic release of ACh. This will help understand the function of the Chrna5 expressing cells during endogenous release of ACh in the PFC. These experiments serve to elucidate the role of the α5 subunit in the cholinergic control of attention circuitry.

Title: The neurophysiological role of the interpeduncular nucleus in α5 subunit mediated nicotine responses

Authors: *S. SIVAKUMARAN[1,2], D. W. SPARKS[2], E. E. TURNER[5,6], E. K. LAMBE[2,3,4]
[2]Physiol., [3]Obgyn, [4]Psychiatry, [1]Univ. of Toronto, Toronto, ON, Canada; [5]Ctr. for Integrative Brain Res., Seattle Children's Res. Inst., Seattle, WA; [6]Psychiatry and Behavioral Sci., Univ. of Washington, Seatlle, WA

Abstract: The interpeduncular nucleus (IP) is a well-known target for the effects of nicotine with potential repercussions regarding the initial physiological reaction to this addictive drug. The α5 nicotinic receptor subunit, encoded by the *Chrna5* gene, is highly expressed in the IP and potentially conveys aversive properties of the drug. Normal *Chrna5* expression appears to be protective against the development of nicotine addiction. In humans, a single nucleotide polymorphism in *Chrna5* that disrupts function of the α5 protein, has been identified among individuals who readily develop chronic nicotine dependence. The α5 subunit likely acts as an accessory subunit and does not appear to participate directly in the nicotinic receptor binding site. Yet, it alters the conductance and desensitization parameters of nicotinic receptors. Here, we probe the contribution of the α5 subunit to baseline properties and nicotine-elicited neuronal excitability in the IP. We further examine the plasticity of these neurons following prior *in vivo* nicotine priming. For these experiments, we use whole-cell patch clamp electrophysiology in brain slices from $\alpha5^{+/+}$ and $\alpha5^{-/-}$ mice together with a novel line of transgenic mice expressing Cre-recombinase from the *Chrna5* locus. These mice were created by BAC recombineering to

manipulate α5-expressing neurons to express fluorescent reporters or optogenetic proteins without mis-expressing the α3 and β4 nicotinic receptors encoded at the same locus. We find that responses to nicotine are attenuated in the IP of $\alpha5^{-/-}$ mice, with initial examination focused on the interneurons of the rostral IP (IPR). Ongoing work will examine the electrophysiological implications of *in vivo* exposure to systemic nicotine as measured in IPR neurons, as well as the relationship between these changes and mouse behavior.

Title: Pharmacological characterization of cmpi interaction with (A4)3(B2)2 neuronal nicotinic acetylcholine receptors

Authors: F. DEBA[1,2], K. MUNOZ[2], A. TAIRU[2], *A. K. HAMOUDA[1,2]
[1]Pharmaceut. Sci., Univ. of Texas At Tyler, Tyler, TX; [2]Pharmaceut. Sci., Texas A&M HSC, Kingsville, TX

Abstract: Positive allosteric modulators (PAMs) of neuronal nicotinic acetylcholine receptors (nAChRs) have emerged as a favorable pharmacological class to enhance brain ACh signaling for potential clinical applications. They enhance ACh potency and/or efficacy by binding at site(s) distinct from the ACh binding sites and thus potentially unique to a nAChR subtype. While a number of nAChR PAMs have been identified, CMPI and NS9283 are unique because they selectively potentiate (α4)3(β2)2 nAChR. CMPI and NS9283 potentiate responses of (α4)3(β2)2 but not (α4)2(β2)3 nAChR isoforms by binding to overlapping pockets at the "non-canonical" α4:α4 subunit interface which only exists in the (α4)3(β2)2 nAChR. NS9283 and CMPI potentiation of the (α4)3(β2)2 nAChR was characterized using ACh, a full agonist of (α4)3(β2)2 nAChR that binds with higher affinity at α4:β2 agonist binding sites and with lower affinity at the α4:α4 subunit interface. In addition, ACh binding site at the α4:α4 subunit interface overlaps with the NS9283 and CMPI binding sites. Here we extend these studies to characterize NS9283 and CMPI potentiation of a panel of (α4)3(β2)2 nAChR agonists including partial agonists and agonists that bind at the α4:β2 but not α4:α4 agonist binding site. Our results indicate that NS9283 and CMPI effect on the dose-response curve of a given nAChR agonist

(enhancing its potency, efficacy, or both) depends on the agonist's ability to bind at α4:α4 subunit interface.

Title: Quantal fluctuation in transmitter release can be accounted for by fluctuations in presynaptic Ca^{2+} entry

Authors: *S. RODRIGUEZ[1], M. POTCOAVA[1], S. RAMACHANDRAN[2], S. T. ALFORD[3]
[1]Univ. of Illinois At Chicago, Chicago, IL; [2]Univ. Illinois, Chicago, Chicago, IL; [3]Dept. of Anat. and Cell Biol., Univ. of Illinois at Chicago, Chicago, IL

Abstract: Neurotransmitter release is initiated by action potential-evoked Ca2+ influx through voltage-gated Ca2+ channels (VGCCs). Various spatio-temporal Ca2+ requirements for release have been proposed in different presynaptic terminals, by Ca2+ influx through many, or few open channels with varying structural relationships to the release machinery. In some cases, channels are tightly clustered in domains close to the release apparatus, in others clustering is more diffuse. The number of functional VGCCs in central synapses appears to as few as a dozen or less. This implies that variability of channel opening between individual action potentials is high. However, this variability is difficult to measure because channels and terminals are inaccessible to direct recording approaches and imaging lacks temporal and spatial resolution to determine Ca2+ entry at active zones. We have utilized the lamprey giant reticulospinal (RS) synapse, cell attached recordings and Lattice Light Sheet Microscopy at high sampling rates to overcome these limitations. Using an acute dissociation of axons from lamprey spinal cords we recorded from presynaptic terminals devoid of apposing postsynapses. Active zone VGCCs were characterized by single channel recordings. N-type, P/Q-type, and R-type were all present with mean P_{open} for each channel type at 0 mV of 0.26 ± 0.02, 0.29 ± 0.03 and 0.22 ± 0.02 and maximum numbers of channels at each synapse of 10, 9, and 32 respectively. With a mean of 33 channels and a very small number (3-6, mean 4) of Ca2+ channels opened on single stimuli, it is likely that variation in Ca2+ entry contributes to variation in transmitter release. We imaged Ca2+ entry to RS axons in the spinal cord, using high-speed imaging with either epifluorescence or Lattice Light Sheet imaging of single planes through axons labeled with Ca2+ sensitive dyes. This reveals a reliable signal throughout the axon. Rise times were fit with single exponentials

with time constants from 5 to 20ms and decays from 1.0 to 1.5 s. However, at high temporal resolutions, Ca2+ hotspots were recorded with rise times as fast as the imaging system (3ms) and decays fit with two exponentials. The first had an extremely short decay time of 14.0 ± 0.9 ms, the second identical to the entire axon. The fast component was readily separable from the slow component and varied substantially in intensity. At a small number of high intensity sites the fast component was seen following each action potential. At a larger number of low intensity sites it failed at each location in 44 ± 11 % of action potentials. We conclude that quantal fluctuation in transmitter release can be accounted for by fluctuations in presynaptic Ca2+ entry.

Topic: B.07. Synaptic Plasticity

Title: Probabilistic synaptic plasticity induction due to stochastic gating of synaptic receptors

Authors: *C. O'DONNELL[1], Y. RODRIGUES[2], H. MARIE[3], R. J. VELTZ[2]
[1]Computer Sci., Univ. of Bristol, Bristol, United Kingdom; [2]MathNeuro, INRIA, Sophia Antipolis, France; [3]Inst. de Pharmacologie Moleculaire et Celluaire (IPMC), Valbonne, France

Abstract: When different synapses are stimulated with identical plasticity induction protocols, the magnitude and direction of plasticity typically varies from synapse to synapse. The origins of this variability are poorly understood, and its implications or possible functions for learning remain unknown.
We propose a new biophysical computational model of synaptic plasticity that depends on the dynamics of calcium signals local to the synapse. Unlike classic plasticity models that operate on the relative timing of pre- and post-synaptic action potentials, this model relies on entirely local variables: pre-synaptic glutamate pulses and dendritic spine voltage. When we simulate stochastic activation of AMPA, NMDA and VGCCs in response to glutamate pulses, we find highly variable levels of activation of calcium's downstream targets from trial to trial. We model two additional downstream pathways, Calcineurin / CamKII, using deterministic activation equations which shows high variability as consequence of stochastically-driven calcium dynamics.
We automatically fit the model's parameters to reproduce the mean activation of CaMKII and Calcineurin from Fujii et al, Cell Rep (2013) as averaged across multiple synapses. We then compare the model's prediction for the level of synapse-to- synapse variability with the same data. We are also able to capture the variability in the data with our simple model.

We then extended the model by adding a phenomenological stochastic rule that maps the activation of CaMKII and Calcineurin to synaptic strength change via addition or removal of AMPARs from the synapse. We automatically fit the parameters of this model to data from spike-timing-dependent plasticity experiments by Tigaret et al, Nat Comms (2016). We compare the predictions of the model for data from held-out plasticity protocols that it was not fit to, both for the mean outcome and the level of synapse-to- synapse variability.
The two advances from this work are: 1) a new local computational model of synaptic plasticity that is suitable for use in dendritic neuron models; 2) evidence that the variability of plasticity expression across synapses is due to stochastic gating of synaptic receptors and ion channels.

Title: Contribution of single synapses on dendritic spines to electrical signaling in individual neurons

Authors: J.-Y. WENG[1], C. CELIS[2], *D. ZECEVIC[3]
[1]Dept. of Cell. and Mol. Biol., Yale Univ. Sch. of Med., New Haven, CT; [3]Dept Cell & Mol. Physiol, [2]Yale Univ. Sch. Med., New Haven, CT

Abstract: The objective of this study was to describe the contribution of individual excitatory, glutamatergic synapses on dendritic spines to electrical signalling in single neurons. The functional role of single synapses on individual dendritic spines is important because nonclustered, widely distributed spines are active *in vivo*, as documented repeatedly (see Chen, Rochefort, Sakmann and Konnerth, 2013). We carried out experiments using a combination of electrophysiology, pharmacological tests, 2-photon uncaging of glutamate, and voltage-sensitive dye recordings from dendritic spines in rat brain cortical slices. Our goal was to analyse temporal summation of excitatory postsynaptic potentials (EPSPs) at synaptic sites on dendritic spines. We first confirmed, in several classes of principal cortical neurons, our earlier result that optical recording of electrical signals has the adequate sensitivity and spatiotemporal resolution to monitor synaptic signals in individual dendritic spines. Using these techniques, we explored the temporal summation of glutamate uncaging evoked responses that mimic unitary EPSPs. The results showed that the excitatory postsynaptic currents (EPSCs) recorded electrically from the

soma as well as EPSP signals recorded optically at the site of origin (dendritic spines) do not exhibit temporal summation up to the frequency range of 50-100 Hz. This is because local EPSP signals in spines return to the baseline in 10-20 ms at different synapses. At common physiological frequencies (below 50 Hz), this feature prevents synaptic saturation by maintaining the synaptic driving force during repetitive activation of synapses. At the same time, the somatic electrical recordings reveal a powerful temporal summation of EPSP at these frequencies due to widening of the EPSP signals as they propagate in the dendrites. We also found that, at higher frequency of synaptic activation (100 and 200 Hz), both the electrical EPSC signal from the soma and the local optical EPSP signal from spines exhibit temporal summation. However, the summating signals saturate at a range of values from 15-80 pA for EPSCs and from 3-17 mv for local EPSPs. In another series of experiments, we could not detect any changes in local EPSPs size and shape after NMDA receptors were blocked using receptor antagonist AP5. Thus, we conclude that, in slices, NMDA receptors in spines were not significantly activated either by unitary or by repetitive quantal EPSPs. Finally, we obtained preliminary data suggesting that AMPA-R desensitization is, at least partially, responsible for the saturation of local EPSP summation response in spines during repetitive synaptic stimulation.

Abstract: We discovered a new type of dendritic spine. It is found on space-specific neurons (SSNs) in the barn owl auditory map, a known site of experience-dependent plasticity. Partial

reconstruction of a >250,000 cubic micron volume derived from serial block face scanning electron microscopy (SBEM) revealed proliferate large, branched spines exhibiting unprecedented morphology and patterns of synaptic convergence. These spines are located on the soma and proximal dendrites of SSNs and most closely resemble thorny excrescences found in mammalian hippocampus and amygdala, but in contrast, typically exhibit a narrow tubular structure, lack bulbous heads, and have up to seven holes, hence 'toric' spines. No single feature is present in every spine (n = 78). More significantly, presynaptic terminals associated with individual toric spines display many active zones (max = 49) derived from multiple axons (max = 11) with incoming trajectories distributed widely throughout 3D space. This novel arrangement is well suited to integrate input sources. Compartmental simulations show that toric spines are electrically compact and predict that inputs sum to produce an approximately uniform membrane potential throughout the spine. At the same time, activation of responses at one spine are predicted to have only a negligible effect on neighboring spines. Together, these results suggest that toric spines may act as independent processing units. *In vitro* slice recordings using electrical stimulation of the input nucleus, or photorelease of caged glutamate, reveal the intrinsic and synaptic properties of SSNs, and provide a path towards uncovering the cellular computations performed by toric SSNs. Finally, complete reconstruction of synaptic convergence onto one toric spine revealed that it was unconnected with the majority of intertwined axons (connection fraction = 0.16), indicating a high capacity for new information storage. We propose toric spines are a cellular locus of information processing, plasticity and learning.

Title: Investigation of optical methods for monitoring synaptic input to ca1 pyramidal neurons

Authors: *M. ADOFF, D. A. DOMBECK
Neurobio., Northwestern Univ., Evanston, IL

Abstract: Understanding the computations performed by CA1 pyramidal neurons would benefit from precise measurements of the excitatory synaptic inputs each cell receives across the dendritic arbor. However, few approaches exist for monitoring synaptic input (glutamate release) patterns, and the sensitivity of those that do exist has not been established for CA1 pyramidal neurons. Here we evaluated the effectiveness of the fluorescent calcium indicator GCaMP6 and glutamate indicator iGluSnFR for such recordings. Presynaptic glutamate release can result in calcium influx through NMDA receptors that might be detectable with GCaMP6 as spine isolated calcium transients, but the voltage-dependent magnesium block of NMDA receptors makes these transients also dependent on the membrane potential of the postsynaptic cell. Therefore, it is unclear if presynaptic glutamate release can be detected with GCaMP6, particularly for cells near their resting potential of ~-65 mV. iGluSnFR directly binds to glutamate, is not dependent on the membrane potential of postsynaptic cell, and therefore can directly report synaptic glutamate release, but the fluorescence change upon glutamate binding is relatively small (vs GCaMP6 calcium binding), making its detection sensitivity unclear. To test the efficacy of these indicators for reporting synaptic inputs we sparsely expressed either GCaMP6s or SF-iGluSnFR.A184S in adult mouse hippocampal slices. We then stimulated individual CA1 spines using two-photon glutamate uncaging and simultaneously imaged the spines to monitor changes in fluorescence. Slices were maintained at ~32°C and bathed in ACSF containing 3 mM MNI-caged L glutamate, 1 μM TTX and 2 μM gabazine. First, using whole-cell patch clamp recording, we established the uncaging parameters (laser intensities and illumination durations) that evoked spine potentials resembling miniature EPSPs (~0.5 mV) at resting potential. Using these uncaging parameters on single spines of GCaMP6s-labeled cells resulted in detectable calcium transients during only ~25% of stimulations. When magnesium was removed from the bath, the fraction of stimulations resulting in detectable calcium transients significantly increased (~95%), suggesting that magnesium block of NMDA receptors can significantly hinder the ability to detect synaptic input to CA1 neurons at rest using GCaMP6. Conversely, using these uncaging parameters on single spines of iGluSnFR-labeled cells resulted in detectable transients (~35-50% $\Delta F/F$) during ~90% of stimulations. These findings indicate that SF-iGluSnFR.A184S may be an effective tool for optically measuring synaptic inputs to CA1 pyramidal neurons.

Title: A tight lower bound on the storage capacity of synapses in the rat middle stratum radiatum in hippocampal area CA1

Authors: *M. SAMAVAT[1], T. M. BARTOL, Jr.[2], C. BROMER[2], K. M. HARRIS[3], T. J. SEJNOWSKI[2]
[1]Computat. Neurobio. Lab., Salk Inst. For Biol. Studies, LA Jolla, CA; [2]Computat. Neurobio. Lab., Salk Inst. for Biol. Studies, La Jolla, CA; [3]Dept. of Neurosci., The Univ. of Texas at Austin, Austin, TX

Abstract: A detailed experimental analysis of a dense three-dimensional reconstruction of serial section electron microscopy from the middle of stratum radiatum in hippocampal area CA1 of rat has been analyzed to determine how much information can be stored at a synapse through synaptic plasticity. In a previous study (TM Bartol Jr, Elife 4 (2015)) the authors measured the coefficient of variation of spine head volumes of 10 same-dendrite same-axon (SDSA) pairs from this data set and applied a good guess of Signal-to-Noise Ratio (SNR) with a value of 1. Then, with a simulation analysis approach, it was found that 26 Gaussian distributions could span the range of spine sizes of the 10 SDSA pairs, implying that the storage capacity of the rat brain synapses for this region is 4.7 bits of information.
We have analyzed the complete data set of 287 spine head volumes using novel clustering approaches and advanced information theory and found that there are 42 distinguishable synaptic strengths equivalent to storing 5.39 bits of information at each synapse. This is a new tight lower bound on the storage capacity of synapses in stratum radiatum in rat hippocampal area CA1. Moreover, we determined the SNR of the synapse sizes to be 0.10 by analyzing the spine head volume clusters with fitted distributions and overlaps of consecutive clusters. Lastly, we have calculated the exact amount of overlap between the consecutive Gaussian distributions to be 56% by assuming 42 normal distributions spanning the range of 287 spine head volumes, which ranged in size over a factor of 163.

Title: Simultaneous optical and electrophysiological analysis of presynaptic excitability and GCaMP Ca^{2+} signals: Kinetic properties and spatial distribution in glutamatergic and aminergic synaptic boutons of *Drosophila* motor terminals

Authors: *X. XING[1], C.-F. WU[2]
[1]Dept. of Biol., [2]Univ. of Iowa, Iowa City, IA

Abstract: The Drosophila neuromuscular junction (NMJ) consists of tonic and phasic glutamatergic (types Ib, Is) and modulatory aminergic (type II) motor terminals. We report a first simultaneous imaging and electric recording study to directly contrast the three synapses to establish the physiological significance of their GCaMP Ca^{2+} responses. Several GCaMP variants were applied in genetic and pharmacological perturbation in low Ca^{2+} (0.1 mM), and the results reveal different combinations of K+ channel types that underlie the excitability control of type Ib, Is and II synapses. Type II synapses were most sensitive to K^+ channel perturbations, reaching extreme hyperexcitability (near saturation-level responses evoked by single stimulus), following only one insult of either Shab or eag channels, while type Is required double insults of eag with Sh, or Shab and Sh together to reach the same level of extreme hyperexcitability. In contrast, type Ib requires perturbation of triple insults, i.e. disrupting Shab and Sh, together with the application of tetraethylammonium (TEA), a broad-spectrum K^+ channel blocker. Consistent results were obtained with other mutant and drug combinations, involving TEA, 4-AP and quinidine. Simultaneous focal recording of extracellular focal excitatory junction potentials (efEJPs) showed that these striking single stimulus-evoked GCaMP signals were correlated with a remarkable high-frequency repetitive motor axon firing (> 100 Hz), representing a state of extreme hyperexcitability after deprivation of K^+ channel repolarization mechanisms. Further analysis confirmed that GCaMP responses displayed a distal-proximal gradient in type I synaptic terminals. We discovered that drug inhibition of ATP-dependent Ca^{2+} clearance or mutational enhancement of membrane excitability could obscure this gradient. However, simultaneous efEJP recording showed that the GCaMP gradient did not correlate with a clear gradient of transmitter release efficacy, a process of millisecond time course, in contrast to the slow GCaMP signals reflecting accumulation of intracellular Ca^{2+} over seconds. This simultaneous optical and

electrical measurements can provide baseline information for interpretations of GCaMP signals in the proper context of synaptic physiology.

Abstract: In previous studies, we showed that in contrast to artificial culturing media, hCSF significantly enhances neuron viability and maintenance of network activity. Keeping adult human cortical neurons intact in their physiologically built environment for functional and morphological analysis has been an intriguing strategy to study these neurons in vitro. Here we describe in detail the relative stability of adult human cortical neurons maintained in an organotypic slice culture for up to 21 days in vitro (DIV). To quantify the stability of function and morphology we measured electrophysiological parameters, including firing properties, action potential shape and synaptic properties as well as morphological properties of 3D reconstructed Layer 2/3 Pyramidal neurons in these slices over time. We found a surprisingly robust stability of the morphological features of the neurons including spine morphology and maintenance of firing properties. In addition, we used two-photon live cell imaging to investigate AAV-retro-h-Synapsin-eGFP transduced GFP expression to access the morphology of the neurons and directly measure the plasticity of the spines. These direct measurements of the morphology and physiology of adult human neurons over an extended period constitute our method an indispensable tool for investigating plasticity in human neurons in their physiologically built environment over a substantial amount of time.

Title: Patterns of presynaptic connectivity and modulation in the mouse medial prefrontal cortex

Authors: *A. L. BAKER[1], A. T. GULLEDGE[2]
[1]Dept. of Mol. & Systems Biol., Geisel Sch. of Med. at Dartmouth, Hanover, NH; [2]Geisel Sch. of Med. At Dartmouth Col., Hanover, NH

Abstract: Neocortical pyramidal neurons in layer 5 of the medial prefrontal cortex (mPFC) efficiently integrate cortical and extracortical synaptic input. Little is known about the selectivity of afferent input to these neurons, or how these presynaptic inputs are influenced by modulatory transmitters. Here, we explore the connectivity and modulation of afferent input to two broad classes of layer 5 neurons: commissural / callosal (COM) neurons that provide interhemispheric connectivity, and corticofugal neurons, including corticopontine (CPn) neurons that project to the pontine nuclei. To this end, we expressed channelrhodopsin-2 (ChR2) in three distinct afferent inputs to the mPFC: callosal input from the contralateral mPFC, thalamocortical input from the medial dorsal nucleus of the thalamus, and input from local synaptic terminals of CPn neurons. We then made simultaneous paired electrophysiological recordings of light-evoked synaptic events in physiologically-identified COM and CPn neurons. Callosal afferents targeted COM and CPn neurons with equal probability, and generated excitatory postsynaptic potentials (EPSPs) of similar magnitude in both neuron types (n = 70 pairs). Thalamocortical afferents preferentially targeted, and generated larger EPSPs in, COM neurons (n = 38 pairs). Application of tetrodotoxin (TTX) and 4-aminopyridine (4-AP) to isolate monosynaptic input revealed that both callosal (n = 12 pairs) and thalamocortical (n = 8 pairs) afferents preferentially drive COM neurons relative to CPn neurons. Preliminary results suggest that local input from CPn terminals preferentially activate CPn neurons (n = 6 pairs), a result consistent with previous studies testing unitary connections among these populations. We also tested neuromodulatory control of glutamate release from these afferents onto COM and CPn neurons. We found that serotonin (5-HT, 40 µM) modestly suppressed callosal (n = 17 pairs), but spared thalamocortical (n = 10 pairs), inputs to both postsynaptic targets. Acetylcholine (ACh, 20 µM), on the other hand, potently suppressed input from both callosal (n = 10 pairs) and thalamocortical (n = 11 pairs) afferents. We are currently testing the effect of ACh and 5-HT on glutamate release from local CPn terminals. These results contribute to our understanding of the connectivity and neuromodulatory control of cortical circuits.

Abstract: Disabling Gβγ-SNARE interaction disrupts GPCR-mediated presynaptic inhibition leading to physiological and behavioral phenotypes.
Zack Zurawski, Analisa D. Thompson Gray, Lillian J. Brady, Brian Page, Emily Church, Nicholas A. Harris, Michael R. Doh[n], Yun Young Yim, Karren Hyde, Douglas P. Mortlock, Danny G. Winder, Simon Alford, Carrie K. Jones, Heidi E. Hamm
$G_{i/o}$-coupled receptors modulate neurotransmission presynaptically through inhibition of exocytosis. Release of Gβγ subunits decreases the activity of voltage-gated calcium channels (VGCC), decreasing excitability. A less understood Gβγ-mediated mechanism downstream of calcium entry is the binding of Gβγ to SNARE complexes. Here, we create a transgenic mouse via CRISPR-Cas9 partially deficient in this interaction by premature truncation of the SNAP25 carboxy terminus by three residues. The SNAP25Δ3 mutation results in inhibited Gβγ-SNARE binding and diminished ability of Gβγ to compete with synaptotagmin 1 for binding sites on SNARE complexes. SNAP25Δ3 homozygote animals are viable, with a normal appearance, and have normal presynaptic inhibition by $GABA_B$ receptors that inhibit voltage gated calcium channels. Despite this, they exhibit deficits in presynaptic inhibition by receptors that work directly on the SNARE complex such as $5\text{-}HT_{1b}$ and α_{2a} receptors. Simultaneously stimulating receptors that work by both mechanisms show synergistic inhibitory effects. The SNAP25Δ3

homozygote exhibits a number of behavioral phenotypes, including elevated stress-induced hyperthermia, and defective spatial learning, as well as impaired gait and supraspinal nociception. In addition, differences in insulin sensitivity and food intake are observed. The individual $G_{i/o}$-coupled GPCRs responsible for these deficits have yet to be elucidated. These data suggest that $G_{i/o}$-coupled GPCR
inhibition of exocytosis through the Gβγ-SNARE interaction is a crucial component of numerous physiological and behavioral processes.

Title: Connexin36 in the mouse inferior olive is a component of the post-synaptic protein complex of glutamatergic synapses

Authors: Z. ZHU[1], J. D. LAUTZ[1], E. A. BROWN[1], S. E. P. SMITH[1,2], *J. P. WELSH[1,2]
[1]Ctr. for Integrative Brain Res., Seattle Children's Res. Inst., Seattle, WA; [2]Pediatrics, Univ. of Washington, Seattle, WA

Abstract: Connexin36 (Cx36) is the protein that forms electrical synapses between the dendritic spines of inferior olivary (IO) neurons. Such electrical synapses are essential for robust and continuous oscillations in membrane potential that are synchronized among coupled IO neurons. NMDA receptor activation strengthens weak electrical coupling among IO neurons and there is strong co-localization of Cx36 and the GluN1 subunit of the NMDA receptor in IO dendritic spines (Turecek *et al* 2014). To further our understanding of how Cx36 and NMDA receptors interact, we investigated at the level of protein-protein association whether Cx36 interacts with proteins comprising the glutamatergic postsynaptic density (PSD). Protein lysates were prepared from the IO of adult mice dissected from the brainstem. The first experiment used western blot and demonstrated that Cx36 and GluN1 co-immunoprecipitate from IO lysates of c57BL/6J wild-type mice. The second experiment exposed IO lysates from 4 wild-type mice to a panel of 18 antibodies against glutamate synapse proteins conjugated to specific Luminex bead regions, before separation into 96 well plates and secondary incubation with a panel of 21 fluorophore-

conjugated antibodies (Lautz *et al* 2018). This Quantitative Multiplex co-Immunoprecipitation (QMI) technique measured 207 binary combinations of synaptic proteins to determine the relative frequency that Cx36 occurs in shared complexes with glutamate synapse proteins. Cx36 was found to exist in protein complexes containing the glutamate receptor subunits GluN1 and GluR2, as well as scaffolding proteins Shank1, Shank3 and Homer1, signaling proteins Homer1a and SynGap, and the structural protein neuroligin3. The experiment was repeated in 4 pairs of mice, each pair containing a wild-type mouse and a mouse heterozygous for deletion of the C-terminus of Shank3 protein [*Shank3*(+/ΔC)]. Direct pairwise comparisons by QMI revealed significant or trend-level reductions in the association of Cx36 with GluN1, GluR2, and SynGap in *Shank3*(+/ΔC) mice as compared to the wild-type, all of which were replicated and quantified to be significant 30-50% reductions by immunoprecipitation determined by flow cytometry. As initially found in goldfish (see Pereda 2014), our results support the view that neuronal electrical synapses are integrated into the cellular machinery of chemical synapses via structural interactions of Cx36 with glutamatergic PSD proteins. Our results extend the concept to mouse by indicating that Cx36 may be part of an "extended postsynaptic complex" that allows neuronal gap junctions to be scaffolded by shank3 to the glutamatergic PSD.

Title: Calpain-2 conditional knockout mice are resistant to cell death induced by traumatic brain injury

Authors: *Y. WANG, Y. LIU, J. SUN, A. MCCLOUD, S. BIAGI, X. BI, M. BAUDRY
Western Univ. of Hlth. Sci., Pomona, CA

Abstract: Our laboratory has recently reported that two of the major isoforms of calpain found in the brain, calpain-1 and calpain-2, play opposite functions in both synaptic plasticity and neuroprotection/neurodegeneration. In particular, while calpain-1 activation is required for long-term potentiation (LTP) induction and is neuroprotective, calpain-2 activation limits the magnitude of LTP and is neurodegenerative. Homozygous disruption of the calpain-2 gene results in pre-implantation embryonic lethality. Here, we created a calpain-2 conditional knockout (CKO) mouse by crossing loxP-calpain-2 mice with Cre-CamKII promoter mice.

These mice do not express calpain-2 in excitatory neurons of the forebrain. Roles of calpain-1 and calpain-2 were then examined by comparing calpain-1 KO mice and calpain-2 CKO mice and their controls under different conditions. Cultured hippocampal neurons from calpain-1 KO mice at 21 days *in vitro* had significantly more filopodia-like immature spines, as compared to neurons from WT mice, while cultured hippocampal neurons from calpain-2 CKO mice exhibited normal spine morphology. During postnatal development, calpain-1 KO mice exhibited enhanced neuronal apoptosis throughout the cerebrum and cerebellum, while calpain-2 CKO mice showed the same levels of apoptosis rate as wild-type (WT) mice. Calpain-1 KO mice had enhanced cell death and larger lesion volume in the ipsilateral cortex and hippocampus after traumatic brain injury (TBI), as compared to WT mice. In contrast, calpain-2 CKO mice had reduced cell death and smaller lesion volume, as compared to WT mice, thereby confirming our previous result that pharmacological inhibition of calpain-2 by a selective calpain-2 inhibitor reduced TBI-induced cell death. In summary, these results indicate that calpain-1 and calpain-2 have separate functions in the brain and that selectively inhibiting calpain-2 could be protective in various brain diseases without disrupting the physiological functions of calpain-1.

Title: A smarter mouse created by conditional deletion of calpain-2 gene in forebrain using the Cre/loxP system

Authors: *Y. LIU, S. BIAGI, K. BROWN, Y. WANG, J. SUN, X. HAO, X. BI, M. BAUDRY
Western Univ. of Hlth. Sci., Pomona, CA

Abstract: The hypothesis that calpain plays a significant role in synaptic plasticity and learning and memory was proposed in 1984. Since then, many studies have been directed at understanding the roles of various calpain isoforms in numerous cell functions and in the nervous system. Our laboratory has recently shown that two of the major isoforms found in the brain, calpain-1 and calpain-2, play opposite functions in both synaptic plasticity/learning and memory and neuroprotection/neurodegeneration. In particular, while calpain-1 activation is required for long-term potentiation (LTP) induction and for certain forms of learning and memory, calpain-2 activation limits the magnitude of theta burst stimulation (TBS)-induced LTP. We previously

reported that a relatively selective calpain-2 inhibitor enhanced LTP magnitude and learning & memory by prolonging ERK activation. Homozygous disruption of the Calpain-2 gene results in pre-implantation embryonic lethality between the morula and blastocyst stage (Previn Dutt, 2006). We used the Cre/loxP system to create a conditional calpain-2 knockout mouse by crossing a loxP-calpain-2 with a Cre-CamKII promoter mouse. These mice do not express calpain-2 in excitatory neurons in the forebrain. The C2KO mice displayed enhanced TBS-induced LTP in field CA1 of adult hippocampal slices, and enhanced context-fear memory in the fear conditioning paradigm. Performance in the tone test was not significantly different for that of respective control mice. The results confirm the results obtained with the selective calpain-2 inhibitor and strengthen the importance of calpain-2 function in learning and memory. This conditional calpain-2 knockout mouse represents a powerful tool for further exploring the role of calpain-2 function in brain. Our results also indicate that a selective calpain-2 inhibitor could be very beneficial in various diseases associated with learning and memory impairment.

Title: Slow glutamate clearance triggers postsynaptic calcium amplification and impairs synaptic plasticity via calpain-2

Authors: *J. R. BARNES, M. P. PARSONS
Biomed. Sci., Mem. Univ. of Newfoundland, St John's, NL, Canada

Abstract: Recent evidence suggests that poor glutamate clearance may contribute to the synaptic plasticity deficits observed in various neurodegenerative diseases. Presumably, the plasticity deficit is triggered by over-activation of extrasynaptic NMDA receptors (exNMDARs). As glutamate transporters limit exNMDAR activation by rapidly clearing glutamate from the extracellular space, an attractive and well-cited hypothesis states that glutamate transporter dysfunction underlies the long-term potentiation (LTP) and cognitive impairments in disease states. However, the precise relationship between the spatiotemporal dynamics of extracellular glutamate and synaptic plasticity has yet to be investigated. Here, we used a novel optogenetic sensor of glutamate, termed iGluSnFR, to monitor extracellular glutamate dynamics in real-time (205 Hz) in the mouse hippocampus during standard LTP-inducing protocols. We found that TBOA, a non-selective glutamate transporter blocker, slowed glutamate clearance and inhibited LTP magnitude in a concentration-dependent manner. The TBOA-induced LTP impairment was

not a result of the simultaneous activation of competing long-term depression (LTD) pathways, including presynaptic LTD, NMDAR-dependent LTD, or postsynaptic metabotropic glutamate receptor-dependent LTD. Surprisingly, impaired glutamate clearance during LTP induction caused rapid NMDAR desensitization, indicating that NMDAR over-activation cannot explain the subsequent LTP impairment. Despite NMDAR desensitization, GCaMP6f calcium imaging revealed that postsynaptic calcium transients were increased three-fold during LTP induction when glutamate uptake was compromised by TBOA. This elevated calcium response, which resulted from both L-type voltage-gated calcium channel activation and the release of internal calcium stores, was sufficient to recruit the calcium-dependent protease calpain-2 that limits LTP strength. In all, our data characterize the relationship between glutamate dynamics and LTP, and identify a novel mechanism underlying LTP impairment in cases where glutamate uptake is compromised. These results may be applicable to numerous neurodegenerative diseases associated with impaired synaptic plasticity and glutamate transporter dysfunction, including Alzheimer and Huntington disease.

Title: SynDIG4/Prrt1 establishes a reserve pool of extra-synaptic AMPARs required for LTP

Authors: *E. DIAZ, K. E. PLAMBECK, D. J. SPECA
Dept Med. Pharmacol, UC Davis Sch. of Med., Davis, CA

Abstract: Altering AMPA receptor (AMPAR) content at synapses is a key mechanism underlying the regulation of synaptic strength during learning and memory. Previous work demonstrated that SynDIG1 (SD1; synapse differentiation-induced gene 1) encodes a transmembrane AMPAR-associated protein that regulates excitatory synapse strength and number in vitro and in vivo (Kalashnikova et al., 2010; Chenaux et al., 2016). Activity-dependent palmitoylation underlies SD1 localization and function at synapses (Kaur et al., 2016). Previously, we demonstrated that loss of the related protein SynDIG4 (SD4; also known as Prrt1) results in reduced extra-synaptic AMPARs while long term potentiation (LTP) is abolished by single tetanus stimulation of hippocampal slices from SD4-knockout (KO) mice (Matt, Kirk, Chenaux et al. 2018). We hypothesize that SD4 regulates AMPAR trafficking through maintenance of an extra-synaptic pool of GluA1-containing AMPARs required for LTP. Here we

investigate the role of SD4 in synaptic targeting of GluA1-containing AMPARs during LTP. We find that surface GluA1-containing AMPARs are reduced in SD4-KO hippocampal neurons compared with WT cultures. Furthermore, synaptic targeting of GluA1-containing AMPARs from extra-synaptic sites is abolished during glycine-induced chemical LTP (chemLTP) in SD4-KO hippocampal neurons. Intriguingly, chemLTP stimulus of primary hippocampal neurons results in increased co-localization between SD4 and GluA1-containing AMPARs at both synapses and extra-synaptic sites, suggesting that at least some proportion of a SD4-AMPAR complex traffics to the synapse during LTP. Super-resolution microscopy is currently being employed to determine the precise subcellular localization of SD4 in relationship with GluA1-containing AMPARs in hippocampal neurons during chemLTP. SD4 is palmitoylated at two conserved cysteine residues and experiments are in progress to determine the role of activity-dependent palmitoylation in SD4-dependent chemLTP. Given that LTP requires an extra-synaptic pool of AMPARs, these data are consistent with a model whereby SD4 establishes an extra-synaptic pool of GluA1-containing AMPARs and is required to facilitate their trafficking to the synapse during LTP.

Abstract: Impaired synapse function is the underlying cause of many brain disorders including Alzheimer's disease, schizophrenia, intellectual disabilities and Huntington's disease. Emerging evidence suggest that palmitoylation, the reversible addition of the fatty acid, palmitate, to substrate proteins, is disrupted in many of these neurological and psychiatric disorders. Palmitoylation is mediated by a family of 23 DHHC (Asp-His-His-Cys) enzymes and almost half of DHHC enzymes have been associated with disorders of the brain including Alzheimer's disease (DHHC12), schizophrenia (DHHC5, DHHC8 and DHHC18), intellectual disability (DHHC9, DHHC12 and DHHC15), Huntington's disease (DHHC12 and DHHC17). Presynaptic and postsynaptic membranes are enriched in palmitoylated proteins with over 41% of all synaptic proteins reported as substrates for palmitoylation. Palmitoylation of a few synaptic proteins have been to be shown to be regulated by synaptic activity suggesting that this post-

translational modification may be important for the plasticity of synaptic connections. However, a comprehensive proteomic analysis of all proteins that are differentially palmitoylated following increased synaptic activity is lacking and is essential to understand disrupted synaptic function in neurological disorders. We are currently examining the role of palmitoylation during activity-mediated synaptic plasticity. Using primary hippocampal culture and hippocampal lysates we aim to elucidate differential palmitoylation of synaptic substrates following chemical LTP and fear conditioning, respectively.

Title: Distinct patterns of long-term potentiation within the hippocampal CA1 stratum radiatum

Authors: T. L. FONG, J. S. THACKER, Y. XU, B. LAIRD, *J. G. MIELKE
Sch. of Publ. Hlth. and Hlth. Systems, Univ. of Waterloo, Waterloo, ON, Canada

Abstract: Long-term potentiation (LTP) is the most widely studied model of synaptic plasticity and is regarded as a critical cellular mechanism underlying learning and memory. For several decades, a large proportion of LTP experiments have taken advantage of the conserved neurocircuitry in the acutely prepared hippocampal slice; in particular, these studies have stimulated the Schaffer collaterals and measured responses in the CA1 stratum radiatum. However, large variations in the magnitude and induction patterns of LTP exist in the literature, which makes cross study comparisons challenging. One possible reason for these variations may be differences in the placement of the recording electrodes in these reports, which is notable given that increasing evidence suggests synapses within the CA1 stratum radiatum are not homogeneous. Hence, we investigated the possibility that LTP within the CA1 stratum radiatum of hippocampal slices, induced either electrically (with a 100 Hz tetanus), or chemically (using tetraethylammonium, glycine, and modified levels of Ca^{2+} and Mg^{2+}), would vary with respect to the distance between the recording position and the pyramidal somata. Using a multi-electrode array recording system, we examined LTP expression approximately 100, 200, and 300 μm away from the cell body layer in the stratum radiatum of acutely prepared rat hippocampal slices. Preliminary results show that LTP induction patterns and magnitude is different among the three recording points. In particular, tetanus induced the greatest magnitude of LTP expression at points that were 100 μm from the pyramidal cell layer. Furthermore, LTP induced by chemical

means was also substantially different across the recording points. Specifically, an immediate and dramatic increase in response amplitude was followed by an eventual decrease during washout at points 100 μm and 200 μm from the soma; in contrast, an immediate decrease was seen at points 300 μm away, and was followed by an increase during washout. Our results show that LTP is not homogeneously expressed within the CA1 stratum radiatum (regardless of the method of induction) suggesting the coexistence of multiple patterns of synaptic plasticity in the region. Furthermore, we have demonstrated the importance of precisely documenting recording position in LTP experiments involving the hippocampal slice.

Title: The interplay of interactions controlling postsynaptic AMPA receptor localization in synaptic transmission and plasticity

Authors: *J. F. WATSON[1], H. HO[2], A. PINGGERA[2], I. H. GREGER[2]
[1]MRC Lab. of Mol. Biol., Cambridge, United Kingdom; [2]MRC LMB, Cambridge, United Kingdom

Abstract: AMPA receptors (AMPARs) are localized at the postsynaptic membrane, mediating fast excitatory synaptic transmission on presynaptic glutamate release. A multitude of protein interactions have been identified, modulating receptor trafficking, gating and localization at synaptic sites, both intracellularly in the postsynaptic density, and extracellularly in the synaptic cleft. Controlling the postsynaptic AMPAR content is a critical mediator of synaptic plasticity, and a cellular mechanism of learning and memory. Recruitment and stabilization of additional AMPARs at postsynaptic sites allows synaptic strengthening, and therefore the interactions controlling receptor enrichment at synaptic sites are fundamental to our understanding of information storage in the brain.
Recent insights into synaptic function demonstrate that not only is postsynaptic recruitment of receptors important for transmission, but their precise sub-synaptic localization is essential for transmission fidelity, and control of this positioning could mediate synaptic plasticity. Both intracellular interactions with the postsynaptic density, mediated by the TARP auxiliary subunits,

and extracellular interactions of the AMPAR NTD control the synaptic localization of the receptor. Using electrophysiological and imaging techniques in wild-type and AMPAR-null neurons, we dissect the interplay between these interactions, and their roles in the positioning of AMPARs at the synapse. These interactions can act differentially to fine-tune the postsynaptic response, underlying the synapse-specific changes occurring during synaptic transmission and plasticity.

Title: Diverse changes in synaptic plasticity at distinct inhibitory synapses within the CA1 region of the mouse hippocampus

Authors: *M. UDAKIS, S. E. L. CHAMBERLAIN, J. R. MELLOR
Bristol Univ., Bristol, United Kingdom

Abstract: The hippocampus hosts a complex diversity of inhibitory interneurons which form an integral component of hippocampal network function. Despite some overlapping expression, Parvalbumin (PV) and Somatostatin (SST) expressing interneurons are generally considered to form synapses onto proximal and distal regions of pyramidal cells respectively [1.] They are therefore considered to perform distinct roles in network activity and alterations in synaptic inhibition at these synapses may have profound impacts on the hippocampal network. One mechanism for altering network inhibition is the capacity of inhibitory connections to undergo synaptic plasticity - increasing or decreasing the 'strength' of inhibition. However, the requirements for PV and SST synapses to undergo plasticity and the network consequence of altering the level of inhibition at these synapses remains unclear.
To investigate inhibitory plasticity, using whole-cell patch-clamp electrophysiology we recorded inhibitory synaptic transmission from CA1 pyramidal cells in acute hippocampal slices. We selectively stimulated inhibitory synapses arising from PV or SST expressing interneurons using PV-Cre or SST-Cre transgenic mice crossed with Ai32 mice expressing Cre-dependent channelrhodopsin (ChR2). Short light stimuli evoked Inhibitory Postsynaptic Currents (IPSCs) in slices from both PV-ChR2 and SST-ChR2 mice but with markedly divergent characteristics. In agreement with the proposed proximal vs distal targeting, the IPSC kinetics for PV IPSCs were faster than SST IPSCs for both rise and decay times. Furthermore, paired pulse ratios for PV

IPSCs were lower than SST IPSCs consistent with the prominent paired pulse depression observed at PV synapses. High frequency stimulation of inhibitory synapses led to long-term depression (iLTD) and long-term potentiation (iLTP) of PV IPSCs and SST IPSCs respectively. Both forms of plasticity were independent of glutamatergic activity since they were not prevented by inclusion of AMPA/kainate and NMDA receptor antagonists NBQX and D-AP5. By selectively activating distinct inhibitory synapses via optogenetics, we show that two interneuron populations exhibit opposing changes in synaptic weight in response to high frequency stimulation. This may provide a mechanism by which these two interneuron populations can regulate and update hippocampal network function in response to ongoing activity patterns.

Title: Synaptic function of microRNA-34a

Authors: J.-Y. WANG, X. MIN, *K.-W. HE
IRCBC, Chinese Acad. of Sci., Shanghai, China

Abstract: MicroRNAs (miRNAs) are a group of short non-coding transcripts that play essential role in post-transcriptional modulation. They function by binding and further suppressing the translation or destabilizing the target mRNAs. Hundreds of miRNAs have been discovered, but their roles are scarcely known. Here we focus on understanding the neuronal function of miRNA-34a, one of the miRNA-34 family that is mostly enriched in the brain. By taking advantage of the miRNA-34a +/- mice, which has about 40% of miRNA-34a left in the hippocampus compared to their wildtype litter mates, we found miRNA-34a was a key regulator of synaptic plasticity in the schaffer collateral synapses.

Title: Endogenous neuropeptide Y release attenuates long-term potentiation in the temporoammonic pathway of hippocampus

Authors: *Q. LI, L. E. DOBRUNZ
Neurobio., Univ. of Alabama at Birimgham, Birmingham, AL

Abstract: Neuropeptide Y (NPY) is one of the most abundantly expressed neuropeptides in the central nervous system, and it has emerged as an important mediator of stress, neuroplasticity and memory processes. Multiple studies using acute or chronic administration of NPY receptor agonists and antagonists have supported a role for NPY in different functions of learning and memory. However, far less is known about how endogenous NPY release affects long-term synaptic plasticity. We have previously shown that release of endogenous NPY can modulate short-term plasticity at temporoammonic (TA) synapses onto hippocampal CA1 pyramidal cells. In particular, endogenous NPY release can be detected by observing NPY receptor dependent changes in short-term plasticity during stimulation with a physiologically-based spike train (PST). To test whether endogenous NPY release can also affect long-term potentiation (LTP), we first tested whether PST stimulation can induce LTP in the TA pathway. We find that PST stimulation induces robust potentiation of TA synapses that is maintained for at least 1 hour, indicating that it is LTP. In addition, the selective NMDA receptor antagonist AP5 prevents the induction of TA LTP by PST stimulation, indicating this type of LTP is NMDA receptor dependent. To improve the efficiency of NPY release, we used NPY Cre/ChR2 mice that express channelrhodopsin 2 in NPY interneurons; this enables us to directly activate NPY cells using photostimulation to cause NPY release. To test the effects of endogenously released NPY on PST induced LTP, we used combined electrical stimulation of the TA pathway and optical stimulation of NPY cells applied simultaneously during the PST protocol. The combined stimulation also consistently induces TA LTP lasting over 1 hour. Blocking NPY receptors with the Y1 antagonist BIBP and the Y2 antagonist BIEE before PST stimulation caused a significant increase in the magnitude of LTP. This indicates that endogenous NPY release can attenuate LTP in the TA pathway. This study is the first demonstration of the impact of endogenously released NPY on long-term plasticity in the TA pathway, and provides a possible link between NPY's effects on circuit function and its role in regulating hippocampal-dependent behavior.

Abstract: Changes in the structure and function of synapses underlie learning and memory. We have recently demonstrated a novel role for netrin-1, a chemotropic guidance cue, in activity-dependent synaptic plasticity through activation of the canonical netrin-1 receptor, deleted-in-colorectal cancer (DCC). These findings suggest that dynamic trafficking of DCC may contribute to on-going modification of cellular excitability and synapse function. Plasma membrane distribution of DCC is regulated by strong depolarization induced by changes in extracellular K^+ concentration. Excitatory neuromodulation, such as cholinergic receptor activation, may contribute to network connectivity via promoting dynamic changes in DCC distribution through potent depolarization of membrane potential. Here, we show that muscarinic and nicotinic cholinergic-induced membrane depolarization recruits DCC to the plasma membrane of cultured cortical neurons. Cholinergic receptor activation also increases DCC co-localization with both pre- and post-synaptic markers. In adult brain slices, we show that bath application of netrin-1 facilitates cholinergic-mediated persistent firing activity in layer V entorhinal neurons in acute adult brain slices, a form of long-lasting depolarization that has been associated with working memory processes. Together, these findings show that acetylcholine can modulate cortical synapses through the active recruitment of DCC, and this can, in turn, promote synaptic plasticity via enhancement of netrin-1-signaling.

Abstract: Background: Long-Term Potentiation (LTP) of the Schaffer collateral pathway in the hippocampus is a well-established cellular model of learning and memory. Although it is based on changes in excitatory synaptic transmission, LTP is also under the control of GABAergic inhibition. To test whether α5-$GABA_A$Rs located on interneurons are instrumental in controlling LTP, we created mice that lack α5 subunits in interneurons. Here we compared LTP in "pseudo-WT" mice that are homozygous for the a5 floxed allele α5-$GABA_A$Rs (fl/fl-α5) vs. "true WT" C57BL/6J (WT) mice, and assessed the effects of the $GABA_A$R modulator etomidate (ETOM, 1μM) on LTP in WT, fl/fl-α5, and interneuron-specific α5-$GABA_A$R knockout mice.
Methods: To generate mice lacking α5-$GABA_A$R subunits in interneurons, we crossed fl/fl-α5 mice with fl/fl-α5 fl/fl-a5 mice also expressing Cre-recombinase under the control of the vesicular inhibitory amino acid transporter (VIAAT) promoter. We measured population EPSPs in coronal hippocampal brain slices by stimulating the Schaffer collateral pathway and recording from the *stratum radiatum* in the CA1 region. To induce LTP we used a theta-burst stimulus (TBS) consisting of one train of 40 stimuli, delivered as ten 100Hz bursts of 4 stimuli each repeated at 5Hz (TBS-40), or three such trains separated by 20 seconds (TBS-120). Recordings continued for 1 hour post-TBS. LTP was expressed as the % increase of the average EPSP slope during the last 10 minutes of recording. Groups were compared using Student's t-test.
Results: There were two differences between WT vs. pseudo-WT (fl/fl-α5) mice: i) LTP produced by TBS-120 under drug-free conditions was significantly greater in WT compared to fl/fl-α5 mice (60±9% vs. 43±4%, p=0.007); and ii) ETOM suppressed TBS-120 LTP in WT (65±9% vs. 40±6%, p=0.02) but not in fl/fl-α5 mice (43±4% vs. 43±5%, p=0.49). However, ETOM was able to suppress LTP in fl/fl-α5 mice using the weaker TBS-40 stimulus (38±2% vs.

17±3%, p<0.0001). We also found two differences between fl/fl-α5 and VIAAT-α5-KO mice: i) there was a trend toward lower potentiation in VIAAT-α5-KO vs. fl/fl-α5 mice (25±5% vs. 38±4%, p=0.06); and ii) VIAAT-α5-KO mice resisted LTP suppression by ETOM (25±5% vs. 14±5%, p=0.07).
Conclusions: The differences between WT and fl/fl-α5 mice indicate that the a5 floxed allele mutation is not entirely silent. Acknowledging this change in background characteristics, the lack of effect of ETOM in VIAAT-α5-KO mice, and the trend toward reduced LTP in these mice, indicate that α5-$GABA_A$Rs located on interneurons are instrumental in GABAergic control of synaptic plasticity.

Title: Effects of social isolation rearing and ketamine on hippocampal synaptic plasticity

Authors: *J. B. LOGUE[1], K. J. SCHOEPFER[2], Y. ZHOU[3], M. KABBAJ[4]
[1]Col. of Med., [2]Dept. of Biomed. Sci., [4]Biomed. Sci., [3]Florida State Univ., Tallahassee, FL

Abstract: Social isolation is a long-term stressor that produces lasting effects including memory deficits, cognitive impairments, and hippocampal functional and structural alterations. Ketamine (KET) is a non-competitive N-methyl-d-aspartate receptor (NMDAR) antagonist currently of interest for its antidepressant effects at subanesthetic doses. Previous work in our lab has shown that the subject's sex and gonadal hormone status play a critical role in mediating sensitivity to the antidepressant-like effects of KET in rats, as female rats behaviorally respond to a lower dose of KET than males, an effect that requires both estradiol (E2) and progesterone (P4) on-board. However, electrophysiological mechanisms underlying female-specific dose sensitivity remain unclear. This study aims to investigate the interaction between social isolation rearing stress and low-dose KET on hippocampal synaptic plasticity in rats of both sexes. We hypothesize that: 1. The field excitatory post-synaptic potentials (fEPSPs) in dorsal hippocampus Schaffer collateral (CA3-CA1) synapses may be impaired by isolation stress in both sexes, 2. A single low dose of KET (2.5 mg/kg, i.p.) given *in-vivo* 3hr prior to slice recording may rescue stress-induced fEPSP deficits in females, but not males, 3. Female-specific KET rescue effects may be modulated by

estrous stage (Proestrus: high E2/P4, Diestrus: low E2/P4), and 4. Stress-induced fEPSP deficits in both sexes may be ameliorated with a single treatment of 5 mg/kg KET (i.p.). Postsynaptic plasticity is evaluated by measuring tetanic stimulation-induced long-term potentiation (LTP), while the responsivity of the synapse to electrical stimulation is measured with fEPSP input-output curves and presynaptic transmitter release probability is measured by paired-pulse facilitation experiments. Completion of this project will generate insights into the interactions between gonadal hormones and KET at this synapse and the potential restoration of neural plasticity.

Title: Activity in the ventral-tegmental area modulates synaptic plasticity in the insular cortex

Authors: *L. F. RODRIGUEZ-DURAN[1], M. L. ESCOBAR[2], F. BERMÚDEZ-RATTONI[3]
[1]IFC, UNAM, Ciudad de Mexico, Mexico; [2]UNAM, Fac Psicologia, Mexico City, Mexico; [3]Inst. de Fisiología Celular, Mexico City, Mexico

Abstract: It is widely accepted that the consumption of addictive substances modifies the activity of the mesocorticolimbic dopamine (DA) system. This system originates in the ventral tegmental area (VTA) and projects to cortical areas, including the insular cortex (IC). The agranular IC in its rostral region also receives afferents from the basolateral amygdaloid nucleus (Bla). In this sense, it has been reported that Bla is involved in the search for cocaine and heroin. Previous studies show that in vivo tetanic stimulation of Bla induces long-term potentiation (LTP) in IC, and this synaptic facilitation can modulate learning. In this work, we analyze whether the LTP induced by Bla-CI could be modulated by activating the VTA-DA pathway. For this purpose, we injected stereotaxic vectors expressing channelrhodopsin-2 (ChR2) -eYFP in the VTA of transgenic TH-Cre mice. Then the animals underwent implantation of electrodes in the Bla-IC projection. The mice were subjected to 15 minutes of VTA optogenetic stimulation. Within this time period, the mice received high frequency stimulation (1s, 100 Hz, 10x trains) in order to induce LTP in the Bla-IC pathway. Our results showed that animals that underwent VTA optogenetic stimulation in the VTA expressed an increase in the magnitude of LTP

compared to the e-YFP controls. These results suggest that the Bla-IC synaptic plasticity can be modulated by VTA-dopaminergic neurons, and that the IC plays a role in the modulation of addictive memories.

Title: Cell surface expression of GluA1-containing AMPA receptors is enhanced by secreted amyloid precursor protein-alpha; visualized by BioPLAy

Authors: *J. M. WILLIAMS[1], M. K. ELDER[2], W. P. TATE[1]
[1]Univ. of Otago, Dunedin, New Zealand; [2]Ctr. for Neural Sci., New York Univ., New York City, NY

Abstract: Cell surface expression of AMPA-sensitive glutamate receptors (AMPARs) is tightly regulated. All AMPARs permit flux of sodium and potassium ions, but receptors composed of GluA1/2 subunits possess slower ion channel kinetics, and allow greater ion flux than GluA2/3 AMPARs. While the later continuously cycle in and out of the postsynaptic membrane, GluA1-containing AMPARs are trafficked to the membrane in response to depolarization, thus underpinning synaptic plasticity. Furthermore, calcium-permeable GluA1-homomeric receptors are suggested to insert transiently into the synaptic membrane in response to stimulation. Visualizing modulations in glutamate receptor surface expression is key to understanding the mechanism/s underpinning long-term potentiation (LTP)-enhancing agents such as secreted amyloid precursor protein-alpha (sAPPα). Existing light microscope methods are limited by the requirement for a primary antibody recognizing surface-expressed epitopes and challenged by low surface expression. We have developed a technique to quantify changes in the surface expression of target proteins. BioPLAy combines membrane-impermeable biotin tags with the specificity and amplification properties of the proximity ligation assay (PLA), enabling highly sensitive, subregion-specific analysis of target proteins. As proof of concept, we present BioPLAy-mediated detection of surface levels of GluA1-containing AMPARs on dendrites of cultured primary hippocampal neurons. Cells (>DIV25) were exposed to glycine (100 μM, 20 min), to induce chemical LTP, or stimulated with sAPPα (1 nM; 2 h). BioPLAy was carried out by sequential incubation with Sulfo-NHS-SS-biotin (2.5 mg/mL; Pierce), anti-GluA1 (Abcam) and anti-biotin (Sigma) primary antibodies followed by the PLA (Duolink PLA rabbit^{plus} and mouse^{minus} probes) and signal amplification (Duolink). Using BioPLAy we found both glycine

(1.49 ± 0.16; 5-10 neurons/experiment, 3 experiments per condition; one sample t test p = 0.004) and sAPPα (1.95 ± 0.23; 10-16 neurons/experiment, 3 experiments per condition; one sample t test p = 0.0003) induced a robust increase in surface expression of GluA1. Incubation of cells without anti-GluA1 antibody, or without the biotinylation step precluded production of BioPLAy signal. Together, these data support BioPLAy as a valid tool for investigating changes in surface expression of target molecules following various stimuli, and support the hypothesis that sAPPα facilitates LTP through the increased availability of GluA1-containing AMPARs.

Title: Lactate induces a Hebbian form of LTP on the recurrent collateral synapses of hippocampal area CA3

Authors: *G. HERRERA-LOPEZ, E. J. GALVAN
CINVESTAV SUR, Mexico City, Mexico

Abstract: Neuronal activity within physiological range is accompanied by the production of lactate, a metabolic intermediate involved in the production of ATP. However, at the central level, lactate receptors (HCA1) were recently described, and increasing evidence supports the notion that activation of HCA1 controls neuronal excitability at various levels. Here, we explored the effects of external perfusion of lactate on the synaptic transmission converging on CA3b pyramidal cells of the hippocampus. Baseline Mossy Fiber (MF)- or Recurrent Commissural (RC)-evoked EPSC were acquired in acute slices, and lactate (1 or 2 mM) was perfused for 10 min. Lactate caused a sustained increase in the RC-EPSP that lasted up to 30 min after lactate washout (184% of basal response). Contrary to this, isolated MF EPSCs (in the presence of D-AP5 + bicuculline) did not exhibit such increase induced by lactate perfusion. The enhancement of the RC EPSC was abolished entirely when NMDARs were blocked with D-AP5. Similar results were found when CA3 pyramidal cells were intracellular loaded with BAPTA (20 mM) or were held at -100 mV during perfusion of Lactate, indicating a postsynaptic locus of RC LTP. In the presence of α-cyano-4-hydroxycinnamic acid (4-CIN; 0.5 mM;), a monocarboxylate-transporter blocker, or oxamate (10 mM) a lactate dehydrogenase inhibitor did not alter the induction of RC LTP, suggesting that lactate does not require neuronal transport and further metabolism to induce LTP. Lastly, perfusion of 3,5-DHAB (0.5 mM) an HCA1 selective agonist, mimicked the actions of lactate suggesting dependence of HCA1 activation for RC LTP. Consistently, the inclusion of pertussis toxin in the patch pipette blocked the potentiation

observed with lactate. We conclude that lactate can induce an NMDA-dependent form of LTP mediated by the activation of HCA1 receptor.

Title: Single-spine LTP modulates plasticity at neighboring GABAergic inhibitory dendritic synapses

Authors: *T. RAVASENGA, M. RUBEN, E. PETRINI, A. BARBERIS
NBT, Inst. Italiano Di Tecnologia, Genova, Italy

Abstract: A proper balance of synaptic excitation and inhibition is essential for the functioning of the neuronal networks. Traditionally, the flexibility of neuronal network was thought to mainly rely on the potentiation and depression of excitatory synapses. In contrast, inhibitory synapses were assumed to be relatively invariant. However, an increasing body of evidence has revealed several types of inhibitory plasticity, raising the important question of how GABAergic and glutamatergic plasticity are coordinated during neuronal activity. Here, we characterized a non-Hebbian form of inhibitory postsynaptic potentiation (iLTP) induced by postsynaptic depolarizations of principal cells in hippocampal cultures. Interestingly, the same protocols induced depression at glutamatergic synapses (LTD), thus indicating an anti-homeostatic relation between inhibitory and excitatory plasticity. Photolysis of caged glutamate or caged GABA revealed that the aforementioned glutamatergic LTD and GABAergic iLTP are expressed postsynaptically. Subsequently, we investigated the interplay between excitatory and inhibitory plasticity following the delivery of a hebbian-like plasticity protocol. We induced “single spine LTP” to study how plasticity induced at individual glutamatergic spines affects the strength of neighboring GABAergic synapses. In particular, we paired the postsynaptic depolarization with repetitive glutamate uncaging at individual spines while simultaneously measuring the strength of adjacent dendritic GABAergic synapses by GABA uncaging. Interestingly, we found that GABAergic synapses located within 3 microns from a stimulated spine showed depression (iLTD), while farther synapses still showed iLTP as described above. This spatial dependent reversion of inhibitory plasticity induced by heterosynaptic plasticity required the activation of the protease calpain, induced by calcium influx through L-type voltage gated calcium channels.

Our findings suggest that, following the induction of synaptic plasticity, changes of calcium concentration in dendritic micro-domains locally tuned dendritic E/I balance.

Title: Evolutionarily conserved site on Neurexin3-α modulates balance between excitation and inhibition

Authors: *S. RESTREPO[1], K. A. NELSON[2], J. AOTO[2]
[2]Pharmacol., [1]Univ. of Colorado Denver Anschutz Med. Cam, Denver, CO

Abstract: Imperative for proper synapse formation, Neurexins are a group of evolutionarily conserved presynaptic cell-adhesion molecules whose mutations have been implicated in several neuropsychiatric disorders. Although Nrxns have been studied for decades, many of their functions have yet to be elucidated. In particular the role of **Neurexin3α**, has only been weakly decoded. Little is known regarding how the extracellular portion of **Nrxn3α** governs synaptic function. We identified a point mutation in an evolutionarily conserved region of **Nrxn3α**. The patient with this mutation suffers from severe intellectual disability and epileptic seizures. We found that this mutation, has profound effects on ligand binding and alters presynaptic morphology. Moreover, excitatory transmission is altered in the mutant. Knockdown of endogenous **Nrxn3α** and replacement with WT or mutant **Nrxn3α** brought to light the role of **Nrxn3α**'s involvement in excitatory and inhibitory transmission. These data exemplify the distinct role of **Nrxn3α** as a molecule necessary for the balance between excitation and inhibition at the synapse, and how this molecule's dysfunction can lead to unfavorable phenotypes often associated with the E/I misbalance such as epilepsy.

Title: NYX-2925 facilitates auditory-evoked long-term potentiation in rats: A translational approach for measuring NMDA receptor-dependent synaptic plasticity

Authors: *J. S. BURGDORF[1,2], K. LEADERBRAND[1,2], X.-L. ZHANG[3], P. K. STANTON[3], T. M. MADSEN[2], M. A. KAHN[2], R. A. KROES[1,2], J. R. MOSKAL[1,2]
[1]Falk Ctr. for Mol. Therapeutics, McCormick Sch. of Engin., Northwestern Univ., Evanston, IL; [2]Aptinyx Inc., Evanston, IL; [3]Cell Biol. & Anat., New York Med. Col., Valhalla, NY

Abstract: Aptinyx has developed a novel class of small molecule N-methyl-D-aspartate receptor (NMDAR) modulators with broad applicability for neurologic and psychiatric disorders. A member of this platform, NYX-2925, enhances NMDAR-dependent long-term potentiation (LTP) in hippocampal slices and facilitates learning and memory in rats. NYX-2925 also facilitates synaptic plasticity as measured by enhancement of LTP in slices *ex vivo* 1-7 days post-dosing (1-10 mg/kg, PO). The present studies examine the effects of NYX-2925 (0.1, 1, 10 mg/kg, PO) on *in vivo* NMDAR-dependent auditory-evoked LTP as well as NMDAR-dependent mismatch negativity responses in the prefrontal cortex of freely behaving rats. NYX-2925 (1-10 mg/kg, PO) facilitated auditory-evoked LTP as measured by an increased N100 response to a standard tone 1 hr after auditory tetanization (6 kHz tone, 50 ms in duration, presented 10 times per second for 5 min). In addition, NYX-2925 caused an attenuation in response to the deviant tone (8 kHz). In the mismatch negativity experiment, NYX-2925 (1-10 mg/kg, PO) facilitated habituation of the N100 response to the deviant tone, whereas an NMDAR antagonist inhibited this habituation. The effects of NYX-2925 were observed 1 hr to at least 1 week following a single dose in both the *in vivo* LTP and mismatch negativity paradigms. NYX-2925 (1-10 mg/kg, PO) also increased resting qEEG power in the alpha-beta bands without affecting gamma oscillations. In contrast, NMDAR antagonists primarily facilitate gamma oscillations. These data demonstrate that NYX-2925 facilitates synaptic plasticity *in vivo*. The potential for these findings to translate to humans is currently being explored.

Title: Immediate perisynaptic membrane expansion after LTP induction visualized by correlative light and electron microscopy

Authors: *Y. SUN, N. KAMASAWA, R. YASUDA
Max Planck Florida Inst. for Neurosci., Jupiter, FL

Abstract: Dendritic spines are the major sites receiving excitatory synaptic transmission, and are widely accepted as the structural units for learning and memory. Synaptic plasticity induced by long-term potentiation (LTP) leads to both structural and functional changes in dendritic spines in an input-specific manner. More specifically, LTP is known to be associated with immediate increase of AMPA receptor-mediated current and expansion of spine volume (within ~min). In contrast to these rapid changes, the growth of the post-synaptic density (PSD), where the majority of AMPA receptors reside in, takes much longer time (~hour). It is unknown how this difference in the time scale can be reconciled.
In order to address this question, we used 2-photon microscope system to induce LTP in single dendritic spines by uncaging MNI-glutamate and to confirm input specific structural plasticity

induction. By establishing an efficient correlative light-electron microscopy workflow using serial sectioning and array tomography scanning electron microscopy, we relocated the uncaged dendritic spines and observed their sub-spine ultrastructure in the early phase of LTP (<20 minutes). As expected, we observed a dramatic increase in spine head volume following uncaging. Interestingly, the axon-spine interface expanded immediately after LTP induction, while PSD size did not increase within this period. Importantly, we identified the significant expansion of perisynaptic membrane, defined as the spine membrane without an attached PSD but having a typical synaptic cleft (<40 nm) opposing to presynaptic membrane. This perisynaptic membrane could serve as the physical location for transient accumulation of AMPA receptors to support increased synaptic transmission in early phase LTP as the first morphological response of plasticity.

Title: Model of paradoxical LTP maintenance predicts multiple intermediate states between early and late LTP

Authors: *P. D. SMOLEN[1], D. A. BAXTER[2], J. H. BYRNE[2]
[1]Dept. of Neurobio. and Anat., McGovern Med. Sch. of UTHSC At Houston, Houston, TX;
[2]Dept. of Neurobio. and Anat., McGovern Med. Sch. of UTHSC at Houston, Houston, TX

Abstract: The transition from early long-term potentiation (e-LTP) to late long-term potentiation (l-LTP) is a multistep process that involves both protein synthesis and degradation. The ways in which these two opposing processes interact to establish l-LTP are not well understood, however. For example, l-LTP is attenuated by inhibiting either protein synthesis or proteasome-dependent degradation prior to and during a tetanic stimulus (e.g., Huang et al., *Learn Mem* 3:74, 1996; Karpova et al., *J Neurosci* 26:4949, 2006), but paradoxically, l-LTP is not attenuated when synthesis and degradation are inhibited simultaneously (Fonseca et al,. *Neuron* 52:239, 2006). These paradoxical results suggest that counter-acting 'positive' and 'negative' proteins regulate l-LTP. To investigate the basis of this paradox, we developed a model of LTP at the Schaffer collateral to CA3 pyramidal cell synapse. The model consists of nine ordinary differential equations that describe the levels of both positive- and negative-regulator proteins (PP and NP, respectively) and the transitions among five discrete synaptic states, including a basal state

(BAS), three states corresponding to e-LTP (EP1, EP2, and ED), and a l-LTP state (LP). An LTP-inducing stimulus: **1)** initiates the transition from BAS to EP1 and from EP1 to EP2; **2)** initiates the synthesis of PP and NP; and finally, **3)** activates the ubiquitin-proteasome system (UPS), which in turn, mediates transitions of EP1 and EP2 to ED and the degradation of NP. The conversion of e-LTP to l-LTP is mediated by the PP-dependent transition from ED to LP, whereas NP mediates reversal of EP2 to BAS. We found that the inclusion of the five discrete synaptic states was necessary to simulate key empirical observations: **1)** normal L-LTP, **2)** block of L-LTP by either proteasome inhibitor or protein synthesis inhibitor alone, and **3)** preservation of L-LTP when both inhibitors are applied together. Although our model is abstract, it correctly captures the dynamics of protein synthesis- and degradation-dependent phases of LTP, and elements of the model can be correlated with specific molecular processes. Moreover, the model makes testable predictions, such as a unique synaptic state (ED) that precedes the transition from e-LTP to l-LTP, and a well-defined time window for the action of the UPS (i.e., during the transitions from EP1 and EP2 to ED).

Title: Over-expression of GluR2 in hippocampal parvalbumin-positive interneurons impairs synaptic plasticity and memory performance

Authors: *M. J. COOPER[1], M. MONIRI[2], D. BANNERMAN[2], E. O. MANN[1]
[1]Dept. of Physiology, Anat. and Genet. (DPAG), [2]Dept. of Exptl. Psychology, Univ. of Oxford, Oxford, United Kingdom

Abstract: Parvalbumin-expressing (PV+) inhibitory interneurons are critical for controlling spike timing and spike rates in hippocampal circuits. Excitatory synapses onto PV+ interneurons predominantly express AMPA receptors lacking the GluR2 subunit. The GluR2-lacking AMPAR are Ca^{2+}-permeable and display polyamine-dependent inward rectification. These properties enable anti-Hebbian learning at excitatory synapses onto PV+ interneurons, whereby inputs associated with membrane hyperpolarisation trigger Ca^{2+} influx and synaptic potentiation. However, the behavioural importance of anti-Hebbian plasticity in PV+ interneurons remains to be established.
In this study, we generated a virus that drives Cre-dependent expression of the Q/R-edited GluR2

AMPA receptor subunit, and injected it into the hippocampus of PV-Cre mice. We were able to selectively transfect PV+ interneurons and alter single-cell and network properties, including substantially reducing synaptically-evoked dendritic calcium signals and impairing anti-Hebbian plasticity.
Following this, we performed bilateral full hippocampal injections of the virus into a cohort and performed a battery of behavioural tests. We found that whilst locomotor activity, anxiety, and spatial reference memory were largely unaffected by the transfection, the animals showed a substantial impairment on the spatial working memory-dependant rewarded alternation T-maze task compared to a GFP virus-injected control cohort, but only with extended (30-second) delays between the sample and choice phases of trials. Additionally, whilst the animals were equally capable of learning the location of a platform during a spatial reference memory version of the Morris water maze task, the GluR2-injected group took longer to react to subsequent changes in platform location (spatial reversals). Overall, our results suggest that replacement of Ca^{2+}-permeable AMPA receptors in hippocampal PV+ interneurons with GluR2-containing AMPA receptors increases interference between competing memory traces, potentially as a consequence of impaired anti-Hebbian plasticity.

Title: Long-term potentiation requires a rapid burst of dendritic mitochondrial fission during induction

Authors: *S. DIVAKARUNI[1,2,3], A. VAN DYKE[1], R. CHANDRA[4], T. A. LEGATES[1], M. CONTRERAS[1], P. A. DHARMASRI[1,3], H. N. HIGGS[5], M. LOBO[4,3], S. M. THOMPSON[1,3], T. A. BLANPIED[1,3]

Abstract: Long-term potentiation (LTP) is the prevailing mechanism of synaptic strengthening by which neurons encode experience. Baseline synaptic function is bioenergetically demanding, and this demand is elevated during episodes of synaptic plasticity. Therefore, mitochondrial functions such as ATP synthesis and calcium handling are likely required for plasticity. It has recently become apparent that synaptic transmission relies on the adequate presence and function of mitochondria. However, whereas axonal mitochondria have been extensively studied, LTP induction predominantly occurs postsynaptically, where the roles of mitochondria are less well understood.

Mitochondria in dendrites at rest are stationary and rarely undergo fission or fusion. However, we found that chemical induction of LTP (cLTP) by NMDAR activation in cultured rat hippocampal neurons prompted a rapid burst of dendritic mitochondrial fission. Mitochondrial fission canonically requires actin nucleation and membrane constriction by the GTPase dynamin-related protein 1 (Drp1). Consistent with this, inhibition of actin polymerization or expression of a dominant negative (DN) mutant Drp1 each suppressed the cLTP fission burst. Furthermore, the GTPase Dynamin 2 (Dyn2) was recently implicated in fission in cell lines, and we found similarly that expressing DN Dyn2 abolished the fission burst. Drp1 function is also known to be regulated by phosphorylation, with CaMKII as a possible activator based on studies of non-neuronal cells. In line with this, we found that fission was triggered by cytosolic calcium elevation via glutamate photolysis at dendritic spines, and also that the fission burst was prevented by acutely inhibiting CaMKII activation. We then tested whether mitochondrial fission is required for LTP expression. Knocking down Drp1 or expressing DN Drp1 suppressed dendritic spine growth and synaptic AMPA receptor trafficking following LTP induction. Remarkably, postsynaptic expression of DN Drp1 prevented LTP at Schaffer collateral-CA1 synapses in acute hippocampal slices, with no effect on basal transmission or intrinsic electrophysiological properties of neurons.

Taken together, these data suggest that CaMKII activation during LTP induction rapidly increases dendritic mitochondrial fission, and that this is required for LTP expression. Impaired synaptic function is implicated in myriad neuropsychiatric diseases, many of which are also associated with mitochondrial dysfunction. Our findings raise the important question of whether neuronal mitochondrial dysfunction contributes to cognitive impairment by perturbing dendritic and/or synaptic plasticity.

Title: Endocannabinoid-mediated regulation of LTP at mossy cell to dentate granule cell synapses

Authors: *K. R. JENSEN, P. E. CASTILLO
Albert Einstein Col. of Med., Bronx, NY

Abstract: Within the dentate gyrus of the hippocampus, excitatory hilar mossy cells (MCs) synapse extensively onto granule cells (GCs), the principal cell type and main output of the dentate gyrus. MCs also mediate powerful feed-forward inhibition (FFI) onto GCs through a MC-inhibitory interneuron (IN)-GC connection. Although information transfer from MCs to GCs is important for multiple forms of hippocampal-dependent learning and memory, as well as spatial navigation, we know very little about the dynamic properties of MC-GC synapses, and the feed-forward MC-IN-GC circuit. Using electrophysiology in acute rat hippocampal slices, our lab recently discovered a novel type of presynaptically-expressed, NMDA receptor-independent form of long-term potentiation (LTP) of MC-GC transmission, which involves both PKA and BDNF-mediated signaling. New results indicate that MC-GC LTP is inhibited by endocannabinoid (eCB) signaling. To mobilize eCBs from GCs in a timely manner, we delivered brief bouts of depolarizations (from -45 mV to 0 mV; for 5 seconds every 10 seconds; x12; 2 minutes total). We found that GC depolarizations delivered 1.5 minutes before and during induction of MC-GC LTP caused a significant decrease in MC-GC LTP magnitude, an effect that was abolished in the presence of the type-1 cannabinoid receptor (CB1R) inverse agonist AM251 (5 μM). To investigate the mechanism downstream from the $G_{i/o}$-coupled CB1R, we used selective pharmacology for the βγ- or α-limb. We found that inhibition of the βγ-limb with Gallein (75 μM) rescued the deficit in MC-GC LTP that resulted from GC depolarization *during* induction, while inhibiting the α-limb with NF-023 (10 μM) rescued the deficit in LTP that resulted from GC depolarization *before* induction. In contrast, multiple depolarizations delivered 1.5 and 15 min *after* LTP induction only transiently (~1.5-30 min, respectively) decreased LTP magnitude. To further examine eCB-mediated effects on MC-mediated transmission, we used optogenetics to selective activate MC axons and recruit FFI onto GCs. We found that FFI exhibits robust eCB-mediated short-term plasticity. Together, our findings highlight diverse and powerful mechanisms by which eCBs may contribute to dentate gyrus-dependent computations.

Title: Endocannabinoid-mediated spike-timing dependent plasticity in the lateral habenula glutamatergic synapses is modulated by early life stress

Authors: *L. D. LANGLOIS[1], R. D. SHEPARD[2], M. E. AUTHEMENT[2], F. S. NUGENT[2]
[1]Pharmacol., Uniformed Services Univ. of Hlth. Sci., Bethesda, MD; [2]Pharmacol., Uniformed Services Univ., Bethesda, MD

Abstract: The lateral habenula (LHb) is an epithalamic structure involved in depression and aversion by sending negative reward signals to monoaminergic systems. We have previously demonstrated a link between maternal deprivation (MD), an early life stress model, and metaplasticity of GABAergic synapses onto ventral tegmental area (VTA) dopamine neurons. Given the negative control of VTA dopamine neurons by the LHb, we extended our MD studies to the LHb and found that LHb neurons of MD rats (P21-P30) are hyperexcitable and exhibit postsynaptic glutamatergic synaptic potentiation. Up to date no study has shown that glutamatergic synapses onto LHb neurons are capable of expressing spike-timing dependent plasticity (STDP) whose modulation could underlie MD-induced changes in LHb neuronal excitability and DA signaling from the VTA. Our study here demonstrates that glutamatergic STDP can be triggered in LHb neurons in response to near-coincident pre- and post-synaptic activities. We defined the STDP window using different pre post spiking order and time intervals (ranging from -50 to +50 ms). Coincident pre and postsynaptic firing is required for glutamatergic STDP of LHb neurons as pre or postsynaptic activity alone is insufficient to induce plasticity. We classified LHb neurons based on their firing pattern. Tonic firing neurons showed presynaptic NMDAR- and Ca2+ dependent long-term potentiation (LTP) regardless of spiking order. Instead, silent and irregularly firing neurons expressed no plasticity in response to similar protocols. This suggests that LHb neurons display activity-dependent symmetrical Hebbian STDP. LTP was abolished by bath application of a CB1 receptor antagonist. Moreover, our preliminary data suggest that endocannabinoid 2-Arachidonoylglycerol (2-AG) but not anandamide may mediate this plasticity. MD impaired LTP in response to pre-post protocols and even shifted LTP toward LTD in response to post-pre protocol (-5ms interval) in tonic firing neurons suggesting an induction of metaplasticity by MD at glutamatergic synapses onto LHb neurons. The induction of STDP was unaltered for silent and irregularly firing neurons

suggesting that MD-induced metaplasticity was specific to neurons with tonic activity. We are testing the possible interaction between 2-AG and GABA-B signaling pathways as potential mediators of this form of LTP and their dysregulation during MD-induced metaplasticity.

Abstract: Long-term operations carried out by military personnel, pilots, and astronauts are often conducted in extreme conditions such as exposure to high altitude (HA)-associated hypobaric-hypoxic environment, which have reported to result in impairments of different cognitive functions such as learning and memory. While the cerebral effects of acute HA exposure have been more extensively studied, much less is known about chronic exposure to HA and the possible biological or pathobiological mechanisms involved in the adaptive or maladaptive responses of the brain to chronic HA. In this context, we sought to investigate if synaptic protein expression levels were altered as possibly due to HA for a prolonged period of time. We chose to examine synaptic proteins in the pre- and post-synaptic compartment that have been shown to play a role in the release of neurotransmitters, formation and recycling of synaptic vesicles, neurite formation as well as anchoring of excitatory and inhibitory receptors. To address the effects of chronic HA on synaptic protein expressions, we exposed twelve C57Bl6 male mice to an altitude of 5000m (HA) above sea level (SL) for 12 weeks. We initially focused on the following proteins: synaptophysin, spinophilin, post-synaptic density protein (PSD95), and the growth associated protein 43 (GAP43). We used western blot (WB) methods to quantify the selected synaptic proteins through different regions of the brain: olfactory cortex, cerebellum and brainstem. Our preliminary findings show a significant decrease in the expression levels of

synaptophysin and spinophilin in the olfactory cortex of chronically exposed HA mice in comparison to mice kept at SL for an identical period of time. Intriguingly, we did not observe changes in the PSD95 and GAP43 levels. Moreover, we did not observe changes in any of the considered synaptic markers in the cerebellum and brainstem of mice exposed to chronic HA. These findings seem to suggest that chronic exposure to HA can regulate specific synaptic changes across different brain regions and possibly linked to specific cognitive and behavioral changes. Elucidating the molecular mechanisms by which these synaptic and other synaptic-associated changes occur in mammalian brains will have potential implications for the preservation of cognitive and behavioral skills of subjects exposed to prolonged periods of time to HA.

Title: Reduction of alcohol-seeking behavior by optogenetic reversal of alcohol-evoked input- and cell type-specific synaptic plasticity in the dorsomedial striatum

Authors: *J. LU, Y. CHENG, T. MA, X. WANG, J. WANG
Dept. of Neurosci. & Exptl. Therapeut., Texas A&M Univ. Hlth. Sci. Ctr., Bryan, TX

Abstract: Addiction is believed to be triggered by drug-evoked plasticity. The dorsomedial striatum (DMS), a brain region critically involved in drug and alcohol addiction, contains medium spiny neurons (MSNs) expressing either dopamine D1 or D2 receptors. D1-MSNs positively and D2-MSNs negatively control rewarding behaviors. The DMS receives glutamatergic inputs from the medial prefrontal cortex (mPFC). We recently found that chronic alcohol intake increased glutamatergic activity selectively at mPFC inputs onto DMS D1-MSNs. Here, we combined the dual-channel optogenetic approach and a “post-pre” spike timing-dependent protocol (STDP) to test whether the induction of input- and cell types-specific LTD at the mPFC-D1 MSN circuit could reverse the alcohol-evoked enhancement of glutamatergic activity at this circuit, thereby persistently reducing their alcohol intake. This circuit-specific LTD induction was achieved by expressing one channelrhodopsin, chronos, at the mPFC

terminals for selective presynaptic stimulation, and by expressing another channelrhodopsin, Chrimson, in the D1-MSNs for postsynaptic depolarization of this specific neuronal type. First, we used field potential recording to measure LTD from water controls, and observed that ex vivo "post-pre"-STDP induction successfully induced LTD in striatal slices, whereas mPFC stimulation alone did not cause any changes. Next, we delivered same LTD induction in slices from alcohol-drinking animals. We found that the same induction caused reliable LTD, however, the optogenetic stimulation needed to be repeated 3 times to obtain the same magnitude of LTD. Then, we examined the effect of this LTD-inducing protocol on alcohol-seeking behavior. We found that in vivo delivery of this optogenetic protocol produced significant decreases in lever presses and alcohol intake; these decreases last two days after induction. Taken together, these data suggest that optogenetically inducing D1-MSN LTD from alcohol-drinking rats reversed alcohol-evoked glutamatergic potentiation in this neuronal population, thus persistently reducing alcohol drinking in vivo. Reversal of alcohol-evoked synaptic plasticity could provide a novel circuit-based therapeutic strategy for the treatment of alcohol addiction.

Title: Theta phase-dependent competitive long-term potentiation in area CA1 of the hippocampal slices caused by feed-forward and feedback gabaergic control

Authors: *T. TOMINAGA, Y. TOMINAGA
Inst. of Neuroscience, Tokushima Bunri Univ., Sanuki, KAGAWA, Japan

Abstract: The theta burst stimulation (TBS, a train of short 100 Hz. burst stimulations repeated in 5-7 Hz.) that mimics theta oscillation in the rodent hippocampal system is a well-used induction stimulation of the long-term potentiation (LTP) at area CA1 Schaffer (Sch)-pyramidal synapses. The TBS-induced LTP is different from the LTP induced by an also well-known "tetanic" stimulation (tetanus, 100 Hz. 1 sec stimulation). We found the significant difference of

the degree of the action of potential firing during the induction phase with voltage-sensitive dye (VSD). That is, tetanus did not cause action potentials during tetanus while a TBS exaggerated action potential. We also reported that the TBS caused exaggerated action potential firing during the sequence, even in the form of the pair of brief burst stimulations [PBS; a 100 Hz. burst stimulation consists of four stimuli with 10ms intervals (a priming burst) precedes a 170ms interburst interval to the same 100 Hz. burst stimulation (a test burst)]. A PBS applied to the Sch induced a facilitated response upon a test burst (a paired burst facilitation; PBF). The PBF accompanied the action potentiation of E-S (EPSP-spike firing) coupling without accompanying an increase of excitability of the postsynaptic cells. This is dependent on the GABA-A receptor-dependent GABAergic circuit control. In the CA1 neural circuit, the GABA-A receptor acts either as a feedforward or feedback inhibition. When we divided Schaffer collateral fibers into two groups with microsurgery and applied stimulation to these two separate input pathways, we found that feedforward inhibition is responsible for the action potential facilitation, while feedback inhibition causes suppression just after the first burst stimulation. Here, we examined the phase-dependent effect of the TBS in the different input pathways in area CA1. The TBSs on both inputs show a competitive LTP induction depending on the phase of the theta oscillation. The result shows that the input from CA3 to CA1 can carry information on the phase of the theta oscillatory activity and cause the plastic change in the synapses.

Title: Differential learning from pre- vs. postsynaptically expressed STDP

Authors: *B. E. P. MIZUSAKI[1,2], S. S. Y. LI[2], R. P. COSTA[3], P. J. SJOSTROM[2]
[1]UFRGS, Porto Alegre, Brazil; [2]McGill Univ., Montreal, QC, Canada; [3]Univ. of Oxford, Oxford, United Kingdom

Abstract: Most theoretical studies of long-term synaptic plasticity implement changes in synaptic efficacy postsynaptically, ignoring the rich presynaptic short-term dynamics, as well as

the interaction between pre- and postsynaptic expression (Costa et al, RSTB 2017 DOI: 10.1098/rstb.2016.0153). Since both forms of expression are found experimentally, this assumption has resulted in a long-standing postsynaptic bias in theoretical studies. As a consequence, the specific computational impact and functional benefits of pre- vs. postsynaptic expression remain relatively poorly studied.
To explore the functional impact of pre- and postsynaptic expression, we simulated two scenarios in which a postsynaptic neuron learns to respond to excitatory inputs via spike-timing-dependent plasticity (STDP). Each scenario quantified a particular aspect of information coding: latency to spike and correlated activity, respectively. In the first, periodic volleys of presynaptic Poisson activity were temporally ordered along the inputs. After learning, synaptic efficacy was organized according to stimulus order within the volley, with postsynaptic response latency and duration reduced (Song et al, Neuron 2000 3:919). In the second scenario, stimulation consisted of two input populations of which one had correlated activity, which lead to its selective potentiation (Song and Abbott, Neuron 2001 32:339).
Initially, we used Song and Abbott's (2000, 2001) simple additive model of STDP. As a model extension, presynaptic plasticity was implemented via alterations in release probability and short-term depression, and postsynaptic expression via quantal amplitude changes. For added biological realism, we next carried out simulations with a triplet model tuned to physiological pre- and postsynaptic expression data (Costa et al, eLife 2015, DOI:10.7554/eLife.09457), obtained from monosynaptic connections between visual cortex layer-5 pyramidal cells.
We found that presynaptic plasticity could adjust learning rates and affinity for correlated inputs, whereas postsynaptic expression was more effective for amplitude enhancement. We also found that under constant stimulation, presynaptic plasticity did not affect postsynaptic firing rates, suggesting that associative learning and frequency saturation can be uncoupled. In summary, our results highlight key differences between pre- and postsynaptic expression of STDP, demonstrating that the default postsynaptic assumption in modelling of plasticity is not neutral but may introduce a bias.

Title: A spike timing-dependent plasticity rule for single, clustered and distributed dendritic spines

Authors: *D. E. MITCHELL, S. TAZERART, S. MIRANDA-ROTTMANN, R. ARAYA
Dept. de neurosciences, Univ. De Montréal, Montreal, QC, Canada

Abstract: Dendritic spines can undergo structural remodeling, and are the preferential site for the induction of long-term potentiation (LTP) and long-term depression (LTD). In a variant of LTP and LTD, known as spike-timing dependent plasticity (STDP), the sign and magnitude of the change in synaptic strength depends on the timing between the spikes of two connected neurons. Although STDP has been extensively studied in cortical pyramidal neurons, the precise structural organization of excitatory inputs that supports STDP, as well as the structural, molecular and functional properties of dendritic spines during STDP remain unknown. Here we developed a spine STDP protocol, in which two-photon glutamate uncaging over single or multiple spines from the basal dendrites of layer 5 pyramidal neurons, which mimics presynaptic release of glutamate (pre), was paired with somatically generated postsynaptic spikes (post). We found that the induction of STDP in single spines follows a classical Hebbian STDP rule, where pre-post pairings at timings that trigger LTP (t-LTP) produce shrinkage of the activated spine neck and a concomitant increase in its synaptic strength; and post-pre pairings that trigger LTD (t-LTD) decrease synaptic strength without affecting the activated spine shape. Furthermore, we tested whether the *single spine*-Hebbian STDP rule could be affected by the activation of neighboring (clustered) or distant (distributed) spines. Our results show that the induction of t-LTP in two clustered spines (< 30 μm apart) enhances LTP via a mechanism that requires actin polymerization-dependent neck shrinkage, which permits AMPA receptor transport to the spine head and insertion into the postsynaptic density (PSD). Moreover, the induction of t-LTD is disrupted when two clustered spines (< 30 μm apart) are activated, but can be recovered if the activated spines are separated by > 30 μm. These results indicate that the induction of STDP in single, or distributed spines (separated by > 30 μm), follow a Hebbian STDP rule. Interestingly, synaptic cooperativity, induced by the co-activation of clustered spines and the local spatio-temporal summation of clustered synaptic inputs, provides local dendritic depolarization that is sufficient to disrupt t-LTD, leading to STDP only encompassing LTP.

Title: Acetylcholine controls input selectivity in CA1 of the hippocampus by pathway specific muscarinic regulation of feedforward excitatory-inhibitory ratio

Authors: *J. PALACIOS, J. R. MELLOR
Physiology, Pharmacol. and Neurosci., Univ. of Bristol, Bristol, United Kingdom

Abstract: Acetylcholine fundamentally reconfigures cortical circuits to switch their function. In the hippocampus acetylcholine is thought to prioritise input to CA3 and CA1 circuits from sensory modalities containing new information about the environment and away from internally held representations. This reconfiguration enables acetylcholine to signal that previously held representations require updating with new information (Dannenberg et al., 2017). However, the mechanism by which acetylcholine enables this critical switch in function is unclear. In the CA1 region, internally held representations are proposed to enter via the Schaffer collateral (SC) pathway from CA3 whereas new information enters via the temporoammonic (TA) pathway direct from the entorhinal cortex. Therefore, it is predicted that acetylcholine will reduce SC input whilst enhancing TA input to CA1. Previous studies have reported that acetylcholine reduces excitatory synaptic transmission in both SC and TA pathways apparently contradicting this prediction. However, these studies did not measure the effects of acetylcholine on feedforward inhibition which have a major role in determining the CA1 response to SC or TA input. Therefore, our goal was to test the core hypothesis that acetylcholine prioritises TA input over SC input. We used electrical stimulation to obtain monosynaptic excitatory or disynaptic inhibitory postsynaptic currents (mEPSC or dIPSC respectively) from SC and TA pathways on the same CA1 pyramidal neuron. The acetylcholine receptor agonist carbachol (CCh) or optogenetically evoked release of acetylcholine reduced both mEPSC and dIPSC synaptic responses for the SC input which resulted in no change to excitatory-inhibitory balance and indeed a decrease in postsynaptic spiking. In contrast, TA mEPSC and dIPSC were also reduced by cholinergic receptor activation, but a boost in facilitation of excitatory and the lack of it in the inhibitory drive resulted in an increase of excitatory-inhibitory balance, which produced an increment in postsynaptic spiking. Our data suggest that distinct interneuron populations engaged by SC or TA pathways participate in input selective modulation. Pharmacological interventions revealed that presynaptic muscarinic M3 receptors mediated cholinergic induced facilitation of excitatory-inhibitory balance on TA pathway, in contrast the SC pathway where muscarinic M4 receptors mediate presynaptic inhibition. We conclude that differential expression of presynaptic muscarinic receptors on SC and TA inputs to CA1 enable acetylcholine to reconfigure the network to favour new information over internally held representations.

Title: A dendritic model of CA1 place-field formation and remapping through excitatory and inhibitory synaptic plasticity

Authors: P. A. BOZELOS[1,2], E. J. AGNES[1], *T. VOGELS[1], P. POIRAZI[2]
[1]DPAG, Univ. of Oxford, Oxford, United Kingdom; [2]IMBB-FORTH, Heraklion, Crete, Greece

Abstract: Spatial navigation learning and memory have been in the spotlight of neuroscience research for decades, producing a compelling amount of evidence on the critical role of hippocampus, and particularly of the CA1 subregion, in the construction of flexible cognitive maps. Indeed, place field formation and spatial remapping are now well-characterized computational functions at the neural population level. However, our understanding at the single-cell level lags behind. What are the contributions of dendritic non-linearities and / or synaptic plasticity mechanisms in place-field formation? How is remapping actualized at the individual neuron level? What are the effects on learning flexibility and memory capacity of the network? Here we explore these questions by investigating the spatial encoding properties of a plasticity-enabled network model consisting of multi-compartmental neurons. We simulate an environment exploration task by anchoring the spike-timing tuning of excitatory and inhibitory network afferents to a series of consecutive locations across a virtual environment. We allow the neurons to organise their dendritic inputs according to excitatory and inhibitory plasticity rules that interact locally at the level of dendrites. We show how the afferent connectivity patterns that allow the emergence of place representations can arise naturally via branch-specific allocation of the spatially-tuned excitatory drives and selective inhibitory gating. When the network model experiences a novel environment (i.e., a shuffled set of correlated inputs), synaptic allocation patterns restructure to accommodate the matching afferents along same dendrites. Remapping thus follows from a complex interaction between new and previously learned receptive fields. We show that encoding capacity is dramatically increased through the introduction of dendrites that allow for the branch-wise registration of more than one place-field per neuron, corresponding to distinct virtual environments, and allowing for the possibility of context dependent switching.
To our best knowledge, this is the first modelling study to show how place-fields can be learned

via the implementation of codependent synaptic plasticity rules to explain how spatial remapping can occur.

[1]Neurosci., [2]Redwood Ctr. for Theoretical Neurosci., UC Berkeley, Berkeley, CA

Abstract: A major challenge in Neuroscience is to develop models that bridge both the computational and mechanistic levels. We have made recent advances understanding the structured representations in connectionists models known as Vector Symbolic Architectures (VSA). Here, we demonstrate the utility of VSA models in a neuroscience theory framework by developing algorithms for navigation at the computational level that can also explain hippocampal data at the mechanistic level. Specifically, we focus on a VSA model based on high-dimensional vectors of complex numbers, Fourier Holographic Reduced Representations (FHRR). We have developed a novel model of synaptic integration to implement FHRR with spiking neurons that express periodic population firing, where the timing of a spike relative to an internal oscillation represents the phase of a complex number. This makes FHRR useful for understanding the theta-rhythm and phase coding in hippocampus. We propose synaptic circuitry and dynamics that transforms a presynaptic spike into an excitation/inhibition-balanced postsynaptic current oscillation. The timing of presynaptic spike and synaptic delay determines the phase of the postsynaptic current oscillation. The oscillatory currents from many synapses will sum in the neuron, effecitively implementing a dot product between complex vectors. The effect of spikes depends now on their relative timing and stored synaptic patterns - it can be small in the decoherent case (A), or large in the coherent case (B). In essence on the computational level, we develop a model that forms a neural code of location in a 2-D environment (C). We demonstrate how the computations in the model can be implemented in spiking neurons to produce neural response activity similar to CA1 principal neurons, exhibiting place fields and phase-precession (D,E). This activity can be decoded by a readout population (F), and used as part of a navigation algorithm, such as for path-integration.

Title: Analysis of complex temporal information streams by dendritic neuron model

Authors: *T. ASABUKI[1,2], T. FUKAI[1,2]
[1]RIKEN Brain Sci. Inst., Wako, Japan; [2]The Univ. of Tokyo, Kashiwa, Japan

Abstract: Maximization of mutual information is widely thought to play a crucial role in sensory and motor information processing by cortical neurons. Hebbian synaptic plasticity may also be regarded as a biological machinery to realize this information theoretical principle. However, if the brain models the external world or monitors its internal processes, it should extract characteristic features from externally or internally driven information streams. This operation requires a certain level of abstraction, and optimal information transmissions do not seem to characterize the principles governing these processes. Here, we propose the conditional entropy minimization as an alternative principle of neural information processing. We derive a learning rule from this principle for a two-compartment neuron model and demonstrate its excellent performance in learning various signal processing tasks. For instance, simple networks of such neurons can perform unsupervised learning and denoising of orientation-tuning maps in the visual processing, chunking of visual and other information streams, detection of population

spike sequences repeated in noisy background, and the blind source separation of mixture signals from significantly correlated auditory sources. In particular, our network model can separate the sounds of music instruments playing the same music piece, which was not possible for the standard ICA-based method. Thus, our model will provide new insights into the principles of neural processing of temporal information.

Title: Imaging STDP: Potentiation and depression with timed dual-site stimulation in hippocampal CA3 region

Authors: *M. B. JACKSON
Neurosci., Univ. of Wisconsin-Madison, Madison, WI

Abstract: Spike-timing dependent plasticity (STDP) enables neural circuits to store information based on the time interval between the activation of synaptic inputs. STDP incorporates a basic Hebbian principle of synaptic plasticity and gives a neural circuit unique storage capabilities. Prior experimental studies of STDP varied the timing between a synaptic input and a postsynaptic spike induced by direct current injection, rather than by varying the timing between the stimulation of two synaptic inputs. Furthermore, prior studies employed recordings from single cells without evaluating the spatial distribution of STDP through the circuitry. The present study used voltage sensitive dye imaging to study STDP in the CA3 region of horizontal hippocampal slices from 4 to 7-week old rats. Electrical stimulation was applied to two sites in the stratum radiatum; stimulating each site alone elicited robust optical responses over broad overlapping areas. Stimulating two sites repeatedly at different times separated by 10 msec induced STDP. Simultaneous stimulation of the two sites did not induce changes in responses. Following dual-site stimulation at 10 msec intervals responses to stimulation of each site were potentiated at some locations and depressed at other locations. In general, with timed induction the potentiation and depression varied in magnitude as well as in location relative to the sites of stimulation. Depression and potentiation occurred in the same slice at different locations. Comparing sites with the greatest potentiation indicated greater potentiation of responses to the site stimulated first compared to the site stimulated 10 msec later. When the sites showing the greatest depression were compared, the amount of depression was similar for responses to the

site stimulated first or second. STDP was not effective in the storage of spatial response patterns elicited by stimulation of one or both sites. These results demonstrate STDP plasticity can be induced by activation of synaptic inputs. Furthermore, both depression and potentiation can be elicited in the same slice to both the site stimulated first and the site stimulated second. Thus, STDP has complex manifestations in the processing of information by the hippocampal CA3 region.

Title: An increase of the readily releasable pool accounts for post-tetanic potentiation at the hippocampal mossy fiber bouton-CA3 pyramidal neuron synapse

Authors: D. VANDAEL, *P. JONAS
Inst. of Sci. and Technol. (IST) Austria, Klosterneuburg, Austria

Abstract: The hippocampal mossy fiber synapse is a key synapse in the tri-synaptic circuit of the hippocampus, characterized by a particularly large post-tetanic- potentiation (PTP) (Salin et al., 1996, PNAS 93:13304). Interestingly, PTP turns mossy fiber boutons (MFBs) from conditional-detonators into full detonators (Vyleta et al., 2016, Elife e17977). MFBs show a large readily releasable pool, but initial release probability is low because of loose coupling of presynaptic calcium channels to the calcium sensors of exocytosis (Hallermann et al., 2003, PNAS 100:8975; Vyleta and Jonas, 2014, Science 343:665). A recent study showed that chemically induced LTP at this synapse leads to tightening of the coupling, thereby increasing release probability (Midorikawa and Sakaba, 2017, Neuron 96:1033). It is thus tempting to hypothesize that MFBs rely on a similar mechanism to achieve PTP. To test this hypothesis, we examined PTP at the unitary level by paired recordings between MFBs and synaptically connected CA3 pyramidal neurons. MFBs were non-invasively stimulated in the cell-attached configuration, and EPSCs were recorded in the CA3 pyramidal neuron. High-frequency stimulation (100 spikes at 100 Hz) evoked highly robust PTP (162.9 ± 26.4 pA before and 441.8 ± 68.9 pA after PTP, 14 pairs; p=0.0002). Bursts of 18 spikes at 100 Hz were sufficient for induction (171.4 ± 39.8 pA before and 425.4 ± 124.5 pA after PTP, n=7). After induction, PTP decayed with a time constant of 91 ± 24.9 s. Unexpectedly, paired pulse ratio (a robust indicator of release probability) was unchanged after PTP (1.8 ± 0.3 before and 1.5 ± 0.16 after PTP;

p=0.28), indicating that PTP may be independent of changes in release probability. To quantitatively analyze vesicle pool dynamics during PTP, we plotted cumulative release against number of stimuli during 50-Hz trains. Fitting the linear portion of the relation revealed that PTP doubled pool size (908 ± 243 pA before versus 2103 ± 450 pA after PTP, 7 pairs; p=0.01), but left release probability unaffected (0.25 ± 0.05 before and 0.22 ± 0.02 after PTP; p=0.3). The effects of PTP on evoked release were accompanied by a 1.5-fold increase in spontaneous EPSC frequency (10.4 ± 1.3 Hz before versus 15.5 ± 2.4 Hz after PTP; p=0.047). This effect decayed with a time constant similar to that of PTP and therefore might temporarily increase the excitability of CA3 pyramidal cells. In conclusion, PTP mechanistically differs from LTP at MFB-CA3 pyramidal cell synapses. Our results suggest that multiple orthogonal forms of presynaptic plasticity coexist at hippocampal mossy fiber synapses, enriching the information processing capacity of this important connection.

Title: The modulation of back-propagating action potential by LTP induction on dendrite in rat hippocampal dentate-granule cells

Authors: *S. SUGIMOTO[1], J. KASAI[1], M. KONDO[2], K. KATO[3], T. AIHARA[1]
[1]Instituition of Engnieering, Tamagawa Univ., Machida, Japan; [2]Grad. Sch. of Med., The Univ. of Tokyo, Tokyo, Japan; [3]Morinomidori mental institution, Yokohama, Japan

Abstract: The hippocampus is an area related to the integration and storage of several sensory information. In recent studies, dentate granule cells of rat hippocampus individually receive place information and the other sensory information (e.g. odor) from entorhinal cortex on dendrites, medial dendrite (MD, at the middle molecular layer) and lateral dendrite (DD, at the outer molecular layer), separately. On the other hand, spike timing dependent plasticity (STDP) were reported in hippocampal pyramidal neurons and granule cells. The associative mechanism is based on the timing of pre-synaptic spikes (associated EPSPs) and post-synaptic spikes (associated back-propagating action potential, bAP) and it determines the sign and magnitude of long-term potentiation (LTP) or depression (LTD). However, the information integration by a cooperative association as STDP in two parts of dendrite, MD and DD, is still unclear. Our previous studies reported that the transmission distance and the magnitude of bAP, which is one of inducing factors for STDP, were modified by induction of LTP along dendrites in hippocampal CA1 pyramidal neurons. It suggested that cooperatively integration of the context

information from CA3 and the other information through a direct pass from EC were facilitated in CA1 pyramidal neurons. However, the influence of synaptic plasticity along dendrites on the bAP modification in the hippocampal dentate gyrus was not investigated. Therefore, the change of integration ways between two input information on MD and DD, during associative consolidation, is not still unclear. In this study, in order to investigated the information integration in dendrites of dentate granule cells, we analyzed the distance and magnitude of the bAP before and after LTP induction by high-frequency electrical-stimuli in the granule cells of the hippocampal dentate gyrus, using optical imaging method with voltage sensitive dye. As the result, the bAP transmission distances were extended from MD to DD and the magnitude of bAP was increased at DD. The result suggests that the cooperative integration of place information to MD and the other sensory information to DD in dentate granule cell was influenced by the bAP modulation based on the plasticity induced on dendrites.

Title: *In vivo*-like irregular activity reveals dominance of firing rate over spike-timing in synaptic plasticity

Authors: *M. GRAUPNER[1], Y. DEMBITSKAYA[2], S. VALTCHEVA[3], S. OSTOJIC[4], L. VENANCE[2]

Abstract: Synaptic plasticity, the change in efficacy of connections between neurons, is thought to underlie learning and memory. Plasticity can be elicited by pre- and postsynaptic activity patterns, where the outcome is determined by the firing rate and spike-timing correlations. Plasticity is typically induced experimentally with regular activity patterns consisting of evenly-spaced firing patterns and fixed relative spike-timings. However, such regularity strongly differs from *in vivo* activity. Therefore, it remains unclear how irregular, *in vivo*-like patterns shape synaptic plasticity. To address this question, we combined mathematical modelling and experiments inducing synaptic plasticity at corticostriatal synapses. As a first step toward natural firing patterns, we studied plasticity induced by spike-pairs with fixed time lag between pre- and postsynaptic spikes (Δt) but irregular occurrence. Theoretical prediction suggested that under

irregular spike-pair stimulation, the firing rate has greater impact on the outcome of plasticity compared to spike-timing correlations, in particular at intermediate to large firing rates. We experimentally verified these predictions and observed that irregular spike-pair stimulation diminished long-term depression (LTD) and widened the Δt range of long-term potentiation (LTP) compared to regular patterns at low firing rate (~1 spk/sec). Furthermore, increasing in the firing rate completely abolished LTD and led exclusively to LTP in the whole range of Δt's (>3 spk/sec). Here, we demonstrate the prevalent importance of firing rate over spike-timing correlations for the emergence of synaptic plasticity under *in vivo*-like irregular stimulation. These results highlight the importance to consider the dependence of plasticity on natural firing statistics and call into question the dominant role of spike timing for plasticity in natural conditions. Instead, our findings suggest that spike correlations shape plasticity at low firing rates, while the influence of firing rate dominates at intermediate and large firing rates.

Title: Dissecting synaptic dynamics underlying the neuronal code with *in vivo* dynamic clamp manipulation of visually-evoked excitation and inhibition in mouse primary visual cortex

Authors: M. GAJOWA, *L. J. GRAHAM
Neurophotonics Lab., CNRS UMR8250, Univ. Paris Descartes, Paris, France

Abstract: A first step towards understanding the mechanistic basis for the neuronal code is describing the coupling between synaptic integration and spiking. Towards this end we have developed a protocol to study functional I/O using blind whole-cell patch clamp recordings in mouse V1 in vivo, comprising successive applications of current clamp recording mode to establish a neuron's functional responses, voltage clamp recording mode to estimate the somatic signature of the underlying synaptic inputs, and dynamic clamp (DC) recording mode for the re-injection of the estimated synaptic inputs and variations of same. This protocol provides a description of how specific patterns of excitatory and inhibitory synaptic input influence the spiking response during visual processing. Our results confirm the feasibility of the closed loop protocol, in particular with respect to recording quality and stability required for the quantitative

measurements. We show how changes in spike number and timing in response to DC injections of variations of the estimated excitatory and inhibitory synaptic conductance waveforms, in particular in comparison to the originally measured visual responses, allow describing integrative properties of V1 neurons depending on their electrophysiological type (RS vs. FS), and illuminate constraints on the functional neuronal code. In particular, when comparing visually-evoked and DC-evoked spiking responses, the averaging over trials inherent in the estimation of evoked synaptic conductances, which necessarily minors the impact of uncorrelated fluctuations between single trials, implicates consideration of the constraints of rate based versus spike-timing based codes.

Title: Fast 3D two-photon Ca2+ imaging in mouse V1 reveals patterns of layer II/III and V pyramidal cell dendrite activity *in vivo*

Authors: *T. J. YOUNTS[1], S. SADEH[2], C. BARAGLI[2], A. R. SILVER[2]
[1]Neuroscience, Physiol. and Pharmacol., [2]Univ. Col. London, London, United Kingdom

Abstract: How sensory information is represented in dendrites in vivo is poorly understood because it is difficult to measure activity within morphologically complex structures. We used a custom built 3D two-photon acousto-optic lens microscope to measure dendritic activity in layer II/II and V pyramidal cells in mouse primary visual cortex in vivo. Pyramidal cells were sparsely co-labelled with the genetically-encoded Ca2+ indicator GCamp6f (to measure activity) and the red fluorophore TdTomato (to detect and correct for brain motion). Patterns of activity were characterized across behavioral states (anaesthesia, awake and stationary, running). Layer II cells exhibited mainly relatively small local multi-branch Ca2+ events that were sometimes coupled to somatic events. Somatic Ca2+ events were rarely associated with global dendritic events. Activity was little affected by anaesthesia and locomotion. In layer V cell apical dendritic tufts, Ca2+ events were either small and localized to a few branches or large and global. Compared to rest, anaesthesia suppressed while locomotion enhanced activity. In vitro slice experiments suggest the patterns of dendritic activity observed in vivo involve synaptically-driven local

events for both cell types, whereas global events in layer V cells involve synaptic and back-propagating action potential coupling. These data indicate that layer II/III and V pyramidal cell dendrites exhibit unique spatial and functional patterns of activity, implying different integration strategies during sensory processing. These results are also consistent with the idea that layer II/III cells are largely driven by bottom-up feedforward inputs, while top-down inputs conveying information about animal state effectively activates layer V cells.

Title: Heterosynaptic plasticity normalizes cortical excitatory-inhibitory balance

Authors: *R. E. FIELD[1], J. D'AMOUR[2], R. TREMBLAY[3], F. ZENKE[4], J. GJORGJIEVA[5], T. VOGELS[4], B. RUDY[6], R. C. FROEMKE[7]
[1]Skirball Institute, Neurosci. Institute, Departments of Otolaryngology and Ne, New York Univ. Sch. of Med., New York, NY; [2]NIH, Bethesda, MD; [3]Neurosci. Inst., New York Univ., New York City, NY; [4]Ctr. for Neural Circuits and Behavior, Oxford Univ., Oxford, United Kingdom; [5]Max Planck Inst. for Brain Res., Frankfurt, Germany; [6]Neurosci. & Physiol., NYU Sch. of Med., New York, NY; [7]Otolaryngology, NYU Med., New York, NY

Abstract: The fine tuning of inhibition to excitation is critical for spike generation, synaptic plasticity, and seizure generation (Isaacson & Scanziani, 2011). During development, cortical excitatory-inhibitory (E:I) balance is refined in an experience-dependent manner (Dornn et al., 2010). Chronic E:I imbalances have been implicated in various neurological and psychiatric conditions, including epilepsy and autism (Rubenstein & Merzenich, 2003; Yizhar et al., 2011). Here we examine how spike-timing-dependent plasticity (STDP) calibrates E:I balance across multiple inputs to layer V pyramidal neurons in developing mouse auditory cortex and human temporal lobe tissue from epilepsy patients. Using an 8-channel array, we monitored multiple inputs before inducing synaptic modifications at one set of inputs by repetitively pairing single E/IPSPs with postsynaptic spikes. Pre-before-post pairing elicited excitatory and inhibitory long-term potentiation (LTP) at paired inputs, while post-before-pre pairing elicited excitatory long-term depression (LTD) and inhibitory LTP (D'amour and Froemke, 2015). Spike pairing also

induced heterosynaptic modifications that increased overall E:I balance. Approximately 10 minutes after pre-before-post pairing, the original best excitatory input and the original best inhibitory input underwent LTD, and the overall E:I correlation across all channels increased. Heterosynaptic modifications were abolished by inhibiting calcium release from internal Ca^{2+} stores, providing a mechanism for regulating heterosynaptic plasticity. 2-photon Ca^{2+} imaging in slices revealed that spike pairing activated internal stores in the dendrites. In addition, heterosynaptic plasticity was activity-dependent, such that removing the original best excitatory and inhibitory inputs from the stimulus set for ten minutes after pairing blocked LTD at the original best inputs and induced LTD at the next best excitatory and inhibitory inputs. These experiments helped to constrain computational studies examining the requirements for activity across channels for heterosynaptic plasticity and the functions of heterosynaptic changes for overall regulation of E:I balance. Our results show that heterosynaptic plasticity rapidly normalizes excitation and inhibition in neurotypical and epileptic circuits, suggesting that larger-scale manipulation of heterosynaptic inputs might allow for rescue of E:I balance within epileptic circuits and offer a promising approach to treating temporal lobe epilepsy.

Title: Sharp wave-ripple associated dendritic signal integration in awake mice

Authors: *B. CHIOVINI[1,2], D. PÁLFI[2,1], G. JUHÁSZ[1,2], L. JUDÁK[1], Z. MEZRICZKY[2], G. KATONA[1,2], B. RÓZSA[1,2]
[1]Inst. of Exptl. Med. Hungarian Acad. of Sci., Budapest, Hungary; [2]Pázmány Péter Catholic University, Fac. of Information Technol. and Bionics, Budapest, Hungary

Abstract: Hippocampal sharp wave-ripple (SPW-R) complexes have crucial role in memory formation and consolidation. SPW-R activities appear during slow wave sleep and consummatory behaviour. These hippocampal patterns are responsible for encoding, storage and retrieval of memory. Several facts suggest that SPW-R-associated cell assemblies can activate dendritic hot-spots. Because of technical and methodical problems the relationship between

SPWs, field ripple oscillations and dendritic hot-spots have not yet been studied in awake animals. Beside the field potential recordings we were able to measure simultaneously the activity pattern of neuronal populations and their dendritic signal integration mechanisms in large volume. We developed new surgical methods in order to apply two-dimensional (2D) and three-dimensional (3D) two-photon random-access point scanning imaging techniques combined with ipsilateral multi-channel electrophysiology. We show complex Ca^{2+} events at different subcellular regions of hippocampal neurons *in vivo*. Moreover, we found the existence of dendritic Ca^{2+} spikes in awake animals. We were able to record hippocampal activity patterns during physiological rhythms among neurons or along their dendrites in high volumes and in real time, in order to better understand the mechanisms of hippocampal coincidence detection and neuronal functions during input-output formation and conversion *in vivo* in deep brain areas.

Abstract: The human cortex exhibits exceptional computational power compared to other species, but the underlying biological mechanisms are unknown. Here, we perform direct patch clamp recordings from human cortical dendrites and report enhanced electrical compartmentalization in layer 5 pyramidal neurons. Distance-dependent voltage attenuation is similar between human and rat dendrites, demonstrating that the longer physical length of human neurons translates into a longer electrotonic length. Compared to rat dendrites, input into human distal apical dendrites is much less effective at driving somatic action potentials, even in the presence of dendritic spikes. Human somas also exhibit less bursting in response to somatic current injection due to decreased recruitment of dendritic electrogenesis. We conclude that greater functional compartmentalization of single neurons increases the number of electrical

processing compartments that can perform independent operations, which may contribute to the computational power of human cortex.

Title: Experience-dependent synaptic plasticity in the lateral habenula

Authors: *M. TRUSEL, S. LECCA, M. MAMELI
Dept. of Fundamental Neurosciences, UNIL, Lausanne, Switzerland

Abstract: In everyday life, proper behavioral responses when foreseeing an unpleasant event are necessary for survival. Seminal work performed in awake monkeys indicated that neurons in the lateral portion of the epithalamic nucleus habenula (LHb) are excited upon a negative event. Furthermore, after conditioning an animal to recognize a neutral stimulus anticipating the occurrence of a punishment, LHb neurons show excitation when the conditioned stimulus is presented (Matsumoto and Hikosaka, 2007). However, whether synaptic adaptations occur within the LHb during learning, allowing anticipating an aversive stimulus, remains unknown. We hypothesized that, during the formation of an association between an external stimulus and the successive administration of a punishment, plasticity at excitatory synapses occurs in the LHb. To investigate this issue, we interrogated synaptic transmission onto LHb neurons in acute brain slices from animals at different stages of learning using an active avoidance paradigm (30 trials/day, 5 days). The animals learned to avoid a footshock preannounced by a tone already from the second and third sessions (“learners”). Control mice instead received the footshocks and the CS randomly, not contingently. 24h after training session 2 we measured spontaneous excitatory postsynaptic currents (sEPSC) in acute brain slices containing the LHb. The frequency of sEPSCs, but not amplitude, was significantly increased in the LHb of learners, compared to control mice. Recording trains of EPSCs revealed similar paired-pulse ratios between learners and controls. We then measured AMPA and NMDA currents elicited by electrical stimulation within the LHb, observing a significant increase in AMPA/NMDA ratio in learners compared to controls. Furthermore, this AMPA/NMDA increase was similarly observed when evoking

EPSCs using uncaged glutamate in the proximity of dendrites. These data suggest that learning to predict an aversive stimulus engages post-synaptic strengthening at excitatory synapses in the LHb.

Title: Resolving plasticity at accumbal to lateral hypothalamus synapse in feeding behaviour

Authors: *S. THOENI, E. O'CONNOR, C. LÜSCHER
Dept. of Basic Neurosciences, Univ. of Geneva, Geneva, Switzerland

Abstract: Inhibition of nucleus accumbens (NAc) dopamine D1 receptor-expressing medium spiny neurons (D1R-MSNs) projecting to the lateral hypothalamus (LH) enables feeding in mice. Here, using whole-cell patch clamp recordings, we investigated the plasticity of this NAc-to-LH synapse in the context of feeding behavior. Surprisingly, a high frequency stimulation protocol previously shown to potentiate NAc-pallidum or NAc-midbrain synapses, was without effect on NAc-LH synapses in slices from control mice. Chemical long-term potentiation (LTP), normally elicited by PKA activation, also had no effect on the NAc-LH inhibitory postsynaptic currents. This was true regardless of the postsynaptic identity of LH neurons receiving NAc inhibition. Conversely, a depression of the NAc-LH synapse was observed following activation of GABA-B or CB1-receptors, but not after low frequency stimulation protocol shown to be efficient at the NAc-pallidum synapse. Consistent with these observations, tracing experiments revealed that NAc-D1-MSNs projecting to LH are largely non-overlapping to those that project to the midbrain and pallidum. Finally, mice were exposed to a regime of food restriction and exercise to trigger hyperphagia and excess weight gain upon resuming *ad libitum* food access. At the timepoint of hyperphagia, PKA activation now led to potentiation of the NAc-to-LH synapse in *ex vivo* brain slices, most likely reflecting a decrease in release probability at these terminals. Taken together, our findings point to a model in which experience-dependent plasticity at the NAc-LH synapse may support rebound food intake in periods following weight loss. This model may reflect elements of weight gain associated with human yoyo dieting.

Title: Exogenous coenzyme Q treatment affects age-related alterations of the motor cortex in aged mice

Authors: *R. INOUE, M. TAKAHASHI, M. MIURA
Tokyo Metro Inst. Gerontology, Tokyo, Japan

Abstract: Motor deficits occur during not only disease like Parkinson's disease but also normal aging. Takahashi et al (2016) found behavioral and histological alterations that were associated with age-related decline of brain mitochondrial function. Mitochondrial function is assessed by measuring mitochondrial oxygen consumption rate (OCR). They suggested that OCR, coenzyme Q (CoQ) content, vesicular glutamate transporter 1 (VGluT1) level in the motor cortex, and motor function were reduced in aged mice compared to young mice. CoQ, which is present in mitochondria, is a coenzyme and an electron transporter in the respiratory chain. They also showed that chronic administration of CoQ to aged mice restored OCR, CoQ content, VGluT 1 level, and motor function. In this study, we examined whether normal aging affects electrophysiological activities in the motor cortex of mice, and whether exogenous CoQ treatment affects the physiological alteration in the aged mice. Brain slices were obtained from aged mice after chronic CoQ treatment. Identification of the motor cortex was done using a brain atlas. In some experiments, Nissl staining was performed to confirm the characteristic layer structure of the motor cortex. Field excitatory postsynaptic potentials (fEPSPs) of motor cortex in brain slices of young or aged male mice were recorded by a multi-electrode array or a glass recording pipette. Electrophysiological measurements revealed that aging significantly affected fEPSPs of aged mice compared to young mice. Considering that motor function declined even in normal aging, the changes observed in the motor cortex might relate to the motor decline. Although more detailed studies are needed to clarify the relation between central nervous system and age-related motor decline, these results may serve as the basis for developing therapy of age-related motor impairment.

Title: Monitoring Rem2 interaction with the CamKIIα holoenzyme by simultaneous homo- and hetero-FRET measurements

Authors: *D. J. LIPUT[1], T. NGUYEN[2], H. L. PUHL, III[4], S. VOGEL[3]
[1]Lab. for Integrative Neurosci., [2]Lab. of Mol. Physiol., [3]NIH/NIAAA, Rockville, MD; [4]NIH, Rockville, MD

Abstract: Rem2, a member of the RGK family of small GTPases, is enriched in the nervous system and implicated in molecular mechanisms of neuroplasticity. RGK proteins are known for interacting with high-voltage-activated calcium channels, resulting in robust channel inhibition. In addition, Rem2 can interact with other cellular molecules, including CaMKIIα. To investigate the interactions between Rem2 and CaMKIIα, we employed a fluorescence polarization technique that can simultaneously monitor Homo- and Hetero-FRET, to study Rem2-CamKIIα binding and subsequent conformational changes in CaMKIIα catalytic domain pairing. HEK cells were transfected with plasmids encoding CaMKIIα tagged with mVenus on the N-terminal catalytic domain (V-CaMKIIα), Rem2 tagged with mCherry on the N-terminus (mCh-Rem2), or untagged Rem2. Approximately 24 h after transfections, cells were harvested and homogenates from each transfection were prepared to measure V-CaMKIIα time-resolved anisotropy (Homo-FRET) and lifetime (Hetero-FRET). V-CaMKIIα homogenates were incubated with Rem2 homogenates and saturating concentrations of calcium calmodulin (CaM) to activate the holoenzyme. Under these conditions, Rem2 increased steady state anisotropy (SSA) compared to V-CaMKIIα alone (0.052 ±0.001, 16.5% decrease in homo-FRET), suggesting that Rem2 disrupts V-CaMKIIα catalytic domain pairing. An increase in SSA also suggests that Rem2 is binding to the catalytic domain T-site as a similar increase in SSA was observed with the NR2B C-terminus (0.090 ± 0.002, 28.7% decrease in homo-FRET), a well characterized T-site ligand. Further corroborating a direct interaction between Rem2 and V-CaMKIIα, incubation with mCh-Rem2 not only increased SSA (0.086 ± 0.02, 26.7% decrease in homo-FRET), but also decreased the lifetime of V-CaMKIIα (0.18 ± 0.01 ns, 6% hetero-FRET), demonstrating a close proximity interaction between Rem2 and the V-CaMKIIα catalytic domain. To further characterize this interaction, we are currently analyzing a library of Rem2 mutants and peptide fragments to define the precise CaMKIIα binding domain. The CaMKIIα catalytic domain T-site is critical for

CaMKIIα functions in neural plasticity. For example, activated CaMKIIα binds to NR2B via the T-site, which is required for CaMKIIα translocation to post synaptic sites and long-term potentiation (LTP). Furthermore, the T-site appears to be required for CaMKIIα scaffolding functions thus promoting the recruitment of additional proteins to post synaptic sites following LTP induction. Therefore, Rem2 may be involved in molecular mechanisms of neuroplasticity by interacting with the CaMKIIα catalytic domain T-site.

Title: Interaction between NMDA receptor- and endocannabinoid-mediated modulation of nociceptive synapses

Authors: *B. D. BURRELL[1,2], S. YUAN[1]
[1]Basic Biomed Sci., Univ. of South Dakota, Vermillion, SD; [2]Ctr. for Brain and Behavior Res., Vermillion, SD

Abstract: Nociceptors, sensory neurons that detect damage or potential damage to the body, are the first stage of communicating noxious stimuli from the periphery to central nervous system (CNS). In this study, long-term potentiation (LTP) in the CNS of the medicinal leech, *Hirudo verbana*, was examined, taking advantage of the ability to intracellularly record from nociceptive synapses in this model organism. High frequency stimulation (HFS) of nociceptors did produce a persistent increase in synaptic transmission and this LTP was both NMDA receptor-mediated and synapse-specific. Surprisingly, inhibition of NMDA receptors during HFS "uncovered" a persistent form of synaptic depression. This long-term depression (LTD) was mediated by the endocannabinoid transmitter 2-arachidonoyl glycerol (2-AG) acting on a TRPV (transient receptor potential vanilloid) -like channels. Previous studies have demonstrated that low frequency stimulation could produce LTD in these nociceptive synapses that was 2-AG- and TRPV-mediated (*J Neurophysiol* 104: 2766-2777; *J Neurosci.* 33:4349-4358). However, it was surprising to find this same form of LTD in the context of HFS plus NMDA receptor blockade. These observations suggest that a synapse-specific, NMDA receptor-mediated form of LTP in nociceptors is an evolutionarily-conserved process that is observed across vertebrate and

invertebrate phyla. Furthermore, there may be an interaction between NMDA receptor-mediated and endocannabinoid-mediated forms of synaptic plasticity in nociceptive synapses. Specifically, the NMDA receptor mediated processes may “suppress” endocannabinoid signaling. Such findings could be significant for understanding cellular mechanisms behind nociceptive sensitization and perhaps even contribute to chronic pain.

Title: Mitochondria dependent metabolic programming drive hebbian long term potentiation

Authors: *H. ROLYAN
Intrnl. Med., Yale Univ., New Haven, CT

Abstract: Long-term potentiation (LTP) and depression (LTD) are the mechanisms that neurons use to modulate their inherent synaptic plasticity and support storage and recovery of memories in the brain. The ability to potentiate a synapse over long term declines significantly in neurodegenerative disorders. In addition to deficiencies in synaptic plasticity, degenerating neurons display acute and chronic mitochondrial dysfunction, suggesting that dysregulated mitochondria play a role in synaptic dysfunction, in addition to their role in apoptosis. Our previous work has shown that the anti-apoptotic protein Bcl-xL not only prevents somatic cell death, but also potentiates long-term synaptic responses. Here, we show that Bcl-XL is responsible for dramatic changes in ATP levels in hippocampal neurons during LTP. Using fluorescence imaging of a FRET based ATP reporter (ATeam) in living hippocampal neurons, we find that LTP induction causes a sharp decrease in ATP levels followed by a persistent long term increase in ATP production. This suggests that after intense synaptic stimulation, neurons may become metabolically more efficient. The long-term increase in ATP levels of LTP-stimulated synapses is blocked by inhibition of Bcl-xL and by inhibition of ATP synthase with oligomycin. Bcl-xL inhibition also prevents the long-term increase in surface glutamate receptor insertion. In hippocampal slice recordings, inhibition of Bcl-xL greatly impairs early stage LTP and prevents late stage LTP. Our findings suggest that long term changes in mitochondrial efficiency brought by activity-dependent translocation of Bcl-xL to mitochondria are required for LTP and shed light on the role of mitochondrial metabolic programming and dynamics in acute induction and long-term maintenance of learning and memory processing. If such mitochondria-

dependent metabolic changes fail to occur, synaptic dysfunction and neurodegeneration may ensue.

Title: Spontaneously hypertensive rat exhibits increased synaptic plasticity

Authors: *S. TANIGUCHI[1], M. OGURA[1], K. TANABE[1], D. YAMANAKA[1], K. ITO[2]
[1]Univ. of Tokyo, Kasama, Ibaraki, Japan; [2]Univ. Tokyo, Kasama, Japan

Abstract: Spontaneously Hypertensive Rat (SHR) is established from Wistar-Kyoto rat (WKY) at Kyoto University and it shows hypertension from 7 weeks old. As recent studies demonstrated that SHR exhibits impulsivity, inattention and hyperactivity, this rat is used as an animal model for attention deficit hyperactivity disorder (ADHD). However, the ability of learning and memory and synaptic plasticity of SHR are poorly understood, while ADHD patients show low cognitive performance. In this study, we recorded field EPSPs (fEPSPs) from Schaffer collateral - CA1 pyramidal cell synapses to elucidate how synaptic plasticity in the hippocampus of SHR differs from that in WKY by evaluating the long-term potentiation (LTP) which is a well-established form of synaptic plasticity. We used the 9-15-month-old male SHR and age-matched WKY. First, we checked the amount of food ingested and body weight to know the characteristics of feeding because ADHD patients sometimes have problems with eating. The body weight of SHR was significantly lighter than that of WKY although the food consumption of SHR was significantly more than that of WKY. Next, we made horizontal hippocampal slices (0.35 mm thickness) for fEPSP recordings, and induced LTP with high-frequency stimulation (100 Hz). The slope of fEPSPs of SHR was comparable with that of WKY. On the contrary, LTP in SHR was significantly larger than that in WKY (SHR:159±7%, WKY:141±3%). Moreover, Morris water maze test, which is commonly used for assessment for spatial learning and memory, revealed that the dwell time in the targeted area of SHR was significantly longer than that of WKY in the probe trial. These results indicate that SHR has increased synaptic plasticity and cognitive function, and that SHR is not always suitable for ADHD model. Although the underlying mechanism of increased synaptic plasticity of SHR is yet to be investigated, the use of SHR as ADHD model requires considerable attention.

Title: Presynaptic DCAF12 is part of a negative feedback loop regulating TGF-beta signaling at the *Drosophila* neuromuscular junction

Authors: *M. TORVUND, L. A. PATRON, K. E. ZINSMAIER
Univ. of Arizona, Tucson, AZ

Abstract: Synaptic growth at the *Drosophila* neuromuscular junction is regulated by a canonical retrograde Transforming Growth Factor-β (TGF-β)/Bone Morphogenetic Protein (BMP) signaling pathway. The ligand Glass bottom boat (Gbb) is secreted from the muscle and activates the presynaptic receptors Wishful thinking (Wit), Thickveins or Saxophone, which phosphorylate the transcription factor Mothers against decapentaplegic (Mad). Phosphorylated Mad (pMad) translocates to the nucleus and regulates transcription, promoting synaptic growth. In addition, non-canonical presynaptic Gbb secretion likely mediates synaptic transmission and plasticity but the precise mechanism remains unclear.
Previously, we showed that *Drosophila* DCAF12 is required for multiple independent synaptic functions at the *Drosophila* larval NMJ, including the upregulation of evoked neurotransmitter release, the downregulation of glutamate receptor subunits, and expression of synaptic homeostasis. Here, we show that presynaptic DCAF12 is a negative regulator of normal TGF-β signaling at larval NMJs. Deletion of DCAF12 increase synaptic levels of pMad, which can be rescued by pre- but not postsynaptic DCAF12 expression.
In addition, presynaptic expression of DCAF12 expression is tightly regulated by TGF-β signaling. RNAi-mediated knock-down (KD) of the TGF-β ligand Maverick (Mav) in glia cells and its putative receptor Punt in muscles strongly reduced DCAF12 levels in motor neurons but not muscles. Similarly, KD of postsynaptic Gbb in the muscle and presynaptic Wit and Mad in the motor neuron strongly reduced DCAF12 levels in motor neurons but not the muscle. Hence, this indicates that DCAF12 expression in motor neurons is upregulated by retrograde TGF-β signaling at the *Drosophila* NMJ. When considered in conjunction with the elevated pMad levels of DCAF12 deletions, we suggest that DCAF12 is part of a negative feedback loop regulating

TGF-β signaling at the synapse. Ongoing experiments aim to identify the mechanisms underlying presynaptic DCAF12's control of synaptic pMAD levels.

Title: Electrical synapses as modulators of behavior

Authors: *L. VOELKER[1,2], I. RABINOWITCH[1], J. BAI[1,2]
[1]Fred Hutch Cancer Res. Ctr., Seattle, WA; [2]Univ. of Washington, Seattle, WA

Abstract: An animal must constantly adjust its behavior in order to respond to changing environments and fluctuations in internal states. Animals achieve this by altering neural activity levels through changes known as neural plasticity. While much research has focused on understanding changes that occur at chemical synapses, it is becoming clear that electrical synapses also have important roles to play. Electrical synapses are specialized sites of cytoplasmic communication between neurons and are known to coordinate local electrical activity and to pass the small molecules associated with neural plasticity. In *C. elegans,* electrical synapses are known to coordinate inputs from multiple different sensory modalities to influence behavior. I have shown that an electrical synapse between the primary quinine sensory neuron ASH and its neighbor ASK is required for modulation of the response to quinine. The innexin INX-18 is necessary within ASK, while INX-19 is necessary in both ASK and ASH. INX-18 and INX-19 colocalize at points of contact between the ASK and ASH neurons. Quinine sensitivity is also modulated by mutations in the cGMP generating guanylyl cyclase GCY-27, which is expressed in ASK but not ASH. This suggests that the ASK/ASH electrical synapse may be modulating behavior via the passage of cGMP.

Title: Distinct mechanisms underlie electrical coupling resonance and membrane potential resonance

Authors: *X. LI[1,2], H. G. ROTSTEIN[1,2], F. NADIM[1,2]
[1]Dept Biol. Sci., Rutgers/Njit, Newark, NJ; [2]Inst. for Brain and Neurosci. Research, NJIT, Newark, NJ

Abstract: Neurons and synapses can exhibit frequency selectivity that influences the dynamics of oscillatory circuits. Many neurons exhibit membrane potential resonance, a maximal subthreshold voltage amplitude response to oscillatory current input at a non-zero (resonant) input frequency. The influence of resonance on network oscillations has been hypothesized to play a role in the generation of brain rhythms.
In electrically coupled networks, an oscillatory current input to one neuron produces voltage oscillations in both pre- and post-junctional neurons. In recent studies, both the post-junctional neuronal response and the coupling coefficient (the ratio of post- and pre-junctional neuronal responses) have been shown to exhibit preferred frequency responses. However, the resonance properties of electrical coupling have been demonstrated in current clamp, but not in voltage clamp experiments. It is therefore unclear whether coupling resonance reflects the properties of the gap junctions, or it emerges from the interaction between the coupling current and membrane properties of the post-junctional neuron. In any case, the relationship between the resonance frequencies of the coupled neurons and that of the electrical coupling remains to be determined. We examined these questions by recording pairs of electrically coupled neurons that show resonance in the oscillatory pyloric network of the crab *C. borealis*. To examine whether the gap junction conductance itself shows resonance, we performed dual voltage clamp recordings and quantified the frequency preference of the coupled neurons, the gap junction conductance, and the post-junctional neuronal response. We found that all three components exhibit frequency selectivity, but with distinct preferred frequencies. Furthermore, the resonance properties of the electrical coupling were subject to neuromodulation. Our modeling results suggest that, resonance in the neurons alone is sufficient to produce resonance in the electrical coupling, but only at the same preferred frequency as the coupled neurons. A distinct resonance frequency therefore emerges from the gap junction conductance itself.

To study the functional effect of the resonance of the gap junction conductance, we examine its role in synchronizing neuronal activities and influencing network frequency in electrically coupled model neurons, and how neuromodulation affects these effects. Together, our findings demonstrate the mechanisms underlying electrical coupling resonance and highlight the interaction between preferred frequency responses at different levels of organization in shaping the network dynamics.

Title: Long-term potentiation of electrical synapses in the thalamic reticular nucleus

Authors: B. A. FRICKER, E. L. HECKMAN, P. CUNNINGHAM, *J. S. HAAS
Dept. of Biol. Sci., Lehigh Univ., Bethlehem, PA

Abstract: Synaptic plasticity is a fundamental process that is thought to underlie human learning and brain development. Activity-based bidirectional learning rules have been well characterized for neurotransmitter-based synapses. However, a bidirectional relationship between physiological activity and synaptic strength has not yet been established for mammalian electrical synapses. In the thalamic reticular nucleus (TRN), gap junctions comprising cx36 form electrical synapses that are the dominant source of communication between neurons. Like all thalamic cells, TRN neurons exhibit two primary modes of activity: bursting, which features a low-threshold calcium spike crowned with regular sodium spikes; and tonic spiking, where the only spikes are regular sodium-based. Our previous work has demonstrated that paired bursting in coupled TRN neurons induces LTD of electrical synapses between them (Haas et al., 2011) that arises from calcium-based mechanisms (Sevetson et al., 2017). Here we show, in whole-cell patch recordings of pairs in rodent brain slices of both genders age p11-p14, that low-frequency tonic spiking in one cell of a coupled pair, in the presence of T-type calcium channel antagonists, leads to LTP of the synapse. We further show that LTP does not result from paired tonic spiking, and depends on calcium dynamics within neurons. Our results lead us to propose a calcium-based bidirectional rule for activity-dependent plasticity of electrical synapses, where small influx of calcium in tonic spiking leads to LTP while larger influx during bursting leads to LTD.

We expect that similar bidirectional plasticity rules are a widely defined principle of electrical synapses in all brain regions.

Title: Na^+-dependent regulation of vesicular glutamate transport at an auditory synapse

Authors: *H. HUANG, D. LI, Y. ZHU
Dept. of Cell and Mol. Biol., Tulane Univ., New Orleans, LA

Abstract: Auditory information is encoded by action potentials phase-locked to sound frequencies at high rates. Accordingly, synaptic vesicles need to be recycled and refilled rapidly to support the high-frequency signaling. Accumulating studies have uncovered the mechanisms of vesicle fusion and recycling; however, the control of the contents of synaptic vesicles has received considerably less attention. We have recently found that a Na^+/H^+ exchanger expressed on synaptic vesicles promoted vesicle filling with glutamate. Using the calyx of Held, a giant glutamatergic synapse in the auditory brainstem that permits direct pre- and postsynaptic recordings and manipulation of the cytosolic environments, we showed that presynaptic cytosolic Na^+ facilitated glutamate loading into synaptic vesicles and increased excitatory postsynaptic currents. During high-frequency signaling, when large amounts of glutamate were released, Na^+ accumulated in terminals. The elevated Na^+ facilitated vesicular glutamate uptake and enhanced the postsynaptic excitatory currents, while did not affect the readily releasable pool or release probability. Moreover, high concentration of Na^+ was required to maintain reliable high-frequency transmission from presynaptic calyces of Held to postsynaptic MNTB neurons. Therefore, we established a new role of intracellular Na^+ as a feedback signal to modulate glutamate loading according to the level of vesicle release.

Title: BDNF induces *in vivo* long-term synaptic plasticity at hippocampal mossy fiber pathway in a transcription and translation-independent manner

Authors: *A. MARTÍNEZ, M. L. ESCOBAR
Univ. Nacional Autónoma De México, Ciudad DE Mexico, Mexico

Abstract: Brain-derived neurotrophic factor (BDNF) is an essential protein synthesis product that has emerged as one of the most potent molecular modulators of synaptic plasticity in the hippocampus. Our previous studies have demonstrated that acute intrahippocampal administration of BDNF induces a lasting potentiation of synaptic efficacy at the MF projection accompanied by a structural reorganization at the CA3 area within the stratum oriens region. In the present study we investigate whether the inhibition of translation and protein transcription interferes with the persistence of the MF functional and structural synaptic plasticity elicited by BDNF in adult rats *in vivo*. Our results show that the inhibition of either transcription or protein synthesis does not affect the expression of the functional and structural synaptic plasticity induced by the administration of BDNF. These findings suggest that BDNF is an essential plasticity related product, that is necessary and sufficient to induce and maintain functional and structural synaptic plasticity at MF-CA3 pathway.

Title: The role of synaptic BDNF-TrkB signaling in ketamine-mediated antidepressant effects

Authors: *P.-Y. LIN[1], E. T. KAVALALI[2], L. M. MONTEGGIA[2]
[1]Neurosci., UTSouthwestern Med. Ctr., Dallas, TX; [2]UT Southwestern Med. Ctr., Dallas, TX

Abstract: Brain-derived neurotrophic factor (BDNF) and its high affinity receptor, tropomyosin receptor kinase B (TrkB), regulate synaptic plasticity in the hippocampus. However, the precise site of BDNF release and location of TrkB receptors in ketamine-mediated synaptic plasticity are still unclear. To directly examine the role for BDNF-TrkB signaling in hippocampal subregions that mediates antidepressants response of ketamine, we used a viral mediated approach to genetically delete the genes in specific subregions of the hippocampus of adult mice. The mice were allowed to recover for 3 weeks following the stereotaxic surgeries before all electrophysiological and behavioral testing, a time point sufficient to induce gene recombination. The mice with deletion of BDNF or TrkB in specific hippocampal subregions were given an acute low dose of ketamine and then tested two hours later in either the novelty suppressed feeding or forced swim test. In separate experiments, we examined synaptic BDNF-TrkB signaling in ketamine mediated synaptic potentiation that correlates with antidepressant efficacy. In preliminary findings, we find that the regional specific deletion of BDNF impacts ketamine mediated antidepressant responses and synaptic plasticity. Further experiments are underway to determine how TrkB initiates its downstream signaling to engage in ketamine-mediated synaptic potentiation and antidepressant-like effects.

Title: Serotonergic modulation on the inhibitory synaptic transmission in the lateral amygdala

Authors: *R. YAMAMOTO, T. SUGAI, N. KATO
Dept. of Physiol., Kanazawa Med. Univ., Ishikawa, Japan

Abstract: Accumulating evidence has shown that serotonergic innervations unto the amygdaloid complex modulate the affective states and behaviors. It has been reported that serotonin suppresses the inhibitory transmission in the lateral amygdala. However the fine mechanisms of the modulation is still unclear. In this paper, we examined the fine effects of serotonin (5-HT) on inhibitory synaptic inputs to principal neurons in the rat lateral amygdala (LA) by whole-cell

recording. The $GABA_A$ component of inhibitory post synaptic currents (IPSCs) was isolated by the blockade of AMPA, NMDA and $GABA_B$receptors. Bath-application of 5-HT suppressed the amplitude of $GABA_A$ currents and increased the paired-pulse ratio. α-m-5-HT, a broad agonist for 5-HT receptors (including $5\text{-}HT_{1A}$, $5\text{-}HT_{1B}$ & $5\text{-}HT_2$ receptors) also suppressed the amplitude of $GABA_A$ current. The $GABA_A$ current induced by the direct application of GABA under the blockade of AMPA, NMDA and $GABA_B$ receptors were not altered by 5-HT. The $GABA_B$ component of IPSCs was induced by repetitive LA stimulation or puff-application of baclofen/GABA to the soma under blockade of AMPA, NMDA and $GABA_A$ receptors. The synaptically induced $GABA_B$ current was reduced by 5-HT. By contrast the $GABA_B$ currents elicited by a focal application of Baclofen or GABA were enhanced by 5-HT, indicating that the suppression of $GABA_B$ component are relatively preserved by the post-synaptic enhancement than the $GABA_A$ component. These results suggest that serotonin generally suppresses inhibitory transmission in LA, whereas under the situation that the GABA neurons exhibit high activities, the long-lasting $GABA_B$ dependent suppression would be relatively preserved and this will maintain the dynamism of inhibitory tone in the LA.

Title: Oxytocin enhances excitatory and inhibitory synaptic transmission in a layer specific manner in the rat medial prefrontal cortex

Authors: *S. M. SINGHAL, S. W. HARDEN, C. J. FRAZIER
Dept. of Pharmacodynamics, Col. of Pharm., Univ. Of Florida, Gainesville, FL

Abstract: Activation of oxytocin receptors (OTRs) in the rodent medial prefrontal cortex (mPFC) has previously been demonstrated to modulate maternal behavior, socio-sexual behavior, and stress/anxiety related behaviors, however relatively little is known about the cellular and synaptic mechanisms underlying such effects. Here we use in vitro electrophysiology to reveal novel effects of OTR activation in the rat mPFC that vary with respect to cortical layer. We report that the specific OTR agonist TGOT can directly depolarize a subset of OTR expressing layer 5 pyramidal neurons via a mechanism that appears to involve inhibition of barium sensitive G-protein coupled potassium permeant leak channels. We also report that OTR activation increases the frequency and amplitude of spontaneous excitatory

postsynaptic currents (sEPSCs) in the same layer 5 pyramidal cells, likely due to direct activation of local recurrent excitatory connections. By contrast, in layer 2 pyramidal neurons, activation of OTRs increases the frequency and amplitude of spontaneous inhibitory postsynaptic currents (sIPSCs) without affecting sEPSCs. Consistent with that observation, we find that a subset of layer 2 GABA interneurons (INs) are depolarized by TGOT, yet these interneurons display significant heterogeneity in their firing pattern in response to direct current injection. Overall, these studies are among the first to demonstrate layer specific effects of OTR activation in mammalian cortex, and should ultimately contribute to our developing understanding of how oxytocin modulates activity of cortical efferent projections to influence behavior.

Title: Effects of temperature during brain slice preparation on the physiology of cortical neurons

Authors: *J. C. MERCADO DEL VALLE[1], A. T. GULLEDGE[2]
[1]Dartmouth Col., Hanover, NH; [2]Mol. and Systems Biol., Geisel Sch. of Med., Hanover, NH

Abstract: Preparation of acute brain slices for *ex vivo* electrophysiology typically involves cooling the brain in "ice-cold" (< 4 °C) artificial cerebral spinal fluid (aCSF), which is thought to slow cellular metabolism and minimize excitotoxicity following ischemic insult during brain dissection. Yet previous studies have reported that preparation of hippocampal brain slices in ice-cold temperature results in a dramatic reduction of dendritic spines in CA1 neurons, with spine regrowth and proliferation occurring during post-slice re-warming of the tissue (Kirov et al., *Neuroscience* 127:69-80, 2004). A subsequent study (Bourne et al., *Neuropharmacology* 52:55-59, 2007) found that preparation at warmer temperatures (~25 °C) prevented the loss and proliferation of dendritic spines. We tested the impact of temperature during tissue preparation on the physiology and morphology of retrogradely-labeled corticopontine (CPn) neurons in layer 5 of the medial prefrontal cortex (PFC). Eighteen Adult mice were injected with fluorescent retrobeads (Lumafluor) in the pons to retrogradely label CPn neurons; acute brain slices were then prepared several days later using either ice-cold (< 4°C; n = 5 female and 4 male mice) or room temperature (25 °C; n = 5 female and 4 male mice) aCSF. After cutting, slices were incubated in 35 °C aCSF for an hour before electrophysiological recordings were made (also at 35 °C) from labeled CPn neurons. Qualitatively, we could not distinguish any obvious

differences in the health or number of targetable neurons (labeled or unlabeled) in slices prepared in iced or room-temperature aCSF. Further, we found no significant differences in resting membrane potentials ($p = 0.23$), input resistances ($p = 0.35$), or HCN-channel-mediated responses ($p = 0.60$) in the two experimental conditions ($n = 30$ for each). Action potential kinetics were also similar in most respects, including spike threshold ($p = 0.76$), amplitude ($p = 0.25$), and rise-time ($p = 0.09$). However, action potential half-widths were slightly longer (at 568 ± 13 vs 510 ± 15 μs; $p = 0.005$) in CPn neurons in slices prepared at room temperature. No sex-dependent differences were observed in either condition. These results confirm that healthy slices can be obtained in the absence of significant brain cooling (see Huang & Uuisaari, *Frontiers in Cellular Neuroscience* 7:48, 2013). We are currently testing the impact of temperature during slicing on spine morphology.

Abstract: Memory formation is believed to result from changes in synapse strength and structure. While memories may persist for the lifetime of an organism, the proteins and lipids that make up synapses undergo constant turnover with lifetimes from minutes to days. The molecular basis for memory maintenance may rely on a subset of long-lived proteins (LLPs). While it is known that LLPs exist, whether such proteins are present at synapses is unknown. We

performed an unbiased screen using metabolic pulse-chase labeling *in vivo* in mice and *in vitro* in cultured neurons combined with quantitative proteomics. We identified synaptic LLPs with half-lives of several months or longer. Proteins in synaptic fractions generally exhibited longer lifetimes than proteins in cytosolic fractions. Protein turnover was sensitive to pharmacological manipulations of activity in neuronal cultures or in mice exposed to an enriched environment. We show that synapses contain LLPs that may underlie stable long lasting changes in synaptic structure and function.

Abstract: Modulation of synaptic strength through trafficking of AMPA receptors (AMPARs) is a fundamental mechanism underlying synaptic plasticity and has been shown to be an important process in learning and memory. However, the in vivo dynamics of AMPAR trafficking into and out of dendritic spines, and how this correlates with learning, have not been defined. Here, we train mice on a forelimb reaching task and use in vivo two-photon microscopy to visualize AMPARs in the mouse cortex over the course of learning. We use in utero electroporation to express the AMPAR subunit GluA1 tagged with Super Ecliptic pHluorin (SEP, a pH-sensitive GFP) in layer 5 neurons of the motor cortex and visualize their apical dendrites after each training session. We found that, following daily motor training, individual spines of layer 5 neurons show vastly different modulation of their AMPAR content. On average, motor learning leads to an increase in surface GluA1 levels at dendritic spines in the motor cortex compared to untrained control mice. This synaptic potentiation is driven by a subset of spines that are spatially clustered. Additionally, we also observed increases of spine GluA1 levels in the

somatosensory and visual cortex of mice learning the motor task. Synaptic potentiation in the visual cortex is dependent on visual input during motor training and follows a different time course than in the motor cortex. These results indicate that motor learning induces synaptic potentiation by increasing the net trafficking of AMPARs into spines not only in the motor cortex but also in sensory brain regions previously not thought to be involved in this behavioral task.

Abstract: The synapse is the fundamental unit of the nervous system, enabling communication between brain cells and providing a substrate for experience-dependent plasticity to drive adaptive behaviors. As AMPA receptors (AMPARs) mediate a majority of fast synaptic transmission throughout the brain, dynamic regulation of AMPARs is though to underlie higher brain functions such as learning and memory. Indeed, roles for AMPARs in long-term potentiation and depression have been elucidated in vitro, and activity-dependent changes in AMPAR expression and function have been reported following learning in vivo. Despite the clear significance of synaptic transmission, a large-scale analysis of how AMPARs across the brain are distributed and change during learning has not been performed. To address this question, we have developed several knockin mouse lines with Super Ecliptic pHluorin-tagged AMPAR subunits (GluA1-4), enabling two-photon imaging of the distribution and dynamics of endogenous AMPARs in behaving mice. By developing methods to image millions of synapses over many weeks, we are able to track changes in synaptic strength with molecular resolution during learning, providing an unprecedented view of how AMPARs dynamics may shape learning and memory.

Title: ICA69-mediated AMPA receptor trafficking regulates activity-dependent synaptic strengthening and learning and memory

Authors: *S.-L. CHIU[1,2], R. L. HUGANIR[1,2]
[1]Dept. of Neurosci., [2]Kavli Neurosci. Discovery Institute, Johns Hopkins Univ. Sch. of Med., Baltimore, MD

Abstract: Long-term potentiation (LTP) has been considered to be one of the major cellular mechanisms for learning and memory. Activity-dependent increase in the surface delivery of AMPA receptors (AMPARs) is important for enhanced synaptic efficacy during LTP. Two major intracellular trafficking pathways regulate surface delivery of AMPARs and synaptic transmission: 1) the de novo secretory pathway in which newly synthesized AMPARs are delivered onto the membrane; and 2) the recycling pathway in which endocytosed AMPARs can return to the membrane. This study aims to study the contribution of AMPAR secretory trafficking in synaptic plasticity and animal behavior through studying a Golgi-localized protein, ICA69. ICA69 is part of the AMPAR protein complex through its interaction with PICK1, which binds to GluA2 or 3 subunits of AMPARs directly. We found that ICA69 determines the subcellular localization of PICK1 in hippocampal neurons, which in turn may regulate AMPAR distribution and function. To test whether ICA69 regulates basal synaptic AMPAR localization and composition, we isolated postsynaptic density (PSD) protein fractions from hippocampi of *Ica1* knockout mice and their wild-type littermates. GluA1, 2 and 3 protein levels in the PSD fractions are comparable between genotypes suggesting that ICA69 does not regulate AMPAR trafficking at basal states. To test whether ICA69 regulates activity-dependent AMPAR trafficking, we examined variety forms of plasticity at the hippocampal Schaffer collateral to CA1 Synapses. We found that *Ica1* knockout mice showed normal NMDAR- or mGluR-dependent LTD. However, *Ica1* knockout mice exhibited impaired NMDAR-dependent LTP and behavioral deficit in inhibitory avoidance learning. In summary, our results show a specific role of ICA69-mediated secretory trafficking of AMPARs in LTP, but not LTD, and associative learning and memory.

Title: Phosphorylation of GluA2 tyrosine 876 is necessary for homeostatic plasticity

Authors: *A. J. YONG[1,2], A. M. BYGRAVE[1,2], H. L. TAN[1,2], R. L. HUGANIR[1,2]
[1]Dept. of Neurosci., [2]Kavli Neurosci. Discovery Institute, Johns Hopkins Univ. Sch. of Med., Baltimore, MD

Abstract: Homeostatic plasticity is a mechanism whereby neurons alter their synaptic strength to maintain firing rates in response to changes in network activity. At excitatory synapses, the dynamic control of AMPA receptor (AMPAR) expression at the postsynaptic surface is crucial for homeostatic scaling. Surface AMPARs increase with scaling up and decrease with scaling down, and the regulation and trafficking of the AMPAR subunit GluA2 is essential for this process. While tyrosine phosphorylation on the C-terminal domain of GluA2 is known to change bi-directionally during homeostatic scaling, the exact tyrosine residue and whether these changes are necessary for AMPAR trafficking during homeostatic scaling is unknown. Here, we show that phosphorylation of GluA2 at the tyrosine residue 876 (Y876) is necessary for homeostatic scaling-up, both in vivo and in vitro. We found that bi-directional changes in phosphorylation of GluA2 Y876 occurs during the homeostatic scaling process. To test the necessity of GluA2 Y876 phosphorylation, we generated phospho-deficient Y876F knockin mice, which have normal synaptic composition and function. Strikingly, cultured neurons derived from these mice show deficient scaling-up induced by TTX and Y876F knockin mice lack scaling-up in the visual cortex after visual deprivation in vivo. Thus, our study suggests that AMPAR trafficking during homeostatic scaling up can be gated by a single phosphorylation site on the GluA2 subunit.

Abstract: Modulation of surface AMPA receptor (AMPAR) expression is a key process implicated in synaptic plasticity and has been shown to play critical roles in higher brain function such as learning and memory. The trafficking of AMPARs into and out of synapses is highly dynamic and regulated by subunit-specific AMPAR binding proteins as well as by various post-translational modifications. In the past, many studies have revealed the molecular mechanisms underlying AMPAR trafficking in vitro. However, an in vivo approach examining intact brains of living animals is necessary to fully understand the role of AMPAR trafficking in synaptic plasticity and brain function. Here, we employed in utero electroporation in conjunction with in vivo two-photon imaging to visualize Super Ecliptic pHluorin (SEP, a pH-sensitive form of GFP)-tagged GluA1 in synapses of layer 2/3 neurons in the visual cortex of living mice. We observed that individual spine GluA1 expression and size were very dynamic over days even under basal states in adult primary visual cortex (V1) neurons and that the changes were negatively correlated with their initial GluA1 levels. Moreover, synaptic GluA1 expression in layer 2/3 V1 neurons was significantly increased at day 7 after visual deprivation. These changes were distance-dependent: deep spines increased faster and more than superficial spines. Further, the deprivation-induced increase of synaptic GluA1 was specific to layer 2/3 neurons, as layer 5 neurons did not show increases in synaptic GluA1 after deprivation. Collectively, our study demonstrates that synaptic AMPAR expression in adult mice is very dynamic under basal conditions and is highly regulated after visual deprivation.

Title: Mitochondrial ROS regulate structural and functional synaptic plasticity

Authors: *H. FANG[1,2], B. LIU[1,2], P.-H. WU[3,4], D. WIRTZ[3,4], R. L. HUGANIR[1,2]
[1]Dept. of Neurosci., [2]Kavli Neurosci. Discovery Institute, Johns Hopkins Univ. Sch. of Med., Baltimore, MD; [3]Johns Hopkins Physical Sci. - Oncology Ctr., [4]Dept. of Chem. and Biomolecular Engin., The Johns Hopkins Univ., Baltimore, MD

Abstract: In the past two decades more and more evidence has emerged showing that mitochondria are involved in neuronal physiology and neurodegenerative diseases. Besides being the powerhouse of the cell, mitochondria are also involved in many other cellular processes, such as apoptosis, protein degradation, calcium homeostasis, and reactive oxygen species (ROS) generation. Mitochondrial ROS represent the majority of cellular ROS and are generated during oxidative phosphorylation. During neuronal activity, mitochondrial ROS have been observed but their functional significance remain unclear. Here, we assessed the role of mitochondrial ROS in long-term potentiation (LTP). We observed mitochondrial flashes (mitoflashes) in neurons, as a cellular marker of mitochondrial ROS generation, and found that mitoflash frequency transiently increased during chemical LTP (cLTP). We also found that in neurons with knockdown of mitochondrial superoxide dismutase (SOD2) leading to increased ROS level, LTP was enhanced, with larger dendritic spines and synaptic AMPA receptors (AMPARs) increase. Phosphorylation of AMPA receptors plays a critical role in their proper synaptic trafficking during synaptic plasticity. We found that ROS scavenger treatment decreased GluA1 phosphorylation at Serine 831 and 845 sites, which was mediated by decreased activity of calcium/calmodulin-dependent protein kinase type II (CaMKII) and protein kinase A (PKA). These results demonstrate that mitochondrial ROS regulate structural and functional synaptic plasticity in neurons potentially through the regulation of CaMKII and PKA activity.

Title: Distinct translocation patterns and biochemical characteristics of SynGAP isoform and gene mutations in diseases during synaptic plasticity

Authors: *Y. ARAKI[1,2], T. R. GAMACHE[1,2], R. L. HUGANIR[1,2]
[1]Dept. of Neurosci., [2]Kavli Neurosci. Discovery Inst., Johns Hopkins Univ. Sch. of Med., Baltimore, MD

Abstract: SynGAP is a Ras GTPase-activating protein (GAP), and is one of the most abundantly expressed proteins in excitatory synapses, along with PSD-95. We previously discovered that SynGAP is rapidly dispersed from the postsynaptic density (PSD) upon LTP, leading to activation of Ras signaling, and resulting in downstream processes such as AMPA receptor insertion and spine enlargement. SynGAP and PSD-95 form highly concentrated liquid-like droplets by liquid-liquid phase separation when combined in vitro. Recent genetic studies have identified a myriad of missense and nonsense mutations of SynGAP linked to human neurocognitive disorders, including intellectual disability (ID), autism spectrum disorder (ASD), and Schizophrenia (SCZ). We have characterized some of these mutations and found that the mutations found in each disease group differentially affect biochemical property and synaptic plasticity. SynGAP has 4 different C-terminal isoforms resulting from alternative splicing: alpha1, alpha2, beta, and gamma. We discovered that SynGAP translocation and function are differentially regulated in an isoform-specific manner during synaptic plasticity. Additionally, the different SynGAP isoforms exhibit distinct biochemical characteristics, including those related to their interaction and phase transition behavior with PSD-95. Coordinated function of each specific SynGAP isoform over the course of development may support proper formation of synapses.

Title: Platform for longitudinal *in vivo* two-photon imaging with sub-micron precision

Authors: *I. HONG[1,2], R. H. ROTH[1,2], J. B. ISSA[3], R. L. HUGANIR[1,2]
[1]Dept. of Neurosci., [2]Kavli Neurosci. Discovery Institute, Johns Hopkins Univ. Sch. of Med., Baltimore, MD; [3]Dept. of Neurobio., Northwestern Univ., Evanston, IL

Abstract: Two-photon in vivo brain imaging has revealed the internal structure and dynamics of neurons in their native environment. Tracking the structural dynamics and activity of neurons and their subcellular compartments quantitatively over days and weeks is crucial for the study of higher order brain function such as synaptic plasticity and learning and memory. However, accurate repeated imaging in vivo has proven difficult, due to non-isotropic resolution, scar tissue growth, inflammation and other obstacles that hinder the reliable longitudinal microscopic tracking of a given field of view. The axially-elongated point spread function of two-photon imaging casts a ‘smear’ depending on the imaging direction and prevents accurate quantitative comparison of images acquired from different axial directions. To resolve this technical challenge, we have developed multi-axis rotational head-fixation stage hardware and 3D-registration software to allow accurate longitudinal imaging of a given focal plane with submicron precision over days and weeks. Our head fixation stage incorporates two goniometers through which the roll and pitch of the specimen can be adjusted to match original imaging conditions. The design is highly modular, allowing anesthetized imaging on a heated pad or awake imaging with a circular treadmill. The accompanying software suite, StackGPS, uses 3D registration to guide rapid position and angle adjustment in 3D. Usage examples demonstrate that our protocol ensures sub-micron, <1° longitudinal tracking of a given field of view, which allows the observation of neurons, dendrites and spines across multiple days. The StackGPS software suite also allows post-hoc 3D registration of in vivo volume images, which can vastly accelerate subsequent analysis for spine dynamics and calcium imaging. Collectively, this platform expands the temporal window and accuracy of chronic brain imaging to allow the tracking of subcellular phenomena in normal brain function as well as dysfunction.

Abstract: Intracellular signaling pathways in the brain play a central role in regulating neuronal activity and synaptic plasticity. Unraveling the dynamic molecular interplay behind these complex physiological processes requires the ability to both detect changes in biochemical states in response to physiological signals and track multiple signaling activities simultaneously. Fluorescent protein-based biosensors have enabled the real-time monitoring of dynamic signaling processes within the native context of living cells, yet most commonly used biosensors exhibit poor sensitivity (e.g., dynamic range) and are limited to imaging single signaling activities at a time. Here, we address this challenge by developing a new class of excitation ratiometric kinase activity biosensors that offer the highest reported dynamic range and enable the detection of small changes in signaling activity that could not be reliably detected previously, as well as a suite of single-fluorophore biosensors that enable the simultaneous tracking of as many as six distinct signaling activities in single living cells. These new tools will allow the imaging of complex multiple signaling pathways occurring during synaptic transmission and plasticity in neurons in vitro and in vivo.

Abstract: Regulation of AMPA receptor (AMPAR) trafficking is a fundamental mechanism underlying synaptic plasticity and has been shown to be a crucial process for learning and memory. AMPAR trafficking is a highly dynamic process involving exocytosis, endocytosis, and lateral diffusion along the plasma membrane. So far, many studies have investigated these processes through overexpression of exogenous fluorescently tagged AMPARs in vitro and in vivo. However, the dynamics and regulation of AMPAR trafficking are still a mystery, partly due to the lack of tools to visualize endogenous AMPARs in vivo. Here, we report the generation of a knockin mouse line in which Super Ecliptic pHluorin (SEP, a pH-sensitive GFP) is tagged to the extracellular domain of the endogenous AMPAR subunit GluA1. This mouse line enables dynamic imaging of endogenous surface GluA1 trafficking in vitro and in vivo. We have characterized these SEP-GluA1 mice using immunohistochemistry, biochemistry, electrophysiology, two-photon imaging, and behavioral examinations, and found that these knockin mice showed regular synaptic targeting of GluA1, normal basal transmission and synaptic plasticity, as well as intact behaviors known to require GluA1. Thus, this SEP-GluA1 knockin mouse line serves as a reliable tool to visualize synaptic plasticity with molecular resolution in behaving animals.

Abstract: In the central nervous system, the trafficking of AMPARs is finely regulated by a large number of intracellular proteins binding to AMPAR subunits. Amongst these interacting proteins it has been recently described that carnitine palmitoyltransferase 1C (CPT1C) binding to GluA1 subunit of AMPARs enhances surface expression of these glutamate receptors in such a way that synaptic AMPAR content in CPT1C deficient animals is diminished. A possible role of CPT1C – together with other proteins as FRRS1L – in priming AMPARs at endoplasmic reticulum has been proposed. This priming would prepare AMPARs to bind to *bona fide* auxiliary subunits (as TARPs and Cornichons) for their delivery to the plasma membrane. Despite a positive role of CPT1C on AMPAR surface expression, the molecular mechanisms of such modulation remain obscure. In this work, we explore a putative depalmitoylating role of CPT1C on GluA1 based on evidences obtained in an *in silico* analysis. We identified a group of three aminoacids in CPT1C (Ser 252, His 470 and Asp 474), which are homologous to a catalytic triad with palmitoyl thioesterase (PTE) activity in palmitoyl thioesterase APT1. The impairment of the CPT1C putative PTE activity with Palmostatin B – a well described inhibitor of the depalmitoylating enzyme APT1 – precludes AMPAR trafficking modulation effect of CPT1C. Indeed, the mutation of these putative catalytic residues in CPT1C avoids the CPT1C-dependent trafficking modulation of AMPARs in both cell lines and hippocampal neurons. Moreover, we found that merely the histidine residue (His 470) of CPT1C is crucial for the increase in GluA1 surface expression. Finally, we show that CPT1C effect appears to be specific for CPT1C isoform (not shared by CPT1A) and it occurs exclusively at the endoplasmic reticulum level. In

summary, this work reveals the mechanism by which CPT1C modulates AMPAR trafficking and it adds a pinch of additional information to the complex mechanisms that are involved in traffic regulation of AMPARs.

Title: Neuronal receptors display cytoskeleton-independent directed motion on the plasma membrane

Authors: *L. C. ANDREAE[1], R. D. TAYLOR[1], M. HEINE[2], N. J. EMPTAGE[3]
[1]King's Col. London, London, United Kingdom; [2]3Leibniz-Institute of Neurobio., Magdeburg, Germany; [3]Univ. of Oxford, Oxford, United Kingdom

Abstract: Neurons need to ensure proteins can be rapidly localized to specific membrane destinations in response to stimuli. The current models for transmembrane protein movement describe either active intracellular trafficking by molecular motor driven vesicles along the cell cytoskeleton, or passive lateral diffusion within the plasma membrane. We developed a pH-sensitive quantum dot probe which exhibits virtually undetectable fluorescence when localized to intracellular transport vesicles but allows single particle tracking on the surface of membranes. Using this probe in dissociated rat hippocampal neurons, we tracked the surface movement and behavior in dendrites of the transmembrane tyrosine kinase receptor, EphB2, a well-known neuronal protein with important roles in synapse formation and plasticity. We applied a ‘time resolved’ sliding window method (based on mean squared displacement, custom written in MATLAB) to analyse the membrane surface trajectories and identified two patterns of movement among the diffusing population of EphB2Rs: diffusive and super-diffusive, as well as, surprisingly, a subpopulation of neuronal EphB2 receptors that exhibit directed motion within the plasma membrane itself. Disruption of the actin cytoskeleton with latrunculin A caused greater movement in the super-diffusive group with no effect on the more freely diffusing receptors, consistent with the concept of an actin ‘fence’ forming part of the membrane skeleton. However, neither actin disruption, nor depolymerization or stabilization of the microtubule

network (with different doses of nocadazole), altered the directed motion, indicating that this was occurring independently of the cytoskeletal network. Instead, directed motion was modulated by the cholesterol composition of the cell membrane. Comparison of trajectories with a postsynaptic marker indicated that while EphB2Rs show diffusive behaviour at synapses, directed motion occurs only outside synapses. Furthermore, increasing neural activity by electrical field stimulation resulted in receptors spending longer periods of time in directed motion mode. We propose that this directed motion mode could provide an alternative energy efficient method of protein delivery to specialized locations within the plasma membrane.

Title: Spatial and geometrical aspects of cAMP dynamics in dendritic spines

Authors: *D. OHADI[1], D. L. SCHMITT[1], T. M. BARTOL[2], T. J. SEJNOWSKI[2,1], J. ZHANG[1], P. RANGAMANI[1]

Abstract: Dendritic spines are the primary excitatory synaptic sites that have been associated with morphological changes observed during long-term potentiation. Despite the central role of some molecular events such as cAMP-PKA signaling pathway in the regulation of the spine formation and its morphological modifications and ultimately, learning and memory, little is known about the geometrical and spatial parameters affecting the cAMP-PKA dynamics in dendritic spines. There is a strong evidence that for cyclic adenosine monophosphate (cAMP) to activate its main effector, protein kinase A (PKA)- an enzyme that can phosphorylate multiple targets in the cell- a distinctive subcellular concentration of cAMP is required. Compartmentalization of different signaling components of cAMP-PKA pathway in subcellular domains may be responsible for activating PKA with significantly different cAMP concentration than in the bulk cytosol. cAMP signaling domains may form as a result of A-kinase anchoring proteins (AKAPs) providing a distinctive subcellular response by anchoring to e.g. PKA to bring it together with key modulators of the signaling system such as adenylate cyclase (AC) or phosphodiesterases (PDEs). In this study, through a reaction-diffusion framework, we developed a computational spatiotemporal model to shed light on the contributions of various compartmentalization mechanisms that control the cAMP local concentrations in dendritic

spines. Using this model, we investigate how geometrical aspects such as shape and size of the spine, or diffusional barriers such as spine apparatus and spine neck can affect the cAMP dynamics. We also study the role of functional barriers such as phosphodiesterases in creating cAMP compartmentalization. Our computational model has important implications for the understanding of cAMP regulations in dendritic spines.

Title: Heteromeric JIP proteins regulate synaptic transport of AMPARs

Authors: *F. J. HOERNDLI[1], P. J. BROCKIE[3], J. E. MELLEM, JR[3], R. WANG[4], D. MADSEN[3], B. E. PULFORD[2], A. V. MARICQ[3], R. DOSER[2]

Abstract: Regulated long distance transport of AMPA-type ionotropic glutamate receptors (AMPARs) is emerging as an important cellular mechanism used to modulate synaptic strength. However, the precise mechanisms for loading and unloading AMPAR cargo from molecular motors at synapses *in vivo*, in intact neuronal circuits, are largely unknown. Using *in vivo* confocal imaging of long distance synaptic AMPAR transport in *C. elegans*, we have previously described a new role for CaMKII in activity-dependent loading of AMPAR vesicles onto Kinesin-1 motors. Here, we show that the scaffold proteins UNC-16/JIP3a and JIP-1/JIP1 are required for the motor-mediated delivery and removal of synaptic AMPARs (GLR-1/2) in *C. elegans*.
Mutations in the scaffold proteins UNC-16 and JIP-1 severely disrupted AMPAR transport, synaptic AMPARs levels as well as glutamate-gated currents. The mammalian homolog of UNC-16 (JIP3a) rescued the defective AMPAR transport in transgenic *C. elegans* mutants, suggesting that the signaling pathways are conserved.
Using *in vivo* simultaneous dual wavelength spinning disk microscopy, we show that UNC-16 and JIP-1 co-transport with GLR-1 and Kinesin-1 motors. Co-transport analyses in loss of

function mutants of JIPs and CaMKII, indicate that JIPs depend on each other and CaMKII function to form a transport complex. To test the hypothesis that JIPs are required for constitutive regulation of AMPAR transport to synapses we will use heatshock-induced gene expression of UNC-16 or JIP-1. To test the hypothesis that these JIPs are essential scaffolds for activity-dependent loading of AMPAR onto Kinesin-1, we will use *in vivo* chromophore-assisted-light-inactivation (CALI) of JIPs and CaMKII at the neuronal soma or at synapses. Together our results and experimental design identify an essential new role for UNC-16/JIP3a and JIP-1/JIP1 in the regulation of long-distance synaptic transport of AMPARs. Since these scaffolds were originally identified as MAPK and JNK signaling scaffolding proteins, our results suggest that both MAPK and JNK, binding to these scaffolds might play important roles in synaptic AMPAR transport dynamics.

Title: Role of sorting nexin-1 in metabotropic glutamate receptor (mGluR's) trafficking

Authors: *R. SHARMA, R. GULIA, S. BHATTACHARYYA
Dept. of Biol. Sci., Indian Inst. of Sci. Educ. and Res., Punjab, India

Abstract: Group I metabotropic glutamate receptors (mGluRs) are G-protein coupled receptors, function as modulators of neuronal physiology and they have also been implicated in various neuropsychiatric disorders. These Group I mGluRs are present at the perisynaptic region of postsynapse and are positively coupled with G-protein. Our work is directed towards understanding the regulation of Group I mGluRs in the central nervous system. The accurate physiological response depends on their specific localization in the neuronal membrane at a specific time. Trafficking is the process which regulates the spatiotemporal localization of these receptors at the synapse, hence playing a crucial role in regulating their function. Trafficking also regulates the activity like desensitization, resensitization, and downregulation of various GPCRs. Despite this obvious significance, we know very little about the cellular machineries that control the trafficking of group I mGluRs in the central nervous system. Sorting nexin 1 (SNX1) has been shown to regulate the endosomal sorting of few cell surface receptors either to lysosomes where they are downregulated or back to the cell surface. It's been reported that mGluR1 gets endocytosed upon ligand stimulation and it follows slow recycling route via recycling endosome. In the current study, we illustrate how sorting nexin 1 (Snx1) regulates the trafficking of Group I

mGluRs in primary hippocampal neurons using “molecular replacement” approach. We have shown that the knockdown of endogenous SNX1 resolutely affects the receptor trafficking. Our data suggest that both, N-terminal and C-terminal region of SNX1 play critical role in the normal trafficking of the receptor. Thus, these studies reveal a mechanistic role of SNX1 in the trafficking of group I mGluRs.
Our study also reveals the role of Snx1 in mGluR mediated AMPAR trafficking, the cellular correlate for the mGluR-dependent synaptic plasticity.

Title: Evaluation of the antiepileptogenic efficacy of promising multitargeted drug combinations

Authors: *L. WELZEL[1,2], F. TWELE[1], P. KLEIN[3], W. LÖSCHER[1,2]
[1]Dept. of Pharmacology, Toxicology and Pharm., Univ. of Vet. Med. Hannover, Hannover, Germany; [2]Ctr. for Systems Neurosci., Hannover, Germany; [3]Mid-Atlantic Epilepsy and Sleep Ctr., Bethesda, MD

Abstract: Symptomatic epilepsies, including temporal lobe epilepsy (TLE), often result from acute brain injuries, such as status epilepticus (SE), traumatic brain injury, ischemic stroke, tumors or infections. Epilepsy prevention in patients at risk remains a major unmet clinical need. The time interval between the initiating brain insult and the onset of spontaneous recurrent seizures (SRS) is defined as the latent period, which would be an ideal time window for treatment preventing or modifying the epileptogenic process. The development of multitargeted antiepileptogenic drug combinations (“network pharmacology”), using clinically approved drugs for rapid translation into clinical trials, is an approach that targets the multiple mechanisms involved in epileptogenesis. We selected drugs with promising mechanisms or already known disease-modifying effects (*Klein and Tyrlikova (2017), Epilepsy Behav.,72: 188-194*) to be combined as the following rationally chosen drug combinations: A) levetiracetam + atorvastatin + ceftriaxone, B) levetiracetam + gabapentin + deferoxamine + fingolimod, C) levetiracetam + alpha-tocopherol. Using an algorithm based on the drug development phases in humans (*Klee et al. (2015), Epilepsy Res., 118: 34-48*), the drug combinations were tested for tolerability in naïve male NMRI mice and in post-SE mice before being tested for antiepileptogenic efficacy in the

intrahippocampal kainate mouse model. We induced a status epilepticus (SE) in groups of male NMRI-mice (age 8 weeks), which were treated with the drug combination 3 times daily over 5 days. Continuous (24/7) EEG- and video monitoring was performed over 7 subsequent days at 4 and 12 weeks post-SE. Blinded analysis of electrographic and electroclinical seizures and blinded histological analysis of neurodegeneration occurring in the hippocampus were performed. Contrary to expected, treatment with the drug combination levetiracetam + atorvastatin + ceftriaxone did not lead to a reduction in frequency or severity of electroclinical seizures 4 or 12 weeks post-SE. Analysis of the drug combinations B) levetiracetam + gabapentin + topiramate, C) levetiracetam + gabapentin + deferoxamine + fingolimod, and D) levetiracetam + alpha-tocopherol is currently being finished. Due to the still incomplete understanding of epileptogenesis, the challenge of finding novel treatment for epilepsy prevention remains problematic. Supported by the European Union's Seventh Framework Programme (FP7) under grant agreement 602102 (EPITARGET).

Title: Inhibition of cholesterol 24-hydroxylase improves the survival of a mouse model of epileptic phenotype and modulates extracellular levels of glutamate

Authors: *T. NISHI[1], S. WATANABE[2], S. HASEGAWA[2], S. FUJIMOTO[2], E. SUNAHARA[2], M. OHORI[2], T. KOIKE[2], M. MIYAMOTO[2], S. KONDO[2]
[1]Res., Takeda Pharmaceut., New York, NY; [2]Takeda Pharmaceut., Fujisawa, Japan

Abstract: Cholesterol 24-hydroxylase (CH24H also known as CYP46A1) is an enzyme responsible for the conversion of brain cholesterol into 24*S*-hydroxycholesterol (24HC). Early experimental evidence supporting the therapeutic potential of CH24H inhibition was observed in the extended life expectancy of amyloid precursor protein (APP) and presenilin 1 (PS1) Tg mice cross-bred with homozygous or heterozygous CH24H knockout mice. The model carryies transgenes implicated in familial Alzheimer's disease, whereas also known for an epileptic character and an altered glutamate regulation. In this study, TAK-935, a potent and selective CH24H inhibitor was tested in the APP/PS1-Tg model. APP/PS1-Tg mice orally treated with TAK-935 showed a dose-dependent reduction in the brain level of 24HC. The dose of TAK-935 10 mg/kg was found to reduce the brain level of 24HC by approximately 50% compared with the vehicle-treated control mice, recapitulating the heterozygous CH24H deficiency. Seven-week old female APP/PS1-Tg mice were orally treated with vehicle or TAK-935 10 mg/kg once daily for

8 weeks (n=30). During the survival observation, the hazard ratio for sudden death was 5.849 in the vehicle-treated arm compared with TAK-935. A significant improvement in mortality was observed in the TAK-935 group ($p<0.01$ vs control). Based on an assumption that high seizure susceptibility is the underlying cause of mortality in these mice, 100 mM potassium chloride (KCl) was continuously injected through a microdialysis probe in the hippocampus to unmask their epileptic phenotype. KCl-challenged APP/PS1-Tg mice were found to be more susceptible than their wild-type (WT) control not only to seizure but also to extracellular glutamate elevation (fold increase from baseline: WT, 4.0; Tg, 22.8, n=4-5, $p<0.05$). Two-week treatment of TAK-935 (10 mg/kg orally every day) significantly suppressed the KCl-induced glutamate elevation in APP/PS1-Tg mice (fold increase from baseline: vehicle, 28.9; TAK-935, 1.6, n=12, $p<0.01$). This result indicates that TAK-935 normalized the high susceptibility of APP/PS-Tg mice to extracellular glutamate elevation, leading to a hypothesis that CH24H inhibition is a potential new pharmacological mechanism to modulate seizure susceptibility in the epileptic brain consistent with our previous studies in kindling development model. The consistency in the survival advantage of genetic and chemical ablation of CH24H in APP/PS1-Tg mice highlights the relevance of CH24H inhibition as a new therapeutic strategy.

Title: Cholesterol 24-hydroxylase inhibition is a novel pharmacological mechanism that exerts neuroprotective effects against glutamate excitotoxicity in rats

Authors: S. HASEGAWA, T. NISHI, S. WATANABE, S. FUJIMOTO, *S. KONDO
CNS-DDU, Takeda Pahrmaceutical Co. Limited, Fujisawa-Shi, Japan

Abstract: Glutamate toxicity plays a central role in a variety of neurological disorders and is thus studied as a promising treatment target. We previously reported that pharmacological

inhibition of cholesterol 24-hydroxylase (CH24H also known as CYP46A1) has a potential to delay the acquisition of kindling seizure, which led us to an assumption that CH24H inhibition can be protective against glutamate toxicity. A small-molecule CH24H inhibitor TAK-935 was tested in the rat kainic acid (KA) hippocampal injury, a representative model of excitotoxicity. The Y maze test was conducted 4 days after KA injection, and dose-dependent effects were observed at doses of TAK-935 10 and 30 mg/kg (orally every day). The spontaneous alteration rates of the saline-treated control, KA-induced vehicle control, and TAK-935 10 and 30 mg/kg were 78.6, 60.9, 71.6, and 74.4%, respectively ($p<0.025$ vs vehicle). Brain samples were obtained 5 days after KA injection and underwent Fluoro Jade-C (FJC) staining, which showed that TAK-935 dose-dependently reduced FJC-positive areas in CA3 by 80% and 85% from that in the vehicle control group, respectively, at 10 and 30 mg/kg ($p<0.025$ vs vehicle). In addition to the neuroprotective effects, tumor necrosis factor alpha and glial fibrillary acidic protein expression levels were reduced in the treatment arm, suggesting a modulation of inflammatory glial reactions. It was also shown that 24S-hydroxycholesterol (24HC), the enzymatic product of CH24H, potentiated cell death induced by glutamate in primary neuron culture. Importantly, its neurotoxic potential was highly dependent on the N-methyl-D-aspartate (NMDA)-type glutamate receptor, but not on the KA or AMPA-type. It was thus presumed that CH24H inhibition exerted neuroprotective effects by reducing 24HC, which has neurotoxic potential mediated by NMDA receptors. TAK-935 was further tested for potential effects on locomotor activity, which is typically increased by NMDA receptor blockade. Under the treatment condition where brain 24HC decreased approximately by 90%, TAK-935 did not affect locomotor activity in mice. Taken together, we infer that CH24H inhibition is a novel neuroprotective mechanism against the KA-induced excitotoxicity. Although its pharmacological mechanisms remain to be fully investigated, CH24H inhibition may reduce glutamate toxicity differently from the conventional NMDA receptor blockade.

Title: Suppression of seizure-induced increased expression of JAK/STAT signaling in kindling model of epileptogenesis using isoxylitones [E/Z]

Authors: *S. U. SIMJEE[1], U. NISAR[2], F. SHAHEEN[2], .. ATTA UR RAHMAN[3], M. I. CHOUDHARY[3]
[1]H.E.J. Res. Inst. of Chemistry, Internatio, Karachi, Pakistan; [2]H.E.J. Res. Inst. of Chemistry, Intl. Ctr. for Chem. and Biol. Sci., Karachi, Pakistan; [3]H.E.J. Res. Inst. of Chemistry, Dr. Panjwani Ctr. for Mol. Med. and Drug Research, Intl. Ctr. for Chem. and Biol. Sci., Karachi, Pakistan

Abstract: Purpose: Epilepsy is a serious neurological disorder marked by recurring seizures. To date a broad category of AEDs are available, but unfortunately over one-third of the epileptic patients do not respond to these drugs. Thus finding new therapeutics to overcome the untreatable epilepsy and side effects of the current drug therapies is needed. The activation of the Janus Kinase (JAK)/Signal Transducer and Activator of Transcription (STAT) signaling pathway has also been reported to link with epilepsy. This can be use as a target molecular pathway to interrupt the process of epileptogenesis. In the present study, we targeted the JAK/STAT pathway using isoxylitones [E/Z] in order to inhibit the development of epilepsy following a brain insult in an animal model. The outcome of these studies could lead to new therapies that can be used to prevent or inhibit development of acquired epilepsy following brain injury.
Methods: Pentylenetetrazole (PTZ)-induced kindling in mice was used as a model of epileptogenesis. Seizure-related behaviors were monitored for 30-45 minutes following PTZ administration. JAK/STAT were analyzed in brain samples of mice using RT-PCR and immunohistochemistry.
Results: The results revealed that isoxylitones [E/Z], a sodium channel blocker halt the development of epileptogenesis in PTZ-kindled mice. Isoxylitones effectively reduces the expression of JAK-1, JAK-3, and STAT-5a in hippocampus and cortex.
Conclusion: The present data suggests that isoxylitones act at the underlying molecular mechanism to control the seizure pattern, such as the downregulation of JAK/STAT most in hippocampus followed by cortex. These findings uncover a potential effect of the JAK/STAT pathway in epileptogenesis and may provide a new therapeutic target that can be harnessed for the prevention of epilepsy development and/or progression. At this stage we propose to examine isoxylitones to determine 1) its potency to inhibit JAK/STAT pathway and cellular toxicity in primary hippocampal neurons, 2) ability to block acute seizure- induced JAK/STAT pathway activation in brain and off-target effects on other kinases. The expected outcome is identification of lead JAK/STAT inhibitors that can be advanced towards clinical testing for epilepsy disease modification.

Title: Targeting exaggerated TGF-β signaling pathway to inhibit pentylenetetrazole-induced epileptogenesis in mice

Authors: *M. SHAHID[1], U. NISAR[1], F. SHAHEEN[1], .. ATTA UR RAHMAN[1,2], M. CHOUDHARY[1,2], M. ASKANI[1], S. U. SIMJEE[1,2]
[1]H.E.J. Res. Inst. of Chem., Intl. Ctr. For Chem. and Biol. S, Karachi University, Pakistan; [2]Dr. Panjwani Ctr. for Mol. Med. and Drug Res., Intl. Ctr. For Chem. and Biol. Sci., Karachi, Pakistan

Abstract: Epilepsy is illustrated by persistent predisposition of the brain to generate seizures and considered as one of the most common, chronic, neurological disorder affecting around 1% of the individuals worldwide. A growing body of advanced researches now points a link between inflammation and various epilepsy syndromes, reflecting both an inflammatory state inside the epileptic brain along with increased permeability of the blood–brain barrier, heading towards enhanced neuronal excitability. The probable contribution of TGF-β in epileptogenesis is reinforced by animal studies viewing TGF-β up-regulation as measure of inflammatory reaction in the brains of kindled animals that are exposed to status epilepticus. While focusing on the other side of TGF-β signaling pathway to explore better treatment targets for epilepsy, Tumor necrosis factor-α receptor-associated factor-6 (TRAF6), transforming growth factor beta-activated kinase 1 (TAK1), which are the crucial elements of TGF-β associated inflammation, are still ambiguous in epilepsy.
The main focus of this study was to investigate the potental relatioship between the TGF-β associated genes and epilepsy which will aid in confirming that up regulation of TGF-β genes can be an underlying cause of epilepsy.
To confirm these evidences, expression levels of TRAF6 and TAK1 genes along with inflammatory cytokine interleukin-1β (IL-1 β) were analyze in pentylenetetrazole-induced epileptogenesis model in mice. A novel anticonvulsant Isoxylitones and its derivatives were used to treat epileptic seizures along with standard antiepileptic drugs Diazepam and Valproic acid. It was observed that gene expression of TRAF6 was increased in pentylenetetrazole-induced status epilepticus group followed by increase expression of TAK1 which is phosphorylated by TRAF6. However expressions of these genes were significantly reduced in Isoxylitones and standard antiepileptic drugs treatment groups. Inflammatory cytokine IL-1b expression was also decreased in treated groups. In conclusion, up regulation of TGF-β genes can be an underlying

cause of epileptogenesis and inhibiting it's upregulated expression can aid in reducing seizure duration and associated neuronal death in epilepsy.

Abstract: Cervical vagus nerve stimulation (cVNS) is an effective clinical alternative for intractable epilepsy and drug-resistant depression, with potential use in heart failure, anxiety disorders, post-stroke motor recovery and tinnitus. However, the stimulation of the entire nerve can cause undesirable side effects such as voice alteration, cough, and dysphagia by the off-target stimulation of axons that innervate the recurrent laryngeal nerve (RLN). Voice alteration is the most common of these side effects, and is caused by activation of the large myelinated Aα branchiomotor efferents, which have a low stimulation threshold due to their size. We hypothesize that specific localization of these fibers combined with localized stimulation could be used to minimize the side effects caused by RLN activation. Using toluidine-blue label of ultrathin left VN sections and histomorphometric analysis, we identify a bimodal distribution in the fiber diameter histogram of the adult rat, corresponding to populations of large myelinated A fibers (peak diameter 7-8 μm) and medium to small myelinated Aδ/B fibers (peak diameter 2-3 μm). Image analysis of the left cVN using DBSCAN in R allowed the identification of clusters of large A and small/medium Aδ/B myelinated axons approximately 2 cm from the subclavian branching point of the RLN. Furthermore, a k- means algorithm was employed to divide each nerve into different regions. The cluster centroids were used to generate Voronoi diagrams, which were fitted to the dimensions of the nerve and used to create local density maps. Results show a statistical significance between the density of the densest region and the least dense region for both large A fibers and smaller Aδ/B fibers. In order to evaluate if the bundled large A axons can be avoided using localized stimulation, we fabricated a custom multi-contact cuff

electrode to selectively stimulate the nerve. Using this method, we selectively minimize the activation of the Aα fibers in the RLN while effectively evoking Aδ/fiber activation in the proximal cVN. Together, the results show that the main fascicle of the rat cVN has significant clustering of both large and small myelinated fibers, and that localized stimulation using multi-contact cuff electrodes can be used to selectively target the Aδ-fibers while avoiding some of the off-target activation of Aα motor axons in passage to the larynx. Avoiding the activation of Aα RLN fibers can prevent deleterious side effects otherwise caused by the concomitant RLN activation that occurs when the cVN is stimulated indiscriminately. This work supports the use of multi-contact cuff electrodes in cVNS applications.

Title: Enaminone modulators of extrasynaptic alpha$_4$beta$_3$delta GABA$_A$receptors reverse electrographic seizures and prevent neuronal cell death after acute organophosphate poisoning

Authors: T. JOHNSTONE[1], H. S. MCCARREN[2], J. SPAMPANATO[3], F. E. DUDEK[4], J. H. MCDONOUGH[2], D. HOGENKAMP[1], *K. W. GEE[1]

Abstract: The current specifications for a standard medical countermeasure to organophosphate (OP) chemical nerve agent exposure is the development of a pharmaceutical agent that can augment or replace clinically-used anticonvulsant benzodiazepines (BZs) to effectively control OP-induced epileptogenesis. BZs do not fully control nerve agent induced seizures because they only engage synaptic gamma-aminobutyric acid A receptors (GABA$_A$Rs) that rapidly internalize under status epilepticus (SE) conditions. Extrasynaptic GABA$_A$Rs such as those containing alpha$_4$beta$_3$delta subunits are a putative pharmacological target to comprehensively manage nerve agent seizures since they do not internalize during SE and are continuously accessible for activation. Neurosteroids related to allopregnanolone have been tested as a possible replacement for BZs because they target both synaptic and extrasynaptic GABA$_A$Rs. Delayed treatment duration/efficacy and neuroprotection represent significant advantages of neurosteroids over BZs, but neurosteroid use is limited by poor physicochemical properties arising from the intrinsic

requirement of the androstane or pregnane steroid core structure for efficacy, rendering drug formulation problematic. We tested a non-steroidal enaminone $GABA_AR$ modulator that interacts with synaptic and extrasynaptic $GABA_A$ receptors on a binding site distinct from neurosteroids or BZs for efficacy to control electrographic seizures induced by diisopropyl fluorophosphate and soman intoxication. We found that the enaminone 2-261 has an extended duration of seizure termination (>10 hrs) in the DFP intoxication model in the presence or absence of midazolam. 2-261 moderately potentiates midazolam in GD-induced seizure model, but has limited efficacy alone due to slow onset of action. 2-261 significantly reduces neuronal cell death in brain areas associated with either diisopropyl fluorophosphate or soman induced SE. Thus, 2-261, may represent a more drug-like chemical template directed towards enhancing extrasynaptic $alpha_4beta_3$delta $GABA_AR$ activity for OP intoxication because it and related compounds may have a wider latitude for synthetic optimization than a neurosteroid-based template.

Title: Retinoic acid decreases the epileptic activity through the interaction of Sox-1 with β-catenin in the cerebellum of kindling rats

Authors: *A. ROSILES[1], C. RUBIO-OSORNIO[1], C. TREJO-SOLÍS[2], V. CUSTODIO[1], C. MENDOZA[1], L. HERNÁNDEZ-LÓPEZ[1], E. GONZALEZ-RUIZ[1], J. C. MARTÍNEZ-LAZCANO[1], E. GONZALEZ[1], C. PAZ[1]

Abstract: The role of cerebellum in the physiopathology of epilepsy remains subject of study. Bergmann glia (BG) in the cerebellar cortex regulates the homeostasis of Purkinje cells, whose axons targets the dentate and interpositus nuclei, which form the main cerebellar output to other structures in the central nervous system involved in Epilepsy. Sox-1 is a transcription factor expressed in BG and its binding to β-Catenin (βC) further inhibits the canonical Wnt pathway. In the cerebellum of rat with the kindling model, it is known that there is a decreased expression of Sox-1 with generalized seizures, furthermore it has been reported, higher activity of the βC signaling with the recurrence of seizures associated with apoptosis, one of the mechanisms proposed is the interaction o Sox-1 with βC. It is known that retinoic acid (RA) has an

antiepileptic effect through its metabolite alls-trans-retinoic acid (ATRA), in addition it has been seen that the ATRA causes an increase in the expression of Sox-1. Here we present the effect of RA in the duration of the epileptic activity (EA) and its relationship with the Sox-1 expression and the signaling of βC in the cerebellum of kindling rats. We used Wistar rats separated into groups with and without administration of RA, that received 3, 15 and 45 stimuli, recording and analyzing the EA. The cerebellum was processed for immunohistochemistry assay for Sox-1 and βC. We found that the administration of RA decreases the duration of the EA in the group of generalized seizures. For βC we found an increase of the immunopositivity in the groups of 45 stimuli with and without administration of RA. For Sox-1 we found a progressively increase of the immunopositivity, in the groups with RA administration. We conclude that the administration of RA produces a decrease in the duration of the EA associated with the regulation in the expression of Sox-1 and the signaling of βC, in the cerebellum. In this way we suggest this mechanism as a one of the possible explanations of the antiepileptic effect of RA.

Title: Delayed post-traumatic neuronal death in the developing hippocampus

Authors: *T. BALENA[1], N. RAHMATI[3], K. P. LILLIS[4], K. J. STALEY[2]
[1]Massachusetts Gen. Hosp., Charlestown, MA; [2]Massachusetts Gen. Hosp., Boston, MA; [3]Harvard Med. Sch. & Massachusetts Gen. Hos, Boston, MA; [4]Neurol., Harvard Med. Sch. Dept. of Neurol., Charlestown, MA

Abstract: New fluorophores and microscopy techniques have made possible more detailed explorations of the process of neuronal death. In the present study we evaluated the death of neurons in a chronically epileptic *in vitro* preparation in which multiphoton microscopy could be performed over a period of several days. Organotypic hippocampal slice cultures were made from P6 wild-type C57BL/6J mice, and two-photon imaging was performed using transgenic fluorophores as well as the ratiometric Na^+ dye SBFI-AM. We report the following sequence of events in delayed neuronal death following the substantial trauma involved in brain slice preparation. The first detectable event was loss of participation in network activity and mild, sustained elevation of cytoplasmic Ca^{2+}. The second stage was marked by activation of caspases evidenced by FLICA staining. During the second stage, fluorescence of transgenic fluorophores was lost. pH and ionic sensitivity did not influence fluorophore quenching. In the third stage, neurons admitted AM dyes including SBFI-AM and Fura-AM. The fourth stage was marked by steady increases in cytoplasmic Na^+ concentrations from 10 mM to concentrations approaching that of the extracellular solution. Cytoplasmic Ca^{2+} remained elevated during this interval. During this fourth stage, cytoplasmic membrane damage could be demonstrated by Annexin V staining, retraction of dendrites and axons was completed, and condensation of nuclear chromatin visualized by NucBlue became progressively evident. Throughout the fourth stage, TMRM staining, pharmacological antagonists, and ion-sensitive fluorophores confirmed ongoing glycolysis and mitochondrial respiration and ATP production, sodium transport via Na^+/K^+ ATPases, and secondary transport including cation-Cl^- cotransport and Na^+/Ca^{2+} exchange. The transition to the fifth and final stage was marked by progressively more intense propidium iodide staining. Key final events included microglial engulfment (as indicated by isolectin staining), sharp rises in Na^+ and Ca^{2+} concentrations, and terminal cell shrinkage. A number of pharmacological interventions ameliorated ionic disequilibria but did not prevent or retard eventual cell death. These studies provide a framework with which to understand the stages of delayed neuronal death in relation to the clinical evolution of brain injury, as well as the effects of neuroprotective and disease-modifying treatments.

Title: Evaluation of repurposed antiepileptic drugs to treat spontaneous recurrent seizures in instrumented male C57Bl/6 mice following a sublethal soman exposure

Authors: *D. L. NGUYEN, M. R. EISEN, C. E. ARDINGER, E. N. DUNN, K. M. HAINES, A. N. SANTORO, P. M. BODNER, P. B. DUBEE, H. S. MCCARREN, P. M. MCNUTT

Abstract: Exposure to nerve agent (NA) can result in rapid onset of generalized status epilepticus (SE), which if uncontrolled can cause permanent brain damage and death. Many efforts have focused on ways to stop the initial seizure, but few have addressed the long-term symptoms and complications of exposure. Following SE, individuals may develop spontaneous recurrent seizures (SRS) or epilepsy that often leads to severe neurological deficits and lower quality of life. Though dozens of FDA-approved antiepileptic drugs (AEDs) are on the market, it is unknown which, if any, would be effective against NA-induced SRS. We designed this experiment to test five AEDs (levetiracetam, phenobarbital, valproate, carbamazepine, and clonazepam) on SRS onset and characteristics in telemetry-instrumented mice following a sublethal, supraconvulsant soman (GD) challenge. Starting 24 hours after SE, mice were repeatedly dosed with an AED or vehicle for 14 days, followed by a 14-day washout period. Dosing regimens were based on published pharmacokinetic data. Levetiracetam and valproate had no apparent effect on SRS number, duration, or onset of SRS. Although phenobarbital-treated mice exhibited a delay in SRS onset compared to vehicle, mice developed phenobarbital resistance prior to the end of the treatment period. Data are still being acquired on the effects of carbamazepine and clonazepam on SRS activity. Continued analysis will focus on the effects of these AEDs on SRS activity and low frequency epileptiform events.

Abstract: Dravet syndrome (DS) is a catastrophic childhood epilepsy often caused by genetic mutations in the voltage-gated sodium channel gene *SCN1A*. The currently available antiepileptic drugs fail to provide adequate seizure control for these patients. Recently, preclinical and clinical evidence suggests that compounds which activate serotonin receptors can have therapeutic benefits for DS patients. This study aimed to uncover the precise antiepileptic mechanism of action of these compounds using a zebrafish phenotypic drug screening approach. Zebrafish with a mutation in the *SCN1A* homologue, *scn1lab*, have spontaneous seizure activity in the brain and convulsive behavioral movements. Importantly, *scn1lab* mutant zebrafish also show pharmacoresistance to many antiepileptic drugs (AEDs), emulating the persistent drug resistant seizures observed in human patients. Given the zebrafish *scn1lab* mutant replicates the genetic, behavioral and pharmacological phenotype of DS patients they offer a valuable model for phenotypic drug-screening for antiepileptic compounds. Using the *scn1lab* mutant zebrafish in a two-stage drug screening platform (consisting of behavior screening and electrophysiology confirmation), approximately 3000 compounds spanning several drug classes underwent blind testing to identify potential antiepileptic properties. Only three compounds were identified as potential anti-epileptics (trazodone, clemizole and lorcaserin) and all are modulators of HTR2 receptors. Structure-activity relationship (SAR) studies were performed by synthesizing a library of clemizole analogs (n = 28) and screening them for antiepileptic activity in the *scn1lab* zebrafish. Three “clemalogs” were identified as capable of suppressing the convulsive seizure behaviors. In vitro radioligand binding assays confirmed binding affinities to human HTR2B receptors for all three compounds. Using a more traditional target-based approach, commercially available compounds were also screened based on their potency and agonism of HTR2 receptors. Despite similar in vitro binding profiles many of these compounds failed to elicit anti-seizure activity. We conclude that in vivo phenotypic drug screening can successfully identify a class of compounds with a common mechanism which are clinical relevant for patients. Additionally, for AED discovery, phenotypic drug screening using appropriate disease models can overcome many of the difficulties observed when translating results from other traditional drug discovery methods.

Title: Role of protein kinase c phosphorylation in neurosteroid modulation of extrasynaptic gaba-a receptors in the hippocampus

Authors: *S. CHUANG, S. REDDY
Neurosci. and Exptl. Therapeut., Texas A&M Univ. Hlth. Sci. Ctr., Bryan, TX

Abstract: Endogenous neurosteroids such as allopregnanolone (AP) are powerful modulators of GABA-A receptors. Phosphorylation status of GABA-A receptors play a critical role in receptor surface expression, channel conductance, and sensitivity to neurosteroids. Therefore, alterations in the phosphorylation status of these receptors can dramatically affect neurosteroid actions. Here, we sought to determine the role of phosphorylation of extrasynaptic GABA-A receptors in neurosteroid potentiation of tonic currents in the δ-subunit-rich dentate gyrus granule cells (DGGCs). Adult male mice were used for electrophysiology studies. GABAergic tonic currents were recorded from DGGCs using whole-cell patch clamp. To explore the effects of phosphorylation on neurosteroid potentiation of tonic currents, a protein kinase C (PKC) inhibitor GF109203X was applied to the bath solution for 15 or 30 minutes before the perfusion of GABA and the application was continued during GABA and neurosteroid co-perfusion. In hippocampus slices, synthetic neurosteroid GX potentiated and directly activated tonic currents in DGGCs in a concentration-dependent fashion. However, these responses were significantly diminished in DGGCs from δ-subunit knockout (δKO) mice, confirming the selectivity of GX for extrasynaptic δGABA-A receptors. Pretreatment of PKC inhibitor significantly attenuated GABA-evoked tonic currents. Moreover, the GX potentiation of tonic currents was completely prevented by PKC inhibition. The endogenous neurosteroid AP also potentiated tonic currents in a PKC-sensitive fashion, signifying an important role of receptor phosphorylation by PKC in neurosteroid modulation of tonic inhibition. These results demonstrate a critical role of PKC-mediated phosphorylation of neurosteroid-sensitive, extrasynaptic δGABA-A receptors in the dentate gyrus that regulate hippocampal network inhibition and seizure susceptibility.

Nacional de Psiquiatria, Ciudad de Mexico, Mexico

Abstract: Ruta chalpensis, known as “ruda”, is one of the oldest natural drugs and is often used to treat a wide variety of conditions such as vertigo, stomachaches, intestinal parasites, intoxications, headaches, anxiety, ocular problems and epilepsy. Preliminary data of their effects was described in the acute model of seizures induced by PTZ, using a polar extract and evaluating the motor behavior in mice. Nevertheless, the effects using median polarity substances and the associated electroencephalographic activity (EEG) have not been described. In the present study, under such conditions, different doses were evaluated (100, 300, and 1000 mg/kg, i.p.) using behavioral and EEG recordings for 30 min and during tonic-clonic seizures induced with PTZ (85 mg/kg, i.p.) in 36 SW mice (27-36 g; n=6 per experimental condition). The vehicle, 100 mg/kg, diazepam (1mg/kg, i.p.) and naïve mice groups didn’t present significant changes neither in the ambulatory activity nor EEG. On the other hand, a decrement in such activity was observed in mice that received 300mg/kg and 100 mg/kg, suggesting a hypnotic effect at the time of the first application and in the case of higher doses a “burst-suppression” alteration in the EEG pattern was observed. With respect to convulsive seizures, diazepam, 300 mg/kg and 1000 mg/kg of R. chalepensis protected against generalized tonic-clonic seizures mediated by the depressor effect over brain electrical activity. In conclusion, the EEG can be used to detect sedating or alerting effects of different doses of plant extracts and its effects on PTZ induced seizures in mice. On the other hand, these data reinforced the anticonvulsive properties of this medicinal species, although in higher doses the extract could produce neurotoxic effects, indicating that is important to be careful about its uses.

Title: NKCC1 is not obligatory for epileptogenesis and the manifestation of seizures in the intrahippocampal kainate mouse model

Authors: *P. HAMPEL[1,2], K. RÖMERMANN[1], A. VOGEL[1], W. THEILMANN[1], B. GAILUS[1], M. JOHNE[1,2], K. TÖLLNER[1], K. KAILA[3,4], W. LÖSCHER[1,2]

Abstract: Epileptogenesis is a process of pathological changes in the brain that take place after epilepsy-initiating insults and result in acquired epilepsy. In humans, e.g., craniocerebral injury, infections, or *status epilepticus* (SE), can lead to the development of acquired epilepsy with spontaneous recurring seizures (SRS). Epileptogenesis has often been shown to be associated with upregulation of Cl^- uptake by Na^+-K^+-$2Cl^-$ cotransporter isoform 1 (NKCC1) in neurons. This in turn, is expected to lead to a change from inhibitory to excitatory GABA actions. NKCC1 upregulation has been described in post-SE rodent models in subsequent days after SE. However, it is yet unknown whether this process is protective or proepileptogenic. This study aimed at determining whether the disruption of NKCC1 expression prevents the development of SRS in the intrahippocampal kainate mouse model of epilepsy or leads to disease modification, e.g., in the progression of SRS, neuronal loss or granule cell dispersion.
Kainate was injected into the CA1 region of the right hippocampus in 10-15 weeks old male and female $NKCC1^{-/-}$- and $NKCC1^{+/+}$-mice of the strain B6-*Slc12a2*$^{sy\text{-}ns}$/J to induce SE. A bipolar electrode was implanted at the injection site. EEG- and video-monitoring was performed following kainate injections and both one month and three months after SE for seven days each. Results up to this point can be summarized as follows: 21/21 $NKCC1^{-/-}$-mice developed polyspikes, which are characteristic for the SE, or showed behavioral seizures during SE following kainate injection. Similarly, polyspikes were observed in 8/10 $NKCC1^{+/+}$-mice. One month post SE, 6/6 $NKCC1^{-/-}$-mice showed clinical seizures (range: 3-8 seizures/week). These

included focal and generalized seizures ranging from type III-V on the Racine scale. Neuronal loss and granule cell dispersion are currently assessed.
This study demonstrates that NKCC1 does not play an obligatory role in epileptogenesis and manifestation of SRS in the intrahippocampal kainate mouse model.

Title: Pronounced antiepileptic activity of the subtype-selective $GABA_A$ positive allosteric modulator PF-06372865 in the GAERS model

Authors: *C. ROUCARD[1], R. GURRELL[2], D. BUHL[2], A. EVRARD[1], C. RUGGIERO[1], V. DUVEAU[1]

Abstract: Absence epilepsy is a form of epileptic syndrome where patients show generalized non-convulsive seizures characterized by a brief unresponsiveness to environmental stimuli and cessation of activity. In human, typical absence seizures are associated with bilateral, synchronous and regular spike-and-wave discharges (SWD). Genetic absence epilepsy rat from Strasbourg (GAERS) is a selectively inbred strain of Wistar rats displaying spontaneous SWD. For the last twenty years, the GAERS has become a reference model for absence epilepsy, since these rats were shown to present behavioral, electrophysiological and pharmacological features of absence seizures. The pharmacology of the GAERS model is like the human one. For instance, valproate, ethosuximide and levetiracetam show an anti-epileptic effect. In the present work, we tested the dose-dependent effect of a newly developed subtype-selective $GABA_A$ positive allosteric modulator, PF-06372865. PF-06372865 induced a dose-dependent reduction of the number of SWD in the GAERS model. At the low dose (0.3 mg/kg), no significant effect as compared to vehicle and baseline was observed. At the dose of 1 mg/kg no significant effect was detected immediately after administration (10-30 min post-administration). A partial effect started to appear 30-50 min after administration of this low dose: at this time-point, the number of SWD was reduced by 59% of baseline value. It was significantly different from baseline and from the vehicle. The number of SWD continued to reduce 50 min after administration of the

low dose, to reach almost complete reduction at time-point 70-90 min. At the two higher doses (3 and 10 mg/kg), the inhibition was significant already at the first post-treatment time-point (10-30 min) as compared to the baseline and the vehicle. The reduction was complete and persistent from 30 to 90 min after administration. No significant difference was found as compared to the reference compound valproate, except for the 3 mg/kg dose at the first time-point (10-30 min post-administration). In comparison, the reference compound diazepam showed a complete reduction of SWD during the 10-30 min time-period. This effect is gradually disappearing but remained significant for the rest of the recording period (between 30 and 90 min post-treatment). PF-06372865 dose-dependently reduced the occurrence of SWD in the GAERS model with a significant effect at 1, 3 and 10 mg/kg. In comparison to the reference compound diazepam, PF-06372865 has a slower peak time effect but a longer efficacy. The subtype-selective $GABA_A$ positive allosteric modulator PF-06372865 shows an anti-epileptic potential to treat absence epilepsy.

Abstract: Hyper-excitability of neuronal networks underlies the pathophysiology of epilepsy, and is known to be a component of other neurological disorders including cancers of the brain. Previous work has shown that genetic removal of neuronal microtubule organizer and stabilizer tau can significantly reduce epileptiform activity and lethality across a number of models of hyper-excitability, including Alzheimer's Disease models, the Kcna1 early lethal mouse model of epilepsy, and the Scn1a mouse model of Dravet syndrome. We recently confirmed a

progressive seizure phenotype in a novel transgenic mouse model of brain tumor related epilepsy. The effect of tau loss on hyper-excitability and lethality in this glioblastoma model was unknown. To answer this question, we generated glial derived brain tumors on a tau knockout background using a CRISPR in utero electroporation strategy. Using chronic video electroencephalography (EEG), we recorded cortical inter-ictal spike and seizure activity in these tumor mice at various timepoints in disease progression, monitored survival, and assessed tumor burden via immunohistochemically methods. tau KO tumor mice exhibited reduced inter-ictal spike activity and slightly longer survival times compared to tau WT tumor-bearing littermates. These data suggest that tau loss may provide a modest protective effect in this model of cortical hyper-excitability.

Title: Adenosine A1 receptor antagonism reduces the effect of gamma-decanolactone on acute and chronic seizures in mice

Authors: *P. PEREIRA[1], G. REGNER[1], L. L. SILVA[1], L. TOUGUINHA[2], M. SALVADOR[2], P. PFLÜGER[1]
[1]Federal Univ. of Rio Grande Do Sul, Porto Alegre, Brazil; [2]Univ. de Caxias do Sul, Caxias, Brazil

Abstract: Gamma-decanolactone (GD) is a monoterpene effective against seizures induced by pentylenetetrazole (PTZ) and it is known to reduce neuronal damage induced by pilocarpine (PIL) in mice. Previous studies have shown that GD acts as an antagonist of glutamate receptors. It also inhibits intracellular reactive oxygen species (ROS) generation and decreases the expression of inducible nitric oxide synthase (iNOS) and tumor necrosis factor-alpha (TNF-α) induced by the lipopolysaccharide *in vitro*. The present study evaluated GD mechanism of action using the chemical kindling and the acute aminophylline (AMPH) seizure models. Considering the strong relation between mitochondrial dysfunction and epilepsy, we also evaluated the effect of GD on mitochondrial complex I in cerebral cortex after AMPH seizure model. CF-1 male mice were injected (i.p.) with Bicuculline (2 mg/kg), a receptor $GABA_A$ antagonist, or DPCPX (2 mg/kg), an adenosine A1 antagonist, or ZM 241385 (3 mg/kg), an A2A antagonist, 15 min before treatment with GD (100 and 300 mg/kg). DZP (2mg/kg) was used in this study as a positive control. In the kindling model, 30 min after the treatments, mice received PTZ (40mg/kg

s.c.) once every third day, in a total of six treatments (16 days). The latency to the first clonic seizure and its occurrence were registered. In the AMPH model, a single dose of AMPH (280 mg/kg, i.p.) was administered and animals were observed for 60 min. The latency to the first seizure and the occurrence of tonic-clonic seizure were registered. The assessment of mitochondrial complex I activity was detected using spectrophotometer. The results were analysed using Fisher's exact test and Kruskal-Wallis analysis followed by Dunn's test. Tukey test was used to analyze the results of mitochondrial activity. The results showed that GD (300 mg/kg) increased the latency to first seizure and decreased seizures occurrence induced by PTZ or AMPH. Both the adenosine A2A receptor antagonist (ZM 241385) and $GABA_A$ receptor antagonist (Bicuculline) were not able to change GD behavioral seizure responses. On the other hand, the administration of adenosine A1 receptor antagonist (DPCPX) reverted GD effect as it was observed in both behavioral models used. Also GD decreased mitochondrial complex I activity in cerebral cortex. In summary, our results demonstrated that the anticonvulsive profile of GD observed in this study may be related to its action on A1 adenosine receptors.

Title: Crispr/cas9-mediated overexpression of cb1 receptors for the control of epileptogenesis

Authors: *V. DI MARIA[1], M. RYDE[1], L. QUINTINO[2], M. LEDRI[1]
[1]Epilepsy Ctr., [2]Dept. of Exptl. Med. Sci., Lund Univ., Lund, Sweden

Abstract: Epilepsy is one of the most common neurological disorders worldwide, affecting 1% of the general population. Epilepsy usually develops after an initial insult, such as head trauma or stroke, which triggers the generation of epileptic seizures. During epileptogenesis, the affected brain regions undergo massive changes in gene expression, including downregulation of the cannabinoid receptor I (CB1).

Recent developments in gene editing technologies, including the bacteria-derived CRISPR-Cas9 system, have opened new avenues for gene therapy. Particularly, the possibility of developing a reversible and precise regulatory system for endogenous genes with spatio-temporal control, overcomes several limitations of the classic gene therapy approaches. On this basis, this study aims to exploit the innovative CRISPR-Cas9 technology to prevent CB1 downregulation during epilepsy.
We generated an inducible CRISPR-Cas9 system to obtain spatio-temporal modulation of CB1. Precise spatial specificity was obtained using viral vectors carrying single guide RNAs (sgRNAs) specific for the promoter region of mouse CB1-receptor and dCas9 fused to either the transcriptional activator VP64 or VPR. To obtain temporal modulation of CB1 we used a Doxycycline sensitive system restricted to glutamatergic excitatory neurons. Real Time qPCR showed a significant upregulation of CB1 receptors in primary neurons infected with viral vectors, paralleled by an increase in protein expression as revealed by Western blot. In the mouse hippocampus in vivo, CB1 receptors were also significantly modulated in animals injected with dCas9-VPR and sgRNA carrying viruses.
Our results indicate that primary neurons and hippocampal neurons can be successfully manipulated with viral vectors expressing the CRISPR-Cas9 system to modulate target genes. These findings show potential for future experiments and will be the basis to apply this system to animal models of epilepsy, with the aim of delaying or completely preventing the development of spontaneous recurrent seizures.

Title: Novel KCNT1 inhibitors of wild-type and a P924L gain-of-function variant identified through comprehensive high-throughput drug repurposing screening

Authors: *G. R. STEWART[1], J. M. ANDRESEN[1], B. C. GAY[1], C. M. MAHER[1], A. C. GERLACH[2], T. A. ATKIN[3], M. D. FULLER[2], M. L. CHAPMAN[2], B. M. ANTONIO[2], D. B. GOLDSTEIN[4], O. DEVINSKY[5], S. PETROU[6]
[1]Pairnomix, Minneapolis, MN; [2]Icagen, Durham, NC; [3]Neurosci., Columbia Univ. Press, New York, NY; [4]Inst. for Genomic Med., Columbia Univ. Med. Ctr., New York, NY; [5]Dept. of Neurol., New York Univ. Med. Ctr., New York, NY; [6]Inst. for Neurosci. and Mental Hlth., Univ. of Melbourne, Melbourne, Australia

Abstract: KCNT1 epileptic encephalopathies arise due to mutations in a sodium-activated potassium channel, also known as $K_{Na}1.1$ or Slack, and present with seizures and profound developmental delay. In the present study, we developed an in vitro cell model expressing the P924L mutation and compared it to a cell line bearing the wild-type KCNT1 channel. Using patch-clamp electrophysiology, Slack potassium channels with the P924L mutation showed significantly increased potassium current compared to wild-type Slack channels, confirming a gain-of-function molecular phenotype associated with early infantile migrating focal seizures (EIMFS). We then performed a comprehensive high-throughput drug repurposing screen with 1,291 approved drugs to identify compounds that inhibited ion flow in the P924L or wild-type KCNT1 cell models. Using a rubidium efflux assay as an output, we identified 55 compounds in the wild-type and 40 compounds in the P924L cell model that inhibited efflux greater than two standard deviations beyond the group mean of all drugs. These hit compounds were then evaluated across a series of concentrations in the rubidium efflux assay and with electrophysiology to confirm activity and to derive an IC_{50} and maximal effectiveness. Compounds with a high degree of novel inhibitory activity in both cell models included ezetimibe (cholesterol-lowering), raloxifene (hormone modulator) and doxazosin mesylate (anti-hypertensive). Ritonavir (anti-viral) and carvedilol (beta-blocker) were two drugs with activity only against the P924L variant cell model. Although there has been interest in quinidine as an inhibitor of KCNT1 channels, the drug displayed only a modest level of inhibitory activity that was substantially less than several other compounds identified by the drug repurposing screen. In line with our previous work on SCN8A ion channels (Atkin et al, Epilepsia 2018), the KCNT1 study demonstrates the utility of comprehensive screening with a large library of approved drugs in order to identify compounds with significant activity against cellular models of epilepsy-related genes. These results provide an enriched starting pool of drug candidates for further development and therapeutic evaluation against gain-of-function KCNT1 epileptic encephalopathies.

Title: Optogenetic control of cerebellar output abolishes generalized seizures

Authors: *J. SCHWITALLA, S. HERITZE, M. D. MARK
Gen. Zoology and Neurobio., Bochum, Germany

Abstract: Absence epilepsy (AE) is a form of generalized epilepsy, characterized by a brief loss of consciousness and behavioral arrest. The electrophysiological hallmarks, bilaterally synchronized 5-9 Hz spike-and-wave discharges (SWDs) occur spontaneously on an otherwise normal electroencephalogram. While genetic factors are most often the cause for developing AE, also trauma, stroke or tumors can be a factor in developing this type of seizures. The common dogma for the development of seizures (ictogenesis) consists of a reciprocally connected TCN that starts to produce hypersynchronous oscillations that spread over the whole cortex. The underlying mechanism of changes making the TCN prone to develop seizures (epileptogenesis) are hardly understood but researchers favoring the TCN to be the point of interest. This widely accepted theory is challenged by patients that developed a tumor in the cerebellum - a so far believed nonepileptic region of the brain - presenting with AE. Moreover, a highly invasive resection of the tumor was beneficial as a treatment, while other pharmacological treatments lacked sufficient seizure control. The favored drugs (e.g. ethosuximide, valproic acid) for the treatment of generalized absence seizures often target the thalamocortical network, but in some patients they lack efficiency indicating that other brain regions might be at least in some cases participating in epileptogenesis. Based on these studies, our laboratory created two conditional KO mouse models to test the cell type (Purkinje cells and granule cells) and area specific contribution of the cerebellum in AE and generate new animal models for the study of AE. Electroencephalography recordings in freely moving animals of both mouse lines showed no sex difference for AE similar to the widely used mouse models with a typical frequency between 4-9 Hz. Treatment with the commonly prescribed antiepileptic drug ethosuximide (intraperitoneal) significantly reduced the occurrence of ictal events in freely moving animals, while valproic acid lacked efficiency. By applying closed-loop optogenetic stimulation (ChR2 H134R) unilaterally

or bilaterally to the lateral cerebellar nuclei, we were able to stop ongoing seizures with a short (1s) light pulse. Taken together these results show the involvement of the cerebellar network in AE and that cerebellar stimulation could be a new therapeutic target for interventional therapies.

Title: CX-8998 and CX-5395, potent, selective T-type calcium channel antagonists suppress seizures in genetic models of epilepsy

Authors: M. S. LEE[1], E. J. NEWBOLD[2], *S. PAPAPETROPOULOS[1]
[1]R&D, Cavion, Cambridge, MA; [2]R&D, Cavion, Charlottesville, VA

Abstract: T-type calcium (Cav3) channels are low threshold voltage-gated channels that regulate neuronal excitability. Cav3 gain-of-function mutants have been identified patients with childhood absence epilepsy (AE) and other generalized epilepsy syndromes. Overexpression of Cav3.1 results in an AE-like phenotype and mice lacking Cav3.1 show resistance to pharmacologically induced absence seizures. Currently approved drugs, including zonisamide and ethosuximide, have been reported to have non-selective Cav3 antagonist activity and while both drugs have shown evidence of efficacy in clinical studies, many patients experience lack of efficacy or intolerable side effects resulting in treatment discontinuation. Thus, selective targeting of Cav3 channels has the potential to improve efficacy and tolerability in indications such as epilepsy where Cav3 is an important component of disease pathophysiology. The objective of the study was to evaluate the efficacy of selective Cav3 antagonists in rodent genetic models of spontaneous AE that show enhanced Cav3 currents and burst-firing during seizures. Potent, selective and state-dependent Cav3 antagonists CX-8998 and CX-5395 were evaluated in two distinct rat models of genetic AE, inbred Wistar Albino Glaxo Rats from Rijswijk (WAG/Rij) and the Genetic Absence Epilepsy Rats from Strasbourg (GAERS). Rats were implanted with telemetric monitors to simultaneously record electrocorticograms. Cohorts of animals received oral vehicle, CX-8998 or CX-5395 at various doses and post-dose recordings were collected and compared to pre-dose baseline. Data were scored with seizure analysis software and results binned into epochs before and after drug administration. Each cohort was averaged and normalized to enable treatment comparisons. Both CX-8998 and CX-5395 dose-

dependently suppressed seizures while vehicle treatment had no effect. In WAG/Rij rats, the ED_{50} for reduction in cumulative time spent in seizure at 4 hours post-dose was 1 mg/kg for both compounds. Higher doses resulted in a longer duration of effect, indicating a minimum threshold for Cav3 inhibitory effects. Cav3 channels are a genetically and pharmacologically validated target for absence seizures and these results demonstrate that potent, highly selective Cav3 antagonists CX-8998 and CX-5395 show dose dependent efficacy in rodent models of AE. These results highlight the potential for selective Cav3 antagonists as a therapeutic option in AE and support their further investigation in a clinical setting. CX-8998 is currently being evaluated in a Phase 2 clinical study in generalized epilepsy syndromes with absences seizures (NCT03406702).

Title: TrkB activation reduces seizure activity in a mouse model of Dravet syndrome via enhanced interneuron function

Authors: *F. GU, I. PARADA, D. PRINCE
Neurol. and Neurolog. Sci., Stanford Univ., Stanford, CA

Abstract: Dravet syndrome (DS) is one of the most severe childhood epilepsies and is mainly caused by loss-of-function mutations in *Scn1a* gene encoding Nav1.1 that is predominantly expressed in Parvalbumin-containing (PV) interneurons. Decreased Nav1.1 impairs PV cell function, contributing to neural circuit hyperexcitability and DS phenotypes. Therapy targeting defective PV interneurons is unavailable. The role of BDNF in development and maintenance of interneurons, and previous results showing antiepileptogenic effects of TrkB receptor agonist in a model of posttraumatic epilepsy via improved function of PV interneurons, lead us to hypothesize that early treatment with TrkB receptor agonist might prevent or reduce seizure activity in DS mice by enhancing PV interneuron function. Saline or LM22A-4 (LM), a partial agonist at the BDNF TrkB receptor, was given to DS mice (50mg/Kg I.P.+5mg/Kg intranasal once a day x7d) starting at P13 before spontaneous seizures start. Immunocytochemistry was used to assess the density of perisomatic PV-IR and colocalized PV/gephyrin-IR around layer V

pyramidal cells in the cortex, as well as Nav1.1- and synaptotagmin 2-IR. Whole cell recordings of mIPSCs and sIPSCs were obtained from layer V pyramidal cells to evaluate inhibitory synaptic transmission. Spontaneous seizures were assessed blindly in saline- and LM-treated DS mice monitored 2 days after the last dose of LM during P21-P25. Only seizures with Racine scale 3 and above were included for analysis. Results showed that LM treatment 1) enhanced PV-IR and colocalized PV/gephyrin-IR around pyramidal somata in layer V, indicating an increased number of PV interneuronal synapses; 2) increased Nav1.1- and synaptotagmin 2-IR in PV neurons; 3) increased inhibitory synaptic transmission, indicated by increased frequency of mIPSCs and sIPSCs; and 4) decreased frequency of spontaneous seizures in DS mice. Results suggest that chronic TrkB activation with a partial agonist may be a promising strategy to enhance PV interneuron function and thereby suppress epilepsy and potentially other phenotypes, such as cognitive and social deficits, in DS.

Title: Development of a clinically-relevant nonclinical model to investigate recovery of pilocarpine-induced convulsions by benzodiazepines

Authors: *J. K. DASILVA[1], C. TYSZKIEWICZ[1], K. LEE[1], D. L. BUHL[2], S. M. G. GOODY[1]
[1]Global Safety Pharmacology, Drug Safety Res. and Develop., Pfizer, Inc., Groton, CT; [2]Intrnl. Med. Res. Unit, Worldwide Res. and Develop., Pfizer, Inc., Cambridge, MA

Abstract: Benzodiazepines (BZs), such as lorazepam, are the standard-of-care across a broad spectrum of epilepsy types. A number of nonclinical models exist to evaluate the anticonvulsant efficacy of benzodiazepines, such as altered convulsion thresholds in acute chemo-convulsant models or preventing the onset of new convulsive events in recurrent seizure models. However, these models do not mimic the clinical treatment of status epilepticus events, where lorazepam is often administered by the intravenous (IV) route once seizures have already started. The goal of this work was to develop a novel model to assess BZ-mediated recovery from experimentally-induced convulsions that would more closely resemble the use of lorazepam in emergency settings. Pilocarpine, a muscarinic agonist, was selected as the chemo-convulsant because it reliably induces tonic/clonic convulsions in mice in a single experimental setting. Male CD-1 mice (n=18) were pretreated with scopolamine to minimize the peripheral toxicities associated with pilocarpine. Thirty minutes following scopolamine administration, mice were infused via the lateral tail vein with pilocarpine. Animals were simultaneously tethered, via a surgically

implanted jugular vein catheter, to a second infusion pump containing either lorazepam (n=8) or vehicle (n=10). During the pilocarpine infusion, animals were monitored for behavioral signs of convulsion and scored using the Racine Scale by experimenters blinded to the treatment condition. At the onset of tremor, the pilocarpine infusion was stopped and either lorazepam or vehicle infusion commenced immediately. Lorazepam or vehicle infusions continued until mice either recovered from tremors or progressed to clonic convulsions, or a total combined maximum IV volume of 50 mL/kg for pilocarpine and lorazepam was reached. The pilocarpine-threshold to the onset of tremor, latency to tremor recovery and percentage of animals that fully recovered was determined. Pilocarpine tremor thresholds were similar for the lorazepam (299.5 ± 25.4 mg/kg) and vehicle (274.6 ± 16.2 mg/kg) treatment groups. In lorazepam-treated animals, tremor recovery occurred faster and a greater percentage of animals fully recovered from pilocarpine-induced convulsive behaviors (5.1 ± 1.1 minutes and 87.5%, respectively) compared with vehicle (9.0 ± 0.9 minutes and 30%, respectively). These data indicate that it is possible to successfully recover a chemically-induced convulsion via intervention with IV lorazepam, which resembles the clinical treatment strategy for status epilepticus episodes and may be a valuable tool to evaluate new treatment options.

Title: Anodal and cathodal transcranial direct current stimulation (tDCS) effects on convulsions induced in the kindling model by pentylenetetrazole

Authors: ***I. L. TORRES**[1], G. G. REGNER[2], C. DE OLIVEIRA[2], V. L. SCARABELOT[2], D. E. S. RIOS[2], P. PFLÜGER[2], A. SOUZA[2], R. STRÖHER[2], P. PEREIRA[2]

[1]UFRGS - Univ. Federal do Rio Grande do Sul, Porto Alegre, Brazil; [2]Univ. Federal do Rio Grande do Sul, Porto Alegre, Brazil

Abstract: Introduction: About 30 percent of patients with epilepsy are refractory to drug therapy. Thus, the search for non-pharmacological interventions such as transcranial direct current stimulation (tDCS) may be an alternative treatment, isolated or in the combination with anticonvulsants in lower doses. **Objective:** to evaluate the effect of anodal and cathodal tDCS (a-tDCS and c-tDCS, respectively) on seizures induced by pentylenetetrazole (PTZ) in the kindling model using diazepam (DZP) as the gold standard of anticonvulsant. **Methods:** 152 Male Wistar rats (60 days) divided in: Sal-PTZ, DZP3-PTZ, DZP0.15-PTZ, a-tDCS-Sal-PTZ, a-tDCS-DZP0.15-PTZ, c-tDCS-Sal-PTZ, c-tDCS-DZP0.15-PTZ and SHAM-Sal-PTZ. The tDCS groups were submitted to 10 sessions of anodal or cathodal tDCS (0.5mA / 20min) and every 3 days they received saline (SAL) or DZP (0.15mg / kg, ip, alone or in combination with tDCS), DZP (3 mg / kg, ip) 30 minutes before administration of PTZ (50mg / kg, ip), totaling 6 treatments. After PTZ administration, animals were observed for 30 minutes for convulsive behavior: latency for the first seizure (LFS) lasting more than 3 seconds and percentage of seizure. After the last treatment, animals were euthanized and the hippocampus collected to IL-1β, TNF-α, NGF and BDNF levels evaluation. The percent of seizure was analyzed by Fisher Exact test and the LFS by Generalized Estimating Equations (GEE). Biochemical data were analyzed by one-way ANOVA. ($P \leq 0.05$). **Results:** c-tDCS associated to DZP increased the LFS on the fourth and sixth days. IL-1β levels were reduced by c-tDCS alone or associated with DZP. TNF-α and NGF levels were not altered by c-tDCS or a-tDCS. a-tDCS associated to DZP reduced BDNF levels. **Conclusions:** c-tDCS associated to a benzodiazepine is more effective in suppressing seizures when compared to c-tDCS or the drug alone. IL-1β, but not TNF-α plays a role in the inflammation process as a good marker for fully developed seizures. BNDF is a neurotrophin involved in protection mechanisms during seizures in order to keep neurons damaged and even prevent cells from dying. Therefore c-tDCS associated with low dose of DZP has potential antiepileptogenic effect in the kindling model and provides neuroprotection against neuroinflammation.

Sch. of Med., New Haven, CT; [7]Fac. of Med., Hacettepe Univ., Sihhiye, Turkey; [8]Neurol., Bern Univ. Hosp. and Univ. of Bern, Bern, Switzerland

Abstract: Generalized spike-wave discharges (SWDs) are EEG hallmarks of generalized seizures and epilepsies. These epileptiform discharges, most commonly seen in absence seizures, typically last for 3-10 seconds and often impair behavior and/or cognition. Our previous work shows that the amplitude and duration of SWDs on EEG are predictive of performance on the Repetitive Tapping Task (RTT) and the Continuous Performance Task (CPT). The effect of generalized SWDs on more complex behaviors like driving has been investigated in very limited studies with either small sample sizes or by using computerized driving games. Evidence from these studies suggests that generalized SWDs prolong reaction time and impair drivers' abilities to maintain car positions. At the same time, these generalized SWDs may persist as subclinical epileptiform discharges even in "seizure-free" patients who continue to drive, posing a significant challenge to driver licensing authorities, clinicians and patients. Although not clinically observed and not perceived by patients, these subclinical discharges can be accompanied by transient cognitive impairments. There is a need to study the influence of generalized SWDs on driving behavior and safety in high fidelity simulated driving environments and to identify objective EEG features for predicting SWDs that impair driving ability. We have developed a feasible paradigm to test driving ability in patients with generalized SWDs and identify objective EEG features that reliably predict SWDs that impair driving safety. In this paradigm, subjects 15 years or older drive for an hour in a high fidelity, ½ cab driving simulator (miniSim^{TM}) fully instrumented for HD-EEG and video recording. A visual road obstacle is introduced in the driving course every 5 minutes and during every SWD, and the subjects are instructed to slow down and pull over when they notice the obstacle. The driving simulator continuously records vehicle speed (mph), brake force (lbs.), and rate of change for steering wheel angle (degrees/sec.). Further, we compute the reaction time (milliseconds) between obstacle presentation and driver's application of brakes. We compare the aforementioned variables between periods of no SWDs (as controls) and periods with SWDs. With testing of additional subjects, we aim to identify EEG features of SWDs that impair driving. We hypothesize that generalized SWDs that impair driving will have significantly longer duration and higher amplitude on EEG. Our knowledge of these features will advance our

efforts to develop EEG-based objective tools for determining driving safety in patients with epilepsy.

Abstract: Cross frequency coupling (CFC) phenomenon has been proposed to be functionally involved in neuronal communication, memory formation and learning. Besides, experimental findings have shown that phase-amplitude (PAC) and phase-phase (PPC) couplings are important variants of CFC linked to physiological and pathological brain states. In particular, PAC and PPC have been observed in local field potentials (LFP) recorded during epileptic seizures. PPC represents the phase coherence across frequency bands and/or recording sites, which in general increases between nearby areas of the neural tissue recruited to the ictal event. In PAC, the amplitude of a high frequency band is modulated by the phase of another band with a lower frequency content. Recent works have shown that nested oscillations, associated to the

scale free neural activity, and sharp waveforms both produce PAC, however, they reflect two distinct neural mechanisms that are anatomically segregated in the human brain.
In this work, we study the CFC dynamics during the seizure activity in patients with focal epilepsy who were candidates for surgery treatment. The analysis was performed on LFP obtained from 5 patients undergoing intracerebral electroencephalography (stereo EEG) and 2 patients undergoing subdural electrocorticography (ECoG). To quantify the CFC dynamics during the seizure activity we use non-parametric methods: the Phase Locking Value (PLV) and the Modulation Index based on the Kullback-Leibler distance (KLMI). In addition, we have developed specialized tools to characterize the nature of the observed CFC patterns. Specifically, the Time Locked Index (TLI) and Harmonic Index (HI) were implemented to quantify the presence of harmonics associated to the emergence of CFC. Moreover, the correlation of LFP and CFC for a given recording site across seizures was evaluated in order to quantify the seizure stereotypy.
We have found that the ictal activity gives rise to different types of CFC, which were highly stereotyped during the seizure dynamics. Importantly, two essentially different PAC patterns produced by non-sinusoidal waveforms were identified. In the first one, the PAC was elicited by highly cyclostationary (pseudo-periodic) LFP signals, which were characterized by well-defined harmonic spectral components present in their Fourier spectrum. In the second one, the PAC was produced by sharp waveforms constituted by non-harmonic high frequency components. The proposed tools allowed us to better characterize the CFC patterns emerging during the seizure dynamics, which could pave the way to unveil the underlying neural mechanisms that initiate and propagate the ictal activity.

Title: Deep brain stimulation for seizure control: A role for white matter

Authors: *F. SCHAPER[1], B. R. PLANTINGA[2], A. COLON[3], L. WAGNER[4], P. BOON[4], E. GOMMER[1], G. HOOGLAND[1], L. ACKERMANS[1], R. ROUHL[1], Y. TEMEL[2]
[2]Neurosurg., [1]Maastricht Univ. Med. Ctr., Maastricht, Netherlands; [3]Academic Ctr. for Epilepsy, Heeze, Netherlands; [4]Academic Epilepsy Ctr., Heeze, Netherlands

Abstract: *Background*: Deep brain stimulation (DBS) of the anterior nucleus of the thalamus (ANT) can improve seizure control for patients with drug-resistant epilepsy. Yet, responder rates

vary highly which is possibly explained by crucial differences in brain stimulation sites.
Objective: We hypothesized that stimulation at the junction of the ANT and mammillothalamic tract (ANT-MTT junction) results in increased seizure control in DBS for drug-resistant epilepsy.
Methods: We retrospectively analysed the location of the active contacts and ANT-MTT junction of 11 patients treated with ANT-DBS for drug-resistant epilepsy. Coordinates and Euclidean distance of the active contact relative to the ANT-MTT junction were calculated and compared between 5 responders (≥50% reduction in seizure frequency) and 6 non-responders (<50% reduction in seizure frequency). Stimulation sites were mapped by modelling the volume of tissue activation (VTA) and generation of stimulation heat-maps.
Results: The mean Euclidean distance of the active contacts to the ANT-MTT was 30% smaller in responders to DBS. VTA models and heat maps indicate that the stimulation hot-spot of responders is located at the medio-ventral ANT in closer vicinity to the ANT-MTT junction compared to the hot-spot of non-responders, located at the dorsal ANT. The Euclidean distance between the centres of stimulation hot-spots was a substantial 3.8 mm.
Conclusions: Our findings suggest that there is a relationship between stimulation site and therapy response in ANT-DBS. The ANT-MTT junction is a potential brain stimulation site for increased seizure control.

Title: Using automated detection and classification of interictal HFOs to improve the identification of epileptogenic zones in preparation for epilepsy surgery

Authors: *T. SOBAYO, S. FARAHMAND, D. J. MOGUL
Biomed. Engin., Illinois Inst. of Technol., Chicago, IL

Abstract: For more than 25 million patients worldwide who have drug-resistant epilepsy, surgical resection of brain regions where seizures arise is often the only alternative therapy. However, the identification of this epileptogenic zone (EZ) is often imprecise. Several studies have suggested that localized high frequency oscillations (HFOs) detected during iEEG

recording are a way to spatially locate the EZ. Traditionally, HFO detection is carried out through visual inspection of long hours of iEEG recordings. This is a very time-consuming and tedious process. In this study, an automated method for detecting and classifying HFOs based on noise-assisted, multivariate empirical mode decomposition (NA-MEMD) is proposed to identify the high-rate HFO areas in interictal, multi-channel, iEEG recordings. The NA-MEMD outperforms Fourier and Wavelet methods because it is adaptive and produces a set of finite narrowband components. NA-MEMD is also less susceptible than filtering to ringing artifacts. Interictal iEEG data recorded from 10 patients, who subsequently underwent epilepsy surgery at the University Hospital of Zurich, were used in this study. Recordings were made using subdural strip, grid and depth electrodes. Data acquisition was performed using a Neuralynx system with a sampling frequency of 2000 Hz and 0.5-1000 Hz band-pass filtering. Pre-processing of iEEG data involved the measurement of bipolar derivations from adjacent channels to eliminate the confounding effects of common reference signal and volume conduction. Bipolar-derivate signals were then divided into consecutive, non-overlapping, 1 s windows. For each window, NA-MEMD was performed on the time series to detect and classify HFO events; namely, fast-ripple (FR), ripple (R), and fast-ripple concurrent with ripple (FRandR). In each class, channels with high-rate HFO activity (as defined by a rate threshold) were selected as its corresponding HFO areas. To investigate the clinical relevance of the detected HFO areas, the resection ratio (RR) of all three classes of HFO were measured for each patient and then compared with his/her post-surgical outcome. The performance analysis of the proposed HFO detection and classification method resulted in sensitivity equal to 91.08% and false discovery rate (FDR) equal to 7.32%. Based on the obtained RR values for different HFO classes, it was found that patients with high RR for detected HFO-FRandR areas were seizure-free while those with low RR had recurrent seizures. These results support the feasibility of using this methodology to provide an automated algorithm that can be used in concordance with SOZs to better delineate the EZ.

Abstract: Electrocorticography (ECoG) is an invasive technique currently used to perform seizure onset localization in patients with intractable epilepsy. The location of the ECoG electrodes with respect to a patient's neuroanatomy is critical for planning resection surgeries. However, during implantation of the arrays, brain shift occurs making registration of the preoperative MRI and postoperative CT challenging. Brain shift introduces uncertainty into electrode locations that can propagate through computational models. We aim to quantify the bounds of this uncertainty. We projected ECoG electrodes from the CT into the MRI space with three distinct segmentations approaches. For each segmentation, we used finite element method (FEM) simulations to solve the Poisson equation for the voltage distributions during bipolar stimulation in the brain. Electrode locations between three different segmentation models and their solutions to the bioelectric field model were compared at each of the recording electrodes and to the clinical stimulation recordings. We demonstrated the ability to project electrodes onto the cortical surface and account for brain shift. The Euclidean distance between projected electrodes for the three different models is 0.326 ± 0.057 mm. The projection method for the three different segmentations did not cause a large change in voltage solutions and these voltage profiles match well with the clinical recordings (Figure 1). The small difference in electrode locations for the three projection models did not introduce large uncertainty into the FEM simulations. In the future, further investigation of this uncertainty propagation needs to be addressed related to the spatial distribution of the voltage on the cortical surface instead of the electrode contacts. This will allow for more precise cortical targeting for brain-computer interfaces and improved therapeutic benefit.

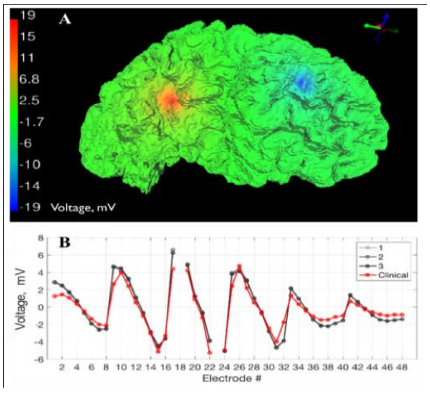

Figure 1. **A.** Representative FEM voltage solution for bipolar stimulation of two ECoG electrodes. **B.** Recorded voltage at each recording contact on the ECoG grids during stimulation for three different electrode projections (1-3) and the clinical recordings (red).

Title: A portable 512-channel system for intracranial recording and mapping inclinical epilepsy research and other high-current neural stimulation applications

Authors: T. POULSON, S. BARRUS, *A. M. WILDER, S. HIATT
Ripple, Salt Lake Cty, UT

Abstract: As the study and treatment of epilepsy progresses, researchers and clinicians require new, advanced tools to pursue important questions and improve the standard of care. The past decades have seen a trend towards increased channel counts in devices for intracranial monitoring, and an increased use of cortical stimulation mapping for surgical planning and research investigations. Many active areas of research into the electrophysiology of epilepsy, for example investigating the network dynamics of ictogenic regions, require the ability to precisely coordinate stimulation and recording across hundreds of implanted electrodes. Over the past ten years we have developed and extensively field tested a portable electrophysiology platform that enables researchers to record and stimulate on hundreds of electrodes. From the beginning, this system was designed to be modular, with a central processor that can be connected to one or more application-specific front ends, and compatible with human use. First generation front ends for this system support recording and stimulating on microelectrodes. Recently we have developed a new front end specifically designed for recording and stimulating on macro electrodes used in epilepsy treatment and research, including intractanial grids, for ECoG and μECoG, and sEEG electrodes. This front end is designed for both research and clinical use and comes in channel counts up to 128. Four 128-channel front ends can be connected to our central processor for a recording capacity of 512 channels. Each bank of 16 channels has a stimulation circuit capable of monopolar (to distant ground) or bipolar (electrode to electrode) stimulation. Stimulation output can be either current-controlled or voltage-controlled and outputs can be programmatically controlled to facilitate complex experiment paradigms. Current output can be specified in 100μA steps up to 15mA, with a max frequency of 10kHz. Voltage output can be specified in 100μV steps up to 15V, with a max frequency of 1kHz.We believe the combination of a large number of recording channels and high-current stimulation output in a single,

programmable interface sets this system apart from others available devices, enabling a wide range of new epilepsy research and offering the potential to substantially improve standard of care for patients.

Abstract: Little is known about the activity of individual cortical neurons during epileptic seizures in humans. We tested a microelectrode array (MEA) implant for safety and efficacy to record single units semi-chronically in epilepsy patients.
We implanted two patients undergoing invasive EEG monitoring with subdural electrodes as part of their workup for epilepsy surgery with an array of 96 microelectrodes arranged in a 4-by-4 mm square (Blackrock array). Recordings were obtained over 180 h (240h, 2nd patient), with short interruptions. Separable action potentials from one or several neurons were present on roughly 50%(60%). MEA recordings were synchronized with the clinical intracranial EEG.
In patient 1, the MEA was situated within the seizure onset zone. Complex activity patterns emerged during seizures. Many neurons showed increased, highly synchronized activity compared to interictal periods. On the other hand, a number of neurons had suppressed activity. Strikingly, activity of individual neurons was very similar across seizures within a cluster. The

patient's typical seizures occurred in clusters, and dozens of seizures were recorded. During discharges of interictal epileptiform activity, single-neuron activity was roughly locked to the spike component of spike-wave complexes. The patient underwent en bloc cortical resection of the right temporo-parieto-temporal junction, including the site of MEA implantation.
In patient 2, the array was located in the arm area of primary sensory cortex, 2 cm away from the seizure onset zone. One seizure was recorded with the MEA. The period leading up to the seizure was characterized by synchronous bursts of action potentials from units across the whole array. These bursts occurred with a frequency of 0.5-1 Hz and lasted until 10 s after seizure onset was detected from clinical EEG. Subsequent action potentials were less synchronized across the array. The MEA was explanted together with the subdural electrodes but no tissue was resected. The patient did not report abnormal somatosensory perceptions related to the array, before or after explantation.
Microelectrode arrays provide unprecedented access to the activity of multiple single neurons in the human neocortex and allow characterizing the dynamics of neuronal activity during epileptic seizures.

Title: Noninvasive skin volatilomics for forcasting and diagnosing seizures

Authors: *K. DESHPANDE[1], D. D. SPENCER[4], R. B. DUCKROW[5], H. P. ZAVERI[2], L. HIRSCH[6], T. EID[3]
[2]Neurol., [3]Dept Lab. Med., [1]Yale Univ., New Haven, CT; [4]Dept Neurosurg., [5]Dept Neurol., Yale Univ. Sch. Med., New Haven, CT; [6]Neurol., Yale Yale Univ. Sch. Med., New Haven, CT

Abstract: Purpose: Volatile organic compounds (VOCs) emitted by the mammalian body are typically small molecule intermediates or end products from metabolism of food, drugs, environmental agents and endogenous constituents of the body. Considering that metabolic perturbations are often associated with seizures we explored the utility of measuring VOCs, emitted through the patient's skin, as a novel, noninvasive and highly informative "volatilomic fingerprint" for forecasting of impending seizures and for diagnosis of ongoing, or recently

completed seizures. VOC can be collected in a rapid, easy and pain-free fashion, making the sample type particularly valuable for frequent monitoring of oscillating disease states such as epilepsy. **Methods:** Adult patients (>18 years) admitted to the Yale Comprehensive Epilepsy Program for long-term video-scalp electroencephalogram (EEG) recordings will be recruited for this study. Samples are collected by swabbing the skin with sterile gauze. Swabs will be collected multiple times in triplicates to establish each patient's baseline (interictal) VOC profile. Additional swabs are collected before and after electrographic seizures to capture seizure-associated VOC changes. Swabs will be analyzed by headspace solid phase microextraction-gas chromatography-mass spectrometry (HS-SPME-GC-MS). Multivariate and univariate statistics with correction for false discovery rate (FDR) will be used to identify statistically significant, "candidate markers". **Results:** We have previously shown the utility of this approach in a different species. In this study we identified 187 VOCs. Many of the VOCs correlated with the individuals' major histocompatibility complex (MHC) profile. In the present study we are establishing baseline VOC profiles as well as pre-seizure and post-seizure VOC profiles in patients with epilepsy and non-epilepsy control subjects. Our expectation is to identify a gradual change in the VOC profile in the hours leading up to a seizure and in the hours following a seizure. Some VOC changes are expected to be strongly associated with all seizures in all patients, suggesting that certain metabolic changes or pathways represent common seizure mechanisms. **Conclusions:** The discovery of easily measurable biomarkers of seizures will be significant because: (a) biomarkers of seizure forecasting will facilitate the development of novel, on-demand treatments for epilepsy, and (b) biomarkers of completed seizures, will fill a critical gap in the way seizures are diagnosed, by eliminating the need to capture a seizure by EEG.

Title: LGI1-IgG levels, subtypes and clinical correlations in faciobrachial dystonic seizures

Authors: *M. BI[1], J. THOMPSON[2], A. G. MURCHISON[2], M. MAKUCH[2], S. R. IRANI[2]
[1]Dementia Res. Unit, The Univ. of New South Wales, Sydney, Australia; [2]Oxford Autoimmune Neurol. Group, Univ. of Oxford, Oxford, United Kingdom

Abstract: Autoantibodies to leucine-rich glioma-inactivated 1 (LGI1) are associated with a highly specific focal seizure semiology called faciobrachial dystonic seizures (FBDS), which often predates the onset of cognitive impairment. This condition is exquisitely sensitive to treatment with immunotherapy and early treatment can prevent the onset of cognitive impairment. Here we characterise the LGI1 autoantibodies involved in FBDS and correlate the levels and subtypes of autoantibodies in FBDS patients with or without cognitive impairment. Standardized questionnaires were distributed to an international network of clinicians between 2008 and 2013. Clinical data from 103 consecutive patients with a diagnosis of FBDS and serum LGI1 antibodies were included. LGI1-antibody determination with a novel flow-cytometry assay (FCA) was developed to quantify serum IgG-subclass deposition on live HEK293T cells with stable-express of membrane-tethered LGI1-EGFP. ADAM22 co-transfection and soluble LGI1 were used for internalisation experiments. All patients underwent informed consent (approval REC16/YH/0013). The novel flow-cytometry assay performed well in comparison to a cell-based assay (CBA) and allowed quantification of LGI1-IgG levels and subtypes. Patients with FBDS alone had LGI1 autoantibodies of predominantly IgG4 subtype and a near absence of the IgG1 subtype. Patients with FBDS and cognitive impairment showed a clear increase in the IgG1 subtype. Mechanistically, LGI1-IgGs are able to cause internalisation of its target membrane bound receptor ADAM22. We demonstrate that total LGI1-IgG autoantibodies and its IgG1 subtype are elevated in FBDS patients who present with cognitive impairment. This implicates complement activation and neuroinflammation as a possible mechanism, which ultimately leads to cognitive impairment in FBDS. Furthermore, patient serum is able to induce internalisation of

ADAM22, a membrane bound receptor of LGI1, suggesting the presence of a second and possibly reversible mechanism in the pathogenesis of FBDS.

Title: Safety of transcranial focal stimulation (TFS) via tripolar concentric ring electrodes (TCREs) in people: Initial results

Authors: *L. M. MCCANE, P. STEELE[1], J. MERCIER[2], D. J. MCFARLAND[4], W. G. BESIO[3]
[1]CREmedical Corp, West Kingston, RI; [2]Univ. of Rhode Island, Kingston, RI; [3]Electrical Computer and Biomed. Engin. Dept., Univ. of Rhode Island, West Kingston, RI; [4]Lab. Neural Injury and Repair, Wadsworth Ctr., Albany, NY

Abstract: The incidence of epilepsy in the US alone is 1 in 26. Over 120 experiments using transcranial focal stimulation (TFS: 300 Hz biphasic pulses, 1-2 min) via tripolar concentric ring electrodes (TCREs) have demonstrated: reduced or abolished electrographic and behavioral activities of induced seizures and status epilepticus in three rat models (pilocarpine, PTZ, penicillin, (Besio, 2013)); prevention of electrical amygdaloid kindling in naïve cat brains (Valds-Cruz, 2015); pain blocking (Besio, 2016); and prevention of glutamate release (Santana-Gómez, 2015). TFS in rats did not cause skin damage or affect memory (Besio, 2013). Here, we report the initial, and encouraging, safety results of applying TFS in healthy people.
TFS safety is being tested on participant's skin and behavior during 3 sessions (S1, S2, S3) about 1-week apart. At S1, participants rate each step of the electrode application process on the arm and scalp for pain (0-10, none to worst) and the experimenter rates skin erythema (Draize scale, 0-4; no change-beet red, Guartienti, 2014) (NuPrep cleansing gel; Ten20 EEG paste; gel + paste; gel + paste + TCRE; gel + paste + TCRE + TFS or SH for 2 mins). Baseline (BL) performance on a working memory task (WMT: 5-min each of 2-back and 3-back) is recorded before scalp TFS or SH while 16 channels of EEG are collected at 512Hz (t-Interface 20, g.USB amplifier

and BCI2000) over the left prefrontal cortex (8 TCRE signals (tEEG), and 8 emulated EEG (eEEG, Makeyev, 2013)). TFS or SH is applied at F3. At S2 they perform a BL WMT, TFS or SH is delivered, then, they perform the WMT at 3 post-intervention time points (in mins: T0, T20 and T40). At S3, they perform the WMT at the 3 time points.
Ten healthy participants have completed the study (6M, 4W, mean age = 32, 6 SH, 4 TFS). Only 1s have been reported for pain (arm: 1 gel, 1 paste; scalp: 1 each for the last 3 scalp steps, 1 at SH at S2) and erythema (4 Draize 1s for NuPrep step: 3 at AF3, 1 arm). There is no significant difference between the TFS and SH groups (Wilcoxon rank-sum) in accuracy (%C) or reaction time (RT) of the WMT at the 3 BLs and 3 S2 and S3 time points (9 block %C (mean ± SD): SH, 86.1 ± 0.11, range 62-100; TFS: 81.6 ± 0.12, range 55-96; mean RTs: SH, 394ms ± 106 SD, range 201-650; TFS: 445ms ± 155, range 280-699). WMT %C and RT change from S2 to S3 between groups are not significantly different. Within subject t-tests of %C and from S2 and S3 are not significant. Significant differences (Wilcoxon rank sum) in tEEG amplitude at F3 (unfiltered, 3-40Hz) between TFS and SH were found for BL2 and S3 T0 ($p<0.05$). These preliminary results indicate TFS is safe in people. Further study will determine if TFS has beneficial effects in people with neurological disorders.

Title: Temporal evolution of features of high-frequency oscillations in human epilepsy

Authors: *J. SCOTT, B. HUNT, S. GLISKE, W. STACEY
Univ. of Michigan, Ann Arbor, MI

Abstract: High-frequency oscillations (HFO) are a promising biomarker of human epilepsy. Increased HFO rates are associated with epileptogenic tissue, and many studies show improved surgical outcomes for resective surgeries targeting pathological tissue with high HFO rates. However, there has been only limited research on the role of signal features of the HFOs. One of the reasons for this is the difficulty in acquiring large numbers of HFOs to allow rigorous evaluation of signal features. In this study, we utilized a validated HFO detection algorithm to identify over 10 million HFOs in 40 patients with intracranial EEG recordings over multiple days. We used this database to analyze HFO rates and features as a function of time, and correlated results with sleep stage. The analysis used a variety of statistical and machine learning methods to determine any temporal correlation of HFOs through seizure onset and beyond. Our findings in general show a wide variation in temporal trends of HFOs between patients. We found that preictal HFO rates were not predictive of imminent seizure onset in most patients. There were no HFO features that consistently indicated seizure onset zone in different patients. However, in many patients there were specific HFO and EEG background features that correlated with seizure onset zone, and which evolved as seizures approached. These results suggest a temporal correlation between HFOs, EEG background activity, and the specific processes of ictogenesis in individual patients. Further work is necessary to correlate these temporal changes with ictogenic mechanisms.

Title: Anatomical evaluation of corpus callosum in MS patients mr images

Authors: *A. D. AYDIN KABAKÇI[1], M. BUYUKMUMCU[1], D. AKIN[2], N. POYRAZ[3], A. UCA[4]
[2]Anat., [3]Radiology, [4]Neurol., [1]Necmettin Erbakan Univ., Konya, Turkey

Abstract: INTRODUCTION
The corpus callosum (CC) is the largest interhemisferic commissural pathway which connecting cortial and subcortical areas of cerebral hemispheres. The brain structures especially CC have a tendency to be affected by morphological changes in the development and growth process. With the usage of tractography and functional MR; its much more easy to understand neurological development process and possible local effection of the brain by neurodegenerative diseases. This study had been planned to investigate morphological changes that can be occured on corpus callosum caused by MS.

MATERIAL AND METHODS
This study was conducted on restrospective images of 50 patients (20 males and 30 females) whom applied to University of Necmettin Erbakan, Faculty of Meram Medicine, Neurology Clinic with Relapsing-Remitting Multiple Sclerosis (RRMS) diagnosis, defined as RRMS or treated for RRMS. We measured many parameters related CC and distance between CC and surrounding structures on midsagittal MRI images. We assessed whether there was a relationship between the parameters CC was was divided into 7 sub-regions based on Witelson classification. The surface area of the each subregion was measured on midsagittal views.
RESULTS
In conclusion, morphometric changes and its statistical significant has been determined in both corpus callosum and its related surrounding structures ($p<0.05$). The results of our study suggest that CC tend to have frontal localization depending on course of diseaese in male and female patients. Also, positive and negative correlation relation has been determined in the conclusion of the study betweens many parameters. There was no correlation between sexes and measurements of subregion surface area, but there was a negative correlation between age and genu surface area measurement only.
CONCLUSION
When we consider the localization and its function, under the many factors CC may have structural changes. Especially for the diagnosis of the diseases, stractural changes of CC has Hint Point importance. We think that the obtained data from this study could be morphometric data sets for MS patients and a preliminary phase for future studies.
Key Words: Corpus callosum, magnetic resonance imaging (MRI), multiple sclerosis (MS).

Title: Stimulation levels determine amplitude and variability of cortico-cortical evoked potentials following single-pulse electrical stimulation

Authors: *T. DAVIS[1], J. D. ROLSTON[2]
[1]Neurosurg., Univ. of Utah, Salt Lake Cty, UT; [2]Dept. of Neurosurg., Univ. of Utah, Salt Lake City, UT

Abstract: Cortico-cortical evoked potentials (CCEPs) are an electrophysiological phenomenon used to explore functional connectivity in human cortex and cortical excitability in epilepsy

patients. CCEPs are typically produced by manually applying single pulse electrical stimulation (SPES) to electrocorticography (ECoG) electrodes. While these responses are used to infer function and connectivity, lack of automation and variable stimulation parameters limits our understanding of the dose-response features of CCEPs. To better understand these features, we systematically explored the SPES amplitude parameter space in five epilepsy patients. Monopolar stimulation was automatically delivered to 294 electrodes as a single biphasic pulse (0.5 ms/phase). Stimulation levels were varied from 2.5 to 10 mA in steps of 2.5 for a total of 10 trials per electrode at each level. Stimulation location and level were randomized across trials. Data were band-pass filtered at 0.3-250 Hz and recorded at 1 kHz. CCEP amplitude was measured by calculating the mean absolute value from 5 to 100 ms post-stimulation using the trial-averaged waveform. The Pearson correlation coefficient was used to calculate the similarity of CCEP waveform shape across trials and levels as a measure of waveform variability. Comparisons between CCEP amplitude, waveform shape, and stimulation level were made using ANOVA ($p<0.001$). CCEP amplitude approached an asymptote near 7.5 mA as levels increased from 2.5 to 10 mA. The median amplitude (and range) for levels at 2.5, 5, 7.5, and 10 mA was 108 (5-2138), 188 (14-2784), 214 (23-3545), and 222 (22-3194) µV, respectively. Inter-trial and inter-level correlation of CCEP waveform shape was found to be significantly lower (higher variability) at 2.5 mA compared to higher levels. No seizures were evoked at any of the levels in all five patients. Stimulation levels have a significant effect on CCEP amplitude and waveform variability. Amplitudes approached an asymptote at 7.5 mA, suggesting response saturation near this level. Amplitudes were smallest and variability highest at 2.5 mA, suggesting a more probabilistic and varied response at this level, likely from stimulation close to an activation threshold. These findings suggest that levels below 7.5 mA have the risk of generating low amplitude CCEPs with higher variability, which may adversely affect CCEP analysis.

Title: White matter tract development disrupted in youth with temporal lobe epilepsy

Authors: *W. I. MATTSON[1], M. MORNINGSTAR[1], J. VENTICINQUE[1], S. SINGER, Jr.[1], B. A. FULLER[1], S. GEDELA[3,2], E. E. NELSON[1,3]
[1]Res. Inst., [2]Neurol., Nationwide Children's Hosp., Columbus, OH; [3]Pediatrics, Ohio State Univ., Columbus, OH

Abstract: Temporal lobe epilepsy (TLE) in adults is associated with profound effects on white matter integrity near seizure foci but also globally (Otte et al., 2012). It is less well understood how this impact is reflected in youth, where brain development is still in progress. Fractional anisotropy (FA), which uses the degree of restriction of water diffusion to infer the location and direction of white matter tracts, has been shown to continue to increase into early adulthood (Lebel et al., 2012). We employed FA to assess how the white matter development of children and adolescents differed between youth diagnosed with TLE and a comparison group without epilepsy. Specifically we were interested in how the association between FA and age was affected bilaterally in five major white matter tracts.

Youth with intractable TLE and comparison youth completed diffusion tensor image (DTI) as part of a larger imaging protocol. DTI imaging was acquired in 64 directions using multi-slice acquisition. Based on anatomical landmarks, DSI studio software was used to bilaterally identify the inferior occipito-frontal fasciculus (IFOF), inferior longitudinal fasciculus (ILF), uncinate (UNC), arcuate fasciculus (AF), and fornix (FX) tracts. Mean FA values for each of these tracts were extracted. Differences in the association between FA values and age were examined within each group and tract.

In preliminary findings from twenty-one comparison youth, age and FA values were associated for the right AF, left and right RIFOF, and right ILF, *r*s = 0.45 - 0.56, *p*s &lt .05, such that white matter integrity increased with age. In contrast, for the TLE group (*n* = 11) no tracts significantly increased in FA with age, *r* = -.39 - .15, *p*s &gt .27, except increasing age approached a significant association with *decreases* in right IFOF FA values *r* = -.53, *p* &lt .10.

These early findings suggest that youth with TLE experience heavily disrupted white matter tract development in comparison to youth without this diagnosis. Of particular concern is that the right IFOF—often linked to attention and visual processing—decreased in the TLE group, which might indicate potential atrophy during a period of major development. With elaboration, these results may elucidate alterations in the trajectory of brain development experienced by youth with TLE. Ultimately this may help identify periods where surgical intervention in intractable TLE patients might best improve clinical outcomes.

Title: Increased spectral power and altered functional connectivity in patients with infantile spasms

Authors: G. KOIRALA[1], N.-Y. KIM[1], H. KIM[2], *D. LEE[2,3]
[1]Electronic Engin., Kwangwoon Univ., Seoul, Korea, Republic of; [2]Pediatrics, [3]Epilepsy Res. Inst., Yonsei Univ. Col. of Med., Seoul, Korea, Republic of

Abstract: This study aims to investigate the changes in spectral power and functional connectivity (FC) in patients with infantile spasms (IS). We examined 19-channel EEG time-series signals in 17 patients with IS and 16 age-matched controls. We extracted 160 noise- and artifact-free preprocessed 2 seconds epochs from each participant. Standard Fast Fourier Transform (FFT) was used to examine the changes in average power spectral density. FC was computed between 19 scalp electrodes using phase locking value. Average betweenness centrality (BC_{av}) in seven brain regions were computed in an acyclic network obtained by utilizing minimum spanning tree (MST) algorithm. Patients with IS showed increased spectral power and significantly increased power (F= 5.527, p=0.025) was observed in theta band (Figure 1). Higher $BC_{av}$was observed in frontal regions, which was significant in beta band and significantly lower (region R1) in delta band. At theta band, both left and right centrotemporalregions (R3 and R4) showed significantly decreased BC_{av}. There was a significant increase in BC_{av}at central node region (R7) in alpha band which was significantly decreased in beta band as shown in Figure 2. These findings suggest that the patients with IS have increased spectral power, especially at theta band and altered topological functional connectivity in different frequency bands as a sign of impaired functional organization of the brain.

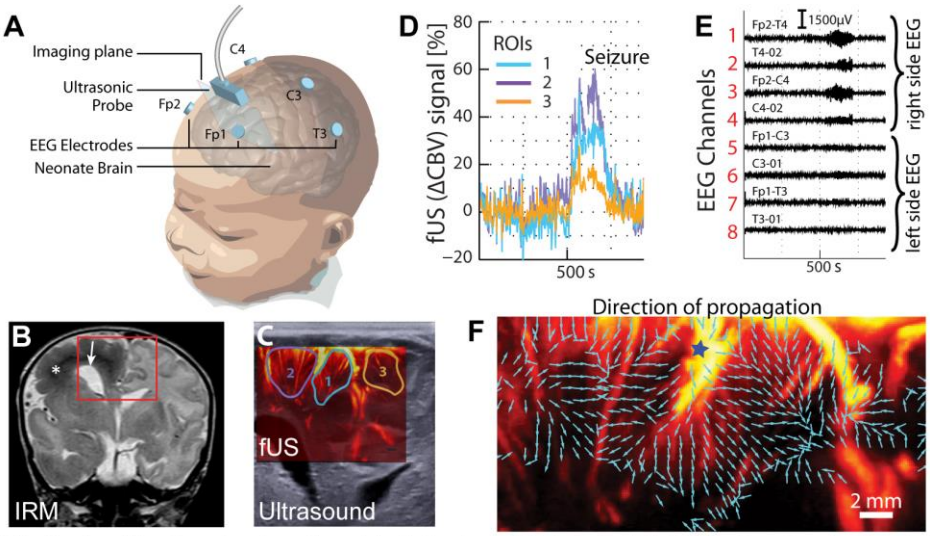
Abstract: Neuroimaging of human newborns remains challenging due to their vulnerability. The recent introduction of functional ultrasound (fUS) based on ultrafast imaging for ultrasensitive blood flow detection unveiled a new field of applications in Neuroimaging. Its very high sensitivity (flows down to 1mm/s), temporal (ms) and spatial (~240µm) resolution enabled to image the neurovascular coupling in unprecedented situations such as epileptic seizures [1] or spatial representation in a mobile animal [2]. However, to date those applications have been restricted to small animal studies. Here we present the first fUS imaging study on human neonates.

A custom light-weight ultrasonic probe (128 elements, 6.4MHz) mounted into an in-house newborn headset, and connected to an ultrafast ultrasound research scanner was used to acquire dedicated fUS sequences (650Hz, 370 frames), monitoring the Cerebral Blood Volume variations (ΔCBV) every 1s. The probe was placed on the anterior fontanel in coronal section along with 8 surface electrodes. EEG and fUS were synchronously recorded on 2 full-term neonates with abnormal cortical development associated with drug-resistant epileptic seizure occurring in one cerebral hemisphere.

During epileptic seizures, important blood inflow was detected (ΔCBV up to +70%) in the pathological cerebral hemisphere, whereas quite moderate activity was detected in the contralateral side, consistently with the lateralized ictal activity depicted on the EEG. Not only fUS enabled to observe precisely the seizure moving in different locations of the pathological cortex, but also, during the post-ictal phase associated with electrical spikes on the EEG, fUS imaging recorded slow waves of blood volume changes propagating from precise cortical locations with measured velocity ranging from 1.09 ± 0.11 mm.s^{-1} to 2.80 ± 0.32 mm.s^{-1}, consistent with values of epileptiform spread observed in neocortical brain slices after seizure. Localizing the precise origin of those waves could potentially lead to new therapeutic strategies for Epilepsy.



A Positionning of the ultrasonic probe on the anterior fontanel and EEG electrode. **B** T2-IRM showing enlarged pathological right hemisphere, with abnormal white matter (*) and dysmorphic ventricle (→). **C** Ultrasound Brain imaging (gray) overlaid with fUS imaging (red) and ΔCBV regions of interest (ROI). **D** ΔCBV in the 3 ROIs, with large increase in the right hemisphere (1 and 2) during the epileptic seizure starting at 500s, which is confirmed by the EEG right channels recording (**E**). **F** Based on the spatio-temporal characteristics of the ΔCBV recordings in the right hemisphere, directions of propagation of the epileptic neurovascular activity can be mapped on the brain.

Title: Characterizing the relationship between functional connectivity and neurocognitive deficits in benign epilepsy with centrotemporal spikes

Authors: *E. SPENCER[1], D. SONG[2], L. OSTROWSKI[2], C. CHU[2], M. KRAMER[1]
[1]Dept. of Mathematics and Statistics, Boston Univ., Boston, MA; [2]Dept. of Neurol., Massachusetts Gen. Hosp., Boston, MA

Abstract: Benign epilepsy with centrotemporal spikes (BECTS) is a common focal epilepsy disorder characterized by a self-limited period of spontaneous seizures as well as subtle

neurocognitive deficits in children. BECTS patients typically enter remission after adolescence, yet the neurocognitive deficits associated with the disease persist, including language and sensorimotor dysfunction. BECTS provides an interesting model to study functional network reorganization in epilepsy because, while there are no structural lesions, children have a period of abnormal electrical activity in a consistent focal cortical region followed by resolution, allowing for comparison across patients and at different stages of disease. We hypothesize that functional connectivity in the seizure focus is increased in during active periods of epilepsy compared to during in remission or comparable regions in healthy control subjects. Because the seizure onset zone includes the pre and post central gyrus and the superior temporal gyrus, we also hypothesize that functional connectivity in the pre and post central gyrus will correlate with performance on a sensorimotor task, and that functional connectivity within the superior temporal lobe will correlate with performance of a language performance. To examine these hypotheses, we construct functional brain networks from sourced electroencephalography recorded during sleep and compare them to performance in sensorimotor function and language tasks in children with active BECTS, patients in remission and healthy controls. We explore the relationships between functional connectivity and disease status, and between functional connectivity and task performance in the three subject groups. Understanding the functional network changes that accompany neurocognitive deficits in BECTS would further understanding of the disease itself and could provide potential diagnostic avenues for clinical application.

Title: Machine learning based responsive brain stimulation device: An epilepsy clinical trial

Authors: *G. O'LEARY[1], D. M. GROPPE[1], R. GENOV[2], T. A. VALIANTE[3]
[2]Electrical and Computer Engin., [1]Univ. of Toronto, Toronto, ON, Canada; [3]Toronto Western Hosp., Toronto, ON, Canada

Abstract: Purpose and hypothesis: A third of epilepsy patients are not successfully treated with current anti-seizure medications (England, 2012). Implanted closed-loop neurostimulation devices can be used to detect the onset of seizures and use electrical stimulation to prevent their

propagation in the brain. However, existing clinically approved devices use information-limited time-domain biomarkers with limited efficacy, where only 13% of patients achieve seizure freedom for at least a year (Sun, 2014). Recent work has found the use of phase locking values (PLV) between brain regions enable 83% seizure freedom with responsive stimulation in rodents (Salam, 2015), however, its efficacy is yet to be demonstrated in humans. A further challenge involves the patient-specific appearance of seizures due to differences in electrode placement and physiology. To overcome this, data-driven machine learning algorithms can learn temporal patterns in biomarkers on a per-patient basis to more accurately classify seizures and apply contingent neurostimulation. **Methods:** Our recent work has demonstrated NURIP, a neural interface processor for brain state classification, which utilizes the exponentially decaying memory support vector machine (EDM-SVM) algorithm to accurately learn the patient-specific nature of seizures (O'Leary, 2017). The device uses spectral energy (SE) and PLV biomarkers in combination with the EDM-SVM to anticipate seizures and trigger a preventative electrical stimulus. This device will be integrated with clinically approved neural recording and stimulation systems in a clinical trial with 50 patients. **Results:** Initial results using the EU intracranial EEG database (Ihle, 2012) has indicated a seizure sensitivity of 100% and a false positive rate (FPR) of 0.81 per hour over 24 hours. **Conclusions:** Patient-specific classifiers combined with information-rich biomarkers could lead to high-efficacy implantable neurostimulation devices, leading to higher rates of seizure freedom and an increased quality of life for those with drug-resistant epilepsy.

Title: Linking data to models to estimate potassium ion concentration during a seizure

Authors: *E. SCHLAFLY, U. T. EDEN, M. A. KRAMER
Boston Univ., Boston, MA

Abstract: Potassium ion concentration plays an important role in neuronal excitability. Moreover, changes in extracellular potassium concentration are associated with seizures and other dysfunctional brain states. Yet it remains difficult to characterize these changes *in vivo* from human patients. To address this challenge we propose a computational method to track changes in ion concentration gradients throughout a seizure. This procedure comprises two steps.

First, we apply two automated spike-sorting methods to local field potential (LFP) data recorded during a seizure using a microelectrode array implanted in human cortex, and from these procedures isolate units sorted consistently by both methods. Second, we apply a particle filter algorithm to link these spike train data with a Hodgkin-Huxley-type biophysical model. The particle filter allows us to estimate model parameters, including the time-varying potassium conductance, from which we approximate the extracellular potassium concentration. We demonstrate the ability of the particle filter to estimate and track more than ten parameters in a simulated neuron. We also present parameter estimates from cells recorded during the early onset of a seizure. We propose that the resulting computational tool provides a technique for linking observed spike train activity to unobserved biological phenomena.

Title: Organization of high frequency oscillations by low freq activity within and between human seizures

Authors: *J. NADALIN[1], L.-E. MARTINET[3], C. CHU[4], S. S. CASH[5], U. EDEN[2], M. KRAMER[1]
[1]Mathematics, [2]Mathematics and Statistics, Boston Univ., Boston, MA; [3]Dept. of Neurol., [4]Massachusetts Gen. Hosp., Boston, MA; [5]Dept Neurol, Mass Genl Hosp, Boston, MA

Abstract: High frequency oscillations (HFO, 140-180Hz) are an important rhythmic activity for brain function and dysfunction. However, the underlying mechanisms and organization of HFO remain largely unknown. Here, we investigate HFO organized in two ways by lower frequency rhythms First, we examine HFO coupling to the low frequency (4-7Hz)phase. We utilize a generalized linear modeling framework to characterize this cross-frequency coupling (CFC), which additionally takes into account the low frequency amplitude of the signal. Second, we examine HFO coupling to interictal epileptiform discharges (IEDs). We detect these IED-HFO events from long duration interictal recordings with an automated algorithm. We apply these analyses of high frequency oscillations tohumaninvivomultiscale recordings, including electrocorticography (ECoG)and microelectrode arrays (MEAs), within and between seizures. Our preliminary results show dynamic changes in cross frequency coupling at seizure onset and termination, notably arise and fall of both phase-amplitude coupling (PAC)and amplitude-

amplitude coupling (AAC), and suggest the co-occurence of HFO and IEDS may serve as a promising biomarker for seizure. A deeper understanding of high frequency oscillations during human seizure may provide insight into seizure mechanisms, and possibly suggest improved therapeutic strategies to treat epilepsy.

Abstract: Epilepsy, one of the most common neurological syndromes, is increasingly recognized as involving complex brain network dynamics, making understanding and treating this disease a unique challenge. To address this issue, we have created a data analysis framework to infer and track brain networks through time during spontaneous human seizures. Our method first infers time-dependent functional networks based on the correlation between voltage time series. Then, it applies to the inferred functional networks the Dynamic Plex Percolation Method (DPPM) - a recently developed graph theory algorithm - to identify and track through time well-connected subsets of nodes, known as communities. We apply this framework to invasive human brain voltage recordings (electrocorticogram or ECoG) obtained from patients with intractable epilepsy. We compute the functional networks and dynamic communities observed at seizure onset using both surface grid electrodes and depth electrodes; while the latter provide better subcortical sampling, the neocortical sampling is reduced. We show that our dynamic community tracking method detects network communities related to seizure onset, with consistent characteristics across a patient's seizures. We propose that dynamic network analysis of human seizure data may provide new approaches to improve patient care of medically refractory epilepsy, such as refinements to surgical target identification, surgical outcome prediction and alternative seizure control strategies.

Abstract: Mitochondria play an important role in maintaining neuronal cell health. Dysfunctional mitochondria are a hallmark of the aging brain and are implicated in the onset of neurodegenerative diseases such as Alzheimer's and Parkinson's disease. Healthy neuron function is dependent on mitochondrial processes, which include the maintenance of mitochondrial redox state, membrane potential, networks, control of superoxide production and cellular bioenergetics. Therapeutics that target and improve these processes may impede the progression of aging-associated mitochondrial dysfunction. One source of therapeutics that targets brain health appears to come from dietary phytochemicals [1]. Urolithin A (UA) is a bioavailable human gut-metabolite of ellagic acid, which is abundant in pomegranates, and UA has been found to improve muscle mitochondrial function [2]. Here, we investigate whether UA improves neuronal mitochondrial function using an *in vitro* retinoic acid-differentiated human neuroblastoma SH-SY5Y culture model. Physiological human plasma concentrations were tested in the range of 0.2 µM up to 25 µM, and *in silico* predictions indicate that UA crosses the blood-brain barrier [3-4]. Using MTT reduction assays, we measured cell and mitochondrial redox activities. We observed a concentration-dependent biphasic response with an initial increase in MTT reduction at 6 h and 12 h of UA treatment and a decrease at higher doses (10 µM & 25 µM) after 24 h and 48 h of UA treatment. High-resolution respirometry following UA treatment (1 µM for 24 h) revealed increased endogenous cell respiration, mitochondrial complex I and II mediated respiration and maximum respiration, especially at complex II. Live-cell microscopy

shows that UA increases mitochondrial branch length and mean number of branches per mitochondrial network while decreasing the number of fragmented mitochondria. Measures of mitochondrial membrane potential and superoxide production were unaffected by UA. We propose that mitochondrial function is enhanced by UA, most likely at complex II, and UA remodels mitochondrial networks. Our findings suggest a beneficial effect of UA on neuronal mitochondrial fitness needed to prevent mitochondrial dysfunction associated with aging.

Title: Neurological effects of moving from an enriched environment to social isolation in adult mice

Authors: *V. HENG[1], M. J. ZIGMOND[2], R. J. SMEYNE[1]
[1]Neurosci., Thomas Jefferson Univ., Philadelphia, PA; [2]Neurol., Univ. of Pittsburgh, Pittsburgh, PA

Abstract: As social animals, our health depends on interactions with others. Yet millions suffer from chronic social isolation (SI), including those living in nursing/assisted living facilities as well as their caregivers. SI also manifests in our criminal justice system, where more than 80,000 people are housed in solitary confinement (SC); defined as segregation from the general prison population for at least 22-23 hours/day for a period longer than 30 days. This condition is known to have toxic physiological and psychological consequences, including depression, stress, cognitive deficits, memory loss, and impaired concentration. Despite these well-known consequences, little is known about the impact of SI on the brain itself. In this study, we have developed a mouse model of SC where animals (C57Bl/6J) are born and raised in an enriched environment (EE) and then as adults (4 months of age) are placed into isolated conditions. After 30 days of isolation, we examined the shape, size, and arborization of neurons in specific regions of the brain selected because of their relevance to known psychological effects induced by SC including alterations in memory (hippocampus), loss of sensory threshold and discrimination (somatosensory cortex) and deficits in motor function (motor cortex). We used a modified Golgi-

Cox method together with confocal microscopy and Neurolucida 360 image analysis to determine the total and average dendritic length per neuron, spine counts, the total neuronal volume, and the extent of dendritic branching. After 1 month of isolation significant differences were observed in the total neuronal volume, with the greatest effect in layer V of pyramidal neurons in the motor cortex. In addition, these changes were sex-dependent, with greater deficits in males. Despite these changes, we do not yet know whether these changes were dependent on the age at which isolation starts, the duration of isolation, are permanent, or alter behavior. We are currently examining the effect of more prolonged isolation (3 months) on these variables, as well as examining if any changes observed after short and prolonged isolation are permanent or can be reversed upon reintroduction to an EE. We hope that these results will then be used to inform public policy, including issues that affect the aging population as well as those that affect the current and future populations housed within the criminal justice system.

Abstract: Age-related cognitive impairment is a major unmet medical need that will continue to grow as human lifespan extends. Research using heterochronic parabiosis identified that the circulation of young blood in aged mice can counteract behavioral and histological deficits found in these aged animals. Recent findings from our group and others have shown that human plasma can have similar rejuvenating effects in mice. However, due to the immunogenic effects of plasma between species, these studies have been exclusively performed in immunocompromised mice. We have identified a fraction of human plasma (PF) that surpasses the beneficial effects observed with young plasma in aged NSG mice and show here, for the first time, that this fraction can be dosed safely in aged C57BL6 WT mice. We demonstrate that dosing of PF in WT mice improves neuronal activity, increases neurogenesis, and reduces neuroinflammation. By using WT mice, we are now able to address immune-related questions that were previously confounded by using immunocompromised mice. These findings are an essential step towards

deepening our mechanistic understanding of how circulating factors in the blood could potentially be used as a treatment to ameliorate age-related cognitive decline.

Title: A focal cerebral ischemic stroke model in the aged mouse: Comparative studies between 2-month and 18-month-old ages

Authors: *Z. Z. WEI[1], X. H. GU[1], C. QU[1], R. K. CHIN[1], L. WEI[1], S. P. YU[1,2]

Abstract: Stroke is a leading cause of human death and disability. Aging and aged populations are the most vulnerable groups to strokes. Previous stroke investigations, however, have often been performed using young adult animals such as 2 to 3-month-old mice and rats. The establishment of an ischemic stroke model suitable for therapy developments using aging and aged rodents is important and necessary in basic and translational stroke research. A focal cerebral ischemic insult targeting the right sensorimotor cortex induces a restrained and well-defined cortical injury with excellent surviving rate and suitable for the examination of neural network repair and functional activities. In this investigation, we tested the similar focal ischemic insult in 18-month-old mice and compared with 2-month-old young adult mice. Animals were subjected to the permanent ligation of the distal branch of right middle cerebral artery (MCA) using a 10-0 suture, paired with bilateral ligations of the common carotid artery (CCA) for 7 min. Cerebral infarct was measured at 1 day and 3 days after stroke. Compared with young adult mice, aged mice had significantly larger infarct volume in the TTC assay. This is accompanied with less GFAP+ reactive astrocytes in the peri-infarct region of aged mice. Meanwhile, there

was significantly higher probability of spontaneous hemorrhagic transformation in the aged brain. The injury caused more severe sensorimotor deficits shown in the corner test and the cylinder test 1 and 3 days after stroke compared with young animals. Furthermore, aged mice with focal ischemia had significantly higher expressions of cytokines such as interleukin (IL)-1β, IL-6, MCP-1, and MIP-1α. Preliminary tests also indicate increased neuronal cell death and increased activation of microglia/macrophage in the ischemic region of aged animals. The RNA sequencing was performed to evaluate differentially-regulated genes and signaling pathways in the young and aged brains. Our data provide information and evidence to explain the distinctive neurological consequences after ischemic stroke at young and old ages. The significant morphological and functional deficits with lower mortality rates of this ischemic stroke suggest that it is an appropriate stroke model for aged rodents and suitable for evaluation of potential stroke therapies under clinically relevant conditions.

Title: Inhibitory effects of phenolic compounds on glioblastoma multiforme

Authors: *Y. K. GUTIERREZ-MERCADO[1], E. E. REZA-ZALDIVAR[2], M. A. HERNANDEZ-SAPIENS[2], S. E. OCHOA-HUGO[2], A. L. MARQUEZ-AGUIRRE[2,3], E. PADILLA-CAMBEROS[2], A. A. CANALES-AGUIRRE[2,3]
[2]Pharmaceut. Med. Biotech. Unit, [3]Preclinical Evaluation Unit, [1]CIATEJ, Guadalajara, Mexico

Abstract: Introduction: Glioma is one of the most frequent primary brain tumor in adults, and the second one most common in children. Gliomas, especially Glioblastoma multiforme (GBM), is a public health problem affecting 5.6 per every 100,000 inhabitants; with 17,000 new cases per year. Despite advances in transcranial surgeries, radiotherapy and the use of chemical substances use, the average life expectancy after diagnosis is 8 to 15 months. Therefore, is important to find new molecules capable of crossing the blood-brain barrier, to reach the tumor site and promote a citotoxic effect. More than 60% of antitumoral treatments are obtained from natural compounds; some of these are the phenolic compounds (PC) and capsaicinoids, which are plant secondary metabolites. PC and capsaicinoids have antitumoral properties, as well as, anti-inflammatory and antiviral activity, among others. Both the capsaicinoids, which are pungent alkaloids, and the PC, possess high antioxidant activity stated by their chemical structure, due to its antitumor capacity

it is important its investigation to define its use as a possible treatment for GBM. Objective: Determine cytotoxic effect of some enzymatically synthesized PC, (methyl-o-coumaric, propyl-o-coumaric and ethyl-o-coumaric) and capsaicinoids (olvanil, dohevanil and punic acid) on GBM in 3D cell culture. Materials and methodsA 3D cell culture was carried out of the cell line U138 and U87 of GBM, and HBEC5i, L929 as controls; different doses of several enzymatic derivatives of coumaric acids (methyl-o-coumaric, propyl-o-coumaric and ethyl-o-coumaric) and capsaicinoids (olvanil, dohevanil and punic acid), (10, 50, 100, 200, 400, 800 µM) and temozolomide (TMZ) at the same doses as control in order to find LD50. MTT was carried out, as well as an immunofluorescence for caspase 3, TUNNEL and Anexin IV in all the cells lines. CD133, L1CAM was also determined, to verify its expression after PC and capsaicinoids treatment. Results: Some enzymatically synthesized PC, like some derivatives from coumaric acids, methyl-o-coumaric and propyl-o-coumaric, as well as, Dohevanil and olvanil (DL50 100µM and 200 µM respectively) showed a cytotoxic activity much higher tan TMZ (DL 50 800 µM) in order to reach cytotoxicity on GBM 3D culture cells.

Title: Secreted alpha-Klotho overexpressed in the hippocampus alters social behavior and memory formation

Authors: D. LI, Y. CHEN, D. JING, Z. LIU, *T. BEHNISCH
Fudan Univ., Inst. of Brain Science, State Key Lab. of Med. Neurobio., Shanghai, China

Abstract: Alpha-Klotho belongs to a gene family whose inactivation leads to a phenotype that resembles aging. Here, we present data showing that the expression level of alpha-Klotho protein in the hippocampal formation of mice decreases with age and that overexpression of secreted human alpha-Klotho alters social behavior and memory formation. Specifically, the expression of endogenous alpha-Klotho decreased significantly in the hilus and CA1 regions of the hippocampal formation within 13-month of life. Interestingly, overexpression of secreted human alpha-Klotho in the CA1 area changed the nest building behavior and improved object recognition, object location and conditional fear memories. Moreover, alpha-Klotho

overexpression increased hippocampal synaptic transmission in response to standardized stimulation strengths, altered paired-pulse facilitation of synaptic transmission and enhanced activity-dependent synaptic plasticity. These results indicate that the hippocampal alpha-Klotho expression is declining with age and that memory formation benefits from an augmented level of secreted alpha-Klotho.

Title: Inward rectifier potassium channels (K_{IR}) and impaired cerebrovascular dilatory function in mouse models of Alzheimer's disease and cerebrovascular disease

Authors: *M. LACALLE-AURIOLES, L. J. TRIGIANI, M. BOUROUROU, E. HAMEL
Lab. of Cerebrovascular Res., Montreal Neurolog. Institute, McGill Univ., Montreal, QC, Canada

Abstract: Background: Neurovascular coupling (NVC) refers to the tight relationship between local neuronal activity and cerebral blood flow. Neurons, astrocytes, smooth muscle cells (SMCs) and endothelial cells (ECs) all contribute to this process, but the specific mechanisms remain elusive[1]. Potassium (K^+) release by astrocytic endfeet, acting through vascular inward rectifier K^+ channels (K_{IR}), has been proposed as a key effector of NVC, as well as in the upstream signaling from capillaries to arteries[2].
Objectives: We investigated whether the vasodilation mediated by K_{IR} channels in cerebral arteries would be altered in mouse models of *i)* Alzheimer's disease (mice overexpressing a mutated form of the human amyloid precursor protein, APP mice) or *ii)* cerebrovascular disease (mice overexpressing transforming grow factor-β1, TGF mice) compared to wild-type (WT) mice; and whether K_{IR} channels are located only in SMCs or also in ECs.
Methods: Vasodilation was measured in isolated and pressurized segments of the middle or posterior cerebral artery in APP, TGF and WT mice (n=4-5 mice/group, ~7 months old). Dilatory responses were quantified as the increase in diameter in vessels submitted to a myogenic tone (80 mmHg) and exposed to increasing concentrations of K^+ (4-16 mM)[3].

Maximal dilation was determined in calcium free medium. In some vessels, the endothelium was removed to assess the cellular localization of K_{IR} channels in the vessel wall. In other experiments, vessels were incubated with antioxidant (catalase 1000U/mL) or anti-inflammatory (indomethacin, 10µM/L).
Results: In WT mice, K_{IR} channels located on ECs contributed to approximately 50% of the maximal dilation (90% at 16mM K^+). In APP and TGF mice, maximal dilation was reached at 8 mM K^+ (APP=35% and TGF=9%), and then vessels constricted to higher K^+ concentrations. In APP and TGF mice, dilation did not differ in intact vs. EC denuded arteries. Antioxidant treatment rescued K_{IR} channel function in APP mice only, whereas anti-inflammatory treatment was exclusively effective in arteries from TGF mice.
Conclusions: Impaired NVC observed in APP and TGF mice could be, in part, mediated by dysfunctional K_{IR} channels as a consequence of oxidative stress and inflammatory processes in APP and TGF mice, respectively. Our results confirm that K_{IR} channels exist in both SMCs and ECs of brain arteries, each contributing to K^+-induced dilation.

Title: Effect of the chronic administration of curcumin on the neuronal morphology and protein expression of the hippocampus and prefrontal cortex in senile mice

Authors: *A. E. GONZÁLEZ, SR[1], S. I. GONZÁLEZ CANO[1], D. GNECCO[2], G. FLORES[1]
[1]Inst. de Fisiología, [2]Inst. de Ciencias, Benemérita Univ. Autónoma de Puebla, Puebla, Mexico

Abstract: In the last years, the number of older people (+65) has gradually increased at a rate of growth due to the advancement in healthcare, which leads to a longer life expectancy. For this reason, it's critical to improve the life quality in elderly, and health research aiming to geriatrics has increased its relevance. It has been postulated that treatments aimed at curbing aging could offer a much greater benefit than those focused on a specific disease. Therefore, it is possible to extend the useful life of an organism through dietary, pharmaceutical or genetic intervention that

modifies its metabolism. Several studies have shown the molecular mechanisms of many natural products and their therapeutic effects. For example, the turmeric (rhizome of the Curcuma longa plant), has different medicinal properties attributed. Curcumin (CUR) (the main active compound of turmeric) helps in the treatment of many diseases, such as Parkinson, Alzheimer, and dementia. The main pharmacological mechanisms attributed to CUR are its antioxidant properties as a scavenger of many oxygen-free radicals, including the superoxide anion and the hydroxyl radical. In this study, we evaluated the effect of a chronic administration of CUR in senile mice, measuring different behavioral and cytological markers related to cognitive processes, that is, Morris water maze and novel object recognition tests to evaluate learning and memory, Golgi-Cox staining to analyze dendritic spine density and neurological morphology, as well as Nissl staining for the stereological analysis of neuronal density and immunofluorescence assay for synaptophysin (SYP), glial fibrillary acid protein (GFAP) and metallothionein 3 (MT3) markers in the hippocampus and prefrontal cortex. The results obtained in the experiments, lead us to conclude that the chronic administration of CUR improved learning and memory capacities of the senile mice. Despite the CUR treatment had no effect in the number of neurons, it generated a restructuring of the cytoskeleton of the pyramidal neurons of the prefrontal cortex and the hippocampus, increasing the length of the dendrites and the density of spines, and increased the synaptic communication observed with the expression of SYP, as well as a decrease in oxidative stress and neuroinflammation. (Supported by: CONACyT grants No. 572907 to AEGG and 252808 to GF).

Title: Long term ingestion of drinking water containing sodium pyruvate prevents brain or neuronal damages in the models of epilepsy

Authors: *J.-Y. LEE, M. KIM, S. PARK, H. SON
Asan Inst. for Life Sci., Seoul, Korea, Republic of

Abstract: A large amount of study has demonstrated that sodium pyruvate (SP) has the potential neuroprotective activity in a variety of brain disorders. Most of the studies, however, showed that SP could significantly reduce brain damage or improve neurological impairments when it was

intravenously or intraperitoneally given at a large bolus dose immediately before or after the insults.
This study was performed to evaluate the effects of the long routine drinking of SP-containing water on brain or neuronal damages following epileptic insults. We found that pretreatment of neuronal cells with SP markedly increased cell viability or reduced cell death following exposure to kainate, glutamate, H2O2, etc. For in vivo animal study, we allowed mice free and routine access to SP-containing water for 6 months, and then subjected them to kainate-induced epileptogenesis. The progress or severity of seizure development, behavior or motor performance, and neuronal cell death were monitored and assessed following kainate treatment, in comparison with those of saline-ingestion groups. This study would uncover the preventive actions of long routine diet of SP against brain aging or neurological damages in brain disorders such as epilepsy or stroke.

Title: Investigating the potential of dexamethasone to modulate focused ultrasound-mediated increases in blood-brain barrier permeability

Authors: *D. MCMAHON[1,2], W. OAKDEN[1], K. HYNYNEN[1,2]
[1]Sunnybrook Res. Inst., Toronto, ON, Canada; [2]Med. Biophysics, Univ. of Toronto, Toronto, ON, Canada

Abstract: Therapeutic treatment options for diseases of the central nervous system are greatly constrained by the presence of the blood-brain barrier (BBB). Focused ultrasound (FUS), in conjunction with circulating microbubbles, can be used to induce a targeted and transient increase in BBB permeability, providing a unique approach for the delivery of drugs from the systemic circulation into the brain. Preclinical research has demonstrated the utility of FUS; however, recent work has shown that an acute inflammatory response accompanies this increase in BBB permeability. While the magnitude and duration of this response is relatively small when compared to alternative interventions, it may become a concern for the treatment of diseases that require multiple FUS exposures in short succession, as deleterious effects may accumulate. Dexamethasone (DEX), a corticosteroid, has anti-inflammatory properties and is known to

rapidly reduce BBB permeability in brain tumours. Work presented here demonstrates that DEX administration following FUS may have value in modulating the duration and degree of increased BBB permeability. For this work, male Sprague Dawley rats received unilateral hippocampal sonication; BBB permeability was assessed 15 minutes later by dynamic contrast enhanced magnetic resonance imaging (DCE-MRI). Following imaging, animals received either DEX (10 mg/kg; intraperitoneal) or saline and were imaged again 2-3 hours later. Results indicate that a single dose of DEX induces a significant reduction in Ktrans hours after FUS, relative to Ktrans measured shortly following sonication. While further work is necessary, a more rapid return of BBB permeability to baseline, combined with the anti-inflammatory properties of DEX, may lead to a reduction in the magnitude of acute inflammatory response following FUS. This may provide greater clinical flexibility for FUS, allowing repeated treatments in short succession due to the reduced risk for deleterious effects to accumulate.

Title: The GSK3 inhibitor AR-A014418 promotes oligodendrogenesis in adult white matter

Authors: *F. PIEROPAN, A. M. BUTT, A. D. RIVERA
Univ. of Portsmouth, Portsmouth, United Kingdom

Abstract: Oligodendrocytes (OLs) are the myelin-forming cells of the central nervous system (CNS). Myelin insulates axons enabling rapid communication and its loss is the hallmark of demyelinating diseases such as multiple sclerosis (MS). Myelinating OLs are generated from precursors (OPCs) throughout life, under the control of multiple intrinsic and extrinsic factors. In the developing forebrain, OLs are generated from OPCs originating from neural stem cells (NSC) of the dorsal subventricular (SVZ). Previously, using a pharmacogenomic analysis of the dorsal SVZ, we determined that the GSK3β inhibitor AR-A014418 promotes oligodendrogenesis in the developing SVZ. Here, we have examined the effects of AR-A014418 on the generation of OLs in adult white matter of the mouse optic nerve. Sox10-eGFP mice were used to identify OLs and OPCs; mice were killed humanely in accordance with the Home Office Animals (Scientific) Act 2012 (UK), and optic nerves isolated with retina intact. Nerves were maintained ex vivo in organotypic culture in control medium or medium containing 20 μM AR-A014418. After 3 days

in vitro (DIV), optic nerves were analysed by confocal microscopy, immunohistochemistry, microarray, and qRT-PCR. AR-A014418 dramatically increased the number of Sox10+ cells in the adult nerve; Sox10 is expressed by both OLs and OPCs, but only the latter are proliferative, indicating that AR-A014418 promoted oligodendrogenesis in adult OPCs. Genomic analysis identified the Rho-GTPase pathway acting via Rac1 and Cdc42 as the key mechanisms of action of AR-A014418. The results demonstrate that AR-A014418 promotes oligodendrogenesis in adult white matter and indicates GSK3β inhibitors are potential therapeutics in demyelinating diseases such as MS. A.D. Abstract: With aging, a significant risk of motor impairment, including bradykinesia, exists for those age 65 and older, affecting 15% of those age 65 to 30-50% by age 80. Unlike PD, the primary neurobiological basis for impaired movement initiation associated with aging may not be related to changes in dopamine (DA) biosynthesis in the striatum, given <15% loss of tyrosine hydroxylase (TH) in the human lifespan. We recently reported that calorie restriction prevented aging-related motor decline in male rats, which was associated with tyrosine hydroxylase (TH) expression decreased in striatum, but increased in substantia nigra (SN). Furthermore, pharmacological inhibition of TH activity in striatum did not reduce movement frequency in an open-field. Nigral neuron loss in older adults is associated with daily physical activity. We tested the hypothesis that nigral DA neurotransmission could affect motor performance in male rats by two approaches. First, we verified the TH inhibitor alpha-methyl p-tyrosine (AMPT) and DA

transporter inhibitor, nomifensine, reduced DA tissue content or increased extracellular DA levels in SN, respectively. The inhibition of TH emulated aging-related DA loss in young rats, without effect in striatum. In the opposite direction, nigral nomifensine increased extracellular DA, with no coincident change in striatum. In separate cohorts, bilateral guide cannula were implanted to target infusions to the ventrolateral SN to enable direct nigral infusion of AMPT or nomifensine. Movement frequency and speed were evaluated following nigral saline infusion (as the control) versus that following infusion of AMPT or nomifensine in a within-subjects design. In young 6 month old rats, movement frequency was significantly reduced following nigral AMPT infusion, consistent in a time period following AMPT -mediated DA reduction. Conversely, nigral blockade of DA uptake via nomifensine, in young and aged rats, increased movement frequency following infusion. Taken together, these results support an essential and unique contribution of nigral DA to movement frequency that may be important in age-related decline in motor impairment and, by extension, its improvement.

Title: Effects of probiotics on Alzheimer's disease progression: Assessing cognitive and cellular markers

Authors: *D. MEDEIROS, K. MCMURRY, N. BUITRAGO, C. LYONS, A. TANG, A. SILVER, P. SACCHETTI
Univ. of Hartford, West Hartford, CT

Abstract: Alzheimer’s disease (AD) is the sixth leading cause of death within the United States and the projected number of affected individuals is on the rise. Currently, no effective treatments have been identified, but the rise in costs and number of affected patients requires identification of easily accessible and affordable strategies to help manage symptoms. Recently, there has been growing interest in the gut-brain axis (GBA), a bidirectional communication system between the brain and the gastrointestinal system, for its potential impact on brain health. The gut microbiota, microorganisms populating the gut, plays an essential role in the host health and microbial imbalances (dysbiosis) have been correlated to several neurodegenerative disorders. We sought

to explore probiotics as a potential therapeutic treatment for Alzheimer's disease in a triple transgenic mouse model (3xTg-AD). In a preliminary study, probiotic treatment decreased cell death and normalized the number of $GFAP^+$ cells present in AD mice. Due to the abnormal behavior of control animals, we repeated the experiment with a new cohort of mice to confirm our original findings. Here, AD mice received a control diet (ADC; n=5) or a diet supplemented daily with probiotic strains *Lactobacillus curvatus* and *Lactobacillus plantarum* (ADP; n=5) and were compared to wild-type mice on control diet (B6129SF2J-1 - WTC; n=5). Behavioral analysis using the Barnes Maze indicated a decreasing trend in escape latency of ADP mice in comparison to ADC mice after 12 weeks. Upon completion of the probiotics treatment, mice were sacrificed and immunohistological analysis was performed on brain tissue. ADC mice showed an overall decrease in total number of $DAPI^+$ cells and a correlated decrease in neurons ($NeuN^+$), while increases in amyloid $beta^+$- and $GFAP^+$-cells were detected. In comparison, AD mice treated with probiotics showed higher cell counts for $DAPI^+$ and $NeuN^+$. Further assessment of the effects of probiotics on all cell populations is being conducted. Overall, our results point toward a beneficial effect of these probiotics on AD pathology progression, possibly driven by a mitigation of the previously reported dysbiosis in the current AD model.

Title: Decreasing rest intervals within a moderate exercise regimen boosts efficacy to prevent aging-related motor decline

Authors: *E. A. KASANGA[1], T. MCINNIS[1], M. F. SALVATORE[2]
[1]Inst. of Healthy Aging, Univ. of North Texas Hlth. Sci. Ctr., Fort Worth, TX; [2]Inst. for Healthy Aging, Univ. of North Texas Hlth. Sci. Ctr., Ft Worth, TX

Abstract: A physically active lifestyle can decrease the risk of aging-related impairments, including the prevention of motor decline similar to Parkinsonism. However, the extent to which a controlled exercise regimen will be beneficial, especially when started in well into the latter half of the lifespan, and the balance of exercise to rest periods needed to reduce aging-related locomotor impairment has not been fully elucidated. Furthermore, a number of exercise studies

show no change in striatal dopamine regulation despite motor improvement. A moderate intensity treadmill exercise regimen of equal exercise and rest periods, initiated at 18 months of age in Brown-Norway/Fischer 344 F1 hybrid (BNF) rats attenuates aging-related motor decline after 5 months of exercise. However, the same regimen initiated in 24 month old rats does not reverse motor decline, suggesting neurobiological changes associated with aging can limit exercise efficacy. Increasing the frequency of exercise is one variable that may be easily altered and evaluated for possible exercise benefit in older rats. A controlled longitudinal exercise study (without any negative reinforcement) was conducted with an increased frequency of exercise (15 days of exercise followed by 5 days of rest wherein we evaluated locomotor activity daily) in sedentary 18 month old BNF rats for 5 months to evaluate if an increased frequency and decreased rest period could lead to a more rapid and sustained recovery in motor function. Exercise attenuated the rate of decline in movement frequency. As compared to an identical exercise regimen, but with a longer rest period, the shorter rest period led to a faster onset and sustained effect of exercise to prevent locomotor decline. The exercise group exhibited a 25 % increase in nigral tyrosine hydroxylase (TH) with no significant effect on striatal TH. Taken together, our results indicate that exercise can be initiated in advanced middle age and reduce aging-related decreases in movement frequency, which may be related to the prevention of aging-related loss of TH in the substantia nigra. Our results suggest that moderate exercise, if practiced consistently, is an effective lifestyle strategy to prevent aging-related motor impairment.

Title: Calorie restriction prevents age-associated increase in amyloid beta in aged rhesus macaques

Authors: *G. A. STONEBARGER[1,2], H. F. URBANSKI[1,2], R. WOLTJER[3], K. VAUGHAN[4,5], E. M. TILMONT[4], J. A. MATTISON[4], P. L. SCHULTZ[6], S. M. CALDERAZZO[6], D. L. ROSENE[6], S. G. KOHAMA[1]

Abstract: Calorie Restriction (CR) has been shown to extend maximum life span and reduce the prevalence of several age-related diseases in a variety of species. However, it is unclear whether CR can delay the onset of age-related neuropathologies, such as the accumulation of amyloid beta (Aβ) plaques found in Alzheimer's Disease (AD). To address this question, we used immunohistochemistry to examine Aβ levels in the prefrontal cortex (PFC) of rhesus macaques, aged 20-41 years (old to oldest-old). Postmortem brains were collected from animals belonging to a longitudinal CR study conducted by the NIA Intramural Research Program. Both male and female control (CON; n=6) and CR (n=8) monkeys were included. CON animals were fed approximately ad libitum, whereas CR-treated animals were fed at 80% of their normal intake of a nutritionally complete diet. We tested the hypothesis that CR would prevent accumulation of plaques using an antibody specific for Aβ (4G8). Like humans, old rhesus monkeys exhibit an age-associated increase in Aβ plaques in the gray matter of the PFC, a brain area that is especially susceptible to aging effects. Aβ density was quantified by calculating the percent area of gray matter surrounding the central sulcus that was occupied by Aβ. Using regression analysis, we found an age-related increase in percent area occupied by Aβ ($F[1,11]=6.54$, $p<0.03$, $R^2=0.37$); however, this increase was found to be driven by CON ($F[1,4]=15.39$, $p<0.02$, $R^2=0.79$). Critically, there was no statistically significant increase in Aβ in the CR-treated animals ($F[1,5]=0.33$, $p>0.10$, $R^2=0.33$). This suggests that chronic CR can have a protective effect against age-related increase in Aβ in susceptible brain regions in the nonhuman primate, and in the human may be able to delay development of AD.

Title: *In vitro* effects of a polyphenol-rich blue berry extract on adult human neural progenitor cells

Authors: *T. ZHENG, D. F. BIELINSKI, D. R. FISHER, B. SHUKITT-HALE, D. A. STEINDLER
Neurosci. and Aging Lab., HNRCA, Tufts Univ., Boston, MA

Abstract: The aging process affects all cells within the central nervous system, including neural stem cells. Significant declines in neurogenesis could contribute to neuronal dysfunction in aging. Pathology of aging and age-related neurodegeneration has been linked to increases in brain oxidative stress as well as inflammation, leading to interest in the protective effects of plant polyphenols, which possess both antioxidant and anti-inflammatory properties. Berries, including blueberry and strawberry, are rich in polyphenols and have been shown to improve cognition and memory in both aged animals and humans. While our previous studies have shown that blueberry and strawberry supplementations can increase neurogenesis in aged rodents, it is not clear whether this can be extrapolated to humans. We thus investigated the effects of berry fruit treatments on the viability, proliferation, and fate choice of adult human neural progenitor cells (AHNPs) that are neurogenic astrocytes potentially involved in memory and other brain functions. AHNPs from both control and Parkinson's disease (PD) patients, isolated and characterized previously in our lab, were used here as an *in vitro* model for testing the effects of berry extract on human neural progenitor cells. AHNPs were cultured in N2 medium plus 5% fetal bovine serum, bovine pituitary extract and growth factors. Blueberry extract was prepared by homogenizing blueberries with deionized water (1:1 w/v) followed by centrifugation and freeze-drying. AHNPs were treated with blueberry extract at concentrations from 0.1 to 0.5 mg/ml for 5-7 days. The viability of cells was examined using the Trypan Blue exclusion method, and proliferation was evaluated using the ethynyl-deoxyuridine (EdU) assay. A subset of treated cells was labeled with antibodies against neuronal markers to examine the differentiation of these cells. To determine whether blueberry could protect AHNPs from induced oxidative stress by dopamine (DA) present in the media, some pre-treated cells were exposed to DA for 2 hours; their viability, proliferation, and calcium buffering were then examined. Our data show that blueberry has beneficial effects on the viability and proliferation of both human control- and PD-AHNPs. The extract was also able to reverse a decrease in viability, proliferation, and calcium buffering following stress induced by DA. Polyphenol-rich berry extracts thus confer a neuroprotective effect on control and Parkinson's AHNPs, suggesting a role for dietary nutrients in helping to prevent and slow progression of neurodegenerative diseases.

Title: The effects of intermittent wild blueberry feeding on inflammation and motor and cognitive behavior

Authors: D. R. FISHER, D. S. CAHOON, M. G. MILLER, D. F. BIELINSKI, *B. SHUKITT-HALE
USDA, ARS, USDA-ARS Human Nutr. Res. Ctr. on Aging, Boston, MA

Abstract: Neuroinflammation has been identified as a major contributing factor in the behavioral declines seen in aging and neurodegenerative diseases. Previous studies from our laboratory have shown that continuous daily consumption of blueberry (BB) improved age-related declines in motor and cognitive function in old animals and animal models of accelerated aging and neuroinflammation. However, the optimal intake of BBs is currently unknown, and most people do not consume them every day. It is possible that intermittent consumption of BBs could: 1) have increased beneficial effects relative to continuous consumption, due to the repeated stimulation of cellular repair mechanisms; 2) have a reduced beneficial effect, as the total dose is lower; or 3) have the same effect as continuous consumption, if metabolites are retained in tissue. To evaluate the beneficial effects of blueberries on motor and cognitive function relative to the frequency of blueberry consumption, the diets of aged F344 rats (18 mo; n = 15/group) were supplemented with either a continuous control diet (modified NIH-31 diet), a continuous 2% wild blueberry diet, or an intermittent 2% wild blueberry diet for 2 months prior to behavioral testing. Rats in the intermittent 2% blueberry diet group consumed the 2% blueberry diet for 3 days, followed by a 4-day control diet (washout period) each week for the duration of the study. Serum samples were collected pre-diet and at the end of the study to assess inflammation. Results showed that continuous BB-fed rats performed better on the motor tasks and committed less errors in the radial arm water maze compared to control-fed animals. The intermittent-fed BB group had some positive effects, but did not perform as well as the continuous-fed BB group. A subsequent in vitro study using the serum showed that BB supplementation could enhance anti-inflammation capability, and frequency of intake determined level of protection. Based on these findings, daily consumption of BB may improve age-related deficits in motor function, cognition, and inflammation, and the frequency of eating BBs can have an effect on these measures.

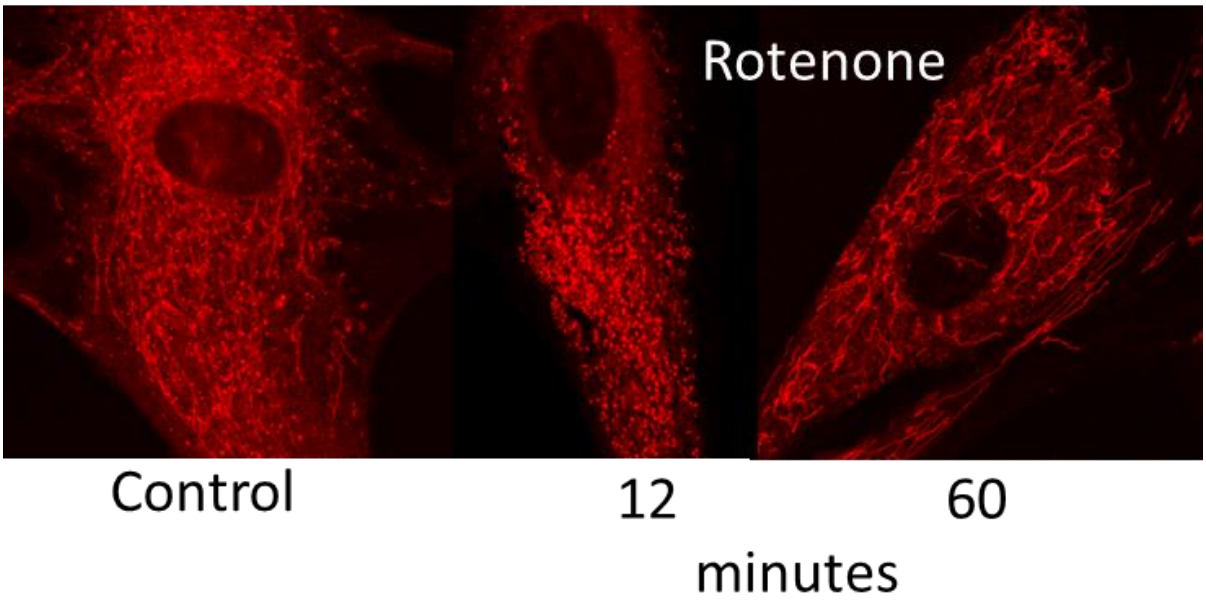
Title: Influence of dopamine compounds on mitochondria motility

Authors: *M. P. VAWTER[1], L. MORGAN, 92697[2], A. TRINH[3]
[1]Dept Psychiatry & HB, UC Irvine Schl Med., Irvine, CA; [2]Psychiatry, [3]Biomed. Engin., Univ. of California, Irvine, CA

Abstract: The hypothesis that some psychiatric medications impair mitochondria functions has received support from our investigation of the dorsolateral prefrontal cortex and decreased Complex I activity in medicated subjects. To further this investigation, we are undertaking live imaging of mitochondria in human fibroblast cell lines. **Method:** The method involves plating fibroblast cells in 8 well imaging slide in varying densities. Acute treatments involve dopaminergic compounds, mitochondrial inhibitors, and alteration of calcium levels. Treated cells are stained with MitoTracker for 30 minutes, washed, and imaged after approximately 30 min. Imaging parameters are a collection of 100- 300 frames and using correlation analysis to track the amount of movement of thresholded mitochondrial images.
Results: Experiments are ongoing at this time, and we have shown that rotenone acutely decreases mitochondrial motility compared to control cells ($p = 0.049$; $N=8$ control cells and $n = 7$ rotenone-treated cells). Notably, rotenone altered the shape of mitochondria and is being studied to determine whether this alteration is reversible or can be blocked.



Conclusion: The preliminary results show possible modification of mitochondria biogenesis pathway by rotenone involving both the fission and fusion components.The information from this study will be able to identify whether dopaminergic compounds that we are studying inhibit mitochondrial motility and parameters of mitochondria biogenesis. This will be important for understanding the alterations of mitochondria in disorders that are treated with dopaminergic compounds. The ultimate goal is to further study induced dopamine cell lines and to monitor mitochondrial motility and biogenesis.

Title: Mitochondrial permeability transition pore-mediated mitochondrial stress is essential in age-related cognitive decline

Authors: *E. D. NOLTE, Q. YU, F. DU, F. AKHTER, S. S. YAN
Dept. of Pharmacol. and Toxicology, Univ. of Kansas, Lawrence, KS

Abstract: As the average population age continues to rise, many diseases with aging as a primary risk factor have been identified, including Alzheimer's disease (AD), stroke, and cardiovascular disease. Understanding the behavioral changes of wild type mice with aging will help to inform translational models of aging and disease. Additionally, aging animal models can serve as a model for molecular changes that may explain non-clinically significant cognitive declines seen with aging.
As mice age from 3 to 24 months (n=19-24), clear, sex-based patterns develop. Female mice show significant increases in anxiety in an open field paradigm, while both sexes maintain general locomotion patterns. Locomotion patterns are not sex or age dependent, appearing consistent across both conditions. Both male and female mice show reduced ability in daily-task performance in a nest building behavioral test. Failure to perform daily tasks adequately is an early behavioral marker of cognitive decline often associated with dementia, and is a sensitive marker of cognitive decline.
Cyclophilin D (CypD) is a mitochondrial matrix protein that functions as the activator of the mitochondrial permeability transition pore (mPTP). Opening of the mPTP triggers mitochondrial failure and apoptosis, a common cause of neuronal death. In patients with AD, CypD is upregulated by 3 fold compared to healthy, age matched controls; this is also seen in animal models of Alzheimer's disease. Additionally, healthy persons experience a significant upregulation of CypD during the aging process, making it an attractive target for research in the aging phenotype. Overexpression of CypD leads to earlier onset of age related declines in mice and a more aggressive phenotype in AD mice. Blockage of CypD by genetic deletion or pharmacological inhibitor improves both mitochondrial dynamics and synaptic structure and function, leading to protection from age related cognitive declines. Thus, CypD is a key mitochondrial target for age- and AD-induced mitochondrial degeneration. Targeting mitochondrial mPTP through CypD may be a new therapeutic approach for halting age related dementia and cognitive dysfunction by powering mitochondrial function.
This research is supported by the NIH.

Title: Phytohaemagglutinin (PHA)-induced oxidative stress in SH-SY5Y cells: A possible model to studyAβ toxicity and its modulation by pharmacological intervention

Authors: *K. RAFI[1], S. HUSSAIN[2], S. U. SIMJEE[1,2]
[1]Dr Panjwani Ctr. for Mol. Med. and Drug Res., Intl. Ctr. for Chem. and Biol. S, Karachi, Pakistan; [2]H.E.J. Res. Inst. of Chem., Intl. Ctr. for Chem. and Biol. Sci., Karachi, Pakistan

Abstract: Alzheimer's disease (AD) is one of the leading causes of dementia worldwide. The neuropathological features associated with the disease are extracellular insoluble Aβ plaques and intracellular neurofibrillary tangles. Neuroinflammation and oxidative stress are involved in the onset and progression of AD. The production of inflammatory mediators, ROS and RNS causes synaptic dysfunction that is responsible for memory decline in AD. Therefore, the therapeutic options based on anti-inflammatory and anti-oxidant therapy are of important concern in targeting AD. The aim of this study was to develop a suitable *in vitro* model of Aβ deposition and to determine the role of novel neuroprotective agents for their therapeutic role thus targeting the disease at early stage or delay its onset.

Our preliminary studies were conducted to observe plaques formation using the cells stimulant PHA that releases cytokines upon stimulation. SH-SY5Y cells were incubated with PHA at the concentrations 5-40 µg/ml for 24 hours. After incubation, cells were observed using phase contrast microscopy. Oxidative stress was analyzed using 2',7'-dichlorodihydrofluorescein diacetate at concentrations of PHA 5-40 µg/ml by fluorimetric method. Immunocytochemistry was conducted to confirm the presence of Aβ plaques after stimulation with PHA. RT-qPCR was used to analyze the expression of α and β-secretase genes involved in the formation of plaques. Morphological analysis of PHA stimulated cells showed that 5 µg/ml of PHA did not cause any prominent changes in cellular morphology, while 10, 20 and 40 µg/ml concentrations caused visible aggregation when compared with unstimulated cells. Oxidative stress analysis of PHA stimulated cells demonstrated increased ROS levels upon stimulation with significant increased at 10 µg/ml of PHA. Later immunocytochemistry analysis at 10 µg/ml PHA concentration showed that expression of Aβ was increased significantly in stimulated cells. Quantitative gene expression analysis showed that expression of β-secretase gene was increased in PHA-treated cells.

Based on these observations, we suggest that PHA has a role in generating oxidative stress. Further we have screened different compounds for their neuroprotective effect to use for the treatment of PHA induced AD symptoms and neurodegeneration. In preliminary studies quinic acid and N-(2-hydroxyphenyl) acetamide were found to increase cell viability as compared to control cells. Next, we will use these compounds to check whether they are effective in reducing PHA induced Aβ generation and also, we will determine the molecular mechanism of action involved in the functioning of these compounds.

Title: As an FDA-approved drug, the small molecule suppresses LPS-induced neruoinflammatory responses in BV2 microglial cells and wild-type mice

Authors: *H.-S. HOE[1], H. NAM[2], J. NAM[4], J.-Y. LEE[3]
[1]X, X, Korea, Republic of; [2]Korea Brain Reserach Inst., Daegu, Korea, Republic of; [3]Korea Brain Reserach Inst., Deagu, Korea, Republic of; [4]Korea Brain Res. Inst., Deagu, Korea, Republic of

Abstract: Background: As an FDA-approved drug, the small molecule B8 is an effective targeted therapy for patients with chronic lymphocytic leukemia (CLL). It inhibits Bruton's tyrosine kinase (BTK), a kinase involved in B cell receptor signaling. However, researchers have not comprehensively examined whether small molecule B8 regulates neuroinflammatory responses in the brain. **Methods:** BV2 microglial cells were treated with B8 (1 μM) or vehicle (1% DMSO), followed by lipopolysaccharide (LPS; 1 μg/ml) or PBS, and then we performed RT-PCR, immunocytochemistry, and subcellular fractionation to examine the effects of B8 on the neuroinflammatory response. In addition, wild-type mice were sequentially injected with B8 (10 mg/kg, i.p.) or vehicle (10% DMSO, i.p.), followed by LPS (10 mg/kg, i.p.) or PBS, and then we measured microglial and astrocyte activation using immunohistochemistry. **Results:** B8 significantly reduced LPS-induced increases in pro-inflammatory cytokine levels in BV2 microglial and primary microglial cells but not in primary astrocytes. B8 further suppressed LPS-mediated increases in pro-inflammatory cytokine levels when co-administered with a Toll-like receptor 4 (TLR4) inhibitor. B8 significantly decreased LPS-induced increases in p-AKT and p-STAT3 levels, suggesting that it attenuated LPS-induced neuroinflammatory responses by inhibiting AKT/STAT3 signaling pathways. In addition, B8 reduced LPS-mediated BV2 microglial cell migration. Moreover, B8-injected wild-type mice exhibited significantly reduced microglial and astrocyte activation. **Conclusions:** Our data illuminate the mechanisms of a potential therapeutic strategy for neuroinflammation-related diseases.

Title: The *in vitro* effect of different coffees and extraction of coffee in Alzheimer's disease-associated cell line

Authors: *H. YANG[1,2], C. CAO[4,1], P. PHAM[3], U. KHAN[3], Y. HONG[1], X. LIN[1], N. SHEN[2,1]
[1]USF Hlth. Byrd Alzheimer's Inst., Tampa, FL; [2]Chem., [3]Univ. of South Florida, Tampa, FL; [4]Pharmaceut. Sci., Col. of Pharm. Univ. of South Florida, Tampa, FL

Abstract: Coffee is one of the most popular drinks in the world and naturally contains a variety of compounds including caffeine, antioxidants and diterpenes. Epidemiological data and recent scientific publications provide support for the neuroprotective effects of coffee against Alzheimer’s disease (AD). Our previous studies have shown that moderate caffeine administration protects/restores cognitive function and suppresses brain amyloid-β (Aβ) production in AD transgenic mice. We also proved that the function of coffee is different from caffeine and decaf coffee lost some of the beneficial functions compared with regular coffee. The aim of this study is to dig into the machoism that leads the difference between coffee and caffeine. In the present study, we compared the effect of different types of coffee on AD associated cell lines and gavage in mouse model. As result, we found that different brands of coffee showed differences after treatment. Even the effect of different types, such as instant, commercial or decaf coffee, of same brand coffee are varied. Furthermore, these differences showed no correlation with the concentration of caffeine in coffee. The result of Caffeine single treatment indicated that caffeine had stronger cell toxicity than coffee and the up-regulation function with Aβ level. Adding caffeine back into decaf coffee cannot restore the beneficial functions of regular coffee. We also found a mixture of several water-soluble compounds (WPI) which are extracted from coffee has antagonism with the toxicity of coffee and caffeine in AD-associated cell line. In conclusion, the toxicity of coffee is not related with the caffeine level but associated with the processing technology of coffee. The mechanism of coffee and the extraction of coffee still need to be explored.

Abstract: Alzheimer disease (AD) incidence is expected to more than double by the year 2050. Considering that less than 10% of AD cases are the result of genetic factors, external elements must be involved in this increase. Animal studies relying on humanized genetic mutations have been useful for studying the pathology of AD, but non-genetic models are now needed to elucidate the factors that contribute to the etiology of the far more prevalent late-onset sporadic form of the disease. These potential factors - diabetes, chronic stress, sleep deprivation and inflammation - are quickly becoming the norm in our society rather than the exception. Disturbingly, each of these conditions have been shown to contribute to mild neurodegeneration in isolation. Could these rising conditions be responsible for the growing AD epidemic, and what effects might they have when present in combination? By combining low-dose intraperitoneal injections (0.1 mg/kg delivered once per month for 3 months) of the endotoxin lipopolysaccharide (LPS) with the addition of 20% sucrose (hS) to animal drinking water (for 6 months), we explore the individual and cumulative effects of chronic inflammation and excess carbohydrate-based caloric intake on wild-type female mice. Given the fact that hS consumption can induce a brain insulin resistant state increasing GSK3β activity and that lithium is a potent GSK3β inhibitor, additional groups of mice received 0.001% lithium (by concentration) in their drinking water to assess the prophylactic potential of trace lithium in the management of diet- and inflammatory-induced conditions. Open field, forced swim and Barnes maze testing suggest an effect of high-sucrose on learning, memory and anxiety/despair. Interestingly, combined LPS and high-sucrose treatment increased anxiety-like behaviour relative to high-sucrose or LPS treatment alone. Sustained supplementation with trace lithium abolished the observed effect on the hS+LPS-mediated increase in anxiety-like behavior without effect on hS-mediated changes in immobility or learning and memory. Increased despair, increased anxiety-like behaviour, and impaired memory are behavioral patterns consistent with both brain insulin resistance and neuroinflammation. In addition to behavior, hippocampal neurogenesis, and various

neurochemical markers were also assessed to help further characterize this environmental animal model of neurodegeneration.

Title: Levels of cerebrospinal fluid amyloid-β 40 and 42 are decreased in amyloid PET-negative idiopathic normal pressure hydrocephalus patients

Authors: *Y. KIM[1], J. CHANG[1,2]
[1]Dept. of Biomed. Sci., Ajou Univ. Grad. Sch. of Med., Suwon, Korea, Republic of; [2]Dept. of Brain Sci., Ajou Univ. Sch. of Med., Suwon, Korea, Republic of

Abstract: The comorbidity of Alzheimer's disease (AD) with idiopathic normal pressure hydrocephalus (iNPH) is known to be associated with shunt unresponsiveness and is usually suspected by a decrease in the levels of β-amyloid (Aβ) 1-42 (Aβ42) in the cerebrospinal fluid (CSF). In the recent studies, it has been reported that the well-established CSF AD biomarkers could be misled in iNPH. In this study, we investigated levels of CSF AD biomarkers in amyloid PET (+) AD, amyloid PET (-) iNPH, and cognitively normal (CN) subjects. Ten patients diagnosed with probable AD, 10 probable iNPH, and 8 CN subjects were included in the experimental groups. To detect amyloid deposition, we performed 18F-florbetaben amyloid positron emission tomography (PET) and calculated the mean cortical standardized uptake value ratio (SUVR). We then analyzed the levels of Aβ40, Aβ42, total tau (t-tau), and phosphorylated tau (p-tau) protein in the CSF by using enzyme-linked immunosorbent assay. Amyloid PET gave positive (+) results for the ten AD subjects but negative (-) for the ten iNPH subjects. The mean cortical SUVR was significantly higher in AD than iNPH subjects (AD, 1.97 ± 0.25; iNPH, 1.37 ± 0.16; $p < 0.001$). Levels of CSF Aβ40 and Aβ42 were significantly decreased in iNPH subjects compared to CN subjects. The level of Aβ42 was significantly decreased in the AD group compared to iNPH and CN groups while there was no significant difference in the level of Aβ40 between AD and iNPH groups. Total tau and p-tau levels were significantly increased in the patients with AD compared to iNPH and CN. There was no statistical difference in the levels of total tau and p-tau between iNPH and CN groups. Our results suggest that the mechanism underlying the observed low CSF Aβ42 levels is different between amyloid PET (-) iNPH and

amyloid PET (+) AD subjects. Moreover, the proportionate decrease observed in both Aβ42 and Aβ40 levels in iNPH patients might be the result of defective amyloid metabolism and/or reduction in the clearance of amyloid species, due to glymphatic dysfunction. Future longitudinal studies should shed more light into these hypotheses.

Title: Intensive interval training as promising approach to imporve cognitive function in mild cognitive impaired older persons

Authors: *S. RUEDIGER[1], T. STUCKENSCHNEIDER[1,2], S. SCHNEIDER[1,2]
[1]Inst. of Movement and Neurosciences, German Sport Univ., Cologne, Germany; [2]Fac. for Science, Health, Educ. and Engin., Univ. of the Sunshine Coast, Maroochydore, Australia

Abstract: Background: Considering the rising prevalence of neurodegenerative diseases recent research focuses on early intervention strategies. Particularly Mild cognitive impairment (MCI), defined as prodromal stage of dementia, is of special interest. Continuous physical activity over a time period of 6 months is recommended by recent guidelines for the treatment of MCI to prevent further cognitive decline. However, which kind of physical activity is most effective to delay cognitive decline in older adults needs to be defined. First studies indicate that intensive interval training might be more beneficial than moderate aerobic exercise training to improve some cognitive functions in older adults. The aim of this study was to investigate the effect of intensive interval endurance training on the progression of cognitive performance of older adults with diagnosed MCI over a time period of 6 months. It was hypothesized that an intensive exercise load might reveal positive effects on cognition in a shorter training period than the currently proposed 6 month.
Method: 23 persons with diagnosed MCI (74.6± 6.9 years; MOCA: 22.8± 2) exercised 2-3 times/week on a cycle ergometer for a period of 35 min with 4x4 min of intensive load (80- 90% of their max. heart rate). Cognitive function was determined by using the Montreal Cognitive Assessment Battery (MOCA) and the Trail Making Test A and B (TMT A, B).
Results: A first data analysis after 12 weeks of training showed significant improvements of the MOCA total score (p= .008) and the MOCA memory index score (p= .0001) as well as in the

TMT A (p= .042) and B (p= .000) performance time.
Discussion: Regarding those results it seems that short but intensive exercise loads might be a valuable tool to improve cognitive function and influenced the ageing brain in a positively. These results are supported by data from animal models revealing a positive effect of short intensive interval training on neurogenesis in the ageing mouse brain.

Title: Nutritional strategies against synaptic and metabolic alterations in obese rats

Authors: *T. SYEDA[1], L. PÉREZ-JIMÉNEZ[1], M. SÁNCHEZ-TAPIA[2], N. TORRES-TORRES[2], C. PEREZ-CRUZ[1]
[1]Dept. of Pharmacol., Ctr. de Investigación y de Estudios Avanzados, Mexico City, Mexico; [2]2Instituto Nacional de Ciencias Médicas y de la Nutricion, Mexico City, Mexico

Abstract: Background: Mild-life obesity has been associated with alterations in expression of genes associated with cell metabolism, with a decreased metabolic expenditure and learning and memory deficits. Healthy life style and adherence to Mediterranean diet seems to reduce incidence of obesity and improve cognition. Bioactive components of our daily diet can modulate cellular metabolism and brain function. However, the mechanism of action of bioactive food (BF) remains unclear.**Objective:** To elucidate the mechanism by which bioactive food can improve synaptic and metabolic function in diet induced obesity. **Method:** BF diet contained dried nopal (5%), chia seed oil (9%), soy protein (19.4%), and turmeric (0.1%). High fat diet+5% sucrose was used for inducing obesity. AIN-93 was used as control diet. Two months old wistar rats were used for this study. Rats were randomly divided into 2 groups: 1) Rats fed control diet (AIN-93 group), and 2) Rats fed High fat+5% sucrose (HF group) for 4 months. After 4 months the HF group was divided into two group one group continued with the same diet, the other group were fed bioactive food along with High fat+5% sucrose for 3months (HF+BFgroup). Cognitive performance was assessed at the end of study by T-maze and novel object recognition test. We quantified spines ,inflammation markers and metabolic protein in the cortex. Short-chain-fatty acids (SCFAs) were analyzed by Gas chromatography.**Results:** There was a significant decrease in cognition in HF group, addition of BF improved cognition in HF-BF group. There was decrease in number of spines, increase in number of astrocytes and

microglia, increase in Tlr 4 receptor expression in HF group. There was decrease in short chain fatty acid, Butyrate in this group. Addition of bioactive food restored this parameters.
Conclusion: Our results shows that obesity caused cognitive alterations and decreased the number of spines, accompanied by a increase in inflammation and decreased Butyrate. The food combination used in the present study was able to improve cognitive performance and decrease inflammation. Several components of the BF diet have prebiotic properties and it been postulated that gut microbiota metabolites can modulate brain function (brain-gut axis). Interestingly, we observed that BF altered levels of Butyrate. Hence, a nutritional portfolio can be proposed as a therapeutic strategy against brain alterations induced by obesity.

Title: The VBrain system: Innovative training for cognitive diseases based on 3D and virtual reality

Authors: *O. ARANCIO[1], C. LUCIOTTO[2], S. M. PAPPALARDO[3], D. BARATTA[4], D. PUZZO[5]
[1]Dept of Pathol, Columbia Univ., NEW YORK, NY; [2]Action 4 Care Srls, Bracciano, Italy; [3]Software Engin. Italia Srl, Messina, Italy; [4]Software Engin. Italia Srl, Catania, Italy; [5]Dept Biomed. and Biotechnological Sci. Section Of Physiol., Univ. of Catania, Catania, Italy

Abstract: The VBrain system is an innovative solution for cognitive training based on 3D Virtual Reality (VR). Born as a fully immersive 3D Virtual Reality computerised system (based on a CAVE Virtual Environment), VBrain soon integrated a huge set of cross-visualization features. Nowadays VBrain can also operate on Tablet PCs, Personal Computers, Touch TVs, Touch Tables, Head Mounted Displays (Oculus VR, etc).
VBrain developed a complex device, inseparably interconnecting Reality and Virtuality through a simulation game, to facilitate the understanding of the territory-map link in people suffering for cognitive diseases and help them to learn what the digital interaction is and how it happens. The game will motivate young and elders to use VBrain, make learning easier and be a focusal experience in the process leading persons to understand the world. Reality and Virtuality will be integrated to build innovative settings for cognitive rehabilitation. Patients suffering for mental retardation will understand how to take part to cognitive rehabilitation and development of new cognitive resources activities.

VBrain is highly innovative thanks to dynamic evolution of software models for monitoring in tele-medicine and to the cognitive rehabilitation through VR. In fully immersive VR, the user manipulates virtual objects and feels haptic sensations thanks to instrumented gloves. That allows to evaluate functions in 3D space, visuo-spatial deficits in perception, attention and memory as well as the fine control of manipulation gestures in 3D and understanding of verbal instructions.
The VBrain system was designed and developed by a highly translational team where neuro-scientists worked together with engineers. It is tele-supervised by health professionals located in remote health structures (hospitals, research centres, etc.) for quantitative and qualitative evaluation and rehabilitation of motor-cognitive functions in patients suffering for Mental Retardation, Language and Communication Diseases, Alzheimer's and Parkinson's Diseases. The VBrain System, by its enormous potential, can totally change the current approach to cognitive diagnosis and rehabilitation.

Cologne, Köln, Germany

Abstract: Background: Dementia will affect over 150 million older adults by 2050 (Prince, 2016). To prevent cognitive decline, the current focus has shifted to mild cognitive impairment

(MCI), which presents a prodromal stage of dementia (Petersen et al., 2017). The American Academy of Neurology (AAN) updated their guidelines for the treatment of MCI recently and stated that 6 months of exercise training is likely to improve cognitive measures shown by improvements in neuropsychological tests and changes in MRI scans (Petersen et al., 2017). Besides these methods, the electroencephalography (EEG), especially the P300 and N200 components of auditory event-related potentials (AERPs), have shown promise as a diagnostic tool for cognitive impairment (Morrison, Rabipour, Knoefel, Shepard, & Taler, 2018). However, the effect of exercise on AERPs in individuals with MCI is not known. It was hypothesized that exercise leads to an increased amplitude and a shortened latency. Method: 43 participants with MCI (72.5±5.3 years) were recruited from the NeuroExercise project (Devenney et al., 2017). They were either included in the exercise interventions (nonaerobic (n = 11) or aerobic exercise (n = 17)) or a standard care control group (n = 15). AERPs were recorded before and after 6 months and latencies and amplitude of N200 and P300 were determined at scalp sites Fz, Cz and Pz. Results: The control group tended to have a prolonged latency and a decreased amplitude after 6 months, whereas the intervention group showed an opposite trend. This development was particularly present in the CZ amplitude (P300: $p = 0.072$; N200: $p = 0.095$), but overall no significant differences were found. Discussion: The lack of significance might be due to differences in the exercise interventions, which might lead to different adaptations in the brain (Niemann, Godde, Staudinger, & Voelcker-Rehage, 2014). However, the described tendencies are supporting the findings of the AAN that exercise might improve cognitive function. As the EEG presents a cost effective, non-invasive method to assess cognitive function validly, future research should include this method in trials with bigger samples and a longer intervention period.

Abstract: It has been recently uncovered a direct link between mutations in the GBA1 gene (the one coding for beta-glucocerebrosidase) and the development of synucleinopathies such as Parkinson's disease (PD) and dementia with Lewy bodies (DLB). Although the exact mechanisms through which glucocerebrosidase (GCase) regulates the homeostasis of alpha-synuclein still is not fully understood, the identification of reduced GCase activity as a common feature promoting the neuropathological findings underlying PD and DLB led to the development of novel strategies intended to increase GCase activity to further reduce alpha-synuclein aggregation and preventing neuronal death. Here we took advantage of neurospecific recombinant adeno-associated vectors coding for the mutated form of human alpha-synuclein (rAAV9-SynA53T) to further induce a bilateral progressive dopaminergic neuronal death together with the underlying pro-inflammatory microglial reaction in the substantia nigra pars compacta (SNc) in mice. Next, another rAAV coding for the GBA1 gene under the control of the constitutive promoter GUSB (rAAV9-GBA1) was delivered unilaterally in the left SNc. Animals have been sacrificed 3 weeks post-rAAV9-GBA1 delivery (e.g., 6 weeks after rAAV9-SynA53T injections). Obtained results showed that rAAV-mediated enhancement of GCase activity induced an almost complete clearance of aggregated alpha-synuclein, both in dopaminergic cells within the SNc as well as in nigrostriatal terminals. Unbiased stereological estimation of tyrosine hydroxylase-positive neurons revealed up to 70% of neuronal death 6 weeks after rAAV9-SynA53T delivery, in contrast with 17% of neuronal death observed in the SNc treated with rAAV9-SynA53T + rAAV9-GBA1. Furthermore, microglial reaction was tuned down and indeed microglial cells returned back to normal phenotype upon treatment with rAAV9-GBA1. Data reported here sustain the potential use of glucocerebrosidase gene therapy as a disease-modifying treatment for PD and related synucleinopathies.

Title: Variation in dopamine modulation by P2X4 receptor modulators, ivermectin (IVM) and moxidectin (MOX)

Authors: *A. M. WARNECKE[1], M. S. KANG[1], M. W. JAKOWEC[2], D. L. DAVIES[1]
[1]Titus Family Dept of Clin. Pharm., [2]Neurol., USC, Los Angeles, CA

Abstract: Dopamine is a key neurotransmitter within the brain that plays a role in the mesolimbic pathway (associated with reward based behavior), and the nigrostriatal pathway (associated with motor control and reward based cognition). The ability to modify dopaminergic activities within these pathways provides a potential target for the treatment of dopaminergic disorders including Parkinson's disease and addiction. We previously found that IVM and MOX significantly reduced alcohol consumption in P2X4 knock-out (P2X4KO) mice and littermate controls. Notably, the degree of alcohol reduction was significantly less in P2X4KO mice, suggesting a role of P2X4Rs in IVM and MOX modulation. In addition, we found that IVM significantly enhanced the effect of levodopa (L-Dopa) on the motor system in both P2X4KO and littermate controls. Similarly, L-Dopa enhancement was significantly less in P2X4KO mice, suggesting another role for P2X4Rs. The current study tested the hypothesis that MOX would significantly increase L-Dopa rotations, a surrogate behavior marker of dopamine neurotransmission.
In the current study, we measured MOX enhancement of L-Dopa on motor activity in male and female C57BL6J mice. We unilaterally lesioned mice in the medial forebrain bundle with 6-hydroxydopamine. As positive controls, we administered amphetamine (2.5mg/kg) to the mice and measured the degree of ipsilateral rotational behavior followed by treatment with L-Dopa (5mg/kg, S.C) to measure contralateral rotation behavior. Mice were next allowed a 3 day washout (minimum) period followed by treatment with MOX (2.5mg/kg, I.P.) which was next followed by administration of L-Dopa injection (5mg/kg S.C.; 4 hours after MOX) and measured rotational behavior. After MOX washout (3 day minimum post-test), IVM (5mg/kg, I.P.) was administered 8 hours prior to L-Dopa injection (5mg/kg S.C.) as a positive control and mice were again observed for changes in rotational behavior. Unexpectedly, we found minimal changes in L-Dopa induced rotations when treated with MOX. On the other hand, IVM significantly increased L-Dopa induced rotational behavior in the same group of mice. Of note, there were gender specific differences in rotational behavior when mice were given IVM with L-Dopa; with female mice showing a significantly greater number of total rotations. Collectively, these findings suggest IVM superiority compared to MOX for L-Dopa adjunct therapy for Parkinson's disease. In addition, this work suggest differences in drug sensitivity that is sex specific in that females had an enhanced response to dopamine replacement therapy.

Title: Immunohistochemical analysis of cellular transfection in the brains of rats given intranasal GDNF pDNA nanoparticles with focused ultrasound (FUS)

Authors: *B. L. WASZCZAK[1], A. E.-E. ALY[1], Z. LI[1], T. SUN[2], Y. ZHANG[2], O. SESENOGLU-LAIRD[3], L. PADEJIMAS[3], M. J. COOPER[3], N. J. MCDANNOLD[2]
[1]Dept Pharmaceut Sci., Northeastern Univ., Boston, MA; [2]Radiology, Brigham & Womens' Hosp., Boston, MA; [3]Copernicus Therapeutics, Inc., Cleveland, OH

Abstract: The potential of glial cell line-derived neurotrophic factor (GDNF) for Parkinson's disease (PD) is limited by its inability to cross the blood brain barrier (BBB), necessitating surgical delivery. We have shown that intranasal administration of PEGylated lysine 30-mer (CK30PEG10K) plasmid DNA nanoparticles (NPs) encoding hGDNF offers a non-invasive, non-immunogenic approach that bypasses the BBB and generates a long-lasting source of GDNF expression within the brain sufficient to provide neuroprotection in the rat 6-hydroxydopamine model of PD. We also showed with double-label immunohistochemistry (DL-IHC) that transgene expression in the rat brain is widespread, but the transfected cells were not neurons or astrocytes. They were consistently perivascular, located abluminal to the vascular endothelium, and resembled pericytes morphologically. In an attempt to enrich transgene expression in target regions for PD and improve tissue penetration, we next combined intranasal delivery of our DNA NPs with focused ultrasound (FUS). FUS with circulating microbubbles has been proposed as a way to enhance localized drug delivery to brain by temporarily widening tight junctions between cells. FUS did enrich transgene expression in the sonicated regions, but DL-IHC showed that it caused recruitment of cells to the sonication site that were neither astrocytes nor neurons, and not perivascular in location. We speculated that the transfected cells might be microglia. To test this hypothesis, we assayed brain tissue from rats given intranasal NPs encoding a reporter plasmid, which produces an eGFP-GDNF fusion protein, and used DL-IHC to assess whether GFP-positive cells co-expressed Iba1, a marker for microglia. FUS with microbubbles was applied to the right forebrain and midbrain just before and after intranasal administration, and rats were sacrificed one week later. Transfected (GFP-positive) cells were again found throughout the brain, commonly adjacent to microvessels in areas distant from apparent sonication sites. They were occasionally but not always Iba1-positive. However, at sonication sites, indicated by discrete clumps or clusters of transfected cells extending deep into

the parenchyma, essentially all GFP-positive cells were also Iba1-positive, identifying them as transfected microglia. Thus, we conclude that FUS with circulating microbubbles increases transfection of cells at sonication sites and improves tissue penetration, and the transfected cells are predominantly microglia. The implications of using FUS to promote microglial expression of a neurotrophic factor at disease target sites remain to be determined.

Title: Delayed treatment of capsaicin enhances functional recovery of dopamine neurons in MPP^+ model of Parkinson's disease

Authors: *K. Y. KYOUNG IN
Kyunghee Univ., Seoul, Korea, Republic of

Abstract: We recently demonstrate capsaicin (CAP) neuroprotection of dopamine neurons by astrocytic transient receptor potential vanilloid 1 (TRPV1) derived ciliary neurotrophic factor (CNTF) in MPP^+ rat model of Parkinson’s disease (PD). However, the neurorestoration of delayed CAP treatment several weeks after toxins remains elusive. To test this, we utilized MPP^+ model that the loss of nigrostriatal DA neurons was complete at 2 weeks post MPP^+ and that showed prolonged expression of astrocytic TRPV1 up to 10 weeks post MPP^+. Here, we report that astrocytic TRPV1 activation by CAP 9 weeks post MPP^+ improves amphetamine-induced rotation. In parallel, CAP increases level of CNTF and TH enzyme activity via CNTFR-a in substantia nigra (SN) and striatal dopamine level in MPP+ rat model. TH immunohistochemical analysis revealed that increase in biochemical indices was not accompanied by neurorestoration. Instead, delayed CAP treatment transiently improved dopamine function and behavioral recovery when astrocytic TRPV1-derived CNTF expression is switched on.

Abstract: Heat shock proteins (Hsps) constitute a network of chaperone molecules that mitigate the detrimental sequelae of proteotoxic stress by refolding misfolded proteins or enabling their clearance. Our prior work revealed that inhibitors of the stress-inducible heat shock protein 70 (Hsp70) exacerbate proteotoxic cell death in postnatal primary neurons from the sensorimotor neocortex, entorhinal allocortex, hippocampal allocortex, and olfactory bulb. Here we tested the hypothesis that exogenous delivery of recombinant Hsp70 might mitigate the proteinopathy of Lewy body disorders *in vivo*. We recently showed that infusions of preformed α-synuclein fibrils into the mouse olfactory bulb lead to the emergence of dense Lewy-like pathology in the limbic temporal lobe. In that model, intense Hsp70 immunoreactivity was present in some α-synuclein^{+} inclusions, suggesting that Hsp70 may be trapped within the aggregates and unable to perform some of its chaperone functions. These findings supported the view that providing additional, exogenous Hsp70 might be beneficial. Hsp70 has lipophilic properties and can enter the brain when administered intranasally. Following intranasal delivery, Hsp70 has been shown to improve cognition, reduce neurodegeneration, and extend lifespan in mouse models of aging and dementia, and to improve insulin sensitivity in mouse models of diabetes. However, intranasal delivery of Hsp70 has not been tested in models of Lewy body disorders to our knowledge. In a small pilot study, we infused yeast Hsp70 into the left nares every day for 28 days in aged male mice (20 months) following infusions of preformed α-synuclein fibrils in the left olfactory bulb. Two blinded investigators independently observed that daily intranasal Hsp70 delivery significantly mitigated 1) fibril-induced smell loss, measured as the latency to contact buried

food, and 2) fibril-induced α-synucleinopathy, visualized by immunostaining for pathologically phosphorylated α-synuclein (pSer129). Furthermore, we confirmed that Hsp70 entered the mouse brain from the nares within three hours post-infusion, as demonstrated by immunoblotting on tissue lysates from the olfactory bulb and the caudal recesses of the temporal lobe. Finally, inhibition of Hsp70 activity *in vitro* with the small molecule inhibitors MAL3-101 and/or VER155008 dramatically increased the number of $pSer129^{+}$ inclusions in primary neurons harvested from the rat sensorimotor neocortex, entorhinal allocortex, and hippocampus, suggesting a generalizable effect. These collective findings support further testing of the ability of intranasal Hsp70 to impede the propagation of Lewy pathology.

Abstract: Copper (Cu) is an important micronutrient in living beings due to its participation as an allosteric component or co-factor for various essential enzymes in several physiological processes. Cu homeostasis is strictly regulated by a large variety of proteins. Deficit or accumulation of this metal can trigger various diseases and even compromise the development of living beings. It has been suggested that neurodegenerative diseases such as Parkinson's are related to Cu concentrations in brain tissue. This study is aimed to determine the temporal course of an acute administration of Cu and its absorption in healthy rats. Oral administration of 79.5 mg/kg of Cu (as gluconate) was carried out in fed male Wistar rats weighing 250-290g (n=4).

Blood and liver, striatal and mesencephalic tissues samples, were collected at 0, 5, 10, 15, 30, 60, 90, 120, 180, 240, 300 and 360 minutes, digested in nitric acid (70%) and the Cu content was determined by atomic absorption spectrophotometry. A control group was administered with calcium gluconate and the Cu level was determined to establish basal content. Our data showed that Cu plasmatic concentration increases almost in 60% from basal levels 10 min after oral administration. Maximum plasmatic concentration was observed at 90 min post-administration increasing in almost 95% when compared to basal level. After 180 min of administration, Cu elimination starts and 360 min after administration metal levels return to baseline. In brain tissue increase of Cu level did not reach the percentages observed in plasma. Peak concentrations were observed 15 minutes after oral administration increasing basal levels in almost 36% in mesencephalon and in 49% in striatal tissue and basal values were observed again 90 min and 300 min after administration respectively. Additionally, maximum concentration of Cu determined in liver was observed 180 min after administration and it was 241.0% more when compared to basal value. In conclusion, the oral administration of 79.5 mg/kg Cu increase its plasmatic level, however, the observed increment is not proportional to concentration in brain tissues. On the other hand, liver seems to plays a relevant role regulating copper homeostasis after oral administration, since this organ shows significant retention of the metal when compared to levels observed in the rest of the tissues evaluated during this protocol.

Title: 5-alpha reductase inhibitors dampen L-DOPA-induced dyskinesia by normalizing D1-receptor downstream signaling pathway

Authors: *S. FANNI[1], F. ROSSI[1], F. TRACCIS[1], P. SABA[1], S. SCHEGGI[2], E. TRONCI[1], A. MELIS[1], P. DEVOTO[1], M. BORTOLATO[3], M. CARTA[1], R. FRAU[1,4,5,6]

Abstract: Although 1-3,4-dihydroxyphenylalanine (L-DOPA) is the mainstay therapy for treating Parkinson's disease (PD), its long-term administration is accompanied by the development of motor complication that dramatically affects patients' quality of life, particularly L-DOPA induced dyskinesia (LID). LID has consistently been related to an excessive dopamine receptor transmission, particularly at the down-stream signaling of the striatal D1 receptors, resulting in an exaggerated stimulation of cAMP-dependent protein kinase and extracellular signal-regulated kinase (ERK) pathway. We previously reported that pharmacological blockade of 5-alpha reductase (5AR), the rate-limiting enzyme in neurosteroids synthesis, attenuates the severity of a broad set of behavioral alterations induced by selective and non-selective dopamine receptor agonists, without inducing extrapyramidal symptoms. In light with these evidence, we hypothesized that inhibition of 5AR may also counteract dyskinesia in 6-OHDA-lesioned rats by normalizing the striatal D1 receptor signaling cascade. Thus, in this study we investigated the impact of the inhibition of 5AR on the development and expression of dyskinesia and related molecular alterations on D1 receptor downstream signaling. We used two 5AR inhibitors, already approved for clinical use, finasteride (FIN) and dutasteride (DUTA), that differ in affinity for two 5AR isoform. First, to characterize the therapeutic potential of FIN and DUTA on preventing of LID, we assessed the abnormal involuntary movements in hemiparkinsonian male rats chronically injected two weeks prior to L-DOPA administration. Furthermore, a battery of motor tasks was administered in order to verify the impact of 5AR inhibitors on the therapeutic efficacy of L-DOPA. Finally, in order to investigate a potential molecular alterations induced by the chronic treatment with FIN and DUTA, we analyzed striatal markers of dyskinesia in 6-OHDA lesioned rats treated with L-DOPA alone or in combination with FIN and DUTA. The results indicated that both FIN and DUTA preventive administration significantly reduced development and expression of LID; however, DUTA appeared more effective than FIN at a lower dose and produced its antidyskinetic effect without impacting the ability of L-DOPA to increase motor activation, or ameliorate forelimb use in parkinsonian rats. Moreover, we found that both 5AR inhibitors, prevented the increased phosphorylation of DARPP-32 and ERK1/2 induced by L-DOPA treatment. These results support 5AR as an intriguing target for LID and suggest DUTA as promising therapeutic agent for treatment of dyskinesia in PD patient.

Title: Co-treatment with rivastigmine and idalopirdine reduces the propensity for falls in a rat model of falls in Parkinson's disease

Authors: *A. KOSHY CHERIAN[1], A. KUCINSKI[1], R. WU[1], I. E. M. DE JONG[2], M. SARTER[1]

Abstract: Falls in patients with Parkinson's disease (PD) are associated with cognitive, specifically attentional impairments and with losses in cholinergic projection systems. We previously established an animal model of the combined basal forebrain cholinergic - striatal dopaminergic losses of PD fallers (DL rats) and a behavioral test system (Michigan Complex Motor Control Task, MCMCT) to measure falls associated with traversing dynamic surfaces. Traversal through the rotating square rod surfaces requires limb coordination, carefully timed and placed steps, and persistent control of gait. We also demonstrated that treating DL rats with an acetylcholinesterase inhibitor (AChEI), donepezil, together with a $5HT_6$ receptor antagonist, idalopirdine, reduced fall frequency and improved associated performance of DL rats traversing rotating rods (Kucinski et al., 2017). Here we employed a longer and more taxing rotating beam apparatus to determine the potential therapeutic efficacy of idalopirdine when combined with the pseudo-irreversible, and thus relatively long-acting, AChE- and butyrylcholinesterase- (BuChE) inhibitor rivastigmine. As before, vehicle-treated DL rats fell more frequently, committed more slips and exhibited more movement stoppages than intact control rats. Semi-chronic administration of rivastigmine and idalopirdine significantly improved the performance of DL rats. Rivastigmine alone produced some trends for improved performance but the combination treatment was robustly more effective in reducing stoppages and stoppage-associated falls. As before, idalopirdine treatment alone was ineffective. These results extend the prediction that the combined treatment with idalopirdine and an AChEI enhances the fluency and efficacy of forward movement and thereby reduces the propensity for falls in patients with movement disorders.

Title: Luminopsin-mediated stimulation of transplanted dopaminergic cells in unilateral 6-OHDA lesion model of Parkinson's disease

Authors: *K. A. ANDERSON, E. D. PETERSON, A. PAL, R. A. BYRD, E. L. BURKETT, B. WHITEHEAD, A. S. HAULER, R. R. ANCOG, K. E. AZINGER, M. D. HILL, U. HOCHGESCHWENDER, M. I. SANDSTROM

Abstract: Of the treatments for Parkinson's disease (PD), stem cell transplantation demonstrates high potential. Preclinical data suggests a waning of benefit prior to or without significant disruption of the transplant. We theorize that a gradual adaptive response is occurring due to imprecise regulation of grafted cells that results in a constant, tonic release of dopamine (DA). While previous research in our lab has witnessed grafts such as this subtly reduce asymmetrical behavior using the unilateral 6-OHDA model, further improvements could center upon stimulating DA release to prevent gradual habituation and reveal more apparent reduction in asymmetry. Of the various tools for stimulating cellular activity, one recent development shows promise: bioluminescent optogenetics. Bioluminescent optogenetics makes use of luminopsins—pairs of proteins comprised of a luciferase and an opsin. This provides the ability to activate the opsin by administering a substrate compatible with the luciferase rather than with direct light. We created a stable transgenic cell line that expressed the luminopsin construct LMO3 and used these cells in a dopaminergic differentiation protocol followed by their *in vivo* transplantation into 6-OHDA lesioned rats. By using a repeated measures design where eight rats were injected with either the active substrate or an inert vehicle in randomized sequence, we compared benefits of transplants alone with those produced by stimulating luminopsin-expressing DA cells in restoring symmetrical limb use while the animals were swimming. This was done along with concurrent microdialysis to correlate DA release from the lesioned hemisphere with the animals' symmetrical limb use. We expected that stimulating DA release would rectify asymmetric behavior far more successfully than transplants left to their own devices. It was found that after stimulation, asymmetrical biases in behavior were reduced and in some cases reversed in direction. Results of vehicle stimulation were curiously mixed. It was found that vehicle injections that preceded the stimulation condition showed the expected, unreduced asymmetry, while vehicle injections that followed stimulations showed reduced asymmetry. Preliminary

results indicate no clear correlation has been seen between neurotransmitter levels and reduced asymmetry following either vehicle or substrate injection. Regardless, the behavioral data supports the notion that the transgenic cells can be stimulated via the luminopsin construct. This stimulation, however, may initiate a more complex dynamic that combines acutely driven release with residual levels of diffused dopamine.

Title: Regulation of corticostriatal transmission and motor function by phosphodiesterase 9A: Implications for the treatment of Parkinson's disease

Authors: *A. R. WEST[1], F. ALTWAL[1], S. CHAKROBORTY[1], N. VOELKNER[1], R. MALIK[1], I. M. SANDOVAL[2], K.-Y. TSENG[4], F. P. MANFREDSSON[3]

Abstract: While L-DOPA remains the gold standard treatment for Parkinson’s disease (PD), chronic administration is thought to restore dopamine (DA) tone in the striatum in a non-physiological manner which induces debilitating motor side effects termed L-DOPA-induced dyskinesias (LIDs). Thus, there is a critical need to identify novel non-DAergic targets as co-therapies for PD and LIDs. Among these, cyclic nucleotides and phosphodiesterases (PDEs) involved in their metabolism are emerging as promising targets for reversing striatal dysfunction associated with PD. The high affinity cyclic GMP (cGMP)-specific enzyme PDE9A exhibits moderate levels of expression in human and rodent striatal medium-sized spiny projection neurons (MSNs), however, it is not yet known how up or down regulation of cGMP signaling via PDE9A-specific manipulations may affect corticostriatal transmission or motor behavior in naïve animals and PD models. The current study investigated the effects of the selective PDE9A inhibitor PF-04447943 and genetic manipulations (knockdown or overexpression of PDE9A using rAAV2/9) on motor function and cortically-evoked activity recorded in naïve and

dyskinetic or non-dyskinetic hemi-parkinsonian rats. Augmentation of cGMP signaling following acute and chronic disruption of PDE9A did not affect motor behavior in naïve or untreated parkinsonian rats, and did not alter the prokinetic effects of L-DOPA or measures of LIDs in dyskinetic animals. However, electrophysiological studies performed in naïve animals showed that downregulation of PDE9A induced a significant decrease in the onset latency of cortically-evoked spikes recorded in striatal MSNs, indicating that increased cGMP tone facilitates corticostriatal transmission. Opposite genetic manipulations designed to down-regulate the cGMP signaling pathway in parkinsonian rats utilized viral vectors incorporating the PDE9A transgene and/or a dominant-negative form of PKG1-α (d-PKG1-α) or GFP as a control. Interestingly, overexpression of the PDE9A transgene in striatum significantly reduced the severity of LIDs and turning behavior in L-DOPA-treated PD rats. These findings point to new cGMP-dependent mechanisms for modulating striatal function to reduce the incidence and severity of LIDs, and potentially, improve motor control and quality of life in patients with PD. Moreover, as this gene therapy regime does not require striatal cell- or pathway-specific manipulations, it may be more readily translated to patients with PD than approaches requiring more restrictive genetic targeting.

Title: Multimodal serotonergic drugs for the treatment of L-DOPA induced dyskinesia in an experimental model of Parkinson’s disease

Authors: *F. ALTWAL, N. VOELKNER, R. MALIK, V. OLIVERA, A. PASTWA, A. R. WEST
Neurosci. Dept., Rosalind Franklin Univ., North Chicago, IL

Abstract: Parkinson’s disease (PD) is a devastating neurodegenerative disorder affecting over one million Americans. The gold standard treatment for PD is levodopa (L-DOPA), which is effective for increasing dopamine (DA) tone and improving motor dysfunction, but unfortunately produces debilitating motor side-effects termed L-DOPA-induced dyskinesias (LIDs). Recent studies in dyskinetic parkinsonian models have implicated serotonergic raphe-striatal terminals

in the uptake and conversion of L-DOPA to DA, as well as the non-physiological release of DA and serotonin (5-HT) which may underlie the pathophysiological mechanisms of LIDs. Indeed, the utility of co-treatments with either selective 5-HT reuptake inhibitors (SSRIs) which block the 5-HT transporter (SERT), or selective 5-$HT_{1A/B}$ receptor (5-$HT_{1A/Br}$) ligands which stimulate 5-HT autoreceptors to potentially suppress DA release from 5-HT terminals, has been assessed in pre-clinical models and clinical trials. Many of the drugs tested were found to reduce LIDs, but unfortunately also reduced the prokinetic effects of L-DOPA. The goal of the current study was to identify a multimodal 5-HT drug which can act to attenuate the expression and severity of LIDs, without interfering with the antiparkinsonian efficacy of L-DOPA. Vortioxetine is of interest in this regard as it is known to exhibit potent SSRI, 5-HT_{1Ar} agonist, and 5-HT_{1Br} partial agonist properties, and can act as an antagonist at other 5-HT receptors. Unilateral 6-OHDA-lesioned rats modeling PD were treated with either vehicle and L-DOPA (2.5 - 5.0 mg/kg), vortioxetine (5.0 mg/kg) and L-DOPA, or escitalopram (3 mg/kg). Rats were treated for 5 consecutive days/week, for 2 weeks. On the second day of each week, stepping tests were performed prior to drug administration, and 60 minutes post L-DOPA treatment. Behavioral assessment of LIDs was performed (30-180 min) at the end of each week. Vortioxetine pretreatment (30 min) significantly reduced LIDs in 6-OHDA lesioned rats, but had no effects on forelimb akinesia or L-DOPA-induced prokinetic effects. Escitalopram pretreatment also induced a significant reduction in LIDs and did not affect the prokinetic effects of L-DOPA. Additional studies are ongoing to assess the impact of these treatments on corticostriatal transmission and striatal neuronal activity. The current results indicate that together with L-DOPA, multimodal 5-HT drugs such as vortioxetine may be safe and efficacious co-therapies for reducing side-effects such as hyperkinesia and dystonia in PD patients, potentially allowing for more flexibility in L-DOPA dose ranges and protracted chronic treatment.

Title: A gene therapy approach to knock-down Fyn in the striatum reduces levodopa induced dyskinesia in the 6-hydroxydopamine mouse model of Parkinson’s disease

Authors: *M. P. BORDONE[1], A. DAMIANICH[2], M. A. BERNARDI[1], S. SANZ-BLASCO[1], O. S. GERSHANIK[1], M. E. AVALE[2], J. E. FERRARIO[1]

[1]Facultad de Farmacia y Bioquímica, Univ. de Buenos Aires-CONICET, Inst. de Investigaciones Farmacológicas, Ciudad Autonoma Buenos Aires, Argentina; [2]INGEBI - CONICET, Ciudad Autónoma de Buenos Aires, Argentina

Abstract: Levodopa (L-DOPA) induced dyskinesia (LID) is the main side effect that appears after long-term treatment with that drug for Parkinson's disease (PD). To reduce the development and severity of LID is a significant challenge because to date there are no available pharmacological alternative therapies to PD with full clinical benefit. We have recently proposed Fyn as a novel target to control LID. Fyn is a Src tyrosine kinase located at the postsynaptic density zone that regulates the N-methyl-D-aspartate (NMDA) receptor by phosphorylation of the NR2B subunit at Tyr-1472 in response to dopamine D1 receptor stimulation. Here we propose to genetically manipulate Fyn expression aiming to downregulate LID in a mouse model of PD, by intra-striatal injection of lentiviral (LV) particles carrying a micro-RNA against Fyn (miR-Fyn). Four miR-Fyn sequences were designed, cloned in LV vectors, tested *in vitro* for silencing efficacy and selected the one with the highest silencing effect. Next, we generated the PD mouse model in C57 female mice (3 months of age) by injecting 6-hydroxydopamine (6-OHDA) into the medial forebrain bundle, selected the animals with a remarked deficit of the contralateral forepaw in the cylinder test and challenged them with L-DOPA to induce LID before (n=16) or after (n=19) the intra-striatal injection of miR-Fyn or a control sequence (n=5 for each group). A group of non-injected animals with LV particles was run in parallel as a positive control for dyskinesia (n=9). LIDs were determined every 3 days for 2 weeks. *Postmortem*, we determined the degree of dopaminergic denervation by counting the number of tyrosine hydroxylase (TH) positive cells in the substantia nigra, to ensure an equal level of degeneration in all groups, and the level of striatal TH, Fyn silencing and the marker of LID, FosB-ΔFosB, all by Western blot. We found that the selected miR-Fyn reduces Fyn protein by ~50% in N2a neuronal cell line, and it significantly downregulated LID in a pretreatment paradigm of dyskinesia by ~60% or ~40% compared to the non-injected animals or the group injected with the control sequence, respectively. Also, the miR-Fyn was able to reduce the severity of already established dyskinesia (postreatment paradigm) by ~35% compared to both control groups. Our results demonstrate that Fyn is a potential target to control LID and set the grounds for a potential translation to therapeutic use in PD.

Title: NPT520-34 administration improves grip strength, limb posture, and balance and gait-related measures in a transgenic mouse model of Parkinson's disease

Authors: *D. L. PRICE, A. KHAN, M. MAILE, C. WITTMER, K. TATSUKAWA, E. STOCKING, W. WRASIDLO, D. BONHAUS
Neuropore Therapies, Inc., San Diego, CA

Abstract: The accumulation of neurotoxic misfolded and aggregated proteins and the associated neuroinflammation are implicated in the pathogenesis of most neurodegenerative diseases. NPT520-34, a compound with good drug-like properties and an excellent in vitro safety profile, has demonstrated beneficial effects in multiple in vivo studies on alpha-synuclein (ASYN) protein accumulation, striatal dopamine transporter levels and a clinically translatable marker of neuroinflammation (Translocator protein - TSPO) in the Line 61 transgenic (Tg) mouse model of Parkinson's disease (PD). The Line 61 mThy1-ASYN Tg mouse develops extensive accumulation of ASYN neuropathology, inflammation, and motor and non-motor functional deficits recapitulating key features of PD.

The objective of the current study was to confirm the actions of NPT520-34 on neuropathology and grip strength and extend findings to measures of limb posture (clasping), and measures of gait and balance in a new 3 month administration study in the Line 61 Tg mouse model. Male Tg and non-Tg littermates received vehicle or NPT520-34 (0.5, 1, 5 or 10 mg/kg, IP) once daily for 3 months. Experimenters were blinded to genotype and treatment group.

Grip strength was evaluated at baseline (prior to treatments) and re-evaluated after 70 days of treatment. Consistent with previous 3 month studies, statistically significant grip deficits in Line 61 Tg mice were present at baseline and re-test. All doses of NPT520-34 from 0.5 to 10 mg/kg produced improvements in Line 61 Tg grip strength relative to vehicle-treated Line 61 Tg control mice.

Hind and forelimb clasping were evaluated (~day 70) as measures of striatal dysfunction and/or dysregulation of motor pathways. There were statistically significant increases in hind and forelimb clasping in vehicle-treated Line 61 Tg mice compared to vehicle non-transgenic control mice. Forelimb clasping was reduced in Line 61 tg mice treated with NPT520-34 (0.5 up to 5 mg/kg).

The effects of NPT520-34 at 10 mg/kg on gait and balance were evaluated (~day 20 and 70) in a separate cohort of Line 61 mice utilizing the automated CatWalk apparatus (Noldus Information Technology). Compared to non-transgenic mice, Line 61 Tg mice displayed multiple alterations in CatWalk indices of gait and balance, including statistically significant increases in abnormal lateral stance support (ipsilateral limbs) that were normalized in L61 tg mice treated with 10 mg/kg NPT520-34.

Taken together the present results confirm benefits of 10 mg/kg NPT520-34 treatment on Line 61 Tg grip strength and extends to findings of benefit on additional measures of limb posture, gait and balance with doses as low as 0.5 mg/kg.

Title: VEGF-B overexpression in PINK1 gene knock out rats improves motor function: Is this effect due to neuroprotection or to functional improvement of dopaminergic neurons?

Authors: *M. J. BARTLETT[1], S. CRISTIANI[2], S. I. B. SMIDT[2], D. C. FARRELL[4], K. P. DOYLE[5], M. L. HEIEN[6], S. J. SHERMAN[2], T. FALK[3]

Abstract: Therapies to slow the progression of Parkinson’s disease (PD) or protect against the loss of dopaminergic neurons in the substantia nigra pars compacta (SN) remain a critically under met need. We have previously identified vascular endothelial growth factor B (VEGF-B)

as a novel therapeutic candidate and published neuroprotective effects of VEGF-B *in vitro* and *in vivo*. VEGF-B was shown to be upregulated in dopaminergic cells of a rat midbrain culture model upon exposure to rotenone, a suspected PD-inducing toxin, and to be neuroprotective against a rotenone insult (Falk et al. 2009). We have also demonstrated VEGF-B's neuroprotective effects in the progressive unilateral 6-hydroxydopamine rat PD model, after a single injection of VEGF-B in the striatum (Yue et al. 2014). In a first pilot study, we injected adeno-associated virus expressing human VEGF-B (AAV2/1-hVEGF-B) unilaterally into the SN and striatum of male PTEN-induced putative kinase 1 (PINK1) knockout (KO) rats at 5 months of age (n=4-5 per group). In this genetic PD model we saw a reduction in cumulative foot slip errors during monthly tapered balance beam (TBB) tests as compared to untreated PINK1 KO rats. The motor improvements were bilateral, in forelimbs (ipsilateral, *$p<0.05$; contralateral, **$p<0.01$), and hindlimbs (ipsilateral, **$p<0.01$; contralateral, *$p<0.05$). At 12 months of age these rats were euthanized and showed an ~30% increase in striatal dopamine (DA) content in the VEGF-B-injected hemisphere compared to the untreated PINK1 KO rats, analyzed via HPLC-EC (One-way ANOVAs; $p<0.05$; n=3-5). We also saw an increase in the VEGF-B-injected hemisphere in striatal levels of pigment epithelium-derived factor, a known negative regulator of apoptosis (*$p<0.05$). We expanded our previous pilot with a second cohort of male PINK1 KO rats, injected unilaterally with AAV2/1-hVEGF-B as above at 5 months of age (October 2017). AAV2/1-hVEGF-B treated PINK1 KO (n=8), untreated PINK1 KO (n=9) and wild type (WT; n=8) rats are currently being tested monthly under blinded conditions for changes in motor function with the TBB. At 12 months of age the rats (n=6/group) will be transcardially perfused. Unbiased stereology of dopaminergic cells in the SN and striatal terminals will be performed after co-staining for tyrosine hydroxylase and the neuronal marker, NeuN. The remaining rats will be used to increase the n number of the first pilot. The results will allow us to determine if VEGF-B's therapeutic effects on motor function and increased striatal DA content in PINK1 KO rats are due to a neuroprotective reduction in the loss of dopaminergic neurons, or a functional improvement in the surviving dopaminergic neurons.

Title: Effect of complete bee venom on fine-tune motor behavior in a 6-OHDA rat lesion model

Authors: *S. J. LOPEZ-PEREZ, A. K. LOMELI-LEPE
Univ. of Guadalajara (CUCBA), Zapopan, Jalisco, Mexico

Abstract: Bee venom has been historically used to alleviate human diseases, as arthritis and rheumatism, being currently popular as analgesic and anti-inflammatory, and experimental works have found neuroprotective effects in animal models of Parkinson´s disease, whose hallmarks can be replicated in rats throughout intra-striatal injection of 6-hydroxidopamine (6-OHDA). Animals whit this pharmacological manipulation lose fine motor capacity, as can be seen by the standardized "vermicelli handling test", consisting in manipulation and consumption of thin pieces of dried pasta. Intact animals regularly use one paw to hold the piece, and the other paw to guide the piece into the mouth. As the piece became shorter, the paws moved together into a symmetrical holding pattern. Unilateral 6-OHDA lesions resulted in atypical eating patterns and changes in movements used to manipulate the pasta, including increased movements made with the forepaw ipsilateral to the lesion, or even, incapacity to take the pasta. In this work, we analyzed the effect of "complete" bee venom on the capacity for handling pasta, to analyze its beneficial potential in the model of dopaminergic neurodegeneration by 6-OHDA. Male Wistar rats were injected with a single dose of 6-OHDA under isoflurane anesthesia, in the right striatum. After two weeks, damage was assessed by rotation induced test. Three weeks after lesion, a group was administered with filtered complete bee venom, obtained from beekeeping scholar group (CUCBA, University of Guadalajara, México). 6-7 weeks after lesion, vermicelli handling test was verified, providing the animals with 7 cm long segments of uncooked semolina spaghetti, and recording in video its behavior, in an acrylic cage. Intact animals took the segments with both forepaws, using one paw to hold, ant the other to push and guide the segment to the mouth, and ate the segments in 25.17 ± 98.2 seconds; 6-OHDA lesioned rats held the segments precariously, some released the segments in the middle of the procedure, and some were unable to get up off the floor of the cage, just sniffing the segments, without eating them. The animals that managed to eat them did so in a longer average time than controls. Animals treated with 6-OHDA and bee venom held and ate the segments in a similar time than controls, even thought its strategies to sustain and guide the pasta segments were different than controls. These results suggest that complete bee venom could have a protective effect on dopaminergic degeneration caused by 6-OHDA, maybe favoring a re-wiring of survival neurons, since animals use different strategies than intact subjects for stereotyped behavior.

Title: Pramipexole reverts the development of tactile allodynia in a rat model of Parkinson's disease

Authors: *A. M. AUSTRICH OLIVARES[1], L. MENDIETA[2], V. GÓMEZ-GARCÍA[1], A. ESPINOSA-ROMERO[1], A. MATA-BERMÚDEZ[1], T. PASTRANA-QUINTO[1], B. GODÍNEZ-CHAPARRO[1]

Abstract: Pain is the non-motor symptom with the highest prevalence in patients with Parkinson's Disease (PD) affecting up to 85%. In studies with PD patients, it is contradictory if antiparkinsonian therapy is enough to alleviate this non-motor symptom. Although there is scarce researching about the pain mechanisms underlying this pathology. The aim of this study was to investigate the development of tactile allodynia after the nigrostriatal dopaminergic lesion induced by the unilateral 6-hydroxydopamine (6-OHDA) injection at different doses in the *sustantia nigra pars compacta* (SNc) and study the possible anti-allodynic effect of a dopamine agonist drug, Pramipexole (PPX) in rats. First, dopaminergic lesion was realized by the unilaterally injection of 6-OHDA into the SNc at different concentrations (6, 10, 13 and 16 µg/µL). To know the establishment of motor deficits, we measure number of turns, bradykinesia and forelimb-use asymmetry in the assays of rotational behavior (apomorphine, 0.1 mg/Kg, s.c.), open field and cylinder, respectively. On the other hand, to investigate the allodynia by 6-OHDA, we used the *up-down* method with von Frey filaments to measure the 50% of withdrawal response of both paws. In addition, the anti-allodynic effect of PPX was examined at different doses (0.03, 0.3 and 3 mg/Kg, s.c.) in an acute and chronic manner daily for 10 days. We found that the group of animals with the higher doses of 6-OHDA (10, 13 and 16 µg/µL) induced motor damage in the tests of open field and cylinder. Moreover, a greater number of contralateral turns by apomorphine were found in a dose-dependent manner in rats. Lesioned animals with the higher dose administered of 6-OHDA (16 µg/µL) presented significant tactile allodynia in both paws from day 16 to 32 days post-injury. The middle dose of PPX decreased significantly the 50% of withdrawal response of both paws without secondary effects. In conclusion the unilateral lesion with 6-OHDA is able to induce allodynia in both paws; interestingly the treatment with PPX reverses this nociceptive response then we suggest that PPX would have efficacy as an analgesic drug for patients with PD.

Title: Preclinical efficacy of systemically administered NPT189 in a mouse model of α-synuclein transmission

Authors: *K. MCDOWELL, E. ASP, M. PROSCHITSKY, M. LULU, C. ROCKWELL-POSTEL, J. WRIGHT, R. KRISHNAN, R. FISHER, J. LEVENSON

Abstract: The key neuropathological feature of Parkinson's disease (PD) is the appearance of Lewy bodies, which are mainly composed of aggregated α-synuclein (α-syn). Studies have shown that as PD progresses, α-syn pathology spreads throughout the brain. Cell-to-cell transmission of proteopathic α-syn seeds appears to underlie the propagation of pathology, and this process can be recapitulated in preclinical models. We previously described the amyloid targeting activities of the general amyloid interaction motif (GAIM), a virus-derived protein that potently binds and structurally remodels fibrillar aggregates of misfolded proteins, such as amyloid beta, tau, and α-syn. GAIM also effectively reduces transmission of α-syn aggregates in a neuronal cell culture model. Here, we demonstrate the efficacy of systemically administered NPT189, a novel human-IgG1-Fc immunoglobulin fusion protein that is bivalent for GAIM, in a mouse model of α-syn transmission. Beginning 6 days after unilateral stereotaxic injection of α-syn seeds into the dorsal striatum, mice were treated intraperitoneally with NPT189 (15 mg/kg) or vehicle control twice weekly for 3-6 months. Three months after induction of pathology and treatment with NPT189, lower α-syn pathology loads were observed in both substantia nigra and amygdala, brain regions which exhibit high connectivity with dorsal striatum. Six months after induction of pathology, vehicle-treated mice exhibited a pronounced loss of tyrosine hydroxylase in the ipsilateral hemisphere of substantia nigra, whereas NPT189 treatment was associated with higher levels of tyrosine hydroxylase in substantia nigra relative to vehicle-treated mice. Our preclinical data suggest that NPT189 modulates α-syn-associated pathology by interfering with transmission of proteopathic α-syn seeds, which represents one putative mechanism whereby PD pathology progresses in patients.

Title: Adenosinergic drugs control striatal metaplasticity in mice with L-DOPA-induced dyskinesia

Authors: *A. E. SPECK[1], A. S. AGUIAR, JR[2], R. A. CUNHA[3], R. D. PREDIGER[1]
[1]Pharmacol., Federal Univ. of Santa Catarina, Florianópolis, Brazil; [2]Hlth. Sci., Univ. Federal de Santa Catarina, Araranguá, Brazil; [3]CNC -Center For Neurosci. and Cell Biol., Coimbra, Portugal

Abstract: Objectives: The aim of this study was to evaluate the effects of adenosinergic drugs on striatal metaplasticity in dyskinetic mice induced by L-DOPA. Methods and results: C57BL/6 male mice (8-12 weeks) were treated with 6-hydroxydopamine (6-OHDA, 3 μg in 1 μL of 0.02% ascorbic acid diluted in 0.9% NaCl), in two different regions of the right mid-striatum (2 x 2 μL, 0.5 μL/min) to mimic a hemiparkinsonism. After 4 weeks, they were challenged with R(-)-apomorphine (0.6 mg/kg, subcutaneous), to confirm the lesion. During 30 days the animals received a daily intraperitoneal (i.p.) injection with L-DOPA (25 mg/kg) plus benserazide (12.5 mg/kg). The animals were then sacrificed and their brain removed to prepare striatal coronal slices (400 μm) used to measure corticostriatal transmission and synaptic plasticity assessed (WinLTP 2.20b Reanalyzes® software) 30 min after applying a high frequency stimulation protocol (HFS: 100 Hz, 3 times, every 20 seconds). We compared control and 6-OHDA-lesioned striatal slices in the absence and presence of either the selective adenosine A2A receptor antagonist SCH58261 (50 nM) or the analogue of adenosine 2-chloroadenosine (2-CADO, 100 nM) (n=8-12 independent preparations per group). The slices from mice with L-DOPA-induced dyskinesia displayed a shift in striatal plasticity to long-term potentiation (LTP) in control and 6-OHDA side in comparison to both sides in animals who received saline ($F_{3,76}$= 55,11, $p<0.05$). Notably, the incubation of striatal slices from dyskinetic mice with SCH58261 or 2-CADO

induced long-term depression (LTD). Conclusion: These findings demonstrate that animals with L-DOPA-induced dyskinesia display alterations in striatal metaplasticity that can be modulated by the blockade and activation, respectively, of adenosine A2A and A1 receptors. Altogether, these results reinforce the potential of adenosinergic drugs in the treatment of L-DOPA-induced dyskinesia.

Title: A combined pharmacological strategy to block NMDA receptor function and reduce L-DOPA induced dyskinesias

Authors: *S. SANZ-BLASCO, L. ISAJA, M. P. BORDONE, A. K. STARK, O. S. GERSHANIK, J. E. FERRARIO
ININFA (UBA-CONICET), Ciudad Autonoma Buenos Aires, Argentina

Abstract: Levodopa (L-DOPA) induced dyskinesias (LID) are one of the most disabling side effects which appear after prolonged use of this drug for the treatment of Parkinson’s disease (PD). Finding a therapeutic alternative that could reduce LID is of great importance to improve the quality of life of PD patients. Moreover, gaining a more profound knowledge of the pathophysiology of LID is crucial for the development of more effective drugs and understanding the maladaptive changes taking place with the progression of the disease. Amantadine (or its analog, memantine) is a NMDA receptor (NMDA-R) antagonist which has been reported to reduce LID. However, its efficacy is limited and its safety and tolerability restricts its use in some patients. In this context, the aim of this work is to investigate pharmacological strategies, including novel target approaches, to reduce the use of amantadine. The inhibitor of the Src family kinases (SFKs) saracatinib (AZD0530), is an experimental drug currently under a phase 2a clinical trial for Alzheimer's disease, for its blocking effect on Fyn, one of the members of the SFKs. Fyn mediates the regulation of the NMDA-R by phosphorylating Tyr-1472 at the NR2B subunit and regulates NMDA-R redistribution after dopamine depletion and L-DOPA treatment. Recently, we have shown that saracatinib partially reduces dyskinesias in a mouse model of LID (Sanz-Blasco et al., Mol Neurobiol 2017),

suggesting a potential benefit of AZD0530 for PD patients under L-DOPA treatment. Here we have established an alternative approach targeting simultaneously the NMDA-R by two different strategies: reducing its availability at the membrane by inhibiting Fyn activity with saracatinib, and blocking the NMDA-R with amantadine. We have determined the intensity of LID on 6-OHDA lesioned mice treated with L-DOPA and challenged them either with saracatinib, amantadine or a combination of both drugs with the purpose of comparing their antidyskinetic properties at different concentrations. We have observed that, in dyskinetic mice with an equivalent severity of lesion, as determined by tyroxine hydroxilase immunohistochemistry, those treated with a combination of amantadine (at a lower dose than its effective concentration) and saracatinib (at a sub-therapeutic dose) showed reduced dyskinesia scores. LID reduction was greater when both drugs were administered in combination than when given individually at higher doses. Altogether, our results confirm the importance of the NMDA-R in the development of LID and point to a potential alternative strategy to control LID development in PD patients.

Title: Chronic caffeine treatment modulates disease progression in a transgenic α-synuclein prion-like spreading mouse model of Parkinson’s disease

Authors: *N. FERREIRA[1], C. BETZER[2], L. REIMER[1], M. ROMERO-RAMOS[3], P. H. JENSEN[4]
[1]Danish Res. Inst. of Translational Neurosc, Aarhus, Denmark; [2]Dept. of Biomedicine, Aarhus Univ., Aarhus Univ., Aarhus C, Denmark; [3]NEURODIN, Dept. Biomedicine, Aarhus Univ., Aarhus C, Denmark; [4]Univ. Aarhus, Aarhus-C, Denmark

Abstract: Introduction Compiling amount of evidence suggest that cell-to-cell transmission and the self-propagation of pathogenic aggregated α-Synuclein (αSyn) plays a central role in the initiation and the progression of Parkinson’s disease (PD). Epidemiological studies suggest that prolonged caffeine intake may confer neuroprotection against the underlying dopaminergic neuron degeneration, and influence the onset and progression of PD. The present study sought to investigate the chronic protective effects of caffeine intake in a tg αSyn prion-like spreading mouse model of PD.

Methods A53T-mutant ($M83^{-/+}$ and $M83^{+/+}$) Tg mice were injected bilaterally in the upper hind limb muscles (biceps femoris) with fibrilar mouse αSyn and treated in the absence or presence of caffeine (0.3 mg/mL) in the drinking water.
Results Chronic caffeine treatment resulted in significant delay (up to 3 weeks) of the onset of clasping behavior and also increased lifespan (up to 40%) in both $M83^{-/+}$ and $M83^{+/+}$ compared to vehicle treated controls. In addition, western blot analysis of brains homogenates of both $M83^{-/+}$ and $M83^{+/+}$ mice showed significantly reduced levels of total α-syn and pathological P-α-syn in the urea-SDS soluble fraction of caffeine-treated mice compared to controls. The mechanism for the observed protection is being investigated in cell models.
Conclusion Taken together, our data strongly suggest caffeine as modulator of α-syn spreading. Understanding the mechanism of action of caffeine will open the relative narrow therapeutic window for patients suffering from α-synucleinopathies.

Title: The role of dysfunctional BDNF in remodeling of the parkinsonian striatum following dopamine neuron grafting in val68met (rs6265) knock-in rats

Authors: *K. STEECE-COLLIER[1], R. L. DANGREMOND[2], C. E. SORTWELL[2], T. J. COLLIER[2], I. M. SANDOVAL[2], B. F. DALEY[2], M. F. DUFFY[2], N. M. MERCADO[2], J. A. STANCATI[2]
[2]Translational Sci. and Mol. Med., [1]Michigan State Univ., Grand Rapids, MI

Abstract: We recently reported that early-stage Parkinson’s disease (PD) subjects possessing the met allele of the rs6265 *Bdnf* variant exhibit reduced therapeutic efficacy of oral levodopa. Up to 40% of the population possesses the rs6265 *Bdnf* met allele, which results in diminished neuronal release of BDNF. BDNF plays an important role in spine dynamics of striatal medium spiny neurons, sculpting the structure and function of synapses. We hypothesize that BDNF is an unrecognized contributor to the discordant finding of abundant survival of grafted dopamine (DA) neurons and lack of behavioral efficacy reported in a subpopulation of PD subjects and aged parkinsonian rats. To test this hypothesis, we generated a CRISPR knock-in rat model of the human rs6265 BDNF variant to evaluate the impact of reduced host BDNF release on the

function and synaptic integration of new DA terminals in the parkinsonian striatum. In this study we will compare graft survival, integration, and behavioral improvement between val68val wild-type ('WT', BDNF normal) and homozygous met68met ('MET', BDNF reduced) young adult parkinsonian rats. Rats were rendered unilaterally parkinsonian with intranigral 6OHDA and primed with levodopa (12mg/kg, s.c.; M-Fr) 4 weeks after 6-OHDA to induce stable expression of levodopa-induced dyskinesias (LID). This complex behavioral malady was chosen as the primary behavioral endpoint. Amphetamine-induced rotational behavior served as a second behavioral endpoint. Five weeks following levodopa priming, WT and MET rats received a sham graft (WT N=8; MET N=8) or primary embryonic mesencephalic neurons (200,000 cells, E14 WT donors; WT N=7; MET N=8); parameters that we have previously established to significantly improve amphetamine-induced rotations and ameliorate LID in young WT parkinsonian rats. Data thus far reveal significant differences in pre-graft amphetamine rotational asymmetry and LID profiles in WT rats compared to MET rats. Specifically, while both genotypes show a similar time course of LID onset and peak dose LID severity, MET rats show a faster 'wearing off' compared to WT ($p=0.02$). MET rats also display significantly less amphetamine-induced rotational asymmetry (MET 8.5 ± 0.3/min; WT 11.6 ± 0.8/min; $p=0.002$). These findings suggest differences in DA neurotransmission due to the rs6265 met allele. Behavioral responsiveness to mesencephalic grafts between genotypes is currently ongoing. Post mortem analyses will include quantitative assessment of: 1) graft survival; 2) graft volume; 3) neurite outgrowth; 4) synaptic connectivity between grafted dopaminergic neurites and host neurons. Supported by Michigan Parkinson Foundation.

Abstract: We previously demonstrated that pretreatment with Exendin-4, a glucagon-like peptide-1 (GLP-1) receptor agonist, reduces 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) -mediated dopaminergic neurodegeneration. The use of GLP-1 or Exendin-4 for Parkinson's disease (PD) patients is limited by their short half-lives. The purpose of this study was to evaluate a new extended release Exendin-4 formulation, PT302, in a rat model of PD. Subcutaneous administration of PT302 resulted in sustained elevations of Exendin-4 in plasma for >20 days in adult rats. To define an efficacious dose within this range, rats were administered PT302 once every 2 weeks either before or following the unilaterally 6-hydroxydopamine lesioning. Pre- and post-treatment with PT302 significantly reduced methamphetamine-induced rotation after lesioning. For animals given PT302 post lesion, blood and brain samples were collected on day 47 for measurements of plasma Exendin-4 levels and brain tyrosine hydroxylase immunoreactivity (TH-IR). PT302 significantly increased TH-IR in the lesioned substantia nigra and striatum. There was a significant correlation between plasma Exendin-4 levels and TH-IR in the substantia nigra and striatum on the lesioned side. Our data suggest that post-treatment with PT302 provides long-lasting Exendin-4 release and reduces neurodegeneration of nigrostriatal dopaminergic neurons in a 6-hydroxydopamine rat model of PD at a clinically relevant dose.

Title: Short chain fatty acid drug sodium butyrate delays Parkinson's disease progression in transgenic mice comparable to sodium phenylbutyrate treatment outcomes

Authors: *S. M. GARCIA[1], W. ZHOU[2], C. LOZUPONE[2], C. FREED[2]
[2]Dept. of Med., [1]CU Denver Anschutz Med. Campus, Aurora, CO

Abstract: Background: Current therapies for Parkinson's disease (PD) temporarily improve motor function but cannot impact disease progression. Previously, we reported that sodium phenylbutyrate treatment attenuates alpha synuclein (aSyn) neuropathology and improves behavioral deficits in transgenic mice expressing human mutant aSyn Y39C. However, sodium phenylbutyrate for human use costs about $10,000/kg and has several side effects including allergic skin rash in about 10% of people.
Objective: To bypass obstacles associated with sodium phenylbutyrate therapy, we assessed if sodium butyrate can similarly delay disease progression in aSyn Y39C mice.
Methods: 12-month aSyn Y39C mice were separated into 3-groups (n=6) based on rotarod performance and treated with either sodium phenylbutyrate, sodium butyrate, or sodium chloride (vehicle) for 3-months by water supplementation. Disease progression was determined by behavioral and neuropathology outcomes. Rotarod and Morris water maze testing assessed motor and spatial learning abilities. Whole-brain aSyn (SYN-1 antibody) and neuroprotective DJ-1 protein levels were assessed by Western blotting. Cortical brain tissue sections were evaluated by immunohistochemistry analysis to identify Lewy body-like inclusions containing intracellular human aSyn (LB509 antibody) and pathological aSyn (pSerine129) protein aggregates. Feces was collect at 12 and 15-months to perform 16s rRNA sequencing and QIIME1 analysis to identify gut-microbe shifts associated with treatment.
Results: Both sodium phenylbutyrate and sodium butyrate improve motor and spatial learning abilities, attenuate Lewy body-like inclusions, decrease whole-brain aSyn oligomerization, increase DJ-1 protein, and increase plasma aSyn compared to vehicle treatment. Though sodium phenylbutyrate and sodium butyrate treated mice displayed similar motor and cognitive abilities at 15-months, sodium phenylbutyrate more effectively reduced brain aSyn oligomerization. Microbial composition shifts were not associated with treatment, age, or transgene expression.
Conclusions: Sodium butyrate and sodium phenylbutyrate similarly delay disease progression in

a transgenic mouse model of age-related Parkinson's by elevating neuroprotective protein DJ-1 levels resulting in reduced neuropathology and behavioral deficits. Butyrate treatment may promote the clearance of brain aSyn to the cerebral spinal fluid and plasma to delay disease progression. Since sodium butyrate is up to 50-times cheaper than sodium phenylbutyrate, sodium butyrate or calcium magnesium butyrate should be considered for future clinical investigations.

Title: Neuroplastic effects in the striatum contribute to the suppression of the development of L-DOPA-induced dyskinesia by sub-anesthetic ketamine

Authors: *T. FALK[1], M. J. BARTLETT[2], A. J. FLORES[1], H. K. DOLLISH[1], J. A. STANCATI[5], K. P. DOYLE[3], M. L. HEIEN[4], K. STEECE-COLLIER[5], S. J. SHERMAN[1]

Abstract: Sub-anesthetic ketamine infusions are an effective therapy for the treatment of depression and chronic migraine headaches. Parkinson's disease (PD) and L-DOPA-induced dyskinesia (LID) share a commonality with both disorders, hypersynchrony in brain networks, and ketamine alters oscillatory brain activity. We have demonstrated a long-term therapeutic effect of ketamine in PD patient case studies with LID (Sherman et al. 2016). In a preclinical model (Bartlett et al. 2016), we have reported that established LID, measured by abnormal involuntary movements (AIMs) in this model, are reduced by low-dose ketamine infusion (10-hr infusion paradigm with 20 mg/kg, five *i.p.* injections 2 hrs apart). Here, we test if low-dose ketamine can suppress development of LID. Male Sprague-Dawley rats were unilaterally injected with 6-hydroxydopamine to create a PD model. In a first cohort (n=9/group), rats were primed for 4 weeks with escalating daily L-DOPA doses and treated for 10 hrs with ketamine once per week, as described above. Total limb, axial, and oral AIMs were scored every 3-4 days

under blinded conditions. Ketamine treatment led to a 50% reduction in the development of AIMs ($p<0.05$; One-way ANOVAs, Tukey *post-hoc* tests), even on testing days without ketamine, indicating a neuroplastic effect. In striatal tissue an increase in phosphorylation of mTOR, a master regulator of neuroplasticity, was seen after ketamine (intact, $p<0.001$, lesioned, $p<0.05$; two-tailed *t*-test). In a second cohort (n=10/group), PD rats were primed with daily injections of L-DOPA for 14 days, and treated with ketamine on days 0 and 7 for 10 hrs, ketamine plus the tropomyosin receptor kinase B (TrkB) antagonist, ANA-12, or vehicle. On day 14, ketamine treated rats showed a 50% reduction in their AIMs scores as compared to vehicle ($p<0.01$; One-way ANOVAs, Tukey *post-hoc* tests). However, this sustained effect of ketamine was blocked in rats co-treated with ANA-12 ($p<0.05$). The rats were euthanized, and dendritic spines in the striatum were analyzed after a Golgi stain, showing a 2-fold increase in multi-synaptic mushroom spines on the lesioned side of vehicle-injected rats, that is not seen in the ketamine-treated group ($p<0.0001$). In the ketamine+ANA-12 group the mushroom spines on the lesioned side approach the level seen in the vehicle group proving a block of ketamine's effect by ANA-12 ($p<0.0001$). In conclusion, the sustained anti-dyskinetic effect of ketamine is inhibited by blocking the brain-derived neurotrophic factor (BDNF) receptor (TrkB) and involves changes in striatal spine density. Combined, this data suggests a novel use for low-dose ketamine as a therapy to suppress LID development.

Title: Neuroprotective efficacy of nilvadipine in experimental models of Parkinson's disease

Authors: *R. GORDON[1], A. HICKS[2], J. CONROY[3], K. Z. HANTON[2], C. S. FONG[2], V. KUMAR[4], M. A. COOPER[5], K. SCHRODER[5], T. M. WOODRUFF[3], J. D. O'SULLIVAN[2]

Abstract: Abstract Parkinson's disease (PD) pathology is characterized by a profound loss of nigral dopaminergic neurons that is accompanied by chronic neuroinflammation and extensive α-

synuclein inclusions in the form of Lewy-bodies. L-type calcium channel blockers (LCC) have been shown to have protective effects in multiple models of neurodegeneration. However the mechanisms by which these calcium channel blockers could exert their neuroprotective effects remain unclear. In this study, we evaluated the neuroprotective efficacy of the clinically approved antihypertensive drug nilvadipine and its effects on neuroinflammation in experimental models of Parkinson's disease. We found that pre-treatment with nilvadipine caused a dose-dependent reduction in microglial inflammasome activation and neuroinflammatory mediators induced by pathological synuclein aggregates. Further, nanomolar doses of nilvadipine also protected against neuronal death induced by MPP^+ and 6-OHDA in dopaminergic N27 cells. Our *in vivo* studies confirmed that nilvadipine can enter the CNS at therapeutically relevant concentrations with daily dosing. Crucially, daily dosing with nilvadipine (8 mg/kg) protected against behavior deficits, dopamine depletion and neuropathology in the 6-OHDA model of Parkinson's disease. Our results demonstrate for the first time that nilvadipine can mitigate inflammasome activation and microglial neuroinflammation that are closely linked to disease progression in PD. Collectively, our results suggest that nilvadipine could have potential to be repurposed as a disease-modifying therapy for the management of PD.

Title: Modulation of miR-181 influences dopaminergic neuronal degeneration in a mouse model of Parkinson's disease

Authors: *R. L. BOUDREAU[1], N. H. WITMER[2], C. S. STEIN[2]
[1]Univ. Iowa, Iowa City, IA; [2]Intrnl. Med., Univ. of Iowa, Iowa City, IA

Abstract: Parkinson's disease (PD) is a neurodegenerative disorder caused by progressive loss of dopaminergic (DA) neurons of the substantia nigra (SN), which project to the striatum where dopamine release stimulates neuronal circuits controlling voluntary movement. Loss of nigrostriatal dopamine results in classic motor symptoms of PD, such as tremor, rigidity, and bradykinesia. PD pathogenesis is not fully understood and mechanisms are thought to involve

oxidative stress, defective autophapy/mitophagy, and neuroinflammation. Currently no treatments are available to halt PD progression. MicroRNAs (miRs) are a diverse class of small, non-coding RNAs that target mRNAs for translational inhibition and degradation, and several recent studies demonstrate that certain miRs may represent viable therapeutic targets. In this work, we asked whether the microRNA miR-181 family, which has previously been implicated in regulating apoptosis and mitophagy, plays a role in PD pathogenesis. The miR-181 family is abundantly expressed in brain and has been shown by two independent studies to be up-regulated in PD patient brain tissues and cerebrospinal fluid. For our PD mouse model, we employed an AAV5-based vector encoding human α-synuclein (αSyn) driven by the neuronal-specific synapsin I promoter (AAV5-syn1-αSyn) to over-express αSyn in mouse SN via direct injection. Within 14 weeks post-injection, loss of SN neurons was evident; staining for tyrosine hydroxylase (TH), a DA neuron marker, indicated significant loss of SN neuronal bodies and striatal projections (up to 70% striatal TH loss, relative to AAV5-syn1-eGFP controls; n=10/group, $p<0.01$). To evaluate the effects of miR-181 in this model, AAV5 vectors expressing either miR-181 or inhibitory RNAs that sequester and inactivate endogenous miR-181 were co-injected with AAV5-syn1-αSyn. Based on TH staining, we determined that <4-fold over-expression of miR-181 markedly exacerbated SN neuronal loss, while inhibition of endogenous miR-181 almost completely blocked αSyn-induced neurodegeneration, relative to controls (i.e. scrambled inhibitory RNA; n=10/group, $p<0.01$). In addition, follow-up studies showed that miR-181 overexpression in SN alone was capable of eliciting measurable loss of TH staining, whereas miR-181 inhibition was well-tolerated. These new data are intriguing and suggest that miR-181 provokes DA neuronal cell death and accelerates aSyn-induced neurotoxicity, thus warranting future studies to 1) delineate the underlying mechanisms, 2) better define miR-181 regulation in DA neurons and 3) advance pre-clinical testing of miR-181 inhibition as a therapeutic strategy for PD.

Title: Behavioral consequences of neuronally - derived exosomes cargo proteins *in vivo*

Authors: *C. N. WINSTON[1], E. M. ROCKENSTEIN[2], M. MANTE[2], J. FLORIO[2], B. SALEHI[2], A. ADAME[2], E. MASLIAH[3], R. A. RISSMAN[4]

[1]Neurosci., UC San Diego, LA Jolla, CA; [2]Neurosciences, Univ. Calif San Diego, La Jolla, CA; [3]UCSD, Bethesda, MD; [4]Neurosci, UCSD Sch. Med., La Jolla, CA

Abstract: Background: Exosome cargo proteins acutely predict the conversion of mild cognitive impairment (MCI) to Alzheimer's disease (AD), however the pathogenic potential of exosomes has yet to be fully elucidated. We recently reported neuronally-derived exosomes (NDEs) isolated from demented patients acutely (1m) induced AD-like neuropathology in normal mouse CNS. Here, we extended our previous studies to investigate the chronic neuropathological and behavioral consequences of plasma NDE cargo proteins *in vivo.*
Methods: Plasma exosomes derived from stable MCI patients and MCI converting to AD patients (ADC) were extracted, precipitated, and enriched against a neuronal source (L1-CAM) by fluorescent activated cell sorting (FACS) and characterized by Nanosight. Exosome preparations were injected unilaterally into normal mouse CNS and locomotor activity, anxiety, and spatial learning and memory was assessed 6m and 12m post-injection. Neuropathological changes were visualized by immunostaining at 3m, 6m, and 12m post-injection.
Results: We observed no signs of astrogliosis and microglioses however, pathological forms of tau, as measured by PHF1, and oligomeric amyloid beta (oAβ) as measured by 6E10, was observed bilaterally in the entorhinal cortex, hippocampus, and subcortical post-thalamic regions, at all three timepoints. Anxiety-like behavior was not observed, and normal locomotor activity was similar in all groups at all three timepoints. Spatial learning and memory deficits, as assessed by the Morris Water Maze, was observed in
MCI and ADC NDE-injected mice at 6m post-injection, with ADC NDE-injected mice exhibited worsening cognitive deficits as compared to controls. Surprisingly, at 12m post-injection, MCI and ADC NDE-injected mice performed similarly in all behavioral tasks as compared to controls. The attenuated cognitive decline may be a synergistic consequence of age, as demonstrated by degenerating cognition in the 12m control mice as compared to 6m control mice; and increased protein clearance of plasma NDE cargo proteins in MCI and ADC NDE-injected mice.
Conclusion: We are the first to report the pathogenic potential of plasma NDEs *in vivo*. Neural exosomes package and traffic toxic AD-related proteins to the blood where they mediate protein prorogation and induce learning and memory deficits in normal mouse CNS.

Title: Re-expression of differentiation factors in the neuronal DNA damage response: Alteration in tauopathies

Authors: *C. SCHIRMER, Y. DJENIDI, M.-L. REYNAERT, L. BUÉE, B. LEFEBVRE, M.-C. GALAS
UMR-S Inserm 1172, Lille cedex, France

Abstract: No treatments are currently able to effectively prevent the progression of tauopathies, such as Alzheimer's disease, which are the most common neurodegenerative diseases in the elderly. Therefore it is urgent to understand the early mechanisms involved in the etiology of these pathologies to highlight new therapeutical targets. Tauopathies are characterized by the aggregation of hyperphosphorylated forms of Tau protein into neurons. Tau is mainly described as a cytosolic protein involved in microtubules stabilization. However, Tau protein is also located in neuronal nuclei where its functions are still unclear. We previously demonstrated that, *in vivo*, nuclear Tau protects the integrity of neuronal DNA and that, in the Thy-Tau22 mouse model of tauopathy, Tau oligomerization alters its DNA protective function. Tau deletion-induced DNA damage is associated with an alteration of neuronal heterochromatin structure leading to aberrant genes re-expression which could participate to neurodegeneration. Our hypothesis is that the accumulation of neuronal DNA damage could activate the expression of genes playing a crucial role in differentiation. These factors would participate to the neuronal DNA damage response in mouse and human brain. We speculated that their expression could be regulated by Tau. By a combination of RT-qPCR, western blotting, and immuno-fluorescence analyzes we characterized, in N2A cells lines, in WT, KO-Tau and Thy-Tau22 mouse brains and in Alzheimer's brains the re-expression of essential differentiation genes in response to neuronal DNA damage. We also highlighted the deleterious effect of the deletion of Tau and pathological forms of Tau on their expression and functionality. Dysregulated expression of differentiation factors related to Tau-induced neurodegeneration opens the way for promoting efficient tau-based therapies in tauopathies.

Title: Prolyl oligopeptidase is a novel and critical regulator for protein phosphatase 2A

Authors: *T. T. MYÖHÄNEN, R. SVARCBAHS, U. JULKU, M. JÄNTTI
Univ. of Helsinki, University of Helsinki, Finland

Abstract: Background
Protein phosphatase 2A (PP2A) is the main phosphatase in mammalian cells. It is the key regulator of cell cycle but regulates also several kinases, proteins and receptors. Downregulation of PP2A has been connected e.g. to Alzheimer's disease, where it leads to Tau hyperphosphorylation and aggregation. This has made PP2A a tempting drug target but its complicated holoenzyme structure and strict regulation has made the development of PP2A activators difficult. Now, we have found that a serine protease, prolyl oligopeptidase (PREP), negatively regulates PP2A and that small-molecule PREP inhibitors or PREP deletion induces PP2A activity.
Methods
Protein-protein interactions were studied by protein-fragment complementation assay (PCA) in HEK-293 cells, using split Gaussian luciferase (hGluc) tagged constructs for PREP, PP2A catalytic subunit (PP2Ac), a PP2A endogenous inhibitor, protein phosphatase methylesterase 1 (PME-1) and an endogenous PP2A activator, protein phosphatase 2 activator (PTPA). KYP-2047 was used as a PREP inhibitor with concentrations of 1-10 µM. PP2A phosphatase activity assay was used to determine PP2A activity. Levels of PP2Ac/p(Y307)PP2Ac, PME-1, PTPA, regulatory subunit PPP2R2A (B55), p(S2448)mTOR/mTOR, p(T308)Akt/Akt and p(T183/T183/T221)JNK/JNK1+2+3 were determined by Western blot. Generation of PREP-knock-out HEK-293 cells (PREP-KO cells) and PREP-KO mouse have been described earlier. N=3-4 in all assays.
Results
In PCA assays, PREP showed interactions with PP2Ac, PME-1 and PTPA. After 4h PREP inhibition by 1-10 µM KYP-2047, the interaction between PP2Ac, PME1 and PREP was increased but interaction between PP2Ac and PME-1 reduced. In phosphatase assay, PREP inhibition significantly increased PP2A activity, and this was supported by significantly reduced p(Y307)PP2Ac and PME-1 levels. PREP inhibition elevated total PP2Ac, B55 and PTPA levels and dephosphorylated PP2A targets, such as mTOR, Akt and JNK, and PREP overexpression had opposite effects. p(Y307)PP2Ac and phosphorylation levels of several PP2A targets were reduced in PREP-KO cells and in the cortex of PREP-KO mouse.
Conclusions
Our current data shows that PREP regulates functions of both endogenous inhibitor PME-1 and endogenous activator PTPA via direct protein-protein interaction. PREP inhibition modulates these interactions, leading to PP2A activation. Our results with PREP-KO systems indicate that

this regulation is conserved and important for PP2A. When taking in account that PREP inhibition is considered safe even in clinical trials, our findings support the potential of PREP inhibitors as PP2A activators.

Title: Ubiquilin-2 regulation of tau and α-synuclein in neurodegenerative disease

Authors: *J. GERSON[1], S. S. PISTORIUS[2], J. WELDAY[1], L. M. SHARKEY[1], H. L. PAULSON[3]
[1]Neurol., [2]Neurosci., Univ. of Michigan, Ann Arbor, MI; [3]Prof, Neurol, Univ. of Michigan Dept. of Neurol., Ann Arbor, MI

Abstract: Protein dyshomeostasis is a common factor in the most prevalent age-related neurodegenerative diseases. The protein, ubiquilin-2 (UBQLN2), helps ensure protein homeostasis by shuttling ubiquitinated substrates to the proteasome for degradation and by modulating autophagy. UBQLN2 is implicated indirectly in various disorders, including tauopathies and synucleinopathies, due to its accumulation in neuropathological deposits. More recently, UBQLN2 has been directly connected as a cause of frontotemporal dementia when mutated, and our laboratory has linked the toxicity of UBQLN2 to its aggregation. To evaluate whether UBQLN2 regulates tau and α-synuclein expression, aggregation or clearance, we assessed levels of tau or α-synuclein in cells and compared results with UBQLN2 to highly homologous, UBQLN1, which is not robustly correlated with disease. The ability of UBQLN2 to regulate other common aggregate-prone disease proteins was also evaluated. Co-expressed UBQLN2 markedly lowered levels of α-synuclein and tau. Conversely, knockdown of UBQLN2 significantly elevated levels of α-synuclein and tau. In contrast, UBQLN1 did not exhibit the same ability to decrease tau and α-synuclein levels. Likewise, UBQLN2 selectively had an effect on levels of TDP43 and Huntingtin. UBQLN2 expression in mice also lowered levels of tau and α-synuclein. The possibility that UBQLN2 undergoes alterations in disease was evidenced by the

fact that more UBQLN2 was insoluble in human disease and transgenic mouse models of synucleinopathy and tauopathy than in controls, while UBQLN1 levels were highly variable across both control and disease samples. Our findings highlight a new role for UBQLN2—but not UBQLN1—in managing tau and α-synuclein levels. While UBQLN2 and UBQLN1 are highly homologous, our results suggest they are not simply redundant proteins and differences between the two ubiquilins may depend on domains unique to UBQLN2. However, lowered soluble UBQLN2 in disease brain suggests that UBQLN2 may be dysfunctional in synucleinopathies and tauopathies, due to its intrinsic aggregation or accumulation in disease aggregates.

Title: Activity-dependent release of human tau from transgenic *Drosophila* neurons

Authors: *S. K. ISMAEL[1], R. A. COLVIN[2], D. LEE[3]
[1]Biol. Sci., [2]Dept Biol. Sci., [3]Ohio Univ., Athens, OH

Abstract: Alzheimer's disease (AD) is the most prevalent neurodegenerative disease characterized by accumulation of extracellular amyloid plaques and intracellular neurofibrillary tangles (NFT), causing neuronal death. It is known that the tangles are composed of microtubule associated protein tau (MAPT), which is hyper-phosphorylated and aggregated. In recent years, an intriguing concept of prion-like spreading of pathogenic proteins such as tau has emerged. A prion-like mechanism involves the transfer of hyper-phosphorylated and/or aggregated tau between synaptically connected neurons, and underlies the seeding and spread of tau pathology. The first step to understand tau propagation between neurons is to study tau release from neurons. It is well known that disruption of neuronal activity is involved in AD pathogenesis. This finding is directly related to the fact that neuronal excitability increases at the early stage of AD as patients with mild cognitive impairment have shown hyperactivity in the hippocampus. Therefore, we asked whether stimulation of neurons increases 'toxic' tau release. *Drosophila* primary neuronal culture expressing human tau was used to develop a model system to study release of toxic tau, toxicity and propagation of human tau. We found human tau can be released into the media and this release was induced chemically by 50mM KCl depolarization. Additionally, intracellular calcium ion chelation reduced the amount of tau release while extracellular calcium chelation did not affect tau release in our system. We also utilized

optogenetic technique, which allows us to stimulate 'genetically targeted' neurons using blue light (470nm). In this experiment, we have expressed channelrhodopsin (ChR2) in fly neurons. Our results show that one-hour stimulation of neurons that express ChR2 by blue light is enough to induce tau release into the media. Taken together these results strongly support that tau release is activity dependent. *Drosophila* neurons showing activity-dependent release of tau can be an excellent model to study the role of tau toxicity and propagation in AD. Future studies aim to test the effect of different protein kinases on tau toxicity and release.

Title: Rna binding protein tia1 is involved in tau propagation and subsequent neurodegeneration

Authors: L. JIANG[1], P. ASH[1], H. BALLANCE[1], B. MAZIUK[1], S. BOUDEAU[1], L. PETRUCELLI[2], *B. L. WOLOZIN[1]
[1]Pharmacol, Boston Univ. Schl Med., Boston, MA; [2]Neurosci. Div., Mayo Clin., Jacksonville, FL

Abstract: Background: The pathophysiology of tauopathy appears to result from both intrinsic dysfunction of tau metabolism in neurons, as well as extrinsic propagation of aggregated tau among neurons. Recent studies point to pathological stress granules as a significant mechanism contributing to the accumulation of tau pathology in neurons. However, fundamental questions about tau propagation remain unclear, including whether the inclusions induced by propagated tau contribute to the neurodegeneration and whether propagated tau affects stress granule metabolism. We sought to answer these compelling questions by comparing induction of stress granules, tau aggregates and neurotoxicity among different pools of pathological tau.
Methods: *In vitro*, C57BL/6 primary hippocampal cultures were transduced with human wild type 4R0N or mutant P301L Tau via AAV, and then treated with S1p (oligomeric Tau) or P3

(fibrillary Tau) fractions purified from PS19 mice brain tissues. Neurotoxicity were detected by LDH assay, neuronal markers (MAP-2, SYP, NeuN) western blot and cell count. Tau aggregation was measured by tau phosphorylation markers PHF-1 and CP13, and stress granules were imaged with TIA1, eIF3 and PABP. *In vivo*, S1p and P3 fractions are stereotaxically injected into hippocampal CA1 of P301S/TIA1++ and P301S/TIA1+- mice, respectively, at 3-month old. Tauopathy, pathological stress granules and neuronal loss of entorhinal cortex were examined at 3 months after injection.
Results: Oligomeric (S1p) and fibrillary (P3) tau fractions induced similar amounts of tau aggregation after treatment. In contrast, only oligomeric Tau induced neurotoxicity, with treated neurons exhibiting a 5-fold increase in LDH level, and 40% decrease of neuron number in S1p treated cultures. Our previous studies demonstrated that RNA binding protein TIA1 co-localizes with tau inclusions during neurodegeneration in P301S mice. We proceeded to investigate the effects of TIA1 reduction by shRNA in primary neurons over-expressing 4R0N WT or P301L tau. Interestingly, TIA1 reduction reduced the accumulation of tau aggregates and subsequent neuronal loss. These results were confirmed *in vivo*. We observed 30% rescue of neurons in entorhinal cortex of P301S::TIA1+/- compared to P301S::TIA1+/+ mice, which has a 48% neuronal loss after S1p injection.
Conclusions: Our findings suggest that oligomeric tau is more toxic than the fibrillar tau, and that the tau-induced neurotoxicity was unrelated to levels of tau aggregates in tauopathy neurons. Finally, TIA1 reduction appears to play a protective role in oligomeric tau propagation and subsequent neurotoxicity.

Title: Mitochondrial trafficking and clearance in tauopathies

Authors: *V. BHARAT, X. WANG
Dept. of Neurosurg., Stanford Univ., Palo Alto, CA

Abstract: Mitochondria are an essential organelle supporting a wide range of cellular functions by producing ATP, maintaining Ca^{2+} homeostasis, generating reactive oxygen species and signalling apoptosis. Defects in mitostasis - maintaining healthy mitochondria - in neurons has been implicated in the pathogenesis of many neurodegenerative diseases, including tauopathies which includes Alzheimer's disease (AD), frontal temporal lobar degeneration and parkinsonism

(FTLDP), progressive supranuclear palsy (PSP), corticobasal degeneration (CBD) and Pick's disease (1,2). The outer mitochondrial membrane protein, Miro, helps in anchoring mitochondria to microtubule motors for motility and is also removed to stop motility in order to facilitate mitophagy. Recently, we have found a cellular defect in removing Miro protein from damaged mitochondria in skin fibroblasts of Parkinson disease (PD) patients. This defect can delay damaged mitochondrial clearance, causing energy shortage and oxidative stress, and consequently lead to neurodegeneration in neurons (3). Here we discovered the failure to remove Miro from damaged mitochondria in additional PD fibroblast lines which harbour mutations in MAPT gene encoding tau protein. This result suggests that mutant tau protein affects Miro removal from depolarized mitochondria and consequently interrupts mitophagy. Proving the functional relevance of mitochondrial transport and mitophagy in tauopathies, we discovered impaired mitochondrial trafficking in a human neuron model of Alzheimer's disease. Our work links tauopathies to mitochondrial transport and mitophagy in neurons and provides novel targets for therapeutic intervention.

Title: Deficits in nonsense-mediated RNA decay contribute to neurodegeneration in tauopathy

Authors: *G. ZUNIGA, G. CORNELISON, B. FROST
Cell Systems and Anat., UT Hlth. San Antonio, San Antonio, TX

Abstract: Cells utilize the nonsense mediated RNA decay (NMD) pathway for post-transcriptional control of gene expression and degradation of aberrant RNA that could otherwise encode potentially toxic proteins. Preliminary data suggests that transgenic expression of pathogenic tau, a protein that accumulates in Alzheimer's disease and related "tauopathies," promotes neurodegeneration by increased nuclear export of polyadenylated RNA through nuclear envelope invaginations in *Drosophila* and human tauopathy. These invaginations

penetrate deep into the nuclear interior and may protect RNAs from NMD by sequestering RNA away from NMD machinery. We have performed bioinformatic analysis of the transcriptome in tauopathy, which points toward a role for NMD in shaping the transcriptome in *Drosophila*, mouse, and human tauopathy. We find that genetic manipulation of NMD machinery significantly modifies tau-induced neurotoxicity in *Drosophila*, suggesting a causal role for reduced clearance of RNA by NMD as a driver of tau-induced neurodegeneration. We have used fluorescent *in situ* hybridization to examine the relationship between nuclear envelope invaginations, polyA RNA, and NMD machinery, and to determine if reduced clearance of RNAs by NMD may be in part due to physical barriers between polyA RNA and NMD machinery. We are currently utilizing an NMD-sensitive reporter to further investigate the extent of RNA clearance by NMD in *Drosophila* models of tauopathy, and to determine if reduced clearance of RNA by NMD is age-dependent. Our preliminary studies suggest a critical role for NMD in safeguarding the transcriptome and preventing accumulation of RNA transcripts that contribute to neuronal death in tau transgenic *Drosophila.*

Title: Tauopathy associated PERK alleles increase neuronal vulnerability to ER stress via loss of function

Authors: *S. H. YUAN[1], N. HIRAMATSU[2], Q. LIU[3], X. SUN[2], D. LENH[3], P. CHAN[2], K. CHIANG[3], E. H. KOO[4], A. KAO[5], I. LITVAN[6], J. H. LIN[2]

Abstract: Tauopathies are neurodegenerative diseases defined by misfolded hyperphosphorylated tau protein deposits as neurofibrillary tangles (NFT) in the brain.

Endoplasmic reticulum (ER) stress has been implicated in neurodegenerative diseases including tauopathies; however the mechanism is still not clear. *EIF2AK3 (eukaryotic translation initiation factor 2 alpha kinase 3)*, also known as *PERK* (*protein kinase R-like endoplasmic reticulum kinase*), was identified as a genetic risk factor in tauopathies and Alzheimer's Disease (AD) in genome-wide association study (GWAS). The risk single nucleotide polymorphism (SNP) identified in GWAS, rs7571971, is in the same haplotype (haplotype B), which includes three exonic SNPs: S136C, R166G, and S704A. We hypothesized that the SNPs in haplotype B altered normal PERK function; therefore, increased the risk for neurodegeneration. We found that tauopathy-associated *PERK* alleles showed reduced activity in response to ER stress due to decreased kinase activity and increased instability. The human patient induced pluripotent stem cells (iPSC) derived neurons carrying *PERK* risk alleles were highly vulnerable to ER stress-induced injury and were associated with increased tau and p-tau level. Furthermore, iPSC derived neurons carrying normal PERK alleles were susceptible to ER stress and tau protein pathology when treated with PERK inhibitor. Our results suggest that impaired PERK activity sensitizes neurons to ER stress and may underlie the increased risk for neurodegenerative tauopathies. These findings may have implications on designing personalized therapeutics and clinical trials in patients with tauopathy.

Title: Higher-order polyamines and ssat ablation impacts the tau neuropathology

Authors: L. SHELTON, L. SANDUSKY, M. WATLER, A. KOVALENKO, J. B. HUNT, Jr., M.-L. B. SELENICA, *D. C. LEE
Col. of Pharm. & Pharmaceut. Sci., USF Byrd Alzheimer's Inst., Tampa, FL

Abstract: Tauopathies comprise of an increasing spectrum of neurodegenerative disorders, in which no disease modifying therapies exist. Although tau is disordered, its recognized function

consists of stabilizing microtubules in support of neuronal function, yet simple modifications to tau promote neuropathology. Current targeted approaches include posttranslational modifications, activating clearance, aggregation inhibitors, and microtubule stabilizing agents, among others. Polyamines (PA) control growth, support neuronal function, axonal integrity and interact with macromolecules electrostatically and covalently promoting different cellular effects. Polyamines harbor positively charged (+2, +3, +4) nitrogen atoms at physiological pH, which make them "supercations"; yet they distribute the charge along the entire length of the carbon chain permitting unique and distinct bioactive moieties. This intrinsically changes protein, DNA, RNA, and macromolecule folding dynamics. We identified a unique interaction between polyamines and tau biology. Higher-order polyamine (longer chain length) inhibits tau fibrillization and also stabilizes microtubules. Conversely, acetylated (inactive) polyamines fail to inhibit tau and can promote aggregation. Acetylated polyamines also fail to facilitate microtubule polymerization. Using gene therapy approaches that promote prosynthetic polyamine enzymes that endorse higher-order polyamines and genetic knockout models that prevent accumulation of acetylated polyamines, we find that many components of the tau phenotype are reversed in mice. Several models of tauopathy induce spermidine spermine N-acetyl transferase (*SSAT*) and the accumulation of acetylated polyamines, we refer to as the tau-polyamine stress response (tau-PSR). However, *SSAT* ablation mitigates the PSR signature, and reduces acetylated polyamines. Additionally, mice with tauopathy sequester acetylated polyamines in cells but them following increased neuronal activity compared to non-transgenic littermates. Our data signifies an unrecognized crosstalk between the polyamine system and tau neurobiology. Identifying limited entry points within the polyamine system might subvert some components of the tau phenotype and provide therapeutic strategies for tauopathies.

Title: The mechanism of tau oligomer internalization

Authors: *N. PUANGMALAI, G. GHAG, M. MONTALBANO, N. BHATT, S. MCALLEN, A. ELLSWORTH, R. KAYED
Neurol., Univ. of Texas Med. Br., Galveston, TX

Abstract: The microtubule binding protein, tau, aggregates pathologically into neurofibrillary tangles during Alzheimer's disease (AD). A smaller, soluble aggregate of tau known as oligomers, are comprised of a heterogeneous group of biochemically and structurally distinct aggregates. Tau oligomers have been shown by our lab and others to be toxic and self-propagate by seeding endogenous tau. Several studies have also shown that tau oligomers will propagate from cell-to-cell along anatomical connections. In addition, tau oligomers have been shown to be internalized while large fibrils are not efficiently taken up into a cell. Tau forms different aggregates which display distinct conformation (strains), the mechanism for internalization of these strains remains to be elucidated. Thus, we investigated three potential mechanisms for the internalization of recombinant and brain-derived seeded tau oligomers using primary mouse neuron cultures. Using a variety of cell imaging and toxicity measurements in combination with commercial internalization inhibitors for clathrin, caveolae, and macropinocytosis, we studied the mechanisms of exogenous tau oligomer internalization. We were able to observe the internalization of recombinant tau oligomers and attenuate tau oligomer uptake with inhibitors of clathrin-mediated endocytosis. Further, tau oligomers prepared with AD brain-derived tau oligomers showed a consistent mechanism of internalization. In determining the mechanism by which tau oligomers enter naïve cells, especially neurons, we can discover novel drug targets. Disrupting the spread of tau may stop disease progression by preventing the spread of toxicity, inflammation, and synapse loss that lead to cognitive decline in AD and related tauopathies. In addition, tau oligomeric strains may have strain specific internalization mechanisms which will influence their toxicity and ability to spread. This may explain the individual and disease-specific patterns of progression as well as rate of progression.

CA; [2]Inst. of Chemistry, Univ. of Duisburg-Essen, Essen, Germany; [3]Brain Res. Institute, Univ. of California, Los Angeles, Los Angeles, CA; [4]Mol. Biol. Institute, Univ. of California, Los Angeles, Los Angeles, CA

Abstract: Tau self-assembly into neurotoxic oligomers and fibrils underlies the pathophysiology in tauopathies. Molecular tweezers (MTs) act as unique, artificial nanochaperones and are the first small molecules whose activity as modulators/inhibitors of abnormal protein self-assembly has been discovered using a rational approach. Previously, we evaluated the effect of a lead MT, called CLR01, in the 3×Tg mouse model, which overexpresses mutant human PS1(M146V), APP(KM670/671NL), and tau(P301L). Immunohistochemistry (IHC) showed 30-50% reduction of amyloid plaques, neurofibrillary tangles, and microgliosis. Because tau hyperphosphorylation is downstream of Aβ insults, the question whether CLR01 affected tau directly or indirectly remained open. Therefore, we asked if CLR01 could be used for treatment of tauopathies in the absence of amyloid pathology and set up to answer this question using the P301S-tau mouse model. The study included 5 groups of mice, each comprising 8 males and 8 females. The treatment groups included three Tg groups, administered 0, 0.3, or 1.0 mg/kg per day CLR01 and two wild-type littermate groups receiving 0 or 1.0 mg/kg per day CLR01. CLR01 was administered for 35 days via osmotic minipumps implanted subcutaneously at 6-6.5 months of age. The mice were weighed out and grip-strength and open field tests were performed in the beginning, middle (grip-strength only), and end of the treatment. No adverse effects were observed in any of the groups. CLR01 prevented a decline in grip-strength observed in vehicle-treated Tg mice. However, Tg mice did not show deficits in any open-field test precluding evaluation of drug effect. Following completion of the treatment, the mice were sacrificed and the brains were collected and divided into the two hemispheres. One hemisphere was fixed and sectioned for IHC analysis and the other was dissected into regions of interest. Brain regions were snap-frozen and extracted into soluble, membrane-bound, and insoluble fractions. Analysis of seeding activity, phosphorylation, and oligomerization of tau is underway. Initial results show that CLR01 treatment reduced hyperphosphorylated tau and astrocytosis compared to control, suggesting target engagement and beneficial therapeutic effect.

Title: Inherited tauopathy mutation alters the interaction between tau and protein phosphatase 1

Authors: *B. COMBS[1], K. CHRISTENSEN[1,2], C. RICHARDS[1], N. M. KANAAN[1,2,3]
[1]Col. of Human Medicine, Translational Sci. and Mol. Med., Michigan State Univ., Grand Rapids, MI; [2]Neurosci. Program, Michigan State Univ., East Lansing, MI; [3]Hauenstein Neurosci. Ctr., Mercy Hlth. St. Mary's, Grand Rapids, MI

Abstract: The tau protein is implicated in a variety of neurodegenerative disorders characterized by progressive degeneration of axons and neurons closely associated with pathologically-modified forms of the tau protein. The majority of the cases are sporadic but an important subset is caused by mutations within the tau gene, collectively these are known as frontotemporal dementia with parkinsonism linked to chromosome 17 (FTDP-17). Due to the highly toxic nature of these mutations they are often used to model tau dysfunction but the mechanisms of the toxicity remain poorly understood. By identifying the effect of mutant tau we hope to better understand toxic mechanisms engaged by pathological tau in sporadic and inherited tauopathies. Several lines of evidence link tau toxicity to disruptions in axonal transport that may induce degeneration of axons, a common and early hallmark of disease. Previously, we showed that conformation changes in pathological tau activate a protein phosphatase 1 (PP1) and GSK3β signaling cascade that inhibits axonal transport in the squid axoplasm but exactly how tau engages this pathway remained unknown. We hypothesized that FTDP-17 mutations enhanced the tau-PP1 interaction and activation of PP1. To study this, we used WT full-length tau and a P301L mutant version of the protein to determine the nature of tau's interactions with the PP1 gamma isoform by using pulldown assays and bioluminescence resonance energy transfer (BRET) assays. We also used phosphatase activity assays to examine the effects of tau on PP1 enzymatic activity in vitro and from mammalian cell lysates. We found that tau directly interacts PP1 while the P301L mutation significantly enhanced the interaction. We also found that tau increases PP1 phosphatase activity but no significant differences existed among WT and P301L tau. Ongoing studies are evaluating the effects of WT and P301L tau on transport in primary rat hippocampal neurons. The results presented here support a direct interaction between tau and PP1 that can enhance phosphatase activity. This may have direct implications in tau-mediated axonal transport disruption and suggests some FTDP-17 mutations may confer toxicity through altering tau's interaction with PP1.

Abstract: ABSTRACT
Aims: Chronic traumatic encephalopathy (CTE) is a progressive neurodegenerative disease thought to be caused by repetitive traumatic brain injury (TBI) and sub-concussive injuries. While hyperphosphorylation of tau (p-Tau), which is attributed to astrocytic tangles (ATs) and neurofibrillary tangles, are known to be involved in CTE, there are limited neuropathological or molecular data. By utilizing repetitive mild TBI (rmTBI) mouse models, our aim was to examine the pathological changes of CTE-associated structures, specifically the ATs.
Results: Our rmTBI mouse models showed symptoms of depressive behavior and memory deficit, alongside an increased p-Tau expression in their neurons and astrocytes in both the hippocampus and cortex. rmTBI induced oxidative stress in endothelial cells and NO generation in astrocytes, which were mediated by hypoxia and increased HIF1α. There was also a correlated decreased regional cerebral blood flow, mild activation of astrocytes and NFκB phosphorylation, increased expression of inducible nitric oxide synthase (iNOS), increased endothelial nitric oxide synthase (eNOS) uncoupling with decreased tetrahydrobiopterin, and increased expression of nitrotyrosine, Nox2/Nrf2 signaling proteins. Combined, these effects induced peroxynitrite formation and hyperphosphorylation of tau in the hippocampus and the cortex towards the formation of ATs.
Innovation: Our model features molecular pathogenesis events of CTE with clinically-relevant latency periods. In particular, this is the first demonstration of an increased astrocytic iNOS expression in an in vivo model.
Conclusion: Our results propose a novel mechanism of uncoupled eNOS and NO contribution to Tau phosphorylation and AT formation in rmTBI brain, and contribute towards an increased

molecular understanding of the pathophysiology of human CTE (NRF-2016M3C7A1905074, 2016R1A2B4009409

Abstract: Tauopathies are a family of neurodegenerative diseases characterized by abnormal regulation of the microtubule-associated protein tau. It is thought that hyperphosphorylation of tau causes it to mislocalize from the axon to dendritic spines, where it can cause internalization of glutamatergic receptors and, consequently, cognitive deficits. The P301L mutation in tau is the most common mutation underlying familial tauopathies. To study the pathogenic effects of P301L tau in the mammalian brain, we generated two genetically matched transgenic mouse lines harboring a single copy of a Tet-Off regulatable human tau transgene containing exon 10 (E10). Importantly, the transgene is located in a non-disruptive genomic locus, outside of the coding regions of endogenous genes. These mouse lines express E10 tau in forebrain excitatory neurons either with (rT2) or without (rT1) the P301L mutation. Unexpectedly, we observed cognitive deficits in rT1 mice but not rT2 mice at five months of age. This led us to hypothesize that E10 tau without the P301L mutation is pathogenic during development. At eight weeks of age we observed higher levels of tau in rT1 than rT2 mice, explained by a slower clearance rate of E10 tau without the P301L mutation, especially in the biochemically isolated postsynaptic fraction. We also observed that at eight weeks of age, tau in rT1 mice was hyperphosphorylated compared to rT2 mice at sites previously shown to be necessary for tau's pathogenic effects at dendritic spines. To support the idea that E10 tau may indeed cause internalization of glutamatergic receptors in spines, we have shown that within the postsynaptic fraction E10 tau

without the P301L mutation is hyperphosphorylated compared to E10 tau with the P301L mutation. These findings indicate that E10 tau with and without the P301L mutation can be toxic via distinct pathways: 1) without the P301L mutation E10 tau is toxic during development, whereas 2) the P301L mutation is associated with aging-related tauopathy. Indeed, we have shown that by eight months of age, rT2 mice develop cognitive deficits while rT1 deficits remain unchanged. These distinct pathogenic pathways of tau may be explained by enhanced binding of E10 tau to microtubules, a quality lost with the P301L mutation. Future experiments will test whether this is the case, and whether suppressing human tau expression during development ameliorates the rT1 phenotype. This work is important to understand the molecular phenotypes associated with different forms of tau, and reveals abnormal dynamics of E10 tau including a slowed clearance rate and hyperphosphorylation observed at a young age.

Title: Retinal degeneration in PS19 tau transgenic mice

Authors: P. CHAN[1], K. CHIANG[2], N. HIRAMATSU[3], A. P. CHEN[1], E. H. KOO[2], *J. H. LIN[1,4]

Abstract: Tau overexpression in the central nervous system has obvious deleterious effects on both spinal cord and brain, however its effect on the optic nerve and the retina is less clear. PS19 tau transgenic mice, which overexpress the human 1N4R tau isoform bearing a P301S mutation, were previously shown to express abundant levels of pathological hyperphosphorylated tau in the optic nerve and retinal ganglion cells. Furthermore, increased dystrophy was present in the optic nerve axons of PS19 mice as compared to wild-type controls. In this study, we performed

electroretinography (ERG) tests, spectral domain optical coherence tomography (SD-OCT), and histology to further characterize the retinal structure and function of aged PS19 mice. ERG showed that aged PS19 mice displaying motor symptoms exhibited reduced photopic and scotopic responses, with scotopic a- and b-wave amplitudes at lower intensities showing the greatest decreases compared to wild-type mice. SD-OCT analysis demonstrated decreased retinal thickness and increased frequency of retinal detachment in PS19 mice compared to age-matched controls. Retinal histology was performed to assess photoreceptor degeneration, levels of tau and hyperphosphorylated tau, and activation of glial cells. Western blotting and qPCR analyses of brains and retinas showed no changes in levels of the ER chaperone, BiP/Grp78, or induction of PERK in PS19 mice compared to controls In conclusion, PS19 mice exhibit surprisingly severe retinal degeneration whie ER stress-induced markers were not detected in diseased retinas.

Title: Investigating how tau overexpression in the retina of a triple repeat tau transgenic mouse model impacts visual-spatial learning

Authors: *J. NGOLAB[1], E. M. ROCKENSTEIN[1], M. MANTE[1], J. B. FLORIO[1], J. GRUNDMAN[1], N. NANDANKAR[1], E. MASLIAH[1,2], R. A. RISSMAN[1,3]

Abstract: Symptoms of visual impairment usually precede cognitive symptoms in patients with dementia such as Alzheimer's Disease (AD). Thinning of the retinal fiber layer along with deposits of amyloid beta and hyper-phosphorylated tau, pathological hallmarks of AD, in the retina of AD patients suggest impairment may occur at the level of the retina. However, it is unclear how either amyloid beta or tau affects retinal function. Abnormal levels of phosphorylated tau and decrease of total tau have been observed in the inner plexiform layer (IPL) in the retinas of glaucoma patients, suggesting that dysregulation of tau expression may play a role in visual impairment. To understand the role of tau overexpression in the visual pathway, we utilized a transgenic mouse line overexpressing three-repeat tau (3R tau) at different ages: 3 months, 6 months, 9 months and 12 months. Visual-spatial learning was measured in both 3R tau and non-transgenic littermates by performance in the visual probe trial of the Morris Water Maze. Histological analysis of the outer nuclear layer of the retina and expression of

3RTau was assessed through immunohistochemistry. 3R tau mice at 6 months of age took longer to locate the platform in the visual probe trial of the Morris Water Maze compared to non-transgenic mice. There were no differences in outer nuclear layer (ONL) thickness between wildtype and transgenic mice, suggesting 3R tau overexpression does not induce photoreceptor degeneration. However, 3R tau expression in the retina was observed through immunohistochemical analysis as early as 3 months, mainly in the ganglion cell layer (GCL) and the IPL. Expression of 3R tau precedes visual impairment in 3R tau mice. It is possible that early 3R tau expression may alter vision processing at the level of the IPL. The IPL is a stratified structure that houses synapses of the multiple retinal cell types responsible for processing vision. Further investigation into tau expression the IPL may provide further insight into the molecular mechanism of visual impairment and retinal pathology in tauopathies.

Title: Discharge and synaptic input profiles of striatal neurons in models of neurodegenerative disease

Authors: *M. MO[1], M. A. MATHEWS[4], D. JOHNSTONE[2], A. J. CAMP[3]
[1]Univ. of Sydney, Camperdown, Australia; [2]Univ. of Sydney, University of Sydney, Australia; [3]Univ. of Sydney, Sydney University, Australia; [4]USYD, Camperdown, Australia

Abstract: *Objective*: Many neurodegenerative tauopathies lack validated animal models. In order to validate animal models it is necessary to understand the impact on individual neurons in affected brain regions. Here we compared electrophysiological properties of striatal neurons of wildtype mice with an existing transgenic model of Pick's disease (K3 mice) and an occasional Parkinson's model, rotenone injected mice.
Methods: All experiments were approved by the Animal Ethics Committee of the University of Sydney. The electrophysiological discharge properties (n = 55) and synaptic input properties (n = 5) of mouse striatal neurons were characterized in three experimental groups; *wildtype* mice (n= 27), K3 transgenic mice (n= 16), and rotenone-treated mice (n= 12), all on the C57BL/6 background. Recordings were made from coronal slices (200 μm) distributed evenly across the entire striatum in whole-cell current-clamp and voltage-clamp mode at room temperature. Voltage-clamp recordings to interrogate synaptic input profile were carried out under pharmacological blockade using known excitatory and inhibitory receptor blockers.

Results: The proportion of striatal neuron discharge profiles in *wildtype* mice was significantly altered when compared with the K3 transgenic and rotenone- treated groups (p= 0.006). In general this alteration was characterized by a shift towards burst firing discharge profiles in the K3 transgenic and rotenone treated mice. Further, both the K3 transgenic, and rotenone treated mice showed significantly higher subthreshold EPSP activity at rest (p= 0.03). The passive membrane properties including input impedance and capacitance of striatal neurons were not significantly different between the three mouse groups. Preliminary results suggest that the synaptic input profile of striatal neurons is predominantly excitatory in nature.
Conclusion: Neurons in the striatum of K3 transgenic mice display a hyper-excitable state that can be mimicked at least in part by injection of rotenone.

Title: Zebrafish proteinopathy models for target validation

Authors: J. M. HUBBARD, N. RIBEIRO PALHA, A. DEKEYNE, W. BOUCHERON, N. ROGEZ, S. VEIGA, R. BILLIRAS, V. PASTEAU, S. CAIGNARD, S.-P. GUENIN, A. FRANCOIS, *E. SCHENKER, R. JEGGO
Inst. de Recherches Servier, Croissy Sur Seine, France

Abstract: Accumulation and toxic gain of function of misfolded protein assemblies, such as α-synuclein and Tau, are major pathological features of Parkinson's and Alzheimer's disease, respectively. The IMPRiND project aims to map critical steps in the aggregation and propagation of these misfolded proteins. To address these features, Servier is developing zebrafish models for the stable expression of human wild type and mutated variants of α-synuclein and Tau. Zebrafish models are well poised to bridge the gap between *in vitro* models and traditional *in vivo* rodent models, providing an *in vivo* vertebrate system amenable to accelerated throughput. To generate the stable transgenic animals, we designed plasmids for the overexpression of these proteins in zebrafish motor neurons and use biochemical, imaging and electrophysiological based approaches to characterize the lines. Plasmids were individually injected into embryos at the single cell stage and subsequently integrated into the zebrafish genome resulting in stable transgenic zebrafish overexpressing human Tau and α-synuclein protein. Transgenic animals underwent biochemical evaluation to assess Tau and α-synuclein expression levels and the

presence of pathogenic aggregates. The coexpression of either Tau or α-synuclein with GFP allows for the analysis of changes in neuronal morphology due to the presence of these proteins. We are optimizing throughput for live fluorescence imaging of zebrafish larvae *in vivo* by coupling a microfluidics device to a confocal microscope. With this system, individual fish are shuttled into an imaging capillary and automatically positioned prior to image acquisition. Once the images are acquired, the 3D neuronal structure is reconstructed. Axon length and branching can subsequently be quantified and with the addition of a fluorescent postsynaptic marker it is possible to quantify synapse number and size. These metrics will be used to assess the effect of the presence of pathogenic protein aggregates. To characterize functional consequences of wild type and mutant Tau and α-synuclein overexpression, we are investigating their effects on synaptic transmission electrophysiologically. Whole cell patch clamp recordings of postsynaptic muscle fibers and presynaptic motor neurons are employed to quantify changes in neurotransmitter release properties. We present our progress for the development of zebrafish proteinopathy models, focusing on Tau. Altogether, these zebrafish proteinopathy models aim to provide a means by which we may accelerate the screening of therapeutic molecules in vivo and validate new targets generated through the IMPRiND consortium.

Title: Expression change of lipocalin-2 and BIM in ischemic cerebral protection induced by remote preconditioning

Authors: *C. REN[1], M. LIU[2], J. CHEN[2], S. ZHANG[2]
[1]Neurol., Shanghai Dongfang Hospital,Tongji Univ., Shanghai, China; [2]Shanghai No. 5 Hospital, Fudan Univ., Shanghai, China

Abstract: Objective: Our study focused on observing whether RPC was capable of regulating the expression level of LCN2 and BOCT in ischemic, and whether the expression level of the corresponding downstream molecule Bim would be affected. **Methods:** 1, male SD rats (weight between 270 and 330 grams) were randomizedly divided into ICS groups and RPC groups, with each group included five subgroups: sham control, 6 h, 24 h, 48 h, 72 h. Rats in ICS group were treated with focal cerebral ischemia, while rats in RPC group were treated with RPC before receiving focal cerebral ischemia. 2, TTC staining: The core area and salvage area was defined according to the results of the TTC staining. 3, Western blot analysis was used to determine the expression level of LCN2, BOCT, and Bim protein in the brain tissue.. 4, immunofluorescence staining method was used to detect the colocalization of LCN2 with GFAP, BOCT with NeuN, Bim with NeuN. DAPI staining was used for location of the nucleus. **Results:** 1. TTC staining showed that cerebral infarction area could be decreased by RPC($P<0.05$). 2, RPC downregulated the expression levels of LCN2 after cerebral ischemia at the time point of 24 h($P < 0.05$) and 72 h($P < 0.05$), shown by western blot analysis result. The double immunofluorescence staining results further indicated that the RPC could reduce the number of LCN2-positive astrocytes ($P < 0.01$) at all time points, indicating that the RPC could downregulate the expression of LCN2 by astrocytes after cerebral ischemia. 3, the western blot analysis results indicated RPC had no obvious regulation effect on BOCT expression, except the time point of 72 h. Double immunofluorescence staining results further indicated that the RPC had no obvious regulation on the number of BOCT-positive neurons after cerebral ischemia except the time point of 72 h. 4, The western blot analysis result showed that RPC could downregulate the expression levels of Bim after cerebral ischemia at the time 6 point of 24 h ($P < 0.05$).Double immunofluorescence staining results further indicated that RPC could decrease the number of Bim-positive neurons after cerebral ischemia ($P < 0.01$) at all time points, indicating that the RPC can downregulate the expression of Bim neurons after cerebral ischemia. **Conclusion:** Our research results showed that the RPC could reduce the production of LCN2 astrocytes after cerebral ischemia, while having no obvious regulation on BOCT expression except at the time point of 72 h. We further found RPC could downregulate the expression level of Bim in neurons after cerebral ischemia. Our results speculated that downregulation of LCN2 and Bim by RPC may be one of the neuroprotection mechanisms of RPC exerted after ICS.

Title: Proteomic study to uncover neuroprotective mechanisms linked to ischemic preconditioning in rat hippocampus

Authors: *A. TOMASCOVA[1], Z. TATARKOVA[1], D. KALENSKA[1], B. TÓTHOVÁ[2], J. LEHOTSKY[1]
[1]Dept. of Med. Biochem., Jessenius Fac. of Med., Martin, Slovakia; [2]Biomed. Ctr. Martin, Jessenius Fac. of Med., Martin, Slovakia

Abstract: OBJECTIVES: Global ischemic brain injury, for example as a result of cardiac arrest, is among the most common causes of disability and mortality worldwide, and so there is constant effort to find effective neuroprotective strategy. One of the highly studied approaches of improving an outcome of ischemic damage is an endogenous mechanism of neuroprotection called ischemic tolerance. Ischemic tolerance following exposure to brief period of ischemia near to but below the threshold of damage is known as ischemic preconditioning. Such preconditioned tissue then develops a resistance to similar noxious stimuli. Preconditioning is an attractive experimental strategy to identify endogenous protective mechanisms that can be therapeutically induced or supplemented.
MATERIALS AND METHODS: Adult male Wistar rats were randomly divided into control, ischemia-reperfusion (IR) and preconditioned (IPC) groups, 5 animals per group. Global ischemia was induced by 15 min of standard 4-vessel occlusion followed by 24-hour reperfusion. Preconditioning was induced by 5 min ischemic insult 48 hours prior to global ischemia. Proteomic analysis of rat hippocampus homogenates was carried out by 2D-gel electrophoresis with protein identification on matrix-assisted laser desorption/ionization time-of-flight mass spectrometer (Bruker Daltonics, USA).
RESULTS: In total, 273 proteins were detected and 33 identified as significantly changed in IPC group when compared to control and IR group. Deregulated expression manifested particularly molecular chaperones, mainly high overexpression of stress inducible Heat Shock 70kDa Protein 1. Over twofold downregulation was observed in expression of Peroxiredoxin 5 and 6 linked to cellular redox state, and Isocitrate Dehydrogenase and Succinate Dehydrogenase. Upregulated were proteins involved in glutamine metabolism - Glutamine Synthetase and Glutamine Dehydrogenase, and proteins of energy metabolism ATPsynthase subunit β and

glycolytic α-enolase, γ-enolase and Glyceraldehyde-3P Dehydrogenase.
CONCLUSION: Proteomic analysis of preconditioned rat hippocampus showed modified regulation in different metabolic pathways and higher sensitivity to changes in overall redox state. Upregulation in proteins handling glutamate metabolism implies for utilization of alternative energy sources. Moreover, upregulation in enolase isoenzymes suggest connection to hypoxic tolerance and neuroprotection.

Title: Ischemic preconditioning induces cortical microglial proliferation and a transcriptomic program of cell cycle activation

Authors: *A. MCDONOUGH, S. NOOR, R. DODGE, III, J. S. STROSNIDER, J. SHEN, T. LE, J. R. WEINSTEIN
Dept. of Neurol., Univ. of Washington, Seattle, WA

Abstract: Stroke is the 5th leading cause of death in the United States and the leading cause of long-term disability. Progress in the development of effective therapies for acute stroke has been limited and centered on neuronal preservation despite extensive and robust data implicating glial cells, including microglia, in the pathophysiology of ischemic injury. Although microglial activation was once considered to be a strictly pro-inflammatory process, recent studies indicate that microglia can also have a protective function in stroke. Ischemic preconditioning (IPC) in the CNS is a brief period of ischemia that confers robust neuro- and axonal- protection against subsequent prolonged ischemic injury. Elucidating the mechanisms of IPC-mediated protection is widely considered a promising avenue for stroke research. Previously we characterized a robust interferon-stimulated gene signature as a hallmark response to IPC in acutely isolated cortical microglia. Here we report a distinct but equally striking finding from our microglial genomic profiling dataset: the transcriptomicresponse of cortical microglia to IPC is dominated by marked up-regulation of genes involved in cell cycle activation, DNA replication and cell proliferation. In the course of performing these experiments, we noted a significant increase in the number of microglia isolated from the preconditioned cortex. Here we demonstrate using

immunofluorescent microscopy and quantitative stereology that this observed increase is not an artifact of flow cytometry, but reflects *in situ* microglial responses to IPC. The response includes robust proliferation and marked morphological changes in the microglia, even in the absence of cortical infarction. Furthermore, the increase in microglia can be accounted for entirely by a population of cells expressing a proliferative marker (BrdU, Ki67). We also examined microglial proliferation after IPC within two transgenic mouse models: 1.) mice lacking type I interferon receptor (IFNAR1), which we and others have previously reported as necessary for IPC-mediated protection, and 2.) mice with haploinsufficiency for the CX3CL1 (fractalkine) receptor CX3CR1. Based on these studies, we conclude that IPC-induced microglial proliferation is independent of type I interferon signaling, but dependent on fractalkine signaling. Results from this work will refine our understanding of the mechanisms of IPC-mediated endogenous protection and guide our choice of cellular and molecular pathways to study in the development of future stroke therapies.

Title: Neuroprotective effects of oxidative preconditioning against apoptosis induced by H2O2 in differentiated neuroblastoma SH-SY5Y cells

Authors: *R. AKKI[1], R. SIRACUSA[2], R. MORABITO[2], A. REMIGANTE[2], M. CAMPOLO[2], M. ERRAMI[3], S. CUZZOCREA[2], A. MARINO[2]
[1]Fac. of Sciences, Univ. Abdelmalek Essaadi, Tetouan, Morocco; [2]Chemical, Biological, Pharmaceut. and Envrn. Sci., Fac. of sciences, Univ. of Messina, Messina, Italy; [3]biology, Fac. of sciences, Univ. Abdelmalek Essadi, Tetouan, Morocco

Abstract: Background: Oxidative stress plays a role in age-related pathologies such as neurodegenerative diseases, cancer and ischemic stroke. Generally, high levels of oxidative stress are associated with cell damage during ischemic insults. However, a slight rise of reactive oxygen species (ROS) levels can be protective developing a resistance against subsequent challenges in "preconditioning" cells. Therefore, the aim of the study is examine how differentiated neuronal–like SH-SY5Y cells may be adapted to a mild and transient H_2O_2-induced oxidative stress.

Methods: The neuroprotective effects of preconditioning (PC) with hydrogen peroxide against oxidative stress induced ischemic-like damage were examined in neuronal like differentiated SH-SY5Y cells. The Cells were pretreated with mild-concentration H_2O_2 (10 µM -50 µM) for either 6 or 24 hours and then treated with higher H_2O_2 concentrations (100 µM, 200 µM, and 300 µM) for 24 hours. Then, neuronal like differentiated SH-SY5Y cells were divided into 5 groups, as follows: 1) control group; 2) cells treated with 10 µM H_2O_2 followed by higher H_2O_2 concentration; 3) cells treated with 20 µM H_2O_2 followed by higher H_2O_2 concentration, 4) cells treated with 30 µM H_2O_2 followed by higher H_2O_2 concentration; 5) cells treated with 50 µM H_2O_2 followed by higher H_2O_2 concentration.
Results: Our findings demonstrated that mild concentration (10-50 µM H_2O_2) applied before damage (100 µM H_2O_2) could protect neuronal-like differentiated neurons against ischemic insult. Particularly, we observed that cell viability and cell size recovery were effective 24 hours after pretreatment with low concentration H_2O_2 (10-30 µM). Thus, expression of markers for anti-apoptotic as Bcl-2 protein and pro-apoptotic proteins (Bad, Bax, Bid, caspase-9, AIF and PARP-1) were examined.
Conclusions: we conclude that i) PC response to a mild and transient H_2O_2-induced oxidative stress is clearly detected in neuronal like differentiated SH-SY5Y and revealed that both cell viability and cell size improved recovery; ii) apoptotic and inflammatory pathways are involved in such response, which is worthy and interesting of further investigation**.**

Title: Proteomic profiling of exosomes derived from brain microvascular endothelial cells under hypoxia: Identifying molecular pathways of adaptive responses to ischemic stress

Authors: *A. N. CAMPERO-ROMERO[1,2], E. RÍOS-CASTRO[3], L. B. TOVAR-Y-ROMO[2]
[1]Inst. de Fisiología Celular, Univ. Nacional Autónoma de México, Ciudad de Mexico, Mexico;
[2]Inst. de Fisiología Celular, Univ. Nacional Autónoma de México, Mexico City, Mexico;
[3]Unidad de Genómica, Proteómica y Metabolómica, LaNSE, CINVESTAV-IPN, Mexico City, Mexico

Abstract: Extensive data analyses of protein content have been recently conducted in many different populations of extracellular vesicles. Exosomes, formed in late endosomes and released to the extracellular milieu conveying chemical messages to distant targets, have uncovered complex systems of distant cell-to-cell communication. All cell types synthesize and release exosomes upon stress activation, and the characterization of their proteomic content might enable the identification of target signaling that would unveil systemic adaptive responses to stress. Under this premise, we set out to study the protein content of brain microvascular endothelial cells (BMEC)-derived exosomes following hypoxia. Brain microvascular endothelium plays a critical role in the modulation of adaptive responses to stroke, such as the modulation of blood-brain barrier and neuroinflammatory processes that involve crossing of blood-borne molecules and peripheral immune cells into the brain parenchyma, as well as blood flow and reperfusion after stroke. We cultured primary BMEC from adult rat brains and subjected them to hypoxia in an atmosphere of 100% N_2 for 6 h followed by recovery (~21% O_2) for 18 h. After this period, we collected conditioned media and isolated exosomes by differential ultracentrifugation. We also harvested exosomes released by BMEC cultured under normoxic conditions. We characterized the extracellular vesicles by shape and size with transmission electron microscopy and assessed the presence of typical exosome markers by western blot. We resolved exosome proteins by polyacrylamide gel electrophoresis and performed in-gel digestion with trypsin. The proteomic profiling was carried out by tandem mass spectrometry (MS/MS) with electrospray ionization followed by ion mobility separation. MS/MS spectra were deconvoluted and compared against reversed *Rattus norvegicus* databases with ProteinLynx Global SERVER. We obtained 262 high quality hits, among which several exosomal markers and BMEC-specific molecules involved in focal adhesion, prostaglandin synthesis and regulation, integrin signaling, and phagocytosis pulled. We identified 117 proteins not previously reported in other exosome proteomics studies, of which 29 were specific of cells subjected to hypoxia. Overrepresentation and pathway enrichment analyses of data from hypoxia and normoxia-derived exosome proteomes enabled us to identify proteins involved in adaptive responses to hypoxic stress. This exploratory study depicts for the first time the molecular profile of exosomes secreted by BMEC under stress relevant in brain pathologies such as stroke.

Title: Docosahexaenoic acid stimulates autophagy and rescues NGFDPC12 cells from hypoxia-induced cell death

Authors: *M. L. MONTERO, J.-W. LIU, M. A. DELEÓN
Loma Linda Univ., Loma Linda, CA

Abstract: Docosahexaenoic acid stimulates autophagy and rescues NGFDPC12 cells from hypoxia-induced cell deathHypoxia is at the core of neuronal death during traumatic brain injury, spinal cord injury and stroke. We subjected nerve growth factor differentiated pheochromocytoma cell line 12 (NGFDPC12) to .5% [O_2] for 24 to 48hrs. The mRNA levels of the stress response protein HIF-1α went up 3.5, 5 and 6 fold of control at 18, 24 and 48hrs, respectively. Pro-apoptotic protein BNIP3 went up 2.5 and 3.5 fold of control at 18 and 24hrs, respectively. Hypoxia treatment also induced a 2.5 fold increase in ROS after 24hrs and that increase in ROS could be prevented with antioxidant MCI-186 at 50 and 100 μM concentration. In addition, hypoxia increased Annexin V conjugation 2.5 fold of control at 24hrs. Treatment with docosahexaenoic acid (DHA) or the autophagy promoter, rapamycin, during hypoxia increased cell viability and brought back the levels of Annexin V to control level. Interestingly, pre-treat cells with DHA for 24 hours before hypoxic insult also increased cell survival. We found that DHA increased the levels of conjugated LC3 at 24 hrs under hypoxic condition, suggesting that autophagy is involved in DHA-induced neuroprotection. Lastly, treating the cells with the lysosomotropic agent chloroquine during hypoxia eliminates the protective effect of DHA. We propose that DHA inhibits apoptosis, stimulates autophagy and protects NGFDPC12 cells from .5% [O_2] hypoxia.

Title: Spatial memory in zebrafish (Danio rerio) following cerebral hypoxia

Authors: *J. A. WINDELBORN, K. M. MARINO
Washington Col., Chestertown, MD

Abstract: With few reliable therapeutic approaches for cerebral ischemia, developing new laboratory models continues to be a pressing concern. Zebrafish (*Danio rerio*) have recently been utilized to model pathologies associated with cerebral hypoxia, and we aim to develop the model

to further understanding of the cellular and molecular mechanisms of memory impairment following cerebral hypoxia. First, a behavioral assay has been designed to test the effects of hypoxia on spatial memory. We take advantage of the species' preference to swim in shoals rather than alone, when given the choice. A T-maze has been developed in which fish are trained to associate one arm of the maze with shoaling. The effects of hypoxia (10 minutes at <1mg/L dissolved oxygen) on the formation and maintenance of spatial memory are tested by hypoxia exposure prior to or immediately following maze training, respectively. Brain tissues are extracted at the termination of each experiment, and damage is assessed by 2,3,5-Triphenyltetrazolium Chloride (TTC) absorbance.

Title: Attenuated response to hypoxia in hippocampal slices from mice lacking the glutamate antiporter, xCT

Authors: B. S. HEIT[1], A. CHU[1], *J. R. LARSON[2]
[1]Psychiatry, Univ. of Illinois at Chicago, Chicago, IL; [2]Dept Psychiat, Univ. of Illinois at Chicago Dept. of Psychiatry, Chicago, IL

Abstract: Loss of blood supply to brain tissue during ischemic stroke depletes neurons of energy (ATP), leading to failure to maintain membrane potentials and the excitotoxic release of glutamate. In intact neural networks, anoxic depolarization (AD) occurs rapidly and synchronously in large populations of neurons, due to the excitatory effects of released glutamate. Both the latency to AD and the duration of time spent in AD dictate the extent of ultimate cell death and represent the most reliable determinants of ensuing brain damage. One particularly vulnerable area to ischemic trauma is the hippocampus, insomuch that with any non-specific blood loss to the brain, the CA1 neurons are the first to experience cell death. Importantly, much of the "ischemic cascade" can be reproduced by transient deprivation of oxygen to *in vitro* hippocampal slices. xCT, glutamate antiporter, is identified as the primary source of extracellular glutamate in the brain during physiologic and pathologic conditions. This glial membrane-bound transport system serves as a source of cystine, which is intracellularly converted to cysteine - the rate-limiting substrate for glutathione synthesis. The high rate of oxygen consumption in the brain renders this antiporter vital to antioxidant defense, and its expression is rapidly upregulated during oxidative stress. However, the release of glutamate into the extracellular space, accompanying the uptake of cystine, could exacerbate ischemic

excitotoxicity. The present study compared mice lacking xCT (xCT-KO) with wild-type (WT) littermate control mice for response to hypoxic challenge in hippocampal slices *in vitro*. Slices prepared from eight-week old mice were tested for two measures of hypoxia sensitivity: (a) the time required to induce AD after total O_2 deprivation, and (b) the sensitivity of synaptic transmission to hypoxia ($30\%O_2/70\%N_2$). Slices from xCT-KO mice showed extended AD times and attenuated neuronal response suppression during hypoxia. These results suggest that loss of the antiporter affects hypoxia sensitivity due to (a) its contribution to extracellular glutamate levels, (b) the downstream effects of xCT-mediated glutamate release, or (c) an unknown consequence of its action.

Title: Dysregulation of mitochondrial quality control mechanisms during *in vitro* ischemia-reperfusion injury

Authors: *A. R. ANZELL[1], S. RAGHUNAYAKULA[2], J. M. WIDER[2], T. H. SANDERSON[3]
[1]Wayne State Univ., Detroit, MI; [2]Emergency Med., Univ. of Michigan, Ann Arbor, MI; [3]Emergency Med., The Univ. of Michigan, Ann Arbor, MI

Abstract: Ischemic brain injury caused by cardiac arrest or stroke continue to be leading causes of death and disability in the U.S. While the restoration or reperfusion of blood flow is essential to salvage ischemic tissue, reperfusion paradoxically exacerbates damage via the excessive production of reactive oxygen species (ROS) from mitochondria. Mitochondria are the key regulators of cell fate during ischemia-reperfusion (I/R) injury. They promote cell survival through the production of ATP that fuels cellular processes and, conversely, cell death through the production of ROS and the release of pro-apoptotic factors such as cytochrome C. Therefore, stringent quality control mechanisms are critical to ensure a healthy mitochondrial network. The role of mitophagy during I/R injury still remains to be elucidated and previous studies are confounded by the dynamic nature of this process. Therefore, we characterized mitophagic flux utilizing primary cortical neurons isolated from mitochondrial quality control (mito-QC) reporter transgenic mice (C57BL/6-Gt(ROSA)26Sortm1(CAG-mCherry/GFP)Ganl/J) in an *in vitro*oxygen-glucose deprivation (OGD) real-time imaging system. The reporter allele contains a CAG promoter and mCherry-GFP-mtFIS1 fusion protein inserted into the *Gt(ROSA)26Sor*locus

on chromosome 6. mCherry is stable in acidic pH (pKa 4.5) while GFP (pKa 5.9) is quenched in the acidic lysosomal environment, allowing identification of mitochondria inside autolysosomes. Simulation of I/R injury was achieved with a media-gas exchange system coupled to a Zeiss microscope with LED based fluorescent imaging for real-time imaging during OGD and reoxygenation.The combination of these two novel models allowed us to characterize mitophagic flux in primary cortical neurons with precise temporal resolution. These novel findings provide key evidence for the role of mitophagy in neuronal death following I/R injury as well as further insight into the basic mechanisms of mitochondrial dysfunction that may play a role in a variety of neurodegenerative disease.

Title: NAD^+ precursor reverses ischemia-induced increase of mitochondrial fission protein P-Drp1 (S616) via a SIRT3 mediated mechanism

Authors: N. KLIMOVA[1], A. LONG[2], *T. KRISTIAN[1,2]
[1]Dept Anesthesiol, Univ. of Maryland Sch. of Med., Baltimore, MD; [2]VAMHS, Baltimore, MD

Abstract: Global cerebral ischemia depletes brain tissue NAD^+, an essential cofactor for mitochondrial and cellular metabolism, leading to bioenergetics failure and cell death. The post-ischemic NAD^+ levels can be replenished by the administration of nicotinamide mononucleotide (NMN), which serves as a precursor for NAD^+ synthesis. Ischemic insult also leads to excessive fragmentation of mitochondria in vulnerable CA1 neurons. We have shown that NMN administration shows a dramatic protection against ischemic neurodegeneration. To assess the effect of NMN administration on ischemia-induced mitochondrial dynamics we used a transgenic mouse model with mitochondria targeted expression of neuron specific enhanced yellow fluorescent protein. The animals were subjected to transient forebrain ischemia and NMN was administered 30 minutes after the start of reperfusion at a dose of about 60 mg/kg. Alterations in mitochondrial fission and fusion were examined in post-ischemic animals treated with vehicle or NMN at 2, 4, and 24 hours of recovery. Fusion and fission protein levels were determined by western blots. NMN reversed the excessive mitochondrial fragmentation in CA1 neurons that was permanent in vehicle-treated ischemic groups. Thus, NMN administration

promoted normal mitochondrial morphology at 24 hours after the ischemic insult. Western blot analysis showed that NMN treatment reversed ischemia-induced increase of mitochondrial fission protein P-Drp1(S616). Similar results were also observed in non-ischemic naïve mice treated with NMN. Calcineurin, a calcium and calmodulin dependent phosphatase that dephosphorylates P-Drp1, did not contribute to the NMN mediated decrease in P-Drp1(S616) levels. This suggests that kinases, either CDK1 or PKCδ that phosphorylate Drp1 (S616), could be involved. As expected there was an increase in tissue NAD^+ levels following NMN administration that were associated with decrease in mitochondrial protein acetylation. Therefore, we examined the role of mitochondrial SIRT3 in NMN induced effect on mitochondrial dynamics by using SIRT3 null mice (SIRT3 KO). Interestingly, in SIRT3 KO animals the NMN-induced changes in P-Drp1 levels were attenuated. Our data thus suggest that maintaining normal mitochondrial morphology is essential for cell bioenergetics metabolism and survival. Furthermore, using NMN to target mechanisms of fission and fusion regulation could represent new therapeutic targets for neurobiological diseases.

Title: Focal cerebral ischemia and reperfusion induces brain injury through alpha2delta-1-bound NMDA receptors

Authors: *Y. LUO, H. MA, J.-J. ZHOU, L. LI, S.-R. CHEN, J. ZHANG, L. CHEN, H.-L. PAN
Univ. of Texas MD Anderson Cancer Ctr., Houston, TX

Abstract: Background and Purpose: Glutamate *N*-methyl-*D*-aspartate receptors (NMDARs) play a major role in the initiation of ischemic brain damage. However, NMDAR antagonists have no protective effects in stroke patients, possibly because they block physiological functions of NMDARs. α2δ-1 (encoded by *Cacna2d1*) is strongly expressed in many brain regions. We determined the contribution of α2δ-1 to NMDAR hyperactivity and brain injury induced by ischemia and reperfusion. **Methods**: Mice were subjected to 90 min of middle cerebral artery occlusion (MCAO) followed by 24 h of reperfusion. Neurological deficits, brain infarct volumes, and calpain/caspase-3 activity in brain tissues were measured. NMDAR activity of hippocampal

CA1 neurons was recorded in brain slices. **Results**: MCAO caused a significant increase in α2δ-1 protein levels in the cerebral cortex, hippocampus, and striatum. Coimmunoprecipitation showed that α2δ-1 physically interacted with NMDARs in the mouse brain tissue. Inhibiting α2δ-1 with gabapentin, uncoupling the α2δ-1-NMDAR interaction with an α2δ-1 C-terminus-interfering peptide, or genetically ablating *Cacna2d1* genetic ablation had no effect on basal NMDAR currents but strikingly abolished oxygen-glucose deprivation-induced NMDAR hyperactivity in hippocampal CA1 neurons. Systemic treatment with gabapentin or α2δ-1 C-terminus-interfering peptide or *Cacna2d1* ablation reduced MCAO-induced infarct volumes, neurological deficit scores, and calpain/caspase-3 activation in brain tissues. **Conclusions**: α2δ-1 is essential for brain ischemia-induced neuronal NMDAR hyperactivity, and α2δ-1-bound NMDARs mediate brain damage caused by cerebral ischemia. Targeting α2δ-1-bound NMDARs, without impairing physiological α2δ-1-free NMDARs, may be a promising strategy for treating ischemic stroke.

Title: Detrimental role of neuropeptide Y in cardiac arrest-induced cerebral ischemia

Authors: *R. H.-C. LEE[1], T.-H. HSIEH[1], A. DO COUTO E SILVA[2], H. POSSOIT[1], C. T. CITADIN[1], C. Y.-C. WU[1], J. T. NEUMANN[3], H. W. LIN[1]
[1]Neurol., LSU Hlth. Sci. Ctr. Shreveport, Shreveport, LA; [2]Cell. Biol. and Anat., LSU Hlth. Sci. Ctr., Shreveport, LA; [3]Biomed. Sci., West Virginia Sch. of Osteo. Med., Lewisburg, WV

Abstract: Cardiopulmonary arrest (CA) is the leading cause of death and disability in the United States. Although multi-faceted treatment strategies against CA (i.e. rapid ambulatory responses and better automated external defibrillation training and awareness) have improved, the survival rate and prognosis following CA remain poor. Of utmost importance is CA-induced hypoperfusion (a decrease in cerebral blood flow, CBF) is essential for the progression of neuronal cell death and learning/memory deficits. Thus, identifying the unknown regulatory mechanisms that influence hypoperfusion will provide high therapeutic potential in the treatment

of CA. We previously found that enhanced sympathetic nervous system (SNS) activity is one of the major contributors to CA-induced hypoperfusion. It is important to note that neuropeptide Y (NPY, a 36-amino acid neuropeptide) is released upon SNS activation to induce a long-lasting and potent vasoconstriction (100-fold more potent than other sympathetic neurotransmitters, such as norepinephrine), as a result of reduced blood supply to the brain. We sought to inhibit NPY release from pre-synaptic sympathetic nerves via peptide YY $(PYY)_{3-36}$ (a pre-synaptic NPY2 receptor agonist) to study the role of NPY in CA-induced hypoperfusion and brain injury. A rat model of global cerebral ischemia (6 mins asphyxial cardiac arrest, ACA) was utilized. Results from intra-vital two-photon laser scanning microscopy and laser speckle contrast imaging indicate post-treatment with PYY_{3-36} at 120 μg/kg (56.87 ± 4.48%; $p<0.05$ evaluated by Student's t test) attenuated cortical hypoperfusion (-33.20 ± 2.65%) 24 hrs after ACA. Interestingly, post-treatment with PYY_{3-36} (40 μg/kg) inhibited neuronal cell death (via hematoxylin/eosin and fluoro-Jade C stain), while maintained synaptic transmission (via hippocampal slice recording) in the CA1 region of the hippocampus. Finally, we assessed cognitive/behavioral function (via Y-maze and novel object recognition test) to evaluate the rats' functional learning/memory after ACA. Rats post-treated with PYY_{3-36} (0.64 ± 0.02) presented with better neurological outcomes than untreated rats (0.48 ± 0.05) after ACA. In conclusion, NPY is detrimental to CA-induced brain injury. Attenuation of NPY release via PYY_{3-36} affords neuroprotection against CA-induced hypoperfusion, neuronal cell death, and neurological deficits.

Title: Neuroprotective effect of intracranial chronic toxoplasma gondii infection in cerebral ischemia

Authors: *S. LEE[1], B.-K. JUNG[2], H. SONG[2], E. HEO[1], H. SEO[1], J.-Y. CHAI[2], G. LEE[3], J.-H. LEIGH[4], B.-M. OH[1]
[1]Dept. of Rehabil. Med., Seoul Natl. Univ. Hosp., Seoul-City, Korea, Republic of; [2]Inst. of Parasitic Dis., Seoul, Korea, Republic of; [3]Incheon Workers Compensation Hosp., Incheon, Korea, Republic of; [4]Incheon St. Mary's Hosp., Incheon, Korea, Republic of

Abstract: Purpose *Toxoplasma gondii* (*T. gondii*) is an intracellular protozoan parasite spread all over the world and can invade various organs of the host body and forms tissue cysts in the

central nervous system. It is known that the *toxoplasma* tissue cyst, which is latent in the brain, interacts with brain cells in various ways. The purpose of this study is to investigate the neuroprotective effects of chronic *T. gondii* infections in cerebral ischemia and to explore its mechanism. **Methods** Eighteen ICR mice were used in the experimental group and the control group, respectively. Middle cerebral artery occlusion (MCAO) was used to induce cerebral ischemia and reperfusion was performed 90 minutes after occlusion. In the experimental group, *T. gondii* (ME49 strain) was injected through intraperitoneal route 4 weeks before the surgery. The neurobehavioral effects of cerebral ischemia were assessed by measurement of Garcia score and Rotaroad test on the 1st and 3rd day after surgery. After behavioral tests, mice were sacrificed and brains were harvested. The volume of brain ischemia was measured by Triphenyl tetrazolium chloride (TTC) staining. In addition, isolated brain tissues were analyzed the changing of genes expression to investigate the protective effects of *toxoplasma* chronic infection. **Results**
The survival rate of the mice was much higher in the infected group. (33% in control group, 61% in infected group) Corrected infarction volume was significantly reduced in infected group (control, n = 6, 168.8 ± 40.4; infected, n = 11, 112.5 ± 39.2, $P < 0.05$), and the neurobehavioral function of the infected group was significantly better than control group. We found that *T. gondii* chronic infection induces the HIF-1 and VEGF gene expression in the brain. **Conclusion** Chronic intracerebral infection of *T. gondii* causes neuroprotective effects in mouse cerebral ischemia and reduces the volume of cerebral infarction with better neurobehavioral function.

Title: Contribution of cyclophilin A and CD147 receptor in brain ischemia

Authors: *Q. FANG[1], L. LEE[1], S. KANG[1], J. WONG[2], R. A. NOWAK[3], T. V. ARUMUGAM[1], E. H. KOO[4,2,1]
[1]Dept. of Physiology, Yong Loo Lin Sch. of Med., [2]Dept. of Medicine, Yong Loo Lin Sch. of Med., Natl. Univ. of Singapore, Singapore, Singapore; [3]Dept. of Animal Sci., Univ. of Illinois at Urbana-Champaign, Urbana, IL; [4]Dept Neurosciences, UCSD, La Jolla, CA

Abstract: A recent study from Bell and colleagues (2012) proposed that the immunophilin, cyclophilin A (CypA), induces MMP-9 expression in pericytes in an ApoE dependent manner resulting in blood-brain barrier (BBB) leakage. Previous studies have also implicated CypA playing a role in cerebrovascular disease principally from the beneficial effects of cyclosporin A given in stroke models, which inhibits CypA mediated signalling pathways. To test whether the neuroprotection seen following cyclosporin treatment is due to inhibition of CypA, we tested the effects of unilateral middle cerebral artery occlusion (MCAO), a model of acute stroke, in CypA deficient mice. As compared to control littermate mice, there was a significant 75% reduction in infarct area associated with about 50% improvement in functional outcome in CypA knockout animals, thus showing that CypA is the likely substrate that mediates the beneficial effects of cyclosporin A treatment. We next asked whether CD147 (also known as *basigin* or EMMPRIN) the only established receptor for CypA, is involved in neuroprotection or in activating downstream effects to modulate BBB function given that CD147 is a known inducer of MMP expression. The precise distribution of CD147 expression in brain has not been described previously. By immunohistochemistry, we found that CD147 was widely expressed in brain, primarily in neurons and endothelial cells. In the former setting, CD147 was most abundant in both axons and dendrites but relatively sparse within neuronal cell bodies. Interestingly, in the hippocampus, there was a striking localization of CD147 to processes of CA1 and CA3 neurons and virtual absence of immunostaining in CA2 neurons. This differential distribution was confirmed using targeted deletion of CD147 in CA1 or CA3 neurons, respectively. In the latter setting, CD147 was primarily expressed in capillaries and a small subset of arteries but absent in most of the smaller arteries in brain. This heterogenous distribution of CD147 expression suggests that this receptor plays multifunctional roles in brain. Studies are underway to

determine the contribution of neuronal or endothelial CD147 in neuroprotection using targeted deletion of CD147 in neurons or endothelial cells.

Title: Protective effects of melatonin in corpus callosum astrocytes during ischemia

Authors: *B. S. ALGHAMDI
Physiol. Dept., King Abdulaziz Univ., Jeddah, Saudi Arabia

Abstract: Stroke is a leading cause of adult death and disability worldwide. Around 80% of all stroke cases are classed as ischemic stroke, which affects both gray and white matter brain regions. During ischemia, reactive oxygen species (ROS) are generated and initiate multiple damaging processes such as lipid peroxidation, DNA injury, mitochondrial dysfunction, blood-brain barrier (BBB) damage and brain edema. Melatonin is a potent antioxidant which can act as a direct oxygen species scavenger. Melatonin can also act at receptors (MT1 and MT2), which are expressed in the nervous system cells including astrocytes. Using live cell imaging of GFAP-GFP mice, the viability of astrocytes in the corpus callosum of adult brain sections was monitored during a standard 60 minutes period of modeled ischemia (oxygen-glucose deprivation: OGD). Addition of melatonin (10 µM) significantly reduced the level of astrocyte death during OGD from 71.94% ± 1.45 to 37.84% ± 1.9. This protective effect was blocked by luzindole (10µM), a nonselective melatonin receptor (MT1/MT2) antagonist, or PDOT (10µM), a selective MT2 melatonin receptor antagonist. Using a glial injury scoring system, ultrastructural studies confirmed the protective action of melatonin against acute ischaemic injury in the white matter glial cells.

Title: Deletion of FosDT an abundantly expressed lncRNA in vertebrates does not affect normal development, but improves post-ischemic functional outcome

Authors: *S. L. MEHTA, T. KIM, K. C. MORRIS-BLANCO, A. K. CHOKKALLA, S. BATHULA, R. VEMUGANTI
Neurolog. Surgery, Univ. of Wisconsin, Madison, WI

Abstract: Long noncoding RNAs (lncRNAs) are a unique class of ncRNAs that are thought to control transcription and translation. We recently observed that that lncRNA called Fos downstream transcript (FosDT) transcribed from Fos locus is significantly induced in the brain following stroke (focal ischemia) in adult rats. We further showed that knockdown of FosDT promotes neuroprotection and better functional outcome following stroke. Mechanistically, FosDT scaffolds the transcription factor REST and its corepressors enabling REST-mediated suppression of neural genes. To understand its roles, we conducted further studies on FosDT expression and function. FosDT is observed to be abundantly expressed in both peripheral organs and brain with cerebral cortex showing the highest levels. FosDT expression is also developmentally regulated with adults showing higher expression than neonates. Its expression is highest in the cerebral cortex of adult as compared to the P7 stage. When FosDT was knocked-out in rats using CRISPR/Cas9, there were no developmental effects. FosDT knockout rats showed normal body weight and fertility compared to wildtype rats. However, when challenged with a focal cerebral ischemic insult, FosDT knockouts showed better survival and smaller infarcts than wild-type controls at 7 days of reperfusion. FosDT deletion also significantly reduced post-ischemic functional deficits and improved sensory-motor recovery as noticed with Rotarod, foot faults and adhesive removal tests. Thus, our results show that FosDT levels have to be maintained properly in the brain and its induction under pathological conditions like stroke promotes secondary brain damage. Targeting lncRNAs such as FosDT is a viable strategy to minimize post-stroke brain damage. Funded by NIH.

Title: Hyperacetylation as a response to neurodegeneration process

Authors: *B. TÓTHOVÁ[1], M. KOVALSKÁ[2], D. KALENSKÁ[3], A. TOMAŠCOVÁ[3], E. HALAŠOVÁ[1], J. LEHOTSKÝ[3]
[1]Dept. of Mol. Med., BioMed Martin, Jessenius Fac. of Med., Martin, Slovakia; [2]Dept. of Histology and Embryology, [3]Dept. of Med. Biochem., Jessenius Fac. of Med., Martin, Slovakia

Abstract: OBJECTIVES: Epigenetic regulation plays an important role in normal condition as in pathological situations of the organism. These epigenetic modifications are closely affected by the overall metabolic state of the cell, that is influenced by various exogenous and endogenous factors. One of such triggers is hyperhomocysteinemia (hHcy), referred to elevated plasma homocysteine (Hcy) level, a non-esential amino acid formed during the methionine cycle. Hcy can act via epigenetic pathways, predominantly by modifying the methylation potencial, thus affecting the acetylation process as well. Moreover, hHcy is considered as a risk factor and a target of preventive strategies for neurodegenerative diseases including cerebral stroke, during which occur considerable changes in epigenetic patterns. **MATERIAL AND METHODS:** Adult male Wistar rats were used in the study. They were randomly divided into control and hyperhomocysteinemic group and the latter was subjected to subcutaneous Hcy administration for 21 days at a dose 1.2 μmol Hcy/g of body weight per day. After this period, animals from both groups were further divided into control, ischemic and ischemia-reperfusion (IR) group, 4 animals/group. Global forebrain ischemia was induced for 15 min by standard 4-vessel occlusion, in the IR group it was followed by 72-hour reperfusion. To assess the extent of neuronal tissue damage, cresyl violet staining was used and the alterations in acetylation levels of histones H3 at lysine 9 and H4 at lysine 12 in the rat brain cortex were examined by fluorescent immunohistochemistry as well as by western blot. **RESULTS:** Cresyl violet staining revealed massive neural disintegration in the M1 *(primary motor cortex)* region as well as in the CA1 *(cornu ammonis)* area of hippocampus induced by IR. The neural tissue damage was significantly bigger in the groups with induced hHcy. Moreover, immunohistochemistry showed prominent changes in the acetylation of H3 (Lys9) and H4 (Lys12) in all experimental conditions with significant changes between the control and hHcy groups, especially in the levels of

acetylated H3 (Lys9). Similar results were observed by western blot analysis. **CONCLUSION:** Combination of hHcy and IR injury increases the extent of neuronal tissue damage. In the cortical region, these conditions manifest different histone acetylation patterns. Taken together, it seems that hyperacetylation have a preferred role in pathological processes such as neurodegeneration and should be considered in therapeutical strategies.

Title: DNA hydroxymethylation of neuroprotective genes by Tet3 ameliorates ischemic brain injury

Authors: *K. MORRIS-BLANCO[1], M. J. BERTOGLIAT[1], T. KIM[2], R. VEMUGANTI[2]
[1]Univ. of Wisconsin-Madison, Madison, WI; [2]Neurolog. Surgery, Univ. of Wisconsin, Madison, WI

Abstract: Epigenetic factors are known to play a role in the pathophysiology of ischemic brain injury. The mammalian ten-eleven translocases (TET1-3) convert methyl groups in cytosine in DNA to hydroxymethylcytosine (5hmC) and this epigenetic modification is known to regulate transcription and thus neuronal function. We presently evaluated if TETs play a role in neuronal survival by enhancing 5hmC in neuroprotective genes following cerebral ischemia. Adult C57BL/6J male mice subjected to experimental stroke showed increased 5hmC and TET activity in the cortical penumbral tissue as early as 5 min to as late of at least 24h of reperfusion following stroke. TET3 mRNA expression, but not TET1 and TET2, showed induction from 6h to 24h after stroke. TET3 protein expressed preferentially in neuronal cells in the cortical penumbra following stroke. Knockdown of TET3 by intracerebral injection using siRNA blocked the post-stroke 5hmC and led to increased brain degeneration and mortality. TET3 knockdown also resulted in alterations in the expression of several genes that modulate autophagy, apoptosis, oxidative stress and DNA repair in the post-ischemic brain. Treatment of mice with a known TET inducer ascorbate increased TET activity and decreased post-stroke brain damage. We further show that ascorbate specifically acts via TET3 as TET3 knockdown

prevented ascorbate-induced 5hmC levels and neuroprotection after stroke. These results demonstrate that TET3 is a major regulator of DNA hydroxymethylation and provides endogenous neuroprotection after cerebral ischemia. Furthermore, ascorbate can promote neuroprotection after stroke by inducing TET3 and 5hmC in beneficial genes. Funded by NIH.

Title: DNA methylation and gene expression of astroglia before, during and after oxygen and glucose deprivation

Authors: *I. PONCE, L. B. TOVAR-Y-ROMO
Inst. de Fisiología Celular, Univ. Nacional Autónoma de México, Ciudad de México, Mexico

Abstract: Epigenetic mechanisms such as DNA methylation are well known regulators of genetic expression and they play key roles in the development of neurodegenerative diseases, mainly through a substantial transcriptional regulation of active and inactive promoters and by modifying transcription elongation and splicing in CpG islands located intra and inter-genically. It is also widely recognized that astrocytes, that are critical regulators of neuronal function, play a crucial role in neurovascular-related disorders like ischemic stroke. However, few studies have addressed at the molecular resolution the overall genetic and epigenetic changes of these complex phenomena, and in events like reperfusion damage that occurs after ischemic stroke, these processes are practically unknown. We performed RNA-seq and methylated DNA immunoprecipitation sequencing (MeDIP-seq) analyses of cultured human astrocytes-like cells derived from grade I non-tumorigenic glioblastoma subjected to oxygen and glucose deprivation (OGD), in order to establish a relationship between DNA methylation and gene expression under normoxia, OGD and recovery. We identified several genomic features including proximal and distal promoters whose methylation levels change not only during OGD but also after 8 h of recovery that showed statistically significant differences in both; high (house-keeping and ubiquitous genes) and low (cell lineage-specific genes) CG promoters. Moreover, DNA methylation remodeling was correlated with gene expression of several genes under OGD and recovery, and the organization of the transcriptome and methylome resulted different under normoxia, OGD and recovery. These results can help to elucidate the overall transformation of

cells in terms of transcription and DNA methylation in pathological occurrences involving ischemia and characterize the damage that occurs during reperfusion at the genomic scale that has been incompletely described until now. Supported by DGAPA-PAPIIT IN226617.

Title: The DNA repair enzyme apurinic/apyrimidinic endonuclease-1 (APE1) improves oligodendrocytic survival following ischemic insults

Authors: J. CHEN[1], M. V. BREGY[1], K. ZHANG[1], *R. A. STETLER[2]
[1]Pittsburgh Inst. for Brain Disorders and Recovery, Neurol., [2]Neurol., Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Objective: Induction of oxidative DNA damage is a hallmark event following cerebral ischemic insults and has been identified to be predictive of subsequent cellular injury and adverse outcomes. We have previously demonstrated that induced global knockout of APE1 sensitizes the brain to cerebral ischemia. Although neurons have classically been the focus of oxidative stress-related injury following stroke, we wished to investigate whether oligodendrocytes are sensitive to changes in APE1 expression in the context of ischemic injury. **Methods:** Stroke was induced by 30 or 60 min transient middle cerebral artery occlusion (tMCAO, suture method) in adult male C56BL/6J mice with or without tamoxifen-induced global APE1 knockout. Viability was determined using TTC staining and MAP2 immunostaining. White matter tracts were visualized with MBP/smi32 or APC immunostaining co-labeled with TUNEL staining for apoptotic nuclei. Primary cultured oligodendrocytes (OL) were derived from oligodendrocyte percursor cells from P1 rat pups, differentiated in culture, and subjected to 90 min oxygen/glucose deprivation (OGD). Lentiviral vectors were constructed to overexpress APE1 or a non-phosphorylatable mutant (S163A), or shRNA targeted to APE1, and mature OLs were transduced 72 h prior to OGD. Toxicity was determined using the live/dead assay (calcein green/propidium iodide) and lactate dehydrogenase release. **Results:** Deletion of APE1 caused extensive loss of white matter tracts after mild ischemic injury (30 min MCAO) as well as significant increase in APC+/TUNEL+ cells in the corpus callosum/external capsule compared to wildtype ischemic brain. Similar to the animal model, knockdown of APE1 in cultured OL led to exacerbated toxicity following OGD. Viral verexpression of APE1

decreased OGD-induced OL cell death. Overexpression of the non-phosphorylatable APE1 mutant APE1-S163A further protected OL from OGD toxicity compared to mock transduction or transduction of APE1. **Conclusion:** The DNA repair enzyme APE1 functions in a protective manner in ischemic oligodendrocytes, and elimination of phosphorylation at S163 further improves the protective effects of APE1 against ischemic injury.

Title: Developmental transcription factors in post-stroke axonal sprouting

Authors: *C. A. SCHWEPPE, I. BAGGA, S. T. CARMICHAEL
Univ. of California Los Angeles, Los Angeles, CA

Abstract: Ischemic stroke produces a limited process of neural repair, characterized by axonal sprouting and cortical reorganization in the peri-infarct region. Previously, our lab has used transcriptional profiling of single sprouting neurons to identify their unique gene expression profile, a post-stroke sprouting neuron transcriptome. Within this transcriptome dataset are a number of transcription factors known to play a role in cortical development that are differentially regulated in sprouting neurons following stroke. Developmental transcription factors present an intriguing target for study due to their inherent ability to act as master regulators of genes responsible for neuronal growth. As such, a number of these differentially regulated developmental transcription factors have been investigated for their ability to regulate axonal sprouting following stroke. Transcription factor targets were initially screened for their ability to promote axonal outgrowth following lentiviral overexpression in primary cortical neurons obtained from P12 mice. Two genes, Ctip2 (BCL11B) and Hhex demonstrated an ability to promote neurite growth in culture. To test the ability of these targets to promote post-stroke axonal sprouting in vivo, adult Rosa26 Cre-reporter knock-in Ai14 mice received a focal stroke via photothrombosis in the forelimb motor cortex, followed by delivery of lentivirus expressing genes of interest and Cre reporter. Four weeks following injury, relative axonal sprouting was evaluated via tracing of tdTomato+ projections both the peri-infarct region and subcortical structures. The results of these studies begin to explore the role of development-associated transcription factors in neural regenerative processes in the adult cerebral cortex.

Title: Mechanistic gain-of-function and loss-of-function studies of Wnt7A in post-stroke neural repair

Authors: *H. ZHAO[1], T. LENGNING[2], A. BRUMM[1], S. T. CARMICHAEL[1]
[1]Neurol., UCLA, Los Angeles, CA; [2]Univ. Med. Ctr. Hamburg-Eppendorf, Hamburg, Germany

Abstract: Stroke is a leading cause of adult disability without treatments for long-term recovery. Stroke itself induces a wide-range of repair mechanisms, including the proliferation and long-distance migration of immature neurons (neuroblasts) from the subventricular zone (SVZ) to peri-infarct tissue, a process termed post-stroke neurogenesis. These neuroblasts localize to angiogenic blood vessels, forming a neurovascular niche in the peri-infarct zone. The reciprocal signaling between neuroblasts and endothelial cells has not been clearly characterized. Understanding these endogenous signaling systems may provide novel targets for pharmaceutical intervention to enhance functional recovery.
In genome-wide expression profiling studies, we identified Wnt7A as a candidate signaling gene that is down-regulated in stroke-responsive neuroblasts. Wnt7A stimulates neural stem cell proliferation and is important for neuronal differentiation and maturation in the hippocampus of adult mouse brains (Qu, et. al, 2013). However, its role in post-stroke neural repair is not well understood. In a set of gain- and loss-of-function studies, we show that Wnt7A regulates long term vessel growth, blood brain barrier formation, and neural progenitor cell maturation. In addition, we demonstrate these long-term effects are mediated by Wnt7A stimulation of vessel remodeling and neural progenitor cell migration from the subventricular zone in the acute period after stroke. Here, we provide assessment of Wnt7A-mediated tissue repair at subacute and chronic time points after stroke in the photothrombotic model in rodents.

Title: Elovanoids are novel class of homeostatic lipid mediators that protect brain after experimental ischemic stroke

Authors: *N. G. BAZAN[1], A. OBENAUS[2], H. MENGHANI[1], S. MARCELL[1], L. KHOUTOROVA[1], N. PETASIS[3], L. BELAYEV[1]
[1]Neurosci. Ctr., Louisiana State Univ. Hlth. Sci. Ctr., New Orleans, LA; [2]Dept Pediatrics, Univ. of California, Irvine, Irvine, CA; [3]Chem., USC, Los Angeles, CA

Abstract: Ischemic stroke triggers a pattern of cellular and molecular disturbances that include lipid peroxidation and neuronal injury. Recently, we have uncovered and characterized a novel neuroprotective signaling mechanism, which involves the activation of the biosynthesis of a family of lipid mediators in the brain made from omega-3 very-long-chain polyunsaturated fatty acids, that we named Elovanoids (ELVs). This study evaluated ELVs, which are made of 32 to 34 carbon atoms in length (ELV-N32 and ELV-N34) in cerebral ischemia, and their potential mechanisms. Male Sprague-Dawley rats were subjected to 2 h of middle cerebral artery occlusion (MCAo). As sodium salts (Na) or methyl esters (Me), ELVs were dissolved in artificial CSF and administered into right lateral ventricle at 3 h after onset of stroke. There were five groups: ELV-N32-Na, ELV-N32-Me, ELV-N34-Na, ELV-N34-Me (5µg/50µl), and CSF (50µl). Neurological function was evaluated on days 1, 3, and 7 after MCAo. *Ex vivo* MRI and immunohistochemistry were conducted on day 7. All ELV treatments greatly improved neurologic scores in a sustained fashion up to the 7-day survival period. Ischemic core and penumbra volumes (computed from T2WI) were significantly reduced by all ELV treatments, and total lesion volumes were significantly reduced by ELV-N32-Na, ELV-N32-Me, ELV-N34-Na, and ELV-N34-Me compared to CSF-treated group (by 60%, 56%, 99%, and 91%, respectively). ELV-treated rats showed less infarction with an increased number of NeuN- and GFAP-positive cells as well as SMI-71-positive vessels in the cortex and less IgG staining in the cortex. ELV-mediated protection was extensive in the frontal-parietal cortex (tissue was salvaged by 57-96%), subcortex (73-75%), and total infarct volume, correction for brain swelling was dramatically reduced in all ELV-treated groups by 55-91%. Conclusion: We have shown that the administration of ELVs provides high-grade neurobehavioral recovery, decreases ischemic core and penumbra volumes, as well as attenuates cellular damage, blood vessel integrity, and BBB

disruption. These treatments might provide the basis for future therapeutics for patients suffering from ischemic stroke.

Title: Role of Semaphorin 3E signaling in the developing brain vasculature and remodeling after ischemic stroke

Authors: *R. YU, D.-G. KIM, W.-J. OH
Structure and Function of Neural Network, Korea Brain Res. Inst., Daegu, Korea, Republic of

Abstract: Most major axon guidance molecules have been shown to play a role in developing vascular network formation. As shown in the previous studies, secreted Semaphorin 3E (Sema3E), and its receptor Plexin-D1 pair which is one of the traditional axon guidance cues seems to have diverse roles in vascular topology in the periphery as well as retinal vasculature by regulating VEGF signaling. However, in spite of significant expression of Plexin-D1 in the angiogenic vessels, it remains still unclear whether the Sema3E-Plexin-D1 axis is implicated in the brain vasculature formation during development and remodeling process in the injured vessels. In this study, to address whether Sema3E-Plexin-D1 signaling is playing any roles in the developing brain vasculature, we performed 3D vascular network analysis using tissue clearing method and found that the vascular network of Plexin-D1 knockout exhibited a significant increase in the multiple parameters such as vascular length, branch, and density. Next, to elucidate whether the patterning role of Sema3E-Plexin-D1 axis during development can be recapitulated in the injured vessel remodeling process, we first analyzed their gene expressions in the stroke-induced brain. Interestingly, after ischemic injury by transient middle cerebral artery occlusion (tMCAO) method, Sema3e mRNA expression is markedly elevated in the penumbra of the ipsilateral cerebral hemisphere. Also, the brain was more severely damaged by ischemic stroke in the Sema3E knockout. Moreover, we observed that critical process involved in vascular remodelings such as tip cell sprouting and pericyte coverage was significantly less developed in the penumbra under ischemic condition. Taken together, these results demonstrate that Sema3E-Plexin-D1 signaling serves as a major player to establish proper brain vasculature during normal development as well as remodeling after vascular impairment such as stroke.

Title: Astrocytic Na/H exchanger modulates Wnt/b-catenin signaling activation in cerebral vessels following ischemic stroke

Authors: *G. BEGUM[1], X. GUAN[1], S. SONG[1], V. PIGOTT[1], H. HUANG[1], M. SUN[2], D. B. STOLZ[2], G. E. SHULL[3], D. AGALLIU[4], D. SUN[1,5]

Genetics, Biochem. and Microbiology, Cincinnati, Cincinnati, OH; [4]Pathology and Cell Biol., Columbia Univ., NewYork, NY; [5]Geriatric Research, Educational and Clin. Cente, Veterans Affairs Pittsburgh Hlth. Care Syst., Pittsburgh, PA

Abstract: Astrocytes play an important role in tissue repair following brain injury including ischemia or hypoxia and maintains the functional integrity of the blood-brain barrier. We have previously shown that in response to ischemia and hypoxia, reactive astrocytes stimulate Na^+/H^+ exchanger isoform 1 protein (NHE1) activity to counteract the acidic pHi. This leads to intracellular Na^+ overload, astrocytic swelling, and impaired glutamate uptake which exacerbates ischemic brain damage. In this study, we find that targeted deletion of *Nhe1* in astrocytes using *Gfap-Cre$^{ERT2+/-}$;Nhe1$^{f/f}$* mice (*Nhe1* KO) abolishes ischemic stroke-mediated astrogliosis, preserves blood-brain barrier (BBB) function, and reduces cerebral microvessel damage after transient middle cerebral artery occlusion (t-MCAO), a mouse model for ischemic stroke. RNA-sequencing transcriptome comparison of reactive astrocytes isolated from either control or *Nhe1* KO ischemic brains reveals that genes involved in nervous system development, ion transport, establishment of blood-brain barrier, and Wnt signaling are highly upregulated in *Nhe1* KO mice. In particular, the canonical Wnt signaling pathway is significantly upregulated with *Wnt7a* mRNA as the top upregulated gene in *Nhe1* KO astrocytes. This was accompanied by upregulation of several additional Wnt pathway genes (Wnt7b, Fzd9, Fzd10, Sox1, Sox21, and Ndp). Elevation of both Wnt 7a/b and β-catenin proteins are detected in microvessels of the ischemic peri-lesion areas in astrocytic *Nhe1* KO brains. Most importantly, *Nhe1* KO brains display intact tight junctions and increased expression of the tight junction protein occludin indicating that reactive astrocytes are involved in potential repair of the cerebral vessel through upregulation of canonical Wnt signaling. Taken together, our findings suggest that NHE1 functions as a modulator of Wnt expression in astrocytes to fine tune the levels of Wnt/β-catenin

signaling activity in cerebral endothelial cells to promote stabilization of the BBB function and tissue repair after ischemic stroke.

Abstract: Dickkopf3 (Dkk3) is a secreted glycoprotein member of the dickkopf protein family widely characterized as a pro-apoptotic and angiogenic factor in tumor development and involved in the pathophysiology of neurodegenerative disorders. A role of Dkk3 in molecular mechanisms of the blood pressure regulation is actually unknown. Remarkably, Dkk3 gene maps inside a WKY/SHR (Wistar Kyoto/Spontaneously hypertensive rat) chromosome 1 QTL (Quantitative Trait Locus) included between D1Mit3 and D1Rat57 markers and linked to the hypertensive phenotype. This observation raises the intriguing possibility that Dkk3 gene may be considered as a candidate gene for high blood pressure. We addressed this hypothesis by performing experiments of cerebral lentiviral Dkk3 hyperexpression in stroke-prone SHR rats (SHRsp), which develop high blood pressure and increased stroke occurrence after high-salt/low potassium diet (Japanese diet, JD). Dkk3 cerebral overexpression reduced blood pressure levels and led to a lower rate of cerebrovascular accidents in SHRsp rats. Coherently, by using Dkk3 knockout mice, we observed that the Dkk3 genetic deletion was associated to higher blood pressure levels under basal condition as compared to the wild-type mice. Furthermore, cerebral

lentiviral Dkk3 overexpression in Dkk3 knockout mice led to blood pressure levels similar to those observed in the wild-type mice. In both SHRsp rats and in Dkk3 knockout mice, the cerebral lentiviral Dkk3 overexpression led to a massive downregulation of the angiotensin receptor AT-1 and of the catalytic subunit of the NADPH oxidase, gp91phox, and to an increased phosphorylation of both extracellular signal-regulated kinase (ERK) and endothelial NO synthase (eNOS). Finally, vascular reactivity analysis performed on mesenteric vessels of Dkk3 knockout mice showed that the genetic deletion of Dkk3 led to endothelial dysfunction with a reduced eNOS phosphorylation. Moreover, incubation of mesenteric vessels with the human recombinant Dkk3 peptide rescued these alterations suggesting that the glycoprotein Dkk3 directly modulates vascular reactivity. Taken together, these data raise the hypothesis that Dkk3 may represent a novel molecule acting as a key component of peripheral and central control of blood pressure.

Title: Amyloid β reduces pannexin-1 channel opening during ischemia through a novel mGluR1-mediated mechanism

Authors: *L. A. PALMER[1], A. K. J. BOYCE[2], A. W. LOHMAN[2], R. J. THOMPSON[2]
[1]Neurosci., [2]Cell Biol. and Anat., Univ. of Calgary, Calgary, AB, Canada

Abstract: Alzheimer's disease (AD) is associated with over-production of the amyloid β (Aβ) protein. Genetic causes of AD account for ~5% of cases, indicating that there are unknown co-morbidities for the disease. Ischemic stroke has been identified as an important risk factor, and accounts for up to five-fold increase in risk of developing AD. Interestingly, hypoxia upregulates production of Aβ. The purpose for this is unknown, but was previously assumed to be a pathological consequence of ischemia. We hypothesized that Aβ may play a physiological role during hypoxia, such as modulating the anoxic depolarization (aDP). The aDP is a large inward current that occurs in response to excessive glutamate release, activating *N*-methyl-*D*-aspartate

receptors (NMDARs). Previously, our group has demonstrated activation of pannexin-1 (Panx1), a large, non-selective ion channel, downstream of NMDARs during hypoxia. Furthermore, mGluRs are known to regulate NMDARs, and may contribute to the aDP. Since NMDARs/mGluRs are a known target of Aβ, we hypothesized that Aβ would modify Panx1 opening during ischemia. Using whole-cell patch clamp electrophysiology in rat hippocampal slices, the aDP was assayed using low oxygen (~5 mmHg) artificial cerebral spinal fluid. Rat (r) and human (h) $Aβ_{1-42}$ were matured into a mixture of small to large oligomers. We report that low concentrations (pM to nM) of exogenous rAβ attenuated the aDP, and also blocked Panx1 opening on an NMDA overstimulation assay. Reducing endogenous Aβ levels using L-685,458 increased aDP severity. Human Aβ also had a protective effect on the aDP, and hippocampal slices from transgenic mice that overexpress hAβ oligomers had reduced aDP compared to those of wild-type littermates. Importantly, Aβ failed to block Panx1 currents directly in Panx1-expressing HEK cells. The apparent neuroprotective effect of Aβ on the aDP was reversed with co-application of mGluR1 antagonists, but not with an mGluR5 antagonist. Furthermore, the mGluR1 inverse agonist, Bay 367620 blocked the aDP in a similar manner to Aβ, and had no additive block with concurrent Aβ application, suggesting that Aβ may function as an mGluR1 inverse agonist. These data suggest a novel modulation of Panx1 opening by mGluR1, which is regulated by Aβ. Aβ production could be increased during hypoxia to reduce activation of Panx1, thereby attenuating the aDP and downstream cell death pathways.

Title: Exosomes derived from human neural stem cells-stimulated by interferon gamma enhance cellular stress mechanisms and accelerate neurological recovery of cerebral ischemic rats

Authors: *G. ZHANG[1], L. CHEN[2]
[1]Dept. of Neurosurgery, Zhongda Hosp., Sch. of Medicine, Southeast Univ., Jiangsu, China;
[2]Dept. of Neurosurg., Zhongda Hospital, Sch. of Medicine, Southeast Univ., Nanjing, China

Abstract: Ischemic stroke recovery is associated with neural stem cells (NSCs) development and neurovascular unit reconstruction. Exosomes, as important intercellular players in cellular communication, mediate neuro-restorative events, however, their effects / mechanisms in the injured brain is unknown. The objective of this study is to determine the effect of human NSCs-derived exosomes on the repair of ischemic stroke, and whether interferon gamma (IFN-γ)

stimulating can enhance the functions of NSCs exosomes. This study finds that IFN-γ stimulating managed the abilities of human NSCs-derived exosomes (hNSCs-Exo), including alleviated the level of oxidative stress of NSCs following H2O2 stimulating, augmented the NSC survival, and promoted the neuronal differentiation of NSCs. Furthermore, in rats ischemic stroke model, IFN-γ-hNSCs-Exo further facilitated the neurological functional recovery (such as modified Neurological Severity Score, Rotarod test, etc.) compared to hNSCs-Exo group, enhanced nerve cell survival and promoted neovascularization (microvessel density, MVD). Importantly, exosomes can be internalized or endocytosed by cells, after labeled with PKH67, it showed that exosomes migrated to the infarct regions together with cells, as interestingly, many exosomes entry into the nucleus. Next generation sequencing (NGS) revealed significant enrichment of hsa-miR-3656 and hsa-miR-133a-3p in IFN-γ-hNSCs exosomes compared with hNSCs exosomes. The mechanisms or effects of exosomes was to deliver specific exosomal microRNAs to cells for increasing cell survival and proliferation. In summary, hNSCs-derived exosomes possess the ability of neural regeneration and modulate neurological functional recovery, and play more positive roles by stimulating with IFN-γ (IFN-γ-hNSCs Exo). Exosomes provide a novel and promising strategy in modulating disease treatment and tissue regeneration, avoiding the risk of teratomas associated with cells.

Title: Liquefaction of the brain following stroke shares characteristics with atherosclerosis

Authors: *K. P. DOYLE[1,2,3], A. CHUNG[1], J. B. FRYE[1], J. C. ZBESKO[1], E. CONSTANTOPOULOS[4], M. HAYES[1], A. G. FIGUEROA[5], W. A. DAY[6], J. P. KONHILAS[4], B. S. MCKAY[5], T.-V. V. NGUYEN[1,2]
[1]Dept. of Immunobiology, [2]Dept. of Neurol., [3]Arizona Ctr. on Aging, [4]Dept. of Physiol. and Sarver Mol. Cardiovasc. Res. Program, [5]Dept. of Ophthalmology and Vision Sci., [6]Arizona Hlth. Sci. Ctr. Imaging Core Facility, Arizona Res. Labs, Univ. of Arizona, Tucson, AZ

Abstract: In response to ischemia, the brain degenerates by the process of liquefactive necrosis while the heart degenerates by coagulative necrosis. Liquefactive necrosis intensifies post-stroke injury, persists for months following a stroke and occurs for unknown reasons. Cholesterol is a central structural component of myelin. This means that in the aftermath of a brain injury the immune system must clear away substantially more cholesterol than in the aftermath of an injury to an alternative area of the body such as the heart following a myocardial infarction. Therefore, the goal of this research was to understand if the brain undergoes liquefactive necrosis following stroke due to cholesterol derived from myelin debris overwhelming the processing capability of phagocytic cells in the brain, leading to the overproduction of degradative enzymes. To that end, we used mouse models of myocardial infarction and ischemic stroke to compare the kinetics and characteristics of the inflammatory response to ischemia in the heart, a protein rich organ, to the inflammatory response to ischemia in the brain, a lipid rich organ. We then looked-for evidence of overlap in the molecular profile of the chronic inflammatory response to stroke and atherosclerosis. Finally, we tested if targeting pathways involved in the pathophysiology of atherosclerosis also modulate the damaging effects of liquefactive necrosis following stroke. We show that the brain takes substantially longer than the heart to heal from ischemia, and that intracellular and extracellular cholesterol crystals form within the infarct in the weeks following stroke. This is proceeded by the expression of many of the same proteolytic enzymes and pro-inflammatory cytokines associated with atherosclerosis. We then show that the expression of these proteolytic enzymes and pro-inflammatory cytokines is profoundly reduced in osteopontin (OPN) deficient mice, and that this is concordant with an accelerated recovery of motor function and a reduction in secondary neurodegeneration compared to wildtype mice. We anticipate these

findings to be a starting point for testing if treatments that target cholesterol overloading in microglia and macrophages are also useful for improving recovery in stroke patients. **Efforts to ensure scientific rigor:** Studies were performed in male wildtype and transgenic mice on the C57BL/6 background. Groups numbers were determined by power analysis and experimenters were blind to experimental condition. All antibodies, kits, and chemicals were obtained from established vendors that authenticate their reagents prior to shipment as part of a standard quality control procedure.

Title: $CD11b^{+}$ cells in developing brain and it's phagocytotic function change in neonatal hypoxia and ischemia model

Authors: *F. LI, Y.-J. MIN, L. YAN, Q. WANG, F. WANG, H.-R. HUA, Y. YUAN, H.-Y. JIN, Y. YANG
Kunming Med. Univ., Yuannan, China

Abstract: Hypoxia ischemia brain damage (HIBD) is one of the major causes of mortality in neonatal diseases and leads to long-term behavior abnormalities. The pathogenesis of long term behavioral disorder after HIBD is still unclear. However, the current studies suggests that this is associated with active brain inflammation and synaptic dysfunction. Synapses, during the developmental period experienced "synaptic pruning", this is the brain with phagocytotic cells to remove the weak synapses, and thus ensure the advantages of synaptic full growth process. HIBD causes local inflammantory response and phagocytotic cells activation, which involves both resident microglia cell (MC) and infiltrating monocyte-derived macrophage (MDMs). Due to lack of specific discriminate cell makers, little is known about the functional differences between resident MC and MDMs following hypoxia and ischemia, especially their phagocytotic function change in the developing brain. Therefore, we used a HIBD model of P9-11d mouse pups to investigate the dynamic changes of these two populations in the brain and their roles in phagocytosis. Immunofluorescence was used to test the expression of protein NeuN, CD11b, LAMP1 after HIBD 1d and 3 d. The flow cytometry was applied to detect target proteins

expression in $CD11b^+$ cells. CD11b/CD45 were used to distinguish MDMs ($CD45^{high}/CD11b^+$) and inherent MC ($CD45^{low}/CD11b^+$). In addition, CD36, TLR2, LAMP1 were used to indicate the phagocytotic function of $CD11b^+$ cells in mice' brain cortex after HIBD 1 d and 3 d. Analyses by flow cytometry and immunocytochemistry found that number of $CD11b^+$ cells within the brain increased after 1-3d with the severe injury and the increased $CD11b^+$ cells were mainly MDMs. So the CD11b cannot be used alone as a marker for the inherent MC in the brain. Additionally, the inherent MC is still the major cell that plays phagocytosis in early period after HIBD in $CD11b^+$ cells.

Abstract: Sedative and anesthetic drugs can injure neurons and oligodendrocytes in the developing brain. They can cause widespread cell death, impair synaptic maturation and plasticity, inhibit neurogenesis in the brains of rodents and non-human primates (NHP) and trigger long term behavioral and cognitive deficits. Hypothermia (HT) is successfully applied in neonatal and pediatric medicine to minimize brain injury from perinatal asphyxia and during cardiac surgery. We investigated HT as a potential protective treatment of the developing primate brain against histological toxicity of the anesthetic sevoflurane in NHP infants. Neonatal rhesus monkeys underwent sevoflurane anesthesia over 5 hours. Body temperature was regulated to lie in the normothermic (>37^{o}C), mild hypothermic (mean 36.27^{o}C) and moderately hypothermic (<35^{o}C) range. Animals were euthanized and brains collected at 8 hrs and examined immunohistochemically (activated caspase 3) and stereologically to quantify apoptotic neuronal and glial death. Sevoflurane anesthesia was well tolerated with oxygen saturation, end tidal CO_2

and electrolytes remaining at optimal levels throughout the procedures. Brains displayed significant apoptosis in both the white and gray matter. Areas predominantly affected included the visual, frontoparietal, cingulate and retrosplenial cortex, the thalamus, globus pallidum and putamen. Approximately 50% of the dying cells were glia and 50% were neurons. Mild hypothermia (35-37^{o}C) conferred significant protection from apoptotic injury whereas moderate hypothermia (<35^{o}C) did not. Our findings indicate that exposure of the infant rhesus macaque to sevoflurane for 5 hours is sufficient to cause widespread apoptosis of neurons and oligodendrocytes and that mild hypothermia is cytoprotective in the neonatal primate brain.

Abstract: Exposure to either NMDA antagonists or $GABA_A$ agonists produces a massive neuroapoptotic response in numerous animal models and has caused great concern since these two drug classes include many commonly used sedatives, anesthetics, and anti-epileptic drugs. This has resulted in the FDA requiring labels on 11 commonly used drugs warning they may disrupt brain development in children under 3 years of age if exposure exceeds 3 hours or occurs

multiple times (estimated to include around 160,000 children a year in the United States alone). Since clinical studies have produced conflicting results, animal models have become critically important. The initial studies in rodents were met with healthy skepticism based on the limited translatability to humans and the inability to continuously monitor small neonatal rodents during anesthesia. To address these concerns, studies in nonhuman primates (NHPs) confirmed this toxicity still occurs even when anesthesia is accompanied with mechanical ventilation and vital signs are maintained within normal limits. However, a second criticism is that the pain from surgery may protect the developing brain from anesthesia induced apoptosis. Rodent studies examining this possibility have produced inconsistent results with some finding inflammatory pain with anesthesia increases apoptosis and others finding neuroprotection. However, these studies might be criticized since: 1) they used a rodent animal model, 2) the inflammatory pain administered may not accurately simulate surgery, and 3) vital signs were not monitored throughout anesthesia. In order to address these deficiencies, we examined whether anesthesia with surgery can still increase apoptosis in the neonatal NHP. To eliminate possible confounding variables, animals were mechanically ventilated and vital signs were monitored throughout surgery. Necrotizing enterocolitis is the most common condition of the newborn requiring surgical intervention. We therefore exposed neonatal NHPs to either no anesthesia, isoflurane anesthesia alone, or isoflurane anesthesia with surgical resection of the bowel and anastamosis prior to sacrifice for histological assessment for apoptosis. Results revealed that isoflurane anesthesia increased both oligodendrocyte and neuronal apoptosis that was not altered by surgical intervention even when vital signs, blood gasses, and metabolic values are maintained within normal limits. These results indicate that the noxious stimulation from surgery has no effect on the apoptotic effects of anesthesia.

Title: DREADD-mediated activation of dopaminergic neurons ameliorates mild TBI-induced depression-like behavior in the adolescent female rat

Authors: *L. L. GIACOMETTI, D. LENGEL, R. A. ESPAÑA, R. RAGHUPATHI
Drexel Univ. Col. of Med., Philadelphia, PA

Abstract: Following mild TBI, girls report more emotional symptoms and take longer to recover from their symptoms than boys. Thirty five-day-old female rats were used to model mild TBI in the adolescent human. Rats were anesthetized and directly impacted on the skull using a 5mm metal tip just behind bregma over the midline suture (2mm depth, 5.5m/s velocity); sham-injured rats were anesthetized, but not injured. We have previously reported that female, but not male, adolescent rats subjected to this mild TBI exhibit depression-like behavior using the forced swim test (FST) at 5-6 weeks post-injury during the estrus phase of the estrous cycle. The dopaminergic system has been implicated in depression-like behavior and chronic alterations in dopaminergic neurotransmission, suggestive of a state of hypodopaminergia, have been reported following moderate-severe TBI. We hypothesized that a state of hypodopaminergia may contribute to depression-like behavior. Brain-injured tyrosine hydroxylase (TH)-Cre rats received bilateral ventral tegmental area (VTA) injections of the Cre-dependent Gq DREADD virus, pAAV-hSyn-DIO-hM3D(Gq)-mCherry, in order to activate dopaminergic neurons in the VTA or control virus, pAAV-hSyn-DIO-mCherry. Rats were tested 5 weeks later in the forced swim test 45 min following IP injection of clozapine-N-oxide (0.5mg/kg) or saline. CNO-injected, Gq-DREADD-expressing rats exhibited significantly lower immobility in FST than either saline-injected, Gq-DREADD-expressing rats or CNO-injected, control virus-expressing rats. We next hypothesized that the depression-like behavior occurred specifically in the estrus phase due to the surge in progesterone and estradiol occurring during proestrus as this has been shown to reduce dopamine D2 receptor density during estrus. Brain-injured rats were injected with the estrogen receptor antagonist, tamoxifen, and the progesterone receptor antagonist, mifepristone, during proestrus and tested in FST the following day during estrus. Tamoxifen and mifepristone administration during proestrus prevented the depression-like behavior in estrus. Administration of the dopamine D2-like receptor agonist, quinpirole (0.05, 0.1mg/kg), 1hr prior to testing in FST also ameliorated depression-like behavior during estrus in brain-injured rats.

Taken together, this data suggests that mild TBI-induced hypodopaminergia in combination with estrous phase-dependent changes in dopamine D2 receptor density may contribute to depression-like behavior in female rats.

Title: Sex-dependent cellular and cognitive deficits following traumatic brain injury in neonate rats are reversed by progesterone

Authors: *D. LENGEL[1], J. W. HUH[2], R. RAGHUPATHI[3]
[1]Neurobio. & Anat., Drexel Univ., Philadelphia, PA; [2]Children's Hosp. of Philadelphia, Philadelphia, PA; [3]Drexel Univ. Col. of Med., Philadelphia, PA

Abstract: Childhood traumatic brain injury (TBI) is associated with an increased risk for anxiety disorders, impaired cognitive function, and alterations in hypothalamic-pituitary-adrenal (HPA) axis function in adulthood. In order to investigate the long-term consequences of pediatric TBI on anxiety-related and cognitive function, 11-day-old male and female Sprague-Dawley rats were subjected to closed-head injury or sham surgery, and were evaluated for behavioral deficits in the novel object recognition (NOR) test, elevated plus maze (EPM), and forced swim test (FST), and for changes in neuronal excitability in the prefrontal cortex (PFC) 4 weeks following injury. Injured male rats showed a significant impairment in novel object recognition (NOR), which was associated with an increase in spontaneous excitatory post synaptic current (sEPSC) frequency and excitability in layer V Prelimbic area (PrL) pyramidal cells. In females, there was a deficit in NOR that did not reach statistical significance, but that was associated with an increase in sEPSC frequency in layer II/III PrL pyramidal cells and an increase in excitability in layer V PrL pyramidal cells. Treatment with progesterone following injury reversed NOR deficits and electrophysiological changes in both male and female injured rats. These deficits combined suggest that TBI may lead to increased dopamine release or increased D1 receptor activation in the PFC. Thus, progesterone may reduce cognitive and cellular deficits by modulating D1 receptor signaling in the PFC, presumably by inhibiting sigma-1 receptors. Male and Female injured animals also showed reduced anxiety in the elevated plus maze (EPM)

compared to sham animals. Further, female but not male injured rats had decreased immobility in the forced swim test (FST) specifically in the estrus and metestrus phases of the estrous cycle. The acquisition and retention of immobility in the FST are regulated by hippocampal glucocorticoid receptors (GRs), and are sensitive to changes in glucocorticoid levels. These data combined suggest that TBI may impair GR signaling, potentially to a greater degree in female rats, leading to altered anxiety-like behavior and stress-related adaptive behavior in the FST. Future experiments will focus on investigating the impact of pediatric TBI and sex differences on HPA axis function and GR expression associated with anxiety-related deficits, and on changes in DA transmission associated with cognitive and cellular deficits.

Title: Repetitive mild traumatic brain injury impairs performance in a rodent assay of cognitive flexibility

Authors: R. L. NAVARRA[1], C. P. KNAPP[1], *D. M. DEVILBISS[1], D. P. FOX[1], R. RAGHUPATHI[2], L. L. GIACOMETTI[2], S. B. FLORESCO[3], B. D. WATERHOUSE[1]
[1]Cell Biol. and Neurosci., Rowan Univ. - Sch. of Osteo. Med., Stratford, NJ; [2]Drexel Univ. Col. of Med., Philadelphia, PA; [3]Univ. British Columbia, Vancouver, BC, Canada

Abstract: Mild traumatic brain injury (mTBI) occurs in almost 80% of the 3 million reported cases of TBI-related emergency department visits each year in the United States. The majority of mTBIs, sometimes classified as concussions, are due to sports-related activities and typically occur repeatedly over the course of an athlete's career. mTBI symptoms are generally classified as either somatic or neuropsychiatric/cognitive in nature and include impairments in prefrontal cortex mediated functions, including attention, memory, processing speed, reaction times, problem solving, and cognitive flexibility. To date, there remains a major gap in our understanding of the behavioral manifestations, underlying neurobiology, and treatment of mTBI. An even greater gap exists in our understanding of the consequences of repeated mTBI incidents. The goal of the present study was to examine the effects of repetitive mTBI within a rodent assay of cognitive flexibility. Rats were exposed to a series of three closed head injuries (controlled cortical impact model) within a week prior to performing an automated strategy

shifting task, which required rats to learn and shift strategies according to changing task demands. Rats initially acquired a visual cue strategy in which a light illuminated above one of two possible levers (left or right) indicated the correct response for reward. Twenty-four hours after initial acquisition, rats again performed the task using the visual cue strategy followed by a series of strategy shifting and reversal learning challenges. Repetitive mTBI reduced throughput scores, a performance index that blends accuracy and response speed, and increased reaction times within the task. Preliminary immuno-histological analyses of brain tissue from experimental animals revealed a reduction of noradrenergic fiber density in the anterior cingulate, medial prefrontal, and lateral orbitofrontal cortical regions of injured vs un-injured sham animals. These results indicate that performance and task efficiency in an operant test of cognitive flexibility are impaired after repetitive mTBI. As such, this model presents a useful approach for further investigating the behavioral deficits and potential treatment strategies for patients who have experienced multiple mTBI insults. Moreover, evidence of reduced noradrenergic function in prefrontal cortex provides a potential link between a neuromodulatory system normally associated with arousal, attention, and decision making and this model of repetitive head trauma-induced behavioral deficits.

Title: Modeling the neural circuit of rodent lower urinary tract

Authors: *T. BANKS[1], V. GUNTU[2], M. GAHL[3], G. JONES[1], D. J. SCHULZ[4], S. S. NAIR[5]
[2]Dept. of Electrical and Computer Engin., [1]Univ. of Missouri, Columbia, MO; [3]Univ. of Missouri, Columbia, ; [4]Div. of Biol. Sci., Univ. of Missouri-Columbia, Columbia, MO; [5]Electrical & Computer Engin., Univ. of Missouri Columbia, Columbia, MO

Abstract: We report results from an interdisciplinary study focused on an understudied but crucial aspect of how spinal cord injury (SCI) alters the properties and activity of uninjured neural networks focusing on the rodent lower urinary tract. Our hypothesis is that neurons are fundamentally altered when inputs are removed by injury. Understanding how and why these neurons and networks are altered by denervation as a result of injury is essential for studies aimed at restoring function. Computational models complement biological experiments very well

in such a study.The sympathetic pathway controls bladder filling and includes pre-ganglionic neurons in the spinal cord and post-ganglionic cells of the inferior mesenteric ganglion. Sacral parasympathetic outflow controls bladder voiding and includes the pre-ganglionic cells and the postganglionic neurons of pelvic ganglia. The urethral sphincter is innervated by motor neurons projecting through the pudendal nerve. While urine storage mechanisms are largely dependent on spinal reflex pathways, urine voiding is dependent on a rapid switch from filling to voiding mediated by descending Supraspinal inputs. Sensory information regarding bladder fullness is conveyed to the spinal cord through the pelvic and splanchnic nerves.We have developed biophysical models of the cells in all major ganglia using information from the literature and first-hand biological recordings pelvic ganglia neurons from Schulz Lab. Sensory afferents are modeled presently using a regression fit with filling rate. The model successfully reproduced the sympathetic storage reflex and guarding reflex. With the base model, we added spinal interneurons which makes the circuit more realistic and give us flexibility to explore how these spinal circuits complement normal functioning of LUT. On-going work focuses on simulating both normal as well as abnormal (e.g., detrusor-sphincter dyssynergia) functioning at neuronal and micro-circuit level. This improved model will then be modified for SCI studies by disconnecting the top down control and investigate mechanisms that might restore the reflexive arc.

Title: Repeated mild traumatic brain injury in a mouse model: The effect of BDNF genetic polymorphisms on recovery and personalized treatment approaches

Authors: *S. THAKKER-VARIA[1], S. L. TENG[2], A. O. GIRRATANA[2], C. ZHENG[2], J. ALDER[2]
[1]Dept Neurosci & Cell Biol, [2]Rutgers University-Robert Wood Johnson Med. Sch., Piscataway, NJ

Abstract: Traumatic Brain Injury (TBI) is a serious and potentially life threatening clinical problem. Clinicians have long noticed that certain patients recover better after TBI, and identifying what makes some patients more susceptible is a vital step in understanding the

underlying mechanisms through which TBI causes its deleterious effects. Following TBI, a number of factors are regulated; among them are neurotrophic factors, such as brain derived neurotrophic factor (BDNF). Previous studies in our lab have shown that TBI results in the activation of proBDNF pathway while the mature BDNF pathway is downregulated, which may play a role in the poor recovery that is seen. In this study, we sought to determine the effect of specific single nucleotide polymorphisms (SNPs) on recovery after TBI, and to investigate the underlying mechanisms that may be a factor. We have investigated cellular and behavioral outcomes in genetically engineered mice with the BDNF Val66Met polymorphism following repeated, mild TBI (rmTBI) in a lateral fluid percussion model. We have found that Met carriers have a larger injury volume as assessed by MRI and increased levels of neurodegeneration, apoptosis, p-tau, microglia, and gliosis in the cortex compared to Val carriers at 1 and/or 21 dpi. We have done rotarod and balance beam testing to examine sensorimotor ability, and found that injured mice have worse motor function than sham mice, but that there are no differences in sensorimotor function across genotypes. We have done novel object recognition testing and Morris water maze to investigate learning and memory in this paradigm. In the novel object paradigm, we have found that Met carriers in general spend less time exploring the open field and the novel object, but that there is no difference in the preference index after our injury paradigm. In order to gain insight into the mechanism of action of the cellular differences that we have seen, we used western blot analysis to investigate the levels of pro and mature BDNF after injury across the genotypes at 1 and 21 dpi, and found Met carriers have more proBDNF and less mature BDNF than Val carriers. As a result, we have concluded that the Met allele is a risk allele after rmTBI and have begun rescue experiments in injured mice by targeting the altered BDNF pathway using an AAV vector that overexpresses BDNF.

Title: Hippocampal synaptic plasticity changes following exposure to high frequency head impacts (HF-HI)

Authors: *S. S. SLOLEY[1], B. S. MAIN[2], C. N. WINSTON[5], M. S. PARSADANIAN, 20057[2], J.-Y. WU[3], J. G. PARTRIDGE[6], S. VICINI[7], M. P. BURNS[4]

[1]Interdisciplinary Program in Neurosci., [2]Dept. of Neurosci., [3]Neurosci., [4]Dept of Neurosci., Georgetown Univ., Washington, DC; [5]Neurosci., UC San Diego, LA Jolla, CA; [6]Pharmacology-Physiology, [7]Dept Parmacology & Physiol., Georgetown Univ. Med. Ctr., Washington, DC

Abstract: Mild traumatic brain injury, or concussion, accounts for over 70% of all cases of TBI reported each year. Sustaining multiple concussions is associated with the development of long lasting cognitive and memory impairments. The severity of these impairments increases longitudinally, and in an injury frequency-dependent manner. Chronic traumatic encephalopathy (CTE), a slowly developing tauopathy, has been associated with the development of these impairments; however, it is unknown if the cognitive deficits associated with CTE can occur prior to the deposition of tau and death of neuronal cells. We therefore sought to identify any tau-independent mechanisms associated with deficit development following exposure to high frequency concussive impacts. To perform these studies, our group has developed an experimental model of high frequency head impacts (HF-HI) in which mice receive 5 hits a day for 6 days (30 hits total). Immunohistochemical analyses revealed that HF-HI did not cause cell death or inflammation. Golgi staining for dendritic spines indicated that there was no excitatory synapse loss detectable compared to sham mice. Despite the normal synapse number, behavioral testing at one month post injury showed that HF-HI results in deficits in the acquisition and probe phases of the Morris water maze, as well as a reduction of spontaneous alterations in the T-Maze, suggesting impaired learning and memory. Given the development of these deficits in the absence of structural or synaptic loss, we hypothesized that HF-HI was eliciting synaptic adaptations to confer neuroprotection at the cost of normal physiological function. To examine this, we first tested the effect of HF-HI on hippocampal synaptic plasticity using the long-term potentiation (LTP) paradigm and extracellular field recordings. Input/output curves for HF-HI mice were identical to sham mice, indicating that the Schaffer collateral pathway remained undamaged after HF-HI - however there were significant impairments in LTP. Whole cell patch clamp electrophysiology done on individual CA1 pyramidal neurons after HF-HI reveal differences in intrinsic membrane properties, excitability, and NMDA receptor contributions to excitatory post synaptic currents after HF-HI, reinforcing the hypothesis that synaptic adaptations alter function following HF-HI. These changes in synaptic transmission also provide a mechanism for altered plasticity. We have concluded that exposure to a high frequency of concussive and sub concussive head impacts causes synaptic adaptations to promote cellular survival that ultimately hinder plasticity and neurotransmission.

Abstract: Severe traumatic brain injuries (TBIs) are a major cause of death and disability in the United States and account for around 30% of injury-related deaths. Severe TBIs are commonly caused by penetrating or blunt force injuries to the brain. Individuals who sustain these injuries, encounter significant loss of brain tissue, which directly contributes to the debilitating long-term disabilities and sensorimotor and cognitive dysfunction in this population. Current standard-of-care is limited to the acute administration of anti-inflammatory drugs followed by aggressive rehabilitation upon patient stabilization. There are currently no tissue-replacement or regenerative therapies for severe TBI. We hypothesized that a hydrogel-based brain tissue mimicking implant containing sulfated chondroitin sulfate glycosaminoglycans (CS-GAGs) native to the brain extracellular matrix (ECM) will bind and retain neurotrophic factors, enhance paracrine signaling of infiltrating neural stem cells (NSCs), and provide physical support to facilitate tissue repair after a severe TBI. Adult male Sprague-Dawley rats (2 months old) were subjected to a controlled cortical impact injury, which produced a severe TBI in the frontoparietal cortex of the brain. Sham control rats received a craniotomy but did not receive a TBI. Animals assigned to the CS-GAG treatment group received 20 µl of CS-GAG hydrogel intraparenchymally at the site of injury. The brains were harvested 20-weeks post-injury/sham treatment, sectioned and stained for neuron, astrocyte, oligodendrocyte, NSCs, growth factors, and vascularization specific markers. Administration of CS-GAG matrices significantly reduced the extent of glial scar when compared to TBI only controls ($p<0.05$). CS-GAG matrix treated animals also demonstrated a significant increase in the number of proliferating NSCs (Ki67, Sox1) and biomarkers for vascularization (Collagen, RECA) at the site of injury when compared to TBI-only controls ($p<0.05$). These results provide evidence suggesting that CS-GAG matrix implants can reduce inflammation and promote NSC mediated repair and recovery from severe TBI. **Supported by NIH R01NS099596-01 to LK.**

Title: Developing potential quantitative tractography biomarkers of epileptogenesis following experimental traumatic brain injury

Authors: *R. P. CABEEN[1], D. DUNCAN[1], A. BRAIMAH[1], R. IMMONEN[2], X. NDODE-EKANE[2], O. GRÖHN[2], D. WRIGHT[3], I. ALI[3], R. BRADY[3], S. SHULTZ[3], N. JONES[3], P. CASILLAS-ESPINOSA[3], C. Sch., Monash Univ., Melbourne, Australia; [4]Dept. of Neurol., [5]Dept. of Neurosurg., Ronald Reagan UCLA Med. Ctr., Los Angeles, CA

Abstract: Objectives:
Some traumatic brain injury (TBI) cases subsequently develop epilepsy, and research on antiepileptogenic therapies is hampered by a lack of biomarkers for identifying high risk individuals. This work develops techniques for identifying potential quantitative magnetic resonance imaging (MRI) biomarkers of epileptogenesis in a rodent model following experimentally-induced TBI. We examine tractography imaging metrics of brain connectivity and white matter microstructure.
Methods:
The Epilepsy Bioinformatics Study for Antiepileptogenic Therapy (EpiBioS4Rx) is an international, multicenter Center without Walls (CWOW), and the animal imaging component of the study has collected in vivo MRI across three sites. Rats were separated into sham and experimentally-induced TBI groups, anesthetized, and imaged in Bruker scanners at high-field strength (one at 4.7T and two at 7T). The MRI protocol included 3D-multiecho GRE for T2* and magnetization transfer ratio (MTR) mapping and a 3D-EPI sequence for diffusion MRI with 42 gradients at a b-value of 2800 s/mm2. Multi-fiber deterministic tractography was performed using the Quantitative Imaging Toolkit with masks drawn to select the fibers from the internal capsule, corpus callosum, fimbria fornix, and perforant pathway. The following bundle metrics were analyzed: track density, volume, length, and averages of fractional anisotropy, mean diffusivity, axial diffusivity, radial diffusivity, MTR, and T2*.

Results:
Our results demonstrate the feasibility of extracting quantitative tractograhy metrics across subjects, which may be used for detecting structural brain alterations related to epileptogenesis. We also show the improved anatomical accuracy of tractography with multi-fiber tracking in the study's data and the value of deriving metrics through multimodal analysis.
Conclusions:
This work demonstrates the potential value of combining tractography models with other MRI modalities to develop biomarkers of epileptogenesis in our continuing work. This is in part due to the added structural information provided by diffusion MRI in delineating relevant white matter pathways, which can then be combined with other discriminative quantitative MRI parameters identified by previous studies. Future work will combine these findings with epilepsy parameters and biospecimens collected as part of EpiBioS4Rx and potentially translate them to human imaging to facilitate the discovery of novel antiepileptogenic therapies.

Title: Assessing cognitive correlates of cellular regeneration after brain injury in adult zebrafish

Authors: *K. SKAGGS
Biol., Univ. of Findlay, Findlay, OH

Abstract: Zebrafish (*Danio rerio)* have become a popular vertebrate model organism for analyzing disorders of the nervous system because, unlike mammals, they have the ability to regenerate neurons following brain injury or degenerative neuronal loss. In the past, experiments have focused on scientific inquiry concerning the genomic and cellular mechanism of neuronal regeneration following brain injury. More recently, studies using learning and memory tasks have provided evidence that zebrafish can also be useful models for investigating cognitive function. The purpose of these experiments was to extend previous cellular work by examining the effect of neuronal loss and regeneration on behavior. We examined several established tasks

to determine their sensitivity of neuronal loss and recovery following telencephalic injury in adult zebrafish. The tasks selected use natural behaviors, such as shoaling and scototaxis, that assessed anxiety, learning, and memory: light-dark preference (LDT), associative learning (AL), and latent learning (LL). Groups of adult zebrafish (equal numbers of males and females) were randomly assigned to task, condition within the task (if appropriate) and injury condition. Results indicated that LDT and AL, but not LL, were potentially sensitive to the effects of injury on behavior and recovery. Modifications to test conditions, such as extended habituation to the test apparatus, were employed to minimize inter- and intra-individual variability in behavior on all tasks both before and after injury.

Title: Chronic neurocognitive sequelae of tbi & ptsd: An animal model

Authors: *A. FESHARAKI
Yale Sch. of Med., New Haven, CT

Abstract: There an increasing level of awareness of the long term neurocognitive impact of mild traumatic brain injury (mTBI), both in the civilian population, as well as the veterans. The individuals with brain injury are more susceptible to developing chronic neurodegenerative disorders, such as chronic traumatic encephalopathy (CTE), which was initially diagnosed in the domain of contact sports, such as boxing. The characteristic of CTE is comprised of neurofibrillary tangles (NFTs), pre-tangles, dot-like and thread-like neurites within the neocortex, depth of sulci, and proximal blood vessels. The animal model that we are proposing to study using C57BL/6 mice, utilizes the synergism of mTBI and chronic stress, and will be used as a simulation of the real life CTE. This will in turn will create a robust model for functional deficits of chronic traumatic encephalopathy (CTE). As per our preliminary data, the combination of CVS and CHI creates induces tauopathy, as early as one week after receiving injury, as well as significant neurocognitive deficits, as measured by performance in memory paradigms, such as Morris Water Maze task, novel object recognition test, and passive avoidance test.

Abstract: Traumatic brain injury (TBI) is one of the leading causes of neurological deficits and death worldwide, and over 1.7 million individuals suffer a TBI each year in the United States. Sustaining a TBI can result in immediate and long-term behavioral, physical, and cognitive deficits, and older adults are at a higher risk for death following a TBI. Our laboratory has previously characterized the neuropathological and behavioral consequences of varying degrees of TBI in both mice and rats of varying ages. To develop a high-throughput platform upon which to test the effects of therapeutic interventions, we have started to assess behavior and physiological parameters in Drosophila melanogaster (the fruit fly) using the High Impact Trauma (HIT) device- a model of fly closed-head TBI described by Katzenberger et al. (2015). Briefly, the procedure involves placing flies into a plastic tube that is mounted via a spring to a table. The tube is lifted against the force of the spring and allowed to slam back into the table, causing the flies in the tube to accelerate toward the inner surface of the tube at high velocity. Adult, wild-type Drosophila were purchased as a culture, bred, and raised through metamorphosed adult fly. At various ages, groups of Drosophila received TBI via the HIT device (or a “sham” procedure for controls), followed 24 hours later by motor performance testing using the Rapid Iterative Negative Geotaxis (RING) assay. The data demonstrate a significant age-related decline in motor function, and preliminary results suggest that TBI exacerbated the decline. This model of TBI in flies thus corroborates clinical observations of aging humans, providing a viable, high-throughput model of aging and its interaction with TBI that may be used in future studies to assess therapeutic interventions.

Abstract: Disabilities resulting from cerebellar damage in humans, ranging from motor to cognitive disorders, produced both by traumatic brain injury as for hereditary diseases. This study aimed to identify the motor sequelae after cerebellar injury produced by ferric sulfate administration in adult rats and to know the noradrenergic status in the hippocampus, pons and cerebellum during functional recovery. Because rats have a spontaneous recovery of the levels of noradrenaline (NA) as well as the motor sequelae after cortical brain injury and considering that the cortex has anatomical relations with the cerebellum through the pontine relay, we have the hypothesis is that the cerebellar injury the same effects can be happen. Rats were subjected to surgery, one group received saline infusion in the cerebellum and the other group ferric sulfate. Motor activity was recorded using the paradigm of the balance beam for 10 days, the rats from the saline group and from the iron group were sacrificed by decapitation to obtain the cerebellum, pons and hippocampus. The NA was measured by a chromatograph (HPLC) coupled to an electrochemical detector. The data obtained from the behavioral assessment were analyzed and compared using the Mann Whitney test, the concentrations of NA were analyzed by the Student's t test for independent groups. The animals were improving their motor skills days after receiving the injury. NA levels in the cerebellum, pons and right hippocampus showed a nonsignificant increase, however, the left hippocampus did have a significant increase. This study suggest that the NA is affected in a similar way that is observed in cortical lesions during functional recovery.

Title: Pattern separation deficits and enhanced dentate gyrus activity following mild traumatic brain injury

Authors: *R. T. SOMACH[1], S. SAMUEL[2], H. METHENY[2], A. S. COHEN[2]
[1]Univ. of Pennsylvania, Philadelphia, PA; [2]Anesthesiol. and Critical Care Med., Children's Hosp. of Philadelphia Univ. of Pennsylvania, Philadelphia, PA

Abstract: Cognitive deficits are one of the most common outcomes after mild Traumatic Brain Injury (mTBI). Patients have symptoms of attentional deficits, difficulties in cognitive planning and memory impairments. An important component of many of these symptoms is pattern separation, which is the ability to discriminate between similar information for better cognitive processing. The dentate gyrus (DG) of the hippocampus has been shown to be particularly involved with pattern separation. The hippocampus is also especially vulnerable to mTBI. After injury, shifts in neural excitability are seen throughout the hippocampus in DG, CA1 and CA3. The purpose of this study was to examine the behavioral changes in pattern separation after injury and examine shifts in neural excitability that would correspond with these behavioral changes. Using the lateral fluid percussion injury (LFPI) model, mice were injured and trained with a modified spatial object learning task to test pattern separation. Injured animals showed a deficit in the ability to recognize objects as compared to sham animals. In addition, hippocampal slices were taken from these animals within 2 weeks following the behavioral tasks. Post-synaptic field potentials and paired pulse ratio were measured extracellularly in these hippocampal slices. Recordings were taken by stimulating either the Lateral Perforant Pathway or the Medial Perforant Pathway and recording in DG, or by stimulating the Schaffer Collaterals and recording in CA1. Injured animals were found to have an increase in excitability in the Medial Perforant Pathway of DG as compared to sham animals.

Title: Chronic stress exposure provided during adolescence confers protective effects on experimental traumatic brain injury acquired as an adult

Authors: *P. BARRA DE LA TREMBLAYE, J. L. WELLCOME, K. M. WILEY, I. H. BLEIMEISTER, M. S. HELKOWSKI, J. P. CHENG, C. O. BONDI, A. E. KLINE
Physical Med. & Rehabil., Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Early-life stress experiments have been developed to model early adverse events in humans. However, the long-term consequences of early-life adversities on adult behavioral outcomes after traumatic brain injury (TBI) have not been examined. Hence, we propose to focus on early-life stress specifically in adolescence, a time of dynamic developmental changes, to examine the long-term effects on adult emotional and cognitive behavior post TBI. On postnatal days (PND) 30-60, adolescent male Sprague-Dawley rats were exposed to 4 weeks of chronic unpredictable stress (CUS). After an additional 4 weeks of resting (PND 60-90), the rats were anesthetized and receive either a controlled cortical impact of moderate severity (2.8 mm tissue deformation at 4m/s) or sham injury. The rats were assessed for anxiety-like behavior in the open field test (OFT), and learning and memory in the novel object recognition (NOR) and Morris water maze (MWM). CUS exposure in adolescence lead to better outcomes relative to non-CUS TBI controls as evidenced by increased time exploring the open field and more focus on the novel task ($p < 0.05$). The CUS rats also performed significantly better in the spatial learning task relatively to the non-CUS controls ($p < 0.05$). Despite the CUS rats performing better on each task relative to the non-CUS controls, they were still significantly impaired on all tests relative to the uninjured sham controls ($p < 0.05$). These preliminary data suggest that moderate chronic unpredictable stress provided during adolescence may provide a protective effect against TBI acquired during adulthood and/or induce adaptive behavioral responses after TBI. These speculations as well as potential mechanisms for the effects are currently being investigated.

Title: Amantadine confers significant motor and cognitive benefits after experimental brain trauma

Authors: A. OKIGBO, B. ROYES, I. H. BLEIMEISTER, J. P. CHENG, D. M. BROOKS, C. O. BONDI, *A. E. KLINE
Phys Med. & Rehab, Psych, Safar Ctr. Resuscitation Res., Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Introduction: Traumatic brain injury (TBI) is a pervasive health care issue affecting 10 million individuals worldwide each year. Approximately 1.7 million reside in the United States. Currently, treatments are limited and therefore various pharmacotherapies have been, and continue to be, evaluated. The ability of amantadine (AMT), a dopamine$_2$ receptor agonist, to attenuate the behavioral and histological deficits that manifest following a traumatic brain injury (TBI) was assessed in rats using three doses to determine the dose with greatest efficacy. Hypothesis: AMT will produce increased motor and cognitive benefits over vehicle-treated controls. Methods: Isoflurane anesthetized adult male rats received either a controlled cortical impact (CCI) of moderate severity (2.8 mm tissue deformation at 4m/s) or sham injury, and then were randomly assigned to receive AMT (10, 20, and 40 mg/kg) or saline vehicle (VEH, 1 mL/kg). Treatments began 24h after injury and were administered intraperitoneally once daily for 19 days. Motor function was assessed on post-operative days 1-5 using beam-balance and beam-walk protocols. Spatial learning and memory was assessed on post-operative days 14-19 using a Morris water maze task with corresponding probe and visible trials. The behavioral data were analyzed by a repeated measures ANOVA followed by a Newman-Keuls post-hoc test to determine group differences. Results: There was no statistical difference between the AMT and VEH-treated sham groups so the data were pooled. The 20 mg/kg dose of AMT enhanced both motor and cognitive performance relative to the other doses and vehicle-treated TBI groups ($p < 0.05$). Conclusion: the data suggest that 20 mg/kg is optimal for improving motor function and spatial learning and memory in this model of TBI. Significance: These results suggest that AMT may be a viable pharmacotherapy for clinical TBI. Future studies should evaluate potential mechanisms for the AMT-induced benefits, but a likely candidate may be restoration of dopaminergic neurotransmission.

Title: The effect of experimental brain trauma on sustained attention and behavioral flexibility in rats

Authors: T. J. CRAINE, L. A. KUTASH, D. A. O'NEIL, A. IOUCHMANOV, J. P. CHENG, A. E. KLINE, *C. O. BONDI

Abstract: Impaired attention is central to the cognitive deficits associated with long-term sequelae for many traumatic brain injury (TBI) survivors. Considering that cognitive deficits are often assessed in the clinic using multi-domain neuropsychological cognitive battery tests, we employed, for the first time, a multimodal approach to determine higher-order attentional capabilities after moderate TBI. We used two frontal cortex-dependent 'attentional tasks', namely the operant 3-choice serial reaction time task (3-CSRT) and the digging attentional set-shifting (dAST) paradigms. We hypothesized that rats subjected to TBI will exhibit attentional deficits on both higher-order cognitive tests. The 3-CSRT, a modified version of the five-choice serial reaction time task, which was designed as an analogue of the human continuous performance test, requires the animal to orient toward and divide attention between three nose poke holes in an operant chamber, in which brief (300 ms) cues are randomly presented, to obtain a sucrose pellet reward. Upon reaching baseline of greater than 70% accuracy, which takes approximately 2 months using incrementally-decreasing cue durations, adult male Sprague-Dawley rats were subjected to a controlled cortical impact (2.8 mm cortical tissue deformation depth at 4 m/sec) or sham injury over the parietal cortex in the right hemisphere. After two weeks of recovery, they were re-tested on 3-CSRT for ten days and then trained and tested on dAST, which involves a series of increasingly difficult stages, including simple and compound discriminations, stimulus reversals, and intra/extradimensional set-shifts, at approximately 28-29 days post-surgery. Preliminary results suggest that rats subjected to parietal TBI display reduced percent accuracy, as well as increased omissions and premature responses (a possible indication of reduced vigilance) when re-tested post-surgery on 3-CSRT compared to Sham rats and to their own pre-insult baseline. Ongoing analyses include post-surgery reaction times, dAST performance (total trials, total errors, and set-loss errors), as well as within-subject correlations

between attention test modalities. The experimental approach to assess complex attention capabilities post-TBI via multimodal testing is clinically-relevant and may provide reliable avenues towards developing therapeutic targets.

Title: Multimodal assessment of executive function and behavioral flexibility after frontal brain trauma: Beneficial effects of milnacipran

Authors: *L. KUTASH, T. J. CRAINE, D. A. O'NEIL, J. P. CHENG, A. E. KLINE, C. O. BONDI
Physical Med. and Rehabil., Univ. of Pittsburgh, Pittsburgh, PA

Abstract: This study aims to investigate complex cognitive deficits after experimental TBI in rats subjected to a clinically relevant frontal lobe injury, and the beneficial effects of chronic milnacipran treatment, a dual serotonin-norepinephrine reuptake inhibitor. We hypothesized that rats will display cognitive deficits in both the operant and digging versions of the attentional set-shifting task, and that chronic milnacipran treatment will attenuate these deficits. To maintain a parallel with the clinic where patients are given multi-domain cognitive test batteries, we employed a multimodal approach to determine executive function after moderate frontal lobe TBI, by using two prefrontal cortex-dependent attentional set-shifting tasks, the operant (oAST) and digging (dAST) paradigms, as analogs of the clinical Wisconsin Card Sorting Test. The oAST requires rats to perform flexible switches between perceptual dimension rules “light” and “side” to obtain a sucrose pellet reinforcer. The dAST involves a series of increasingly difficult discriminative tasks, including simple and compound discriminations, stimulus reversals, and intra/extradimensional shifts. Dependent measures for tasks include number of trials to reach criterion (TTC), as well as total, perseverative, and set-loss errors. Adult male Sprague-Dawley rats reached oAST baseline in approximately three weeks (TTC within 10% variability of previous three days) and then were subjected to a controlled cortical impact (2.4 mm cortical deformation depth at a speed of 4 m/sec) or sham injury over the prefrontal cortex in the right hemisphere. During surgery, they also received intraperitoneal implantation of osmotic

minipumps containing milnacipran (30 mg/kg/day) or vehicle. After ten days of recovery, they were re-tested on oAST for ten days and then trained/tested on dAST, at approximately 26 days post-surgery. Preliminary results suggest that injured rats require higher numbers of total trials to complete oAST post-surgery compared to Sham and to their own pre-insult baseline, while also displaying higher numbers of total and perseverative errors (n=5/group). These alterations are largely remediated by chronic milnacipran treatment. Statistical analyses will employ repeated-measures ANOVA followed by Newman-Keuls post hoc for individual test days when appropriate. In summary, milnacipran appears to be a potential therapeutic option for managing higher-order cognitive deficits following TBI. A scatter plot correlation for individual rats' performance on both tests indicates the dAST and oAST are concurrently valid and sensitive to TBI-induced cognitive disturbances.

Title: Alterations in motivational behavior and executive function in adolescent rats following pediatric traumatic brain injury

Authors: *K. GROBENGIESER, N. PATEL, T. J. CRAINE, D. A. O'NEIL, L. A. KUTASH, J. P. CHENG, A. E. KLINE, C. O. BONDI
Physical Med. and Rehabil., Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Traumatic brain injuries (TBIs) affect 2.5 million individuals in the United States each year, ranging from mild concussions to severe trauma or death. With 500,000 yearly emergency room visits being attributed to childhood-acquired brain trauma (under 14 years of age), patients endure long-lasting cognitive impairments, as well as psychopathological consequences. When head trauma occurs during a critical period of neuronal development and maturation characterized by increased educational and environmental demands, survivors of childhood TBI display reduced learning rates, delays in making age-appropriate developmental gains, as well as behavioral and emotional disturbances. The overarching aim of this proposal was to assess clinically-relevant motivational and cognitive-behavioral dimensions in adolescent rats who received a TBI as pediatrics, by using an instrumental learning task and an attentional set-shifting test (AST). We hypothesized that rats subjected to TBI will display task-dependent

impairments in motivated behavior and executive function. We employed a multimodal approach to determine instrumental learning and cognitive flexibility capabilities after moderate parietal lobe (2.2 mm tissue deformation depth at 4 m/sec) or sham controlled cortical impact injury to the right hemisphere in pediatric Sprague-Dawley rats (PND 17). After ten days of recovery, they were trained on a fixed-ratio schedule of 1 for 12 consecutive days in operant chambers fitted with three nose-poke holes and a food trough, by learning to poke for sucrose pellet reinforcement in the center hole when illuminated. Each session lasted 100 trials or 30 min, whichever occurred first. Outcome measures included the number of total trials completed, task-irrelevant pokes (left or right nose-poke holes), and latency for pellet retrieval following instrumental nose-poking. Rats were then trained/tested on AST at PND 42-43, which involves a series of increasingly difficult stages, including simple and compound discriminations, stimulus reversals, and intra/extradimensional set-shifts. Dependent measures included the number of trials to reach criterion, as well as total and perseverative errors. While testing is currently ongoing, upcoming statistical analyses will employ repeated-measures ANOVA followed by Newman-Keuls post hoc for individual test days when appropriate. These findings will advance our understanding of long-term higher-order cognitive and motivational deficits in adolescent survivors of childhood brain trauma.

Title: An investigation of zinc supplementation in a mouse model of repetitive mild traumatic brain injury

Authors: *C. L. NEELY[1], C. M. HERNANDEZ[1], G. M. GRANT[2], T. H. SHAW[1], J. M. FLINN[1]

Abstract: Chronic traumatic encephalopathy (CTE) is a progressive neurodegenerative tauopathy caused by repetitive mild traumatic brain injury (rmTBI). The condition is characterized by tau hyperphosphorylation in the cortex and limbic structures, disordered memory, and impaired executive functioning. One target for possible intervention is zinc (Zn), a tightly regulated trace biometal found throughout the brain. Brain injury causes an immediate

increase in Zn release followed by a Zn deficiency in the synapse, worsening secondary injury cascades beyond levels caused by initial Zn release. Prophylactic dietary Zn supplementation increased neuronal proliferation and improved behavioral outcomes following a single severe TBI (Cope et al, 2012; Cope et al., 2016); however, other research has suggested that supplemental Zn can exacerbate TBI-related neuropathology such as tau aggregation (Huang et al., 2014). Given the conflicting evidence, this project sought to explore whether Zn possessed the same prophylactic properties in a mouse model of rmTBI to represent the same injury that leads to CTE. Approximately 100 four-week-old male and female C57BL/6J mice consumed either standard lab water or 10 parts per million Zn-supplemented water for eight weeks prior to injury. At 12 weeks of age, mice underwent either 5 sham procedures or 5 closed-head injuries spaced apart by 48 hours using a Leica ImpactOne device (V = 5m/sec; dwell time = 200ms; impact depth = 1mm; impact tip diameter = 5mm). Mice completed a battery of behavioral tests that measured anxiety and locomotion, wellbeing, and spatial memory. Preliminary data collapsed across sex showed no effect of Zn supplementation or TBI on open field or burrowing behavior. In the elevated zero maze, injured mice consuming lab water had a reduced number of head dips compared to their sham counterparts. Both sham and injured mice consuming Zn water had a lower number of head dips compared to injured and sham mice consuming lab water; however, injured mice consuming Zn water had a modest increase in the number of head dips. Injured mice on lab water had the lowest number of total entries; in contrast, injured mice consuming Zn water had the highest number of total entries compared to the other groups. Injured animals showed slower latencies to reach the hidden platform in Morris Water Maze. Histology and western blotting will assess free Zn levels, gross morphological damage, and changes in protein expression associated with CTE-like pathology. Results will further develop evidence for Zn as a potential target for those who are at higher risk for brain injury.

Title: Interaction of chronic variable stress and intranasal zinc treatment following traumatic brain injury

Authors: *E. N. DOHERTY[1], W. R. KOCHEN[2], J. M. FLINN[3]
[1]Psychology, George Mason Univ., Springfield, VA; [2]George Mason Univ., Woodbridge, VA; [3]Psychology, George Mason Univ., Fairfax, VA

Abstract: Mild traumatic brain injury (mTBI) is the most common traumatic brain injury (TBI) affecting soldiers. mTBIs can produce long-term cognitive and behavioral deficits, which tend to be exacerbated by the high stress experienced by soldiers. The role of zinc (Zn) in TBI has been noted for its effect on memory, as Zn may be a neuroprotective agent following injury. This study seeks to examine the interaction between stress and TBI with intranasal Zn therapeutics. Approximately 64 six-week old C57BL/6J mice were subjected to two varied stressors each day for a period of seven days before undergoing burrowing and nesting behavioral tests. The mice then underwent another seven days of chronic variable stress that was accompanied by mTBI and intranasal zinc therapy every 48 hours, for a total of four mTBI hits. A subset of mice will be used for an analysis of acute protein changes via western blots (e.g., GFAP, vasopressin, BDNF) and alterations in ionic Zn concentration using Zinpyr-1. The remaining mice were subjected to a second battery of behavioral tests that assessed longitudinal deviations in activities of daily living (i.e., burrowing and nesting) as well as circadian rhythm. Preliminary pilot data indicates that Zn significantly interacts with stress and brain injury when assessed for activities of daily living (i.e., burrowing). As stress level increased, the difference in ability to perform burrowing increased between mice with and without Zn treatment. These findings suggest Zn treatment can have a therapeutic effect following mTBI and chronic variable stress. As hypothesized, stress was found to exacerbate the deficits seen in mTBIs when not provided with Zn treatment. This study may provide a greater understanding on the nature of how stress exacerbates the effects of TBI and how therapeutic Zn may affect biochemical and behavioral deficits.

Abstract: Traumatic brain injury (TBI) is a pervasive problem affecting millions worldwide. Mild TBIs (mTBI) constitute the majority of cases. These injuries affect athletes and soldiers, and are also very common in young adults. Individuals from ages 0-25 have an approximate 30% prevalence of TBI due to falls, contact sports, and accidents. Many young adults sustain additional injuries after the first TBI. They are at an increased risk of having anxiety, depression,

and attention disturbances. This experiment examined whether social isolation exacerbates the effect of repetitive mTBIs (rmTBI) on young adult mice. Mice sustained a closed-head mTBI once every day for five days starting at 8 weeks old. Half of the mice were socially isolated until the end of the experiment by placing them in a home cage by themselves. Mice subjected to rmTBI demonstrated significantly fewer platform crosses compared to sham mice during probe trials in Morris Water Maze (MWM) one week following the last TBI. Latency to find the platform in MWM was significantly longer for rmTBI mice compared to shams 7 weeks following the last TBI. There was no effect of social isolation in MWM. However, socially isolated mice had significantly fewer open arm entries in the elevated zero maze compared to socially housed mice after being isolated for 8 weeks, but not after only 2 weeks, indicating increases in anxiety over time. There was no effect of rmTBI on anxiety. Brain tissue will be assessed for differences in expression of BDNF and inflammatory markers, including GSK3, IL-1ß, and TNF-alpha.

Title: Intranasal therapeutic zinc following traumatic brain injury with chronic stress

Authors: *W. R. KOCHEN, E. N. DOHERTY, C. CUNNIFF, L. BRADSHAW, M. WIENER, E. Q. MURDOCH, R. H. LIPSKY, J. M. FLINN
George Mason Univ., Fairfax, VA

Abstract: Traumatic Brain Injuries (TBI) are a leading cause of morbidity and mortality across ages. Most TBIs are mild TBIs (mTBI) which are identified by minor loss of consciousness (if any) and no fracturing of the skull. Accumulating evidence indicates that the effects of stress alter the pathology seen following TBI. This is especially relevant in military populations, where post-traumatic stress disorder (PTSD) and chronic stress are hallmark problems seen in soldiers returning from combat. Zinc (Zn) supplementation prior to TBI has been shown to mitigate the damage seen following injury. This experiment examined the efficacy of acute intranasal Zn therapy following repetitive mild TBI in both stressed and unstressed mice. Mice received chronic variable stress for one week which was followed by behavioral testing. Immediately following behavioral testing, mice endured a second week of stress during which four mild TBIs were administered with a 48-hour inter-injury interval. Following each injury, mice received either intranasal Zn or vehicle. The same behavioral tests were then conducted following the

final day of injury. Western Blots were performed for proBDNF, mature BDNF, doublecortin, TrkB, and phosphoTrkB. Results following the first week of stress show stressed mice spent significantly less time in the open areas of the elevated zero maze as well as spent more time helpless in forced swim. Furthermore, Burrowing and Nesting abilities were significantly compromised by stress. A significant interaction effect of stress and TBI was noted with TBI reducing the deficits caused by stress in Elevated Zero and Forced Swim. Intranasal Zn therapy caused significant therapeutic effects, reducing the deficits caused by TBI + Stress in Elevated Zero, Forced Swim, Burrowing and Nesting behaviors. Intranasal Zn therapy caused an increase in doublecortin levels as well as a significant alteration in the ratio of proBDNF to mature BDNF with mice who received intranasal zinc having a higher fraction of mature BDNF. These results indicate that Zn may be a strong candidate for use in an acute therapeutic intervention following TBI.

Title: Spinal cord epidural stimulation and recovery of cardiovascular function in individuals with chronic cervical spinal cord injury

Authors: *B. DITTERLINE[1,2], S. WANG[1,2], C. FERREIRA[1], B. UGILIWENEZA[1], C. A. ANGELI[5], Y. CHEN[1], A. V. OVECHKIN[1,2], M. BOAKYE[3], S. J. HARKEMA[1,2,5], G. HIRSCH[4]

Abstract: Persons with cervical spinal cord injury (SCI) experience persistent and orthostatic hypotension that markedly diminishes their overall quality of life and increases risk of developing and dying from cardiovascular disease. We have found previously that spinal cord epidural stimulation (scES) can acutely increase blood pressure in four individuals with chronic, cervical SCI (Harkema, 2018). We decided to investigate long-term effects of scES in four

individuals with chronic, severe cervical SCI. Prior to intervention, individuals experienced persistent hypotension with bouts of orthostatic hypotension and autonomic dysreflexia. Implanted over the lumbosacral spinal cord was a Medtronic, RestoreAdvanced 16 Electrode Array. Stimulation properties, including electrode polarity, frequency, voltage, and pulse width, were selected to increase systolic blood pressure to between 105-120 mmHg (CV-scES). Cardiovascular response to a sit-up test was assessed before and after 89 ± 13 sessions of daily, two-hour CV-scES. Main outcome measures included beat-to-beat blood pressure and heart rate, heart rate variability, and baroreflex sensitivity and effectiveness during orthostatic stress. After training, orthostatic hypotension resolved in all four chronic cervical, motor-complete SCI participants. Prior to the CV-scES intervention, mean systolic blood pressure significantly decreased from supine to sit (104 ± 3 to 90 ± 6 mmHg, $p = .001$). This drop did not occur with stimulation (116 ± 4 to 117 ± 6 mmHg, $p = .18$) nor after 89 ± 13 sessions of CV-scES intervention without stimulation (106 ± 3 to 107 ± 6 mmHg, $p= .53$). Improved blood pressure response to orthostatic hypotension was associated with significant increases to heart rate variability (SD1: $p = .003$; SD2: $p = .003$) and baroreflex effectiveness ($p = .002$) and sensitivity ($p = .002$) pre-intervention with stimulation. Likewise, post-intervention without stimulation, significant increases to heart rate variability (SD1: $p = .009$; SD2: $p = .01$), baroreflex effectiveness ($p < .02$) and sensitivity ($p = .002$), and correlation between systolic blood pressure and heart rate ($p < .004$) were observed. CV-scES results in immediate normalization of cardiovascular and autonomic regulation during orthostatic stress that, with training, persists even without stimulation. CV-scES has the potential to be a viable therapeutic option to manage cardiovascular dysregulation in individuals with chronic SCI.

Title: Refinement of lumbosacral epidural electrical stimulation enhances performance of stand and step functions after motor complete paraplegia

Authors: *P. GRAHN[1], M. L. GILL[2], J. S. CALVERT[2], M. B. LINDE[2], I. LAVROV[3], D. VEITH[2], L. BECK[2], J. STROMMEN[2], D. SAYENKO[4], M. VAN STRAATEN[2], A. THORESON[2], C. LOPEZ[2], Y. P. GERASIMENKO[6], V. EDGERTON[5], K. H. LEE[2], K. ZHAO[2]

Abstract: To date, there is no cure for spinal cord injury (SCI), leading to permanent disruption of ascending and descending spinal pathways across the injury site and impairment of neural circuitry below the injury site. Epidural electrical stimulation (EES) has been shown to enable motor function in a small cohort of humans with chronic SCI-induced paralysis. In subjects diagnosed with motor complete paraplegia, EES of the lumbosacral spinal cord was initially shown to drive tonic and rhythmic motor activity in the legs in a stimulation setting-specific manner. More recently, EES facilitated intentional control of joint-specific muscles and independent standing after months of training with EES. Initially, we set out to replicate outcomes reported from an initial clinical trial at the University of Louisville that demonstrated EES enabled intentional control of leg movements while subjects were lying down and static standing while subjects used their arms on support bars to maintain posture and balance. We previously reported successful replication of these results and also reported that EES enabled intentional control over rhythmic, step-like motor activity when the subject's legs were freely suspended. From these observations, we set out to determine if continued refinement of EES settings during motor rehabilitation with a focus on improving stand and step function would lead to greater independence and improved performance during motor activities such as standing and stepping. Here, we report that continued refinement of EES settings with rehabilitation improved step and stand functions both on a treadmill and over ground.

Title: Characterization of epidural electrical stimulation evoked motor responses during stepping in humans with complete spinal cord injury

Authors: *J. S. CALVERT[1], P. GRAHN[2], M. GILL[3], I. LAVROV[4], M. LINDE[3], M. VAN STRAATEN[3], J. STROMMEN[3], L. BECK[3], A. THORESON[3], C. LOPEZ[3], D. VEITH[3], D. SAYENKO[5], Y. P. GERASIMENKO[7], V. EDGERTON[6], K. ZHAO[3], K. LEE[2]

Abstract: Epidural Electrical Stimulation (EES) of the lumbosacral spinal cord has shown promise in enabling motor function following spinal cord injury (SCI) in both animal and clinical experiments. Modulation of evoked responses during hind-limb stepping in rat models of SCI have been characterized as the animal regains motor function and during the progression of the step cycle. However, EES-evoked responses during walking with EES in individuals with chronic SCI have yet to be investigated. Here, we report characteristics of human leg muscle evoked responses during EES-enabled stepping and while supine. Two males diagnosed with functionally complete paraplegia due to SCI (American Spinal Injury Association Injury Scale A) were implanted with a 16-contact electrode array (Specify 5-6-5, Medtronic, Fridley, MN) placed over the dorsal epidural surface of the lumbosacral spinal cord (T11-L1 vertebral levels). Following three weeks of recovery, EES was optimized to enable standing, intentional control while supine and side-lying, and intentional control of stepping on a treadmill. Skin surface electromyography (EMG) was collected from proximal and distal flexor and extensor muscles of the leg. EES-evoked motor responses were analyzed during motor activities to characterize spinal network facilitation by EES. Sensorimotor networks were facilitated by EES to produce motor responses that varied in thresholds, amplitudes, and latencies with respect to each muscle,

EES voltage intensity, and step cycle phase. EES-evoked motor responses were comprised of monosynaptic components, defined within EES literature as early response (ER) components that are associated with EES-activation of motor axons, middle response (MR) components that are thought to be of monosynaptic origin, and late response (LR) polysynaptic components. Specific electrode configurations resulted in rhythmic, bursting EMG activity both in supine and EES-enabled stepping activities. These results demonstrate that human spinal networks can be transformed, even years after injury, to reach physiologic states that generate coordinated and robust spinal motor outputs to generate intentional stepping on a treadmill and over ground.

Title: Lumbosacral neuromodulation with task specific motor training enables independent performance of dynamic motor functions following clinically complete sci

Authors: *M. GILL[1], P. GRAHN[2], J. S. CALVERT[3], M. LINDE[3], I. LAVROV[4], D. VEITH[3], L. BECK[3], J. STROMMEN[3], D. SAYENKO[5], M. VAN STRAATEN[3], A. THORESON[3], C. LOPEZ[3], Y. P. GERASIMENKO[7], V. EDGERTON[6], K. H. LEE[3], K. ZHAO[3]
[1]Physical Med. and Rehabil., [2]Mayo Grad. Sch., [4]Neurosurg., [3]Mayo Clin., Rochester, MN; [5]Dept. of Integrative Biol. and Physiol., [6]Dept Integrative Biol. & Physiol., Univ. of California Los Angeles, Los Angeles, CA; [7]Pavlov Inst. of Physiol, St Petersburg, Russian Federation

Abstract: Previously, clinical reports have shown that epidural electrical stimulation (EES) of the lumbosacral spinal cord enabled standing and step-like leg movements in humans with complete lower extremity paralysis due to spinal cord injury (SCI). In addition, investigations

using rodent models with SCI have shown that locomotor training of multiple tasks such as forward and backward stepping on a treadmill improved performance of stepping by dynamically engaging multiple spinal sensorimotor networks. We applied multi task specific motor training with the presence of EES in training sessions that focus on maximizing subject independence of multiple tasks such as standing and stepping. A 16-contact electrode array (Specify 5-6-5, Medtronic, Fridley, MN) was placed over the dorsal epidural surface of the spinal cord at the lumbosacral (T11-L1 vertebral region) level. Following 3 weeks of recovery, task specific training was performed with EES for 113 sessions over 43 weeks. Tasks specific training included step and stand training during each session emphasizing adaptability of EES enabled activity. Training variables, including different stepping speeds and body weight support (BWS), were adapted regularly. Dynamic stand and step training performed with EES resulted in ability to both stand and step with maximum independence with optimal EES-task specific parameters. EES parameter optimization allowed subject control over motor activity based on intention to stand or step. EES alone did not facilitate spinal networks activating motor output of specific activity below the injury without patient intent. These outcomes suggest that repetitive, multi-task specific motor training within each session enhanced the organization of EES-facilitated spinal networks to achieve an adaptable state of functionality.

Abstract: There is growing evidence that electrical stimulation of spinal networks facilitates volitional motor control and induces neuroplasticity after spinal cord injury (SCI). Transcutaneous electrical spinal cord stimulation is a non-invasive strategy for neuromodulation of spinal circuitry. The present study was designed to (1) test the effect of concurrent transcutaneous cervical spinal cord stimulation and task-specific training on restoration of upper extremity function, and (2) quantify the sustained benefits to hand and arm function that persist beyond the period of spinal stimulation. A randomized two-arm cross-over design was used for subjects with chronic (>1 year) SCI. Intervention arms included (A) physical therapy (PT) only or (B) stimulation + PT (AB or BA). For electrical stimulation, we used biphasic, rectangular, 1 ms pulses at a frequency of 30 Hz, filled with a carrier frequency of 10 kHz, which permitted high stimulation intensities to be delivered to the cervical spinal cord through the skin without discomfort. Outcome measurements included the Graded Redefined Assessment of Strength, Sensation and Prehension (GRASSP) test, pinch strength measurements and International Society for Neurologic Classification of Spinal Cord Injury (ISNCSCI) assessment. All measures are performed during baseline, interventions and follow-up periods. Following four weeks of combined stimulation and PT, all of the outcome measurements improved remarkably in our first participant (C-3 AIS D). After stimulation + PT, strength sub-score of the GRASSP test increased 37 points (Fig 1A) and ISNCSCI upper extremity motor score improved 10 points. In our second subject (C-5, AIS B), pinch force was restored despite complete paralysis of the hands during baseline and physical therapy only intervention (Fig 1.B). Our results show that non-invasive electrical spinal cord stimulation conferred both immediate and sustained benefit, and restored functional use of the hands after SCI.

Title: Inter-limb synchronization in standing balance in individuals with chronic incomplete spinal cord injury

Authors: *O. D. HABIB PEREZ[1], J. LEE[1,2], K. MASANI[1,2], K. E. MUSSELMAN[1,3]
[1]Toronto Rehabil. Inst. - UHN, Toronto, ON, Canada; [2]Inst. of Biomaterials and Biomed. Engin., [3]Physical Therapy, Univ. of Toronto, Toronto, ON, Canada

Abstract: ***Introduction*** Incomplete spinal cord injury (iSCI) compromises the neurologic structures and pathways that influence balance control and coordination, resulting in balance instability and an increased risk for falls. Individuals with iSCI have greater postural sway and increased dependency on vision. Though net measures of balance identify overall balance control, it lacks specificity on individual limb contributions. Inter-limb synchronization is a sensitive measure of individual limb contributions to balance control in healthy individuals and other clinical populations. The purpose of this study is to characterize inter-limb synchronization during quiet standing in individuals with iSCI relative to able-bodied controls (AB). ***Methods*** Standing balance was collected from 11 individuals with motor iSCI and 12 age- and sex-matched AB. With each foot on adjacent force plates, force data was sampled at 2000 Hz. Participants stood for 120 second in a standardized position in eyes open and eyes closed conditions. Net centre of pressure root mean square (COP RMS), and the cross-correlation coefficient at zero phase ($R_{xy}(0)$) of the left and right foot COP (i.e. inter-limb synchronization) in the anteroposterior (AP) and mediolateral (ML) directions were calculated, as was the weight-bearing force ratio (WBfratio) of the limb with the lowest vertical force. Independent 2×2 ANOVAs (Condition × Group) were conducted on net AP and ML COP RMS, $R_{xy}(0)$, and WBfratio. ***Results*** A significant interaction effect for AP COP RMS ($F_{1,21}$=9.06, p=0.007, partial η^2 = .30) showed greater AP sway in individuals with iSCI as a change of condition. A significant Condition effect ($F_{1,21}$=6.64, p=0.018, partial η^2 = .24) and Group effect ($F_{1,2}$=26.7, p<0.001, partial η^2 = .56) was found for ML COP RMS with greater ML sway in eyes closed in individuals with iSCI. A significant Group effect was found for AP $R_{xy}(0)$ ($F_{1,21}$=4.97, p=0.037,

partial η^2 = .19) and ML $R_{xy}(0)$ ($F_{1,21}$=7.34, p=0.013, partial η^2 = .26) with reduced inter-limb synchrony in individuals with iSCI. No Group effects were found for WBfratio (p=0.068). ***Conclusions*** Individuals with iSCI showed reduced inter-limb synchrony, which may contribute to increased postural sway.

Title: Extraction and selective activation of muscle synergies through spinal stimulation for SCI

Authors: *R. CHENG, J. W. BURDICK
Caltech, Pasadena, CA

Abstract: Epidural spinal stimulation (ESS) has been shown to enable recovery of motor control in patients with clinically complete spinal cord injury (SCI). It is hypothesized that this results from activation of postural and locomotor circuitry in the spinal cord, but the physiological mechanisms are still unknown. In this study, we extracted muscle synergies for standing in a complete SCI patient under ESS using a novel factorization algorithm, and compared them to muscle synergies in healthy subjects in order to better understand the physiological mechanisms enabling motor control under ESS.

Muscle synergies represent the coordinated recruitment of a group of muscles co-activated by a specific neural activation signal. Standard muscle synergy extraction algorithms (e.g. NNMF, PCA) fail when applied to SCI patients under ESS, because they do not compensate for the physiological delays of an electrically stimulated neural signal to reach different muscles (e.g. a signal takes longer to reach a thigh versus calf muscle). These delays are prevalent in SCI patients under ESS, since an activating signal with fixed frequency is externally induced at a specific area of the spinal cord. Therefore, we utilize a new algorithm -- regularized ShiftNMF -- that accounts for these delays when extracting muscle synergies. We find that muscle synergies extracted by this algorithm are significantly better at reconstructing EMG activity, they are much more reliable when cross-validated on other sections of the EMG, and their resulting features are more physiologically meaningful.

Using this algorithm, we examine muscle synergies for standing from SCI patients under different spinal stimulation conditions, and also compare them to muscle synergies in healthy subjects. We find that (1) SCI patients exhibit fewer muscle synergies than healthy subjects, (2) when stimulated with a fixed stimulation pattern during standing, the patient's muscle activity is composed of only a single muscle synergy, and (3) ESS with certain stimulation conditions (interleaving of multiple stimulation patterns) can activate an additional, distinct muscle synergy that greatly enhances patient standing quality. We provide evidence suggesting that muscle synergies are encoded in the human spinal cord, remain intact but possibly dormant after SCI, and are critical to quiet standing. The results allow us to hypothesize that an important physiological mechanism enabling motor control under ESS is the activation of muscle synergies in the spinal cord.

Title: Corticocuneate pathways are altered after dorsal column injury in New World monkeys

Authors: *C.-C. LIAO, H. X. QI, J. L. REED, H.-S. JEOUNG, J. H. KAAS
Dept. of Psychology, Vanderbilt Univ., Nashville, TN

Abstract: Dorsal column lesions (DCLs) in the cervical spinal cord deprive the cuneate nucleus (Cu) of its major tactile inputs, which immediately inactivate the hand regions in the contralateral somatosensory cortex and impair dexterous hand use. However, substantial neural reactivation and behavior restoration occur over an extended period of time. Since the cortical projections to Cu are part of a feedback loop that may be subject to modulation after loss of transmissions from the peripheral afferents to Cu, we examine whether the corticocuneate pathway is altered after injuries and contributes to the functional recovery over time. 11 adult New World monkeys (5 *Saimiri boliviensis, 3 Saimiri sciureus* & 3 *Aotus nancymaae*; 8 females & 3 males) were used. In 3 normal monkeys, a retrograde tracer, cholera toxin subunit B (CTB), was injected into the hand representation in Cu to label the cortical neurons. In 8 monkeys, unilateral DCLs were made at the C4-C5 level. CTB was injected into the Cu ipsilateral to the DCL in monkeys with 2 weeks (n=3) and 7-10 months (n=5) of DCLs. We mapped the hand regions in the contralateral areas 3b and 1 by electrophysiological recordings, and plotted the labeled neurons in both cortical hemispheres without the knowledge of lesion conditions. Our results revealed that: 1) in normal monkeys, the labeled neurons were extensively distributed in the contralateral cortex, predominately in the hand regions of somatosensory areas 3b, 3a, 1/ 2, parietal ventral (PV), secondary somatosensory cortex (S2), and primary motor cortex (M1). Fewer labeled neurons were located in the premotor cortex (PMC), supplementary motor cortex (SMA), cingulate areas, and cortex in the lateral sulcus. 2) After short recovery times from extensive DCLs, the hand neurons in contralateral areas 3b and 1 remained unresponsive or responded weakly to touch on the hand. The numbers of labeled neurons in the area 3b hand region were considerably reduced compared to the normal monkeys, although other corticocuneate connections remained intact. 3) After long recovery times, the affected somatosensory cortex responded from weakly to strongly to touch on the hand, and sometimes on the face and forelimb. Remarkably, somatotopically more extensive distributions of labeled neurons were found in the contralateral cortex. In addition, many labeled neurons were found in the hand region, with some in the forelimb region in area 3b. 4) The labeled neurons were also present in the ipsilateral cortex after Cu injections, but to a lesser extent. The results demonstrate the existence of a dynamic regulation of effective corticocuneate connections as a result of DCLs.

Abstract: In traumatic injuries to the sacral spinal cord and in different neurodegenerative conditions, motor neurons may undergo degeneration and death. In these tools and technologies set of studies, we have investigated the feasibility of using human embryonic stem cell-derived motor neurons, as a potential replacement of degenerating spinal cord neurons in a non-human primate model of conus medullaris/cauda equina forms of spinal cord injury to restore motor functions. Approximately 250,000 cells (n=2) or 65,000 cells (n=2) were delivered in a single injection into the L5 spinal cord segment of female rhesus macaques subjected to an L6-S3 ventral root avulsion (VRA) injury and replantation of the L6 and L7 ventral roots into the spinal cord. All subjects were immunosuppressed using anti-thymocyte globulin as induction therapy and a combination of tacrolimus, prednisone, and anti-CD40 for maintenance therapy. Spinal cord tissues were harvested at 24 hours after surgery (n=1) or 2 months post-surgery (n=3). Morphological studies identified the injection site and survival of the injected human cells in the ventral horn of the L5 segment in all animals. Studies at 2 months post-surgery showed accumulations of large numbers of transplanted cells in sheets or clusters in both the grey and white matter of the spinal cords. Human identity was confirmed by STEM121 and TRA-1-85

immunostaining. Transplanted cells frequently formed rosettes of neural progenitors expressing SOX2, and NESTIN. Subsets of the transplanted human cells also showed labeling for OLIG2, a marker of motor neuron and oligodendrocyte progenitors, but not astrocytic or microglial markers such as GFAP and IBA1. A neuronal phenotype was also observed among subsets of the human cells which formed elongated axonal structures in the grey and white matter tracts that were positive for both STEM121 and Beta-III-Tubulin. While a small subset of transplanted cells showed Ki-67 labeling, no tumor formation was detected. Ultrastructural studies confirmed integration of human cells in the primate spinal cord using pre-embedding immuno-gold labeling for STEM121 and displayed a cytoplasmic staining pattern. Functionally, the subjects at 2 months post-surgery (n=3) showed a VRA-induced left leg weakness but preserved ability to use the affected limb for climbing, balancing, sitting on perch bar, and stepping. The subjects also showed independence in bladder and bowel control. Overall the immunosuppression protocol was successful with human cell survival and differentiation to neurons and glia progenitors.

Title: Cutaneous mechanoreceptor distributions in the hand change following cervical spinal cord injury in the macaque monkey

Authors: *M. CROWLEY, A. LILAK, J. AHLOY-DALLAIRE, C. DARIAN-SMITH
Comparative Med., Stanford Univ. Sch. of Med., Stanford, CA

Abstract: Meissner's corpuscles (MCs) are cutaneous mechanoreceptors found in glabrous skin that are sensitive to light touch and vibration. They are concentrated in the fingertip pads of macaque monkeys and humans, and in concert with other receptors, provide important sensory feedback during the execution of fine sensorimotor tasks such as object manipulation and grip control. Following cervical spinal cord injuries that block primary afferent input from these receptors, hand use can be severely impaired. However, over weeks to months, there is a significant recovery of digit and hand function. While most research has focused on the reorganization of central neural pathways underlying this process, little is known about the role of peripheral receptors in restoring sensory input during the post-injury recovery period. In this

study we begin to address this question by analyzing the distribution of MCs in the hand following selective injury. We first asked what the normal pattern of MCs is in the distal pads of all five digits in the macaque, which has a similar hand structure to humans and a fully opposable thumb. We then asked what happens to these MCs in animals that received either a dorsal column lesion (DCL; n=2) or a combined dorsal root/dorsal column lesion (DRL/DCL; n=4), 4-5 months earlier. In all of our lesioned monkeys, the lesion removed cutaneous input from the first three digits of one hand. In contrast to earlier reports, our findings in normal hands indicate that MCs are more densely populated in the thumb and index finger than in digits 3-5. This presumably corresponds to the greater dependence of these opposing digits in fine volitional tasks (e.g. grooming or foraging). In addition, in both groups of lesioned monkeys, the density of MCs in the first three digits was considerably less on the injured side compared to the same digits on the contralateral unimpaired hand. Our findings highlight the close functional relationship between MCs and precision grip, and demonstrate that MCs undergo a quantitative change following central and peripheral lesions, suggesting their implicit involvement in the recovery process. A deeper understanding of the changes to these mechanoreceptors following injury will help to elucidate how they are involved in restoring functional integrity of the hand.

Title: Enhanced therapeutic effect of repetitive transcranial magnetic stimulation combined with anti-RGMa antibody treatment in a monkey model of spinal cord injury

Authors: *H. YAMANAKA[1], Y. TAKATA[1], H. NAKAGAWA[1], T. YAMASHITA[2], M. TAKADA[1]

Abstract: Repetitive transcranial magnetic stimulation (rTMS) has widely been used not only for basic research (e.g., investigating brain functions), but also for clinical application (e.g., relieving pain). On the other hand, it has recently been reported that treatment with antibody against repulsive guidance molecule-a (RGMa) ameliorates impairments in motor functions after spinal cord injury (SCI) in rodents and nonhuman primates. Here we analyzed the possible effect

of rTMS in combination with anti-RGMa antibody treatment on functional recovery after SCI in macaque monkeys. To prepare a monkey model of SCI, large hemi-transection lesions were made at the border between the C6 and the C7 segment of the spinal cord, as described elsewhere (Nakagawa et al., Cerebral Cortex, 2018). Simultaneously, the anti-RGMa antibody was delivered around the lesioned site over about four weeks via an osmotic infusion pump (see Nakagawa et al., Cerebral Cortex, 2018). The rTMS trials in the primary motor cortex (especially its forelimb region) started four to five weeks after the SCI surgery and lasted approximately 10 weeks. Behavioral assessments of forelimb movements were performed by means of the Brinkman board test and a reaching/grasping task. The rTMS sessions were carried out more than three times a week and, thereafter, behavioral changes were assessed on the same day. We found that compared with a control monkey group with the antibody treatment only, an experimental monkey group who underwent a combination of the antibody treatment and later rTMS execution exhibited an abrupt recovery from motor impairments. The present results indicate that rTMS combined with anti-RGMa antibody treatment provides an enhanced therapeutic effect in a monkey model of SCI.

Title: Reactivation of spinal locomotor circuits by non-task-specific training after a complete spinal cord injury in adult cats

Authors: *J. HARNIE, A. DOELMAN, E. DE VETTE, E. DESROCHERS, J. AUDET, J. ALIZADEH, N. GAUDREAULT, A. FRIGON
Physiologie, Univ. De Sherbrooke, Sherbrooke, QC, Canada

Abstract: After complete spinal cord injury (SCI), adult cats recover hindlimb locomotion after a few weeks of treadmill training. This recovery is due to the presence of a spinal locomotor central pattern generator (CPG) and its reactivation by sensory feedback from the moving legs. One of the central tenets of motor rehabilitation is that training must be task specific. However, as the locomotor CPG is present at birth, we hypothesized that task-specific training is not required to restore locomotion after complete SCI. To test this hypothesis, we investigated whether providing non-task-specific training in the form of rhythmic manual stimulation of the triceps surae muscles restored hindlimb locomotion after complete SCI in cats. Eight adult cats (>10 months, 4 females and 4 males) were divided into two groups and implanted with

electrodes to chronically record muscle activity (EMG, electromyography). After collecting data in the intact state, we transected the spinal cord at thoracic levels. Group 1 received rhythmic manual stimulation of the triceps surae muscles (0.33 Hz, 10 min per leg, 5 times a week for 5 weeks) while Group 2 received no treatment. We collected hindlimb EMG during manual stimulation in Group 1 and weekly-evaluated standing and locomotion on a treadmill at 0.4 m/s in both groups for six weeks after SCI, at which point we tested locomotion at different treadmill speeds. Cats in both groups recovered full body weight support during standing one week after SCI. Six weeks after SCI, although both groups performed full weight bearing hindlimb locomotion from 0.1 to 0.8 m/s, we observed some group differences. In Group 2, two cats could not perform consistent proper digitigrade paw placement while two other cats required perineal stimulation to facilitate hindlimb locomotion. In Group 1, EMG activity evoked by rhythmic manual stimulation became more structured and locomotor-like over the six-week period. With manual stimulation, we first observed ipsilateral flexor-extensor alternation and tonic contraction of contralateral muscles followed by contralateral flexor-extensor alternation and left-right alternation. The results indicate that the recovery of hindlimb locomotion after complete SCI does not require task-specific training and is partly spontaneous, consistent with the hypothesis that the spinal cord produces locomotion as its default pattern.

Title: Simultaneous versus delayed pairing of rehabilitation and electrical stimulation: Functional recovery and axon outgrowth in rats after chronic unilateral corticospinal injury

Authors: *T. T. BETHEA[1], J. SANTOS[1], H. PARK[1], J. BOLGER[1], A. SINDHURAKAR[1], T.-C. WEN[1], J. B. CARMEL[1,2]
[1]Burke Neurolog. Inst., White Plains, NY; [2]Brain Mind Res. Inst. and Departments of Neurol. and Pediatrics, Weill Cornell Med., New York, NY

Abstract: Electrical stimulation of motor cortex and motor training each drive structural and functional changes. It is unknown how these two very different forms of activity should be combined. We have previously demonstrated that motor cortex electrical stimulation of the

uninjured hemisphere after unilateral corticospinal tract injury promotes axon outgrowth to the impaired side of the spinal cord and recovery of forelimb function. The Schwab laboratory demonstrated that a plasticity treatment is most effective if given two weeks before motor training, rather than simultaneously. We hypothesized that motor cortex electrical stimulation given two weeks before forelimb training would promote greater functional recovery and more targeted axon sprouting than giving stimulation and training simultaneously. Adult Sprague-Dawley female rats were trained to proficiency on the knob supination task, which is highly impaired after corticospinal injury. They then received a cut lesion of the corticospinal tract that controlled the reaching paw. Six weeks later, electrodes were implanted over motor cortex, and used to deliver the electrical stimulation that we previously found to be effective (6 hours daily for 10 days). Rats were pseudorandomized by impairment to receive simultaneous rehabilitation (30 minutes after stimulation) or rehabilitation given 2 weeks later. Control groups included injury only, stimulation only, and rehabilitation only rats. Knob supination was measured weekly from the time of CST injury to 4 weeks after the last intervention. Across groups, the largest effects on recovery were observed in the weeks after training on the supination task. Rats that received simultaneous stimulation and training improved more quickly to the same degree as rats with stimulation and delayed training. To understand how training and stimulation alters CST connectivity, we have anterogradely labeled the intact half of the corticospinal tract and quantified axon length and distribution within the cervical spinal cord spinal cord. Anatomical analyses are ongoing, however early results show no difference in axon length in animals that received rehabilitation 2 weeks after electrical stimulation, compared to the animals where rehabilitation occurs 30 minutes after stimulation. Regional analysis quantifying sprouting axon distribution will also be analyzed. Stimulation has a larger effect on axon outgrowth than rehabilitation.

Abstract: Electrical epidural stimulation (EES) is used to treat chronic pain and spasticity. In clinical trials, it has been shown that EES enables motor function and improves autonomic function following spinal cord injury (SCI). Further development of EES including spatially-selective stimulation in order to provide a specific activation of neural elements is desired. In this study, Orientation-Selective Spinal Cord Stimulation (OS-ES) was delivered through a custom-built four-electrode array placed at S1 spinal segment. Sprague-Dawley rats (*n*=6, male, 325-350 gr) were anesthetized using urethane (1500 mg/kg IP). Electrode array was inserted and slid caudally through a partial laminectomy between Th13-L1. A laminectomy at L2 allowed verification of electrode array positioning. OS-ES was delivered every 45° by means of variable sets of biphasic pulses with chosen amplitudes (Lehto et al., 2017) to 3 or 4 contacts lead configurations using a multichannel stimulator. Rostral electrode on the midline of the spinal cord was defined as 0°. Electrical field was rotated in a clock- and anti-clock wise until completion of 180°. OS-ES was applied at 0.5 Hz in a range of 0.2-1.0 mA. Needle electrodes were inserted bilaterally in flexor and extensor hind limb muscles to record Motor Evoked Potentials (MEPs). From the stimulation pulse, latencies and amplitudes were determined for early (1-3 ms) and middle (>5 ms) responses detected using custom-made MatLab scripts. Our results show that amplitudes and thresholds of MEPs significantly vary depending on the angle of stimulation. In a 3 contacts lead configuration, higher amplitudes were observed when stimulation was delivered at 135° and 180° (Fig.1 A). On the other hand, in a 4 contacts lead configuration, similar amplitudes occurred at 0°-45° and 135°-180°, producing a symmetrical pattern of amplitudes (Fig. 1B). Interestingly, in both 3 and 4 contacts lead configuration, lower MEPs amplitudes were observed at 90°. Our results suggest that OS-ES with multi-contact electrode array can further optimize activation of the spinal cord motor circuits.

Title: Low intensity electromagnetic field exposure on neuronal connectivity and survival in spinal cord injured rats: A potential non-invasive therapy

Authors: *S. BHATTACHARYYA[1], S. JAIN[2]
[1]Physiol., AIIMS, New Delhi, New Delhi, India; [2]Physiol., All India Inst. of Med. Sciences, New Delhi, New Delhi, India

Abstract: Extremely low intensity magnetic (EMF) field has been shown to improve locomotion and general body condition after spinal cord injury (SCI). The aim of the present study was to

observe the effect of EMF on secondary damage and neuronal connectivity. EMF (17.96μT) exposure was given 2h/day for 5 weeks in 25mm contusion rat model of SCI. Basso, Beattie and Bresnahan (BBB) locomotor scoring was used to assess motor behavior, motor (MEP) and somatosensory evoked potentials (SSEP) and retrograde tracing were done to evaluate neuronal connectivity and survival respectively. The extent of lesion due to secondary damage was calculated by cresyl violet staining. A significant (P=0.000) improvement was observed in BBB score in EMF exposed group as compared to SCI after 5 weeks of contusion injury. A significant (P=0.01) increase in the threshold of MEP and SSEP was observed after SCI, which attenuated significantly (P=0.001) in the EMF group. Amplitudes of MEP and SSEP decreased significantly (P=0.001) after SCI as compared to sham, but showed a significant (P=0.001) increase after 5 weeks of EMF exposure. Retrograde tracing with fast blue showed a significant (P=0.001) increase in the number of surviving neurons, rostral and caudal (2cm) to the lesion site after EMF exposure. Further, extent of lesion and volume decreased significantly (P=0.005) after MF exposure as compared to SCI group. The results of the present study provide experimental evidence for the therapeutic potential in EMF spinal cord injured patients.

Abstract: The purpose of this study was to determine the effects of a contusive spinal cord injury (SCI) on spinal motor neuron activity, corticospinal coupling, and conduction time in hindlimb spinal cord (SC) of the rat. Experiments were carried out in adult, male, Sprague Dawley rats using commercial neurophysiological recording equipment. Rats were randomly assigned to either a Healthy or SCI group. SCI rats were given a 175 kDyn contusion injury of

the SC at the T8 vertebrae. Four weeks after SCI, fine wire electromyographic (EMG) electrodes were implanted into 4 muscles of the right hindlimb under ketamine/xylazine anesthesia. A craniectomy was performed over the left hindlimb motor cortex (HLA), and a laminectomy was performed on the T13-L1 vertebrae. Intracortical (ICMS) and intraspinal microstimulation were used to determine the location of specific hindlimb movements evoked by stimulation. Similarly evoked movement sites in HLA and the ventral horn of the lumbar SC were identified and paired for further neurophysiological assessment. In SCI rats, the location of HLA was determined by the known location from previous mapping in healthy rats. At paired sites, a single shank, 16-channel, stimulating microelectrode was lowered into layer V of the HLA, and a similar recording microelectrode was lowered to a depth of ~2.27 mm in the hindlimb SC, spanning multiple laminae of the cord. ICMS was used to test corticospinal coupling by delivering a test stimulus in HLA, and evoked spikes were recorded from the SC and EMG from muscles for 5 min at each cortical/spinal site chosen for pairing. Evoked spikes were recorded, sorted, and displayed in post-stimulus spike histograms with 1-ms bins. In healthy rats, spike histograms showed ICMS-evoked spiking activity at two short latency epochs 7-8 ms (S1) and 10-12 ms (S2), and also at longer latencies. The longer latency responses followed a Gaussian distribution, ~20-60 ms, and were thus separated into three long-latency epochs: the first long-latency response (L1), peak response, and second long-latency response (L2) of the Gaussian distribution. The latency of the ICMS-evoked EMG responses, 25-27 ms, typically occurred between the L1 and peak. Short latency responses were evident in all layers of the SC while the longer latency responses were more evident in the intermediate layers. Within the SCI rats, one or both short latency responses were typically eliminated, the long-latency responses were disrupted or eliminated, and EMG responses were never evoked. The results from this study give insight into the effects of a contusive SCI on the neuronal activity, corticospinal coupling, and conduction time in the hindlimb SC of the rat.

Abstract: The recovery of motor function is one of the main aims of regeneration protocols in the treatment of traumatic spinal cord injury (TSCI), so evaluation is an important step to determine the therapeutic efficacy of the regenerative protocols. Among the most used methods of motor evaluation, we found the motor assessment Basso, Beattie & Bresnahan scale (BBB), an open field test that allows us to observe motor recovery in contusion models. Other methods commonly used to observe recovery are the kinematic analysis, inclined plane test, as well as electrophysiological tests, among many others. This project aims to evaluate the recovery of motor locomotion in a transection model, after transplantation of pre-degenerated peripheral nerve (NPP), bone marrow stromal cells (BMSCs), and the chondroitinase enzyme ABC (ChABC). 70 female Fisher 344 rats with complete section at T9 level were used and divided into 5 groups (Control = 14 animals with TSCI, Group 1 = 14 animals with NPP, Group 2 = 14 animals with BMSCs, Group 3 = 14 animals with NPP + BMSCs and Group 4 = 14 animals with NPP + BMSCs + ChABC). A modified BBB scale and a cinematic motion analysis were used to observe the functional recovery after three months. The modified BBB analysis showed that the combined and non-combined treatment groups had a significant difference with a $p<0.0001$ compared with the control. Also, the combined and non-combined treatments showed a significant difference between them with a $p<0.005$, after the fifth week of treatment. The kinematic analysis of the gait cycle showed greater mobility in the extremities of the hip and knee, in the groups with combined treatment compared with non-combined treatment. We found that the combined-treatment (NPP + BMSCs, and NPP + BMSCs + ChABC) promote a higher functional regeneration of the hind limbs, improving the degree of coordination and mobility of the extremities involved in the walking cycle. In contrast, functional regeneration was also observed in the groups with non-combined treatment (BMSCs, and NPP), but in a lesser grade of mobility in comparison with the join-treatments groups.

Title: Optimal spike-stimulus delay for increasing synaptic efficacy in descending motor pathways using an activity dependent stimulation paradigm in an acute, anesthetized rat model of spinal cord injury

Authors: *J. A. BORRELL[1,5], D. KRIZSAN-AGBAS[2], R. J. NUDO[3,4], S. B. FROST[3,4]

Abstract: The purpose of this study was to determine the optimal spike-stimulus delay for increasing synaptic efficacy in descending motor pathways using an activity dependent stimulation (ADS) paradigm in an acute, anesthetized rat model of spinal cord injury (SCI). Experiments were carried out in adult, male, Sprague Dawley rats with T8 contusion injury. Under ketamine/xylazine anesthesia, fine wire electromyographic (EMG) electrodes were implanted into 4 muscles of right hindlimb. After exposure of the left hindlimb motor cortex (HLA), laminectomy of the T13-L1 vertebrae, and removal of the dura matter, intracranial (ICMS) and intraspinal microstimulation (ISMS) were used to determine the location of evoked hip movements. One pair of sites evoking hip movements were chosen for each experimental procedure. For ADS conditioning, a single shank, 16-channel, Neuronexus recording microelectrode was used to detect neuronal spikes in HLA that were used to trigger ISMS in the spinal cord (SC) grey matter. SCI rats were randomly selected for one of four different parameters of cortical spike-triggered ISMS stimulus delays (10 ms or 25 ms time delay) and number of stimulus pulses used (1 pulse or 3 pulse square-wave stimulation). ADS sessions were conducted in three 1-hour conditioning bouts for a total of 3 hours. Synaptic efficacy was measured by number of ICMS-evoked spikes in the matched site in the lumbar SC in one 5 minute pre-ADS period and three 5 min test periods following each 1 hour ADS conditioning bout. During the testing periods, recording and stimulating microelectrodes were switched and ICMS was applied to the HLA while evoked-spikes were simultaneously recorded from the hindlimb SC for 5 min. Evoked spikes were recorded, sorted, and displayed in post-stimulus spike histograms with 1-ms bins. Post-stimulus spike histograms and EMG recordings were characterized using stimulus triggered averaging techniques. The results showed that after 3 hours of ADS conditioning using a 10 ms time delay and one stimulation pulse, ICMS-evoked spiking activity was significantly increased within the ventral horn at 10 ms post-onset ICMS. ADS conditioning using a 25 ms time delay and one or three stimulation pulses resulted in significant increases in ICMS-evoked spiking activity within the dorsal/intermediate layers of the spinal gray matter at 10 ms post-onset ICMS after 2 hours of ADS and continued to increase after 3 hours of ADS conditioning. EMG responses were never evoked pre-ADS nor was EMG activity increased after 3 hours of ADS. These results show that bouts of ADS conditioning can increase synaptic efficacy in intact descending motor pathways after SCI.

Title: Nogo receptor antagonist LOTUS promotes axonal regeneration and inhibition of neuronal apoptosis after clinically relevant contusive spinal cord injury in adult mice

Authors: *S. ITO[1], N. NAGOSHI[2], O. TSUJI[2], K. KOJIMA[2], S. SHIBATA[2], M. SHINOZAKI[2], K. TAKEI[3], M. NAKAMURA[2], H. OKANO[2]

Abstract: [Introduction] Natural recovery following spinal cord injury (SCI) is extremely limited in mammalian adults. One of the major reasons is the inhibition of axonal regeneration due to Nogo receptor-1 (NgR1) signaling. The ligands of NgR1, such as Nogo, MAG, OMgp, BLyS and CSPG cause collapsing of growth cone and inhibition of neurite outgrowth following SCI. Lateral olfactory tract usher substance (LOTUS), a NgR1 antagonist, binds to NgR1 and inhibits these five ligands, resulting in the decreased collapse of growth cones and inhibition of neurite outgrowth. The purpose of this study is to determine the therapeutic efficacy of LOTUS using clinically relevant contusive SCI model. [Method] Contusive SCI was induced at the Th10 level in LOTUS overexpressed mice (LOTUS group; n=20) and wild-type mice (control group; n=16). Hindlimb motor function was evaluated weekly for six weeks using BMS scores; and the DigiGait analysis was performed on the sixth week post-injury. On this sixth week, biotinylated dextran amine was injected into the primary motor cortex to trace corticospinal tract (CST), or Fluoro-Gold was injected into the lumbar enlargement to trace reticulospinal tract. Two weeks later, electrophysiological analysis using motor evoked potential was conducted. After the mice were sacrificed, histological analyses were examined. Additionally, histological analyses at 7 and 14 days post-injury were also performed. [Result] Tracing analyses showed that CST fibers increased significantly at the rostral to the lesion in the LOTUS group compared to the control group, but not at the caudal sites of the lesion in the two groups. On the other hand, reticular nucleus neurons increased significantly. Histological analyses showed the increase of the NF-H, 5-HT and p-GAP43 positive fibers at the caudal sites. As for 5-HT positive raphespinal tract, a significant increase was seen in the LOTUS group 14 days after SCI and continued to increase up to 56 days. Furthermore, cleaved caspase-3 staining revealed that LOTUS suppressed cellular apoptosis during the acute phase. Significant improvements in BMS scores was seen in the LOTUS group at one week following SCI and thereafter. DigiGait analysis also revealed significantly longer stride length and narrower stance angle in the LOTUS group. Electrophysiological analysis revealed significantly shorter latency and larger amplitude in the

LOTUS group. [Conclusions] LOTUS overexpression showed beneficial effects for functional recovery in clinically relevant contusive SCI model through promoting neuroprotection and axonal regeneration. The administration of LOTUS in the treatment of SCI could be a promising strategy.

Title: Locomotor recovery in the rat after spinal hemisection is impeded by contralesional motor cortex inactivation

Authors: *A. R. BROWN[1,3], M. MARTINEZ[1,3,2]
[1]Dept. de Neurosciences, [2]Groupe de Recherche sur le Système Nerveux Central (GRSNC), Univ. de Montreal, Montreal, QC, Canada; [3]Hop. du Sacre-Coeur de Montreal, Montreal, QC, Canada

Abstract: Locomotor recovery can occur after incomplete spinal cord injury (SCI) where supraspinal structures and spinal circuits remain partially connected through residual descending pathways. The motor cortex is crucial for the voluntary control of movement and can reorganize after injury to promote recovery. The role of the hindlimb motor cortex in supporting locomotor recovery after SCI, however, is poorly understood. After a lateral hemisection of the thoracic spinal cord in the rat, hindlimb movements can no longer be evoked from stimulation of the de-efferented contralesional motor cortex, yet a combined hemisection and cortical trauma impedes recovery of the affected hindlimb. We tested here whether residual activity in the de-efferented contralesional motor cortex after thoracic hemisection impacts hindlimb locomotor recovery. Female Long-Evans rats were subjected to combined hemisection (T8 level) and cannula implantation targeting the contralesional hindlimb motor cortex. Cortical inactivation was achieved with continuous infusion of muscimol (GABA-A agonist, 10mM, 0.11 µL/hr) delivered via osmotic mini-pumps from the time of injury (n = 9). Rats with cortical saline infusion served as a SCI control group (n = 8). Hindlimb recovery was assessed in an open field, on a horizontal ladder, and on a treadmill during both quadrupedal and bipedal locomotion prior to and for 3 weeks after SCI. Inactivation of the contralesional motor cortex after SCI significantly impeded

recovery of the affected hindlimb in all behavioural tasks. During the first week after SCI, cortical inactivation disrupted voluntary control of the affected hindlimb that was maintained to some degree in SCI control rats. In particular, SCI rats with cortical inactivation showed increased foot-faults of the affected hindlimb during ladder walking compared to SCI control rats. During quadrupedal treadmill locomotion, cortical inactivation induced significant increases in toe drag along with decreases in step height and velocity during swing of the affected hindlimb. Coordination between hindlimbs and between fore- and hindlimbs was also more severely affected under cortical inactivation. During bipedal locomotion where the forelimbs were placed on a platform, the hindlimb locomotor pattern was significantly more disrupted in SCI rats with cortical inactivation, suggesting that cortical activity plays a role in the ability to regain an organized stepping pattern after SCI. Present results suggest that residual activity in the de-efferented contralesional motor cortex during the initial stage after SCI plays a prominent role in the recovery of hindlimb locomotor function.

Title: CORM-2 loaded solid lipid nanoparticle enhances anti-allodynic effect of CORM-2 via sustained carbon monoxide delivery

Authors: *J. KYUNG[1], I. HAN[2]
[1]CHA Univ., Seongnam-Si, Gyeonggi-Do, Korea, Republic of; [2]CHA Univ., Seongnam, Korea, Republic of

Abstract: Neuropathic pain is devastating sequelae of neurotrauma. It’s already has been proven that carbon monoxide releasing molecule-2 (CORM-2) attenuates mechanical allodynia. This study compares the anti-allodynic effects of CORM-2 loaded solid lipid nanoparticles (CORM-2-SLNs) with CORM-2 solution (CORM-2-S). CORM-2-SLNs were prepared by nanotemplate engineering technique with slight modifications and physicochemical properties were evaluated. Chronic constriction injury (CCI) was performed to induce peripheral neuropthic pain in Sprague-Dawley rats. Rats were administered with CORM-2-SLNs (10 mg/kg/day I.P) and CORM-2 solution (10 mg/kg/day I.P) for one week. Animals were evaluated for neuropathic pain response before the day and 1, 3, 7 and 14 day after surgery. On days 7 and 14 after surgery, rats were sacrificed and tissues were collected. PCR and western blotting analysis were performed to assess heme-oxygenase (HO-1/HO-2) and other inflammatory mediators (TNF-α, iNOS/nNOS, IBA-1 and GFAP) expression in L4-L6 spinal cord and dorsal root ganglion (DRG)

at 7 day and 14 day after surgery. Allodynia was significantly reduced by CORM-2-SLNs compared to CORM-2-S. TNF-α, iNOS/nNOS, IBA-1 and GFAP expression were pronouncedly decreased by CORM-2-SLNs in comparison to CORM-2-S. HO-1 was significantly increased. However, HO-2 was decreased. Hence, the results demonstrated that CORM-2-SLNs have significant effect in reducing neuropathic pain as compared to CORM-2 Solution.

Title: Pain input after a spinal cord injury increases tissue loss and impairs long-term recovery: A comparison of male and female rats

Authors: R. BAINE[1], M. M. STRAIN-MALAMAKAL[2], Y. J. HUANG[1], J. A. REYNOLDS[1], M. HENWOOD[1], J. DAVIS[1], G. N. FAUSS[1], P. BEAN[1], A. NORRIS[1], T. JOHNSTON[1], C. COX[1], *J. W. GRAU[1]

Abstract: Spinal cord injuries (SCI) are often the result of traumatic accidents resulting in polytrauma. Pain input from associated injuries has been shown to impair locomotor recovery, increase hemorrhage, and expand the lesion site. Our laboratory has studied this effect using male rats. However, with the increasing number of females sustaining injury to the spinal cord, it is important to determine whether females are at risk of developing similar detrimental effects in response to pain input. Research has shown that females show greater tissue preservation and better locomotor recovery following SCI. Given these data, we examined the effect of sex on SCI recovery in two different pain models. Male and female rats were given a moderate contusion at T12. Groups receiving noxious input were treated 24 hours later. In the first experiment, animals received either six minutes of uncontrollable intermittent electrical stimulation to the tail or none at all. In the second experiment, animals received an intradermal injection of the peripheral irritant, capsaicin (3%), or vehicle to the hindpaw. After both treatments, blood pressure and BBB locomotor scores were evaluated at 0, 1, 2, and 3 hours. Animals were then sacrificed and a one-centimeter section of spinal tissue centered on the lesion

site was collected. Protein extracts obtained from the spinal tissue were analyzed for signs of hemorrhage using spectrophotometry. In the shocked condition, all animals receiving electrical stimulation showed impaired locomotor function and increased hemorrhage. Additionally, females showed more hemorrhage than their weight-matched controls. Conversely, only females showed a negative effect with administration of capsaicin, both in locomotor function and hemorrhage. Finally, we assessed the effect of capsaicin and shock treatment on long-term recovery. Rats were treated as described above and behavioral recovery was monitored for 28 days. Shock, but not capsaicin treatment impaired locomotor recovery, suggesting that the effect of pain input on secondary injury is variably affected by sex.

Title: Pain induced hemorrhage after spinal cord injury is blocked by pentobarbital and lidocaine anesthesia

Authors: *J. DAVIS[1], M. M. STRAIN[3], M. K. HENWOOD[2], R. BAINE[1], G. N. LEAL[2], T. JOHNSTON[1], J. W. GRAU[1]
[1]Psychology, Texas A&M Univ., College Station, TX; [2]Inst. for Neurosci., Texas A&M Univ., Bryan, TX; [3]Battlefield Pain Res., Inst. of Surgical Res., Fort Sam Houston, TX

Abstract: We have shown that nociceptive stimulation after a contusion injury increases tissue loss and impairs long-term recovery. We recently showed that the local application of an anesthetic (lidocaine; Turtle et al., 2017, J Neurotrauma, 34, 1200 1208), but not systemic morphine, has a protective effect that counters the adverse effect of nociceptive stimulation. Other work suggests that this local effect depends, in part, on communication with rostral (brain-dependent) neural systems. Supporting this, nociceptive stimulation has no effect on tissue sparing in rats that received a rostral spinal transection after a contusion injury (Reynolds et al., 2017). Given these findings, the present study examines the effect of CNS depressant pentobarbital, on the adverse effects of nociceptive input. In a subsequent experiment, we

assessed the effect of a pharmacological transection induced by applying lidocaine rostral to injury. Rats received a contusion injury at T12 and, 24 hrs later, were given an anesthetic dose of pentobarbital (30 mg/Kg). Animals then received 6 min of intermittent tailshock or nothing. Three hours after shock, rats were sacrificed and one cm of tissue was collected enveloping the injury site. The extent of hemorrhage was assessed by measuring the absorbance of light at 420nm and Western blotting for hemoglobin. In the second experiment, animals received a T12 contusion injury and 24 hrs later lidocaine (3.75mg/kg) was slowly infused rostral to the injury site (at T2-4). Rats were then given intermittent tailshock or nothing and tissue was collected three hours later. In both experiments, nociceptive stimulation increased the extent of hemorrhage in vehicle treated (awake) rats. This effect was attenuated by pentobarbital anesthesia and rostral lidocaine. Further work is exploring the circumstances under which these treatments attenuate hemorrhage.

Title: Pain after SCI expands the area of hemorrhage: Evaluating the spread of secondary injury and the effect of injury severity

Authors: *M. K. BRUMLEY, J. REYNOLDS, J. A. DAVIS, G. FAUSS, J. D. TURTLE, A. NORRIS, P. BEAN, J. GRAU
Neurosci., Texas A&M Univ., Bryan, TX

Abstract: Recovery after spinal cord injury (SCI) is often complicated by additional tissue damage sustained at the time of injury. Previously, we have shown that peripheral noxious input after SCI produces a deficit in locomotor recovery, increases tissue loss, and increases indices of neuropathic pain (J Neurotrauma, 21, 1795). Recent findings suggest that noxious stimulation undermines long-term recovery because it leads to a break down in the blood spinal cord barrier and an expansion in the area of hemorrhage. Interestingly, the development of this effect depends upon spared fibers; if the spinal cord is transected rostral to the contusion injury, noxious stimulation does not induce hemorrhage. Here we evaluated the rostro-caudal extent of the hemorrhage and how the development of this effect varies with injury severity. We hypothesized

that the effect of pain input would be most evident after moderate SCI (12.5 mm drop; MASCIS device). To evaluate the relative effect of stimulation rostral/caudal to injury, adult male Sprague-Dawley rats received a contusion at T12 and a day later were exposed to intermittent shock for 6 minutes or an equivalent period of restraint. Three hours later, we collected a 1-cm section of tissue encompassing the injury site as well as 1-cm sections rostral and caudal to injury. We also collected a 1-cm section of cervical spinal cord tissue. Tissue was analyzed with western blotting for hemoglobin and cytokine content. In a second experiment, we varied injury severity (0, 6.25, 12.5, or 25 mm drop) and applied nociceptive stimulation, or nothing, 24 hours later. A 3-cm section of the spinal cord was collected 3 hours later and sectioned longitudinally. In animals that received a moderate injury, we found that pain input increased the infiltration of red blood cells in the (1 cm) region of injury. While nociceptive stimulation increased cytokine expression rostral and caudal to injury, it did not induce a significant increase in hemorrhage. Further work is being conducted to evaluate whether stimulation affects blood spinal cord barrier permeability outside the area of injury and how this effect interacts with the locus of injury.

Title: Reduction of allodynia following SCI using antioxidant nanoparticles

Authors: *J. J. HERRERA[1], K. H. BOCKHORST[1], L. NILEWSKI[2], W. SIKKEMA[2], J. M. TOUR[2]
[1]Dept. of Diagnos. and Interventional Imaging, The Univ. of Texas Med. Sch. at Houston, Houston, TX; [2]Dept. of Chem., Rice Univ., Houston, TX

Abstract: Traumatic spinal cord injury (SCI) is devastating injury that results in motor neuron dysfunction and death at and below the lesion level. SCI patients not only live with the paralysis but as many as 80% of patients develop clinically significant neuropathic pain described as burning, stabbing, and/or electrical in sensation. We speculate that a one of the key underlying mechanism contributing to both issues is systemic inflammation. Both motor and sensory dysfunction is a combination of early necrotic as well as delayed progressive cell death processes, collectively referred to as secondary injury. Oxidative stress which is the results of

excess production of reactive oxygen species (ROS) and inflammation are widely considered hallmarks of the secondary injury cascade initiated after SCI. ROS are crucial contributors to a range of normal physiologic cell signaling such as energy production/regulation and contributors to our immune response to invading pathogens.
As our understanding of oxidative stress involvement in various human diseases increases, studies involving antioxidants have shown some benefit in disease treatment. The need for efficient antioxidants has led to the development of nanoparticle antioxidants. Antioxidant carbon nanoparticles can scavenge ROS with far higher efficacy than dietary and endogenous antioxidants. These nanoparticles are fabricated with poly (ethylene glycolation) on hydrophilic carbon clusters (PEG-HCC). Our study demonstrated that when antioxidant nanoparticles are administered intravenously following a moderate to severe spinal cord contusion there is a significant reduction in lesion volume determine by ex vivo MRI imaging when compared to saline treated animals ($p=0.0282$). This was also verified using luxol fast blue staining for white matter sparring. Our study also demonstrated that there was a significant improvement in the BBB locomotor scores. In addition there was attenuation in the development of neuropathic pain in the PEG-HCC treated group compared to saline treated. Together this data indicated that antioxidant nanoparticle treatment improved functional recovery after injury and attenuated the development of neuropathic pain.

Abstract: Traumas that lead to spinal cord injury (SCI) frequently induce additional tissue damage (polytrauma) that provides a source of noxious input. Research has shown that pain (nociceptive) input after SCI can enhance tissue loss and undermine long-term recovery (Grau, 2004, J Neurotrauma, 21, 1795). This process can be modeled in rats by applying noxious electrical stimulation, or the irritant capsaicin, caudal to injury. Recent work suggests that nociceptive stimulation impairs long-term recovery because it expands the area of hemorrhage at the site of injury. The present study explores the role of brain systems and nociception-induced hypertension on hemorrhage expansion. Male Sprague-Dawley rats received a contusion injury at T12. Eighteen hrs later, half of the animals experienced a complete spinal transection at T2 to block brain-spinal cord communication. After 6 hours of recovery, half of the rats in each group were given intermittent electrical stimulation to the tail or a subcutaneous injection of capsaicin to one hindpaw. Blood pressure (BP) was monitored at discrete time points and tissue was collected for further examination. We found that shock administered to the tail resulted in an increase in BP. Tissue assays evaluating the extent of red blood cell infiltration at the site of injury showed that nociceptive stimulation increased hemorrhage. Spinal transection blocked both the increase in BP and hemorrhage. Capsaicin too increased hemorrhage and this effect was blocked by a spinal transection. Capsaicin did not, however, induce a significant increase in blood pressure. These results suggest that the adverse effect of pain input on tissue sparing depends upon brain systems. Further work is being conducted to determine whether nociception-induced hemorrhage is linked to alterations in blood pressure.

Title: Neuroprotective and immunomodulatory effects of dimethyl-fumarate after ventral root avulsion

Authors: *P. R. KEMPE[1,2], A. L. OLIVEIRA[2]
[1]Univ. Estadual De Campinas, Campinas, Brazil; [2]Univ. of Campinas - Lab. of Nerve Regeneration, Campinas, Brazil

Abstract: Spinal cord injury causes critical loss of motor and sensory function. Ventral root avulsion (VRA) is an experimental approach in which there is an abrupt separation of the ventral

(motor) roots from the surface of the spinal cord. This rupture, at the interface between the peripheral and the central nervous system (CNS), interrupts the contact between the motoneuron and the target muscle fibers. As a result, most of the axotomized motoneurons degenerate between the second and third week after avulsion. This is worsened by a significant loss of synapses and increased glial reaction, triggering a chronic inflammatory state. Therefore, the use of neuroprotective and immunomodulatory drugs can improve a regenerative response. Dimethyl-fumarate (DMF) is an FDA approved drug for psoriases and multiple sclerosis, and we hypothesize that it could support motoneurons after VRA. DMF promotes gene transcription of anti-oxidant and detoxifying enzymes, leading to cytotoxic protection and reestablishment of cellular homeostasis. Also, it modulates different types of cells of the immune system, reducing pro-inflammatory cytokines and local inflammation. Moreover, DMF was able to preserve myelin, axons and neurons in different experimental models of degeneration of the CNS. Accordingly, adult female Lewis rats subjected to VRA of L4 to L6 roots were daily treated with DMF (0, 7.5, 15, 30 and 45 mg/kg, gavage) for 4 weeks. The results involved analysis of neuronal survival by Nissl staining, glial reactivity by immunohistochemistry (anti-GFAP for astrocytes and anti-Iba-1 for microglia) and synapse preservation (anti-VGLUT1 and GAD65). Our results indicate that treatment with DMF at the dose of 15mg/kg is neuroprotective since it preserves 70% of motoneurons when compared to the vehicle group, in which approximately 20% of neurons survived. Furthermore, we observed a significant decrease of astrogliosis, and microglial reaction in DMF treated rats. Such parameters were combined with synapse preservation at the microenvironment of the motoneurons. Altogether, our results indicate that DMF has neuroprotective and immunomodulatory effects, which result in enhanced motoneuron survival following proximal lesion.

Title: Combined pro-regenerative strategies and targeted rehabilitation to improve behavioral outcomes after spinal cord injury

Authors: *D. B. NOWAK, E. T. EASTWOOD, N. JAYAPRAKASH, M. G. BLACKMORE
Biomed. Sci., Marquette Univ., Milwaukee, WI

Abstract: Regeneration of injured axons following spinal cord injury is critical to restore lost motor function. A low cell-intrinsic capacity for regeneration and hostile extrinsic factors at the injury site both act to limit axon regeneration. To overcome these twin barriers, we have combined overexpression of a pro-regenerative transcription factor called KLF6 in injured neurons with grafts of stem cells into spinal injuries. This combined treatment enables corticospinal tract (CST) regeneration through sites of spinal injury. Furthermore, combined optogenetics and electrophysiology showed that the regenerating axons form functional synaptic connections with host neurons below the injury. Despite the growth and synaptogenesis, however, behavioral gains were minimal. Here we test the hypothesis that elevating neural activity, in the context of stimulated CST regeneration, will improve behavioral outcomes after spinal injury. To do so we have developed a system of combined electrical stimulation, limb constraint, and post-injury rehabilitation in the form of forced irregular wheel running. In initial experiments, adult mice received midline cervical (C4-C5) 1mm deep wire-knife transections followed by casting of the uninjured limb for 4 weeks. Casted animals were placed on an elevated grate for one hour each day, forcing targeted placement of affected forelimbs. After cast removal, animals were exposed daily to forced locomotion on a wheel with irregularly spaced rungs every day for 8 weeks. The combined casting and rehabilitation significantly improved forelimb function on the horizontal ladder task. In our ongoing experiments this behavioral activity is supplemented by sub-threshold, extra-dural electrical stimulation of the motor cortex. By combining pro-regenerative treatments with optimized rehabilitative paradigms, we aim to improve behavioral outcomes after spinal injury.

Title: Daily acute intermittent hypercapnia training to improve respiratory plasticity following spinal cord injury

Authors: *M. RANDELMAN, L. V. ZHOLUDEVA, V. M. SPRUANCE, T. BEZDUDNAYA, T. HORMIGO, H. MURALIDHARAN, M.-P. COTE, L. QIANG, M. A. LANE

Abstract: Cervical level spinal cord injury (SCI) frequently leads to severe respiratory dysfunction due to damage of the spinal phrenic motor system which controls the diaphragm - the primary muscle for respiration. While some spontaneous functional plasticity does occur following cervical SCI, the extent is limited and diaphragm paresis persists. The goal of this research was to determine if respiratory plasticity and diaphragm recovery could be therapeutically enhanced using a novel respiratory training strategy: daily acute intermittent hypercapnia (dAIHc). We hypothesized that increasing respiratory activity with dAIHc will stimulate phrenic neuroplasticity and induce diaphragm recovery following a moderate mid-cervical contusion injury in the adult rat. Anatomical plasticity following injury and treatment was investigated using transynaptic tracing and immunohistochemistry. Pseudorabies virus (PRV) was used to retrogradely, transneuronally trace the spinal phrenic circuitry ipsilateral to injury and assess integration of premotor spinal interneurons with phrenic motorneurons. Immunohistochemistry and western blot analysis were performed to assess changes in serotonin (5-HT) and BDNF expression rostral and caudal to injury. Functional plasticity and respiratory recovery following dAIHc training was assessed with terminal diaphragm electromyography (dEMG). Hypercapnia trained animals showed an increased BDNF expression within the medulla, and greater density of serotonergic axons within the spinal cord when compared with untreated and air control animals. It was also found that 2 weeks of dAIHc training resulted in a greater recruitment of interneurons into ipsilateral phrenic circuitry when compared to untreated and air controls. Diaphragm EMG of the dAIHc trained animals resulted in modest improvement of the ipsilateral and contralateral diaphragm inspiratory amplitude as well as response to respiratory challenge. These results therefore suggest that dAIHc is able to promote plasticity within the phrenic network following cervical SCI.

Title: Timing and stimulation parameters of therapeutic deep brain stimulation of the mesencephalic locomotor region in rats

Authors: *A.-S. HOFER[1], M. I. SCHEUBER[1], A. M. SARTORI[1], A. K. ENGMANN[2], M. E. SCHWAB[1]

Abstract: Functionally or anatomically incomplete spinal cord injury (SCI), characterized by sparing of some fibers and parts of tracts still connecting the brain with the spinal cord caudal to the lesion, affects millions of people worldwide. Loss of motor control and locomotion is common, with limited potential for functional recovery.
A small group of neurons in the pedunculopontine and cuneiform nuclei of the midbrain tegmentum, the mesencephalic locomotor region (MLR), is well known to initiate and control locomotion in vertebrates. Results of experiments recently conducted in our lab in rats with large but incomplete SCI showed that electrical deep brain stimulation (DBS) of the MLR was able to re-establish a high degree of locomotion in animals with functional deficits resembling those observed in severe ASIA C patients (Bachmann et al., 2013).
In order to consider DBS of the MLR as a potential treatment for incomplete spinal cord injury in humans, an evaluation of whether DBS facilitates the re-establishment of physiological movement patterns under voluntary movement control is necessary.
Electrodes were stereotactically implanted into the MLR of intact and spinal cord injured rats. The lesioned rats underwent kinematic analysis under stimulation at different post-injury timepoints. No reaction to the stimulation was obtained up to 7 days after the injury. Reactions started by 2 weeks and were fully developed at 4 weeks after the spinal cord injury. These results suggest that the spontaneously occurring sprouting and rearrangements of spared bulbo-spinal fibers could be required for the MLR impulses to reach functionally appropriate targets in the lumbar spinal cord. To assess the higher brain control over MLR stimulated locomotion, rats were confronted with e.g. place preference choices. Low and medium DBS stimulation strength allowed rats to fully respond to the sensory-motor tasks. At higher stimulation levels, full control over the stimulated locomotion was lost. Ongoing experiments will provide important additional information for a clinical trial in severe ASIA B and C SCI patients.

Title: Anti-Nogo-A antibodies for treating and understanding neurogenic lower urinary tract dysfunction after spinal cord injury

Authors: *A. M. SARTORI[1,2], M. P. SCHNEIDER[1], A. K. ENGMANN[1], A.-S. HOFER[1], C. D. CRUZ[3], T. M. KESSLER[2], M. E. SCHWAB[1]
[1]Brain Res. Inst., Univ. and ETH Zurich, Zurich, Switzerland; [2]Neuro-Urology, Balgrist Univ. Hosp., Zürich, Switzerland; [3]Dept. of Exptl. Biol. - FMUP, Porto, Portugal

Abstract: Lower urinary tract dysfunction arises in a majority of people with spinal cord injury. The most common manifestation is detrusor sphincter dyssynergia (DSD), defined as bladder detrusor contraction with concomitant contraction of the urethral and/or periurethral striated sphincter muscle. DSD can result in high intravesical pressure and reflux of urine to the kidneys. The neuronal mechanisms responsible for the development of DSD after injury are unknown. Thus, no causal therapies are currently available. Here, we used antibodies against Nogo-A, a potent nerve fiber growth inhibitory protein, which have been shown to induce substantial axonal regeneration, enhanced neuronal plasticity and functional locomotor recovery after spinal cord injury in a variety of animal models. Rats were chronically implanted with a tubing system for controlled bladder filling and monitoring of bladder pressure, as well as external urethral sphincter (EUS) electromyography electrodes, allowing for repetitive urodynamic measurement and recording of EUS activity in awake animals over time. A severe but incomplete spinal cord injury was induced in all animals at the thoracic level 8. Afterwards, either control IgG antibodies or anti-Nogo-A antibodies were infused intrathecally for 14 days, and animals were investigated over a 4 weeks period. Anti-Nogo-A but not control antibody treated animals showed a significant normalization of several urodynamic parameters and EMG activity of the external urethral sphincter during voiding. Neurons in the pontine micturition center and their axons contain the neuropeptide Corticotropin Releasing Factor (CRF). Immunohistological analysis of CRF-positive fibers at sacral level S1 revealed three main regions that are densely

innervated by CRF fibers: the dorsal horn (DH), the intermediolateral nucleus (IML), and the lamina X region. Animals with a spinal cord injury had a marked decrease in CRF-fiber density in the lamina X compared to not injured animals. Interestingly, this reduction was not observed in animals treated with anti-Nogo-A antibodies. *In-situ* hybridization studies revealed that the number of GABAergic neurons located in the dorsal gray commissure decreases after injury. Yet, no reduction was observed in animals treated with anti-Nogo-A antibodies. These results suggest that the decreased supraspinal input to specific centers in the sacral spinal cord after injury leads to selective interneuron loss. These processes can be reverted/prevented by Nogo-A neutralization. In parallel, DSD is attenuated and important aspects of micturition are normalized.

Title: Intracortical neuroprosthesis fosters locomotor recovery after spinal cord injury

Authors: *M. BONIZZATO[1,2,3], M. MARTINEZ[1,2,3]
[1]Neurosciences, Univ. De Montréal, Montreal, QC, Canada; [2]Groupe de Recherche sur le Système Nerveux Central, Univ. de Montréal, Montréal, QC, Canada; [3]Ctr. de Recherche, Hôpital du Sacré-Coeur de Montréal, Montréal, QC, Canada

Abstract: Spinal cord injuries (SCI) interrupt the pathways between the cortex, which controls voluntary movements, and the spinal networks that generate locomotion. Over time, both spontaneously and through training, neuroplastic changes occur and partial control of locomotion is reinstated.
First, we aimed at identifying the contribution of the hindlimb motor cortex in recovery of walking after SCI. We developed a chronic cortical mapping technique in awake rats. By using

an electrode array, we delivered targeted trains of stimulation to the hindlimb motor cortex and recorded changes in evoked responses on leg muscles before and after a unilateral thoracic hemisection. In this SCI model the contralesional cortex initially loses its contralateral connections to the leg muscles. Over time, we showed that the contralesional cortex recovers the ability to produce movements of the paretic hindlimb. Re-appearance of evoked muscles potentials paralleled the recovery of stepping, starting 5 to 10 days after injury and peaking at 3 weeks after injury.
Second, we hypothesized that applying cortical stimulation during the recovery period would increase functional cortico-spinal connectivity and facilitate locomotor recovery. We developed a neuroprosthetic system whereby trains of cortical stimulation are delivered coherently during locomotor behavior. By monitoring electromyographic patterns we could detect gait phases and delivered cortical neuromodulation in closed-loop. The stimulation increased leg flexion during treadmill locomotion. In SCI rats, motor deficits including leg dragging were immediately alleviated or abolished. The ladder crossing measures skilled locomotion in the rat. SCI impairs the rat's ability to perform this task. Our therapy cohort and two control groups shared the same level of initial deficits. We found that after 3 weeks rats treated daily with our neuroprosthetic therapy had a success rate far exceeding that of two control animals groups (n=6 per group). This improvement was retained 4 weeks after the therapy was terminated.
Our results show that the motor cortex contributes to recovery of walking after SCI. Furthermore, we proposed the first demonstration of a supraspinal intervention capable to remarkably contribute restoring precise leg control.

Title: The effects of chronic paralysis on the mechanical properties and fibre-type composition of the diaphragm

Authors: *P. M. WARREN[1,2], R. W. P. KISSANE[1], J. C. KWOK[1,3], G. N. ASKEW[1]
[1]Sch. of Biomed. Sci., Univ. of Leeds, Leeds, United Kingdom; [2]Wolfston Ctr. for Age Related

Dis., Kings College, London, London, United Kingdom; [3]Inst. of Exptl. Med., Ctr. for Reconstructive Neurosci., Prague, Czech Republic

Abstract: High cervical hemisection causes a profound and robust deficit in respiratory motor function. Indeed, the disruption to supraspinal respiratory motor pathways causes a paralysis in the ipsilateral hemidiaphragm muscle which lasts from acute to chronic time points. However, we have previously shown that treatment induced recovery to normal diaphragm function can occur rapidly, within as little as two weeks following application. This would suggest that, despite the effects of atrophy and fibre type compositional change, the paralysed muscle retains functional capacity overtime. Here, we investigated how diaphragm mechanical properties change six weeks following chronic cervical spinal cord injury during isometric, isotonic, and cyclical contractions. Bilateral diaphragm electromyographic activity showed that 100% of animals with the C2 hemisection injury had complete paralysis in the ipsilateral hemidiaphragm six weeks following the initial trauma. Interestingly, isometric tetanic stress, twitch kinetics, and force-velocity relationships were similar between both the hemidiphragms in the injured animals and those in control groups. These data would suggest that injury induced paralysis did little to reduce diaphragm muscle mechanical function. However, while reproducible, these measures lack significant ecological validity to provide substantial and meaningful data relating to *in vivo* muscle function. Through the assessment of cyclic contractions, we demonstrated that the hemidiaphragm ipsilateral to the injury had a higher optimal cycle frequency for maximal net power generation compared to controls (8-10 Hz *versus* 5 Hz; $P < 0.001$). Interestingly, the shift in optimal frequency did not affect fatigue resistance during repeated cycles of work at 2 Hz, compared with all controls. Nonetheless, the principal mechanisms underpinning this alteration in optimal cycle frequency result from an increase in work performed during shortening associated with alteration in muscle fibre type. Collectively, these data show that chronic paralysis of the diaphragm adaptively and plastically alters the muscles optimal mechanical and fibre type composition. However, the muscle retains the capacity for conventional functionality, most likely due to continuous passive movement of the muscle within the thoracic cavity over time. These data explain how normal respiratory motor function can be rapidly restored following successful treatment of spinal cord injury and provide substantial information concerning how endogenous and adaptive plasticity may facilitate in this role.

Title: Effects of early and delayed strength training on neuropathic pain and nociceptive afferent sprouting after cervical spinal cord injury

Authors: *M. R. DETLOFF[1], A. ONG[1], A. D. TAMASHIRO-ORREGO[1], T. THAWEERATTANASINP[1], S. J. CHHAYA[2], J. D. HOULE[1]

Abstract: Spinal cord injury (SCI)-induced neuropathic pain is associated with both nociceptor hyperexcitability as well as sprouting of primary afferent c fibers that transmit pain information to the spinal cord. We have previously that early, aerobic exercise prevents development of neuropathic pain but does not ameliorate it once established. While locomotor training is used in the clinic, the standard of care in post-SCI rehabilitation focuses on improving muscle strength. This project will determine whether early or delayed strength training after SCI can affect nociceptive afferent plasticity and pain development and persistence after cervical SCI. Female Sprague-Dawley rats received a C5 unilateral spinal cord contusion corresponding to handedness. A subset of SCI rats underwent isometric forelimb strength training 5 days/week starting at 5 or 42 days post-injury (dpi) lasting 5 weeks. Briefly, rats complete 50 successful repetitions of at least 50g force in an isometric forelimb pull task to receive a food reward. Mean pulling force returned to near normal after 10 strength training sessions regardless of early or delayed initiation of exercise . The recovery of forelimb strength corresponded to improvements in reach-to-grasp behavior as assessed using a single pellet-retrieval task. Delayed strength training reduced paw hypersensitivity and pain behavior as measured by von Frey and mechanical conflict avoidance operant tests compared to unexercised and acute strength training SCI groups. Three days before sacrifice, rats received microinjection of cholera toxin-B (CTB) into the ulnar nerve to identify large diameter sensory afferents. We are currently completing immunocytochemical and quantitative analysis of SCI lesion severity and the degree of primary afferent sprouting associated with forepaw dermatomes. Future experiments will examine the active and passive membrane properties of nociceptive neurons of SCI rats with and without strength training exercise. With the results, we hope to better understand the mechanisms underlying SCI-induced pain, allowing for possible refinement of rehabilitation protocols to reduce chronic pain after SCI.

Title: New therapies in experimental cervical spinal cord injury (C-SCI)-induced spasticity and gait disabilities

Authors: *J. HOU[1,2], R. NELSON[1], N. MOHAMMAD[1], D. PLANT[1], G. MUSTAFA[1,2], S. TSUDA[1,2], J. GODWIN[1], R. MARTIN[1], K. BUCKLEY[1], A. LERNER[1], R. J. BERGERON, Jr.[3], F. J. THOMPSON[1,2,4], P. BOSE[1,2,5]
[1]Brain Rehabil. Res. Ctr. of Excellence, North Florida/South Georgia Veterans Hlth. Syst., Gainesville, FL; [2]Physiological Sci., [3]Medicinal Chem., [4]Neurosci., [5]Neurol., Univ. of Florida, Gainesville, FL

Abstract: C-SCI can produce life-long locomotor impairments, including spasticity disability. The objective of these therapy development studies was to amplify therapeutic impact by combining treadmill locomotor exercise (Tm) and SCI-site magnetic stimulation (TMS). To broaden the scope of potential therapeutic application, we also tested a new hexadentate monosodium iron chelator (NaHBED) therapy in this C-SCI model. Moderate $C_{6/7}$ contusion injuries (200 kdynes, Infinite Horizon Impactor) were produced in anesthetized adult rats. To evaluate acute treatment, Tm was initiated at post-SCI day 8. The treatment was performed 5 days/week for 6 weeks. Beginning at post-SCI day 14, TMS, was applied at the injury site every other day using a protocol that we recently reported (Hou et al., 2014). In a different cohort of acute treatment animals, the NaHBED was injected SC (100mg/kg/d) for 10 days starting on the day of SCI. For chronic studies, simultaneous TmTMS treatment was initiated at post-SCI week-8 and was performed for 6 weeks. Measures of lower limb spasticity (velocity-dependent ankle torques and time-locked triceps surae EMGs) and H-Reflex rate-depression were assessed using methodology that we developed and reported previously. Locomotor disabilities and therapy-induced improvements were assessed using 3-D kinematic (Vicon Motion Systems) and footprints (CatWalk, Noldus) analyses of gait. Lesion size, iron deposition in the injury site, and integrity of the descending pathways were imaged using 7.0 T MRI (MR Solutions) using T1/T2-weigted, QSM, and DTI/GQI imaging, respectively. Acute treatments using TmTMS were observed to completely blocked the development of spasticity compared to data obtained

from untreated SCI controls. Chronic TmTMS treatment yielded significant improvement in spasticity, but was not able to block it. Interestingly, the NaHBED treatment alone exhibited significant reduction in spasticity. Significant improvements in parametric measures of gait were observed in both acute TmTMS and NaHBED groups, respectively. The improvements in spasticity and gait were accompanied by greater spared spinal tissues and less iron deposition in the injury site (particularly, in NaHBED group). These data suggest that simultaneous application of TmTMS can be an effective treatment for C-SCI induced spasticity and gait impairments; acute treatments showing greater efficacy (e.g. earlier opportunity to diminish secondary injuries) than the chronic treatments. Improvements in spasticity and gait induced by treatment using a new iron chelator (NaHBED) are proposed to be associated with reductions in iron-induced toxicity and inflammation.

Title: Inflammation-induced attenuation of locomotor recovery is associated with decreased motoneuronal KCC2 expression

Authors: *R. JEFFREY-GAUTHIER[1], M. PICHE[2], J. BOUYER[4], M.-P. COTE[5], H. LEBLOND[3]
[1]Anatomie, Univ. Du Quebec À Trois-Rivieres, Trois-Rivieres, QC, Canada; [2]Chiropractic, [3]Anat., Univ. Du Quebec a Trois-Rivieres, Trois-Rivieres, QC, Canada; [4]Neurobio. and Anat., Drexel Univ. Col. of Med., Philadelphie, PA; [5]Neurobio. and Anat., Drexel Univ. Col. of Med., Philadelphia, PA

Abstract: Following spinal cord injury (SCI), neuroplasticity in spinal network results in functional recovery as well as in hyperreflexia, spasticity and neuropathic pain development. We recently showed that pro-inflammatory injection of complete Freund adjuvant (CFA) in lumbar muscles below the level of a complete spinal transection attenuates locomotor recovery and decreases the expression of the chloride cotransporter KCC2 in lumbar spinal cord. Other studies suggest that motoneuronal expression of KCC2 could be restored by locomotor training. The

purpose of this study was to evaluate if inflammation-induced locomotor deficits were associated with decreased KCC2 expression in motoneurons assessed immunohistochemically and whether training could restore this deficit. Four groups of CD1 female mice composed of control spinal mice (n=8), spinal mice that were trained daily on a treadmill (n=10), spinal mice which received CFA injection in lumbar muscles (n=9) and trained spinal mice with CFA (n=9) were used in this experiment. Locomotion was assessed on day 2, 7, 14, 21 and 28 after a complete T7 transection. Animals were euthanized on day 28 by a transcardiac perfusion of 4% paraformaldehyde solution (PAF). Spinal cords were sampled, fixed overnight in PAF and cryoprotected in 30% sucrose and then frozen. Spinal tissue was sliced transversally between L1 and L6 in 25µm-thick sections, processed for slide-mounted immunofluorescence staining and probed for KCC2 and choline acetyltransferase (ChAT). Spinal mice with CFA showed impaired locomotor recovery compared to control spinal mice (increased drag, decreased step length, hip, ankle and MTP excursions). Also, our results show that the KCC2 expression in motoneurons was decreased in CFA spinal mice compared to control spinal mice and the observed deficit is restored in trained spinal mice with CFA. In addition, a correlation analysis revealed that locomotor recovery is associated with higher KCC2 expression in motoneurons. Considering the high prevalence of injured and inflammed back tissues in SCI patients, these results suggest that changes in KCC2 expression is a potential mechanism underlying the mutual influence of pain and rehabilitation and support the use of exercise to promote functional recovery.

Title: Low level laser therapy leads to recovery from spinal cord injury by improving behavior and physiological changes

Authors: *P. JENDELOVA[1,2], B. SVOBODOVA[1,2], J. RUZICKA[2], L. NAVRATIL[3], M. JHANWAR UNIYAL[4], L. MACHOVA URDZIKOVA[2]

Abstract: Low level laser therapy (LLLT) is considered as an effective treatment for central and peripheral nervous tissue regeneration by influencing numerous processes that accompany injury of the nervous tissue. LLLT restrain accumulation of inflammatory cells, modulate reactive oxygen species production, activate mitochondrial DNA replication, increase growth factor expression and alter nitric oxide levels. This study is aim to investigate the effect of LLLT on the functional recovery after spinal cord injury (SCI) and evaluate soleus muscle mass and histopathological changes of the spinal cord in rats.
Rats (Wistar male, n=26) with balloon induced spinal cord compression lesions were treated with a low-intensity MLS laser (simultaneously 808 nm continuous emission and 905 nm pulse emission, pulse-wave frequency, 10 Hz) at a light dose of 300 J. Light was applied transcutaneously at the lesion site immediately after injury for 10 days, given for 9 minutes. Functional recovery was assessed weekly by locomotor tests (BBB and Beam walking) and a sensitivity test (Plantar test). The animals were sacrificed 9 weeks after injury; the mass of soleus muscle was weighted and the spinal cord tissue was histologically evaluated. qPCR (Bdnf, Ngf, Nt3, Fgf2, Irf5, Mrc1, Olig2, Casp3, Gap43, Gfap Vegfa and Cntf) and Luminex multiplex cytokines (MIP-1α, IL-4, IL-1β, IL-2, IL-6, IL-12p70, TNF-α, and RANTES) were performed 2 months after SCI, to detect host tissue responses to LLT. Result demonstrated that LLT significantly improved functional locomotor recovery from the first week after lesioning in both BBB test as well as in advanced locomotor test, such as beam walking. Of 13 rats, 7 were able to cross the beam, compared to none in the control group. Phototherapy showed a significantly positive impact on diminishing thermal hyperalgesia after SCI. Laser treated animals displayed less atrophy in soleus muscle mass compared to the control group. Low-power laser radiation had a positive effect on grey and white matter sparing and there was a tendency to increase axonal sprouting. Changes in MIP-1α, IL-4, IL-6 were detected during first week after SCI. There were no significant changes in GFAP-positive area after laser treatment.
In conclusion, non-invasive light therapy promotes functional recovery in acute SCI and underscores use of LLLT as a promising therapy for SCI in humans.

Title: Assessing corticospinal-dependent skilled forelimb movement in mice

Authors: *N. SERRADJ[1], F. MARINO[1], S. AGGER[1], A. M. SLOAN[2], E. R. HOLLIS[1,3]
[1]Res., Burke Neurolog. Inst., White Plains, NY; [2]Vulintus, Inc., Lafayette, CO, Dallas, TX; [3]Feil Family Brain and Mind Res. Inst., Weill Cornell Medicine, NY

Abstract: Current behavioral tools in mice are not sufficient for interrogating complex, corticospinal-dependent, skilled motor behavior. The foundation for skilled motor learning and a potential mechanism for rehabilitation after neurological injury is the remodeling of cortical motor networks, including corticospinal neurons. An understanding of the organization and function of cortical motor networks is critical as neurological diseases and injuries that disrupt these networks, or network output, dramatically impair motor function. Recent advances in optical imaging have allowed for the interrogation of cortical motor network function *in vivo*, however, there is a need for a similar advance in the development of skilled behavioral tasks to use in combination with these imaging techniques. In mice, a simple lever press task has provided the initial insights into network function during learning, however, the execution of this unskilled learned behavior is unaffected by motor cortex injury. We have addressed this critical need by developing unbiased testing devices for complex behaviors to use in concert with modern *in vivo*imaging techniques.Working with Vulintus, Inc., we have adapted automated behavioral tasks of the MotoTrak system for use in head-fixed mice during two-photon imaging. We have validated these skilled motor tasks by testing the impairment of behavioral performance induced by unilateral transection of the corticospinal tract at the medullary pyramids (pyramidotomy). We recorded calcium transients in individual corticospinal neurons expressing the genetically encoded calcium indicator GCaMP6f. Imaging was performed over the course of skilled motor learning and used to determine the effects of pyramidotomy on neuronal activity. Our findings on the corticospinal neuron response to injury will open the door to future studies that focus on the plasticity of cortical motor networks, the incorporation of individual corticospinal neurons during skilled motor learning, and the recovery of motor networks after injury.

Title: H reflex recorded from lumbar external oblique can be used to study effects of optogenetically mediated cortical neuromodulation after a complete T9/T10 spinal transection in rats

Authors: *K. A. SCHMIDT[1], S. F. GISZTER[2]
[1]Drexel Univ., Philadelphia, PA; [2]Dept Neurobiol & Anat, Drexel Univ. Col. of Med., Philadelphia, PA

Abstract: After a complete T9/T10 spinal cord injury (SCI) in adult rats, trunk control becomes very important for postural stability, and crucial for function if stepping of hindlimbs is enabled. We have developed a neuromodulatory technique aimed at promoting plasticity and motor learning in the trunk motor cortex after SCI via subthreshold optogenetic stimulation using virally delivered Channelrhodopsin (ChR2). Virally delivered enhanced yellow fluorescent protein (EYFP) is used as a control. When optogenetically mediated neuromodulation is paired with a 25 day robot assisted rehabilitation paradigm, motor mapping studies reveal a significant increase in cortical representation of trunk muscle segments below the injury (1-way ANOVA with Tukey-Kramer post-hoc comparisons, $p<0.05$) in the ChR2+robot rats, both with induced spinal stepping (N=8) and without (N=8), but not in EYFP+robot rats with (N=8) or without (N=8) spinal stepping enabled. Activation of caudal trunk enabled by these representational changes likely also causes plastic changes in spinal circuitry below the injury by influencing sensory input and motor output in the spinal cord caudal to injury. These plastic changes may be beneficial in functional recovery after injury, and understanding these effects may help direct future rehabilitation efforts. Functional tests, such as AOB or BBB scoring provide little insight into group differences at circuit levels, so a physiological probe is needed to understand the basis of functional differences.
H-reflex testing is used widely to test spinal excitability. Though an H-reflex can be initiated in any muscle if the innervating nerve can be isolated for stimulation, testing typically occurs in muscles of the low extremities since the distance between the muscle of interest and the spinal cord is sufficient to ensure complete separation of the signals representing direct motor activation of the muscle from the spinally driven reflexive activation of the muscle. Here we present a method to test the H-reflex in the lumbar external oblique, an axial muscle with short peripheral nerves and latencies, caudal to injury, in awake behaving rats, employing blind source separation technique, independent component analysis, to separate the overlapping direct motor activation of the muscle from the spinally driven reflexive activation of the muscle. Varying stimulation frequency allows the effects of neuromodulation of trunk motor cortex on spinal excitability below the injury to be revealed. This work has been supported by NIH NINDS NS054894, and NS072651 and the Craig Neilsen Foundation.

Title: Electrical stimulation to promote plasticity in the injured corticospinal tract

Authors: *N. J. BATTY[1], A. TORRES-ESPIN[2], R. VAVREK[2], P. RAPOSO[2], A. BLESCH[3], K. FOUAD[1,2]
[1]Neurosci. and Mental Hlth. Institute, Univ. of AB, Edmonton, AB, Canada; [2]Dept. of Physical Therapy, Univ. of AB, Edmonton, AB, Canada; [3]Stark Neurosciences Res. Inst., Indiana Univ. Sch. of Med., Indianapolis, IN

Abstract: cAMP and its downstream effectors have long been implicated in plasticity in the nervous system, with a vast array of work showing that increases in cAMP leads to an increase in plasticity and neurite outgrowth. Following spinal cord injury (SCI), intracellular cAMP levels have been shown to decrease in the motor cortex, which has been theorized to be caused by the loss of neuronal activity. Restoration of cAMP levels has been achieved following peripheral nerve injury through electrical stimulation and rehabilitative motor therapy. Additionally, stimulation in the uninjured side of the cortex following SCI in conjunction with rehabilitative therapy has shown increases in cAMP. These increases have been shown to result in an increase in neurite outgrowth in the injured nerves in both of the peripheral and central nervous system injury models. There has been limited work on stimulation of the injured side of the cortex. Our goal is to increase motor recovery following SCI by increasing cAMP induced plasticity in the corticospinal tract through a combination of cortical electrical stimulation of the injured cortex and motor rehabilitative therapy.
Adult female Lewis rats were trained in a single pellet grasping (SPG) task for 5 weeks to a baseline success rate of 40%. Following which animals underwent an incomplete unilateral cervical spinal cord transection on the side of the dominant paw. Immediately following SCI the experimental group underwent 30 minutes of electrical stimulation in their forelimb motor cortex. One week following injury, both groups were trained in the same grasping task for an additional six weeks at which point functional recovery was compared to pre-injury levels. Success rates and limb functional scores were analyzed and tissue was processed for histological analysis following BDA tracing of the corticospinal tract, allowing us to measure distribution of collateral sprouting in the grey matter above the lesion site.
Results indicate increased functional recovery in the SPG task in stimulated animals.

Histological analysis of collateral sprouting and their distribution demonstrates that electrically stimulated animals show a significant increase in collateral sprouting immediately above the lesion site, as well as a significant increase in the distance extended from the dorsal funiculus into the grey matter. Further studies aim to investigate the parameters of stimulation required to elicit anatomical and functional changes so as to reach a more clinically feasible means of treatment.

Abstract: Combinatorial therapies for the treatment of spinal cord injury (SCI) are vital if a significant amount of locomotor recovery is to be achieved. Parsing out the behavioral and anatomical changes each treatment is having will allow us to effectively combine therapies needed for SCI recovery. Alone, anti-Nogo-A antibody (11C7), locomotor training, or epidural stimulation of the lumbar spinal cord have been shown to improve locomotor outcomes in animal models of SCI. However combining therapies has not always been successful, with certain treatments, such as training alongside anti-Nogo-A therapy, proving to have negative combinatorial effects. The current study attempts to show the addiditive effects of sequential anti-Nogo-A antibody treatment followed by epidural stimulation and locomotor training with body weight support. Adult Sprague-Dawley rats received a severe contusion injury at T9/T10, epidural electrodes implantation at L2 and S1, and intrathecal delivery of either the Anti-Nogo antibody 11C7 or control IgG (osmotic pumps). Animals were randomly assigned to one of cage control, locomotor training, epidural stimulation (40Hz sub threshold), or combined epidural stimulation and locomotor training. Pumps and catheters were removed after 2 weeks and

training began 3 weeks following injury in order to minimize negative outcomes seen when anti-Nogo-A therapy was simultaneously combined with locomotor training. Rats in the trained groups stepped bipedally-to-quadrupedally with varying amounts of body weight support at speeds of 7-21cm/s (5 days/week, 20 mins/day) for 8 weeks. Kinematic recordings were made and Cholera toxin-B (CTB) tracer injections into the hindlimb and cortical BDA injections were completed before terminal electrophysiology. Surprisingly, our preliminary data showed that there were no significant differences in BBB scores between groups throughout the treatment period. The fact that both drug and control groups did not show significant improvement in the open field suggests that epidural stimulation and locomotor training did not have the effects seen previously. The three week delay in treatment may be the cause for this with the critical period possibly missed. The behavioral results underline the importance of understanding the mechanisms of different treatments in order to be able to combine them in the most effective way.

Title: Changes in descending drive and local spinal reflexes in rats following spinal cord injury, with combinatorial application of locomotor training, epidural stimulation and anti-Nogo (11C7) antibody

Authors: *R. W. KISSANE[1], R. G. DICKSON[1], K. CHEN[2], C. C. SMITH[3], M. E. SCHWAB[4], S. CHAKRABARTY[1], R. M. ICHIYAMA[1]

Abstract: A few therapeutic strategies have shown promise in the recovery of locomotor function following severe spinal cord injury (SCI), however the mechanisms underpinning the recovery of functional capacity are not fully understood. Anti-Nogo antibody (11C7) has been shown to promote sprouting of cortical spinal tract (CST) axons and functional capacity in animal models. Locomotor training and stimulation at the dorsal surface of the spinal cord

(epidural stimulation) has been used as a means of modulating spinal circuits caudal to the lesion, and promoting recovery of function. We sought to explore the effect of combining locomotor training with epidural stimulation, in the presence of 11C7, to assess the supra spinal and local spinal changes involved in the loss and gain of locomotor function following a severe SCI. Simultaneous treatment of 11C7 with locomotor training interferes in the recovery of locomotor capacity. Consequently we treated with 11C7 or a Control IgG antibody for two weeks immediately following SCI and delayed initiation of training by one week. Rats received a severe contusion injury (250 kdyn) to the mid-thoracic spinal cord (T9/10). Three weeks post injury animals were randomly assigned to one of four groups; cage control, locomotor trained, epidural stimulation (40Hz across spinal segments L2 and S1), or locomotor training with epidural stimulation combined. Animals were trained for eight weeks before undergoing kinematic analysis and terminal electrophysiological experimentation. Preliminary data suggest no clear differences in the recovery of open field locomotor capacity between groups. 3D kinematics analysis of bipedal locomotion is currently ongoing. Descending drive through the CST was completely removed following SCI. There was no evidence of modulatory capacity of the CST on the monosynaptic reflex (MSR) following any of the treatment strategies. However, SCI resulted in motor neuron hyperreflexia, which was ameliorated in animals that underwent locomotor training. In the combination animals there appears to be an increased modulatory input from the reticular formation on MSR. Importantly, we have begun to identify potential spared descending pathways able to modulate motor neuron excitability in the absence of CST input.

Title: Bumetanide differently alters spinal reflex inhibition over time after SCI

Authors: *G. CARON, K. YEAKLE, J. BILCHAK, M.-P. COTE
Neurobio. and Anat., Drexel Univ. Col. of Med., Philadelphia, PA

Abstract: Spasticity affects ~70% of people with a spinal cord injury (SCI), and is attributed to an increase in neuronal excitability and a decrease ability to depress spinal reflexes below the

lesion. Neuronal inhibition in the mature CNS mostly rely on GABAergic and glycinergic induced hyperpolarization. Drugs directly targeting GABAergic receptors provide a transient improvement in alleviating spasms and exaggerated reflexes and *de facto* became the most prescribed medication for the management of spasticity (Walter et al., 2002). However, they have significant side effects by decreasing motoneuronal excitability such that the potential for motor recovery is compromised (Dietz and Sinkjaer, 2007). Therefore, restoring inhibitory mechanisms rather than depressing neuronal excitability are promising strategy to decrease spasticity without hindering motor recovery.
A shift in chloride homeostasis has been shown to be involved in the emergence of spasticity after SCI. Chloride homeostasis in CNS neurons, is mainly determined by the relative expression of two chloride transporters, the outward-rectifying KCC2 and the inwardly-directed NKCC1. The decrease in KCC2 expression in motoneurons after SCI is depolarizing the E_{IPSP} and contributes to the emergence of spasticity (Boulenguez et al 2010). We have previously shown that the beneficial effects of exercise on spastic symptoms relied on a return of chloride homeostasis in lumbar motoneurons (Cote et al., 2014).
Chloride homeostasis-related neurological disorders were shown, to be improved when blocking NKCC1 with bumetanide (Ben-Ari, 2017). Here, we explore the therapeutic effect of bumetanide and step-training on restoring chloride homeostasis and improving the locomotor pattern after SCI. Chronic EMGs were implanted into hindlimb muscles of SCI rats to monitor locomotion over the course of 4 weeks. During a terminal experiment, we evaluated the alteration of reflex modulation associated with these interventions. H-reflexes were evoked by stimulating the tibial nerve and were conditioned by PBSt stimulation at different intervals. Our results suggest that acute bumetanide treatment improves reflex modulation, most likely through a recovery of postsynaptic inhibition, when initiated early after SCI. When NKCC1 activity was blocked chronically the improvement of locomotor pattern are comparable to step-trained animals. Correlation between features of EMG bursts (timing, amplitude, etc) and KCC2/NKCC1 levels will also be presented. Together, these results suggest that bumetanide could produce beneficial effects on spastic symptoms and the recovery of locomotion after SCI.

Title: Enhancing KCC2 function attenuates hyper-excitable stretch reflex after SCI

Authors: *J. BILCHAK STROUGHAIR, G. CARON, K. YEAKLE, M.-P. COTE
Neurobio. and Anat., Drexel Univ., Philadelphia, PA

Abstract: After spinal cord injury (SCI), ~75% of individuals develop spasticity – a debilitating condition involving involuntary movements, co-contractions, and hyperreflexia. Most current medications to suppress spasticity act upstream of NDMA and Ca2+-dependent mechanisms, leading to serious side effects including a drastic decrease in motoneuronal excitability. Therefore, there is a pressing need for new options that will treat spasticity without hindering motor activity. We have previously shown that exercise attenuates hyperreflexia after SCI through an increase in lumbar motoneuronal expression of KCC2. KCC2 is a Cl- co-transporter that largely determines the [Cl-]i of neurons and its expression is decreased in SCI. A promising approach is to restore endogenous inhibition directly by targeting Cl- homeostasis via KCC2, which will not affect spinal excitability as current available treatments do. Recently, a novel family of compounds, CLPs, were developed to selectively enhance KCC2 activity and has been successfully used to alleviate hypersensitivity in models of neuropathic pain. We have previously found that CLP257 restores the frequency dependent depression (FDD) of the H-reflex in untrained rats to levels like those observed in exercised rats.
Here, we examine the effects of CLP257 on mechanically induced stretch reflexes and muscle forces. Adult Sprague Dawley rats underwent a complete transection (T12), and either received passive bicycle training or were left untrained. In a terminal experiment 4 weeks post SCI, the triceps surae was lengthened at different amplitudes and velocities, and the resultant forces were quantified before and after administration of CLP. Large velocities were used to induce stretch reflexes, while smaller velocities were used to quantify overall muscle force output. Our results indicate that CLP reduces the hyperexcitable stretch reflex observed in untrained animals and has no diminishing effects on force output. This indicates that CLP avoids the detrimental effects on muscle activity that often accompany current anti-spastic medication. Surprisingly, CLP appears to increase spiking activity in muscle fibers, suggesting that although CLP decreases hyperactive reflexes, it also contributes to increased excitability of certain pathways. This will need to be further investigated to determine if this activity can be used to the benefit of motor recovery. These results indicate that CLP has beneficial effects on the monosynaptic reflex in hyperreflexive rats after SCI. To investigate polysynaptic mechanisms, we will also examine the effects of CLP on long duration reflexes.

Title: Exploring approaches to promote respiratory motor plasticity through varied and fixed interval intermittent hypoxia

Authors: *A. L. SILVERSTEIN, K. J. RITTER, D. R. STOLTZ, L. E. HAGER, C. M. CALULOT, R. S. J. MAGGARD, E. E. HUFFMAN, W. S. WITT, W. J. ALILAIN
Dept. of Neurosci., Univ. of Kentucky, Lexington, KY

Abstract: In the human population, spinal cord injury (SCI) most commonly occurs at the cervical level. Interruptions of descending pathways here can result in breathing motor deficits through paralysis of the diaphragm, sometimes necessitating mechanical ventilation for survival which greatly decreases patients' quality of life. Fixed interval intermittent hypoxia (FIH) treatment is utilized in rat models to attenuate breathing motor deficits resulting from cervical SCI. FIH consists of the repeated, alternating exposure of a subject to consistent and equal durations of hypoxic and normoxic conditions. Specifically, this treatment induces a prolonged increase in phrenic motor output, a type of respiratory motor plasticity known as phrenic Long Term Facilitation (pLTF). FIH exhibits similarity to the psychological construct of operant conditioning in which the increased incidence and persistence of a desired, spontaneous behavior is trained through reinforcement. As such, each interval of hypoxia can be construed as the period during which the subject responds with heightened respiratory drive and is subsequently reinforced by an interval of normoxia. Provided that FIH procedure is a form of operant conditioning, it can be optimized. Using the fixed or variable duration of the hypoxic interval as our independent variable, we hypothesize that Varied Interval Hypoxia (VIH) treatment will induce a greater, more prolonged increase in phrenic motor output than FIH. To test this hypothesis, we utilized electromyographic recording to assess our dependent variable of diaphragmatic activity. In naïve retired breeder rats (female, Sprague-Dawley) treated by VIH (n=2), episodic spinal cord application of serotonin, previously shown to induce pLTF independently from intermittent hypoxia treatment, depressed breathing motor output, an effect opposite from that observed after FIH (n=2). Preliminary data from C2 hemisected animals (n=3) suggests that exposure to VIH results in an increase in diaphragmatic output achieving 44.89% (stdev.p 15.76%) of maximum induced by nasal occlusion. These data suggest that VIH may paradoxically promote a lower level of respiratory motor plasticity than FIH in naïve models,

while potentially inducing significant recovery in post-injury models. Further exploration will focus on post-injury treatment, adjusting the variance of the hypoxic periods for optimum induced recovery, and more robust comparison to control.

Abstract: Translating spinal cord injury (SCI) therapies from preclinical animal models into the human population is challenging. One potential explanation is that human genetic predispositions may limit the efficacy of treatments which enhance regeneration and sprouting. The clinically relevant ApoE4 (E4) allele, present in about 14% of the human population, corresponds to an increased incidence of Alzheimer's disease. Its role in recovery from SCI is poorly understood despite suggestive data implicating its involvement. Two clinical studies found that SCI individuals with the E4 allele had less motor recovery than individuals without the allele despite longer time in rehabilitation. ApoE4 may mediate this diminished recovery by limiting regeneration and sprouting. Robust regeneration is energy intensive and requires efficient mitochondria, and studies have shown that ApoE4 impairs mitochondrial function. Given these mitochondrial deficits, we hypothesize that ApoE4 can impair regeneration and sprouting. To test this hypothesis, we investigated the impact of ApoE4 on sprouting and neurite outgrowth. In our experiments, we cultured dorsal root ganglia neurons from mice expressing the human ApoE isoforms—ApoE2 (E2), ApoE3 (E3), or ApoE4—under the control of the mouse ApoE promoter. We then analyzed differences in 1) neurite complexity and 2) robustness of outgrowth between genotypes. Our results demonstrate that E3 neurons have more robust outgrowth than E4 neurons, as indicated by a higher total combined neurite length. Analysis of neurite branching

indicates that E3 neurons also have higher neurite complexity than neurons expressing ApoE4. Preliminary data from the Spot Assay, an in vitro model of the glial scar and CNS regeneration, suggest that chondroitin sulfate proteoglycans may inhibit regeneration in E4 neurons to an even greater extent than in E3 neurons. Since outgrowth, sprouting, and regeneration all partially mediate recovery after CNS injury, impairments in these processes can adversely affect recovery. These foundational studies address not only the possible genetic influence of ApoE4 on recovery from CNS injury, but also a critical gap in knowledge—whether there is a genetic contribution underlying responses to treatment in SCI individuals.

Title: Balancing neuroprotection with functional recovery: The role of the perineuronal net in preventing excitotoxicity after spinal cord injury

Authors: *D. R. STOLTZ, K. J. RITTER, E. E. HUFFMAN, A. L. SILVERSTEIN, W. J. ALILAIN
Spinal Cord and Brain Injury Res. Ctr., Univ. of Kentucky, Lexington, KY

Abstract: In spinal cord injury (SCI), initial mechanical trauma causes debilitating primary damage to neural cells and blood vessels. Following this, a secondary cascade of downstream events occur, including inflammation, ischemia, and excitotoxicity — an increase in intracellular Ca2+ concentration from overactive glutamate (Glu) receptor activity leading to cell death. Additionally, there is an upregulation of the perineuronal net (PNN), a lattice-like structure of the extracellular matrix which modulates neural communication and homeostasis. The PNN is partially composed of highly negatively charged chondroitin sulfate proteoglycans (CSPGs). While the PNN and CSPGs can support plasticity and neuronal growth during development, after injury these ECM molecules are inhibitory to regeneration, sprouting and plasticity. However, administration of the bacterial enzyme chondroitinase ABC (ChABC) can digest these inhibitory factors and promote functional recovery. What remains unknown is the impact of removing these inhibitory factors soon after injury. We hypothesize that negatively charged CSPGs are

upregulated after SCI as a neuroprotective response that attenuates excitotoxicity by acting as a sink for Ca2+. To test our hypothesis, we induced excitotoxicity by injecting rats with a threshold dose of Glu with or without ChABC utilizing the well defined respiratory motor system. 59% of SCI occurs at the cervical level, and leading causes of death and restriction of independence in these cases stem from mechanical ventilation. Therefore, we administered the dose instraspinally at the C4 level and paired treatment with intrapleural injection of cholera toxin-B to retrogradely label the phrenic motor neuron pool (which innervates the diaphragm). Preliminary results suggest that animals treated with both Glu and ChABC had more extensive phrenic motor neuron loss. Histological analysis of apoptosis with TUNEL staining will further reveal whether CSPGs serve our proposed role in promoting survival after SCI in additional cells. In conclusion, our early findings suggest that following SCI, the body's main focus is to survive and not necessarily to preserve function. CSPG upregulation could promote survival and CNS tissue preservation at the expense of plasticity and functional regeneration. Future directions will investigate the optimal timing of CSPG digestion to balance neuroprotection with alleviation of the inhibitory environment to promote recovery.

Title: Apolipoprotein E4 as a barrier to respiratory motor plasticity

Authors: *L. HAGER, R. S. J. MAGGARD, D. R. STOLTZ, K. J. RITTER, E. E. HUFFMAN, B. N. TURBA, C. CALULOT, A. L. SILVERSTEIN, W. J. ALILAIN

Abstract: More than 50% of spinal cord injuries (SCI) occur at the cervical level. These injuries can disrupt axons that descend from medullary respiratory centers to the phrenic motor nucleus at C3-C6. Since diaphragmatic innervation originates from the phrenic motor nucleus, loss of these descending inputs leads to impairment of breathing function in cervical SCI patients. One approach to promote functional recovery is by enhancing plasticity through activation of spared

but latent pathways or strengthening of synapses. One form of respiratory motor plasticity is long term facilitation (LTF), which is characterized by a prolonged increase in breathing activity. LTF can be induced by intermittent bouts of hypoxia (IH) or through intermittent doses of serotonin (5-HT) applied to the spinal cord. Increased signaling through 5-HT receptors and upregulation of glutamate receptor expression in excitatory synapses mediate LTF. In preclinical animal models of SCI, IH has been successful in promoting breathing recovery. However, human patients have exhibited varying degrees of response to IH treatment, indicating that there is an additional factor influencing plasticity that must be considered. We propose that genetic diversity among the human SCI population could be a key factor in determining an individual's potential for plasticity. Apolipoprotein E (ApoE) is a promising gene of interest since the ApoE4 protein has been shown to reduce synaptic plasticity by decreasing the expression of glutamate receptors on the neuronal surface in vitro. In the present study, long term facilitation was induced in rats in the presence of human ApoE3 and E4 proteins to determine their influence on plasticity in vivo. In animals that received E4, diaphragmatic EMG recordings demonstrated that LTF was abolished and immunohistochemistry revealed that fewer glutamate receptors were localized in synapses. To investigate the effect of ApoE4 on respiratory motor plasticity after injury, C2 hemisections were performed on a second cohort of rats and LTF was induced at a 20-week post injury time point in the presence of human ApoE3 or E4. In ApoE3 treated animals, diaphragmatic activity ipsilateral to the injury increased in response to serotonin dosing, whereas this increase was abolished in Apo4 treated animals. Collectively, these experiments demonstrate ApoE4's ability to inhibit plasticity, emphasizing that genetic diversity is an important factor to consider in the development of therapies for the human SCI population.

Abstract: Severe spinal cord injury interrupts descending sympathetic projections that modulate cardiovascular function. This interruption leads to frequent bouts of hypertension (autonomic dysreflexia) and orthostatic hypotension, conditions that lead to increased risk for cardiovascular disease and potentially death. Here, we developed a conceptual and engineering framework to design an electrical spinal cord neuroprosthesis that targets the sympathetic circuitry within the spinal cord to prevent the development of these conditions. We first developed a rodent model of sympathetic dysfunction after spinal cord injury. For this, we visualized catecholaminergic fibers originating from the brainstem autonomic centers in TH:Cre rats who underwent a severe upper thoracic contusion. We found a near complete interruption of TH+ descending sympathetic axons, which led to an immediate decrease in resting hemodynamics and to the development of aberrant cardiovascular reflexes. To target the sympathetic circuitry within the spinal cord with epidural electrical stimulation, we mapped the hemodynamic responses to stimulation applied at each level of the thoracic and lumbar segments. We identified highly-specific hotspots that effectively modulated hemodynamics. We then used intersectional neuroanatomical tracing and activity-dependent signaling pathways to uncover the connectome of the spinal cord and splanchnic ganglia circuits engaged by the stimulation. Using optogenetic manipulations, we established causal relationships between the modulation of these circuits and the hemodynamic response to the stimulation. We then combined CT scans, MRI sequences and computational modelling to design a neuroprosthesis that targets cardiovascular hotspots in the spinal cord. This neuroprosthesis was fabricated using e-dura technology. We therefore have termed this implant *autonomic e-dura*. The therapeutic efficacy of the *autonomic e-dura* is under investigation.

Abstract: Epidural electrical stimulation (EES) of the lumbar spinal cord restored locomotion in rodents, nonhuman primates and humans with spinal cord injury (SCI). However, the neural structures through which EES enables motor pattern formation remain poorly understood. Using calcium imaging and chemogenetic inactivation experiments, we demonstrate that the activation of proprioceptive feedback circuits contributes to motor pattern formation during EES. However, EES also recruits cutaneous low-threshold mechanoreceptor feedback circuits. Modeling experiments showed that the activation of these pathways with EES is detrimental to the production of locomotion. To augment the facilitation of movements with EES, we thus reasoned that these two types of circuits should be targeted with opposing neuromodulators. This understanding translated into a circuit-specific electrochemical neuromodulation therapy based on noradrenergic receptor modulation that enabled robust locomotion in paralyzed mice and rats. These findings establish a mechanistic framework for the design of targeted neuromodulation therapies in human patients.

Abstract: Severe spinal cord contusions interrupt nearly all brain projections to lumbar circuits producing leg movement. Failure of these projections to reorganize leads to permanent paralysis. Here, we modeled these injuries in rodents. We found that a severe contusion abolishes all motor cortex projections below injury. Using mice expressing light-sensitive channels in cortical projection neurons, we found that electrochemical neuromodulation of the lumbar spinal cord enabled the hindlimb motor cortex to regain a graded control over hindlimb locomotor movements in otherwise paralyzed animals. Virus-mediated tract tracing and circuit-specific inactivation techniques revealed that the cortical drive accessed the lumbar spinal cord through glutamatergic reticular neurons with residual projections below the injury. Gravity-assisted rehabilitation enabled by electrochemical neuromodulation reinforced these reticulospinal projections, rerouting cortical information through this pathway. This cortico-reticulo-spinal circuit reorganization mediated a motor cortex-dependent recovery of walking and swimming without requiring neuromodulation. Similar mechanisms may improve functional recovery in humans.

Title: Subcutaneous maturation of neural stem cell-seeded scaffolds to treat spinal cord injury

Authors: *T. R. HAM[1], D. D. PUKALE[2], N. D. LEIPZIG[2,1]
[1]Biomed. Engin., [2]Chem. and Biomolecular Engin., Univ. of Akron, Akron, OH

Abstract: Neural stem cells (NSCs) represent a promising treatment approach to restore neurologic function following spinal cord injury (SCI). However, survival and engraftment must be maximized to coax them into achieving their full regenerative potential, while simultaneously promoting a permissive microenvironment by reducing inhibitory cues. Here, we formed 3D scaffolds from a biomimetic polysaccharide (methacrylamide chitosan), containing immobilized interferon-γ and rat NSCs. Previously, we have shown that these scaffolds generate both neurons and neural rosette-like structures from encapsulated NSCs when matured in subcutaneous tissue. To harness this phenomenon and prime the cells for regeneration we subcutaneously matured (SubQ) our scaffolds prior to transplanting them into a subacute (2w post-injury) T10 right lateral hemisection. To reduce chondroitin sulfate proteoglycan inhibition, we also administered intracellular σ peptide (ISP) after SCI for 16w while assessing functional improvements over time through BBB score and a novel open-source gait analysis technique which captures gait data using high-speed imaging (AGATHA). Statistical analysis (ANOVA, $\alpha = 0.05$) of week 4 BBB scores found that the interaction between NSCs, SubQ, and ISP was significant ($p = 0.001$, $n = 8$), while NSCs ($p = 0.03$) and ISP ($p = 0.014$) alone also made significant differences. Tukey's *post-hoc* analysis indicated that the full treatment group (NSCs + SubQ + ISP) scored significantly higher (14.2 ± 1.3, mean ± SD) than all other groups (11-12 range) after 4w: we will monitor the rats weekly for the remaining 12w to see if improvement continues. Additionally, we took advantage of the open-source and high-resolution (we can generate images of each paw showing individual digits during stance phase) nature of AGATHA to calculate additional SCI-specific parameters, which we show are sensitive and track recovery: paw placement accuracy (the distance between ipsilateral fore/hind paw placement), and phase dispersion (% step cycle difference between diagonal limb placement), alongside more general parameters: duty factor, step width, stride length, etc. After 16w, we will confirm locomotor improvements by retrograde tracing and immunohistological (IHC) staining to assess tissue-level integration between the scaffold and surrounding cord, and examine the contributions of our

implanted (GFP+) NSCs. Overall, we show that our approach has promise for improving functional recovery after SCI, as well as highlight a new, open-source technique for gait analysis of SCI animal models.

Title: Understanding the underlying neuronal circuitry and spatial specificity of epidural cervical spinal cord stimulation

Authors: *N. D. JAMES[1], S. ODOUARD[1], B. BARRA[3], N. GREINER[3], N. CHO[1], M. CAPOGROSSO[4], G. COURTINE[2]
[1]SV BMI UPCOURTINE, [2]EPFL, Geneve, Switzerland; [3]Dept. of Med., [4]Dept. of Neurosci., Univ. of Fribourg, Fribourg, Switzerland

Abstract: MC and GC contributed equally to this work
Contusion of the cervical segments is the most common form of spinal cord injury (SCI). Patients surveys have identified improvements in upper limb function as a top priority for individuals that have suffered this type of injury, but no clinical solution is available for improving the recovery of skilled arm movements. Electrical neuromodulation therapies of the spinal cord have enhanced lower limb function in numerous preclinical models, from rodents to primates, as well as a number of clinical case studies. Despite this success, and the high priority of improved upper limb function for the SCI patient community, efforts to translate this promising technique to the cervical spinal cord and upper limbs have so far been limited. Given the complex patterns of muscle activation required for the execution of skilled arm movements, adaptation of epidural electrical stimulation (EES) to the cervical spinal cord necessitates a thorough understanding of the functional specificity that can be achieved using this technique, as well as the neuronal circuitry that underlies its effect. Here we present functional and anatomical data indicating that lateralised epidural stimulation of the rodent cervical spinal cord effectively targets specific upper limb motor pools, dependent on the rostrocaudal location of the stimulation site. Further to this, we have assessed how the specificity and efficacy of this stimulation is

affected following a clinically relevant cervical contusion injury. To gain a greater understanding of key neuronal circuitry we have utilised targeted pharmacological and chemogenetic manipulations in transgenic rats, allowing us to demonstrate the pivotal role of proprioceptive feedback circuits in the generation and modulation of motor responses during cervical EES. Taken together, these results establish a conceptual framework for the design and optimisation of targeted cervical implants to facilitate upper limb movements after spinal cord injury.

Title: Anatomical asymmetries in the injured human spinal cord

Authors: Y. LEI[1,2], M. OUDEGA[1,2], *M. A. PEREZ[1,2]
[1]Dept. of Neurolog. Surgery, The Miami Project to Cure Paralysis, Univ. of Miami, Miami, FL; [2]Bruce W. Carter Dept. of Veterans Affairs Med. Ctr., Miami, FL

Abstract: Most injuries to the human spinal cord results in bilateral damage. The aim of our study was to assess to which extent both sides of the spinal cord are affected after injury using the Human Spinal Cord Injury Tissue Bank at The Miami Project to Cure Paralysis at the University of Miami. Spinal cords were removed from donors and fixed in paraformaldehyde. The injured segments were dissected out, embedded in paraffin, and cut on a microtome in 8 um thick transverse or sagittal section. The sections were stained with hematoxylin and Eosin (H&E) to recognize cells or H&E combined with luxol fast blue (LFB) to recognize cells and myelin. The cytoarchitecture of the damaged tissue was evaluated under the light microscopy. We found that the degree of damage as well as the location of the injured tissue was largely variable between specimens. In all cases, the damage to white and grey matter was asymmetric. We observed pronounced asymmetric presence of cells resembling Schwann cells, indicating that Schwannoma formation showed signs of asymmetries after injury. In most cases, some white matter was spared at the periphery of the spinal cord indicating continuity between the segments

rostral and caudal to the injured area. Our observations indicate that white and grey matter undergo bilateral asymmetric changes regardless of the extent of the injury, supporting the view that most spinal cord injuries in humans are asymmetric and anatomically incomplete.

Med., Univ. of Southern Denmark, Odense, Denmark; [4]Dept. of Exptl. Med. Sci., Neuronano Res. Ctr., Lund, Sweden

Abstract: BACKGROUND. The neurological dogma states that motor deficits secondary to traumatic brain injury and stroke arise due to the aberrant activity of neural pathways descending from injured brain to the spinal cord. We tested this dogma by analyzing hindlimb motor response to unilateral brain injury in the rats with completely transected spinal cord. METHODS. The spinal cord was first transected at T2/T3 levels, and then the cortical hindlimb representation area was unilaterally ablated. Motor outputs were analyzed under pentobarbital anesthesia during 3-4 hours. Formation of hindlimb postural asymmetry was assessed as differences between the contra- and ipsilesional legs in *a*) their position; *b*) hip, knee and ankle joint angles, and *c*) stretch forces. The nociceptive withdrawal reflexes, quantified as EMG responses evoked by electrical stimulation of digits and heel, were compared between the ipsi- and contralesional hindlimb muscles. Expression of plastic genes was analyzed in the lumbar spinal cord, i.e. below the transection level by qRT-PCR. RESULTS. Behavioral, electrophysiological and molecular evidence demonstrated the development of the contralesional-side specific response to the unilateral brain injury. The spinal rats, which then received cortical ablation but not sham operation, developed asymmetric hindlimb posture with flexion of the contralesional leg. The hindlimb withdrawal reflexes of the flexor muscles (the extensor digitorum longus and

semitendinosus) were enhanced on the contralesional side while extensor muscle (the interosseous) on the ipsilesional side. Unilateral cortical ablation in spinal rats produced robust changes in the expression of neuroplastic genes in the lumbar spinal cord. mRNA levels were elevated on either the ipsilesional (*c-Fos*) or contralesional (*TGF-beta*) side resulting in the asymmetric expression patterns, or bilaterally (*Gap43*). Unilateral brain injury failed to induce postural asymmetry in the hypophysectomized spinal rats. CONCLUSIONS. These results demonstrate that, in parallel with neural pathways, signals elicited by injured brain are transmitted to the lumbar spinal cord by alternative, likely endocrine mechanism. Spinal plastic and hindlimb motor responses induced by these signals are side specific.

Title: Enhancement of plasticity for functional recovery after spinal cord injury

Authors: *S. F. IRVINE[1], S. GIGOUT[1], P. M. WARREN[1,2], J. C. F. KWOK[1,3]
[1]Sch. of Biomed. Sciences, Fac. of Biol. Sci., Univ. of Leeds, Leeds, United Kingdom; [2]Wolfston Ctr. for Age Related Dis., Kings Col. London, London, United Kingdom; [3]Ctr. of Reconstructive Neurosciences, Inst. of Exptl. Med., The Czech Acad. of 7 Sci., Prague, Czech Republic

Abstract: To promote recovery after spinal cord injury (SCI), treatments aim to enhance regeneration of severed axons and the plasticity of surviving circuitry. Enzymatic removal of perineuronal nets (PNNs), a plasticity brake in the adult central nervous system (CNS), using intrathecal chondroitinase ABC (ChABC) injections successfully enhances plasticity and functional recovery, particularly in SCI models. PNNs envelop neuronal sub-populations throughout the CNS providing stabilisation of circuitry and thus regulation of plasticity. Whilst ChABC has proven beneficial to recovery alongside other treatments including rehabilitation, there are significant hurdles in regards to clinical application. This study aims to investigate an

alternative method of PNN removal via non-invasive systemic PNN inhibition (PNNi) in combination with rehabilitation and its efficacy to enhance motor recovery after acute SCI. Firstly, as much of the PNN-associated neuronal populations are still relatively unknown in the spinal cord, we characterised normal PNN expression in the ventral motor pools using immunohistochemistry alongside specific motoneurone (Mn) markers. Compared to the acclaimed universal PNN marker *Wisteria floribunda* agglutinin lectin, the major PNN component aggrecan denoted significantly more PNNs around Mns. Selective Mn labelling revealed that PNNs encircled ~90% of alpha Mns, likely reflecting the population involved in the above mentioned motor recovery after SCI. To test the therapeutic efficacy of PNNi, adult female Lister Hooded rats received a moderate contusion to the T9 spinal cord and were assigned to treatment groups receiving PNNi or vehicle, with or without combination of rehabilitative treadmill training. Recovery was assessed using behavioural tests such as open field test hindlimb tests (BBB), horizontal ladder and von Frey assay. Preliminary results suggest that the systemic PNNi predominantly removes PNNs from the spinal cord, rather than the brain. Hindlimb motor functions were improved following rehabilitation. However, systemic plasticity enhancement seems to affect the forelimb function. Current experiments focus on defining the therapeutic window for optimal plasticity. Our data suggests that chronic PNNi application may provide a non-invasive strategy to enhance plasticity and regeneration after SCI.

Abstract: In North America alone, spinal cord injury (SCI) leaves more than 1 million patients with life-long sensory, motor, and autonomic deficits. Stem cell therapies offer an attractive approach to repairing and regenerating the injured spinal cord. While previous studies have shown that human induced pluripotent stem cell-derived neural stem cells (hiPSC-NSCs) can improve locomotion, few have been able to demonstrate graft-host integration. Viral and non-viral tracing methods have been used to map neural circuits; however, they often require additional invasive procedures and tracing may not overlap with grafted cells. Furthermore, viral tracing causes neurotoxicity; therefore, long-term tract tracing is not feasible. To overcome these

challenges, we aimed to engineer hiPSC-NSCs to express both antero- and retrograde trans-synaptic tracers to map transplant integration. A bicistronic vector encoding ANTERO-mCherry and GFP-RETRO was non-virally integrated into hiPSC-NSCs and sorted into monoclonal lines. The resultant self-tracing NSCs were characterized for self-renewal and proliferation potential by neurosphere assay, and pluripotency by immunocytochemistry of neuroglial markers following in vitro differentiation. Neurons derived from self-tracing NSCs were co-cultured with wild-type neurons and monitored under fluorescent microscopy to assess the extent of tracing. Functional connectivity of traced neurons will be determined by patch clamp recording. To assess tracing in vivo, T-cell deficient rats with a chronic C6/7 SCI were randomized to receive (1) self-tracing NSCs, or (2) GFP-hiPSC-NSCs followed by viral tracing. NSCs retained typical hiPSC-NSC properties and they traced synaptic connections more precisely than conventional techniques. This work provides exciting proof-on-concept data demonstrating how self-tracing NSCs can be used as a tool to delineate synaptically integrated sensorimotor pathways involved in stem-cell mediated recovery.

Title: Molecular determinants of macrophages with a proregenerative phenotype supporting axonal growth

Authors: *E. KIM
Ajou Univ. Sch. of Med., Suwon, Korea, Republic of

Abstract: Although intrinsic capacity of CNS axon regeneration is highly limited, injuries to the peripheral nerves frequently result in successful axon regeneration. We have previously shown that macrophage activation in the dorsal root ganglia (DRGs) following peripheral nerve injury contributes to the enhanced axon regeneration capacity. We further demonstrated that neuron-macrophage interaction occurring in the DRGs is essential linking injury-triggered neuronal chemokine expression with the proregenerative macrophage activation. However, it is not known how activated macrophages, which we defined as regeneration-associated macrophages (RAMs), in turn contribute to the enhanced capacity of axon regeneration in DRG neurons. The present study sought to characterize molecular signatures of RAMs and to identify key signaling

pathways that drive the activation of the proregenerative phenotype in RAMs. To generate RAMs, we employed an in vitro neuron-macrophage interaction model where co-cultures of DRG neurons and peritoneal macrophages are treated with cAMP. In this model, conditioned medium of primed macrophages promotes robust neurite outgrowth. We performed transcriptomic profiling using RAMs obtained in this co-culture paradigm. Ingenuity Pathway Analysis indicated that genes related to cancer and wound healing processes, which are known to increase in tumor-associated macrophages, were highly upregulated in RAMs. Furthermore, analysis of upstream transcriptional networks suggested that beta-catenin and Hif1-alpha could play a role in shaping the transcriptomic signatures. To verify the upregulated genes in an in vivo neuron-macrophage interaction setting, CX3CR1-GFP mice were utilized to isolate activated macrophages in DRGs following peripheral nerve injury using Fluorescence-Activating Cell Sorting (FACS). Ongoing experiments involving analysis of the FACS-isolated macrophages with immunohistochemistry and real time PCR will characterize the molecular determinants of RAMs promoting capacity of axon regeneration in vivo.

Title: Subtle changes in intrinsic properties of V1 and V0c interneurons after spinal cord injury

Authors: *K. M. LETT, B. R. JOHNSON, R. M. HARRIS-WARRICK
Neurobio. and Behavior, Cornell Univ., Ithaca, NY

Abstract: Spinal cord injury (SCI) causes a loss of descending and modulatory inputs to spinal locomotor networks; this deafferentation could cause changes in the intrinsic firing properties of network neurons. Spinal interneurons (INs) are critical in shaping patterned locomotor output, but little is known about changes in their electrophysiological properties after SCI and more importantly, their possible role in spasticity. Using perforated patch recording and a mouse SCI model, we explored the effects of SCI on the intrinsic properties and excitability of lumbar V1 and V0c INs. We previously reported that after SCI, the V1 INs show a slight increase in bistability marked by a significant negative hysteresis during ramp current injections, while the V0c INs did not show any change in bistable behavior. In this study, we explore other firing properties of these neurons after SCI. Both IN types showed a mix of tonic or phasic behavior during current steps: the percentage of tonic and phasic INs was unchanged after SCI. We

measured excitability using increasing current steps and f/I plots: for both IN types there was no significant change in excitability (measured either as initial instantaneous spike frequency or average frequency during the step) after SCI. There was also no significant change in input resistance or rheobase in both IN types after SCI. Our previous studies in mice have also found no significant increase in the intrinsic excitability and bistability of lumbar spinal motoneuron excitability. Both V1 and V0c IN types have direct synaptic connections onto motoneurons. Our results show only subtle changes in the intrinsic properties of V1 and V0c INs after SCI, limited to a slight shift in persistent firing in V1 INs during ramp current injection. These results could have implications in identifying changes in locomotor circuitry driving lower limb spastic behavior after SCI. Supported by NIH grant NS17323 to RHW.

Title: Long-term effects of spike-timing dependent plasticity in humans with severe paralysis due to spinal cord injury

Authors: *A. WILSON[1,2], H. JO[1,2], M. A. PEREZ[1,2]
[1]Dept. of Neurolog. Surgery, The Miami Project to Cure Paralysis, Univ. of Miami, Miami, FL; [2]Bruce W. Carter Dept. of Veterans Affairs Med. Ctr., Miami, FL

Abstract: A single session of repeated non-invasive stimulation using the principles of spike-timing dependent plasticity (STDP) improved voluntary motor output in hand muscles in humans with cervical spinal cord injury (SCI). Here, we examined the effects of repeated sessions of STDP on residual motor output and corticospinal excitability in proximal arm muscles in humans with high severe cervical SCI. During STDP, we used 180 pairs of stimuli where corticospinal volleys evoked by transcranial magnetic stimulation (TMS) over the shoulder representation of the primary motor cortex were timed to arrive at corticospinal-motoneuronal synapses of the bicep brachii or deltoid muscle ~1-2 ms before antidromic potentials were elicited in motoneurons by electrical stimulation of the brachial plexus. Participants were randomly

assigned to the stimulation (STDP+exercise) or sham (sham STDP+exercise) groups for 10 sessions in 2-3 weeks, which were followed by an upper-limb exercise program for ~40 min. We found that the group of SCI participants that received STDP+exercise increased maximal voluntary contraction of the targeted muscle to a larger extent than the group that received sham STDP+exercise. The size of motor evoked potentials elicited by TMS in the biceps brachi or deltoid increased only in the group that received STDP+exercise. Our findings demonstrate that STDP-like changes at residual spinal synapses combined with exercise enhances voluntary motor output in proximal arm muscles in humans with severe paralysis representing a new strategy to potentiate its therapeutic effects.

Title: Arm cycling increases corticospinal excitability of trunk muscles in spinal cord injured subjects

Authors: S.-Y. CHIOU[1,2], A. GALL[3], *P. H. STRUTTON[1]
[1]Imperial Col. London, London, United Kingdom; [2]Sch. of Sport, Exercise, and Rehabil. Sci., Univ. of Birmingham, Birmingham, United Kingdom; [3]London Spinal Cord Injury Ctr., Royal Natl. Orthopaedic Hosp., Stanmore, United Kingdom

Abstract: Impaired trunk motor control is seen in the majority of individuals with spinal cord injury (SCI) and this can severely compromise upper limb and locomotor function. Evidence has shown that increasing corticospinal drive to impaired muscles after SCI can improve motor function, leading to greater independence and improved performance of activities of daily living. We have shown that the excitability of corticospinal drive to muscles of the trunk is increased during voluntary contractions of the upper limb muscles in healthy subjects and, more recently, in some individuals with SCI. Whether arm exercise can increase corticospinal excitability of the impaired trunk muscles in SCI remains unknown and was hence the aim of this study. Subjects with incomplete SCI undertook unilateral arm cycling for 30 minutes in an upright seated position. Electromyographic (EMG) activity was recorded bilaterally from erector spinae (ES). Motor evoked potentials (MEPs) from ES were examined prior to (baseline) and 20 minutes into the arm cycling, and immediately and 5 minutes following the arm cycling using transcranial magnetic stimulation over the hotspot for contralateral ES. We found that ES MEPs were greater immediately (mean ± standard deviation: 138.72±58.74% MEP at baseline) and 5 minutes (131.62±44.70%) following the arm cycling compared with the baseline, whereas the ES MEPs

obtained at 20 minutes (123.74±44.10%) into the arm cycling did not differ from that at the baseline. This indicates that arm cycling for 30 minutes can increase the corticospinal drive to the trunk muscles in SCI. In addition, EMG activity of the ES was comparable across all time points, suggesting that the changes in ES MEPs are likely due to increases in the excitability of corticospinal projections to ES. Further, there was no difference in the change in ES MEPs between subjects who showed increases in ES MEPs during the arm contractions and those who did not. The changes in ES MEPs following the arm cycling did not relate to the level of injury. Our results demonstrate the potential of using arm exercise for increasing the excitability of the corticospinal drive to the trunk muscles after SCI. Whether arm cycling has therapeutic effects on improving trunk motor function following SCI remains to be investigated.

Title: Cervical excitatory interneurons sustain breathing after spinal cord injury

Authors: *K. SATKUNENDRARAJAH[1], S. K. KARADIMAS[2], A. M. LALIBERTE[3], G. MONTANDON[5], M. FEHLINGS[4]
[1]Genet. and Develop., Toronto Western Res. Inst., Toronto, ON, Canada; [2]Dept. of Surgery, Univ. of Toronto, Toronto, ON, Canada; [3]Genet. and Develop., [4]Dept. of Surgery, Krembil Res. Inst., Toronto, ON, Canada; [5]Med., Keenan Res. Ctr. for Biomed. Sci., Toronto, ON, Canada

Abstract: Traumatic cervical spinal cord injury (SCI) leads to significant ventilatory impairment. Non-traumatic SCI (ntSCI), in which the cervical spinal cord is progressively compressed over time, results in milder respiratory dysfunction despite the significant disruption of the cervical neural network. Using a mouse model of ntSCI, we found a significant loss of phrenic motoneurons (PMNs) that innervate the main inspiratory muscle, without severe respiratory insufficiency similar to what is observed in human ntSCI patients. Progressively increased Vglut2 positive boutons on the preserved PMNs indicates that despite the significant loss in the number of PMNs, respiratory motor output is maintained via compensatory and progressive increases in glutamatergic input onto preserved PMNs. While the PMNs were decreased there was an increase in the number of prephrenic cervical interneurons connected to the PMNs. To confirm the role of the cervical glutamatergic interneurons in promoting respiratory plasticity and preservation of ventilation in ntSCI we injected *AAV-FLEX*-

PSAML141F–GlyR-IRES-eGFP in the ventromedial area of C3-7 spinal levels of *Vglut2::cre* mice two weeks prior to the induction of ntSCI. Subsequently, PSEM mediated silencing of these neurons disrupted ventilation in ntSCI mice. Further, chemogentic stimulation of cervical glutamatergic neurons following SCI promoted diaphragmatic motor recovery. In conclusion, this study provides novel insights into respiratory plasticity that occur in the setting of ntSCI and a greater understanding of the neural control of breathing. Further, the data indicates that this neurons can be manipulated to promote respiratory recovery following traumatic SCI.

Title: Cholinergic modulation of postnatal cell proliferation in the spinal cord

Authors: *N. ALTUWAIJRI, S. A. DEUCHARS
Univ. of Leeds, Leeds, United Kingdom

Abstract: There are numerous ailments that ultimately lead to demyelination and neurodegeneration. Most commonly, spinal cord injury; during which loss of neurons and demyelination are followed by inflammation and cyst formation (Profyris et al., 2004) and the progressively debilitating form of demyelination; multiple sclerosis.
While current treatments aim to manage the symptoms and modifying the course of demyelination, a relatively new field investigates the spinal cord neurogenic niche to determine its overall neuroregenerative potential. The ependymal cells of the spinal cord are thought to be the neural stem/progenitor cells of this niche. Since ependymal cells respond to manipulation of nicotinic acetylcholine receptors (Corns et al., 2015); we aimed to investigate the effect of an acetylcholinesterase inhibitor on neural and glial cell proliferation and differentiation *in vivo* and *in vitro*.
Adult C57BL/6 -6 week old mice (N=4 experimental group, N=4 control) received daily i.p injections of *donepezil* (1mg/kg) or vehicle (0.1ml saline) along with the thymidine analogue 5-ethynyl-2'-deoxyuridine (EdU) (10mM) for 7 days. Spinal cord sections were treated for EdU detection then immunohistochemically analysed for astrocytic and oligodendrocytic differentiation using antibodies against S100β and PanQkI respectively. In the central canal of *donepezil* treated animals there were significantly lower (mean 2.56 ± SEM 0.311, N=4 animals, n=88 sections; P=0.002) numbers of EdU positive cells compared to control (mean 3.95 ± 0.36, N=4 animals, n= 75 sections). The differentiation of EdU positive cells into astrocytes but not

oligodendrocytes was modulated by *donepezil.* The positive control to this experiment was the hippocampus of each animal. The cholinergic modulatory effect of *donepezil* on the hippocampus was clearly discernable; significantly increasing proliferation in the dentate gyrus (P=0.0054).
The effects of *donepezil* were tested *in vitro* by the addition of (5μM) of *donepezil* and (1μM) EdU to 500 *μm* spinal cord slices and compared to a control group. The numbers of EdU positive cells around the central canal in *donepezil* treated slices were significantly lower (P=0.002, mean 3.95 ± 0.38 SEM, N=3, n=23) in comparison to control (mean 5.05 ± 1.57 SEM, N=3, n=17). Slices treated with cytisine (20 μM; a partial nicotinic acetylcholine receptor agonist had significantly lower (P=0.016, mean 1.1875 ± 0.22 SEM, N=3, n=16) numbers of EdU positive cells in the central canal compared to those in control. Thus it is clear that the identity and role of each receptor subtype needs to be elucidated in the spinal cord.

Title: Sleep-disordered breathing following experimental cervical spinal cord injury

Authors: *T. BEZDUDNAYA, A. OSHOBAJO, V. MARCHENKO, M. A. LANE
Neurobio. and Anat., Drexel Univ. Col. of Med., Philadelphia, PA

Abstract: Sleep-disordered breathing (SDB) is a common deficit in patients with spinal cord injury (SCI). Clinical studies show that individuals with cervical SCI can develop symptoms of SDB within few weeks/months post-injury indicating SCI as an independent risk factor for this disorder. However, the anatomical and physiological underpinnings of SDB are not well defined. The goal of the current study was to determine sleep-related respiratory deficits following C2 cervical spinal cord hemisection (C2Hx) in adult female rats. C2Hx results in a unilateral interruption of bulbospinal inputs to phrenic motoneurons and immediate ipsilateral paralysis of the diaphragm - the main muscle of inspiration. Here, we monitored diaphragm activity, before and during 6 weeks post-injury in awake and sleeping rats. All animals were chronically implanted with bilateral diaphragm electromyogram (EMG) electrodes and recorded for at least 4 hours on a weekly basis. In addition, neck EMG and electrocorticogram activities were recorded

to identify different stages of sleep (awake, non-rapid eye movement (NREM) and rapid eye movement (REM) sleep). Our data show spontaneous recovery of the ipsilateral hemidiaphragm within a few weeks post-injury. However, despite recovery seen in awake animals, the activity of the ipsilateral hemidiaphragm can be significantly attenuated and abolished in the course of NREM and REM sleep. Moreover, we observed an increased number of arousal events during sleep often accompanied by episodes of hyperexcitation on the injured side of the diaphragm. Overall, our data demonstrate that C2Hx leads to sleep-disordered diaphragm activity which can result in an intermittent decrease of tidal volume and oxygenation during sleep in adult rats.

Title: Combined administration of electro-magnetic stimulation (EMS) at spinal level and at leg muscles to modulate neurophysiological properties at spino-muscular circuitry in healthy and SCI humans

Authors: *V. L. ARVANIAN[1], H. A. PETROSYAN[1], A. TESFA[1], M. FAHMY[1], C. ZOU[2], S. SISTO[3]
[1]Res. Services, Norhtport VAMC, Northport, NY; [2]StonyBrook Univ., Stony Brook, NY; [3]Univ. of Buffalo, Buffalo, NY

Abstract: H-reflex is recognized as an important neurophysiology tool used in evaluation of spino-muscular circuitry. H-reflex is sensitive to conditions and activity. For example, H-reflex diminishes after several days in zero gravity and is modulated differently depending on muscle activity. Spinal cord injury (SCI) reportedly affects threshold intensity and frequency dependent depression (FDD) of H-reflex. We examined 4 healthy and 3 SCI participants; study was approved by the IRB and conducted in accordance with the Declaration of Helsinki. We measured soleus M-wave and H- reflex recruitment curves using peripheral tibial nerve stimulation after each following condition: (i) baseline, (ii) initial 25 min session of EMS over spinal L5 level (SEMS; 0.2 Hz frequency, 70% coil intensity), (iii) additional 15 min session of

SEMS, (iv) 15-min session of EMS at leg muscles. FDD of H-reflex (stim current was set to evoke 40% of H-max, using 0.2, 1, 2 and 5 Hz stim rate) was examined after taking baseline measures and then after end of muscle stimulation. Baseline measurements (prior SEMS]) revealed a less steep (flatter) rise phase and more prolonged plateau of the recruitment curve of H-reflex, as well as a lesser depression rate of FDD in SCI vs healthy participants. In both healthy and SCI subjects, 1st application of SEMS for 25mins induced substantial facilitation of both M-response and H-reflex; this associated with a significant leftward shift of the recruitment curves for M- and H-responses and a marked decrease in the threshold currents to evoke H- and M-responses. 2nd follow-up application of SEMS for 15 min did not induce further changes, thus indicating that effects of SEMS reached its maximum after initial 1st 25 min of SEMS. However, EMS application over leg muscles induced further facilitation of M-wave and H-response. These results suggest that EMS over spinal level and leg muscles exert their effects on H-reflex through different mechanisms. Results also revealed improvement of FDD rate following SEMS/leg stimulation in SCI participants. Importantly, one SCI participant was engaged in 20 min exercise training sessions (NUSTEP exercise machine) after completion of SEMS/leg stimulation protocols; after 5 sessions the subject, who is 12 years post SCI, reported an increase in sensation and function for the first time. It is important to note that this subject had been performing similar exercise on a regular basis prior to this study without functional changes. Results suggest that spinal/leg EMS stimulation combined with exercise may be a potential approach in clinics for a variety of spinal or peripheral nerve conditions.

Title: Viral-mediated gene therapy targeting Rac1 alleviates spasticity after SCI

Authors: *C. BENSON[1,2], M. HILL[1,2], S. LIU[1,2], L. AKIN[1,2], S. G. WAXMAN[1,2], A. M. TAN[2,1]
[1]Neurol., Yale Univ., New Haven, CT; [2]Ctr. for Neurosci. and Regeneration Research, VA Connecticut, West Haven, CT

Abstract: Spasticity is a significant complication associated with SCI, and is a clinical symptom of hyperexcitability within the spinal cord reflex system, e.g., H-reflex. Up to 90% of SCI patients, including US Veterans, experience clinically significant spasticity, which can negatively impact quality-of-life, e.g., hinder personal hygiene and intimate relationships. Spasticity can be incapacitating, triggered at any time by a variety of stimuli, and can exacerbate other SCI complications, e.g., pressure ulcers, infection. Poorly treated, spasticity often leads to permanent deformity and contractures (hardening of soft tissues in joints and muscle), which can be painful. A major hurdle facing novel therapeutic development for spasticity is the lack of mechanistic insight into the cellular and molecular factors that contribute to spinal reflex circuit pathology after injury. Maladaptive changes to motor reflex function after injury, e.g., SCI, TBI, or stroke, can lead to excessive H-reflex excitability associated with spasticity. Previous studies have demonstrated that changes to dendritic spines within the motor reflex circuit leads to loss of H-reflex rate-dependent depression (RDD), indicative of increased excitability. This hyperexcitability can occur from an increase in spine density, a redistribution of spines to regions closer to the cell body, and an increase in spine head surface area on alpha-motor neurons. Over the past decade, we have gathered considerable evidence that supports two core premises for our proposal: 1) the Rac1-Pak1 signaling pathway contributes to spasticity, and 2) dendritic spine dysgenesis serves as a morphological correlate that predicts spasticity and drug response. The overall objective of this study is to deconstruct the mechanisms underlying spasticity at the circuit-level and provide novel opportunities for developing more effective and safe treatments for spasticity after SCI. Here, we hypothesize that using a gene therapy that disrupts Rac1 function will reduce the formation abnormal dendritic spines and restore normal RDD and spasticity after SCI. To test this hypothesis, we delivered an adeno-associated virus (AAV) 2/9-cre intramuscularly into the soleus muscle group of the left hind limb of Rac1 floxed mice. This delivery method specifically infects alpha-motor neurons comprising the monosynaptic spinal stretch reflex (e.g., H-reflex). Cre-expression in these neurons selectively ablates Rac1 expression. As expected, we observed that viral-mediated knockout of Rac1 normalizes RDD compared to control animals in EMG recording, demonstrating a reduction in H-reflex hyperexcitability.

Abstract: Spinal cord injury (SCI) is a miserable neurological condition that often causes permanent sensory, motor, and bladder-bowel dysfunction. Despite the needs of treatments, clinical options for treatments is limited. Neuronal plasticity is a mechanism underlying the recovery process of motor function after the injury of central nervous systems, and the experience-dependent synaptic AMPA (α-amino-3-hydoroxy-5methyl-4-isoxazole-propionic-acid) receptor (AMPAR) delivery is a molecular and cellular mechanism of neural plasticity. We recently found that a small compound, edonerpic maleate (also known as T-817MA), facilitated experience-driven synaptic glutamate AMPA receptor delivery and resulted in the acceleration of motor function recovery after brain damage in mice and monkeys in a training-dependent manner (Abe et al. Science 2018). Here, we report that edonerpic maleate also facilitates the motor function recovery after spinal cord injury in rats.

Abstract: TRESK (K2P18.1) is a background K^+ channel highly expressed in spinal cord, dorsal root and trigeminal ganglia sensory neurons, where it has been involved in modulating sensory neuron excitability and firing. Changes in channel expression and function have been reported to enhance nociceptor excitability after injury or inflammation. To determine the role of TRESK in sensory transduction, we first compared the excitability and membrane properties of small/medium-sized sensory neurons in whole cell patch clamp recordings of cultured DRG neurons from wild type and TRESK knockout mice, which presented a reduced action potential threshold, increased membrane resistance and enhanced repetitive firing upon depolarization. Recordings of skin nociceptive fibers showed strong activation in response to cold in the absence of TRESK channel. In agreement, behavioral experiments in TRESK ko mice revealed a decreased mechanical threshold to von Frey hairs and an enhanced cold sensitivity. No significant changes were found for thermal sensitivity to warm or hot temperatures. Nocifensive behavior after capsaicin injection was unaltered while the response to AITC was slightly diminished. Interestingly, TRESK ko mice presented a reduced response to hypertonic and hypotonic stimuli even after sensitization with PGE_2. During inflammation, ko mice showed a decreased phase I response in the formalin test, while phase II was unaltered. In the CFA-induced inflammatory model, both mechanical and thermal sensitivity were enhanced compared to wt animals. Mechanical and thermal hyperalgesia were also enhanced in the sciatic nerve cuffing model of neuropathic pain. Finally, the oxaliplatin-induced cold sensitization was absent in ko mice, probably due to the already enhanced cold sensitivity. In summary, our results indicate that TRESK has a significant contribution regulating the excitability of certain populations of sensory neurons mainly involved in mechanical and cold pain sensing. Moreover, a down-regulation of its expression as occurs after nerve injury might contribute to the generation of the hyperalgesia and allodynia observed during chronic pain.

Title: Sodium channel $Na_v1.9$ enables ongoing activity in single mouse C-fibres during zero extracellular potassium

Authors: C. WEIDNER[1], T. HOFFMANN[2], K. KISTNER[2], J. PAKALNISKIS[3], R. DE COL[2], K. MESSLINGER[2], M. A. NASSAR[5], P. W. REEH[2], *R. W. CARR[4]

Abstract: Bouts of spontaneous pain associated with chronic pain are attributed to aberrant action potential activity in primary somatosensory neurons. To explore the mechanistic underpinnings of spontaneous activity animal models have been developed to mimic neuropathic and inflammatory pain states. Dependent upon the prevailing injury this leads to differential regulation of signaling proteins and their transcription. To circumvent this heterogeneity we developed an experimental paradigm for the reversible induction of sustained burst activity in single cutaneous C-fibres using nominally zero extracellular potassium. Low extracellular potassium induced sustained firing in 83% (19 of 23) naive C-fibres in mice. The ongoing discharge was bursting in character comprising bursts of 26±6.5 action potentials at 11.6±15.4 Hz separated by interburst periods of 62.5±167s. Ongoing firing began within tens of minutes (23±6.1 minutes) and persisted throughout the period of exposure to zero potassium for up to 6 hours. Ongoing C-fibre activity subsided upon re-establishment of the extracellular potassium concentration at 3.5mM without lingering effects on heat and mechanical thresholds. Induction of ongoing activity was dependent upon the voltage-gated sodium channel $Na_v1.9$. None of five C-fibres tested from $Na_v1.9$ -/- mice developed ongoing activity during exposure to zero potassium for periods of up to 2 hours. In C-fibres from wild type animals, blockade of hyperpolarization-activated cyclic-nucleotide gated (HCN) channels with ZD7288 (10-30 μM) reduced burst incidence and the number of action potentials in each burst. The data highlight $Na_v1.9$ and HCN as instrumental for the induction of ongoing activity in unmyelinated axons.

Title: Mapping the functional expression profile of Kv7 channels in somatosensory neurons of different sensory modalities

Authors: *F. P. JONES, N. GAMPER
Univ. of Leeds, Leeds, United Kingdom

Abstract: Voltage dependant potassium (K+) channels (Kv) are important in controlling excitability and repolarising neurons after depolarisation has occurred. One subset of these channels is the Kv7 family, which is composed of Kv7.1-7.5 subunits as homo- or heteromers. Kv7 channels are promising targets for treating excitability disorders, including epilepsy and pain, as they are active at negative voltages, thus clamping the resting potential and reduce the excitability of the neuron. Kv7 channels are expressed in many excitable cells, including neurons and muscle cells, though subunit differences exist in different tissues. Therefore, identifying the expression pattern of Kv7 subunits in different cell types will aid development of more targeted therapeutic strategies. Here we used we used immunofluorescent techniques and electrophysiology to identify Kv7 expression profile within rat peripheral somatosensory system, which is responsible for detection and transmission of somatic and visceral stimuli, including these resulting in pain and itch sensations. To this end, rat dorsal root ganglia (DRGs) were co-labelled with antibodies against Kv7.1 - Kv7.5 and modality-specific markers (NF200 for A fibres, Peripherin for C fibres). Kv7.1 showed very limited expression in the DRG (4%±1.5 of total neurons), whereas 85% and 80% of Peripherin positive neurons were Kv7.2 positive and Kv7.3 positive respectively, suggesting that the majority of small diameter neurons are Kv7.2 and/or Kv7.3 positive. Kv7.3 is also expressed in around 50% of NF200 positive neurons. Kv7.5 was expressed in around 60% of NF200 positive neurons and a similar number of Peripherin positive neurons, suggesting that Kv7.5 is similarly distributed between large, medium and small diameter neurons. This data was supported by recording of Kv7 current (M-current) in capsaicin responsive (presumed nociceptive) DRG neurons in the presence of Kv7.2/7.3 heteromer selective agonist, ICA-27243. ICA-27243 increased outward current at -20mV by 67%±6.8 ($p<0.05$ $n=6$) compared to baseline; non-selective Kv7 channel agonist retigabine, when applied after ICA-27243, produced no further current augmentation (while being as efficacious as ICA-2743, when applied alone). Outward current was also reduced by application of Kv7 channel antagonist. In sum, Kv7.2 and 7.3 are predominant Kv7 subunits expressed in small-diameter DRG neurons, these subunits are also responsible for the majority of M current in these cells. Kv7.5 is also expressed in subpopulations of small, medium and large diameter neurons.

Title: Examination of the role of Nav1.7 and Nav1.8 in the generation of action potentials both in-vivo and in-vitro

Authors: L. H. DENG[1], V. JOSEPH[2], K. L. STARK[1], S. LARDELL[3], R. WEIMER[2], P. KARILA[3], *D. H. HACKOS[1]
[1]Neurosci., [2]Biomed. Imaging, Genentech Inc, South San Francisco, CA; [3]Cellectricon AB, Molndal, Sweden

Abstract: Aim of investigation: Loss-of-function mutations in Nav1.7 lead to complete insensitivity to pain (CIP) in humans and a CIP-like phenotype in Nav1.7 KO mice. On the other hand, CIP patients have not been identified with loss-of-function mutations in Nav1.8 and Nav1.8 KO mice show a minimal pain phenotype, suggesting that Nav1.8 plays little if any role in sensory neuron action potential generation or propagation in vivo. Using laser speckle imaging, we established an in vivo assay sensitive to peripheral action potential generation, allowing us to examine the role that Nav1.7 and Nav1.8 play in action potential generation under resting and inflammatory conditions.
Methods: Laser speckle imaging allows real-time detection of blood flow in the glabrous skin of the mouse hind-paw. In this method, AITC (mustard oil) is applied to the skin, which activates TRPA1 channels, allowing calcium influx and depolarization of sensory fibers. Such depolarization is sufficient to generate action potentials, allowing opening of voltage-gated calcium channels that allows more calcium influx, which results in release of peptide neurotransmitters and increased blood flow. Recordings of DRG excitability (using electrophysiology and calcium influx) were also used to examine the interplay between Nav1.7 and Nav1.8 channels in cultured sensory neurons under different conditions.
Results: We observed that AITC-induced increase in blood flow in the mouse hind-paw is dependent on TRPA1 as expected (since AITC is a direct activator of TRPA1 channels). We further observed that the action potential component of this response is Nav1.7-dependent but not dependent on Nav1.8. Recordings of DRG neurons in culture show that the dependence on Nav1.7 vs Nav1.8 can be modified depending on the condition of the experiment (resting membrane voltage and inflammation state).
Conclusions: Here we demonstrate a novel assay that allows indirect examination of action potential generation within the peripheral sensory fibers in the skin. We use this assay to determine the role that Nav1.7 and Nav1.8 play in this process and demonstrate that action potential generation is fully dependent on Nav1.7.

Title: The landscape of nascent protein synthesis in the DRG at single codon resolution

Authors: *P. BARRAGAN-IGLESIAS[1], T.-F. LOU[2], J. B. DE LA PEÑA[2], A. WANGZHOU[1], B. J. BLACK[3], S. MEGAT[1], J. K. MOY[1], P. RAY[1], J. J. PANCRAZIO[3], T. J. PRICE[1], Z. T. CAMPBELL[2]

Abstract: Pro-inflammatory cytokines are harbingers of persistent pain. As a model for probing their effects on nociceptors, we focus on NGF and IL-6. Together, they trigger a rapid induction of cap-dependent translation and promote long-lasting changes in nociceptor plasticity. Accompanying behavioral changes require *de novo* protein synthesis but not transcription. To identify the targets of regulated protein synthesis in cultured dorsal root ganglion (DRGs), we applied the method of translational profiling by ribosome footprinting. This approach yields a global snapshot of ribosomes poised over mRNA fragments at a specific moment in time. We use footprinting to identify the action of NGF and IL-6 on nascent protein synthesis after only 20 minutes. The data provide a comprehensive view of the substantial changes in translation that are induced by these cytokines. From the dataset, we identify motifs which confer preferential translation in response to NGF and IL-6 treatment. We provide evidence for S6 driven translation of immediate early genes following cytokine treatment. Additionally, conserved segments present in 5'UTRs corresponding to key players in sensory detection and nociception, including CGRP and EGR2, are selectively translated. These upstream open reading frames, termed uORFs, do not appear to require the integrated stress response. Peptides derived from CGRP and EGR2 uORFs produce mechanical hyperalgesia when injected into the paw. We propose that non-canonical translation provides a vast and unanticipated potential source of endogenous signaling peptides that may contribute to nociceptor plasticity in response to inflammatory mediators.

Title: Nociceptive stimuli suppress reactions of somatosensory stimuli regardless the location

Authors: *N. TAKEUCHI
Aichi Med. Univ., Aichi prefecture Nagakute city, Japan

Abstract: The sensory repetition suppression, refers to the attenuation of neural activity in response to a second stimulus and plays a pivotal role in inhibition of redundant sensory inputs. Using magnetoencephalography (MEG) recordings, we examined the somatosensory suppression induced by preceding several types of sensory stimuli. Thirteen healthy volunteers participated in this study which was approved in advance by the Ethics Committee of the National Institute of Physiological Sciences, Japan and written consent was obtained from all participants. As the Test stimuli, the intensity of somatosensory stimulus abruptly increased at 1200 ms from onset of somatosensory stimulus lasting 1500 ms and were applied to the dorsum of the left hand. Three types of prepulse stimulus, i.e., auditory stimulus, nociceptive stimulus (using IES: intra-epidermal electrical stimulation) and somatosensory stimulus applying to the dorsum of the right foot were inserted before 600 ms from onset Test stimulus. That is, there were four stimulus conditions: (1) Test alone, (2) Test + auditory stimulus, (3) Test + somatosensory stimulus, (4) Test + nociceptive stimulus. The results showed the amplitude of Test stimuli in each condition were significantly smaller for (3) and (4) conditions in contralateral and ipsilateral SII compared to Test alone. While there were no significant amplitude change for all condition in cSI. Auditory prepulse stimulus condition did not affect the somatosensory suppression in cSI, cSII and iSII. These findings suggested the somatosensory suppression was observed by other sensory stimulus, such as nociception and even though conditioning stimulating body part was far from test stimulating part.

Title: Influence of repeated mechanical stimuli on pain threshold of nociceptor

Authors: *S. NAGAHAMA
Human care, Teikyo Heisei Univ., Tokyo, Japan

Abstract: It is well known that pain receptor is tonic or slowly adapting and it is generally thought that pain receptor is non-adapting type. There is little report about pain sensory and adaptation mechanism of Aδ fiber, and it is not clear of pain sensory mechanism of Aδ fiber. This study focused on the adaptation of pain sensory by measuring the influence of repeated mechanical pain stimuli on pain thresholds. The algometer used in the experiments measured pressure in units of 1g and in the range of 1g-10g. A total of 16 participants took part in this study (ranging from 20 to 22 years; 8 males and 8 females). The author asked the participants that they took their meal more than 2 hours before experiments. The experiments were conducted from 2:00pm-4:00pm at room temperature (24°C). In the experiments participant sat down on a chair and closed eyes. All experiments were done at intervals more than one week. The participant was pricked with the pressure algometer at the same point of right forearm medial cutis. Control was the average of pressure pain thresholds (PPTs) measured 3 times at the same point. After the measurement of control, the participant was stimulated at the same point 15 times every 5 seconds successively, and measured a change of PPTs. In the experiments at 5-second intervals, PPTs significantly increased. PPTs were also measured at 7, 10, 12, 15, 20 and 30-second intervals. In the experiments of more than 7-second intervals PPTs increased in the 2nd and the 3rd stimulus after control, but hardly increased after the 4th stimulus PPTs. In addition, PPTs were further measured by the similar method 1 hour, 4 hours and 24 hours after the first experiments. Then the control was measured in all cases and PPTs were measured by the similar method at the same point of the participant. PTTs of the 6th and the 12th stimulus increased 1hour later and 4 hours later, compared with the first experiments. A tendency of decrease was seen in PTTs of the 6th and the 12th stimulus 24 hours later. These results showed that repeated mechanical stimuli at short time intervals increased PPTs. It was suggested that Aδ fiber was adapted by the repeated mechanical stimuli at short time intervals.

Title: Interferon gamma acutely evokes action potential discharge from vagal c-fibers in mouse lungs

Authors: *M. J. PATIL[1], M. KOLLARIK[2], F. RU[3], B. J. UNDEM[4]
[1]Endodontics, [2]Med., Johns Hopkins Univ., Baltimore, MD; [3]Med., Johns Hopkins Univ., BALTIMORE, MD; [4]Dept Med., Johns Hopkins Asthma Ctr., Baltimore, MD

Abstract: Aim of Investigation: The inflammation associated with airway inflammatory diseases (e.g. asthma COPD, bronchitis, pulmonary fibrosis) can activate vagal airway C-fibers leading to negative symptoms including reflex bronchoconstriction and mucus secretion that can threaten lung function, as well as sensations of dyspnea and urge-to-cough. Type 1 and type 2 interferons are elevated in respiratory viral infections and inflammatory airway diseases. The vast majority of research attention on the role of interferons in the lungs, and elsewhere, has focused on their ability to orchestrate anti-viral defenses and other immunological responses. We previously noted that receptors for both type 1 and type 2 interferons are richly expressed by vagal C-fiber neurons (PLoS One. 2017 Oct 5;12). Here, we show that interferon γ acutely activates airway vagal C-fibers.**Methods:** We used low input RNA sequencing of nodose neurons retrogradely labeled from the lungs to detect the presence of Interferon receptors in presumed capsaicin-sensitive airway afferent C-fibers. To study action potential discharge from C-fiber terminals we isolated the lungs, vagus nerve, along with vagal ganglia from Pirt-cre/GCamp6s mice. The ganglion was positioned beneath a 2-Photon microscope that assessed the elevation in calcium that were caused by action potentials that were conducted from the terminals in the lungs to cell bodies in the nodose ganglion. This allowed us to monitor the activity of hundreds of vagal ganglion neurons in response to interferon γ infused specifically into the trachea/lung compartment.**Results:** The interferon γ receptors (ifngr1 and ifngr2) were richly expressed in airway-specific TRPV1-positive nodose neurons. In our 2 Photon imaging of the nodose ganglion we found that within only a few minutes of exposing the trachea/lungs to Interferon γ action potentials were discharged from more than 70% of capsaicin-sensitive C-fibers (n=4 experiments). **Conclusions:** This study supports the hypothesis that interferon γ, in addition to playing key roles in orchestrating the immune response by regulating chemokine and cytokine gene expression in immune cells, can also more acutely recruit the nervous system by

activating visceral sensory nociceptors. If dysregulated this may contribute to the nocifensive reflexes and symptoms of visceral inflammatory diseases.

Title: Characterization of dental pulp innervation using transgenic reporter mice

Authors: *O. AUSTAH[1], K. METWALLI[2], S. RUPAREL[3], A. R. DIOGENES[4]
[1]Endodontics, UT Hlth. San Antonio, San Antonio, TX; [2]Univ. of Texas Hlth. San Antonio, San Antonio, TX; [3]Endodontics, Univ. of Texas Hlth. Sci. Ctr. at San Antonio, San Antonio, TX; [4]Endodontics, Univ. Texs Hlth. Sci. Ctr., San Antonio, TX

Abstract: Trigeminal ganglia (TG) neurons are heterogeneous and have been broadly classified, based on their degree of myelination and conduction velocity, into C, A**β,** and Aδfibers. Several elegant studies using indirect immunohistochemistry and electrophysiological recordings have demonstrated that dental pulp is mainly innervated with C- followed by Aδ- fibers. However, recent studies have demonstrated that TG neurons can be further classified into: peptidergic (CGRP+) and non-peptidergic C fibers (MrgprD+), low threshold mechanoreceptor (LTMR) Aδ(TrkB+) and LTMR Aβ(TrkC+) fibers, high threshold mechanoreceptor (HTMR) Aδand Aβfibers (Nav1.8+; CGRP-). We hypothesized that the dental pulp is primarily innervated by Aδand Aβfibers, including LTMR subclasses. To test this hypothesis, we employed transgenic reporter mice expressing either GFP or TdTomato under the promoter of either Nav1.8, CGRP, MrgprD, TrkB and TrkC. Mandibular en-bloc sections containing molars were harvested from genotyped mice (8-10 week old) for each reporter line (n=6), demineralized and processed for direct detection of immunofluorescence. Images were acquired using laser scanning microscopy with standardized settings from sequential slides from each sample. The greatest majority of fibers innervating the dental pulp are Aδand Aβfibers, including LTMR subclasses, not previously reported. These fibers innervate the most coronal aspects of the pulp and project extensions into the dentinal tubules. C-fibers are more apically positioned than Aβand Aδfibers. This is the first demonstration of the distribution of LTMR myelinated fibers in the dental pulp. The presence of these fibers, that are typically non-nociceptive, into dentinal tubules sheds light on the uniqueness of dental pulp innervation and neurophysiology and might have potential applications in vital pulp therapy.

Title: Induced pluripotent stem cells generated from skin fibroblasts of a female patient with Fabry disease are susceptible to cell death during nociceptive differentiation

Authors: T. KLEIN[1], K. GÜNTHER[2], J. SCHLEGEL[2], F. EDENHOFER[2], M. SAUER[2], *N. ÜÇEYLER[1]
[1]Dept. of Neurol., Univ. of Würzburg, Wuerzburg, Germany; [2]Univ. of Würzburg, Würzburg, Germany

Abstract: Background and Objective: Fabry disease (FD) is an X-linked lysosomal storage disorder that mainly affects the heart, kidneys, and the nervous system. Due to deficiency of the alpha-galactosidase A (GLA), the glycolipid globotriaosylceramide (Gb3) accumulates in cells, including human dermal fibroblasts (HDF). The major neurological symptom in FD is acral burning pain. The pathophysiology of pain in FD is unknown and research is hindered by the lack of suitable biomaterial. Using patient-derived HDF we generated induced pluripotent stem cells (iPSC) and differentiated peripheral neurons including nociceptors for further investigation of potential intracellular effects of Gb3 accumulations.
Methods: iPSC from a 25 year old female FD patient (FD-iPSC) carrying a missense mutation in *GLA* were generated and characterized using standard procedures. iPSC were differentiated into nociceptors following an established protocol. The gene expression of key markers was analyzed during the first ten days of differentiation and after seven weeks of maturation using quantitative real-time PCR (qRT-PCR). Gb3 load was investigated using Shiga toxin 1, subunit B conjugated with SeTau-647 (StxB-SeTau) for iPSC and neurons and bioorthogonal click chemistry for neurons. Cells were fixed and incubated with the labelled toxin, washed and analyzed. Click chemistry was performed on seven weeks matured neurons by incubation of the cells with 25 µM tetraacylated N-azidoacetylgalactosamine and subsequent incubation with DBCO-sulfo-Cy5. For comparison, a control-iPSC line was used generated from neonatal BJ HDF (Ctrl-iPSC).
Results: FD-iPSC showed typical embryonic stem cell-like morphology, gene expression, and a normal karyotype. The diagnosed heterozygous mutation of *GLA* was retained. Some FD-iPSC displayed Gb3 clusters, as detected by StxB-SeTau whereas Ctrl-iPSC had none. On day eight of differentiation, qRT-PCR revealed lower gene expression of key sensory markers like islet-1 ($p<0.001$), peripherin ($p<0.01$), transient receptor potential vanilloid 1 ($p<0.05$) compared to

Ctrl-iPSC. Gb3 signal continuously declined during the differentiation and was absent in neurons after seven weeks of maturation.
Conclusions: We successfully generated FD-iPSC with a Gb3 positive subpopulation. Altered gene expression of key markers during nociceptive differentiation in combination with declined neuronal Gb3 signal may point to enhanced apoptosis of affected cells e.g. via Gb3 associated enhanced cellular stress. Neuronal cell death *in vitro* might be caused by similar mechanisms as the loss of nerve fibers *in vivo*, associated with the small fiber pathology in FD.

Title: DNA methylation as a regulator of nociceptive sensitization in Manduca sexta

Authors: *J. KIM[1], M. FUSE[2]
[2]Biol., [1]San Francisco State Univ., San Francisco, CA

Abstract: Nociception is the basic neural process that encodes threatening stimuli and is seen even in animals with primitive sensory systems. Activation of nociceptors in response to specific insults triggers the higher-order emotional and psychological perception of pain in organisms with more complex nervous systems. Organisms respond to harmful stimuli with defensive behaviors and maintain heightened behavioral responses, a form of non-associative learning known as nociceptive sensitization. While this behavioral plasticity has been observed across the animal kingdom, little is known about how conserved the molecular mechanisms underlying this response are, an understanding that is critical to improving pain treatments and pharmacological testing to target specific points in nociceptive pathways. DNA methylation (DNAm) has been shown in different species to be critical for memory formation and learning, including nociceptive sensitization in some instances. Using the tobacco hornworm, *Manduca sexta*, to study nociception offers a unique approach because its defensive striking response is well-characterized, and there exist standard *in vivo* and *in vitro* bioassays to directly assess nociceptive sensitization in *Manduca*. This study explores the hypothesis that DNAm is a critical regulator of nociceptive sensitization in *M. sexta*. We have identified putative DNAm genes from the available *Manduca* genome, and use a behavioral assay to determine changes in the threshold

force to elicit a defensive strike. We test individual animals by poking a proleg with von Frey filaments of increasing force before and after a strong pinch, using our established up-down protocol. After a pinch, animals become sensitized, where subsequent testing results in a strike threshold that is significantly lower than baseline. Preliminary results indicate that coupling the pinch with an injection of RG108, a DNAm inhibitor, counters or completely blocks the decrease in nociceptive threshold typically seen in sensitized animals. Thus, RG108 appears to have a direct effect on behavioral sensitivity to a harmful stimulus in *Manduca*. These results demonstrate that DNAm may regulate nociceptive sensitization in *M. sexta*. Methylation and bioinformatics analyses will corroborate findings on a molecular level and help identify genes that are differentially methylated during nociceptive sensitization.

Abstract: Bupivacaine is a commonly used local anesthetic in postoperative pain management. We evaluated the effects of a prolonged, local delivery of bupivacaine on pain behavior accompanying a chronic compression of the dorsal root ganglion (CCD). Poly(lactide-coglycolide) (PLGA) nanoparticles encapsulating bupivacaine were injected unilaterally into the L3 and L4 DRGs of mice just before producing CCD by implanting a stainless-steel rod in the intervertebral foramen of each ganglion. Behavioral sensitivity to punctate mechanical stimuli (Von Frey filaments) of different forces of indentation, delivered to each hind paw, was measured before and on subsequent days of testing after the CCD. Nanoparticles were spherical in morphology and 150±10 nm in diameter. Bupivacaine was steadily released as measured in

vitro over 35 days. A dye that was encapsulated in the nanoparticles was found in the intact DRG after 2 weeks. CCD alone or with injection of blank (control) nanoparticles produced a behavioral hypersensitivity to the punctate stimuli on the ipsilateral paw without affecting sensitivity on the contralateral, over a period of 7 - 14 days. The hypersensitivity was manifested as an increased incidence of paw-withdrawal to indentation forces normally below threshold (allodynia) and an increased shaking to a filament force that always elicited withdrawal prior to CCD (hyperalgesia). In contrast, nanoparticles with bupivacaine prevented any manifestation of allodynia or hyperalgesia on the ipsilateral hind paw while leaving normal nociceptive responses largely intact on both hind paws. We hypothesize that bupivacaine-loaded PLGA nanoparticles may prevent the occurrence of this neuronal hyperexcitability without reducing the nociceptive information normally conducted from the periphery to the central nervous system. The slow, sustained delivery of bupivacaine by nanoparticles may provide a means of preventing the occurrence of postoperative neuronal hyperexcitability that could develop into chronic neuropathic pain.

Title: Dexmedetomidine inhibits voltage-gated sodium channels via α2-adrenoceptors in trigeminal ganglion neurons

Authors: *Y. KIM[1], S.-T. IM[2], S.-M. HWANG[3]
[1]Dept. of Anesthesiol. and Neurobio., Gachon Univ., Incheon, Korea, Republic of; [2]Gachon Univ., Inchon-City, Korea, Republic of; [3]Gachon Univ., Incheon, Korea, Republic of

Abstract: Dexmedetomidine, an α2-adrenoceptor agonist, is widely used as a sedative and analgesic agent in many clinical applications. However, little is known about the molecular mechanisms responsible for its analgesic properties in the trigeminal system. Two types of voltage-gated sodium channels, $Na_v1.7$ and $Na_v1.8$ as well as α2-adrenoceptors are expressed in primary sensory neurons of the trigeminal ganglion (TG). Using whole-cell patch-clamp recordings, we investigated the effects ofdexmedetomidine on voltage-gated sodium channel currents (I_{Na}) via α2-adrenoceptors in dissociated small-sized TG neurons. Dexmedetomidine caused a concentration-dependent inhibition of I_{Na} in small-sized TG neurons. The I_{Na} inhibition by dexmedetomidine was blocked by yohimbine, a competitive α2-adrenoceptor antagonist. Dexmedetomidine-induced inhibition of I_{Na} was mediated by G protein-coupled receptors

(GPCRs) since this effect was blocked by intracellular perfusion with the G protein inhibitor GDPβ-S. Our results suggest that the I_{Na} inhibition in small-sized TG neurons, which is mediated by the activation of Gi/o protein-coupled α2-adrenoceptors, might contribute to the analgesic effects of dexmedetomidine in the trigeminal system. Therefore, these new findings highlight a potential novel target for analgesic drugs in the orofacial region.

Title: Identification of a population of peripheral sensory neurons projecting to blood vessels

Authors: *C. MORELLI, L. CASTALDI, S. BROWN, A. WEBSDALE, B. CERRETI, A. BARENGHI, P. A. HEPPENSTALL
EMBL Rome, Monterotondo, Italy

Abstract: Sensory neurons have the fundamental role of detecting stimuli from the periphery and are therefore considered afferents. Their endings are located in skin, muscles, joints and vessels and they are important to detect touch, itch, heat, cold and pain sensations, while their cell body is located in Dorsal Root Ganglia (DRG). We have identified a population of sensory neurons that project to blood vessels that have instead an efferent function. Like motor and sympathetic neurons, they directly act on blood vessels to regulate blood flow. Using transgenic mouse lines expressing fluorescent reporters, DREADDs (Designer Receptors Exclusively Activated by Designer Drugs) or optogenetic activators, we have characterised this new population from a histological and a functional point of view. These neurons account for around 10% of all DRG neurons and when they are specifically activated they act on arteries and arterioles regulating the blood flow. These results have been confirmed both with *ex vivo* live imaging experiments and with behavioural studies. The discovery of a new population of sensory neurons innervating blood vessels to regulate blood flow is an important step towards a better understanding of the relationship between the peripheral nervous system and the cardiocirculatory system. This in turn may help to develop new therapeutics for diseases like hypertension or fibromyalgia, where the nervous component seems to play an important role.

Title: Cellular and behavioral requirements for calcium induced calcium release mechanisms in cold nociception

Authors: *A. A. PATEL[1], N. J. HIMMEL[2], J. J. YANG[3], D. N. COX[2]
[2]Neurosci. Inst., [3]Chem., [1]Georgia State Univ., Atlanta, GA

Abstract: Calcium (Ca^{2+}) plays a pivotal role in modulating neuronal-mediated responses to multimodal sensory stimuli. Recent studies in *Drosophila* reveal class III (CIII) multidendritic (md) sensory neurons function as multimodal sensors regulating distinct behavioral responses to innocuous mechanical and nociceptive thermal stimuli. Functional analyses reveal that CIII-mediated multimodal behavioral output is dependent upon activation levels with stimulus-evoked Ca^{2+} displaying relatively low vs. high intracellular levels in response to gentle touch vs. noxious cold, respectively. However, the mechanistic bases underlying modality-specific differential Ca^{2+} responses in CIII neurons remains incompletely understood. We hypothesized that noxious cold evoked high intracellular Ca^{2+} responses in CIII neurons may rely upon Ca^{2+}-induced Ca^{2+} release (CICR) mechanisms to promote noxious cold nociceptive behavior. Neurogenomic analyses revealed that ER localized Ca^{2+} channels including the Ryanodine receptor (RyR) and Inositol triphosphate receptor (IP_3R) are enriched in CIII neurons. CIII-specific knockdown of the RyR or IP_3R results in a specific impairment in noxious cold evoked behavior, whereas gentle touch behavior was unaffected. Likewise, disruptions in both RyR and IP_3R in CIII neurons leads to significantly lower levels of cold evoked Ca^{2+} responses as revealed by the cytoplasmically localized Ca^{2+} integrator CaMPARI suggesting these channels are required in CICR from the ER. To more directly investigate how Ca^{2+} localization is altered when disrupting RyR or IP_3R, we generated novel transgenic strains bearing the ER localized Ca^{2+} sensor CatchER^{+}. As predicted, CIII-specific RyR knockdown results in significantly higher ER luminal Ca^{2+} indicative of a role in regulating Ca^{2+} release from intracellular stores. We further demonstrate that CIII-specific knockdown of RyR or IP_3R results in dramatic reductions in cold-evoked GCaMP cytoplasmic Ca^{2+} responses further supporting a role for CICR. Morphological analyses revealed that RyR or IP_3R knockdown in CIII neurons results in varied, but subtle reductions in dendritic arborization. To differentiate potential roles of RyR and IP_3R in general excitability vs. sensory transduction, we combined CIII-specific knockdown with optogenetic

activation revealing that these molecules appear to act in the sensory transduction stage rather than in action potential propagation. Collectively, these analyses support novel, modality-specific roles of RyR/IP_3R function and CICR mechanisms in regulating intracellular Ca^{2+} levels and cold evoked behavioral output from multimodal CIII neurons.

Abstract: Primary somatosensory afferent neurons transduce environmental stimuli into electrical activity that is transmitted into central nervous system to be decoded into corresponding sensations. How different stimuli are encoded by a population of afferents remains poorly studied. To address this, we performed video-rate two-photon functional imaging from thousands of dorsal root ganglion (DRG) neurons in anesthetized mice, and applied natural mechanical and thermal stimuli to the hind paws. We found that approximately half of the DRG neurons were polymodal (including >30% being both mechano- and thermoceptive). Further parametric analysis revealed that thermoceptive neurons displayed distinct encoding behaviours in the heat vs. cold ranges. As temperature increased, more heating-sensitive neurons were

activated and most individual neurons responded more strongly. It is consistent with graded coding at population and single-neuron levels, respectively. In contrast, most cooling-sensitive neurons responded in an ungraded fashion, which is inconsistent with graded coding and instead suggests combinatorial coding based on the co-activation pattern of an ensemble of DRG neurons. Thus, our study found that polymodality is a common phenomenon of DRG neurons, and thermoceptive afferents use different strategies to encode heat and cold.

Title: Conserved strategy for nociceptive stimulation by animal venom

Authors: Y. L. YANG[1], *T. W. LAI[1,2,3]
[1]Grad. Inst. of Biomed. Sci., [2]Drug Develop. Ctr., China Med. Univ., Taichung, Taiwan; [3]Translational Med. Res. Ctr., China Med. Univ. Hosp., Taichung, Taiwan

Abstract: The induction of pain by animal venom discourages predation and competition, and is therefore crucial to natural selection. Despite the common pain-evoking property of many animal venoms, an evolutionarily conserved algogenic substance has not been identified. Here we show that citrate sufficiently recapitulated the biphasic nociceptive effects of crude rattlesnake venom when injected in mice. The initial nociceptive response (P1N) was reconstituted by citrate at native venom pH, and occurred through potentiation of acid-sensing ion channel. The delayed and prolonged nociceptive responses (P2Ns) were caused by stimulation of a novel pain receptor on peripheral terminals of nociceptors, and were abolished by its genetic deletion or pharmacological inhibition. Intriguingly, the abundance of citrate in most animal venoms explains their common pain-evoking nature, and the lack thereof explains how some species, such as the brown reclusive spider, bite painlessly to produce intoxication in stealth.

Title: Immunohistochemical characterization of sensory neurons surrounded by postganglionic sympathetic baskets in the mouse trigeminal ganglia

Authors: *H. ALSAADI[1], N. GHASEMLOU[1,2,3], M. D. KAWAJA[1,2]
[1]Ctr. for Neurosci. Studies, [2]Dept. of Biomed. and Mol. Sci., [3]Dept. of Anaesthesiology & Perioperative Med., Queen's Univ., Kingston, ON, Canada

Abstract: Following peripheral nerve injury, postganglionic sympathetic axons sprout into affected sensory ganglia and form perineuronal plexuses around a subpopulation of primary sensory neurons. These sympathetic basket-like structures have been shown to play an important role in the development and maintenance of chronic pain. In this study, we sought to determine a more precise phenotype trigeminal ganglia neurons surrounded by sympathetic plexuses. Here we utilized mice that express nerve growth factor (NGF) under the control of glial fibrillary acidic protein promoter, as these mice display the spontaneous formation of sympathetic baskets in sensory ganglia (i.e., in the absence of nerve injury). Preliminary immunostaining results show that the vast majority of those sensory neuronal cell bodies surrounded by sympathetic plexuses in the trigeminal ganglia are immunopositive for 1) the NGF receptor trkA, 2) a second NGF receptor p75, 3) calcitonin gene-related peptide, and 4) neurofilament heavy chain (NF200). These same sensory neurons with sympathetic basket lack immunostaining for NGF receptor trkB, isolectin B4, substance P, TRPV1, aquaporin, and ASIC3. These results reveal that the nociceptive sensory neurons surrounded by sympathetic plexuses are NGF-sensitive, peptidergic, and heat insensitive. This study begins to shed light on the mechanisms that provide specificity in the formation of sympathetic plexuses following peripheral nerve injury. This knowledge is imperative for developing targeted interventions for sympathetically maintained chronic pain conditions. This work is funded by Queen's University School of Medicine to (MK), and King Saud bin Abdulaziz University for Health Sciences Scholarship to (HA).

Title: Functional and molecular characterisation of cold-responsive DRG neurons *in vivo* using GCaMP

Authors: *E. EMERY[1], A. P. LUIZ[2], D. I. MACDONALD[3], J. N. WOOD[1]
[1]Univ. Col. London, London, United Kingdom; [2]Dept. of Med., WIBR/University Col. London, London, United Kingdom; [3]UCL, London, United Kingdom

Abstract: The ability to sense environmental cold serves as an essential survival tool. The ablation of the Trpm8 or $Na_V1.8$-expressing sensory neurons causes a profound deficit in noxious cold sensation in mice, despite these populations having limited overlap. To explore this further, we used mice expressing Pirt-GCaMP3, $Na_V1.8$-Cre and a Cre-dependent reporter to investigate the population of sensory neurons responsive to different cooling stimuli, *in vivo*. Plantar application of a variety of cooling stimuli down to 1^oC caused the activation of distinct, threshold-specific cold-responsive neurons. Interestingly, the majority of cold-responsive neurons were negative for $Na_V1.8$ expression, and the deletion of $Na_V1.8$ did not affect the relative number, distribution or maximal response of cold-sensitive neurons. Furthermore, the genetic deletion of $Na_V1.8$ had no observable effect on cold-induced behaviours in mice, as measured by the cold plantar, cold plate or acetone tests. Fluorescent-activated cell sorting (FACS) and subsequent microarray analysis of putative cold-sensitive sensory neurons, highlighted an enriched repertoire of ion channels that is potentially required for cold sensing in mouse DRG neurons. These data demonstrate the complexity of cold sensing mechanisms in sensory neurons, and reveal a major role for $Na_V1.8$-negative neurons in sensing innocuous and noxious cooling.

Title: Effect of high omega-6 diet on sensory neuron excitability and pain behavior

Authors: *J. T. BOYD[1], S. RUPAREL[2], K. M. HARGREAVES[3]
[1]UT Hlth. - San Antonio, San Antonio, TX; [2]Endodontics, [3]Univ. of Texas Hlth. Sci. Ctr. at San Antonio, San Antonio, TX

Abstract: Background: Physicians recommend dietary interventions for management of cardiovascular disease, diabetes and many autoimmune diseases; however, there is a large gap in knowledge on the role of diet as a risk factor or potential therapy for chronic pain. Our group and others have demonstrated that oxidized metabolites of the omega-6 polyunsaturated fatty acids (PUFAs) lead to increased activation of transient receptor potential vanilloid 1 (TRPV1) expressed on nociceptive neurons, as shown in several pain models. Since these are essential fatty acids, tissue levels of omega-6 PUFAs are regulated by dietary intake; however, the mechanisms by which dietary omega-6 lipid modulates pain is not understood. The current study characterizes changes in sensory neuron signaling and its contribution to increases in thermal and mechanical nociception. **Methods:** Male C57BL6 mice were placed on isocaloric diets with high (10%) and low (0.5%) levels of omega-6 PUFAs for 8 weeks. Thermal and mechanical nociceptive thresholds were measured pre and post-diet. Patch clamp electrophysiology was used to determine changes in excitability in different dorsal root ganglion (DRG) sensory neuron subgroups, while calcium imaging was used to assess alterations in capsaicin-induced calcium accumulation, post diet. Data were analyzed with two-way ANOVA with Bonferroni post hoc test. **Results**: Thermal nociceptive thresholds decreased by 30% in the high omega-6 group ($p<0.001$, $n=25$), and baseline mechanical thresholds decreased by 15% ($p<0.001$, $n=25$) as compared to pre-treatment levels. Hyperexcitability of DRG sensory neurons, due to high omega-6 diet, was observed within specific sensory neuron subgroups but not all subgroups. Capsaicin induced calcium influx in DRG neurons increased by 50% in the high omega-6 group ($p<0.05$, $n=53$) compared to control. **Conclusions:** Collectively, these novel data suggest that chronically elevated dietary omega-6 PUFAs lead to increased thermal and mechanical pain response as well as neuronal hyperexcitability within specific subclasses of sensory neurons. Future work will focus on mechanisms by which omega-6 PUFAs contribute to increased neuronal signaling and nociception.

Title: Touch device for accurate detection of acute mechanical pain stimulus

Authors: *J. A. DALE[1], J. WANG[2]
[2]Anesthesiol., [1]New York Univ. Sch. of Med., New York, NY

Abstract: Pain poses a major clinical, social, and economic problem. Approximately one in three adults suffer from chronic pain and the economic cost associated with chronic pain management is estimated to be about $600 billion annually. Despite the critical importance of pain management, the diagnosis of pain remains poorly developed. In either the laboratory setting or the clinical setting, there is currently no means of assessing acute mechanical pain. We meet this need through a device that records the onset and offset of painful mechanical stimulations. The device allows for a needle, syringe, or any metal item to act as both the stimulus and touch trigger. With an item such as a needle, when applied properly, one can use contact time as a surrogate for stimulus onset. Additionally, withdrawal times can be accurately and precisely determined by the loss of contact. A tool for accurately assessing these parameters of painful stimuli has both research and clinical applications. Such a tool allows for accurate analysis of neuronal reactions to pain where exact timing is crucial, advancing the field of pain research. And this tool provides a unique insight into the conditions of patients with pain related ailments such as peripheral neuropathy, and chronic pain by providing a means of measuring and monitoring patient's mechanical pain thresholds. Our data show observable differences in withdrawal speeds elicited by different needle gauges. This shows the device's ability to measure pain thresholds to a level of sensitivity previously not possible. Additionally, data shows that there are differences in response to painful stimulus in rats under normal and chronic pain conditions, demonstrating the tool's ability to be used not only to assess pain thresholds, but to also assess hypersensitivity. There are currently no other means to objectively detect hypersensitivity and is thus a boon to the study and treatment of pain.

Title: Phenotyping of somatosensory afferents mediating cold and cold pain sensations

Authors: *S. YAMAKI[1], S. ONGUN[1], C. WEI[2], D. D. MCKEMY[3]
[1]Mol. Biol. Grad. Program, [2]Neurosci. Grad. Program, [3]Neurobio., USC, Los Angeles, CA

Abstract: Ion channels of the Transient Receptor Potential (TRP) superfamily are non-selective cation channels that mediate the influx of small ions, as well as larger positively-charged molecules. This ability to permeate large cations has been used to cell-specifically target local anesthetics to afferent nerve fibers expressing these channels, thereby allowing a functional phenotyping of these cells *in vivo*. We have previously shown that the principle mediator of neuronal cold responses, the menthol receptor TRPM8, permeates large cations *in vitro*. Additionally, *in vivo*, nerve block by selective entry of the cell-impermeant sodium channel blocker QX-314 with cold stimuli (both chemical and thermal) blocks cold and cold pain. Thus, these cells are critical mediators of this somatosensory modality. However, afferents expressing the ion channels TRPV1 and TRPA1 have also been implicated in mediating cold and cold pain. Therefore, using QX-314-specific nerve block via cell permeation after activation of TRPV1 and TRPA1 channels, we have examined the role of these afferents in cold perception. Our findings show that both channels, depending on stimulation conditions and pathological state, are components of a cold sensory pathway.

Title: Identification of pyruvate dehydrogenase as a target of prostaglandin E2-induced Epac signaling in mouse dorsal root ganglion neurons

Authors: *D. J. GOODE, R. GEGUCHADZE, D. C. MOLLIVER
Biomed. Sci., Univ. of New England, Biddeford, ME

Abstract: The phenomenon of hyperalgesic priming has been used to investigate molecular mechanisms underlying the transition from acute to chronic pain. In this model, an initial injury produces a persistent "primed" state in which a second mild insult (injection of the prostaglandin PGE2) produces prolonged hyperalgesia. Priming is caused in part by a switch in cyclic adenosine monophosphate (cAMP) effectors from protein kinase A (PKA) to exchange protein activated by cAMP (Epac). Epac is a guanine nucleotide exchange factor that activates Rap1, and Epac/Rap1-dependent activation of protein kinase C (PKC) epsilon has been implicated as a critical pathway for some forms of hyperalgesic priming. A significant challenge has been to identify proteins downstream of Epac that may contribute to nociceptor sensitization. We characterized Epac-dependent PKC activity in dorsal root ganglion (DRG) neurons from male mice by first enriching total phospho-protein by immobilized metal affinity chromatography (IMAC), then analyzing samples by Western blot using an antibody recognizing serine residues phosphorylated by PKC. Application of PGE2 or the Epac agonist 8-pCPT-2-O-Me-cAMP-AM (8Cpt) to dissociated DRG neurons produced a consistent profile of phospho-protein bands that were reversed by inhibitors of PKC (GF109203X) or Epac (ESI09), but not of PKA (cAMPS-Rp and KT5720). A major band ~41kD was excised from the polyacrylamide gel and processed for liquid chromatography-mass spectrometry, identifying the major protein as pyruvate dehydrogenase Pdha1. Multiplex Western blot staining showed that the band for Pdha1 overlapped completely with the PKC phospho-serine band at 41 kD. The Pdha1 band was depleted in phospho-enriched samples from neurons treated with 8Cpt plus ESI09 compared to 8Cpt alone, indicating that ESI09 suppresses phosphorylation of Pdha1 and supporting the identification of the 41kD band as Pdha1. Phosphorylation of Pdha1 by pyruvate dehydrogenase kinases (PDK) at S293 inhibits conversion of pyruvate to acetyl-CoA and the production of energy through the TCA cycle; inhibition also reduces mitochondrial buffering of intracellular calcium and production of reactive oxygen species. However, analysis of predicted PKC-phosphorylation sites in the mouse Pdha1 sequence revealed several sites, but did not include S293. This suggests that Epac-dependent PKC phosphorylation of Pdha1 may represent a novel mechanism for the regulation of Pdha1 and mitochondrial function in response to Gs-coupled receptor signaling. Regulation of mitochondrial function by GPCR-induced Epac signaling may contribute to the critical role of Epac in hyperalgesic priming.

Title: DRG cell-type enriched TSS usage and alternative splicing in humans and mouse implicate important sensory genes

Authors: *P. R. RAY, J. KHAN, A. WANGZHOU, S. MEGAT, V. RAJESH, T. J. PRICE
Behavioral and Brain Sci., The Univ. of Texas at Dallas, Richardson, TX

Abstract: Problem: Whole gene expression profiles of human and mouse sensory tissues have been comprehensively characterized in recent works (Flegel et al, PLoS One 2015; Usoskin et al, Nat Neuro 2015) at varying resolutions (whole tissue, small cell pool and single cell) identifying genes enriched in sensory cell types. However, only a handful of studies (Lerch et al, PLoS One 2012) have analyzed gene expression profiles in the mammalian dorsal root ganglia (DRG) or trigeminal ganglia (TG) at the level of individual isoforms and none have performed such analysis on a whole genome basis in mammalian single cell studies or in human datasets. To remedy this, we created a genome wide map of alternative splice (AS) variants and transcription start site (TSS) usage in human and murine DRG and TG. Methods: Based on publicly available human and mouse whole tissue, and mouse DRG single cell RNA-seq datasets, we computationally contrast these isoform expression maps between DRG, TG and several central nervous system tissues to identify differential isoform usage in human and mouse DRG and TG , and in sensory neuronal subpopulations in the mouse DRG. SpliceTrap, rMATS, Tophat/Cufflinks, STAR and Salmon toolkits were used to analyze RNA-seq datasets. 6 kinds of alternative isoform usage (alternative TSS, alternative 5’ and 3’ splice sites, retained intron, skipped exon and mutually exclusive exons) were analyzed. Information theoretic measures based on Shannon's entropy were used to identify differential isoform enrichment. Results: We identified several sensory tissue enriched isoforms in both humans and mouse. WNK1 (lysine deficient protein kinase 1), has a skipped exon alternative splicing event known to be associated with peripheral neuropathy enriched in both the human and mouse DRG. OGT (O-GlcNAc Transferase), essential for sensory neuron maintenance, also has a differential alternative splicing event in the human DRG. In the mouse DRG, we characterized isoform enrichment across sensory neuronal subpopulations (neurofilament, peptidergic, non-peptidergic, Tyrosine hydroxylase positive cells) including Trpv1, Piezo2, and Trpa1, whose splice variants have been linked to specific functions. We also analyzed alternatively spliced regions of the genes in terms

of their content of RNA binding sites, motif and secondary structure, and protein domains (from PFAM and Interpro), and Short Linear Motifs (from ELM). Discussion: Our results yield the first comprehensive multi species map for isoform expression in mammalian sensory tissues, that can be mined for diagnostic and therapeutic studies in human disease, and mechanistic and functional single gene studies in rodent models.

Title: Palmitic acid induces pain behavior via toll-like receptor-4 (TLR4) on sensory neurons

Authors: *J. TIERNEY, T. SZABO-PARDI, H. S. JEONG, M. D. BURTON
Univ. of Texas at Dallas, Richardson, TX

Abstract: New studies reveal that western diet (WD) consuming populations experience pain states independent of diabetes or obesity. It appears as if components of the diet sensitize the body. Saturated fats, which are a large component of WD, lead to obesity and have a role in insulin resistance and diabetes. A subset of free fatty acids (FFA), which are formed from the breakdown of saturated fats, are proposed to interact with Toll-like receptor 4 (TLR4). TLR4 is a receptor that recognizes lipid components of bacteria, and similarly, the lipid-A backbone of FFAs. In particular the FFA, Palmitic Acid (PA), has been shown to directly activate TLR4. To determine how PA could activate sensory neurons via TLR4, we utilized a novel transgenic model that allows for specific expression of TLR4 in peripheral sensory neurons in otherwise whole-body null animals. In order to re-express TLR4 in these cells we used a cre recombinase animal that is driven by the $Na_v1.8$ promoter. We hypothesize that PA through action on TLR4 on sensory neurons is important for mediating pain plasticity. Male and female: wild-type (WT), TLR4 null-or knock-out mice (KO), and mice that had TLR4 re-expressed in peripheral nociceptors (SNS^{React}), were used in all experiments. For behavioral assessments, mice underwent intraplantar injection of PA into the hind paw; both mechanical hypersensitivity and spontaneous pain measurements were assessed 1hr, 3hr, 24hr, 3d, 5d, and 7d post injection of PA. Dorsal root ganglia neurons were treated with a 100μM dose of PA followed by 50mM KCl as a positive identifier of neurons. In both sexes, WT and SNS^{React} mice that received an intraplantar injection of PA had a lowered paw withdrawal threshold and higher grimace score,

indicating the animals were hypersensitive. While the KO animals had mechanical thresholds and grimace scores similar to vehicle treated animals. In calcium imaging experiments, PA was able to activate a subset of about 30% of WT neurons indicated by a calcium influx. The 30% of cells that responded to PA also responded to application of capsaicin demonstrating they were TRPv1+ cells. These experiments demonstrate that the breakdown of saturated fatty acids in food can lead to pain-states in the absence of diabetes or other gross conditions.

Title: Characterizing YPEL3 gene function in *Drosophila melanogaster*

Authors: *A. J. LOPEZ[1], H. LEE[1], B. BOSSE[1], B. YE[3], J.-H. KIM[2]
[2]Dept. of Biol., [1]Univ. of Nevada, Reno, Reno, NV; [3]Life Sci. Inst., Univ. of Michigan, Ann Arbor, MI

Abstract: The Yippee-like gene family is a group of genes that show high conservation through many different types of organisms including various animal, bacterial, and fungal species. This uncharacterized gene was recently associated with a disease found in a human patient that showed neurological defects including areflexia and hypotonia. An ortholog of YPEL3 was found in *Drosophila melanogaster* (dYPEL3) that showed 85% amino acid identity. We successfully generated mutants of dYPEL3 similar to the human mutation in *Drosophila*. Here we show that the nociceptive circuit is the likely target for dYPEL3 mutations due to optogenetic manipulation of dYPEL3 mutants using Channel Rhodopsin II (ChR2) to activate nociceptive circuitry, thus displaying a phenotype of increased rolling behavior in larva. We also show through the use GRASP (GFP Reconstitution Across Synaptic Partners), that the synaptogenesis between the nociceptive neurons and their immediate projection neuron target, Basin-4, is reduced in strength in the mutants compared to wild-type. Calcium influx analyzed using GCaMP live imaging showed increased total Basin-4 activation in the mutant lines. Thus, dYPEL3 has role in regulating the nociceptive circuit in *Drosophila* which could have definite implications in sensory response and neurological defects.

Title: Effects of the VGF-derived peptide TLQP-62 on primary afferent neurons

Authors: A. G. J. SKORPUT, 55455[1], R. GORE[2], M. S. RIEDL[5], J. L. COOK[3], E. MARRON FERNANDEZ DE VELASCO[4], W.-J. LIN[6], S. R. SALTON[7], *L. VULCHANOVA[8]

Hosp., Sun Yat-Sen Univ., Guangzhou, China; [7]Fishberg Dept. of Neurosci., Icahn Sch. of Med. at Mount Sinai, New York, NY; [8]Neurosci., Univ. of Minnesota Dept. of Neurosci., Minneapolis, MN

Abstract: The neurosecretory protein VGF (non-acronymic) is rapidly and robustly upregulated by primary somatosensory afferent neurons following peripheral nerve damage. VGF is proteolytically processed to yield a number of bioactive peptides, including the C-terminal peptide TLQP-62. This peptide has been shown to induce BDNF-dependent synaptic plasticity in the hippocampus and function during learning and memory. We have demonstrated that spinal TLQP-62 is increased after nerve injury and that immunoneutralization of C-terminal VGF peptides attenuates the development of mechanical allodynia. Furthermore, calcium imaging in spinal cord slices from naïve mice revealed TLQP-62-induced potentiation of glutamatergic responses in a subset of dorsal horn neurons. This effect was inhibited by the non-selective TrkB inhibitor K252a, and exposure of spinal cord slices to TLQP-62 increased TrkB phosphorylation. These observations suggested that TLQP-62 may facilitate BDNF release. Since primary afferent neurons are a potential source of spinal BDNF, we examined the effects of TLQP-62 on these neurons. Using mice that express a genetically encoded calcium indicator restricted to primary afferent neurons (Pirt-GCamp3 mice), we observed that TLQP-62 induced calcium transients in a subset of primary afferent fibers in the dorsal horn of spinal cord slices. The responses occurred immediately after TLQP-62 exposure and were sustained during prolonged exposure. TLQP-62 also induced calcium transients in DRG cultures. These responses were seen in a subset of capsaicin-responsive neurites as well as in neurites that did not respond to capsaicin.

Ongoing work is investigating the functional consequences of these TLQP-62 effects and their relationship to BDNF via patch-clamp and BDNF-pHluorin imaging, respectively. Our observations of TLQP-62-induced calcium responses in the processes of primary afferent neurons are consistent with the idea that the peptide may modulate release of signaling mediators.

Title: GABAergic system in the spinal sensory ganglia

Authors: *R. RAMLI[1,2], H. HAN[3], J. DEUCHARS[1], X. DU[3], H. ZHANG[3], N. GAMPER[1,3]
[1]Sch. of Biomed. Sci., Univ. of Leeds, Leeds, United Kingdom; [2]Sch. of Dent. Sci., Universiti Sains Malaysia, Kota Bharu, Malaysia; [3]Dept. of Pharmacol., Hebei Med. Univ., Hebei, China

Abstract: Peripheral nerves convey to the brain versatile information about the body's environment and report the state of the muscle, joints and viscera. Brain interprets this information in terms of haptic, somatic and visceral experiences including that of pain. Healthy nerves conduct action potentials from their peripheral endings to the dorsal spinal cord, where synaptic transmission first takes place. It is assumed that the peripheral somatosensory signals are first integrated in the spinal cord (the 'Gate Control' theory) and subsequently analyzed in higher brain centers. Our recent work challenged this view (1). We focused on cell bodies of sensory neurons, which are situated in the dorsal root ganglia (DRG), outside of the main nerve conduction pathway. Surprisingly, these DRG cell bodies express receptors for classical CNS neurotransmitters, such as glutamate and GABA, even though there is no known synapses in

DRG. We report that DRG cell bodies contain a fully functional GABAergic system that can modulate nociceptive signals before these enter the CNS. Thus, *i)* DRG neurons express the proteins necessary for GABA synthesis and release; *ii)* DRG neurons release GABA in response to depolarization; *iii) in vivo* infusion of GABA into DRG dramatically reduced acute and chronic pain while application of GABAA antagonists induced pain or exacerbated peripherally-induced pain; *iv)* chemogenetic or optogenetic depolarization of GABAergic DRG cell bodies *in vivo* reduced acute and chronic pain. In a follow-up study we performed simultaneous *in vivo* recordings of firing in the peripheral (spinal nerve) and central (dorsal root) branches of L5 spinal nerve of a rat, which allowed to focally apply drugs to DRG during the recording. We show that hind paw injection of capsaicin induced firing in both peripheral and central branches of the nerve. DRG application of GABA strongly reduced capsaicin-induced firing in the dorsal root without any effect in the peripheral branch. In contrast, DRG injection of GABAA antagonist bicuculline significantly increased tonic firing rate in the dorsal root. Intriguingly, basal firing rates were consistently lower in the dorsal root as compared to the spinal nerve but after bicuculline the difference disappeared, suggesting existence of tonic GABAergic filtering at DRG, which can be modulated via endogenous and exogenous mechanisms. Collectively, our findings indicate that peripheral somatosensory ganglia may represent a new type of a 'gate' within the somatosensory system.

Title: Failure of somatic spike invasion in primary afferent neurons

Authors: *D. AL-BASHA[1,3], S. A. PRESCOTT[2,4]
[1]Neurosci. and Mental Hlth., [2]Neurosciences and Mental Hlth., The Hosp. For Sick Children, Toronto, ON, Canada; [3]Dept. of Physiol., [4]Dept. of Physiol. and Inst. of Biomaterials and Biomed. Engin., Univ. of Toronto, Toronto, ON, Canada

Abstract: The peripheral terminals of primary afferent neurons convert the external somatosensory stimuli into action potentials, or spikes, that propagate centrally into the central nervous system (CNS). Primary afferent neurons have a unique pseudounipolar structure in which a single axon protrudes from the soma and splits into one central and one peripheral

branch, thus forming a T-junction. For spikes to reach the CNS, they must pass through the T-junction, which can impede spike propagation. Computational work suggests that spikes continue to propagate towards the central terminals even if they fail to invade the soma. However, it is not an uncommon practice for researchers to record from the soma when characterizing different primary afferent neurons and (at least some) spikes do invade the soma. By recording extracellular spikes from the soma in response to sustained mechano- and photo-stimulation of the peripheral terminals *in vivo* in transgenic mice that express channelrhodopsin-2 in all primary afferents, we observed three types of spike patterns: irregular, regular and an unexpected semi-regular pattern. The semi-regular pattern was characterized by what appeared to be missing spikes from an otherwise regular spike pattern. We confirmed this observation computationally in an abstract mathematical model and a biophysical neuron model. Both models show that a noisy spike initiation process cannot reproduce the semi-regular spike pattern, but that subtraction of a random subset of the spikes from a regular pattern, generated via either model, does. We therefore hypothesized that the missing spikes occur as a result of failure of spike propagation into the soma. To investigate this, we encouraged spike propagation failure by blocking sodium channels with lidocaine. As predicted, lidocaine converted the regular spike pattern into the previously observed semi-regular pattern. These results confirm that spikes intermittently fail to propagate into the cell soma in vivo. These findings demonstrate that spike propagation failure occurs in vivo and that this is important to consider when characterizing primary afferent response properties.

Title: Identifying the molecular components of cold nociception in *Drosophila melanogaster*

Authors: *R. M. BARBOREK[1], K. COMBS[2], A. NEIGHBORS[2], M. KNICK[2], S. HALSELL[1]
[1]Biol., [2]James Madison Univ., Harrisonburg, VA

Abstract: Nociception, the central nervous system's processing of noxious stimuli, gives rise to conscious perception of pain and protective reflexes. This study aims to explore the molecular mechanisms of nociception by researching the potential role of *Drosophila melanogaster* Innexin gap junction proteins in cold nociception. Invertebrate Innexins are functionally analogous to mammalian Connexins. To screen for a possible role of these Innexins in cold nociception, the

expression of each Innexin was knocked down by cell-specific expression of *innexin* RNAi constructs in the class III dendritic arborization (da) neurons. Wild type (WT) third instar *Drosophila* larvae exhibit a characteristic "cringing," or shortening, response when exposed to noxious cold (6°C). Larvae were subjected to a cold plate and their behavior was video recorded. 100 larvae were tested for each genotype. The larval images were processed using Image J software to quantify the "percent cringe". By comparing the percent cringe of the protein-lacking larvae to the WT, the involvement of the knockdown protein in the cold nociceptive pathway was inferred. A control was established using Oregon-R WT larvae (positive for WT cringe response). Tetanus toxin, a potent neurotoxin, was expressed specifically in class III da neurons and significantly inhibited cringing. This provided evidence that class III da neurons function in cold nociception and moving forward this test served as a negative control. To date, every Innexin has been tested with at least one RNAi construct, and six of the eight Innexins have been tested with two different RNAi constructs. In class III da neurons, down regulation of four Innexins - Inx2, Inx5 (with both RNAi constructs), Inx1 and Inx3 (only tested with one construct) - significantly inhibited cringing. This provides evidence that these four Innexins function in the cold nociception pathway of third instar larvae, and also, therefore, that this pathway utilizes electrical synapses. Down regulation of Inx4, Inx6, Inx7, and Inx8 significantly inhibited cringing with one RNAi construct but not the other. To clarify the potential role of these Innexins, mutant flies lacking a functional Innexin will be tested to eliminate confounding variables that may exist with the RNAi constructs.

Title: TRPV1 and TRPV4 involvement in cinnamaldehyde-evoked itch in female and male mice

Authors: T. FOLLANSBEE[1], M. IODI CARSTENS[1], T. NGUYEN[1], A. NGUYEN[1], M. CHEN[1], D. DOMOCOS[1], *E. E. CARSTENS[2]
[1]NPB, Univ. of California, Davis, Davis, CA; [2]Neurobiology, Physiol. & Behavior, Univ. of California Davis, Davis, CA

Abstract: Cinnamaldehyde (CA) elicits itch sensation in humans (Namer et al., Neurorep 16:955-9, 2005; Hojland et al., Acta Derm Venereol 95 :798-803, 2015). We presently

investigated CA-evoked scratching behavior in male (M) and female (F) mice and potential TRP channel involvement. Female (F) and male (M) C57BL6 wildtype (WT) and TRPV1 knockout (KO), TRPA1KO and TRPV4KO mice were used. CA (1-5% in 5% Tween80) was delivered unilaterally to the cheek via intradermal (id) injection (10 μL). Mice were videotaped and numbers of hindlimb scratch bouts and forelimb wipes directed to the injected cheek, and bilateral facial groom bouts, were scored offline by blinded observers. To test for alloknesis, 40% CA was applied topically to the rostral back. At 5-min intervals, a von Frey monofilamant (0.7 mN bending force) was applied 3 times to the treatment area and occurrences of immediate hindlimb scratch bouts directed to the stimulus, and wet dog shakes, were counted. CA elicited a dose-dependent increase in numbers of scratch bouts that peaked at 10-25 min post-CA and then declined. There was no sex difference in the numbers of CA-evoked scratch bouts in WTs. Importantly, CA elicited significantly fewer scratch bouts in both F and M TRPV1KO and TRPV4KO mice ($p<0.05$ for both) compared to WTs. Counts of CA-evoked scratch bouts were not significantly different in F or M TRPA1KOs, or in M mast-cell deficient (Sash) mice, compared to WT counterparts. CA did not elicit any significant increase in forelimb wiping or facial grooming behavior compared to vehicle controls, and there were no sex or genotype differences in these behaviors. As TRPV1 and TRPV4 are associated with histaminergic itch, we tested if CA-evoked scratching was suppressed by the histamine H1 antagonist cetirizine. Neither a low (1.5 mg/kg) nor a high (15 mg/kg) dose of cetirizine significantly affected the number of CA-evoked scratch bouts, indicating a lack of involvement of histamine receptors. Topical application of CA resulted in a significant increase in alloknesis scores in M and F WTs, as well as wet dog shakes. We are currently investigating if CA-evoked alloknesis scores are different in various KO groups. The data indicate that CA elicits itch via a novel non-histaminergic pathway that partly involves TRPV1 and TRPV4 ion channels.

Title: Novel morphine delivery technique with rat pain model -subpial injection-

Authors: K. KAWAMITSU[1], *K. KAMIZATO[2], M. KAKINOHANA[1]
[1]Anesthesiol., Univ. of the Ryukyus, Nishihara, Japan; [2]Univ. of the Ryukyus, Nakagami-Gun, Japan

Abstract: Introduction: The subarachnoid administration is one of the most effective drug delivery methods in clinical, especially opioids delivery. But the pia matter which is a cell layer cover the spinal parenchyma.We established more effective AAV9 injection method than the subarachnoid administration, which is “sub-pial injection”. The goal of the present study was to show the effectiveness of sub-pial opioid injection as compare with the subarachnoid administration in rat pain model.Methods: All studies are approved by the Institutional Animal Care Committee. Adults SD rats (male 250-310 g) had formalin test. The sub-pial group (Morphine group n=4/dose, Control n=4) were received laminectomy at Th13/L1. Following the laminectomy, animals were received the sup-pial morphine injection or saline injection. The subarachnoid group (Morphine n=4/dose, Control n=4) were implanted with chronic intrathecal catheter (PE-5) 5 days prior to morphine injection. The formalin tests were started 30min after morphine injection (2% paraformaldehyde injection subcutaneously into the hindpaw). In both group, the quantitative bioassay for the analgesic effect of sub-pial / subarachnoid morphine on formalin tests was performed to calculate 50% effective dose values (ED50) for induced pain 30min after morphine administration.Results: The scoring of stereotypical behaviors such as flinching, licking, and biting of the affected hindpaw were decreased in sub-pial / subarachnoid morphine administration in comparison with saline injection. $ED50_{SubPial}$were 0.003ug/ml on the early stage and 0.004ug/ml on the late phase. On the other hand $ED50_{subarachnoid}$were 0.10ug/ml on the early stage and 0.17ug/ml on the late phase. The sub-pial injection can decrease the value of ED50 in comparison with subarachnoid administration ($p<0.05$ on the early stage and the late phase).Conclusion : These data show the efficiency of sub-pial morphine injection. The novel morphine injection can give more strong analgesic effect than the traditional subarachnoid morphine administration.

Title: Does behaviour in rats change over the time course of MIA induced osteoarthritis?

Authors: *C. MONTAGUT-BORDAS[1], A. FISHER[2], A. H. DICKENSON[1]
[1]Neuroscience, Physiology, Pharmacol., Univ. Col. London, London, United Kingdom;
[2]Transpharmation Ltd., London, United Kingdom

Abstract: Osteoarthritis (OA) is a chronic condition characterized by cartilage damage around the joints, resulting in pain, swelling and stiffness. There is currently no cure for OA. Treatments vary from non-steroidal anti-inflammatory drugs, opioids and capsaicin creams to alleviate pain and knee replacement surgery in severe cases. 13% of patients that undergo surgery still suffer from pain. Patients report the pain as burning, shooting pain with wide spread sensitization, suggestive of pain with neuropathic features. Studies have found these patients to have nerve damage in areas surrounding the joint. Together this suggests that OA pain can have both nociceptive and neuropathic features, having implications for future treatment. Here we studied animals subjected to the monoiodoacetate (MIA) model of OA. Behavior was assessed in 12 MIA and 6 sham control rats to address differences between two different stages of the disease: early inflammatory stage with nociceptive features (2-4 days post-injection) and late stage with neuropathic features (14 days post-injection). Animals were habituated and trained for two tests: Catwalk Gateway System and LABORAS. Behavior was tested before injection of MIA (OA animals; 2mg/animal) or saline (sham animals; 0.9%) and post injection at days 2, 4, 7 and 14. LABORAS measurements were taken over the course of 20h, allowing for the recording of naturalistic behavior over both dark and light circle. In addition, blood samples were processed at each time point to measure the level of cytokines in serum. The Catwalk system revealed a decrease in Print Area hind paw ratios of OA animals at day 2, day 4 and day 14. Hind paw ratios of OA animals were also significantly different for Swing, Swing Speed and Single Strance. Differences in rearing at day 2 post-MIA and locomotor duration at day 4 post-MIA were observed during the light cycle. No differences were observed in sham animals in both Catwalk or LABORAS. The cytokine profile revealed higher levels of anti-inflammatory cytokines IL-10 and IL-4 at day 14 post-MIA injection than at baseline. TNFα was increased at day 4 post MIA injection. These data suggest that OA animals use the injured limbed less during the early stages of inflammation (day 2 and 4) and during later stages (day 14) where neuropathic components may start to appear. No difference in walking is observed at day 7 where inflammation has thought to be resolved. Cytokine profile revealed an increase in TNFα in the inflammatory stage as previously reported but not in the later stage. Anti-inflammatory cytokines appear increased at day 14, suggesting that their action is necessary to aid the decrease in inflammation in the late stage.

Title: Task switching impairment under chronic neuropathic pain: Role of the intralaminar thalamus

Authors: *C. D. MONTES-ANGELES[1], E. PERRUSQUIA-HERNÁNDEZ[2], A. HERRERA-VALDIVIA[2], I. PÉREZ-MARTÍNEZ[2]
[1]Neurobio. of Oral Sensations, Univ. Nacional Autonoma de Mexico, Cuautitlan, Mexico; [2]Univ. Nacional Autónoma de México, Cuautitlan, Mexico

Abstract: Chronic pain involves central and peripheral changes in neural activity, impairing processes including attention, adaptation and action selection. The affected structure underlying this impairment might be the intralaminar thalamus, known as a mediator of the affective dimension of pain, of attention to salient stimuli and decision-making as an outcome, as well. The aim of this study is to assess the processing of action task switching under the influence of chronic neuropathic orofacial pain following a behavioral and physiological approach.
Methods: C57BL/6 male mice were divided in two groups: (1) mental nerve constriction injury (MnC) and (2) sham surgery. Spontaneous and evoked orofacial responses were measured in order to assess persistent pain and mechanical allodynia. The action selection process was evaluated during a switch-task and a
two-alternative forced choice task, in both freely moving and head restrained mice. Both evaluations will allow an adequate manipulation of different variables, and the precise control of neural circuits for its electrophysiological characterization and further optogenetic manipulation.
Results: Trigeminal injury increased the latency to correct switch responses to a stimulus. MnC decreased its responses frequency during an early phase of the task, and increased it in a late phase, as a sign of a lack of adaptation to the choice of the response to emit. Two alternative forced choice task was performed in order to test this impairment was due to disturbance in a cognitive but not in a sensory process.
The behavioral assessment of the cognitive impairment induced by chronic orofacial pain and a psychophysical approach of the mentioned processes will allow its study from a physiological and structural perspective, in order to find therapeutic alternatives, and to achieve the precise modulation of neuronal circuits commanding specific cognitive processes.

Abstract: Current pain medications that activate mu-opioid receptors have high abuse potential and are limited in their ability to effectively treat chronic pain. Here we evaluate the novel kappa-opioid receptor (KOPr) salvinorin A (SalA) analogues, 16-Ethynyl SalA and 16-Bromo SalA, alongside the prototypical KOPr agonist U50,488, for their ability to modulate both acute and chronic pain alongside behavioural side-effects. Dose-response warm water tail-withdrawal assays in mice shows SalA and the novel analogues 16-Ethynyl SalA and 16-Bromo SalA were more potent than the traditional KOPr agonist U50,488 with 16-Ethynyl SalA being more efficacious than U50,488. Both 16-Ethynyl SalA and 16-Bromo SalA had improved duration of action of analgesic effects evaluated in hot plate and tail-withdrawal assays compared to SalA. In the intraplantar formaldehyde test, both 16-Ethynyl SalA and 16-Bromo SalA significantly reduced nociceptive and inflammatory pain, paw oedema and infiltration of neutrophils in a KOPr dependent manner. In a mouse model of paclitaxel-induced neuropathic pain 16-Ethynyl SalA and 16-Bromo SalA were potent in reducing both mechanical and cold allodynia when administered acutely. In paclitaxel-treated mice administered KOPr agonists daily for 22 days, U50,488, 16-Ethynyl SalA, 16-Bromo SalA all significantly reduced paclitaxel-induced neuropathic pain with reduced tolerance effects compared to morphine. 16-Ethynyl SalA and 16-Bromo SalA have fewer aversive and anxiogenic side-effects when compared to SalA and U50,488 in conditioned place aversion and light dark tests. However, 16-Ethynyl SalA and 16-Bromo SalA showed significant impairment of motor co-ordination in the accelerating rota rod tests. Overall, our data suggests that 16-Ethynyl SalA and 16-Bromo SalA are effective in modulating nociceptive, inflammatory and neuropathic pain with reduced KOPr mediate side-effects and hold promise for development of effective pain medications without abuse liability.

Title: Pain-like withdrawal responses to conditioned auditory cues associated with repeated von Frey stimuli in two rat models of neuropathic pain

Authors: *B. R. BERKEMEIER, Q. R. SHIM, W. XIE, J. A. STRONG, J.-M. ZHANG
Univ. of Cincinanti, Cincinnati, OH

Abstract: Von Frey filaments are nylon monofilaments used to exert varying amounts of force to specific test sites by stimulating mechanoreceptors. The animal typically exhibits a behavioral paw withdrawal response when the filament is pressed against the paw. The question remains: does the von Frey filament evoke a reflex or is it an effective tool in measuring pain, which is a higher-order brain function? In order to test this we examined whether withdrawal responses evoked by von Frey filaments (unconditioned stimulus) could be conditioned by pairing with a conditioned stimulus (auditory tone). Groups of male Sprague-Dawley rats (n=4 rats per group) underwent surgeries to implement a neuropathic pain model - either Chronic Constriction Injury (CCI) or the longer-lasting Spared Nerve Injury (SNI). Control rats were uninjured. The rats were then tested as to whether or not they could learn to associate the conditioned stimulus (a 5 kHz sine wave played at approximately 60-65 dB for 10 seconds) with the unconditioned stimulus (von Frey poke) which was administered during the last second of the tone. Rats could avoid the von Frey poke by withdrawing the paw in response to the sound, prior to the filament application. Conditioning occurred 2 days per week and consisted of 3 sets of 10 trials. Rats with either neuropathic pain model, but not control rats, could learn to associate the tone with the von Frey poke. Behavioral responses to the tone included withdrawal of the paw, sometimes with licking and flicking of the paw, and sometimes other behaviors such as trying to bite the filament on sight. CCI rats had a peak in learned associations around day 20 and could no longer make associations by day 40. SNI rats could make associations for longer than the CCI rats, continuing to at least day 60. In another experiment, control rats were also tested with modified von Frey filaments with sharp pricking tips. These rats still could not make the learning association. We suggest that these findings demonstrate that von Frey filaments evoke pain, as spinal reflexes cannot generate these higher-order learning connections made within the brain. If these pathways

of association could be identified, we could potentially disrupt them, allowing for a new approach to alleviating neuropathic pain.

Title: Paraventricular hypothalamic stimulation restores spontaneous day/night activity in rats with neuropathic pain through spinal oxytocin receptors activation

Authors: *A. D. MANZANO GARCÍA, A. GÓNZALEZ HERNÁNDEZ, A. ESPINOSA DE LOS MONTERO ZÚÑIGA, G. MARTÍNEZ LORENZANA, M. CONDÉS LARA
Univ. Nacional Autónoma De México, Queretaro, Mexico

Abstract: Background and aims: Loose sciatic nerve ligation (LSN) induces hyperalgesia and allodynia, pain behaviors evoked by mechanical or thermal stimuli. Nevertheless, spontaneous (ongoing) pain is also relevant, but, little attention has been paid to this topic. In this context, we analyzed the changes in spontaneous day/night behavior (distance traveled, movement time, rest time, stereotypy time, vertical activity) in rats with LSN induced neuropathic pain. Then, we evaluated if hypothalamic paraventricular nucleus (PVN) electrical stimulation (with parameters to induce antinociception) restored the impaired spontaneous day/night behavior. Finally, we studied the role of spinal oxytocin receptors (OTR) in PVN-mediated antinociception.
Methods: At day 1 (D1) we did the LSN (left sciatic nerve) to male Wistar rats (180-220 g). Seven-days later (D7), we implanted a bipolar electrode into the left PVN; in the groups used to assess the role of OTR we implanted an intrathecal canula reaching the lumbar spinal cord also at D7. Fourteen-days after LSN (D14), spontaneous behavior was assessed 23-h/day/5 days using an automated open-field monitoring system. We performed the electrical PVN stimuli (1-ms, 60Hz, 6s, 100-300 µA) 3 times a day (9:00, 14:00 and 19:00); with the same schedule, we administered the OTR antagonist L368,899 (2µg/10µl) intrathecally.
Results: We found that the LSN diminished all the spontaneous behaviors except for the rest time, those behavioral changes were more notorious at night. PVN stimulation restored all the

behaviors; however, the sole electrode implantation (Sham group) had behavioral effects too. Data suggest the OTR participation in the PVN-mediated restoration of some behaviors (distance traveled, rest time) but not in others (stereotypy time). Moreover, OTRs seem to participate in a tonic way in antinociception since the sole antagonist L368,899 administration potentiated the behavior diminish produced by neuropathic pain. Finally, by using locomotor activity plots and heat-maps, we found that healthy animals tend to move in the periphery of plexiglass box avoiding the center of it, neuropathic animals tend to stay in one corner avoiding movement, and stimulated rats seem to stay more time in the center of the box.
Conclusions: The present data demonstrate that LSN diminishes spontaneous behaviors, preferentially at night. PVN stimulation (an antinociceptive procedure) restores those behaviors. Finally, data suggest the tonic antinociceptive participation of the oxytocinergic system in neuropathic pain.Acknowledgments: Special thanks are due to Dr. Daisy Gasca-Martínez for her technical assistance.

Title: Probing roles of sensory neuron subtypes in nociception via chemo-optogenetics

Authors: *B.-Y. JIANG[1], C.-C. CHEN[3], S.-H. LIN[2], C.-H. LEE[4]
[1]Inst. of Biomed. Sciences, Academia Sinica, Nangang, Taiwan; [2]Inst. of Biomed. Sciences, Academia Sinica, Taipei, Taiwan; [3]Academia Sinica, Taipei, Taiwan; [4]Inst. of Biomed. Sci. Academia Sinica, Taipei, Taiwan

Abstract: Clinically, pain can be divided into evoked pain and spontaneous pain. Evoked pain is pain behaviors triggered by noxious thermal stimuli (thermal nociception), mechanical stimuli (mechanical nociception) or chemical stimuli (chemical nociception); spontaneous pain is pain behaviors without external stimuli such as flinching or guarding behaviors. Accumulated evidence has shown that several nociceptive neuron populations involved in different evoked pain sensation such as thermal nociception, mechanical nociception and chemical nociception. However, little is known about the nociceptive neuron populations contribute to spontaneous pain. In formalin test, we found that formalin-induced mechanical hyperalgesia resolved earlier

than guarding pain behaviors in mice. Therefore, we hypothesized nociceptive neurons contribute to evoked pain are distinguishable from those contributed to spontaneous pain. Here, we aim to develop a chemo-optogenetics method to activate specific nociceptive neuron subtypes from periphery, in which channelorhodosin is activated via a chemical ligand. Thus this chemo-optogenetics approach allows us to probe the roles of all neuron subtypes in evoked pain or spontaneous pain. We first generated a Cre-dependent reporter mouse line that carries a luminopsin 3, a fusion protein of channelorhodosin and luciferase. We then used coelenterazine (CTZ), a natural subtract of luciferase to activate LMO3-positive dorsal root ganglion neurons via peripheral nerve terminals and tested the evoked and ongoing pain behaviors in neuron subtype-specific Cre-line::LOM3 mice. Results showed that CTZ dose-dependently increased both von Frey responses (evoked pain) and flinching behaviors (spontaneous pain) in TRPV1-Cre::LMO3 mice. We then further tested the roles of different neurons subtypes (e.g., neurons expressing tyrosine hydroxylase, ASICs, Nav1.8, etc.) in evoked pain and/or spontaneous pain. Together, we have successfully established a mouse model ideal for probing the roles of sensory neuron subtypes in nociception via chemo-optogenetics.
Key words: spontaneous pain, ctz, luminopsin 3, chemo-optogenetics, TRPV1

Title: Perturbation of central amygdala neuron excitability reduces pain- and anxiety- like behaviors

Authors: *Y.-L. LIN[1], C.-C. LIEN[2]
[1]Inst. of Neuroscience, Natl. Yang Ming Univ., Taipei, Taiwan; [2]Natl. Yang-Ming Univ., Taipei, Taiwan

Abstract: Chronic pain disorder is associated with anxiety- and depression-like behavior. Although the amygdala is thought as a key node of the neural circuits mediating emotions, it also serves a major receiver of purely nociceptive signals. However, the circuit mechanisms by which the amygdala contributes to the pain-related anxiety has remained unclear. Here, we investigated circuit mechanisms underlying comorbid symptoms in chronic pain mouse models, including

acid-induced muscle pain. We first found that the phosphorylated ERK (pERK) level increased in the lateral subdivision of central amygdala (CeL) after chronic pain development. To address the role of the CeL in chronic pain, we attempted to manipulate CeL neurons using chemo- and opto-genetic approaches. We hypothesized that silencing of somatostatin-positive (SOM^+) neurons in the CeL, which may activate CeL output neurons (i.e., SOM^- neuron) and thereby suppresses the CeM projecting neurons, which reduces mechanical sensitivity and chronic pain-related behavior. In chemogenetic part, selective expression of designer receptors exclusively activated by designer drugs (DREADDs) was achieved by injecting a virus encoding Cre-dependent inhibitory DREADDs (i.e., hM4Di receptor) into a SOM-Cre driver, a mouse line specifically expressing Cre recombinase in a major population of the CeL. In optogenetic part, we expressed inhibitory halorhodopsin (eNpHR) in SOM^+ cells in the CeL. Consistent with this hypothesis, we found that both chemo- and opto-genetic silencing of SOM^+ neurons in the CeL reduced mechanical sensitivity and comorbid anxiety-like behavior.

Title: Antinociceptive action of achillea biebersteinii methanolic flower extract is mediated by interaction with cholinergic receptor in mouse pain model

Authors: *S. M. JAFFAL[1], M. ABBAS[2]
[1]Dept. of Biol. Sci., The Univ. of Jordan, Amman, Jordan; [2]Fac. of Pharm. and Med. Sci., Al-Ahliyya Amman Univ., Amman, Jordan

Abstract: *Achillea biebersteinii* is a perennial aromatic herb that grows in the Mediterranean area. In folk medicine, it is used for the treatment of abdominal pain and stomach ache. In this study, *A. biebersteinii* flowers were collected from Al- Bukaan, Jordan and the extract was prepared in methanol. The analgesic effect of *A. biebersteinii* methanolic flower extract was tested in three pain models namely: writhing, hot plate and formalin tests in BALB/c mice. The intraperitoneal (ip) administration of *A. biebersteinii* extract (300 mg/kg and 500 mg/kg) inhibited acetic acid induced abdominal cramps. The effect of 300 mg/kg *A. biebersteinii* was comparable to that of 70 mg/kg indomethacin. No effect of the extract was observed in a thermal pain model. In formalin test, *A. biebersteinii* extracts (300 mg/kg and 500 mg/kg) decreased paw-licking and flinching responses in the early and late phases. Atropine (5 mg/kg, ip) blocked

the action of *A. biebersteinii* extract in late phase only. This indicates the involvement of cholinergic receptor in the antinociceptive action of this plant. Other mechanisms are currently being investigated in the lab. In conclusion, our study supports the use of *A. biebersteinii* as a painkiller in folk medicine.

Sci., Seoul, Korea, Republic of

Abstract: A long term functional and reliable coupling between neural tissue and implanted neural electrodes are the key issue to acquiring neural signals or to restore neural functions after peripheral nerve injury. Prior to the clinical application neural electrode for patients with neurological disorders to restore their sensory and motor functions in patients with neurological disorders, the behavioral and histological consequences of these devices must be investigated. In the present study, we investigate changes in the sensory and motor functions in sciatic nerve injured rats after the implantation of neural electrode, sieve type neural electrodes that can acquire bidirectional neural signals with multi channels and high selectivity. The sciatic nerve injury (SNI) was made by the ligation in right side sciatic nerve and neural electrode was implanted above the injured site 2 weeks after injury. The overall consequences of implantation including motor and sensory function were performed in rats with SNI, skin incision (SI: sham) and sieve type neural electrode implantation after SNI. Motor function was assessed by physical activity such as total distance, mean of velocity. Mechanical sensitivity was assessed by Paw withdrawal threshold (PWT) to von Frey filaments in the hind paw. After the SNI, total distance and mean of velocity were significantly decreased and then spontaneously recovered from 4 days

after injury. In the skin incision group, there was no significant difference in both total distance and mean of velocity when it compared to those of pre-values. After the sieve type neural electrode implantation, rats showed a significant decrease in total distance and mean of velocity. The decreased velocity of movement and the decreased total distance of movement were maintained to 28 days after implantation. In the skin incision group, there was no significant difference in both total distance and mean of velocity when it compared to those of pre-values. In sensory function, rats with skin incision did not show a significant change in PWT compared to that of pre-value. PWT in rats with electrode implantation was decreased from 7 days but there was no significant difference compared to those of SNI group. These results indicated that the general physical activity was slightly decreased after the sieve type neural electrode implantation but neural electrode implantation does not exacerbated mechanical sensitivity.

Title: Haploinsufficiency of the brain-derived neurotrophic factor (BDNF) gene causes reduced pain sensitivity in an animal model and humans with the WAGR copy number variant

Authors: *M. R. SAPIO[1], M. J. IADAROLA[1], A. J. MANNES[1], J. C. HAN[2]
[1]NIH, Bethesda, MD; [2]Dept. of Pediatrics, Univ. of Tennesee Hlth. Sci. Ctr., Memphis, TN

Abstract: Rare pain insensitive individuals offer unique insights into how pain circuits function, and have led to the development of new strategies for pain control. We investigated pain sensitivity in humans with WAGR (Wilms tumor, aniridia, genitourinary anomaly, mental retardation) syndrome, who have variable-sized hemideletion of the 11p13 region. The deletion region can be inclusive or exclusive of the brain-derived neurotrophic factor (*BDNF*) gene, a crucial trophic factor for nociceptive afferents. By mapping the deletion boundaries, and by using trancriptomic analyses of gene expression, we narrowed the possible causal genes to a small locus shared by the pain insensitive individuals, supporting that *BDNF* deletion was the most likely candidate to explain the pain insensitivity phenotype. Nociceptive responses assessed by quantitative sensory testing (QST), demonstrated pain insensitivity only in the WAGR subjects whose hemideletion included the *BDNF* gene. This pain insensitivity was present in

both hot and cold modalities. At highly noxious stimuli, the pain insensitive WAGR subjects were able to rate these stimuli as noxious, suggesting some degree of preservation of the nociceptive circuit. Analogous experiments in heterozygous *Bdnf* mutant rats revealed impairment in a variety of tests for cold and Aδ- and C-Fiber mediated heat nociception similar to what was observed in the human. These rats also responded to highly noxious stimuli but showed insensitivity to pain in the mildly noxious hot and cold range. Many pain insensitivity phenotypes to date have been localized to ablation or inactivation of primary afferent sensory neurons in the dorsal root ganglia. RNA-Seq analyses were performed on rat dorsal root ganglia and spinal dorsal horn, together containing the first two neurons in the pain circuit. In these analyses, *Bdnf*+/- rats showed gene signatures indicative of normal sensory neurons but a greater degree of abnormality in the spinal cord, consistent with the idea of altered spinal circuits related to processing and transmitting painful sensory inputs. Our parallel observations in humans and rats assign causality to the heterozygous loss of the *BDNF* gene and establish BDNF as a major determinant of nociceptive sensitivity.

Nacional de Psiquiatría Ramón de la Fuente Muñiz, Tlalpan, Mexico; [4]Dirección de Investigaciones en Neurociencias, INPRFM, Ciudad dE Mexico, Mexico

Abstract: Background. Opioidergic drugs are the most potent and efficacious treatment for pain relief, but its use is limited by the adverse effects that the chronic use entails. D2-like receptor (RD2) agonist induces significant analgesia at spinal cord level, but its effectiveness is more modest compared with opioids. At synaptic level, between C-fibers and dorsal horn neurons, it has been reported a synergic effect of quinpirole co-administrated with the mu-opioid receptor (MOR) agonist. Increased expression of MOR and RD2 has been observed in dorsal root

ganglion (DRG) and the superficial laminae of the dorsal horn in rats after sciatic nerve injury, also there were more DRG neurons co-expressing both receptors when neuropathy was installed. There is no evidence at behavioral level if intrathecal (i.t.) co-administration of D2-like agonist (quinpirole) potentiates the analgesic effect of a MOR agonist (DAMGO) in nociceptive (NOC), inflammatory (IF) and neuropathic (NP) models of pain. *Methods*. Male Wistar rats were used (250-350 g) for the study. Hargreaves' apparatus and aesthesiometer were used for the thermal and mechanical behavioral test respectively. Drugs were i.t. administrated at lumbar level. Intraplantar injection of complete Freund's adjuvant (CFA) was used to induce the IF model, and sciatic nerve loose ligation for the NP model. All the experiments were approved by our Institutional Ethics Committee. *Results*. Dose-response curves were obtained for both agonists; maximal analgesia was seen at 15 min. Analgesia produced by DAMGO was statistically significant in thermal and mechanonocicepive tests meanwhile quinpirole was significant only in mechanonociception. Quinpirole co-administration (1 nmol; this dose produced the 50% of the maximal effect) potentiated the DAMGO analgesic effect diminishing its ED_{50} 6-fold only in mechanonociception. In the IF model, we used the first dose that produced analgesia in the synergy assay and was compared with the agonists administrated alone. Co-administration reverted hyperalgesia and returned latencies to its basal levels in both behavioral tests, which didn't happen when agonists were administrated alone. In NP, the results were similar. Co-administration produced partial reversion of allodynia, but drugs alone did not. *Conclusions*. I.t. co-administration of quinpirole and DAMGO potentiated the analgesia produced by MOR activation in NOC, IF and NP pain models. The results suggest that the combination of sub-effective doses of D2-like agonist could increase the analgesic effects of μ-receptor agonists, in a dose-specific manner and could reduce the secondary effects mediated by the same receptor.

Title: Behavioral scaling of the intensity of mechanical and heat stimulation of the cheek in mice

Authors: N. M. MALEWICZ[1], Z. ZHANG[1], N. KUMOWSKI[1], O. HURWITZ[1], S. G. SHIMADA[1], H. NIE[2], *R. H. LAMOTTE[1]

[1]Dept Anesthesiol, Yale Univ. Sch. Med., New Haven, CT; [2]Pharmacodynamics, Col. of Pharmacy, Jinan Univ., Guangzhou, China

Abstract: Sensory testing of the cheek in mice with mechanical and thermal stimulation is not standardized nor validated and difficult to apply. We developed a stimulation procedure and a discomfort rating score (DRS) to evaluate behavioral responses of mice to innocuous and nociceptive heat and punctate mechanical stimuli, of different intensities applied to the cheek. C57BL/6 mice (6 - 8 weeks old) were stimulated on the cheek in a meshed test chamber with Von Frey-type filaments (VFFs) delivering different bending forces (2 - 40 mN) but with the same tip diameter (either 0.1, 0.2 or 0.4 mm), or with a contact thermode (2 x 3 mm, 38 °C, warmth; 52 °C, noxious heat) (n=10-12 per group). Behavioral responses were video recorded and scored with experimenters blinded as to treatment condition. The DRS differentiated between no reaction, looking, withdrawal, flinching, biting, shaking, jumping and vocalizing with each wipe added into each score. Additional tests were conducted with the 0.1 mm VFFs to validate the DRS as a means of using aversive behaviors to scale graded nociceptive stimuli by measuring 1) facial grimaces using the Mouse Grimacing Scale (MGS, after Langford et al. 2010) (n=12) 2) Withdrawal latencies (measuring skin contact electrically) (n=14) and 3) by measuring the changes in DRS produced 48 hrs after intradermal injection of a desensitizing dose of capsaicin (n=8) or by the development of allergic contact dermatitis (ACD) produced by sensitizing the abdomen and subsequently challenging the cheek with topical 1% squaric acid dibutyl ester (n=10). All procedures were consistent with IASP guidelines and approved by Yale IACUC.

The thermode evoked a significantly different DRS for 52 vs. 38 °C. VFFs of a given tip diameter elicited monotonically increasing DRS scores with increases in force. The force required to elicit a given DRS decreased with tip diameter. Responses to VFFs with a 0.1 mm tip resulted in best statistically distinguishable behaviors and DRS. For the 0.1 mm tip VFFs, higher DRS values correlated with increased MGS ratings and shortened withdrawal times. A significant increase of DRS correlating with higher MGS and shortened withdrawal times was detected for heat vs warmth. DRSs in response to the 0.1 mm VFFs or to warmth and to noxious heat decreased significantly after capsaicin (desensitization) and increased after ACD (hyperalgesia).

The findings provide a validation of methods to score aversive behavioral responses that can be used to differentiate between and scale different intensities of punctate mechanical and heat stimuli delivered to the cheek.

Title: Mental nerve injury induces novelty-seeking behavior leading to increasing ethanol intake in wistar rats

Authors: E. PERRUSQUIA, R. C. ACEVEDO, C. D. MONTES-ANGELES, *I. O. PEREZ-MARTINEZ
Lab. of Neurobio. of Oral Sensations, Cuautitlán Mexico, Mexico

Abstract: The chronic neuropathic orofacial pain (CNOP) is freque ntly induced by dental treatment and orofacial surgeries. This kind of pain affects the adaptability to environmental changes in both model animals and humans.
Part of adaptation process depends on the ability to recognize between familiar and novel stimuli. CNOP induces novelty-seeking behavior as a deficit in environmental adaptation. Another side, the novelty-seeking is a sign for susceptibility to development abuse of drugs. Evidence shows that CNOP leads to alcoholism in animal models. The behavioral relationship between CNOP, novelty seeking behavior, and substance abuse is unknown. In this article, we address if CNOP produces increasing in novelty seeking and leads to alcoholism. At first, we used the mental nerve injury as neuropathic orofacial pain model; we evaluate both thermal and mechanical allodynia. We used the novel recognition task to determine the novelty-seeking behavior and the drink-in-darkness protocol to assess binge ethanol intake. Our results show that mental nerve constriction increases the novelty-seeking behavior ($p=0.01$) and correlates with ethanol binge consumption ($r2=0.68$, $p=0.0008$). The increasing of novelty-seeking behavior can serve as a predictor of risk to developing drug abuse. The treatment of chronic neuropathic orofacial pain involves the high risk to produce addiction when is used opioids. The level of novelty-seeking evaluation in patients with neuropathic pain before treatment is critical. The present study demonstrates for the first time that trigeminal injury, which induces CNOP, is enough to provide the novelty-seeking behavior and lead to ethanol binge intake.

Title: Spinal mobilization mitigates NGF induced reduction of rat exploratory behavior

Authors: *W. R. REED[1], J. W. LITTLE[5], T. J. NESS[2], R. E. SORGE[3], P. LI[4]
[1]Physical Therapy, [2]Dept Anesthesia, [3]Psychology, [4]Biostatistics, Univ. of Alabama at Birmingham, Birmingham, AL; [5]Dept. of Surgery, St. Louis Univ. Sch. of Med., Saint Louis, MO

Abstract: Low back pain (LBP) is a complex and poorly managed global health problem with lifetime prevalence rates ranging from 60-80%. Spinal mobilization (SM) is a commonly used non-pharmacological approach for the treatment of non-specific LBP. However, greater utilization and clinical optimization of SM has been hampered by a lack of knowledge regarding its underlying physiological mechanisms and good preclinical models in which to study the development and/or treatment of chronic LBP. Nerve growth factor (NGF) is a naturally occurring neurotrophin implicated in the regulation of mechanical/thermal hyperalgesia in both animals and humans. Damaged or overworked skeletal muscles experience increased NGF levels which likely contribute to the physical complaints associated with non-specific LBP. To determine the impact of SM on rat exploratory behavior in a LBP model, two unilateral L5 multifidus injections of NGF (0.8µM, 50µL) or Phosphate buffered saline (PBS; 50 µL) were delivered at an interval of 5 days (on Day 0 and Day 5) in experimental groups with or without 10 minutes of daily SM. Four groups (PBS, PBS+SM, NGF, NGF+SM) of adult female Sprague-Dawley rats were used (n=8 per group). SM (1.2Hz, 0.9N) was delivered under isoflurane anesthesia beginning on Day 1 using a computer controlled feedback motor. All experimental animals regardless of group received 10 minutes of daily isoflurane to control for this experimental variable. The change between baseline and day 11, a time point of established persistent LBP, for each group was evaluated using paired t tests and the difference across groups was evaluated with an ACOVA model and post hoc t tests. Compared to 10 minutes of baseline open field testing, at Day 11 the number of rearing events decreased for all groups ($P<0.05$), where the NGF group decreased more than the PBS group (24±9 vs 11±11, $P=0.04$) and the NGF+SM group had a significantly greater number of rearing events compared to the NGF group (36±13 vs 16±5, $P<0.01$). Similarly at day 11, the total distance (in) traveled significantly decreased for all groups ($P<0.05$), where the NGF+SM group traveled significantly greater distances than the NGF group (953±171 vs 675±192, $P=0.01$). While the physiological

mechanisms responsible for these SM-related effects on exploratory behavior are currently unknown; clinically, the therapeutic effect of spinal manual therapy is thought to be related to the diverse cutaneous and musculoskeletal mechanoreceptor stimulation inherent to manual therapy delivery. Future work using this LBP animal model will investigate potential peripheral/central mechanisms of SM and other manual therapies.

Title: Sex-dependent age-differences in response to an acute model of post-surgical pain

Authors: *N. DOS SANTOS, L. T. THOMPSON, M. D. BURTON
Sch. of Behavior and Brain Sci., Univ. of Texas At Dallas, Richardson, TX

Abstract: Aging-related studies in animal models of pain plasticity leading to chronic pain remain rare. This is in spite of the prevalent association of aging with chronic pain in human populations. Several studies show significant age differences in the onset and development of chronic pain. Young males develop more robust mechanical allodynia than old males in response to spared nerve injury and to chronic inflammation. Decreased spontaneous activity of C-fibers from aged animals has also been reported. In the present study, to explore both sex- and age-differences in the development of acute pain, we modified the traditional Brennan incision model to involve a more extensive injury to underlying muscle, to mimic a more severe trauma. This involved incision of skin and musculature of the plantar aspect of the hind paw in both young (4-5 mo) and aged (>22 mo) male and female FBN hybrid rats. To reveal differences in the plasticity circuitry to chronic pain, we utilized a hyperalgesic-priming model. All groups of animals received a sub-threshold dose of prostaglandin E2 (100 ng) in the plantar aspect of the surgerized hind paw 21 d after incision. Withdrawal threshold to mechanical stimuli was tested using von Frey filaments around the surgery site. Thermal hyperalgesia was assessed using the Hargreaves apparatus. Additionally, to assess post-surgical inflammation, temperature of the plantar aspect of the hind paw was recorded using a forward-looking infrared (FLIR) camera. Preliminary data reveals sex- and age-differences in response to the incision. Males in both age

groups resolve mechanical hypersensitivity and thermal sensitivity within 7 d after injury, but females present more variability on the resolution of pain. Temperature of the plantar skin is significantly higher during 7 d post-injury, with no significant difference between groups. Old males take longer to exhibit mechanical sensitization, showing aggravated response 3 d after incision in comparison to 1 d after incision in young males. No age-related differences in mechanical allodynia were seen between old and young females. There is no significant difference in the hyperalgesic-priming phase across all groups. FBN rats show sex-dependent thermal sensitivity: Females have greater thermal hyperalgesia following incision than males. These studies are the first of their kind to assess models of acute pain and the transition to chronic pain in aged male and female animals. The results suggest that the age-related delay of the onset of acute pain is exclusive to males.

Title: A low dose of quercetin modifies the antialodynic effects of BD-1063

Authors: *J. ESPINOSA[1], O. A. JARAMILLO-MORALES[2], L. MENA-VALDEZ[3], A. ALEJO-MARTÍNEZ[3], F. J. LÓPEZ-MUÑOZ[3]
[1]Cinvestav-Ipn, Mexico, D.F., Mexico; [2]Cinvestav, Ciudad de Mexico, Mexico; [3]Cinvestav-IPN, Cinvestav-IPN, Mexico

Abstract: BACKGROUND. The treatment of neuropathic pain is performed according to the etiology. The most used drugs are neuromodulators; however, exist others pharmacological strategies that may be potentially useful. The aim of this study was study the anti-allodynic effects of a sigma-1 antagonist (BD-1063) and quercetin in combination using a model of neuropathic pain. **METHODS**: Wistar male rats were employed and subjected to chronic constriction injury (CCI), 10 days after surgery the anti-allodynic effect (acetone test) after single-dose of BD-1063 (5.6 - 56.2 mg/kg s.c.), quercetin (5.6 mg/kg) and the combination of BD-1063 and quercetin 5.6 mg/kg were tested. **RESULTS**: The anti-allodynic effect of BD-1063 increased in a dose-dependent manner. The effect of quercetin (5.6 mg/kg) was 15.85 ± 14.6 au. The time-course shows that BD-1063 (56.2 mg/kg) reached its maximum effect at 30 min, producing an anti-allodynic effect of 89.8 ± 2.4 %, whereas BD-1063 (17.8 mg/kg) + QUER (5.6 mg/kg) produced their maximum effect at 90 min with 77.1 ± 4.2 %. It is possible to observe that the curve of the combination moves to the left. The comparison of the ED_{50} shows that a smaller amount of BD-1063 is required in combination (10.8 mg/kg) to achieve the same level of effect

that the individual administration (22.7 mg/kg). Of the different doses in combination, 2 resulted in supra-additive effects when compared with the theoretical sum. The association of BD-1063 (17.8 mg/kg) with quercetin (5.6 mg/kg) showed a higher percentage of potentiation (182%) with an effect of 192.2 ± 8.3 au. **CONCLUSION**: The pharmacological association of a sigma-1 antagonist and the flavonoid quercetin may be useful in the treatment of neuropathic pain. The anti-allodynic effects shown by BD-63 individually administered were modified when combined with a dose of quercetin which alone did not show anti-allodynic effects.

Title: Losartan, an angiotensin II type 1 receptor antagonist, alleviates mechanical hyperalgesia in a rat model of chemotherapy-induced neuropathic pain by inhibiting inflammatory cytokines in the dorsal root ganglia

Authors: *E. KIM[1,2], H. KIM[2], S.-H. HWANG[2], H.-K. KIM[1], S. ABDI[2]
[1]Dept. of Anesthesia and Pain Medicine, Sch. of Med., Pusan Natl. Univ., Busan, Korea, Republic of; [2]Pain Med., MD Anderson Cancer Ctr., Houston, TX

Abstract: Chemotherapy-induced peripheral neuropathy (CIPN) adversely impacts quality of life and a challenge to treat with existing drugs used for neuropathic pain. Losartan, an angiotensin II type 1 receptor (AT1R) antagonist widely used to treat hypertension, has been reported to have analgesic effects in several pain models. In this study, we assessed losartan's analgesic effect on paclitaxel-induced neuropathic pain (PINP) in rats and its mechanism of action in dorsal root ganglion (DRG). Rats received intraperitoneal injections of 2 mg/kg paclitaxel on days 0, 2, 4, and 6 and received single or multiple intraperitoneal injections of losartan potassium dissolved in phosphate-buffered saline at various times. The mechanical thresholds, protein levels of inflammatory cytokines, and cellular location of AT1R and interleukin 1β (IL-1β) in the DRG were assessed with behavioral testing, Western blotting, and immunohistochemistry, respectively. Data were analyzed by two-way repeated measures analysis of variance for the behavioral test or the Mann-Whitney U test for the Western blot analysis and immunohistochemistry. Single and multiple injections of losartan ameliorated PINP,

and losartan delayed the development of PINP. Paclitaxel significantly increased, and losartan subsequently decreased, the expression levels of inflammatory cytokines, including tumor necrosis factor α and IL-1β, in the lumbar DRG. AT1R and IL-1β were expressed in both neurons and satellite cells and losartan decreased the intensity of IL-1β in the DRG. Our results indicate that losartan may ameliorate PINP by decreasing inflammatory cytokines. Its use as a new or add-on therapy for CIPN patients should be investigated.

Title: Investigating the comorbidity of chronic pain and depression

Authors: *V. MICHAILIDIS, C. CHO, M. SIVASELVACHANDRAN, E. ACLAND, N. LIDHAR, C. CHAN, L. J. MARTIN
Univ. of Toronto, Mississauga, ON, Canada

Abstract: Chronic neuropathic pain patients experience drastic changes in quality of life. In particular, 30%-50% of chronic neuropathic pain patients report depression as a side effect, suggesting a link between chronic pain and depression. Of the patients experiencing the comorbid disease, almost half are female. However, most of clinical research conducted on this comorbidity use male inbred rodent strains, which may not be as transferable to the affected female population. As such, our study aimed to characterize any sex differences in the depressive phenotype following peripheral nerve injury of an outbred mouse strain. We used male and female CD-1 mice (6-8 weeks) characterized on a battery of tests designed to assess sensory thresholds, learned helplessness, anhedonia and anxiolytic behavior for 4 weeks following peripheral nerve injury. Our results indicate that peripheral nerve injury caused mechanical pain sensitivity in both male and female mice. Further, peripheral nerve injury induced anxiety in male mice as evinced by decreased time spent in open areas of the open field test. Conversely, injury caused a depressive phenotype in both sexes, 2 weeks following surgery as determined by the forced swim test. Interestingly, males recovered, while this behavior persisted for the female mice, suggesting a sex difference for the depressive phenotype time course. We also observed that nerve injury did not induce any changes in sucrose preference as both SNI and sham mice exhibited similar preference scores for sucrose across all time points. Lastly, there was a trend that indicated nerve injury increased latency to feed on the novelty suppression-feeding test,

however, this trend was only noticed in females at the 4-week time point, again suggesting a sex difference in the depressive phenotype. Overall, our experiments demonstrate that chronic neuropathic pain can induce sex specific changes in affect and thus demonstrates the importance of female inclusion in experiments.

Title: A mechanistic study of cmt2b peripheral sensory neuropathy

Authors: *C. WU[1], K. J. SUNG[2], W. YANG[4], H. LIU[3], C. JOLIVALT[3], N. CALCUTT[3]
[1]Neurosciences MC0624, UCSD Sch. of Med., La Jolla, CA; [2]Univ. of California San Diego, LA Jolla, CA; [3]Univ. of California San Diego, La Jolla, CA; [4]Dept. of Neurology, Ruijin Hosp., Shanghai City, China

Abstract: CMT2B, a rare but debilitating disease, features a prominent axonopathy - i.e. axonal dysfunction and degeneration - of peripheral sensory neurons. Patients lose pain sensation and frequently undergo amputation of the distal lower limbs. Genetic analyses have revealed missense autosomal dominant point-mutations in Rab7 (L129F, K157N, N161T/I, V162M). Currently, there are no disease-modifying treatments. We generated a knockin mouse model, the first ever rodent model for CMT2B. We have demonstrated in preliminary studies the mutant mice developed sensory deficits both functionally and structurally. The proposed study is to confirm and extend preliminary findings to explicate the mechanisms that underlie disease pathogenesis towards future discovery of treatment methods for CMT2B. The knockin mouse model of CMT2B that we have generated carries the Rab7V162M allele. The creation of the mouse is based on a well-characterized family of human CMT2B-Rab7V162M patients. Our preliminary results in the knockin Rab7V162M mutant mice demonstrate significant deficits in peripheral sensory function in comparison to wildtype littermates (+/+). The findings are consistent with an autosomal dominant effect. Furthermore, mice homozygous for the mutation (fln/fln) display more severe phenotypic manifestation than heterozygous littermates (+/fln), pointing to a possible gene-dosage effect. Consistent with findings in human CMT2B patients, mutant mice display no apparent deficits in learning and memory. Encouraged by these results, we propose to confirm and extend findings on the Rab7V162M knockin mouse, to demonstrate both its fidelity with respect to the human disease, and to decipher CMT2B disease mechanisms at the cellular and molecular level. Importantly, our preliminary studies and published work

shows that in mammalian cells CMT2B Rab7 mutations enhance activation of Rab7, resulting hyper-functional lysosomes and autophagy. Based on these studies, we will take advantage of the Rab7V162M knockin mouse to test the hypothesis that axonal dysfunction and degeneration in CMT2B is due to increased activation of Rab7 with consequent hyperactivity of the lysosome and autophagy pathways.

Abstract: Neonatal surgical trauma leads to exacerbated pain hypersensitivity after adult incision. Previously, we and others have reported that spinal Src homology-2 domain-containing protein tyrosine phosphatase-2 (SHP2) and brain-derived neurotrophic factor (BDNF) contribute to neuropathic pain and inflammatory pain in adult rodents. In this work, we investigated mechanisms in the spinal dorsal horn underlying the exaggeration of incisional pain induced by neonatal hindpaw incision. (1) Neonatal incision elevates the phosphorylation and expression of SHP2 in synaptosomal fraction of the spinal dorsal horn in adult rats subjected to neonatal incision and adult incision (nIN-IN), and the upregulation of SHP2 is highly correlated with pain hypersensitivity. Blockade of SHP2 phosphorylation in the dorsal horn using a SHP2 protein tyrosine phosphatase inhibitor NSC-87877, or knockdown of SHP2 by intrathecal delivery of small interfering RNA (siRNA), attenuates exacerbated pain hypersensitivity in nIN-IN rats.

Furthermore, the concentration of spinal phosphatidylinositol 3-kinase (PI3K) is significantly increased, which is highly correlated with pain behaviors in nIN-IN rats. Intrathecal application of PI3K inhibitors, LY294002 or wortmannin, alleviates exacerbated pain hypersensitivity in nIN-IN rats. Additionally, intrathecal administration of NSC-87877 or SHP2 siRNA attenuates the upregulation of PI3K. However, the phosphorylation of SHP2 and the expression of PI3K in the dorsal root near the dorsal surface of the spinal cord are not changed at the same time points used in detections of the spinal cord. (2) Spinal BDNF is significantly upregulated in nIN-IN rats. Coincidently, blockade of spinal BDNF alleviates pain hypersensitivity in nIN-IN rats, while spinal administration of exogenous BDNF in adult rats with only neonatal incision mimics exacerbated pain hypersensitivity, which have been found in nIN-IN rats. Finally, intrathecal application of minocycline to inhibit microglial reactivity attenuates the upregulation of BDNF and alleviates pain hypersensitivity in nIN-IN rats. Altogether, we provide solid evidence that spinal SHP2 and BDNF contribute to neonatal incision-induced exacerbation of incisional pain following adult incision.

Title: Electrophysiological characterisation of nociceptive lamina I spinoparabrachial neurons in the anesthetized mouse

Authors: *J. ALLARD
E-Phys, Clermont-Ferrand, France

Abstract: Recent behavioural and ex vivo electrophysiological experiments using wild type and KO mice have highlighted the role of lamina I projection neurons (PN) for the generation of pain sensation in pathological conditions. However, data on the in vivo properties of lamina I PN of the *mus* gender are markedly limited. The aim was to establish the physiological properties of lamina I spinoparabrachial neurons in naïve mice, and to evaluate the effect of “pharmacological disinhibition” on neuronal responses to light touch. Experiments were conducted in ventilated, isoflurane anesthetized, Swiss mice. Electrical activity was recorded using a tungsten microelectrode. Lamina I PN were searched for using antidromic stimulations from the parabrachial region. Mechanical and thermal stimuli consisted of brush, Von Frey hair (VF), pinch with haemostat clamp, and water jet (10 ml). Responses to electrical stimuli (ES) were generated using needles inserted in the receptive field. After the initial characterisation,

responses to brush and VF were reassessed before and after application of vehicle or a mix of bicuculline + strychnine (BS) on the spinal cord. Responses were measured as peak firing frequency over 0.1 s and number of action potentials (AP) over 5 s. Electrolytic lesion was performed to locate the recording site. Seventy one lamina I units satisfying classical PN criteria were characterized, with conduction velocities of 4.7 (3.0-6.5) $m.s^{-1}$ (data given as median (25^{th}-75^{th} percentiles)). Fifty seven units were classified as polymodal PN, and 14 as modality specific/preferential PN (2 heat, 2 mechanical, 10 cool/cold). Five, 14, 11, 9, 8 and 10 polymodal PN had mechanical thresholds corresponding to brush, VF 25, 50, 100, 200 mN and pinch, respectively. Polymodal PN responded to pinch with 96 (53-169) AP at 70 (45-105) Hz, and to WJ 50 °C with 163 (20-230) AP at 120 (55-170) Hz. Cool/cold PN responded to WJ 0 °C with 127 (110-156) AP at 105 (47-152) Hz. The maximum number of C fibre-induced AP in response to ES was 3 (1-5) AP. Upon repeated ES at 1 Hz, 12/27 PN did not show wind up. Increased response to brush was observed in 1/13 (+3 AP, +60 Hz) and 24/47 (+11 (6-22) AP, +85 (40-130) Hz) PN after vehicle and BS application, respectively. Increased responses to VF paralleled enhanced response to brush after BS application. Lamina I spinoparabrachial PN constitute a highly heterogeneous population, with about 70 % being nociceptive specific, and 50 % showing appearance/increase of responses to light touch upon local disinhibition. The specific physiological properties of the subgroup of lamina I PN responsible for abnormal pain in pathological conditions require further investigation.

Title: Reduced muscle growth hormone levels regulate peripheral sensitization after incision through macrophage-dependent sequestering

Authors: *A. J. DOURSON[1], C. E. MCCROSSAN[1], Z. K. FORD[1], M. C. HOFFMAN[1], M. P. JANKOWSKI[1,2]
[1]Anesthesia, Cincinnati Children's Hosp. Med. Ctr., Cincinnati, OH; [2]Dept. of Pediatrics, Univ. of Cincinnati, Col. of Med., Cincinnati, OH

Abstract: Growth hormone (GH) is a well-known regulator of growth and homeostasis. Reports have also shown that in addition to growth problems, children with deficits in GH have a resting pain in their limbs. Furthermore, exogenous GH treatment may relieve pain in subsets of patients with fibromyalgia and in children with cutaneous ulcers. However, the role of GH in nociceptive processing is largely unknown. Our recent preclinical data showed that low dose GH pre-treatment could significantly block inflammation induced afferent sensitization and pain-related behaviors in neonatal mice. We therefore sought to determine if similar results could be obtained in other models of pain and whether the effects of GH were localized to the site of injury. We used a rodent surgical pain model and found that GH was significantly reduced in the muscles after neonatal incision. A single, local, and low dose injection of GH to the incision site at the time of injury could block spontaneous and evoked pain-related behaviors 24 hours after injury. Using a neonatal *ex vivo* hind paw muscle/tibial nerve/dorsal root ganglion (DRG)/spinal cord recording preparation, we found that group III/IV primary afferent sensitization after incision was also blocked with local GH treatment. Upregulation of specific sensory transducing receptors in the DRGs after injury was additionally inhibited by local GH injection. Reduced GH levels after incision appeared to be due to infiltrating macrophages sequestering GH at the incision site. Macrophage-specific growth hormone receptor knockout mice (MacGHrKOs) showed blunted pain-related behaviors and no upregulation of incision-induced receptor expression in DRGs after injury. These mice also did not show any reduction in muscle GH after incision. Decrease in muscle GH levels appeared to mediate its effects on pain-related behaviors through a loss of neuronal microRNA-133a (miR-133a) mediated inhibition of serum response factor (SRF) regulated transcription. This data suggested that GH may provide a tonic inhibition of afferent sensitization that is removed upon peripheral injury. This hypothesis is currently being tested using afferent specific GH receptor knockout mice (Advillin-Cre x GHrfl/fl). Results may thus provide novel therapeutic targets for treating neonatal pain.

Title: Alterations in cerebellar neuropeptide expression and astrocyte activation in a repetitive acidic saline exposure jaw pain model

Authors: *J. MORRIS-WIMAN[1], C. G. WIDMER[2]
[1]Biomed. Sci., West Virginia Sch. of Osteo. Med., Lewisburg, WV; [2]Orthodontics, Univ. of Florida, Gainesville, FL

Abstract: Several imaging studies provide evidence that the cerebellum is activated with pain, but it remains unclear what role the cerebellum has during nociceptive processing. No studies have assessed cerebellar expression of pain-related neuropeptides or alterations in astrocyte activity. We have previously reported on a model for orofacial pain in which repetitive unilateral injections of acidic saline into masseter muscle elicited persistent bilateral pain that was associated with changes in chewing behavior and with significant increases in neuropeptide expression and astrocyte activation within trigeminal ganglia. Blocking ASIC3 channels prevented all pain-associated alterations. The objective of this study was to determine if similar changes in neuropeptide expression and astrocyte activation within the cerebellum occur with persistent pain in our model. **Methods**: Female CD-1 mice were repetitively injected with either neutral saline (pH 7, n=5), or acidic saline (pH 4, n=5) into the right masseter separated by five days. Five additional mice were injected with 10µl of APETx2 (3µM) into the right masseter just prior to a second acidic saline injection and 5 mice were used as unmanipulated controls. Seven days after the second injection, the mice were sacrificed, the cerebellum harvested, snap-frozen, and stored at -80° until cryosectioned. 12µm cryosections were immunostained for substance P (SP) and GFAP and images were acquired using a Zeiss MRm digital camera and Axiovision software. Images were histogram-matched and thresholded to produce binary images to eliminate bias. The total number of SP-positive Purkinje cells per folia length and the number of Purkinje cells associated with GFAP-immunostaining were counted for three sections, 150µm apart, for each animal. **Results**: No differences were detected among the groups in relative numbers of SP immunostained Purkinje cells. No significant differences were observed between control and neutral saline-injected groups in the percentage of SP-positive Purkinje cells co-localized with GFAP. However, a significant increase was observed between acidic saline-injected and neutral and control groups (91% acid, 52% control, 52% neutral). APETx2 did not prevent this increase. Additionally, SP-negative Purkinje cells were associated with GFAP immunostaining in the APETx2 group but not in other groups. **Conclusions**: The results of this study suggest that astrocyte activation occurs within the cerebellum in persistent pain and is associated with SP-positive Purkinje cells. Unlike in other pain processing regions of the CNS, astrocyte activation does not appear to be dependent on ASIC3.

Abstract: Spinal lamina I projection neurons (PNs) relay peripheral nociceptive inputs to the supraspinal pain processing centers. Yet, the principle of signal encoding by population of these neurons is poorly understood. Here we identified two groups of nociceptive-processing PNs with distinct input-output characteristics. The vast majority of neurons are excited only by a strong afferent stimulation, generate one-two spikes, and function as nociceptive input detectors. However, 85% of action potentials in the entire PN population originated from a small fraction of high-output neurons (16%). These receive a large number of direct C-fiber inputs, generate intrinsic bursts and efficiently integrate network activity via NMDA-receptor-dependent mechanisms and plasticity. The high-output PNs gradually encode the intensity of peripheral nociceptive input to the number of generated spikes. Thus, two groups of PNs, detectors and intensity encoders, play principally different roles in nociception.

Title: Evidence of direct interactions between somatic sensory afferents and pre-ganglionic sympathetic neurons and their modification by peripheral nerve injury

Authors: *W. XIE, J. A. STRONG, J.-M. ZHANG
Anesthesiol., Univ. Cincinnati Coll Med., Cincinnati, OH

Abstract: We previously reported that sympathetic innervation helps maintain immune homeostasis and that surgical sympathectomy reduces pain by suppressing inflammation in axotomized or inflamed DRGs. In this study, we investigated anatomical and functional interactions between the sympathetic and somatosensory systems in the spinal cord. Retrograde tracing with Dextran-Texas red injected into the transected L5 spinal nerve (spinal nerve ligation, "SNL" neuropathic pain model) revealed sensory fiber projections to the intermediolateral dorsal horn and the central canal that associated closely with clustered Choline Acetyltransferase (ChAT)-ir pre-ganglionic sympathetic neurons (PreGNs). Immunohistochemical studies demonstrated that the sensory fibers interacting with PreGNs included CGRP-ir sensory neurons. In other experiments, AAV8 expressing green fluorescent protein (GFP) was injected into both L5 spinal nerves to preferentially label larger diameter sensory neurons. SNL was performed on one side 2 weeks later. GFP positive fibers projected to the intermediolateral dorsal horn and formed close interactions with PreGNs in spinal cord samples obtained 3 weeks after SNL. These projections appeared to be more extensive on the ipsilateral side of the spinal cord. In vivo recordings were performed on microfilaments teased out from the postganglionic sympathetic chain at the level between L5 and L4 DRGs, after cutting the grey rami that bring postganglionic sympathetic axons into the L4 and L5 spinal nerves. In anesthetized rats, electrical stimulation of the sciatic nerve at C-fiber strength consistently evoked action potentials both monosynaptically (presumed PreGNs) and polysynaptically from the sympathetic chain fibers. These responses remained when the L4 and L5 ventral roots distal to the recording site were cut just prior to recording, indicating the evoked activities were triggered by primary sensory inputs. In recordings made 7, 28, or 56 days after spared nerve injury (model of neuropathic pain), both A- and C-fiber strength stimuli evoked responses in the sympathetic chain; the number of fibers that could be activated (both monosynaptically and polysynaptically) increased, and spontaneous

activity increased. This is to our knowledge the first report of direct activation of the sympathetic neurons by somatic sensory inputs, which may contribute to previously described spinal-level sympathetic reflexes. We suggest that abnormal activities originating from injured peripheral nerve or DRG neurons drive sympathetic activity, which in turn enhances pain by regulating inflammatory responses in the peripheral nervous system.

Title: Different effects of deletion of the serine racemase gene on nociceptive behavior among different models of neuropathic and inflammatory pain

Authors: *E. KATO, T. FUKUSHIMA, M. MAEKAWA, Y. HORI
Dept Physiol & Biol Inf, Dokkyo Med. Univ., Tochigi, Japan

Abstract: Peripheral nerve injury and tissue inflammation often induce abnormal pain. The activation of *N*-methyl-D-aspartate (NMDA) receptors mediates the development and maintenance of this abnormal pain. D-serine co-localizes with NMDA receptors and acts as an endogenous co-agonist of the NMDA receptor at the glycine binding site. D-serine is synthesized from L-serine by serine racemase (SR), an enzyme that is abundant in the central nervous system. How alterations in SR activity are involved in the modulation of neuropathic and inflammatory pain behavior remains unclear. In the present investigation, we compared pain behaviors in SR knockout (KO) mice and wild-type (WT) mice after subjected to a chronic constriction injury (CCI model of Bennett), partial sciatic nerve ligation (PSL model of Seltzer), spinal nerve ligation (SNL model of Chung), and an inflammatory pain induced by subcutaneous formalin.
Seven- to nine-week-old male WT and SR-KO mice were used for the experiments. Under halothane anesthesia, the mice were subjected to neuropathic surgery. Three types of nerve ligations were performed, as previously described by Bennett et al. (1988), Kim and Chung (1992), and Seltzer et al. (1990). The left sciatic nerve was tied loosely with four ligatures of chromic gut at the mid-thigh level (Bennett model), the left L5 and L6 spinal nerves were isolated and ligated tightly with a 4-0 silk thread (Chung model), and the dorsal one-third to one-half of the left sciatic nerve was tightly ligated (Seltzer model). Mechanical allodynia was

assessed by measuring the frequency of withdrawal responses using von Frey filaments both before and after ligation. To induce inflammatory pain, paraformaldehyde (50 μL, 25% in distilled water) was injected subcutaneously in the dorsal surface of the left hind paw. The mice were continuously observed for 60 min after the formalin injection, and the time of licking of the injected paw was measured during the observation period.
Behavioral observations showed the following results: 1) The formalin-induced licking response was prolonged during the second phase in SR-KO mice, whereas the first phase was not affected. 2) Mechanical allodynia in the Seltzer model was quite similar between SR-KO mice and WT mice. 3) Mechanical allodynia in both the Chung and Bennett models was significantly enhanced in SR-KO mice compared with WT mice.
The present results may reflect the different involvements of NMDA receptors in different models of neuropathic and inflammatory pain. We are currently investigating how differently synaptic circuit activity in the spinal dorsal horn is affected by SR knockout in different pain models.

Title: TLR4 knockout rats show reduced signs of paclitaxel-related chemotherapy induced peripheral neuropathy

Authors: *P. M. DOUGHERTY, Y. LI
Pain Med., Howard Hughes Med. Inst. - Univ. of Texas MD Anderson Cancer Ctr., Houston, TX

Abstract: The contribution of the toll-like receptors (TLRs), TLR4 in particular, has been reported in the initiation and maintenance of paclitaxel-related chemotherapy-induced peripheral neuropathy. Furthermore, paclitaxel produces peripheral neuropathy by sensitizing transient receptor potential vanilloid subtype 1 (TRPV1) through Toll-like receptor 4 (TLR4) signaling. In current study, TLR4 knock-out rats have been used to further test the interaction of TLR4 and TRPV1 in paclitaxel-induced peripheral neuropathy. Western blot data shows that TLR4 and TRPV1 appear to physically interact, evidenced by their co-immunoprecipitation from L4-L5 DRG at 7 days after paclitaxel treatment using either as the anchoring epitope. TNFα levels of macrophage culture in response to paclitaxel or LPS were reduced in homozygote knock-out

compared to heterozygote and wild type rats which indicates that TLR4 is nonfunctional in homozygote knock-out animals. The behavior data show that paclitaxel-induced behavioral hypersensitivity is reduced in TLR4 knock-out rats. Calcium imaging in dissociated DRG neurons from homozygote knock-out rats and wild type rats with vehicle or paclitaxel treatment was used to assess whether TLR4 functionally enhances TRPV1 signaling. DRG neurons from paclitaxel-treated TLR4 knock-out rats were observed to show relatively weak (340/380 ratio) and slow response to capsaicin compared with DRG neurons from paclitaxel-treated TLR4 wild type rats. In summary, TLR4 is one of major players in paclitaxel-induced peripheral neuropathy by inducing sensitization of TRPV1.

Title: Contribution of peripheral brain-derived neurotrophic factor (bdnf) signaling in oral cancer pain

Authors: *D. ARRIS, M. GRAYSON, V. VALENZUELA, S. RUPAREL
Univ. of Texas Hlth. Sci. Ctr. At San, San Antonio, TX

Abstract: Background: Pain is the primary presenting symptom of patients with head and neck carcinoma (HNC) and one of the most common persisting complaints, contributing to a tremendous reduction in quality of life. Many patients subsequently require opiates and tolerance develops rapidly. Developing a therapy that blocks cancer pain is of critical importance; however; little is known about the mechanisms by which HNC cells evoke pain. The current study seeks to decipher a novel peripheral role of brain-derived neurotrophic factor (BDNF) signaling in oral cancer pain. **Methods:** We use an *in vivo* tongue cancer pain model in male mice to study the role of BDNF in oral cancer pain by injecting either human Oral Squamous Cell Carcinoma (OSCC) or normal oral keratinocyte cells in the tongue. Upon cell inoculation, OSCC cells produce a localized tumor that mimics patient-reported pain-like symptoms in mice. Using this *in vivo* model, we performed human BDNF ELISA as well as immunohistochemical analysis of BDNF and TrkB (BDNF receptor) expression in tongue tissue of tumor-bearing and normal animals. Additionally, we also determined the effect of systemic and local administration of a TrkB antagonist in reversing pain-like behavior in the orthotopic model. **Results:** BDNF

signaling is significantly increased in HNC tumors, contributing to epithelial to mesenchymal transition, preventing apoptosis, and inducing chemo-resistance. Consistent with clinical findings, our data demonstrated that BDNF levels are up-regulated in oral tumors of a mouse orthotopic cancer pain model compared to normal animals**.** Moreover, our data show that BDNF is expressed specifically on the invasive front of tumor cells and BDNF positive cells were in close proximity to sensory fibers within the tumor. Antagonizing the TrkB receptor systemically and locally in the tongue significantly reverses pain-like behaviors *in vivo***.** This is a novel finding and, to our knowledge, the first demonstration of a peripheral role for BDNF signaling in HNC pain. **Conclusions:** Our data supports a novel role of BDNF signaling in mediating oral cancer pain. Targeting BDNF may prove an effective approach for treating cancer-induced pain, tumor progression as well as chemotherapy resistance. We are currently identifying different types of sensory fibers in the tongue that may be regulated by BDNF release from OSCC cells, using a novel electrophysiological method allowing for single-fiber recordings of normal tongue and tumor-bearing tongue in mice.

Ctr., West Haven, CT; [6]Neurobio., Children's Hosp. Boston, Boston, MA

Abstract: Pain is a critical adaptive sensation required for protection against danger and which facilitates healing after injury. However, when this system functions abnormally, either as a consequence of congenital or acquired abnormalities, pathological pain is generated. Mutations in ion channels expressed by sensory neurons have a major impact on pain sensibility. Among them, SCN9A which encodes Nav1.7 has been extensively studied because it is the most abundant voltage-gated sodium channel in these “pain” sensory neurons. Gain-of-function

mutations in Nav1.7 lead to inherited pain disorders including inherited erythromelalgia(IEM) and paroxysmal extreme pain disorder(PEPD), whereas loss-of-function mutations cause congenital insensitivity to pain(CIP). Most studies investigating the pathophysiology of Nav1.7 mutations do this by overexpressing human channels heterologously in non-neuronal cells or in rodent sensory neurons *in vitro*, which limits translational implications. We have successfully exploited CRISPR/Cas9 genome editing to introduce gain-of-function (GOF) and loss-of-function(LOF) point mutations in the SCN9A gene to generate IEM, PEPD, and CIP models *in vitro*(primary mouse and human induced sensory neurons) and *in vivo*(mutant mice) and have made multiple mutant lines. Nav1.7 GOF mutations in human iPSC induced sensory neurons dramatically increased spontaneous firing and burst firing rate in a temperature dependent manner as measured using multi-electrode arrays(MEA). Female mice carrying a Nav1.7 GOF mutation related to IEM in humans had difficulty nursing pups due to the pain and swelling of teats when lactating. For Nav1.7 LOF mutation studies, we have performed MEA and whole-cell patch clamp recording and observed less spontaneous firing (MEA), less Nav1.7 currents and an increased threshold to generate action potentials. We also observed a high mortality in pups carrying Nav1.7 LOF mutations, similar to that observed in global Nav1.7 knockout mice. These genetically engineered murine and human pain models not only enable us to mimic key features of the clinical presentation of the genetic pain disorder, but also provide a powerful tool to investigate pathophysiological mechanisms of the pain phenotype and to screen for novel therapeutics for these channelopathies.

Title: The effect of an insect pyrokinin on nociceptive sensitization of the defensive strike response in larval Manduca sexta

Authors: *M. FUSE, A. D. RICE
Biol., San Francisco State Univ., San Francisco, CA

Abstract: The opioid epidemic has necessitated a re-evaluation of the use of opioids in treating chronic pain. An insect-specific pyrokinin peptide (PK) defined by its conserved C-terminal FXPRLa amino acid sequence was previously suggested to act in an antinociceptive manner via opioid receptors, using both the hot-plate and tail immersion tests (Rykaczewska-Czerwinska et al., 2001). Given that this peptide does not appear to be structurally similar to opioids, this could be an alternative to opioid use in pain regulation, but may also be the endogenous "opioid-like" compound in insects. The defensive strike response in the hornworm, *Manduca sexta*, has been used to study pain-like responses, where nociceptive sensitization occurs after application of single noxious stimulus such as a pinch. Following a pinch, the force required to elicit a defensive strike response is attenuated, indicative of a state of hyperalgesia. The goal of this research was to determine whether the insect PK had antinociceptive effects in *M. sexta*, and whether this activity occurred via opioid receptors. Larvae were tested for baseline threshold to strike, then injected with naloxone, an opioid-receptor inhibitor, along with PK, and as with PK alone, the pinch threshold was significantly elevated. This suggested that naloxone could not counter the effects of PK. However, injection of naloxone alone significantly reduced the baseline threshold, suggesting that an opioid-like effect might be countering the mildly noxious effects of injection. Feeding naloxone did not reduce the baseline threshold, and a subsequent pinch still sensitized the larvae. Finally, multiple injections limited the efficacy of PK, but the effects of early naloxone injection could not fully block these effects. Taken together, these data suggest that the injection may be a mild stimulus to trigger an upregulation of endogenous opioid-like peptides, the effect of which is to maintain the high baseline threshold when no major aggravations exist. In contrast, the pinch appears sufficiently noxious to inhibit the analgesic effects of injection, lowering the opioid/PK levels, and allowing larvae to become sensitized.

Title: A cortical gain control mechanism for pain

Authors: *J. WANG[1], J. A. DALE[2], H. ZHOU[3], Q. ZHANG[4], E. MARTINEZ[2], Z. W. CHEN, 10024[2]
[1]Anesthesiol., [2]New York Univ. Sch. of Med., New York, NY; [3]NYU Sch. of Med., New York, NY; [4]New York Univ., New York, NY

Abstract: Acute pain induces salient neural and behavioral responses that protect us from injury and harm. Chronic pain, however, is known to disrupt normal nociceptive processing. The prefrontal cortex (PFC) has been shown to exert critical top-down regulation of sensory inputs. Unfortunately, how individual neurons in the PFC respond to acute nociceptive inputs *in vivo* remains little-known. We recorded neurons from the prelimbic region of the PFC (PL-PFC) in freely behaving rats. We found that a significant number of PFC neurons increased their firing rates after noxious stimulations. Chronic pain, however, suppressed prefrontal activity by decreasing both basal spontaneous and pain-evoked firing rates. Importantly, we identified a linear correlation between basal and evoked firing rates of PFC neurons. As a result, even a small decrease in basal firing leads to a nearly two-fold reduction in the pain-evoked response in the chronic pain state. In contrast, enhancing basal PFC activity with low frequency optogenetic stimulation could scale up prefrontal outputs to inhibit pain. These results define a mechanism whereby PFC neurons can function as gain controllers for pain, and hence scaling up prefrontal outputs is a novel neuromodulation strategy to inhibit pain.

Title: Ex-vivo human models of inflammatory and neuropathic pain states for enabling translational research and drug discovery

Authors: *A. GHETTI, Y. MIRON, A. TON, T. INDERSMITTEN, N. NGUYEN, P. RATCHADA, A. ALAMILLO, K. SWEAT, I. TAPIA, G. PAGE, P. E. MILLER
Anabios Corp., San Diego, CA

Abstract: The incomplete understanding of chronic neuropathic and inflammatory pain mechanisms poses a major challenge for the development of new, non-addictive pain medications. In addition, cross-species differences in pharmacological responses and analgesic effects lead to poor translation of preclinical animal models to clinical studies in humans. We have previously shown that human sensory neurons, isolated from organ donors, can be

maintained in culture for several days (1); cells remain phenotypically stable for up to 14 days in culture and can be used to assess pharmacological responses by employing imaging- or electrophysiology-based methods. Here we present a novel preclinical discovery strategy, which utilizes human sensory neurons to establish cellular models of pathological states. These models recapitulate key features of inflammation-related and neuropathy-related pain. To generate these different pathological states *in vitro,* we incubated human sensory neurons with pro-inflammatory agents (PGE_2 and bradykinin) or with Oxaliplatin, a chemotherapy drug associated with peripheral neuropathy. Treatment with PGE_2 and bradykinin for 2 to 72 hrs. induced changes in neuronal excitability and in the nociceptive profile of human sensory neurons: sensory neurons had increased excitability, heightened responsiveness to TRPV1 agonists and increased expression of TTX-resistant voltage gated sodium channels. These changes are consistent with phenotypes of inflammatory pain observed in the clinic. Incubation with oxaliplatin for 24 hrs. resulted in cell hyperexcitability and enhanced response to cold buffer. These changes are consistent with cold allodynia frequently reported by cancer patients undergoing oxaliplatin treatment. Furthermore, we demonstrate that these cell-based models can be used to differentiate the preferential effects of pain drugs on diverse pain states and can be used to rank drug candidates based on potential analgesic efficacy and to predict the most appropriate pain indication for clinical trial development. Title: Neural oscillations and biomarkers of chronic pain in the rat

Authors: *A. KELLER, C. RAVER, D. SEMINOWICZ, A. FURMAN
Univ. of Maryland Sch. of Med., Baltimore, MD

Abstract: Chronic pain is a debilitating, multidimensional disease that affects millions of individuals. A significant barrier to improved treatment of is that pain presentation is highly variable and, therefore, difficult to diagnose. Identifying biomarkers of chronic pain represents one promising avenue for addressing this obstacle. We used electrocortigraphy (ECoG) to record brain activity from female rats before and after constriction of the infraorbital nerve (CCI-ION), a validated animal model of chronic pain, to test the hypothesis that there exist neural oscillation patterns that are predictive of chronic pain. We recorded brain activity and behavioral metrics of pain at multiple time points, spanning from 7 days before to 21 days after injury. To ensure that recording are obtained during reproducible behavioral states, we recorded while the rats performed a stereotyped behavior, facial grooming. Our preliminary results indicate that CCI-ION is associated with decreases in the power of 4-7 Hz (theta) range oscillations, and that these changes emerge shortly after CCI-ION and persist for as long as three weeks after the injury. These results provide novel evidence that theta oscillations may serve as a reliable biomarker for chronic pain.

Title: Cannabis for chronic pain results in decreased alpha frequency activity in the left frontal lobe measured by electroencephalogram

Authors: *K. P. SEYMOUR[1], T. W. BROWN, 76402[2], C. M. BOTELLO, 76402[2], A. L. HARRIS BOZER[3]
[1]Psychology, [3]Psychological Sci., [2]Tarleton State Univ., Stephenville, TX

Abstract: Chronic pain effects over 100 million Americans. Some individuals suffering from chronic pain may utilize cannabis for analgesia. Increasing marijuana legality in the United States calls for an investigation of the neurophysiological effects of cannabis for pain. While there is an abundance of studies on the efficacy of cannabis as an analgesic, there is less information on the interaction between cannabis and pain on the brain. Previous research has indicated that marijuana use is related to a decrease in alpha frequency band activity. In a

previous study, we found that chronic pain results in a widespread inhibition of activity in the alpha frequency band. We hypothesized that pain and marijuana will create a combinatorial decrease of alpha frequency band activity in the frontal lobe. Participants (aged 18-30, right-handed, 3 males) were placed into groups based on report of current pain for more than 6 months (chronic pain) and presence of cannabis use resulting in four groups (pain/cannabis, pain/no cannabis, no pain/cannabis, and no pain/no cannabis). Five minutes of electroencephalogram activity (20 active electrodes) was recorded using iMotions software and B-Alert EEG hardware (referenced to mastoids). Data were exported from iMotions into Matlab for filtering (.02-50Hz), channel distributions, and artifact rejection. Data were imported into Notepad++ and Cartool to apply Fast Fourier Transform (delta 0-3 Hz, theta 4-7 Hz, alpha 8-12 Hz, beta 13-30 Hz, gamma 31-50 Hz). Microsoft Excel was used to compute prefrontal asymmetry as the natural log of right side alpha (F4)- natural log of left side alpha (F3). SPSS was used to run ANOVA with group by alpha power (8-12 Hz). Cannabis and pain produce a decrease in alpha frequency activity in the left frontal lobe (confirmatory analysis), p=.04. An exploratory analysis (ANOVA) indicated that there was a significant interaction effect between pain and cannabis on prefrontal asymmetry (p=.03). There was a left hemisphere lateralization in the cannabis/no pain and pain/no cannabis groups. We conclude that pain and cannabis result in meaningful changes in brain activity in the left lobe that should be taken into account when making decisions about cannabis for analgesia.

Title: EEG alpha power decreases during approach of pain for reward in participants with chronic pain

Authors: *C. M. BOTELLO[1], T. W. BROWN[2], A. L. HARRIS BOZER[2]
[2]Psychological Sci., [1]Tarleton State Univ., Stephenville, TX

Abstract: Pain does not occur in a homeostatic vacuum and chronic pain sufferers do not have the choice to avoid or relieve pain. Approach-avoidance in the context of pain is a decision-making conflict consisting of approaching pain to achieve a reward or satiate a drive. This research was designed to elucidate the neural mechanisms that accompany approach-avoidance behaviors among chronic pain sufferers. We hypothesized (1) a chronic pain group would avoid

pain stimuli more than a painless control group and (2) a pain group would demonstrate increased prefrontal asymmetry, driven by increased left hemisphere activity related to avoidance. Participants included 31 right-handed people aged 19-55 (4 males) that reported current pain for more than 6 months (chronic pain) or reported being pain free controls. iMotions software recorded electroencephalogram activity from B-alert hardware containing 20 active electrodes (referenced to mastoid leads) attached to the scalp during a hypothetical approach-avoidance task. Participants chose to approach varying levels of pain (low-moderate-high) to receive varying levels of a monetary reward (low-moderate-high). MatLab was used for post-processing (filters at .02-50Hz with manual artifact rejections). Fast Fourier Transforms were calculated in Cartool (delta 0-3Hz; theta 4-7Hz; alpha 8-12Hz; beta 13-30Hz; gamma 31-50Hz). Prefrontal asymmetry was calculated in Microsoft Excel as the natural log of right side alpha (F4)- natural log of left side alpha (F3). SPSS was used to compute independent samples t-tests. The pain group avoided pain stimuli significantly less than controls, $p<.05$. The pain group did not demonstrate increased prefrontal asymmetry ($p>.05$), but had significantly less alpha frequency activity in 5 electrodes (F4, C3, Cz, C4, P3 & PoZ) during high threat trials, $p<.05$. High threat trials altered decision-making during the pain approach-avoidance task. This was powered by a widespread decrease in alpha band cortical activity, rather than the hypothesized hemispheric lateralization. High-threat level approach-avoidance stimuli produced a more salient threat to homeostasis. The broader impact of this research lies the development of a body of literature to continue exploring pain as a multidimensional, complex disruption of homeostasis.

Title: Ensembles of change-point detectors for real-time acute pain detections

Authors: *Z. XIAO[1], S. HU[3], Q. ZHANG[1], J. WANG[2], Z. CHEN[1]
[2]Anesthesiol., [1]New York Univ. Sch. of Med., New York, NY; [3]Col. of Biomed. Engin. and Instrument Sci., Zhejiang Univ., Hangzhou, China

Abstract: Brain-machine interfaces (BMIs) have been widely used to study basic and translational neuroscience questions. In real-time closed-loop neuroscience applications, many

practical issues arise, such as trial-by-trial variability, and spike sorting noise or multi-unit activity. In this paper, we propose a new framework for change-point detection based on ensembles of in-dependent detectors in the context of BMI application for detecting acute pain signals. Motivated from unsupervised ensemble learning, our proposed “ensembles of change-point detectors” (ECPDs) integrate multiple decisions from independent detectors, which maybe derived based on data recorded from different trials, or data recorded from different brain regions, or data of different modalities. By integrating more information, the ECPDs are aimed to improve the detection accuracy (in terms of true positive and true negative rates) and to achieve an optimal trade-off of sensitivity and specificity. We validate our method using computer simulations and experimental recordings from freely behaving rats. Our results have shown superior and robust performance of ECPDS in detecting the onset of acute pain signals based on neuronal population spike activity from single or multiple brain regions.

Title: The relationship between experimental thermal pain and autonomic nervous response in the parameters including pulse oximeter

Authors: M. MIYAMAE[1], T. SOSHI[2], Y. TSUGITA[2], R. URABE[1], Y. MINEGISHI[1], K. NAKAI[1], *A. NAKAE[2], T. YANAGIDA[2]

Abstract: Background: Pain is a kind of biological defense reaction wherein the autonomic nervous system plays an important role. Autonomic reactions are monitored easily using pulse oximeter. We conducted the study to observe autonomic reaction to long-lasting thermal stimuli and investigated the possibility of using pulse oximeter as a tool for objective pain evaluation. Methods: After receiving the approval of the ethical committee of Osaka University, 12 females and 12 males who were recruited through the university intranet participated in this study. After the written informed consent, 59-second experimental heat stimulation at 48℃ with 60 seconds rest was presented to the left forearm using Pathway (Medoc, Israel) which was repeated 5 times, monitoring pulse oximetry. Subjective pain intensity was continuously evaluated using visual

analogue scale(VAS). Relationship between pulse rate(PR), pulse wave amplitude(Amp) extracted from the pulse oximeter, and subjective pain intensity were analyzed by paired t-test using JMP 12.0.1. Results & Discussion: Both male and female groups showed maximum pain intensity 9 seconds after reaching 48℃ and these changes lasted until the stimulation ended ($p<0.05$). PR was significantly higher after stimulation in both groups($p<0.05$). In both groups, Amp reached the lowest value when pain intensity hit the maximum. After reaching the lowest value, the Amp gradually increased($p<0.05$) and returned to the baseline despite the high pain. Amp showed a rebound increase after the stimulation ended. These rebound change patterns were significantly different between female and male groups. PR and Amp changed maximally in response to painful stimuli of the highest pain intensity. However, while VAS was consistently high during stimulation, PR and Amp returned towards baseline($p<0.05$). Conclusions: PR and Amp significantly changed after painful thermal stimulation. However, even though participants felt the same intensity of pain for over 60 seconds, these changes reversed significantly. By monitoring physiological parameters using pulse oximeter, the existence of pain may be detected. To evaluate pain objectively, another parameter should be added to perform precise objective pain evaluation.

Abstract: Calcium/calmodulin-dependent serine protein kinase (CASK)-interacting protein1 (Caskin1) is originally identified as a direct binding partner of the synaptic adaptor protein CASK. Furthermore, it forms homo-multimers and binds to not only CASK but also other functional molecules in vitro. In our previously study, we identified Caskin1 as an increased protein in the spinal dorsal horn in the chronic pain condition. It seems likely that Caskin1 has neural functions, such as pain transmission in vivo, however the function of it in vivo remains unclear. To clarify the protein distribution and neural function of Caskin1 in vivo, we generated anti-Caskin1 antibodies and Caskin1 knockout (Caskin1-KO) mice. Caskin1 was broadly distributed in all the spinal cord and brain areas. Caskin1-KO mice exhibited high sensitivity to noxious stimulation, such as heat and electro stimulations. In addition, several behavioral abnormalities were also demonstrated in Caskin1-KO mice by a behavioral test battery. These results suggest that Caskin1 plays multiple neuronal functions in the central nerve system.

Title: Neuropeptide regulation of adaptive immunity in the tibia fracture model of complex regional pain syndrome

Authors: *W. LI[1,2], T.-Z. GUO[3], X. SHI[1,2], F. BIRKLEIN[4], T. SCHLERETH[4,5], W. S. KINGERY[3], J. D. CLARK[1,2]

Abstract: Background: Both dysfunctional neuropeptide signaling and immune system activation are characteristic of complex regional pain syndrome (CRPS). Unknown is whether substance P (SP) or calcitonin gene related peptide (CGRP) support autoantibody production

and, consequently, nociceptive sensitization.
Methods: These experiments involved the use of a well-characterized tibia fracture model of CRPS. Mice deficient in SP expression ($Tac1^{-/-}$) and CGRP signaling ($RAMP1^{-/-}$) were used to probe the neuropeptide dependence of post-fracture sensitization and antibody production. The deposition of IgM in spinal cord, sciatic nerves and skin was followed using Western blotting, as was expression of the CRPS-related autoantigen cytokeratin 16 (Krt16). Passive serum transfer to B-cell deficient muMT mice was used to assess the production of functional autoantibodies in CRPS model mice. The use of immunohistochemistry allowed us to assess neuropeptide-containing fiber distribution and Langerhans cell abundance in mouse and human CRPS patient skin, while Langerhans cell deficient mice were used to assess the functional contributions of these cells.
Results: Functional SP and CGRP signaling were required both for the full development of nociceptive sensitization after fracture and the deposition of IgM in skin and neural tissues. Furthermore, the passive transfer of serum from wildtype but not neuropeptide deficient mice to fractured muMT mice caused enhanced allodynia and postural unweighting. Langerhans cells were increased in number in the skin of fracture mice and CRPS patients, and those increases in mice were reduced in neuropeptide signaling deficient animals. Unexpectedly, Langerhans cell deficient mice showed normal nociceptive sensitization after fracture. However, the increased expression of Krt16 after tibia fracture was not seen in neuropeptide deficient mice.
Conclusions: Collectively, these data support the hypothesis that neuropeptide signaling in the fracture limb of mice is required for autoantigenic IgM production and nociceptive sensitization. The mechanism may be related to neuropeptide-supported autoantigen expression.

Title: Inhibition of nerve growth factor specific receptor, tropomyosin receptor kinase A, modulates glutaminase production in rat dorsal root ganglion during inflammation

Authors: *V. GUJAR, K. E. MILLER
Anat. and Cell Biol., Oklahoma State University, Ctr. For Hlth. Scien, Tulsa, OK

Abstract: Background: Apart from regulating the maturation of sensory developing neurons, nerve growth factor (NGF) also acts as a neurotrophin for a subset of nociceptive sensory neurons. It has been well established that, after NGF binds to its specific receptor tropomyosin receptor kinase A (TrkA), a signalling endosome is formed that is retrogradely transported via axons to the cell soma located in dorsal root ganglion (DRG). This complex is responsible for regulating the transcription of several important nociceptive genes. It is surprising, however, the role of NGF in modulating glutamate production during peripheral inflammation. Glutamate functions as the major excitatory neurotransmitter for CNS primary afferents and has a crucial role in sensitizing peripheral nociceptor terminals producing peripheral sensitization. Glutaminase (GLS) is the synthetic enzyme that converts glutamine to glutamate. GLS-immunoreactivity (-ir) is elevated in DRG neuronal cell bodies during chronic peripheral inflammation, but the mechanism for this GLS elevation is yet to be fully characterized. This study addresses the effect of TrkA inhibition on GLS expression in rat DRG during adjuvant induced arthritis (AIA) allowing us to understand the crosstalk between GLS production and the NGF-TrkA complex during peripheral inflammation. **Methods:** AIA was induced by injecting complete Freund's adjuvant in the right hind paw of 8-10 week old male Sprague Dawley rats (200-300 gm). Selective TrkA inhibitor (GW 441756, Tocris) dissolved in DMSO was injected in the same paw used for CFA treatment. L4 and L5 DRG were collected at different time points during inflammation. Immunohistochemistry, immunoblotting and quantitative real time PCR was performed for determining the expression of GLS. **Results:** We found that TrkA inhibition attenuated the GLS levels in DRG primary afferent neurons during acute phase of AIA and we observed reduced paw swelling in animals treated with TrkA inhibitor as compared to CFA treated animals. **Conclusion:** We conclude that the mechanism of GLS expression in DRG neurons during peripheral inflammation involves the NGF-TrkA complex retrogradely transported from the periphery to DRG.

Title: Imaging large scale brain networks alterations in arthritic rats using functional ultrasound imaging

Authors: *L. RAHAL[1,2], M. THIBAUT[2], M. TANTER[1], S. PEZET[2]
[1]Inst. Langevin, ESPCI Paris, PSL Res. Univ., CNRS UMR 7587, INSERM U 979, Paris, France; [2]Lab. of Brain Plasticity, ESPCI Paris, PSL Res. Univ., CNRS UMR 8249, Paris, France

Abstract: Chronic pain (CP) diseases affect ~30% of the European population, however effective treatments are often missing. Only 50% of patients receive appropriate alleviation, due to a lack of treatment specificity and efficacy, as a result of a current poor understanding of the underlying mechanisms. Neural plasticity both in the peripheral and central nervous systems was already reported to be a key element in pain maintenance.
Over the last three years, through the collaboration with the team of Mickael Tanter, who developed the Functional Ultrasound (fUS) imaging technique[1], our team had the unique opportunity to be at the centre of new technological achievements. For instance, we showed that this highly resolved technique can image functional connectivity (FC) in the adult rat brain[2]. Also, using contrast agents, we performed fUS imaging through the intact skull[3] and went beyond doing super-resolution[4] in the living rat brain.
In the present project, we used this neuroimaging approach for the study of brain networks alterations in two animal models of peripheral inflammation, through the study of FC. FC defines a neural network through the emphasis of brain areas which haemodynamic fluctuations are temporally correlated. Using fUS, we show that FC is altered in several cortical and sub-cortical networks, in rats suffering from long-term inflammatory pain. However, this is not observed when pain lasted only two days, suggesting that these changes require long-lasting pain. Interestingly, analysis of the degree of pain does not show any significant segregation, suggesting that such networks alterations are observed even when CP is of mild amplitude. These results are in agreement with observations performed in CP patients, where alteration of the default-mode network was consistently observed across pathologies, while distinct intra-cortical alterations of FC were observed in some CP pathologies[5]. Besides, we observed that alterations in some networks are significantly associated with behavioural aspects of long-term inflammatory pain, suggesting a close link between alterations of these networks and the clinical manifestation of inflammatory pain.
The next step of our work is to analyse FC in awake, freely moving animals, suffering from either inflammatory or neuropathic pain. We expect to better understand the neurobiological nature of such brain plasticity and the functional effects of current beneficial treatments.

Title: Nerve growth factor and pain-related neuropeptide up-regulated by macrophage-derived inflammatory cytokines in degenerated human intervertebral discs

Authors: *M. MIYAGI, K. UCHIDA, S. TAKANO, M. NAKAWAKI, J. AIKAWA, H. SEKIGUCHI, G. INOUE, T. NAKAZAWA, T. IMURA, W. SAITO, E. SHIRASAWA, M. TAKASO
Kitasato Univ., Sagamihara City/Kanagawa Prefecture, Japan

Abstract: Introduction: The expression of various pain-related molecules including inflammatory cytokines, nerve growth factor (NGF), and pain-related neuropeptide in degenerated or injured Intervertebral disc (IVD) and sensory nervous system was associated with discogenic low back pain (LBP). We previously reported that macrophages in the IVD in injured mice produced inflammatory cytokines, but not growth factors. The aim of the current study was to evaluate the regulation and interaction of pain-related molecules by macrophages in human degenerated IVDs. **Methods:** Degenerated IVD samples were harvested from 11 patients including 8 with lumbar spinal stenosis and 3 with adult spinal deformity during spinal interbody fusion surgery. Harvested IVD-derived mononuclear cells were obtained and CD14 positive (+) and CD14 negative (-) cells were separated using CD14 antibody and streptavidin-labeled magnetic beads. Inflammatory cytokines including tumor necrosis factor alpha (TNF-alpha), Interleukin 1 beta (IL-1beta), NGF and calcitonin gene-related peptide (CGRP) in the CD14(+) or CD14(-) cells were determined using real-time polymerase chain reaction (RT-PCR). We compared expression levels of each molecular between CD14(+)and CD14(-) cells. To evaluate factors controlling the regulation of pain-related molecules, cultured CD14(-) cells from IVDs were stimulated with TNF-alpha and IL-1beta and the levels of NGF and CGRP were determined using RT-PCR. **Results:** The levels of TNF-alpha and IL-1 betain CD14(+) cells were significantly increased compared with those in CD14(-) cells ($p<0.05$). However, the levels of NGF and CGRP were not significantly different between CD14(+) and CD14(-) cells ($p>0.05$). NGF and CGRP levels increased significantly following TNF-alpha and IL-1beta stimulation ($p<0.05$). **Discussion:** In the present study, CD14(+) macrophages produced more TNF-alpha and IL-1 beta compared with CD14(-) cells in human degenerated IVDs similar to the findings in the present animal model study.. In addition, CD14(+) macrophage-derived inflammatory

cytokines promote the up-regulation of NGF and CGRP. These findings indicated that NGF and pain-related neuropeptide were stimulated by macrophage-derived inflammatory cytokines and were associated with the pathomechanism of chronic discogenic LBP in humans. <!--EndFragment-->

Title: Serotonin attenuates endotoxin-induced nociception by inhibiting IKKα/β in the dorsal root ganglia and GSK3α/β, CREB, and IKKα/β in the spinal cord dorsal horn

Authors: *C. M. MOTA[1], C. RODRIGUES-SANTOS[2], C. R. A. LEITE-PANISSI[2], L. G. S. BRANCO[1,2]
[1]Med. Sch. of Ribeirao Preto/Department of Physiol., [2]Dent. Sch. of Ribeirao Preto/Department of Morphology, Physiol. and Basic Pathology, Univ. of Sao Paulo, Ribeirao Preto, Brazil

Abstract: Serotonin (5-HT) is a neurotransmitter that plays an important role in endogenous analgesia, but its involvement in the nociceptive signaling during systemic inflammation (SI) remains unclear. Our hypothesis was that intracerebroventricular (icv) administration of 5-HT attenuates nociceptive responses by reducing pro-nociceptive and pro-inflammatory signaling pathways in the lumbar dorsal root ganglia (DRG) and in the spinal cord dorsal horn (DH) during SI. Thus, we administrated 5-HT in the 3rd ventricle of male adult *Wistar* rats and assessed for 120 min the thermal latency and the paw withdrawal threshold during endotoxin-induced SI. Endotoxin (LPS) caused thermal hyperalgesia at 30, 45, and 60 min, and mechanical allodynia at 15 and 30 min after administration. Moreover, 5-HT icv administration attenuated all the nociceptive responses during SI. Furthermore, we investigated whether the nociceptive signaling was altered in the DRG and DH at 45 and 120 min after endotoxin administration, which represented the phases of hyperalgesia and resolution, respectively. Interestingly, SI activated the inhibitor of κB (IκB) kinases type α and β (IKKα/β) within the DRG and DH whereas the cAMP-response element binding protein (CREB) was activated only in the DH. Central 5-HT

administration reduced these responses, activated CREB in the DRG and inhibited the glycogen synthase kinase-3 types α and β (GSK3α/β) in the DH during SI. Moreover, we observed no change in cyclooxygenase-2 (COX-2) relative expression in any of the groups. Interestingly, all significant alterations were observed in the period of hyperalgesia (45 min) only, indicating that these molecules probably contribute to the nociceptive responses. In summary, we suggest that 5-HT administration within the brain induces analgesia during SI, probably by modulation of crucial signaling pathways in the DRG (CREB and IKKα/β) and DH (GSK3α/β, CREB, and IKKα/β).

Abstract: Osteoarthritis (OA) frequently develops in the population over 65 years of age with the loss of cartilage and subsequent structural changes of subchondral bones by the progression of aging. Because OA-triggered pain is tightly related with TLR4 signaling cascades, TLR4 is a reasonable target in developing therapeutics for OA pain. Here, we revealed that PAT4, a peptide antagonist of TLR4, debilitated long-termly monoiodoacetate (MIA)-induced OA pain in rats by decreasing the expression of proinflammatory mediators in knee joints and the microglial activation in spinal cords. First of all, we established the MIA-induced OA pain model by an intra-articular injection of MIA (2 mg/20 μl) into a left knee. In this MIA-administrated rats, TLR4 was highly expressed in chondrocytes and synoviocytes of knee joints. A single intra-

articular injection of PAT4 (25 nmol/rat) molecules targeting TLR4 at day 7 after MIA injection attenuated dramatically pain behavior for ~3 weeks in von Frey filaments by reducing the cartilage loss in knee joints and microglial activation in dorsal horn of spinal cords. Likewise, the level of inflammatory cytokines including TNF-alpha, IL-1beta and IL-6 was decreased by ~50% compared with the control in quantitative RT-PCR and ELISA when PAT4 was delivered to MIA-induced rats. Interestingly, the duration of PAT4 in weakening OA pain remained longer than that of chemical antagonists of TLR4 such as C34 and M62812 lasting for ~7 days. Taken together, PAT4 reduced powerfully the strength of OA pain promoted by MIA in rats by blocking TLR4 and its corresponding reactions and could be a prospective medicine for the patients of OA pain.

Abstract: The occurrence of chronic pain increases by up to 50% in patients suffering from autoimmune inflammatory diseases, such as multiple sclerosis (MS), suggesting the existence of an intricate connection between the development of chronic pain and the immune system. Here, we investigated whether the proinflammatory cytokine interleukin-1β (IL-1β), produced during MS relapses and the induction of its animal model experimental autoimmune encephalomyelitis (EAE), could be responsible for pain modulation mechanisms. Our histological analysis identified a laminae I and II projecting dorsal root ganglion (DRG) neuronal subpopulation that highly expresses the type 1 interleukin-1 receptor 1 (IL-1R1). We found that these neurons also

express the transient receptor potential vanilloid subfamily member 1 (TRPV1) and the neuropeptide somatostatin (Sst), but neither calcitonin gene-related peptide (CGRP) nor tyrosine hydroxylase (TH), and do not bind the isolectin B4 (IB4). Since IL-1R1-expressing neurons co-express TRPV1, we generated a new conditional knockout mouse in which IL-1R1 is selectively deleted in $TRPV1^+$ nociceptors (*Trpv1*-cre::$Il1r1^{flox/flox}$ or *Il1r1* cKO mice), and assessed in these mice the clinical severity of EAE and EAE-induced mechanical allodynia using the von Frey test. Conditional knockout of the *Il1r1* gene from $TRPV1^+$ neurons affected neither the onset nor severity of EAE, but prevented the development of allodynia. Because peripheral neuropathic pain may also contribute to the development of EAE, we performed a unilateral chronic constriction injury prior to EAE immunization and observed a significant increase in disease severity in those mice. Taken together, our results show that inflammation mediated by IL-1β during EAE can cause pain via the activation of neuronal IL-1R1, thus establishing the potential benefit of anti-IL-1β therapies for pain management in MS.

Title: Alterations in pain behavior and physiology in a mouse model of palmoplantar keratoderma

Authors: *R. WEINBERG[1], Z. PANG[1], B. PAN[2], L. QU[1], S. YOUNG[4], M. POLYDEFKIS[3], M. CATERINA[1]
[1]Dept. of Neurosurgery, Neurosurg. Pain Res. Inst., [2]Dept. of Neurol., [3]Johns Hopkins Univ. Sch. of Med., Baltimore, MD; [4]Dept. of Med., UCLA, Los Angeles, CA

Abstract: Palmopantar Keratodermas (PPKs) are a group of rare hereditary or acquired skin disorders characterized by a thickening of the epidermis on the palms of the hands and soles of the feet. Some PPK patients experience intense pain that can severely impact quality of life yet there are no established pharmacologic treatments for PPK-associated pain, in part because the mechanisms underlying such pain have been largely unexplored. Many patients with Mal de Meleda (MdM), a diffuse PPK caused by a mutation in the gene encoding secreted mammalian Ly6/urokinase plasminogen activator receptor-related protein (SLURP) 1, exhibit pain at the lesion sites. The aim of our investigation was to characterize pain behavior and neurophysiology of peripheral sensory neurons in a mouse model of MdM. We characterized nociceptive pathway

structure and function in SLURP2X KO mice, which recapitulate many histological features of human MdM. Behavioral assays, histological analyses, and qPCR arrays were performed on SLURP2X KO mice and wild-type littermate controls. In vitro patch clamp electrophysiology and spinal cord c-fos staining was utilized on hindpaw-innervating DRG neurons to assess sensory functional changes. We observed enhanced behavioral withdrawal responses to thermal, mechanical and irritant chemical stimuli in SLURP2X KO mice. We also observed histological and molecular changes in the skin and DRG of these animals, including altered epidermal innervation, immune cell infiltration, and molecular markers of pain. In addition, DRG neurons isolated from SLURP2X KO mice exhibited higher incidence of spontaneous firing and hyperexcitability in our electrophysiology experiments.Taken together, these data demonstrate a robust pain phenotype in SLURP2X KO mice, analogous to that in human MdM patients. In addition, our data suggest that these changes may be attributable to changes in DRG neuron anatomical, molecular, and physiological phenotypes, potentially assisting in the generation of more targeted analgesic therapies for these patients.

Title: The role of inflamm-aging in the hyperalgesic priming state of aged mice

Authors: *H.-J. WANG[1], C. ZHAO[2], C.-F. ZOU[3], C.-Y. SHI[1], Y.-L. SUN[1]
[1]Shanghai Univ. of Med. & Hlth. Sci., Shanghai City, China; [2]Natl. Clin. Res. Ctr. for Aging and Medicine, Huashan Hospital, Fudan Univ., Shanghai, China; [3]Huashan Hospital, Fudan Univ., Shanghai City, China

Abstract: Introduction: Several studies have showed that the feelings of aged people would become dull. However, they are prone to develop chronic pain in the conditions of diseases. Such characters of pain in aging were similar to hyperalgesic priming model, an animal model for studying the transition of acute to chronic pain. However, the mechanisms of chronic pain in

aging were not clarified yet. It is reported that the aged immune cells, including T cells, microglia and macrophages, would release more proinflammatory factors, which keep the aged body in proinflammatory status. This is called inflamm-aging. Here, we tested the hypothesis that aged mice were in hyperalgesic priming state and inflamm-aging may contribute to the development of chronic pain in the aged mice. **Methods:** Male mice older than 12 months were used as aged mice. Male mice which were 8 weeks old were used as young mice for control. For ongoing inflammatory pain model, 10ul CFA was injected intraplantarly into the hind paws. The hyperalgesic priming model was induced by carrageenan as described before. Both mechanical and thermal pain thresholds were determined at different timepoints after the pain models were produced. Mechanical pain thresholds were measured with von Frey test. Thermal pain thresholds were determined with Hargreaves' test. On 0, 2, 7 and 21 days after carrageenan priming, lumbar DRGs were isolated. CD3 and CD4 or CD8 were co-stained to show the subgroups of T cells. Moreover, Iba-1 was used as a marker of microglia to evaluate the changes of microglia activation in the aged and young mice. **Results:** Similar to what has been observed in clinic, the baselines of mechanical and thermal pain thresholds were significantly higher in the aged mice than those in the young mice, showing that the feelings became dull in the aged mice. In CFA-induced inflammatory pain model, the pain were resolved within 7 days in young mice, however, it is prolonged to more than 2 weeks in the aged mice. Similar to our previous work, the PGE_2 induced hyperalgesia lasted about 3 days in young primed mice. While in aged mice, it prolonged to about 5 days. These results suggested that the aged mice were in primed states, prone to get chronic pain in the condition of inflammation. IHC results showed that 7 days after carrageenan primed, there were more CD3+/CD8+, but not CD3+/CD4+ T cells were filtered into DRGs. Moreover, in the DRGs of aged mice, the activation of microglia was significantly higher than those in the young mice. These results indicated that the aged immune cells were involved in the primed state of aged mice. **Conclusion:** The aged immune cells were involved in primed state in aged mice.

Title: Differential regulation of the glucocorticoid receptor in rat models of inflammatory pain

Authors: *S. IBRAHIM, J. A. STRONG, J.-M. ZHANG
Anesthesiol., Univ. of Cincinnati, Cincinnati, OH

Abstract: Anti-inflammatory corticosteroids are a common treatment for different conditions involving chronic pain and inflammation. Clinically used steroids target the glucocorticoid receptor (GR) for its anti-inflammatory effects. We previously reported decreased GR immunoreactivity signal in dorsal root ganglia (DRG) after local inflammation. In the current study, we aimed to determine if similar changes in GR signal also exist in a skin inflammation model, the Complete Freund's Adjuvant (CFA) model, in which the terminals of the sensory neurons rather than the somata are inflamed. Immunohistochemical techniques were used to determine the expression pattern of the GR in the inflamed hindpaw and the associated DRGs. Behavioral signs of pain were confirmed by the presence of static, dynamic, and cold allodynia, and guarding behavior for 14 days (longest time tested). Moreover, paw swelling was confirmed with approximately two-fold increase in the paw cross-sectional area, which lasted at least 14 days. The immunohistochemical staining revealed that GR is widely expressed in the normal DRG and skin tissues. Paw injection with CFA caused upregulation of the GR in the skin tissue on post-injection day one, mostly detected in the dermis area. However, paw inflammation significantly reduced the GR signal in the DRG one day after the injection. Results from this study indicate that there are distinctive patterns of GR activation under different pain conditions, which may have a significant impact on the use of steroids as treatment in these conditions. It will be of interest to determine whether these changes in GR signal levels are transient or long-lasting.

Title: Cardiac sympathetic nerve activity changes induced by mechanical pressure stimulation of a calf are augmented by acute muscle inflammation in isoflurane-anesthetized rats

Authors: *N. WATANABE, H. HOTTA
Dept. of Autonomic Neurosci., Tokyo Metropolitan Inst. of Gerontology, Tokyo, Japan

Abstract: Background and Aim
Muscle inflammation alters nervous system function such as increasing the resting discharge of

primary afferents in affected tissues and lowering mechanical threshold of withdrawal response. In contrast, an impact of muscle inflammation on autonomic nervous function remains to be studied. Recently, we reported that mechanical pressure stimulation of a calf altered cardiac sympathetic nerve activity (CSNA) and heart rate (HR), depending on the tonus level of CSNA; the stimulation induced tachycardia when the tonus was low and bradycardia was elicited when the tonus is high. We aimed to investigate the influence of acute muscle inflammation on CSNA and HR responses to calf pressure stimulation.

Methods

Experiments were performed on 5 Wistar male rats under isoflurane anesthesia. A catheter was implanted into the carotid artery for measuring arterial pressure and into the jugular vein for administering drugs. HR was calculated from arterial pressure waveforms. Mass discharges of inferior cardiac sympathetic nerve were recorded using bipolar hook electrodes. Rats were paralyzed using gallamine, administered after the sufficient depth of anesthesia was confirmed. A probe of 6 mm in diameter with a flat contact area was used and mechanical pressure stimulation was applied to the center of a calf over the skin with a constant force (10 N/cm^2 for 30 sec). To induce inflammation, 3% λ-carrageenan was injected in one side of calf muscles on the day before the experiment. Saline was injected in the contralateral calf as control.

Results

Mechanical pressure stimulation was applied to inflamed (27 trials in total) or non-inflamed (27 trials in total) calf. The stimulation increased or decreased CSNA and HR. As observed previously in naïve rats, changes in CSNA and HR were negatively correlated with pre-stimulus CSNA levels. Such a correlation was observed in responses of both non-inflamed and inflamed calf stimulation ($r < -0.64$, $p < 0.001$). The magnitudes of CSNA and HR changes were significantly larger in inflamed calf stimulation than those in non-inflamed calf ($p < 0.02$). To clarify sympathetic regulation of HR, the data of CSNA and HR changes were plotted, showing positive correlations between those parameters ($r > 0.77$, $p < 0.001$). The slopes of the correlation were identical between inflamed and non-inflamed calves, and naïve and carrageenan-injected rats.

Conclusion

The present study showed that mechanical pressure stimulation applied to acutely-inflamed muscles augmented CSNA and HR changes. Our results indicate that such an augmentation may be due to functional alterations of afferent pathways rather than a change in sympathetic regulation of HR.

Title: Pain control by two types of dental laser irradiation using an animal pain model induced by experimental tooth movement

Authors: *T. TSUCHIYA[1], A. SASAKI[1], M. YUGAWA[1], N. HASEGAWA[1], N. SUDA[1], K. ADACHI[2]
[1]Orthodontology, [2]Pharmacol., Meikai Univ. Sch. of Dent., Sakado, Japan

Abstract: The analgesic effect of CO_2 laser irradiation on the experimental tooth movement-related pain was reported last year. Diode laser is also widely used in dentistry for many purpose including pain control, however, diode laser has higher tissue permeability compared with CO_2 laser. Therefore, the effect of diode laser irradiation on orthodontic pain was examined in this study. General anesthetized rats were applied continuous orthodontic force by Ni-Ti closed coil spring to only the right maxillary first molar. On the following day, rats were general anesthetized and pair of electrodes was inserted bilateral anterior digastric muscle to record EMG activity and the maxillary first molar gingiva to electric stimulation. Passing current (200 μs) was applied to the right then the left maxillary first molar region to determine jaw-opening reflex (JOR) threshold. After measuring JOR threshold, CO_2 or diode laser irradiation (0.5 W;distance CO_2 20 cm diode 3.2 cm ;time 30 s) was applied the right side maxillary first molar region then JOR threshold was determined again for subsequent 60 min with 30 min interval (D1 group). CO_2 or diode laser irradiation (30 s) was also applied to the right maxillary first molar region immediately after orthodontic force application in other animals, and JOR excitability was evaluated on next day (PI-D group). To confirm effect of laser irradiation on JOR excitability, another set of animals received only laser irradiation (30 or 600 s, without orthodontic treatment) to the right maxillary first molar region before JOR excitability evaluation (control group). Since JOR threshold was variable across animals, the right side threshold was standardized with that of left side in each animal. Either laser irradiation did not alter JOR threshold between right and left stimulations in the control group. Application of orthodontic force in the D1 group significantly ($P < 0.05$) decreased right side JOR threshold compared with that on the left side. CO_2 laser irradiation (30 and 600 s) in D1 group significantly ($P < 0.05$) increased right side JOR threshold (30 and 600 s @ 30 min and 60 min). However, diode laser irradiation (30 and 600 s) in group D1 did not alter the JOR threshold on the right side. Interestingly, in the PI-D group, the right side JOR threshold was also significantly increased ($P < 0.05$) by both laser irradiation. Taken together, CO_2 and diode laser irradiations are able to prevent orthodontic pain. Moreover, CO_2 laser irradiation is applicable to analgesic purpose for orthodontic pain.

Title: *In vivo* tracing of single neuron activity with Ca^{2+} imaging of primary somatosensory cortex in mouse models of postoperative pain and inflammatory pain

Authors: *T. OKADA, Y. TACHIBANA, Y. NOMURA, N. OBATA, S. MIZOBUCHI, H. WAKE
Kobe Univ. Grad. Sch. of Med., Kobe / Hyogo, Japan

Abstract: Recently, prolonged postoperative pain and neuropathic pain are major problems with increased numbers of surgical operation. Previous studies using chronic pain models have shown that the activation of glial cells followed by the release of neurotrophic factor resulted in increased neuronal excitability in the spinal cord. In addition, accumulated evidence suggests that plastic changes of neuronal circuits in the primary somatosensory cortex (S1) are essential for the formation of chronic pain. However, little is known about how individual cells in neuronal population in S1 fire differently during the formation and maintenance of chronic pain. In this research, we used two mice models of pain to study the characteristics of individual neuronal activity patterns in the acute pain phase of S1: one which had the incision of hind paw as a model of postoperative pain, the other which received the injection of Complete Freund's adjuvant (CFA) into hind paw as a model of inflammatory pain. Firstly, behavior response to mechanical and thermal stimulation were evaluated before and after the operation of hind paw. The paw withdrawal threshold significant decreased in the affected hind paw of postoperative pain model and inflammatory pain model. Secondly, we used *in vivo* two-photon calcium imaging to trace the single cell activity during the formation of pain. The spontaneous neuronal activity in S1 was measured by fluorescent signal from GCaMP6f expressing in layer II/III pyramidal neurons of S1. The single cell activities were then traced before and after operation and their dynamics changes were analyzed mathematically. Consequently, the activity synchronization among cells increased with both models in acute pain phase and the period was more extended in a model of inflammatory pain. Furthermore, amplitude of Ca^{2+} traces in S1 was tend to increase with inflammatory pain model in acute pain phase, but the increase was not found with postoperative pain model. This result indicates that the intensity of pain with inflammatory pain model is higher than postoperative pain model and the pain lasts longer. This research will be able to clarify the mechanism of transition from acute pain to chronic pain, and in future, it is necessary to examine not only the spontaneous activity but also the change of neural activity against hind paw stimulation in S1.

Title: Experimental inflammation and inflammatory pain reduced by ketogenic diet

Authors: *D. N. RUSKIN, L. S. WYSS, S. A. MASINO
Trinity Col., Hartford, CT

Abstract: Ketogenic diets are very low carbohydrate, high fat, moderate protein diets used traditionally have been used to treat medication-resistant epilepsy. Growing evidence suggests that one of its mechanism of action is reducing inflammation. Here, we examined the diet's effects on experimental inflammatory pain in a rodent model. Adult (10-16 month old) male Sprague-Dawley rats were placed on ketogenic diet (~6:1 fats:(carbohydrates + proteins)) or maintained on control diet. At 2-4 weeks on diets, complete Freund's adjuvant (CFA, 100 μl) was injected in one hindpaw to induce inflammation; the contralateral paw was used as the control. Tactile sensitivity (von Frey) and spontaneous pain behavior (blind video scoring) were measured before and after CFA treatment. Ketogenic diet feeding did not affect baseline tactile sensitivity or body weight, and spontaneous pain behaviors (hindpaw licking, lifting or favoring) were essentially absent. Post-CFA, tactile hypersensitivity (allodynia) was clearly present in all animals (tested at 4 and 48 h post-CFA), but significantly less in the ketogenic diet-fed group at 4 h post-CFA. Spontaneous pain behavior involving the injected hindpaw was present in all animals (tested at 24 h post-CFA), with a strong trend to less in the ketogenic diet-fed group. Injected hindpaw swelling, assessed by weight, was significantly reduced by ketogenic diet feeding (uninjected paws were unaffected by diet). Our data suggest that ketogenic diets might be useful treatments for inflammatory conditions and inflammatory pain.

Title: The expression of aspartate aminotransferase and glutaminase in rat dorsal root ganglion treated with peripheral glutaminase inhibitor during adjuvant induced arthritis

Authors: *R. PANDE[1], K. E. MILLER[2]
[2]Anat. and Cell Biol., [1]Oklahoma State Univ. Ctr. for Hlth. Sci., Tulsa, OK

Abstract: Introduction: Glutamate is a major excitatory neurotransmitter and plays a crucial role in pain pathways. Therefore, it is important to know the precise sequence of expression of enzymes leading to biosynthesis of neurotransmitter glutamate. Intense noxious stimuli or tissue damage causes glutamate to be released from peripheral and central afferent nerve terminals and augmented release occurs during acute and chronic inflammation. Glutamate is synthesized by phosphate-activated glutaminase (GLS) and aspartate aminotransferase (AST) by two main pathways. First, glutamate is produced in mitochondria by glutaminase (GLS) through the glutamine-glutamate cycle and is transferred to the cytoplasm. Second, glutamate is transaminated by AST in mitochondria (mAST), producing alpha-ketoglutarate and aspartate, both of which are then transported out of mitochondria and utilized by cytosolic AST (cAST) to reform glutamate and oxaloacetate. Although cAST can provide a net synthesis of glutamate, its precise functional role in sensory neurons during inflammation remains to be established. For example, the role of cAST in production of glutamate in dorsal root ganglion neurons during adjuvant-induced arthritis (AIA) in rat has not been evaluated. Methods: AIA was induced by injecting complete Freund's adjuvant (CFA) into the right hind paw of anesthetized, 8-10 week old male Sprague Dawley rats (200-300gm). 6-Diazo-5-oxo-L-norleucine (DON) (glutaminase inhibitor) was pre- and co-administered to/with CFA in the same paw. L4 and L5 DRG were collected from naive and AIA animals at 24, 48 and 96 hours of inflammation. Messenger RNA and protein expression of cAST and GLS in dorsal root ganglion (DRG) was determined by quantitative PCR and immunoblot techniques. Result and Conclusion: Our findings show an early and prolonged alteration (24-96hr) in the expression of cAST and GLS in the DRG during AIA. DON treatment mitigated some of the inflammation induced changes. Alterations in GLS and AST appear to contribute to DRG neurotransmitter changes in response to peripheral inflammation.

Title: Characterizing the pathological effects of prenatal alcohol exposure on spinal neuroimmune mechanisms that result in neuropathic touch sensitivity

Authors: *J. SANCHEZ, J. E. SANCHEZ, S. DAVIES, D. D. SAVAGE, E. D. MILLIGAN
Neurosciences, Univ. of New Mexico, Albuquerque, NM

Abstract: A hallmark of peripheral neuropathic pain is increased sensitivity to light touch (allodynia). Glial cells (astrocytes and microglia) contribute to allodynia. Additionally, peripheral leukocytes may infiltrate the spinal cord through the adhesive actions of the β-2-Integrin, lymphocyte function-associated antigen (LFA)-1 (a.k.a. CD11a), in response to proinflammatory cytokines such as interleukin-1β (IL-1β). Recently, we demonstrated that prenatal alcohol exposure (PAE) increased susceptibility to allodynia following minor nerve injury in adult rats. Additionally, studies demonstrate elevated expression of LFA-1 in spinal cords of PAE rats compared to Saccharin (Sac) controls. Furthermore, *in vitro* studies have demonstrated that an anti-inflammatory environment can be induced by preventing LFA-1 activated conformational changes. Here, we examined whether: (1) spinal application of an LFA-1 antagonist suppresses glial activation, elevates anti-inflammatory interleukin-10 (IL-10), and reduces IL-1β to reverse PAE induced allodynia, (2) and whether spinal IL-1β is necessary for its induction. To do this, male (4 mo) PAE or Sac exposed rat offspring were used. Hindpaw response-thresholds to light mechanical touch were assessed prior to and after minor sciatic nerve injury (1-suture chronic constriction injury; CCI) or sham surgery. On Day 28, intrathecal (peri-spinal; i.t.) injection of BIRT-377 (LFA-1 antagonist) or vehicle was administered followed by daily reassessment of allodynia for 4 days (peak drug efficacy), at which time, spinal cords were processed for immunohistochemical detection of glial activation and cytokine markers. Separate groups of PAE rats were assessed prior to and up to Day 10 after CCI. At this time, i.t. IL-1 receptor antagonist (IL-1RA) or vehicle was administered followed by re-assessment of allodynia. Results show that in PAE rats with allodynia, BIRT-377 reversed allodynia and reduced spinal astrocyte, microglial, IL-1β, and CD11a immunoreactivity to basal levels. Sac rats

with minor CCI and vehicle injection displayed elevated expression of glial activation, IL-1β, and CD11a despite the absence of allodynia. IL-10 expression was blunted in PAE rats following CCI given vehicle injection. Furthermore, astrocyte activation was greatest in PAE rats compared to Sac rats following minor CCI. I.t. IL-1RA produced robust reversal of allodynia. These data suggest that in offspring with PAE, minor injury creates pathological susceptibility to neuropathy (allodynia) that is mediated by blunted spinal IL-10 responses in combination with increased IL-1β expression and altered astrocytic function.

Title: Neuronal FcγRI contributes to antigen-induced inflammatory pain in the rat

Authors: *F. LIU[1], T. WANG[2], B. YUAN[2], W. QIU[2], C. MA[2]
[1]Dept. of Anatomy, Histology and Embryology, Inst. of Basic Med. Sciences, CAMS PUMC, Beijing, China; [2]Dept. of Human Anatomy, Histology and Embryology, Inst. of Basic Med. Sciences, Neurosci. Center, Chinese Acad. of Med. Sciences; Sch. of Basic Medicine, Peking Union Med. Col., Beijing, China

Abstract: Pain is a major symptom in certain immune-related disorders that were characterizedwith an elevated level of serum or diseased tissue IgG immune complex (IgG-IC). FcγR type I (FcγRI) is the high-affinity activating receptor of IgG-IC and critically involved in a number of inflammatory and immune diseases. Our previous studies demonstrated that a subpopulation of nociceptive dorsal root ganglion (DRG) neurons express FcγRI and can be directly activated by IgG-IC evoking an increased intracellular calcium level and neuronal excitability. This mechanism may be involved in the development of pain in multiple immune diseases such as rheumatoid arthritis. We hypothesize that IgG-IC directly activates nociceptive neurons innervating the joint by neuronal FcγRI to produce pain and inflammation in the rat model of rheumatoid arthritis. We generate FcγRIα^{loxP} transgenic rat line in which syntropy loxP

sequence were inserted the exon both ends of genome FcγRIα gene and pirt^{Cre} transgenic rat line which the Cre protein was expressed under the control of the pirt promoter, which expressed in the primary nociceptive neurons. The FcγRIα^{loxP} rat was crossed with pirt^{Cre} rat to generate the pirt-control conditional FcγRIα knockout transgenic rat line (Pirt-FcγRIα$^{-/-}$ rat). We found that the mechanical and thermal hyperalgesia induced by intracutaneous injection of IgG-IC (antigen: oval albumin, OVA, antibody: rat anti-OVA IgG) were significantly alleviated in Pirt-FcγRIα$^{-/-}$ rats as compared to the wildtype. We next produced a rat model of antigen-induced arthritis (AIA) using OVA as antigen, and found that both the pain-related behaviors and joint inflammation induced by AIA were significantly reduced in the Pirt-FcγRIα$^{-/-}$ rats as compared to the wildtype. Our results suggest that FcγRI expressed in the peripheral nociceptive neurons innervating the joint can be directly activated by IgG-IC and play an important role in the development of inflammatory pain in antigen-induced arthritis.

Abstract: Dry eye disease (DED) which affects more than 10% of the population worldwide is a multifactorial disease associated with an inflammation of the ocular surface and ocular pain

symptoms. Despite the high prevalence of DED, the underpinning mechanisms of this ocular surface disease are not fully understood.
The aim of this study was to characterize by molecular, cellular, behavioral and electrophysiological analyses a novel preclinical mouse model of DED obtained by an unilateral excision of the extraorbital lachrymal gland (ELG) and Harderian gland (HG). A sham animal group was also constituted.
Experiments were performed at Day (D) 7, D14 and D21 post excision. Corneal inflammation, tear production, as well as the peripheral (trigeminal ganglion (TG)) and central (sensory trigeminal complex) neuroinflammatory mechanisms were evaluated. Corneal nerve fiber activity was evaluated by an electrophysiological approach in an *ex vivo* eye preparation by recording the multi-unit extracellular spontaneous activity of the entire ciliary nerve with a suction electrode.
The unilateral excision of the ELG and HG rapidly and drastically reduced the production of tears, which was associated with strong corneal inflammation. Behavioral studies revealed that DED animal developed a mechanical corneal hypersensitivity measured with von Frey filaments. Additionally, a significant increase of the spontaneous ciliary nerve fiber activity was observed in DED animals at D7, D14 and D21 compared to sham animals. At D21 post excision, RT-qPCR analysis revealed a significant increase of oxidative markers (iNOS2 and NOX4) and pro-inflammatory markers (IL-6 and IL-1β) in the TG.
Immunohistochemistry experiments also showed an increase of Iba1, GFAP and activating transcription factor-3 (ATF-3) staining in the ipsilateral TG compared to sham animals. At D21, pro-inflammatory cytokines (IL-6, TNFα, IL-1β and CCL2), oxidative stress markers (iNOS2), neuronal markers (ATF3 and FOS) and microglia marker (CD68 and ITGAM) expressions were up regulated in the trigeminal sensory complex in the DED group compared to sham. In this central structure, an increase of GFAP immunoreactivity was also noted in DED animals.
In conclusion, we reported a novel and highly relevant preclinical model of DED in mice. This model is characterized by a spread of the corneal inflammation via the TG to the sensory trigeminal complex.
These peripheral and central neuroinflammatory mechanisms are associated with a corneal hypersensitivity and a significant increase in spontaneous corneal nerve fiber activity, all these mechanisms might explain the ocular pain observed in some patients suffering from DED.

Title: Chronic stress induces nociceptive hypersensitivity in rats via down-regulation of KCC2

Authors: *E. CURIEL[1], A. B. SALINA ABARCA[2], J. MURBARTIAN[3], V. GRANADOS-SOTO[4]
[1]Cinvestav Unidad Coapa, Mexico City, Mexico; [2]Cinvestav, Mexico City, Mexico; [3]Cinvestav, Sede Sur, Mexico, DF, Mexico; [4]Dept. de Farmacobiologia, Cinvestav, Coapa, Ciudad de Mexico, Mexico

Abstract: Chronic stress can induce physiological and psychological changes that contribute to stress-induced nociceptive hypersensitivity. In humans, exposure to chronic stress reduces pain threshold, resulting in hypersensitivity. It is known that stress exacerbates the etiology of various pathologies such as fibromyalgia, irritable bowel syndrome and headache. However, the mechanisms by which they are related are unknown. Previous studies have reported that microglia-derived brain-derived neurotropic factor (BDNF) leads to the reduction of K^+-Cl^- co-transporter 2 (KCC2) expression in neuropathic and inflammatory pain models. However, the role of KCC2 in functional pain is unknown. The purpose of this research was to study whether chronic restraint stress induced nociceptive hypersensitivity by increasing BDNF, which then promotes down-regulation of KCC2 protein expression at the spinal cord. Chronic restraint stress (2 h daily for 28 days) produced tactile allodynia and thermal hyperalgesia in both hind paws from day 21 to 28. Moreover, chronic restraint stress enhanced BDNF tissue levels in the dorsal portion of the spinal cord from day 21 and 28 and decreased KCC2 and phospho-Ser940 KCC2 protein expression in the dorsal portion of the spinal cord from day 7 to 28. KCC2 was absent in DRG. Intrathecal injection of the KCC2 activator CLP 257 (100-300 μg), but not vehicle, reduced in a dose-dependent manner chronic stress-induced tactile allodynia. Furthermore, intrathecal injection of the KCC2 inhibitors DIOA (0.02-20 μg) or VU0463271 (0.02-20 μg), but not vehicle, produced tactile allodynia in a dose-dependent manner in naïve rats. Results suggest that chronic restraint stress induces nociceptive hypersensitivity by increasing BDNF, which then leads to down-regulation of KCC2 expression at the spinal cord.

Title: GPR37 regulates macrophage phagocytosis and resolution of inflammatory pain

Authors: ***S. BANG**[1], Y.-K. XIE[2], Z.-J. ZHANG[1], Z. WANG[1], Z.-Z. XU[2], R.-R. JI[1]
[1]Dept. of Anesthesiol., Duke Univ. Med. Ctr., Durham, NC; [2]Dept. of Physiology, Ctr. of Neurosci., Zhejiang Univ. Sch. of Med., Hangzhou, China

Abstract: The pain resolution mechanism is not completely understood. In this study, we showed that the G-protein coupled receptor 37(GPR37) expressed macrophages but not microglia and contributed to resolution in the inflammatory pain. Neuroprotectin D1 (NPD1) that is the Docosahexaenoic acid metabolite, and Prosaposin relative peptide (TX14) elicited intracellular Ca2+ increase and phagocytosis in Gpr37 expressed macrophage. Hind-paw injection of zymosan particles not only induces inflammatory pain and infiltration of neutrophils and macrophages, but also causes GPR37 upregulation in macrophages, phagocytosis of zymosan particles and neutrophils by macrophages in inflamed paws, and resolution of inflammatory pain in wild-type mice. Mice lacking *Gpr37* display deficits in macrophage phagocytic activities and delayed resolution of inflammatory pain. *Gpr37*-deficient macrophages also exhibit dysregulations of pro-inflammatory and anti-inflammatory cytokines. Macrophage depletion delayed the resolution of inflammatory pain. Adoptive transfer of wild-type but not *Gpr37*-deficient macrophages promotes the resolution of inflammatory pain. Overall result suggests that GPR37 has a role in the resolution of inflammatory pain by regulation of phagocytosis and the cytokine in the macrophage.

Title: Blockade of Toll-like receptor 2 partially suppresses mycoplasma superantigen triggered arthritis pain in a mouse mode of autoimmune disease

Authors: *J. ZHANG[1], X. LU[1], C. J. MEANEY[2], X. WANG[2], R. HUGHEN[1], A. R. LIGHT[1], H.-H. MU[2]
[1]Anesthesiol., [2]Div. of Rheumatology, Dept of Intrnl. Med., Univ. of Utah Sch. of Med., Salt Lake City, UT

Abstract: Rheumatoid arthritis (RA) is an autoimmune disease that commonly affects joints and other tissues such as lung, heart, skin and nerves, causing swelling, fatigue and chronic pain. Although the genetic factors and environmental conditions have been widely studied, the cause of RA is not fully understood, and a cure is not yet available. To understand the mechanism of this disease, we recently modified the experimental collagen-induced arthritis (CIA) model by treating animals with a unique superantigen (M. arthritidis mitogen, MAM) from *Mycoplasma arthritidis*. We previously observed that MAM induced early onset of chronic arthritis with enhanced arthritis severity, predominantly by stimulating Th17 responses through TLR2 and TLR4. The current study evaluated pain phenotypes associated with MAM-triggered arthritis, and tested the idea of intervening the onset of the arthritis by interfering with innate immunity. Male B10RIII mice of 8-12 weeks old were separated into 3 groups. Mice in CIA group were treated intradermally at the base of the tail with 2 doses (250 μg) of bovine CII mix emulsified in CFA on Days 0 and 7. Mice in MAM group, however, were given 2 sub-optimal CII dose (150 μg) in CFA on days 0 and 7, followed by intraperitoneal (i.p.) injections of 25 ng MAM on days 14 and 21. Mice in TLR2 group received same pathogenic treatment as MAM group, plus 2 i.p. injections of 100μl αTLR2 antibody on days -2 and 0. Spontaneous and reflexive nocifensive behaviors, including guarding score, *von Frey* responses, inverted screen, hot plate, balance bar, and vertical behaviors were examined from day -1 twice a week for the first 4 weeks and once a week thereafter for 6 weeks. Immunohistochemistry was used to evaluate chemokines in dorsal root ganglia (DRG). We found that in CIA group, pain phenotypes started after day 49. For example, guarding score, an index for spontaneous pain, increased on Day 49 and quickly reached a peak on day 56, and maintained a high level after that. Compared to CIA group, MAM induced earlier onset of pain phenotypes, which started on day 21 and peaked on day 25. Peak value of guarding score (6.0±1.9, n=8) increased by 3 times compared to CIA group (2.1±0.9, n=8). In TLR2 group, although onset time of pain remained unchanged (started on day 18 and peaked on day 25), peak guarding score (2.7±1.2, n=8) significantly dropped to the level of CIA group. In line with this, amount of chemokines CCL2, CCL5 and CXCL12 in DRG also significantly dropped in αTLR2 antibody treated mice. Our results confirmed that MAM acts as a trigger for CIA in mice. Furthermore, it is suggested that TLR2 and other components in innate immune pathway are critical in the control of onset and/or severity of RA.

Ctr. at San Antonio, San Antonio, TX; [4]Endodontics, Johns Hopkins Univ., Baltimore, MD; [5]Univ. of Texas Hlth. Sci. Cntr at San Antonio, San Antonio, TX

Abstract: Persistent pain after root canal treatment is as high as 10-12% of all patients. Interestingly, ~40% of patients with apical periodontitis experience no pain (asymptomatic patients) despite similar radiographic presentation as symptomatic patients. Therefore, mechanisms mediating inhibition of nociception in asymptomatic patients may reveal novel factors or pathways that can be activated and therefore therapeutic in symptomatic patients. We hypothesize that soluble factors released from asymptomatic and symptomatic inflamed human apical tissues differentially regulate mouse TG nociceptor activities. We developed a clinically translational model where patients with either Symptomatic Apical Periodontitis (SAP) or Asymptomatic Apical Periodontitis (AAP) are phenotyped for pain followed by endodontic microsurgery to collect surgical biopsies and superfused to collect conditioned media (CM). Data were abalyzed using *Student's t-test* with $p<0.05$. We have found that 1.) Application of CM from periapical lesions from asymptomatic patients does not evoke calcitonin gene-related peptide (CGRP) release from cultured mouse TG neurons whereas CM from periapical lesions from symptomatic patients does. 2.) CM from periapical lesions from asymptomatic patients desensitizes capsaicin (CAP)-evoked calcitonin CGRP release and CAP-induced nocifensive behavior in mouse vibrissal pad whereas CM from periapical lesions from symptomatic patients show no such effect. 3.) Biopsies from patients without pain had ~2.5-fold greater levels of β-endorphin compared to patients in pain. 4.) Experiments using flow cytometric analyses and immuno-histochemistry revealed that periapical lesions contain large populations (~80%) of CD45+ leukocytes including CD11b+ macrophages, CD3+ T cells as well as CD19+ B cells and ~40% of all CD45+ leukocytes also express β-endorphin; 5.) Lastly, we also demonstrate that μ-opioid receptor (MOR) co-localizes with peripheral afferent sensory neurons in human periapical lesions. Taken together, these studies are consistent with a possible peripheral opioid-mediated regulation of pain in patients with asymptomatic periapical lesions but do not establish causality. Future studies will determine whether there are functional opioid- and non-opioid systems controlling peripheral neuronal activities in AAP patients.

Title: Epigenetic regulation of glutaminase expression in tnbs-induced colitis model of neuro-inflammatory pain

Authors: *S. DAS, K. E. MILLER
Anat. and Cell Biol., Ctr. for Hlth. Sci, Oklahoma State Univ., Tulsa, OK

Abstract: Inflammatory bowel disease (IBD) including ulcerative colitis (UC) and Crohn's diseases (CD) is chronic inflammation of the gastrointestinal tract leading chronic visceral discomfort pain. Many influences, including different biochemical and molecular mechanisms, genetic predisposition, and epigenetic factors, contribute to inflammatory chronic pain in IBD. Current pain management for visceral pain is very limited and is poorly understood. We have shown that glutamatergic sensory neurons play a central role in visceral neuro-inflammation and Glutaminase (GLS) expression, the enzyme that converts glutamine to glutamate, the excitatory neurotransmitter in sensory neurons, is upregulated. In this study, we explore different epigenetic factors controlling the regulation of GLS gene expression and how different epigenetic factors may modulate this chronic neuro-inflammatory pain.
Methods: Eight to ten-weeks old Sprague-Dawley rats were intra-rectally infused with trinitrobenzene-sulfonic acid to induce inflammatory colitis. The MeCP2 (Methyl CpG-binding protein-2) and GLS transcript and protein expression was studied in colon and L6/S1 DRGs in the absence or presence of GLS inhibitor, 6-diazo-5-oxo-L norleucine (DON) and/or Azacytidine (Aza, 50nM), DNA methyltransferase inhibitor. In *in vitro* studies, IEC-18 cells were used to study the effect of Aza on MeCP2 and GLS expression. Bisulphite conversion experiments and other epigenetic techniques were used to study DNA methylation of CpG islands of GLS promoter using methylation-specific PCR.
Results: There are two CpG islands in GLS promoter region. Our methylation-specific PCR studies targeted a sequence in the first CpG island (before TSS) and show increase in CpG DNA methylation in TNBS-induced colitis inflammation. This methylation was reduced in rats pretreated with DON, while in controls, there was no change. In IEC-18 studies, Aza treatment (25-50nM) reduced the GLS transcripts after 24 hours of treatment. Under these conditions, IEC-18 cells did express MeCP2-e2 but not MeCP2-e1.

Conclusion: Neuro-inflammation in TNBS-induced colitis induces different epigenetic factors that contribute to modification of GLS expression. We are investigating different epigenetic factors involved in modulation of pain in glutamatergic sensory neurons in DRG and colon. These epigenetic controls may be developed as crucial biomarkers for the pathogenesis, diagnosis and treatment of ulcerative colitis.

Title: Investigating the expression and function of galanin in colonic sensory neurones

Authors: *T. S. TAYLOR, J. R. F. HOCKLEY, E. S. SMITH
Univ. of Cambridge, Cambridge, United Kingdom

Abstract: Chronic visceral pain and visceral hypersensitivity to normal bowel movements are associated with gastrointestinal disorders such as irritable bowel syndrome (IBS) and inflammatory bowel disease (IBD). The neuropeptide galanin has been previously identified to modulate neuronal excitability in areas of the central and peripheral nervous system, but its role in afferent sensitivity in the distal colon has not been fully investigated.
A comprehensive single-cell RNA sequencing of colonic sensory neurons shows galanin is expressed in subpopulations of neurones with a likely nociceptive phenotype. Here, we have further investigated the expression and function of galanin in colonic sensory pathways in mice using retrograde labeled dorsal root ganglia (DRG) and electrophysiological recordings of lumbar splanchnic nerve activity using an ex vivo colon preparation.
Immunohistochemistry analysis of retrograde labelled DRG neurones demonstrates that galanin is expressed in a significant proportion of colonic sensory neurones in both the thoracolumbar and lumbosacral pathway (lumbar splanchnic and pelvic nerves respectively) and that galanin is coexpressed with the neuropeptide CGRP and Gfrα3, a marker of high-threshold stretches sensitive afferent fibres. In addition, we investigated how galanin modulates lumbar splanchnic nerve activity in response to noxious mechanical stimuli using in C57BL/6 mice. We observed that galanin attenuated peak firing in response to noxious mechanical stimulation and reduced basal firing. Effects of galanin receptor specific agonists and antagonists have also been investigated to determine which galanin receptor mediates the inhibitory effects observed.
In summary, we show that galanin may function in an auto-inhibitory role to attenuate afferent

firing in the lumbar splanchnic nerve in response to noxious mechanical stimulation and therefore contribute to the regulation of visceral pain.

Title: Role of transient receptor potential (TRP) channels in acute inflammatory knee pain

Authors: *S. CHAKRABARTI, L. A. PATTISON, G. CALLEJO, K. SINGHAL, J. R. F. HOCKLEY, E. S. J. SMITH
Dept. of Pharmacol., Univ. of Cambridge, Cambridge, United Kingdom

Abstract: Inflammatory joint pain is ongoing, diffuse and reduces the quality of human life. To determine how changes in joint neuron function during inflammation contribute to inflammatory knee pain, we conducted intra-articular injection of complete Freund's adjuvant (CFA) into the knee joint of mice. Subsequent to this inflammatory insult, mice displayed a decreased ability to perform natural digging behavior. To understand the neural basis of this symptom, we performed retrograde tracing of knee-innervating dorsal root ganglion neurons (knee neurons) and recorded their electrical and chemical sensitivity in culture using whole-cell patch clamp. We found that after inflammation, knee neurons show a decreased threshold of action potential firing and an increased sensitivity to capsaicin, an agonist of the transient receptor potential vanilloid 1 (TRPV1) ion channel. We further showed increased expression of TRPV1 in knee neurons from the CFA-injected side using immunohistochemistry. Nerve growth factor (NGF) signaling is a minor contributor to the increase in TRPV1 expression because there was a small increase in expression of TRPV1 with the NGF receptor, tropomyosin receptor kinase A (TrkA) following CFA injection. We also assessed the role of other TRP channels in inflammatory joint pain, but no change in cinnamaldehyde (TRPA1 agonist) or menthol (TRPM8 agonist) sensitivity was observed in knee neurons. Taken together, our data suggest that following CFA-induced knee inflammation there is a recruitment of TRPV1 sensitive knee neurons, which, combined with a lowered action potential threshold, likely contribute to the decreased digging behavior observed.

Title: General anesthesia activates a central circuit that functions to suppress pain

Authors: *T. HUA[1,2], K. SAKURAI[3], Y. CHEN[1,2], S. ZHAO[1], B.-X. HAN[1], F. WANG[2]
[2]Dept. of Neurobio., [1]Duke Univ., Durham, NC; [3]Tohoku Univ., Sendai, Japan

Abstract: One of the key functions of general anesthesia (GA) is analgesia, or pain relieving. We hypothesized that the GA-induced analgesic process is an "active" pain-suppression process rather than a passive consequence of GA-induced loss of conscious perceptions. Specifically, we hypothesize that there are neurons in the brain that are activated by GA and certain GA-activated neurons function to actively inhibit pain perception. Indeed, using the immediate early gene Fos as a marker for highly activated neurons, we discovered a subset of neurons in the mouse central amygdala (CeA) that become strongly Fos+ under GA (here after referred to as CeA_{GA}). Neurochemical characterization revealed that CeA_{GA} neurons are all GABAergic neurons. Using our recently developed CANE (Capturing Activated Neuronal Ensembles) technology that is ideal to capture and manipulate Fos+ neurons in mice, we are able to label CeA_{GA} neurons and express the optogenetic activator channelrhodopsin in these cells. We showed that optogenetic activation of CeA_{GA} neurons do not induce any fear related responses, which is a function generally associated with CeA. Importantly, activating CeA_{GA} significantly reduced sensory responses to mechanical, heat, cold, and chemical stimuli, also drastically abolished pain-induced self-recuperative behaviors such as wiping and licking of injured regions. Further, the pain-suppressing effects extend to both acute and chronic pain models. Finally, CeA_{GA} neurons project to numerous brain regions implicated in pain processing. Taken together, our study revealed a central pain-suppression circuit that is activated by GA, and is a previously unappreciated key neural substrate for the analgesic effect of GA.

Title: Paclitaxel chemotherapy induced neuropathic pain: Mechanism and neurocircuitry of adult rat brain

Authors: *P. P. KULKARNI[1], X. CAI[2], T. POTTALA[1], K. CRUITE[1], T. KNOX[1], S. NODINE[1], A. G. HOHMANN[3], C. FERRIS[1]
[1]Psychology, Northeastern Univ. Dept. of Psychology, Boston, MA; [2]Ctr. For Translational Neuroimaging, Northeastern Univ., Boston, MA; [3]Indiana Univ., Bloomington, IN

Abstract: Cancer is the second leading cause of death in the US accounting for over 600,000 deaths annually. The most common treatment for inoperable cancer is chemotherapy. Though chemotherapy can improve prognosis, side effects range from cognitive impairment to neuropathic pain. Between 30 and 50 percent of the patients undergoing chemotherapy experience some level of peripheral neuropathy (CIPN) that can continue after cessation of treatment. CIPN putatively results from the reorganization of neural circuits associated with pain perception and manifests as numbness, weakness, and prolonged pain in the extremities. These chemo-induced changes in brain structure and function are not well understood. In this study we characterized the anatomical and behavioral effects of the chemotherapeutic drug Paclitaxel in adult male Sprague-Dawley rats. Rats were given four injections of Paclitaxel at one day intervals followed by a behavioral test for cold allodynia and in vivo magnetic resonance imaging to assess changes in gray matter microarchitecture and functional connectivity. Following exposure to paclitaxel rat showed increased sensitivity to temperature or cold allodynia by a shorter latency to withdraw their paw when in response to a cold stimulus. Diffusion weighted imaging with computational analyses of indices of anisotropy showed putative changes in gray matter microarchitecture that included the basal ganglia, limbic ctx, amygdala and ventral hippocampus. Resting state functional connectivity showed an overall increase on connectivity or hyper-connectivity in many brain regions. The ventral posteriolateral thalamus, a key node in pain transmission to the sensory ctx, shows connectivity to immediate thalamic areas and the sensory ctx with vehicle treatment but loses connectivity to the ctx following paclitaxel treatment. The median raphe a key node in pain perception and integration shows hyper-connectivity to multiple brain areas following paclitaxel treatment. The dorsal medial striatum involved in habit formation and motivation shows an interesting anticorrelation (negative connectivity) with paclitaxel to brainstem and cerebellar regions suggesting a online/offline relationship between the brain might be compensating for neuropathic pain by disconnecting the striatum from the brainstem pain areas and the cerebellum. Together these

finding suggest paclitaxel induces reorganization of neural circuitry related to controlling pain, learning, and memory.

Abstract: Chemotherapy is an indispensable treatment option for many common cancers and is used in neoadjuvant, adjuvant, and metastatic settings. Despite its usefulness, the systemic nature of chemotherapy carries implications for healthy dividing cells, and ultimately overall patient health. The effects of chemotherapy on the CNS are often subtle and may persist well after the end of treatment. There is limited research on the effects of chemotherapy in the pediatric population, specifically chemotherapy-induced changes in brain function and sensory processing. In this study we characterized the anatomical and behavioral effects of the chemotherapeutic drug paclitaxel in prepubescent (30-35 days of age) male Sprague-Dawley rats. Rats were given four injections of paclitaxel (2 mg/kg i.p.) at one day intervals followed by a behavioral test for cold allodynia and in vivo magnetic resonance imaging to assess changes in gray matter microarchitecture and functional connectivity. Behavior testing revealed no difference in chemotherapy-treated animals, when testing for withdrawal latencies on a cold plate assay for neuropathic pain. Diffusion weighted imaging (DWI) showed alterations in gray matter microarchitecture in the primary olfactory system, deep cerebellar nuclei and interestingly, the midbrain dopaminergic neurons. Areas comprising the pain neural circuitry were unaffected. Changes in resting state functional connectivity were modest. These data are in in stark contrast to paclitaxel treatment in adult rats that show robust cold allodynia , alterations in pain neural circuitry (see adjacent poster) as well as reductions in both hippocampal neurogenesis and

reversal learning deficits. Ongoing studies are exploring changes in learning and memory, functional connectivity and immunohistochemical biomarkers of inflammation following chemotherapy treatment in prepubescent rats.

Title: Effect of the Pha1b toxin on spinal cord glia in CFA-induced inflammatory pain

Authors: *H. TENZA FERRER[1], J. DA SILVA[2], L. A. V. MAGNO[1], M. V. GOMEZ[1,2]
[1]Univ. Federal De Minas Gerais, Belo Horizonte, Brazil; [2]Inst. de Ensino e Pesquisa da Santa Casa de Belo Horizonte, Belo Horizonte, Brazil

Abstract: Phα1β (or Tx3-6) is a toxin obtained from the venom of the Brazilian spider *Phoneutria nigriventer*. We have previously showed that this toxin blocks different types of neuronal voltage sensitive calcium channels with preference for N-type, which is directly involved with pain. Although different animal pain models including inflammatory pain were attenuated by acute or chronic administration of Phα1β, it is still unclear the anti-inflammatory mechanisms of this toxin. An intraplantar CFA injection into the hind paw induce an inflammation in the site of the injection, and this conducts to a behavior change in the animal as a mechanical hyperalgesia. The peripheral inflammation in the CFA model also produce a cellular response observed in the dorsal horn of the spinal cord such as glial activation. For example, Ikeda *et al.* (2012) showed that glial activation is observed in the rat spinal cord following peripheral inflammatory pain with CFA, which result in pain behaviour. In the present study, we sought to determine whether anti-inflammatory effects of Phα1β involve glia recruitment or activation in the rat spinal cord. To conduct this, we produced the peripheral inflammatory model injecting a single unilateral injection of CFA into the hind paw. Two days after CFA or vehicle injection, animals were intrathecally injected with Phα1β and, two hours later, we observed antinociceptive effects through an analgesimeter test. Then, we intracardially perfused the animals and performed spinal cord confocal microscopy for Iba1 and GFAP. As expected, our inflammatory model increased the astrocytes and microglia activation and proliferation in the spinal cord two days post CFA injection. The activation was studied through fluorescence intensity and morphology of the cells and the proliferation was conducted by manual counting of cells and BrdU immunofluorescence. Our observations show that the toxin-treated animals displayed reduced astrocytes activation and increased local proliferation of these cells, but no alteration in microglia proliferation. These results suggest that anti-inflammatory effects of Phα1β are related to astrocyte inhibition in the spinal cord.

Title: Pain modulation by delivering gaba$_a$agents across the blood-brain barrier through focused ultrasound

Authors: *K. WANG[1,2], T. HE[1], W. XIONG[1,2], X. YU[1,3], C.-H. TSAI[4], X. LI[3], H.-L. LIU[1,4], H.-Y. LAI[1,2]

Abstract: The pain processing is associated with an extensive cortical network, and the primary somatosensory cortex (S1) is the kernel to modulate the pain sensation. Multiple $GABA_A$ agents have been used in the pain modulation, however, these agents may produce poor modulated effect or side effect because the molecule size of these agents could not cross the blood brain barrier (BBB) locally. Focus ultrasound (FUS) combined with microbubble could temporally disrupt the BBB to induce $GABA_A$ agents delivery. In the present study, we proposed that FUS-induced BBB opening combined with picrotoxin (PTX, a $GABA_A$ receptor antagonist), and muscimol (MUS, a $GABA_A$ receptor agonist) could modulate the pain perception with dosages. We presented FUS at the rat's left primary somatosensory cortex forelimb region (S1FL, 1 mm posterior and 4 mm lateral to the bregma) followed by intravenous administration of PTX (0.2, 0.4 or 1 mg/kg), and MUS (0.2, 0.4 or 1 mg/kg). Behavioral tests were evaluated by mechanical nociceptive threshold (MNT) testing before and after FUS exposure and immunohistochemistry staining was performed after electrical stimulation in forepaw. As compared with the non-FUS side, the paw withdrawal threshold decreased in the PTX group and increased in the MUS group in the FUS side with 3-h post-FUS ($p<0.05$). Moreover,the variation of paw withdrawal threshold was dosage-dependent. Immunohistochemistry staining showed that PTX and MUS respectively excited and inhibited the expression of c-Fos in left S1FL (FUS exposure site) as compared with right S1FL, corresponding with the results of behavioral tests. In addition, the statistical results displayed that most c-Fos expression localized in the layer II/III and IV of S1FL.These results may suggest a further potential to specifically modulate pain sensation by targeting on the layer II/III and IV in S1FL.

Title: The effect of electroacupuncture on cord dorsum potentials produced by sural nerve stimulation in the diabetic rat

Authors: *S. QUIROZ-GONZÁLEZ[1], G. VERÓNICA BEATRIZ[1], Y. GARCIA-PICENO[1], R. LÓPEZ-GÓMEZ[1], B. SEGURA-ALEGRÍA[2], I. JIMÉNEZ-ESTRADA[3]

Abstract: In this study, the effect of low and high frequency electroacupuncture (EA) on the negative components of the spinal cord dorsum potentials (CDPs) generated by the electrical stimulation of the sural nerve was analyzed in diabetic rats induced by streptozotocin (STZ). Two groups of Wistar rats (120-150 gr) were used: one received STZ (60mg/kgi.p.) and the other, the STZ vehicle solution. The animals were anesthetized with ketamine (100 mg / kg) and Xilasine (2 mg/kg) and underwent a laminectomy to expose the L4, L5, L6, S1 spinal segments. To record the CDPs, a "ball" electrode was placed on the back of the spinal cord and the sural nerve (SU) was stimulated with "hook" electrodes (single current pulses. 0.05 ms, 3.5 and 20 times threshold, xU). EA stimulation was applied at 2 and 100 Hz at the acupoints Zuzanli (ST36) and Sanjinjiao (SP6) during 30min. One week after STZ injection, treated animals (n = 9) had an increase in blood glucose (from 110 ± 15 to 421 ± 23.6 mg / dl), which was maintained until the week 5. On the other hand, animals with vehicle (n = 7) had no increase in blood glucose. Body weight also decreased in treated animals (19.5 ± 4.2%). At week 5 a facilitation was observed in the N2 (33 ± 7.1%; n = 9) and N3 (40 ± 8.5%; n = 9) components in the CDPs recorded in diabetic animals, but there was a depression in amplitude of the N1 component (20.5 ± 6.5%; n = 9) in comparation with control animals. Both, facilitation and depression of the negative CDPs were reduced by 2 and 100Hz of EA stimulation (N1; 34 ± 8.8%, N2; 22 ± 6.1%, N3; 43 ± 8.5%). Our results indicate that EA partially reverse the alterations provoked in the negative components of the CDPs in animals under experimental diabetes.

Title: Alterations of spinal inhibitory and excitatory nociceptive transmission in VGAT-ChR2-eYFP mice in different pain models

Authors: *P. ADAMEK[1,2], M. HELES[1,2], J. PALECEK[1]
[1]Inst. of Physiol. of the Czech Acad. of Sc, Prague, Czech Republic; [2]Fac. of Science, Charles Univ., Prague, Czech Republic

Abstract: Disbalance between inhibitory and excitatory neurotransmission in the spinal cord may be one of the underlying mechanisms of different pain syndromes. Our goal was to describe and compare changes in excitatory and inhibitory transmission in the superficial laminae (I, II_o) excitatory dorsal horn neurons in a model of paclitaxel-induced neuropathy, chronic constriction injury of the sciatic nerve (CCI), and peripheral inflammation in adult male mice. Blue light (470 nm) optogenetic stimulation of inhibitory dorsal horn neurons evoked IPSC (le-IPSC) currents in combination with whole-cell patch clamp recordings of spontaneous excitatory and inhibitory postsynaptic currents (sEPSC, sIPSC) from excitatory neurons in spinal cord slices from VGAT-ChR2-eYFP mice were used. Inhibitory interneurons with channelrhodopsin-2 (ChR2) expression were characterized by le-IPSC response with long plateau phase that was missing in the excitatory neurons. Only excitatory, non-ChR2 expressing neurons were analyzed in this study. Our results showed that all three pathological conditions: paclitaxel-induced neuropathy, CCI and also peripheral inflammation lead to significant reduction in the amplitudes of le-IPSC (65 %, 48 and 59 % of the control group). The ratio between the glycinergic and GABAergic component of the le-IPSC did not change substantially in comparison with controls. Frequencies of sIPSC were significantly reduced while sEPSC were increased under the pathological conditions. Mechanical sensitivity was significantly increased in all three models in behavioral tests. Our data suggest that different pathological conditions may induce similar changes in neurotransmission together with corresponding behavioral changes. A better understanding of the specific mechanism of the fragile balance between the excitatory and inhibitory neurotransmission under the pathological conditions may help to improve analgesic therapy in various pain states.

Title: AIBP selectively regulates lipid rafts and inhibits neuroinflammation

Authors: ***Y. MILLER**, S.-H. CHOI, S. WOLLER, T. YAKSH
UC San Diego, La Jolla, CA

Abstract: Apolipoprotein A-I binding protein (AIBP) reduces lipid raft abundance by augmenting removal of excess of cholesterol from the plasma membrane. Here, we report that AIBP prevents and reverses processes associated with neuroinflammatory-mediated spinal nociceptive processing. The mechanism involves AIBP binding to Toll-like-receptor-4 (TLR4) and increased binding of AIBP to activated microglia, which mediates selective regulation of lipid rafts in inflammatory cells. AIBP-mediated lipid raft reductions downregulated LPS-induced TLR4 dimerization, inflammatory signaling and expression of cytokines in microglia. In mice, intrathecal injections of AIBP reduced spinal myeloid cell lipid rafts, TLR4 dimerization, neuroinflammation, and glial activation. Intrathecal AIBP reversed established allodynia in mice in which pain states were induced by the chemotherapeutic cisplatin (as shown in the figure below), intraplantar formalin, or intrathecal LPS, all pro-nociceptive interventions known to be regulated by TLR4 signaling. These findings demonstrate a novel mechanism by which AIBP regulates neuroinflammation and suggest the therapeutic potential for AIBP in treating preexisting pain states.

Toronto, Toronto, ON, Canada

Abstract: Peripheral nerve injury can induce pathological conditions that lead to persistent sensitized nociception. Although there is evidence that plastic changes in the cortex contribute to this process, the underlying molecular mechanisms are unclear. Here, we find that activation of the anterior cingulate cortex (ACC) induced by peripheral nerve injury increases the turnover of specific synaptic proteins in a persistent manner. We demonstrate that neural cell adhesion molecule 1 (NCAM1) is one of the molecules involved and show that it mediates spine reorganization and contributes to the behavioral sensitization. We show striking parallels in the underlying mechanism with the maintenance of NMDA-receptor- and protein-synthesis-dependent long-term potentiation (LTP) in the ACC. Our results, therefore, demonstrate a synaptic mechanism for cortical reorganization and suggest potential avenues for neuropathic pain treatment.

Title: Exploration of sensory integration for nociceptive and tactile inputs in primary somatosensory cortex of rats

Authors: *H. KANDA, J. G. GU
Anesthesiol. and Perioperative Med., Univ. of Alabama At Birmingham, Birmingham, AL

Abstract: We have recently shown that Piezo2 channel is involved in mechano-transduction and serotonin is mechanical transmission in Merkel cells of whisker hair follicles (Ikeda et al, Cell 2014). Since tactile information from whisker hair follicle is relayed to the barrel cortex in primary somatosensory regions of the rat brain, we seek to further understand how tactile signals from a single whisker hair follicle are processed in the barrel cortex and whether the sensory process of tactile signals in the brain may be significantly affected by nociceptive inputs form the periphery. To address these questions, we performed *in vivo* whole-cell patch-clamp recordings from neurons in layer 2/3 of rat barrel cortex (C1 region) to examine excitatory postsynaptic currents (EPSCs) and action potential firing following mechanical stimulation of a whisker hair. Experiments were performed on adult Sprague-Dawley rats that were anesthetized with urethane. The region of recordings was is around 2.5 mm posterior and 5.5 mm lateral to the bregma, and at a depth between 200 and 500 μ m from the surface of the brain. Mechanical stimulation was applied by air puff (20 psi for 50 ms) to a C1 whisker hair. Under the voltage-clamp configuration, the air puff to whicker hair evoked excitatory postsynaptic currents (EPSCs) in recorded neurons. The latency of the first EPSC following the mechanical stimulation was about 22 ms. Around 10 EPCSs usually could be evoked by a single air-pull stimulus. Under the current-clamp configuration, an air-puff stimulus could evoke several excitatory postsynaptic potentials (EPSPs), and some of these EPSPs could reach the threshold to fire action potentials. The responses of layer 2/3 barrel cortical neurons to whisker stimulation at different frequency were also characterized. The development of this *in vivo* patch-clamp recording method should lend us an important tool to explore sensory integration for nociceptive and tactile inputs in primary somatosensory cortex of rats.

Title: The effect of baclofen on mechanical sensitivity following nerve injury

Authors: *R. C. LENNERTZ, III, M. BANKS
Dept. of Anesthesiol., UW - Madison, Madison, WI

Abstract: Baclofen is commonly used to treat muscle spasm. The pain relief associated with its use is often attributed to muscle relaxation. However, baclofen may have multiple mechanisms of action. There is evidence that cortical somatostatin-expressing (SOM) interneurons signal via GABA-B receptors and that SOM neuron activity in somatosensory cortex (S1) is diminished following nerve injury. Further, increasing SOM neuron activity in S1 normalized mechanical sensitivity following nerve injury. These studies suggest that a GABA-B agonist may alleviate mechanical sensitivity following nerve injury. We performed spared nerve injury (SNI) in 7-8 week old C57bl6 mice as a model of neuropathic pain, where the tibial nerve was ligated leaving the peroneal and sural branches of the sciatic nerve intact. We assessed paw withdrawal threshold (PWT) as a measure of mechanical sensitivity. We found SNI significantly lowered PWT in mice for at least 4 weeks, as previously described. Sham mice demonstrated lower PWT for about 1 week before returning to baseline. We performed intraperitoneal injections of baclofen (0.1-1 mg/kg) or vehicle in SNI and sham animals 7-10 days following nerve injury. The experimenter was blinded to the content of each injection. PWT was measured between 30-60 minutes following injection. We found no differences in paw withdrawal threshold in SNI or sham animals. The mice exhibited normal activity and no change in PWT in the contralateral paw at any baclofen concentration. There were no differences between male and female mice. It is possible that a higher concentration of baclofen would influence PWT. Baclofen also may activate GABA-B receptors on SOM neurons themselves or influence GABA-A receptor activity on pyramidal cells in a manner that does not increase PWT following nerve injury.

Title: Probing the spinal mechanisms of pain in human diabetic neuropathy

Authors: *A. WORTHINGTON[1], N. CALCUTT[2], R. MALIK[3], A. MARSHALL[4]
[1]Univ. of Manchester, Manchester, United Kingdom; [2]Dept. of Pathology, Univ. of California San Diego, San Diego, CA; [3]Weill Cornell, Doha, Qatar; [4]Salford Royal Hosp. Fndn. Trust, Salford, United Kingdom

Abstract: Research objective and rationale Rodent models of painful diabetic neuropathy show evidence of disinhibition in the spinal cord dorsal horn. This disinhibition is accompanied by impaired Hoffman reflex rate dependent depression (HRDD). Spinal disinhibition and impaired HRDD are reversed by 5HT2A blockers including duloxetine. The translational potential of these studies is suggested by initial findings of impaired HRDD in painful neuropathy in patients with type 1 diabetes. Whether patients with type 2 diabetes and pain have reduced HRDD and whether spinal disinhibition is associated with impaired diffuse noxious inhibitory control (DNIC), potentially modifiable by drugs enhancing this pathway, are unknown. **Methods** 19 patients with diabetes (7 type 1 and 12 type 2) were assessed and stratified into 'pain' (n=8) or 'no pain' (n=11) groups according to average visual analogue scale pain rating. HRDD was determined by delivering a train of ten stimuli at 1Hz to the tibial nerve in the popliteal fossa. The respective responses were termed H1-H10. Stimulus intensity was set to evoke a response approximately 75% of maximum H-reflex on the rising section of the recruitment curve. HRDD was calculated as a ratio of H2, H3 etc to H1 as well as the mean of H2-H10 to H1. Conditioned Pain Modulation (CPM), to assess the efficiency of DNIC, was performed using immersion of the hand in painfully cold water (4°) as the conditioning stimulus. Test stimuli to determine pressure pain threshold were given using an algometer. Temporal summation was assessed using wind-up ratio (WUR); a comparative pain rating '0-100' of a single pinprick (256mN) to a series of 10 stimuli applied at 1 per second. **Results** Age, gender and clinical severity of neuropathy did not significantly differ between the two groups. Patients with painful diabetic neuropathy showed significant impairment of HRDD (Mean H2-H10: H1) when compared to the non-painful group ($p=0.008$). Significant impairments ($p<0.05$) were also seen when comparing the majority (7/9) of individual stimuli within the train. Efficiency of CPM and WUR were not significantly different between the two groups and showed no significant correlation with HRDD. **Conclusion** The results support the hypothesis that painful neuropathy

in patients with type1 and type 2 diabetes is associated with spinal disinhibition. Whilst anti-neuropathic pain agents targeting this mechanism may represent a therapeutic target in patients with impaired HRDD these preliminary data provide no evidence that impaired HRDD is linked to deficient DNIC.

Title: Comparing the firing patterns of superficial dorsal horn neurons evoked by robotically automated and human manual brushing

Authors: *D. C. LEE[1], J. E. LEE[3], K. LEE[4], Z. KAGAN[2], K. BRADLEY[2]
[1]Nevro, Santa Clarita, CA; [2]Nevro, Redwood City, CA; [3]ANC Robotics, Santa Clarita, CA; [4]Res., Nevro Corp, Mississauga, ON, Canada

Abstract: Background and Aims: Investigations into the response of spinal dorsal horn neurons to afferent inputs typically employ various types of mechanical stimulation to peripheral structures (e.g., a rodent paw). Most often, these stimuli are applied manually (i.e., by the experimenter) to a receptive field; manual application may contribute to inconsistent variation in the parameters of the stimulus: temporal timing, duration, location, etc. This may challenge the analysis and interpretation of the data. In this study, we compared the spinal dorsal horn neural response between custom robot-based brushing system and manual brushing.
Methods: A robot with four degrees of freedom (Dobot Magician, Shenzhen, PRC) was programmed to brush (Paint brush with 0.5 cm width) the hind paw of an anesthetized rat. Multichannel electrodes (NeuroNexus, Ann Arbor, MI) were placed in the ipsilateral superficial dorsal horn (SDH; lamina II-III within the spinal segment L4-6) to monitor single unit firings evoked by a similar brushing motion performed by the robot and from a trained examiner. The proximal and distal boundary of receptive field, identified manually by the examiner using Von Frey probes, was marked on the skin of the paw, and used as start and end points for brushing. The robot brushing was programed to brush in an arc motion at different depths (0.5, 1, 2 and 3mm), speeds (50, 100 and 200mm/s) and directions (proximal to distal vs. distal to proximal). Firing patterns evoked by robot and manual brushing were compared based on their firing rates, durations, and timing with respect to an event marker
Results: Qualitatively, automated brushing generated consistent and repeatable patterns of multiunit SDH activity, while manual brushing revealed a wider variability. Manual forward brushing was most similar to the automated brushing with depth=2mm, speed=100mm/s in terms

of firing rate and duration. Interestingly, it appeared that most recorded neurons, activated by manual brushing were also fired by automated brushing, but certain neurons were activated more by one brushing mode or the other. Using the robot, reverse brushing showed a disrupted firing pattern compared to forward brushing; this difference may have been due to topologic feature differences along the brushed surface of the paw.
Conclusion: Automated brushing appeared to demonstrate a more consistent pattern of response of SDH neurons to afferent input compared to manual brushing. Standardization of the sensory stimulus using this novel robot tool may allow for fewer trials of applied afferent input and greater sensitivity to detect subtle changes in response in sensory experiments.

Title: Cytochrome P450scc and P450c17 increase the production of D-serine in the development of neuropathic mechanical allodynia

Authors: S.-R. CHOI[1], H.-S. CHOI[1], H.-J. HAN[1], *J.-H. LEE[2,1]
[1]Dept. of Vet. Physiol., BK21 PLUS Program for Creative Vet. Sci. Research, Res. Inst. for Vet. Sci. and Col. of Vet. Medicine, Seoul Natl. Univ., Seoul, Korea, Republic of; [2]Seoul Natl. Univ., Seoul-City, Korea, Republic of

Abstract: We have recently shown that spinal D-serine plays an important role in the development of neuropathic pain. However, the modulatory mechanism of D-serine production following peripheral nerve injury is poorly understood. In the present study, we determined whether the levels of spinal D-serine and its synthesizing enzyme, serine racemase (Srr) are modulated by activities of neurosteroidogenic enzymes, P450 side-chain cleavage (P450scc) and P450c17 in the development of neuropathic pain. After chronic constriction injury (CCI) of the right sciatic nerve, mechanical allodynia test was performed in the ipsilateral hind paw. The expression levels of P450scc, P450c17 and Srr in the spinal cord were also evaluated using Western blot assay and immunihistochemistry. Sciatic nerve injury increased the expression of

P450scc and P450c17 in the spinal cord dorsal horn astrocytes. Intrathecal administration of the P450scc inhibitor, aminoglutethimide or the P450c17 inhibitor, ketoconazole on postoperative days 0 to 3 (during the induction phase of pain) significantly suppressed the development of mechanical allodynia in CCI mice. In addition, sciatic nerve injury increased the levels of D-serine and Srr expression, which was co-localized with P450scc or P450c17 in spinal astrocytes. Administration of aminoglutethimide or ketoconazole during the induction phase of neuropathic pain significantly attenuated the CCI-induced increase in D-serine production and Srr expression. Exogenous D-serine restored the development of mechanical allodynia, which was attenuated by administration of aminoglutethimide or ketoconazole. These results demonstrate that spinal P450scc and P450c17 increase D-serine production via modulation of Srr expression in spinal astrocytes contributing to the development of mechanical allodynia induced by peripheral nerve injury.

Title: Anterior nucleus of paraventricular thalamus (PVA) mediates mechanical hyperalgesia in neuropathic and inflammatory pain models

Abstract: Pain-related diseases are the top leading causes of life disability. Identify brain regions involved in persistent neuronal changes will provide new insights for developing efficient chronic pain treatment. Here we showed that anterior nucleus of paraventricular thalamus (PVA) plays an essential role in the development of mechanical hyperalgesia in neuropathic and inflammatory pain models in mice. An increase of c-Fos and pERK staining, hyperexcitability and firing pattern switch of PVA neurons were detected in hyperalgesic mice. Direct activation of PVA neurons using optogenetics and pharmacological approaches were sufficient to induce persistent mechanical hyperalgesia in naïve animals. Conversely, inhibition of PVA neuronal

activity using DREADDs or inactivated PVA ERK at the critical time window blunted mechanical hyperalgesia in chronic pain models. At the circuitry level, PVA received innervation from the central nucleus of amygdala (CeA) a known pain-associated locus. Activation of the right CeA innervated PVA neurons with blue light was enough to induce persistent mechanical hyperalgesia. These findings support the idea that targeting PVA can be a potential therapeutic strategy for pain relief.

Title: Effect of neuropathic pain on the optogenetically activated feedforward inhibition in the central amygdala of rats

Authors: *Y. TAKAHASHI, T. ONOZATO, Y. K. SUGIMURA, F. KATO
Jikei Univ. Sch. Med., Tokyo, Japan

Abstract: The majority of the nociceptive information arising from the spinal cord or the spinal nucleus of the trigeminal nerve targets the lateral parabrachial nucleus (LPB), from which monosynaptic excitatory projection to the central amygdala (CeA) initiates. In particular, a large portion of this projection terminates in the capsular part of the CeA (CeC)". This LPB-CeC synaptic transmission undergoes robust synaptic potentiation in various persistent pain models (Cheng et al. 2011; Han and Neugebauer 2004; Ikeda et al. 2007; Nakao et al. 2012; Neugebauer et al. 2004), thus making it a site for the pain-dependent changes in the nociception-emotion link. By applying the optogenetics, we have demonstrated for the first time that the activation of LPB-CeC fibers results in a large-amplitude bicuculline-sensitive IPSCs that follow the EPSC (Sugimura et al, J Neurophysiol, 2016). This evidence for the "feedforward inhibition" by excitatory inputs of LPB origin had been impossible to obtain because the past studies using electrical stimulation of LPB fibers used drugs that block GABA(A) receptors to avoid complications caused by probable direct stimulation of the CeA GABAergic neurons by the stimulation electrode. Taking this advantage of the optogenetic stimulation, we analyzed the effects of persistent pain on the "direct" LPB-CeC EPSC and the subsequent "feed forward" IPSC. We injected AAV for channelrhodopsin-2 expression into the right LPB of Wistar rats and

made L5 spinal nerve ligation (SNL). Light-evoked EPSCs and IPSCs were separately recorded in the same CeA neurons in acute brain slices. SNL resulted in side-specific mechanical allodynia and appearance of larger-amplitude EPSCs in the right CeC, which was accompanied by a significant increase in IPSC amplitude. However, despite the concurrent increase in EPSC and IPSC amplitudes, we failed to observe any significant correlation between the amplitudes of EPSCs and IPSCs in both sham-operated and neuropathic animals. It is supposed that the enhanced impact of the LPB inputs to the CeA circuit in persistent painful state would increase the LPB influence to the CeA network signaling, further leading to variable consequences of the chronic pain.

Title: Facilitation of touch and tactile neuropathic pain sensations by corticospinal projections

Authors: *Y. LIU[1], A. LATREMOLIERE[2], X. LI[3], Z. ZHANG[1], M. CHEN[1], X. WANG[1], C. FANG[1], C. ALEXANDRE[4], K. H. WANG[3], C. WOOLF[1], Z. HE[1]

Abstract: Although traditionally viewed only as a primary motor pathway, a subset of corticospinal neurons innervates the dorsal horn of the spinal cord, raising the possibility of a role in sensory processing. In support of this, we now show that either ablation of somatosensory corticospinal neurons (CSNs) or transection of their spinal-projecting axons in mice selectively impairs behavioral responses to light touch and greatly attenuates tactile allodynia in peripheral neuropathic pain models, without altering response to noxious stimuli. While tactile stimulation activates somatosensory CSNs, their corticospinal projections facilitate light touch-evoked activation ofcholecystokinin (CCK^+) interneurons in the deep dorsal horn. This CSN-meditated facilitation is also important for the indirect recruitment of nociceptive neurons in the superficial laminae for tactile pain sensation after peripheral nerve injury. In addition to revealing an

underappreciated descending pathway for cortical control over sensory perception, these results open up opportunities for designing new treatments for neuropathic pain.

Title: Deconstructing the role of interneurons in spinal sensory processing

Authors: *A. ALLAWALA[1], C. J. BLACK[1], C. Y. SAAB[2], D. BORTON[1]
[1]Sch. of Engin., [2]Neurosurg. & Neurosci., Brown Univ., Providence, RI

Abstract: While chronic pain continues to affect 1 in 5 people globally, the neural mechanisms underlying its pathology and the therapies targeting its treatment, such as electrical stimulation, remain to be deconstructed. Certain cell types, such as parvalbumin-positive neurons, have been hypothesized to play a role in modulating or disrupting circuits in the presence of nerve injury or inflammation leading to pain. However, a main challenge in electrophysiological characterization of cell types in the spinal cord is the lack of cell specificity innate to electrical recording. Genetically modified calcium indicators (e.g. GCaMP6) have been used with great success in dissecting the role of specific neuronal populations in the brain. Recently, this technique was adapted for use in the spinal cord for *in vivo* imaging. Here, we utilize a "spinal window" technology to visualize, record, and disentangle the role of both heterogeneous and cell-type specific neuronal populations in the spinal cord to elucidate the organization and activity of interneurons in tactile perception and pain in both wild-type and transgenic mice. Enhanced identification of specific cell populations in awake, behaving animals not only enables us to explore the contribution of their activity in normal sensory processing, but further enables us to adapt this methodology to understand how these neurons are modulated under painful conditions. Such results may lead to a greater understanding of the mechanisms mediating pain therapy from pharmacological agents and electrical stimulation of the nervous system.

Title: Bee venom acupuncture suppresses paclitaxel-induced mechanical hyperalgesia through spinal α2-adrenergic activity in rats

Authors: *J. LEE[1,2], W. KIM[1], G. CHUNG[1], H. YOON[2,1], S. KIM[1]
[1]Physiol., Col. of Korean Med. Kyung Hee Univ., Seoul, Korea, Republic of; [2]Dept. of Sci. in Korean Med., Grad. Sch. Kyung Hee Univ., Seoul, Korea, Republic of

Abstract: Paclitaxel, which is a chemotherapy drug for solid tumors, induces peripheral painful neuropathy. Bee venom acupuncture (BVA) has been reported to have potent analgesic effects. Its analgesic effects are known to be mediated by activation of spinal-adrenergic receptor. Here, we investigated the effect of BVA on paclitaxel induced mechanical hyperalgesia and spinal neuronal hyperexcitation. The role of spinal-adrenergic receptor subtypes in the BVA analgesia was also observed. Administration of paclitaxel (total 8 mg/kg, intraperitoneal) on four alternate days (days 0, 2, 4, and 6) induced significant mechanical hyperalgesic signs. This behavioral signs were quantified using a von Frey filament. BVA (1 mg/kg, ST36) relieved this mechanical hyperalgesia for at least two hours, and suppressed the spinal wide dynamic range neurons hyperexcitation evoked by press or pinch stimulation. Both melittin (0.5 mg/kg, ST36) and phospholipase A2 (0.12 mg/kg, ST36), major components of bee venom, were shown to play an important part in this the BVA analgesia, as they significantly attenuated the pain. Intrathecal pretreatment with the α2-adrenergic receptor antagonist (idazoxan, 50 μg) blocked the BVA analgesia, whereas the effect of BVA were not inhibited by α1-adrenergic receptor antagonist (prazosin, 30 μg). These results suggest that BVA has potent suppressive effects against paclitaxel-induced mechanical hyperalgesia, which were mediated by spinal α2-adrenergic receptor.

Abstract: Accumulating evidence suggests the hippocampus being involved in, and modified with, chronic neuropathic pain. However, it is still not clear whether hippocampal activity has direct control over neuropathic behaviors. Here we show that activation of the dorsal, but not ventral, hippocampus, by glutamate microinjection or by chemogenetically increasing excitability (PSAM/PSEM), completely or partially reversed neuropathic behaviors: tactile allodynia and thermal hyperalgesia in the models of spared nerve injury and lumbar spinal nerve ligation. Using a new methodology (chemo-fMRI), where we combine awake resting state brain imaging with viral vector mediated chemogenetic activation (PSAM/PSEM), we could demonstrate that increased excitability of dorsal hippocampus neurons altered resting state functional connectivity within circuitry specifically related to the extent of diminution of neuropathic behavior (tactile allodynia). The identified circuitry most reliably (survived a validation procedure) identified dorsal hippocampal connections to the somatosensory cortex and the thalamus. Moreover, anterograde tracing indicated non-overlapping projections from dorsal and ventral hippocampus. Thus, the present study exhibits a novel causal role for the dorsal hippocampus, and mediating circuitry, controlling neuropathic pain-related behaviors. Altogether, these results imply downregulation of dorsal hippocampus circuitry in chronic neuropathic pain; the activation of which reverses pain behaviors either through disruption of accumulated memories and/or by enhancing extinction circuitry.

Title: Collateral projections of lumbar spinoparabrachial neurons in mouse

Authors: *N. J. STACHOWSKI, L. YAO, M. R. DETLOFF, K. J. DOUGHERTY
Neurobio. and Anat., Drexel Univ. Col. of Med., Philadelphia, PA

Abstract: Chronic pain is the most common cause of long-term disability and has profound effects on the overall quality of life for those afflicted. Pain is a multifaceted sensation consisting of sensory-discriminative and affective aspects, therefore, involving multiple signaling pathways and higher order structures. The anatomical correlate of the sensory-discriminative component of pain is the spinothalamic tract, where the affective component is thought to be primarily signaled via the spinoparabrachial pathway. The main spinal projection to the parabrachial nucleus (Pb) is from neurons in lamina I. Efferents from the Pb project onto emotional nodes of the brain, most notably to the lateral hypothalamus and amygdala, which enable sensory information from the periphery to be integrated towards an emotional response. Dysfunction within this circuit at any level along the neuraxis, particularly when chronic, can result in adverse emotional effects including anxiety and depression. In addition to the Pb, lamina I neurons send projections to several other pain-related regions. The degree to which common lamina I projection neurons share diverse targets varies by both species and spinal segment. The regions receiving collaterals, the extent of overlap, and spinal segmental differences have been well-studied in rat. Although transgenic mice are often used in pain studies, a systematic analysis of spino-Pb collateral projections is lacking in mouse. The goal of the present study was to determine the regions receiving collateral projections from lumbar spino-Pb neurons and to determine the proportions of common source neurons between the Pb and other structures involved in pain processing. Fluorogold and cholera toxin B were used for co-labeling experiments. One tracer was injected into the Pb and the other into hypothalamus, thalamus, periaqueductal gray, or caudal ventromedial medulla, unilaterally in mice. Labeled dorsal horn neurons and degree of co-labeling were quantified in sections taken from the lumbar spinal cord, focusing on lamina I. Anatomical evidence of collateral projections of lamina I spino-Pb neurons provides insights into

the divergence of affective pain information in mice, which may be important for the interpretation of data from mouse models of pain.

Title: Time-course of the effect of continuous theta burst stimulation over primary somatosensory cortex on pain perception

Authors: *N. RAO[1], Y.-T. CHEN[3], S. LI[4], P. J. PARIKH[2]
[1]Hlth. and Human Performance, [2]Univ. of Houston, Houston, TX; [3]UT Hlth., Houston, TX; [4]Physical Med. and Rehabil., Univ. of Texas Hlth. Sci. Ctr. - Houston, Houston, TX

Abstract: Perception of pain involves information processing within a cortical network that includes primary somatosensory (S1), dorsolateral prefrontal, and primary motor (M1) cortices. Reducing the excitability of these areas using repetitive transcranial magnetic stimulation (rTMS) alleviates pain. Importantly, S1 is the final common gateway for ascending afferent pathway. However, it is not known how long the effect of rTMS over S1 lasts on pain perception. In this study, we investigated the time course of effect of continuous theta burst stimulation (cTBS; a form of rTMS) over S1 on pain perception threshold in healthy young adults. We assessed pain and sensory thresholds by delivering electrical pulse of 100 μs width over abductor pollicis brevis muscle. We also estimated tactile sensitivity using Semmes-Weinstein monofilaments over the thumb and index fingertips. The effects of cTBS over S1 on sensory threshold may result from the spread of current from S1 to M1 via reciprocal horizontal axonal connections. Therefore, we also investigated the effects of cTBS over S1 on corticospinal excitability (CSE) by delivering single pulse TMS over M1. Following initial sensory and CSE assessments, we delivered MRI-guided cTBS over S1. Subsequently, we performed sensory and CSE assessments immediately, 10 min, 20 min, 30 min, and 40 min post cTBS. In four healthy young adults, we found that cTBS over S1 increased electrical pain threshold and reduced tactile sensitivity with effects lasting for 40 min. However, cTBS over S1 failed to reduce electrical sensory threshold. Also, cTBS over S1 did not reduce CSE. Our preliminary findings suggest that a single application of cTBS over S1 can be used to alleviate pain for at least 40 min. These effects were not due to spread of stimulation current to M1 as we did not observe modulation of CSE following cTBS over S1. Future studies should investigate the effects of multiple sessions

of cTBS over S1 on pain threshold. Neuromodulation of S1 using cTBS may prove to be an effective intervention in alleviating pain in clinical populations.

Title: Microglial contributions to multidimensional behaviors in neuropathic pain

Authors: *M. J. LACAGNINA, P. M. GRACE
Univ. of Texas MD Anderson Cancer Ctr., Houston, TX

Abstract: Background: Microglia, the resident immune cells of the central nervous system (CNS), constantly survey the tissue microenvironment and dynamically change their morphology and function in response to conditions of altered neural activity. Peripheral nerve injury results in profound activation of microglia in the spinal cord, and the resulting neuroinflammatory glial response contributes to the initiation and maintenance of neuropathic pain. However, it remains unclear if supraspinal microglial activation promotes the behavioral sequelae associated with chronic pain. Here we sought to determine if inhibiting microglial activation in the rodent brain would resolve pain-related behaviors across sensory and affective dimensions.
Methods: To model neuropathic pain, adult male Sprague Dawley rats received unilateral chronic constriction injury (CCI) of the sciatic nerve or sham control surgery. To selectively suppress the activation state of brain microglia, soluble CD200 chimera protein (CD200Fc), a CD200 receptor agonist, was intracerebroventricularly administered daily from days 22-28 following CCI, and multiple behavioral assays were performed during this timeframe. Sensory-discriminative behaviors were interrogated using two methods: mechanical allodynia was measured by von Frey filaments, and thermal hyperalgesia was measured by Hargreaves assay. Affective-motivational behaviors were also investigated by two approaches: novel juvenile social exploration was measured in a three-chamber interaction assay, and goal-directed motivation to acquire food rewards was measured using a progressive ratio operant task.
Results: In relation to sensory-discriminative processes, CD200Fc treatment attenuated mechanical allodynia induced by CCI, while having no effect on sham controls. However, CD200Fc resulted in no change in withdrawal threshold for thermal stimulation. For affective-motivational domains, CCI resulted in reduced social interaction that was reversed by CD200Fc

treatment. In contrast, acquisition of food pellets in the progressive ratio operant task was not significantly impaired following nerve injury or CD200Fc treatment during this post-injury time frame.
Conclusions: These data suggest that inhibition of microglial activity in the brain influences distinct sensory- and affect-related behavioral outcomes in neuropathic pain.

Title: Generalization of sensory modalities in dorsal root ganglion neurons under neuropathic pain in awake mice

Authors: *L. SUN, G. YANG
Dept. of Anesthesiology, Perioperative Care, and Pain Med., New York Univ. Sch. of Med., New York, NY

Abstract: Peripheral sensory neurons are classified into modality-specific or polymodal on the basis of their responses to different sensory stimuli. So far, studies of the dorsal root ganglion (DRG) sensory neurons *in vivo* have been largely restricted to anesthesia preparation. Previous *in vivo* optical studies have suggested most of somatosensory neurons under anesthesia are modality-specific, while electrophysiological studies have suggested that most are polymodal. To reconcile the diverging views on the modalities of DRG sensory neurons and to better understand the function of DRG neurons in somatosensory perception and disorders, we developed a permanent DRG window allowing chronic visualization of the DRG at cellular and subcellular resolution over weeks in awake mice. Combined with genetically encoded fluorescent calcium indicator GCaMP mouse line, we first compared the activity profiles of sensory neurons in the fourth lumbar DRG in mice under awake versus under anesthesia when challenged with different sensory stimuli (punctate and dynamic mechanical, noxious heat and cold stimuli). In addition, we investigated how peripheral nerve injury affects the sensory modalities of DRG neurons. We found that the majority of stimuli-responsive DRG neurons are polymodal in normal awake mice. Though anesthesia silenced more than 75% of the responsive neurons, the majority of stimuli-responsive neurons are still polymodal. Peripheral nerve injury induced spontaneous excitation in 66.2% of DRG neurons compared with 10.2% of DRG neurons in sham-operated

mice, which was almost completely silenced by anesthesia. Modelity-specific population decreases progressively after peripheral nerve injury, from 13.6% (before injury) to 11.8% (2 days post injury) and 6.2% (4 days post injury), and polymodal population increases correspondingly. Together, our present study defines polymodality as a major feature of DRG sensory neurons in awake animals, and this feature is further potentiated after peripheral nerve injury.

Title: Adenylyl cyclase 1 (AC1) in anterior cinglutate cortex and spinal cord in contributed to the pain-related behavior of two fibromyalgia model rats

Authors: *Y. SAKURAI, R. TAMANO, S. YONEDA, T. TSUKAMOTO, M. OYAMA, Y. MASAGO, I. NANCHI, M. FUJITA, E. KASAI, T. OKUDA, T. ASAKI
Shionogi & CO., LTD., Toyonaka-Shi, Japan

Abstract: Adenylyl cyclase 1 (AC1) is a calcium/calmodulin-stimulated enzyme that is predominantly expressed in the central nervous system. It couples NMDA receptor-induced cytosolic calcium elevation to cyclic adenosine monophosphate (cAMP) signaling pathways and has a crucial role in long-term potentiation (LTP) which may develop the pain in both the spinal cord and the anterior cingulate cortex (ACC). In addition, genetic deletion and pharmacological inhibition of AC1 reduced pain in inflammatory and neuropathic pain models. Fibromyalgia (FM) is a disorder characterized by widespread musculoskeletal pain complicated by psychiatric symptoms, such as anxiety and depression. Gabapentinoids, serotonin and noradrenaline reuptake inhibitors (SNRIs) and opioids are used for the pain relief, but these efficacies are not enough. Therefore, the more effective drugs are required for FM patients. In FM patients, the activation of ACC by pressure stimulation enhanced using by fMRI and NMDA receptor antagonist reduces the VAS scale. These studies indicate that AC1 might be involved in the pain of FM patients. In this study, we examined the contribution of AC1 to the pain of two experimental FM models: the acid-induced model and the reserpine model. The acid-induced model was generated by repeated acidic saline (pH 3.0) injection in gastrocnemius muscle and the reserpine model was generated by the repeated subcutaneous injection of reserpine (1 mg/kg), which depleted the monoamine. The both FM models showed the pressure hypersensitivity of bilateral gastrocnemius muscle, mechanical allodynia of bilateral hind paw, the anxiety-like behavior and depression-like behavior. In our pharmacological study, duloxetine

and morphine reduced both the pressure hypersensitivity and the mechanical allodynia, pregabalin reduced only the mechanical allodynia. To investigate the contribution of AC1 to the pain behaviors of FM models, we generated the AC1-deficient rats (AC1-KO). The AC1-KO rats demonstrated no pressure hypersensitivity, and the development of mechanical allodynia was partially improved both in the acid-induced and the reserpine model. In addition, intraperitoneal injection of NB001, an AC1 selective inhibitor, reduced the pressure hypersensitivity of the acid-induced model and the mechanical allodynia of both FM models. Both bilateral intra-ACC injection and intrathecal injection of NB001 and ST034307, another AC1 selective inhibitor, reduced the pressure hypersensitivity in acid-induced model. These results suggested that AC1 in ACC and spinal cord is therapeutic target of the pain in FM patients.

Abstract: Recent clinical findings suggest that substantial overlap may exist between chronic pain conditions such as temporomandibular disorder (TMD), irritable bowel syndrome (IBS) and chronic lower back pain. Although the etiology is unclear, chronic overlapping pain conditions (COPCs) are highly prevalent in women and often impacted by psychological stress. Our previous study showed that in female rats with existing orofacial neuropathic pain, 3-day repeated forced swimming stress led to prolonged visceral hypersensitivity including referred hyperalgesia in the lower back area when compared with male animals. In rats with such comorbid pain, 5-HT3A receptor upregulation occurred in the lumbosacral spinal cord and dorsal root ganglia. Intrathecal injection of 5-HT3R antagonist could transiently attenuate stress-

induced lower back pain, suggesting 5-HT3R-mediated sensitization of primary afferents from the gut. However, the underlying gut mechanisms remain poorly understood. Based on recent literature, psychological stress can lead to gut microbial dysregulation in animal models; and gut microbial dysbiosis is a common finding among IBS patients. In the present study, we further examined microbiota composition in the gut of rats with orofacial pain before and after stress. We found that stress-induced depression-like behavior was positively correlated with the intensity of referred hyperalgesia. We also revealed extensive compositional changes in fecal microbiota of female rats with orofacial pain after stress by using 16S rRNA-based analysis. Compared with nerve injury or stress alone, rats with comorbid pain showed an increase in relative abundance of bacterial species from phylum Firmicutes, including families *Clostridiaceae*, *Ruminococcaceae*, *Eubacteriaceae*, and *Erysipelotrichaceae*, and a reduction in species from phyla Bacteroidetes, Actinobacteria, and Verrucomicrobia. These data are consistent with some clinical reports for IBS patients. Interestingly, we found an increase in relative abundance of genus *Alistipes* from phylum Bacteroidetes, which was reported in clinic to correlate with higher frequency of abdominal pain. Thus, this study for the first time explores dynamic changes in gut microbiota composition in female rats with comorbid visceral pain. Our results suggest that female rats with comorbid pain share multiple features of gut dysbiosis with IBS patients. Understanding gut mechanisms of stress-induced comorbid pain will promote novel therapeutic strategies for managing COPCs including IBS.

Title: Exercise effects on osteoarthritis joint pain: Impact of sex and site in a rat model of osteoarthritis

Authors: *T. E. KING[1], S. SANNAJUST[2]
[1]Biomed. Sci., [2]Univ. of New England, Biddeford, ME

Abstract: Osteoarthritis is a highly prevalent chronic joint disease with incidence predicted to rise due to the aging population and increased obesity. Exercise is commonly recommended for osteoarthritis patients. We examined whether exercise is equally effective in alleviating evoked and persistent ongoing pain in males and females and in load bearing compared to non-load

bearing joints. Adult male or female Sprague-Dawley rats received joint injection of monosodium iodoacetate (MIA) or saline into the knee joint or temporomandibular joint (TMJ). All knee joint MIA treated rats developed weight asymmetry with 7 days post-MIA and TMJ MIA treated rats developed tactile hypersensitivity within 7 days post-MIA. Futher, MIA into the knee-joint and the TMJ induced behavioral signs of ongoing pain, as measured by conditioned place preference to duloxetine, within 14 days of injection. Notably, female rats develop ongoing pain at a 5-fold lower concentration irrespective of whether MIA is injected into the knee joint or TMJ. All rats underwent treadmill exercise starting 10 days post-injection, a time-point that osteoarthritis pathology and pain are established. Treadmill exercise across 4-weeks effectively blocked pain behaviors in male and female rats with knee joint OA. In contrast, treadmill exercise did not produce full reversal of TMJ pain until after 9 weeks of exercise. These observations indicate that MIA-induced osteoarthritis induces evoked and ongoing pain in female rats at a 5-fold lower dose indicating that females are more susceptible to development of advanced osteoarthritis pain. This is consistent with clinical observations that osteoarthritis is more prevalent in women and that women report more severe pain. Treadmill exercise is equally effective in blocking osteoarthritis-induced knee joint pain in males and females. Finally, a longer period of exercise was necessary to block TMJ osteoarthritis suggesting a site dependent difference in the effects of exercise on joint pain. This research was supported by a COBRE award (P20GM103643) and UNECOM Peter Morgane fellowships to medical students.

Title: Ceftriaxone inhibits stress-induced hyperalgesia and alters cerebral micturition and nociceptive circuits in the rat: A multidisciplinary approach to the study of urologic chronic pelvic pain syndrome (MAPP) research network study

Authors: *D. P. HOLSCHNEIDER[1], Z. WANG[1], H. H. CHANG[2], R. ZHANG[2], J. MAO[2], Y. GUO[1], L. V. RODRIGUEZ[2]
[1]Psychiatry & the Behavioral Sci., [2]Urology, USC, Los Angeles, CA

Abstract: BACKGROUND: Chronic emotional stress plays a role in the exacerbation and development of interstitial cystitis/bladder pain syndrome (IC/BPS), with neuroimaging in

patients suggesting a unique functional and structural reorganization of specific brain regions associated with the perception, processing and response to pain. Our prior findings in a rat model demonstrated that water avoidance stress (WAS) elicits a visceral hypersensitivity during bladder filling, as well as an increased engagement of portions of the supraspinal micturition circuit responsive to urgency, viscerosensory perception and its relay to motor regions coordinating imminent bladder contraction. Given the significant overlap of brain circuits involved in stress, anxiety, and micturition, and the documented role of glutamate in their regulation, the current study examined the effects of ceftriaxone (CEF)-dependent upregulation of the glutamate transport on the central amplification of stress-induced bladder hyperalgesia. METHODS: Adult, female Wistar-Kyoto rats were exposed to WAS (1 hr/d x 10 d) or sham paradigms following the daily administration of CEF or vehicle. On day 11, cystometrograms were obtained during titrated bladder dilation, with visceromotor responses (VMR) recorded simultaneously. Functional brain activation was assessed during passive bladder distension (20-cmH2O) following i.v. administration of [14C]-iodoantipyrine. Regional cerebral blood flow was quantified by autoradiography and analyzed in 3D reconstructed brains with statistical parametric mapping. RESULTS: WAS in rats, elicited visceral hypersensitivity during bladder filling as demonstrated by a decreased pressure threshold and visceromotor threshold triggering the voiding phase, as well as by increased VMR to bladder distension. Perfusion mapping revealed stress effects in brain regions noted to be responsive to passive bladder filling. Administration of CEF diminished visceral hypersensitivity and attenuated many of the stress-related functional brain changes within the supraspinal micturition circuit. A significant differential effect of CEF on the brains of stressed rats compared to controls was noted in posterior cingulate/anterior retrosplenial and primary somatosensory cortices. These regions contribute to nociceptive and to micturition circuits, show stress effects, and have been previously reported to demonstrated altered functionality in IC/BPS patients. CONCLUSION: Given the actions of CEF on the glutamate transporter, our results suggest the possibility of glutamatergic pharmacologic strategies in modulating stress-related bladder dysfunction.

Title: Evidence for role of KCC2 and NKCC1 in reserpine-induced nociceptive hypersensitivity

Authors: *E. J. RODRIGUEZ-PALMA, Y. E. DE LA LUZ-CUELLAR, V. GRANADOS-SOTO
Farmacobiologia, Cinvestav Coapa, Mexico City, Mexico

Abstract: Fibromyalgia is characterized by the presence of widespread musculoskeletal pain. This condition affects around 2.7% of population with a slight predominance in women. Despite the relevance of this disease, the current treatments are not effective in all patients. On the other hand, the gradient of chloride in neurons of the nervous system depends on NKCC1 and KCC2 co-transporters. Previous studies have reported that inflammatory and neuropathic pain enhances NKCC1 expression in dorsal root ganglion (DRG) neurons and decreases KCC2 expression in dorsal horn neurons. Changes in these co-transporters have been associated to inflammatory/neuropathic pain. However, the role of these co-transportes in functional pain has been less studied. The purpose of this study was to determine the participation of KCC2 and NKCC1 in the nociceptive hypersensitivity induced by reserpine in rats. Fibromyalgia-type nociception in female Wistar rats was induced by daily reserpine injections (1 mg/kg) during 3 days. Von Frey filaments were used to assess tactile allodynia. Randall-Selitto test was used to determine muscular hyperalgesia. Reserpine-injected rats were administered with bumetanide (10-100 μg, i.t.) and furosemide (10-300 μg, i.t.) (NKCC1 inhibitors), CLP 257 (50-300 μg, i.t., KCC2 activator) or vehicle (DMSO 100%). In addition, the effect of the highest dose of each drug was evaluated in naïve rats. Finally, rats were treated with a combination of bumetanide or furosemide and CLP-257. Reserpine induced widespread tactile allodynia and muscular hyperalgesia reaching the maximal effect at the 5th day post-administration. Intrathecal administration of bumetanide (10-100 μg) and furosemide (10-300 μg), but not vehicle, partially reversed tactile allodynia and muscular hyperalgesia. Furthermore, intrathecal administration of CLP-257 (50-300 μg) reversed tactile allodynia and muscular hyperalgesia in reserpine-treated animals. Drugs did not affect baseline withdrawal threshold and muscle pressure threshold in naïve rats. Co-administration of either bumetanide (50 μg) or furosemide (50 μg) and CLP-257 (50 μg) had an additive effect on tactile allodynia. Taken together, these results suggest that KCC2 and NKCC1 contribute to the hypersensitivity (tactile allodynia and muscular hyperalgesia) observed in a reserpine-induced model of fibromyalgia in rats.

Title: Inhibition of cerebral pain-related gamma oscillations by counter-stimulation and selective attention is abolished in patients with irritable bowel syndrome

Authors: *A. WAGENAAR-TISON[1,2], N. RUSTAMOV[1,2], E. DOYER[1,2], M. PICHÉ[1,2]
[1]Chiropratique, Univ. Du Québec À Trois-Rivières, Trois-Rivières, QC, Canada; [2]Groupe de Recherche CogNAC, Trois-Rivières, QC, Canada

Abstract: Irritable bowel syndrome (IBS) is a chronic functional gastrointestinal disorder characterized by recurrent abdominal pain or discomfort and abnormal bowel function. Several studies indicate that chronic pain in IBS is associated with altered pain modulation mechanisms, including those producing hypoalgesia during counter-stimulation, which involves the application of two competing nociceptive stimuli. However, counter-stimulation hypoalgesia may be confounded with selective attention that also produces hypoalgesia. In this study, we examined hypoalgesia induced by counter-stimulation and by the manipulation of selective attention, in order to determine whether hypoalgesic mechanisms of either or both interventions are altered in patients with IBS.Participants took part to three counterbalanced experimental sessions. The first session involved a series of 80 painful electrical stimuli applied to the right ankle at an inter-stimulus interval of 5 seconds, with no intervention. The intensity of electrical stimulation was adjusted individually at 120 % of nociceptive flexion reflex (NFR) threshold and produced moderate pain. This control session allowed quantifying and controlling for temporal nonspecific effects. The second and third sessions included the same 80 stimuli distributed in four conditions, including baseline, non-painful cold stimulation on the left forearm, painful cold stimulation on the left forearm (counter-stimulation) and recovery. The only difference these two sessions was the focus of attention that was directed either to the electrical stimulation or the cold stimulation. Electroencephalography was measured to test the effects of counter-stimulation and selective attention on brain activity across groups.A robust difference was observed for the amplitude of evoked-potentials (peak-to-peak at Cz) between conditions across sessions and between groups ($p < 0.001$). Planned contrasts revealed that in comparison to the control session, brain activity was decreased by counter-stimulation in controls ($p < 0.001$) but not in patients with IBS ($p < 0.01$). Moreover, compared with the control session, selective attention decreased brain activity in controls ($p < 0.05$) while no effect was observed in patients with IBS ($p = 0.61$). Consistent with these results, pain-related gamma oscillations were decreased by counter-stimulation and selective attention in controls but not in patients with IBS. Together, these results indicate that Inhibition of pain-related brain activity by both counter-stimulation and selective attention are abolished in patients with IBS.

Title: The α_5-$GABA_A$ receptors contribute to nociception in a rat model of fibromyalgia

Authors: *Y. E. DE LA LUZ-CUELLAR[1], A. SALINAS-ABARCA[2], R. DELGADO-LEZAMA[2], V. GRANADOS-SOTO[2]
[1]Ctr. de Investigación Y de Estudios Avanzados, Ciudad de Mexico, Mexico; [2]Ctr. de Investigación y de Estudios Avanzados, Ciudad de México, Mexico

Abstract: Fibromyalgia is a chronic widespread musculoskeletal pain syndrome for which no alternative cause has been identified. Activation of $GABA_A$ receptors in primary afferent fibers induces a depolarization known as primary afferent depolarization. Evidence suggests that this inhibition is reduced or reversed in chronic pain states. There is evidence that extrasynaptic α_5 subunit-containing $GABA_A$ (α_5-$GABA_A$) receptors modulate excitability of sensory neurons. α_5-$GABA_A$ receptors are expressed in the dorsal root ganglion (DRG) and spinal cord in rodents, and play a role in neuropathic and inflammatory pain models. However, the role of α_5-$GABA_A$ receptors in functional pain has not been studied. The aim of this study was to investigate the role of spinal α_5-$GABA_A$ receptors in a reserpine-induced model of fibromyalgia in rats. Fibromyalgia-type nociception was induced by a reserpine injection (1 mg/kg) for three consecutive days. Tactile allodynia and muscular hyperalgesia were assessed with Von Frey filaments and the Randall-Selitto test, respectively. Reserpine-treated rats were intrathecally injected with the selective α_5-$GABA_A$ receptor inverse agonists L-655,708 (0.15-15 nmol) and TB21007 (1.5-150 nmol) or vehicle (DMSO 30%). To corroborate the participation of α_5-$GABA_A$ receptors, rats were treated with a siRNA against α_5-$GABA_A$ receptors during three days. The α_5-$GABA_A$ receptors protein expression in DRG and spinal cord was determined by western blot. In addition, activation of microglia and astrocytes at the spinal cord was assessed by immunohistochemistry.
Reserpine produced tactile allodynia and muscle hyperalgesia in both hind paws 7 days after its last injection in male and female rats. Intrathecal injection of L-655,708 and TB21007, but not vehicle, partially reversed reserpine-induced tactile allodynia and muscle hyperalgesia in a dose-dependent manner in female rats. The effects of these drugs were lower in male rats. Intrathecal injection of L-838,417 reversed the anti-allodynic effect of L-655,708. Furthermore, i.t. siRNA against α_5-$GABA_A$ receptors attenuated allodynia in reserpine-treated rats and induced tactile allodynia in naïve rats. Reserpine injection
increased the expression of α_5-$GABA_A$ receptor at the DRG and spinal cord. Moreover, reserpine enhanced OX-42 and GFAP immunoreactivity at the spinal cord.

Results suggest that spinal α_5-$GABA_A$ receptors contribute in a sex-dependent manner to the nociceptive hypersensitivity induced by reserpine in rats.

Title: Sex differences in visceral hypersensitivity in the Dextran Sodium Sulfate model of colitis in mice

Authors: *S. MARTINEZ GONZALEZ[1], C. PICHARDO[2], Y. CARRASQUILLO[3]
[1]NIH, Gaithersburg, MD; [3]Natl. Ctr. for Complementary and Alternative Med., [2]NIH, Bethesda, MD

Abstract: Visceral pain is the main symptom of multiple abdominal conditions and it represents a frequent reason for patients to seek medical attention, with women disproportionately affected. Despite the female prevalence of visceral pain, pre-clinical studies, especially in rodents, are male dominated and only a few studies have looked at sex differences, particularly in pathological states. For this reason, it is important to systematically evaluate the potential for sex differences in rodent models of visceral pain. The present study measured visceral hypersensitivity in male and female mice using intracolonic capsaicin and the dextran-sodium sulfate (DSS) model of colitis. Our results demonstrate robust sex differences in capsaicin-induced visceral responses both at baseline and following DSS treatment, with female mice exhibiting significantly increased visceral nociceptive responses compared to males. Preliminary results further suggest that visceral hypersensitivity in females is indistinguishable across the different stages of the estrous cycle . Ongoing pathological studies of bowel tissues in DSS-treated male and female mice aim at determining whether differences in DSS-induced colonic pathology underlies the observed sex differences in visceral hypersensitivity. Given the established role of the central amygdala (CeA) in the modulation of persistent pathological pain, ongoing experiments also aim at investigating the contribution of specific CeA cell-types in the modulation of visceral hypersensitivity in the DSS model of colitis.

Title: Somatosensory behavioral alterations in a rat low back pain model

Authors: N. R. REED[1], M. K. SYRETT[1], A. FROLOV[1], W. R. REED[2], *J. LITTLE[3]
[1]St. Louis Univ. Sch. of Med., St. Louis, MO; [2]Sch. of Hlth. Professions, Univ. of Alabama Birmingham, Birmingham, AL; [3]Dept. of Pharmacol. and Physiological Sci., St. Louis Univ., Saint Louis, MO

Abstract: Low back pain (LBP) is a leading cause for global disability. Although a substantial burden, relatively little attention is given to understand its underlying mechanisms. One preclinical model allows examination of LBP mechanisms after two nerve growth factor (NGF) injections into low back muscles of rats. NGF is a neurotrophin involved in pain transduction, critical to many pain states, and implicated in LBP. NGF induces persistent ipsilateral low back mechanical hyperalgesia (LBP) through day (D)14 in rats. The NGF-induced LBP model also had spinal cord changes consistent with central sensitization. Further work is required to reveal the neurobiological events underlying NGF-induced LBP and the somatosensory alterations that manifest from these changes. In LBP patients, somatosensory alterations occur at the low back and distant sites. These are hypothesized to result from sensitization in the central and peripheral nervous systems that manifest as enhanced responses to noxious (hyperalgesia) and non-noxious (allodynia) stimuli. The most consistent finding in LBP patients is a decreased threshold to a deep low back mechanical stimulus (mechanical hyperalgesia) with low back and distant hypersensitivity to cutaneous mechanical and thermal stimuli. Here, we examined the somatosensory alterations that occur during NGF-induced LBP. In addition to low back mechanical hyperalgesia, we examined hypersensitivity to cutaneous mechanical stimulation of the low back and hindpaw (distant) regions. Two injections of NGF (0.8μM/50μL; 5 days apart) or vehicle (50μL of phosphate-buffered saline) were given into the same site (left paraspinal muscles, L5 vertebral level) in male Sprague Dawley rats (215-225 g). For behavioral testing, rats were randomly selected into groups and acclimated to the testing environment and examiners prior to testing. Examiners were blinded to all groups. Behaviors were assessed at baseline (pre-1st injection) and post-1st injection on D2, D5 (pre-2nd injection), and post-2nd injection at D5 + 4 hours, D7, D10, and D14. Mechanical hypersensitivity was assessed superficially on the low back and hindpaw skin using von Frey filaments then assessed deep on the low back (algometer) as reported. NGF rats (n=4/group) had ipsilateral low back mechanical

hyperalgesia from D5 + 4 hours to D14 with increased responses to a low back cutaneous mechanical stimulus from D7 to D14 ($P<0.05$). There were no changes in hindpaw withdrawal threshold. Our results suggest the NGF model has additional somatosensory alterations that mimic clinical features of LBP. These findings support further examination of the NGF model to expand our understanding of LBP.

Title: The role of transient receptor potential vanilloid 1 channel in chronic pelvic pain

Authors: *K. M. ROMAN[1], C. HALL[2], A. J. SCHAEFFER[2], P. THUMBIKAT[2]
[2]Urology, [1]Northwestern Univ., Chicago, IL

Abstract: Chronic Prostatitis/Chronic Pelvic Pain Syndrome (CP/CPPS) is a multifaced disorder that encompasses several symptoms. Effective therapeutic treatments are scarce, due to a poorly defined etiology and pathogenesis of CP/CPPS. Although several studies suggest that the transient receptor potential vanilloid 1 (TRPV1) channel is involved in various pathways of chronic pain, the capsaicin receptor TRPV1 has not been implicated in chronic pelvic pain associated with CP/CPPS. Thus, we sought to determine the role of TRPV1 in CP/CPPS via a rodent model called experimental autoimmune prostatitis (EAP). C57BL/6J (B6; n=3) and TRPV1 knockout (TRPV1 KO; n=3) mice (5-7 weeks old) were administered a rat prostate antigen to induce EAP and then assessed for pelvic tactile allodynia at days 0 (baseline), 7, 14 and 20. Here, we showed that B6 mice with EAP developed markedly enhanced pelvic tactile allodynia at days 7, 14, and 20, compared to naive controls. Surprisingly, our data revealed that TRPV1 KO mice with EAP do not develop pelvic tactile allodynia between days 7 to 20 and demonstrated a similar tactile response observed in controls. The prostate, lumbosacral (L6-S4) regions of the dorsal root ganglia (DRG) and spinal cord were excised from mice at day 20. The prostates were processed and examined via blinded observers. Although we observed a slightly higher number of mast cells in the prostate of TRPV1 KO mice, the number of activated mast cells remained the same between TRPV1 mice with EAP and controls. However, B6 mice with EAP showed a significant increase in the number of activated mast cells, compared to controls.

Moreover, the DRG and spinal cord excised from TRPV1 KO mice with EAP showed no change in levels of ERK1/2 phosphorylation (p-ERK1/2). In contrast, we observed a significant increase of p-ERK1/2 in the DRG and spinal cord of B6 mice with EAP at day 20, compared to controls. In a separate experiment, B6 mice with or without EAP received intraurethral administration (10µl) of either a TRPV1 antagonist peptide (L-R_4W_2; 1µM) or saline after day 10 (every two days) and we investigated the development of pelvic tactile allodynia at days 20, 25, 30, and 35. Our data suggests that B6 mice with EAP that received saline developed pelvic tactile allodynia; yet, B6 mice with EAP that received the peptide treatment show blunted pelvic tactile allodynia. Together, our study demonstrates that TRPV1 is important to 1) establish pelvic tactile allodynia in our model, 2) required to induce mast cell activation in the prostate, 3) crucial for p-ERK1/2 expression in DRG and spinal cord regions relevant to the prostate, and 4) targeted delivery of a TRPV1 antagonist can alleviate chronic pelvic pain.

Title: Separation of roles for nociceptor populations in cancer-induced ongoing and hindpaw movement evoked pain

Authors: *J. J. HAVELIN, T. E. KING
Biomed. Sci., Univ. of New England, Biddeford, ME

Abstract: Patients that suffer from cancer-induced bone pain report two distinct pain. One is a constant ongoing pain that increases in severity over time as the disease worsens, and the second is pain that breaks through medication that is controlling the ongoing pain. Patients are treated with mu opioid receptor (MOR) agonists to manage background ongoing pain, whereas breakthrough pain episodes are often treated with rapid onset MOR agonists such as transmucosal fentanyl. The inability of MOR agonists to successfully treat breakthrough pain indicates that perhaps a unique subset of nociceptors are involved in transducing this pain, and they do not respond to MOR agonists. Utilizing the motivational aspects of pain relief and aversion to the induction of pain in a classical conditioned place preference/aversion (CPP and CPA) paradigm, we are following up on our initial observations that ongoing and breakthrough pain are mechanistically distinct. Female SAS fischer rats had MATB3 cells implanted into their tibia that has been previously shown to induce both ongoing and breakthrough pain. In our

experimental procedure relief of ongoing pain results in CPP whereas the induction of breakthrough pain causes CPA. Our preliminary data indicates the MOR agonist DAMGO treats ongoing pain and the delta opioid receptor (DOR) agonist Deltorphin II blocks movement induced breakthrough pain. We are further investigating the effects of these MOR and DOR agonists in a mouse model of cancer-induced bone pain caused by surgical implantation of the LLC cell line into the femur of C57BL6 mice. CPP/CPA experiments in the mouse are performed 10-12 days post-surgery which coincides with noticeable radiographic bone remodeling and increases in spontaneous and evoked behaviors of pain measured by limb use, flinching and tactile hypersensitivity measured with calibrated von frey filaments. Currently preliminary data in the mouse mimics that in the rat where DAMGO induces CPP to pain relief and Deltorphin II blocks hindpaw movement induced CPA. Using these two rodent models of cancer-induced bone pain, our preliminary data indicate that MOR agonists block ongoing pain but not breakthrough pain, consistent with clinical observations. In contrast, DOR agonists may block breakthrough pain but not ongoing pain. These results may highlight a distinct role for subsets of nociceptive neurons in the periphery involved in differentially transducing these two pain phenomena, and that this pharmacological approach is consistent between species. This work will also allow for further investigation into unique molecular targets for pain relief.

Title: Functional analysis of top-down projections to the zebrafish olfactory bulb

Authors: *C. SATOU[1], K.-H. HUANG[2], R. NEVE[3], R. W. FRIEDRICH[4]
[1]Friedrich Miescher Inst. For Biomed. Resear, Basel, Switzerland; [2]Friedrich Miescher Inst. for Biomed. Res., Basel, Switzerland; [3]Gene delivery Technol. Core Massachusetts Gen. Hosp., Cambridge, MA; [4]Friedrich-Miescher-Institute For Biomed Res., Basel, Switzerland

Abstract: Top-down inputs to primary sensory areas modulate sensory processing and play important roles in perception. The olfactory bulb (OB), the first processing station of the mammalian olfactory system receives dense top-down inputs from cortical and sub-cortical regions that modulate neuronal activity during behavioral tasks and different brain states. However, the functional relevance of these inputs for olfactory processing is unclear. To address

this question, we have developed viral and imaging techniques in adult zebrafish to map and functionally characterize top-down inputs to OB. In order to map top-down inputs to OB, we injected herpes simplex viruses (HSV) into the OB to retrogradely label populations of projection neurons from other brain areas. We found multiple areas in telencephalon that project to OB, including (1) the posterior zone of the dorsal telencephalic area (Dp), a homolog of olfactory cortex, (2) the ventral *area* of the subpallium (*Vv*), a homolog of septum and (3) the medial zone of the dorsal telencephalon (Dm-OB). Furthermore, we found that Dp and Vv areas receive direct input from mitral cells in OB, but Dm-OB area does not. To map the inputs to Dm-OB, we developed procedures for retrograde transsynaptic tracing using glycoprotein-deleted rabies virus in zebrafish. This approach revealed that Dm-OB receives prominent projections from Dp as well as other telencephalic areas that are thought to be related to memory and emotion. In order to functionally characterize top-down inputs to OB, we applied odour stimuli and simultaneously performed two-photon calcium imaging of neuronal populations in telencephalon. We found that while neurons in Dp and Vv responded to odours, neurons in Dm-OB did not. Ongoing experiments combine simultaneous in vivo imaging and behavioral approaches to examine the function of Dm-OB during spontaneous behaviors and in an olfactory learning paradigm.

Title: A computational model of across-individual stereotypy in the responses of mushroom body output neurons

Authors: A. M. MITTAL, *N. GUPTA
Biol. Sci. and Bioengineering, Indian Inst. of Technol. Kanpur, Kanpur, India

Abstract: In the insect olfactory system, sensory neurons on peripheral organs detect odors and carry this information to the antennal lobe. Odors generate stereotypic responses in projections neurons (PNs) of the antennal lobe across individuals. PNs then transmit olfactory information to Kenyon cells (KCs) in the mushroom body. Anatomical studies have shown that PN-KC connections are random and vary across individuals. Expectedly, KC responses are not

stereotyped. But mushroom body output neurons (MBONs), which receive input from KCs, showed partially stereotyped odor responses. We used a computational model to explore the mechanisms underlying stereotypy in MBONs. We modeled the olfactory network using integrate-and-fire neurons, whose parameters were constrained by experimental data. Fly olfactory system has approximately 200 PNs and 2000 KCs; we scaled down the network to 100 PNs and 1000 KCs to reduce the computing time while preserving the ratio of the two types of neurons. PN responses were generated by first setting the spiking rates of neurons, separately for each odor. The PN spikes were then distributed into five bins of 200ms each. For PN-KC synapses, we used a binary connection matrix such that each KC received inputs from approximately seven PNs, mimicking the experimental observed connection probabilities. Synaptic weights were assigned such that physiological levels of spiking activity were maintained in all neuron layers. While PN responses were kept similar for individuals (with some noise), PN-KC connectivity matrix was randomly generated. We analyzed the responses of a single MBON, connected to half the KCs, to different odors across individuals. KC responses produced by the model were sparse in both numbers (10% probability of spiking) and spiking rates (less than 4 spikes/s), while the MBON responded with dense spiking activity (about 60 spikes/s) for all odors. We quantified stereotypy as the accuracy in correctly recognizing the same odor across individuals. We found that the MBON response stereotypy was high (about 70%). Further, we found that the stereotypy depends on the firing rate of the PNs, the number of PNs connected to KCs, the number of KCs responding to the odors, the number of KCs connected to the MBON, noise level, and temporal patterns in the PN responses. A simplified theoretical model using binary neurons corroborated the findings from the simulations. Our results provide insights into how stereotypy can arise despite randomness in a neural network.

Abstract: Many sensory stimuli elicit behavioral responses in naive animals that can be modified or even reversed by learning. In the olfactory system of flies and mice, it is proposed that divergent pathways, targeting distinct higher centres, are specialised for learned and innate behaviour. However little is known about how they interact.
In *Drosophila*, the mushroom body (MB) is critical for associative learned behaviour while indirect evidence suggests that neurons of the Lateral Horn (LHNs) mediate naive odour responses. We now identify LHNs that receive input from an MB output neuron required for recall of aversive olfactory memories. Like the MB output neuron, PD2 LHNs are require for learned but not innate aversive odour behaviour and depress their response to the conditioned odour after training.
EM connectomics reveals that PD2 LHNs also receive direct input from second order projection neurons encoding food odours. PD2 neurons are essential for naive attraction to some of these odours. A single neuronal population therefore mediates both innate attraction and aversive memory retrieval.
Our results show that aversive memory recall depends on a conditioned reduction in drive to innately appetitive olfactory neurons. Furthermore they delineate a complete circuit, from sensory periphery to central integrator neurons, by which learned and unlearned information can interact.
We will discuss a number of apparent advantages of this circuit architecture.
Finally we will contrast this circuit with new and ongoing work to uncover the circuit basis of innate aversive olfactory behaviour. This demonstrates that a circuit with a peripheral labeled line organisation diverges massively at the level of third order lateral horn neurons. It also suggests possible opponent interactions between appetitive and aversive circuitry at the level of the lateral horn.

Title: Integrating information from both nostrils - random or not?

Authors: *J. F. GRIMAUD, V. N. MURTHY
Harvard Univ., Cambridge, MA

Abstract: In most sensory systems, neuronal connections from the periphery to the brain occur in a spatially organized manner, giving rise to topographic maps. By contrast, in the olfactory system, the projections from peripheral regions to the olfactory cortex, as well as the local

cortical connections, appear to be spatially distributed and disordered, which has led to the postulate that these connections are random. Inter-hemispheric cortical projections that arise from the anterior olfactory nucleus and the anterior piriform cortex will, in principle, add even further disorder when integrating information from both nostrils. To gain insight into bilateral integration of information in cortical neurons, we developed a method for unilateral odor delivery in awake mice. We used this method to investigate responses of individual olfactory cortical neurons to 15 distinct monomolecular odors presented to one nostril or the other. We found that the odor tuning (responses to the 15 odors) of many neurons in three cortical regions (anterior olfactory nucleus, anterior and poster piriform cortex) were different when stimuli were presented to each of the two nostrils. However, a significant fraction of neurons in the anterior olfactory nucleus had highly correlated tuning curves to odors presented on the two sides. Our data support the general notion of disordered connectivity in the olfactory cortex, but also point to significant degree of non-random connectivity that could arise through experience-dependent synaptic plasticity. These and ongoing experiments will shed light on how the brain uses bilateral sensory information to make sense of the chemical world.

Title: Learned modulation of innate odor-driven behavior requires the orbitofrontal cortex

Authors: *K. MIYAMOTO, A. LIMARY, J. VICTORIANO, M. KATHROTIA, C. M. ROOT
Biol. Sci., UC San Diego, La Jolla, CA

Abstract: Animals use a combination of innate and learned behaviors to survive. In the natural environment, animals are faced with choices that involve balancing risk and reward. Although behaviors such as feeding and mating are essential to species survival, they subject an animal to the risk of predation or other danger. Thus, innate drives must exist in a balance of risk and reward, which may be modulated by experience and internal need. We seek to elucidate the circuit mechanisms in the mouse brain involved in the executive override of innate odor-driven behaviors.
Our previous work has shown that the cortical amygdala, a third-order olfactory brain structure, mediates innate odor-driven responses. It is thought that prefrontal brain areas are control

complex behavioral planning and decision-making. Specifically, the orbitofrontal cortex (OFC) receives olfactory input from piriform cortex and has outputs to the innate pathways and reward circuitry, which make it a candidate for higher-order control of innate behaviors. We have tested the role of the OFC in modulation of behavioral response to fox odor.
We began by creating a behavioral paradigm that resembles a risk-reward tradeoff foraging task. Briefly, a water-restricted mouse is introduced into a chamber with two water ports that have either the aversive fox odor (TMT) or the attractive rose odor (2-phenylethanol). Innately, mice prefer the rose port to the fox port. However, decreasing the probability of water at the rose port causes mice to learn to prefer the fox port. This behavior persists even if water is unavailable from either port, reflecting a learned override of the innate response to the odors. We optogenetically silenced the OFC, and found that animals revert back to their preference for the rose odor port, whereas control animals exhibited the learned preference for the fox port. These findings reveal that the OFC is indeed required for the learned override of innate behavior. We next plan to record neural activity in the OFC as mice perform the learning task to reveal changes that occur in OFC to accommodate learning, and to map out the relevant downstream targets of OFC.

Title: Value-coding of dopamine neurons in olfactory processing

Authors: *K. P. SIJU[1], V. STIH[2], R. PORTUGUES[2], I. C. GRUNWALD KADOW[1]
[1]Tech. Univ. of Munich, Weihenstephan, Germany; [2]Max Planck Inst. of Neurobio., Martinsried, Germany

Abstract: Value-based decision-making is critical for animals to survive in their environment. Continuously changing environmental cues, internal state, and prior experience greatly influence and modulate decision-making. The neural basis of this behavior is not fully understood. Several recent studies in Drosophila showed that dopaminergic neurons (DANs) in the mushroom body (MB), a higher brain center, are important in assigning value to sensory cues and modulating instantaneous decision-making and fast adaptive behaviors. In the fly brain, DANs are found in two main clusters, PAM and PPL that are thought to encode attractive and aversive contexts,

respectively. Distinct types of DANs innervate the MB in a compartmentalized manner, where they synaptically interact with axons of the MB Kenyon cells and the dendrites of the MB output neurons (MBONs). In this study, we investigated how the population of DANs, rather than single neurons, innervating the MB represent value and how internal state and prior experience influence this representation. Using a systematic volumetric in vivo 2-Photon imaging technique, we characterized the representation of a number of odors in the context of feeding state across the entire DAN population. We developed an automated, unbiased segmentation and registration method to extract the response from each MB/DAN compartment. Our results reveal that in naïve flies, DANs show dynamic activity pattern and odors are represented differentially along the DAN compartments depending on the odor identity and valence. Interestingly, starvation changes this representation to a similar pattern irrespective of the odor valance. Furthermore, we show that, similar to the MBON response profile (Hige et al.,), DANs also show highly variable response profiles across different individuals. This individuality in response profile starts to disappear according to the feeding-state of the animals, and the resulting response profile becomes more similar across hungry animals. This suggests that similar physiological states are reflected in DAN odor representations indicating that state shapes individual experience. Building on these results and developed methods, we aim to elucidate how odor valence and internal state modulate DAN representations to guide perception of different individuals, and ultimately their decision-making and associated behavior.

Title: Inhibitory circuits that gate associative synaptic plasticity in olfactory cortex

Authors: *M. CANTO-BUSTOS, E. KAMBOUROGLOS, A. M. OSWALD
Neurosci., Univ. of Pittsburgh, Pittsburgh, PA

Abstract: The piriform cortex plays a role in the combinatorial representation of odorant features from the olfactory bulb (OB) as well as associating odors with information coded from other cortical areas. OB afferents as well as intracortical inputs form synapses on the apical dendrites of pyramidal cells of piriform cortex. Long-term potentiation of the intracortical synapse is achieved by co-stimulation of the lateral olfactory tract (LOT) coming from the OB

and the intracortical fiber tracts in Layer 1B. It has been shown that this associative LTP is highly dependent of intrinsic inhibition. However, the inhibitory circuits that gate LTP has not been elucidated. In this study, we explored the inhibitory circuits that modulate associative LTP induction in anterior piriform cortex (APC) by using a combination of optogenetic tools and electrophysiological recordings. Three inhibitory interneuron classes were evaluated; somatostatin (SST) cells that inhibit pyramidal cell (PC) dendrites, parvalbumin cells (PV) that inhibit PC somas and vasoactive intestinal peptide cells (VIP) that are postulated to inhibit both SST and PV cells. Our results reveal three main findings. First, inactivation of SST cells but not PV cells promotes associative LTP induction. Second, VIP cells inhibit both SST and PV cells in olfactory cortex. Third, activation of VIP cells promotes associative LTP. These findings support a model in which VIP cells inhibit SST cells and thus, disinhibit PC dendrites to promote LTP induction. Interestingly, our preliminary results suggest an additional functional difference between L2 and L3 PCs. Associative LTP is gated by the VIP-SST disinhibitory circuit in L2 but not in L3 PCs. Our work proposes a disinhibitory circuit gates associative LTP in APC and also suggests different circuits are involved the modulation of synaptic plasticity in distinct layers of piriform cortex.

Abstract: In olfaction, molecular structure determines perception. Chemically-related odors evoke similar percepts within and across individuals, suggesting that the cortex harbors a conserved mapping from chemical to neural space. The specific organization of these representations will define olfactory acuity by setting the balance between odor discrimination and generalization. However, neural representations for odor chemical relationships have not yet been identified in cortex, and thus an understanding of how the olfactory system transforms

chemistry into perception has remained elusive. We hypothesized that chemical representations in cortex could be revealed and explored through a systematic interrogation of chemical space at multiple distance scales; we therefore took a chemoinformatics approach to systematically vary chemical odor distances, and then monitored odor responses in mouse piriform cortex (PCx) during wakefulness, the state most relevant to perception. Given the ability of animals to categorize odors at distinct scales without explicit training, we further hypothesized that the olfactory cortex would contain multiple parallel representations for chemical odor space. Volumetric 2-photon imaging was therefore used to assess neural activity in both the input-dominated PCx layer 2 (L2), as well as the more associational layer 3 (L3). This approach revealed that odor-evoked neural responses are systematically related to distances in odor chemical space in a manner that is preserved across individuals. These relationships are sculpted by the olfactory system to emphasize close similarities amongst a subset of odorants. PCx L2 and L3 differentially balance discrimination and generalization, suggesting they represent two fundamental levels of acuity for the olfactory system. We validated the observed chemical-neural relationships by predicting cortical responses based upon chemistry, and to predict perceptual responses based upon cortical activity. These data provide the first direct evidence for a systematic and invariant remapping of odor chemistry in cortex, demonstrate that the cortex organizes information about odor relationships in parallel at multiple scales, and identify a key neural substrate through which chemically-related odors can be linked to similar perceptual qualities both within and across individuals. <!--EndFragment-->

Title: Robust cortical sensory coding across distinct activity regimes

Authors: *K. A. BOLDING[1], K. M. FRANKS[2]
[1]Dept. of Neurobio., [2]Neurobio., Duke Univ., Durham, NC

Abstract: How does the olfactory system cope with internal dynamics that may degrade or otherwise alter odor representations? As odor information is transformed through successive feedforward projections from periphery to olfactory bulb (OB) and piriform cortex (PCx) it is subject to variable internal network dynamics and modulation. For example, cortical sensory

responses are thought to be “gated” during slow-wave sleep and enhanced during arousal or attentional states. However, PCx circuits are also equipped to recover reliable stimulus-specific odor representations from noisy or degraded input by signaling through extensive recurrent connections. Thus, it remains unclear whether the net effect of olfactory processing is to modify or preserve odor representations when network state varies. Here, recording in awake and anesthetized mice, we find odor representations are more robust to state in PCx than in OB, their immediate upstream input. Odor representations in OB were substantially degraded under anesthesia, but PCx odor representations were intact and could be accurately decoded within and across states. A small subset of OB responses were robust to state. Robust OB responses were not larger, but had shorter latencies than state-dependent responses, suggesting PCx could use a temporal filter to identify reliable odor information. Cortical responses that were robust to state emerged rapidly and from deep cortical layers, where recurrent input is predominant. We used a viral chemogenetic strategy to block neurotransmitter release from PCx principal cells and recorded population activity across states in this circuit lacking recurrent connectivity. Odor decoding was preserved within states, but similar representations could no longer be recovered from one state to the other. These data thus suggest a major role for PCx recurrent circuitry in retrieving stimulus-specific activity patterns from degraded input and maintaining reliable odor identity coding.

Title: Modulation of neural response in olfactory cortex by novelty and familiarity

Authors: *S. HAESLER[1], C. AYDIN[1], M. BROUX[1], S. LIBBRECHT[2], J. NOUTEL[1], J. ESQUIVELZETA RABELL[1]
[1]Neuroelectronics Res. Flanders, Leuven, Belgium; [2]imec, Leuven, Belgium

Abstract: When humans or animals detect novel stimuli in their environment, they respond with distinct orienting and exploratory behaviors. Detection of stimulus novelty is extremely fast - behavioral novelty responses can be observed already less than 100ms after stimulus presentation. In order to accomplish such rapid detection and motor response, the brain needs to

perform a remarkably efficient computation involving a memory-based classification of incoming sensory stimuli. To investigate the algorithm behind this classification, we use a spontaneous olfactory novelty detection task, which allows us to investigate how sensory representations of novel but not familiar stimuli are transformed into motor responses. The task involves a stimulus-driven, bottom-up attentional process that is intimately linked to olfactory sensory processing. Hence, we systematically characterize neural responses in olfactory cortical areas, specifically in the anterior olfactory nucleus (AON) and piriform cortex, using multielectrode recordings in awake, behaving animals. We evaluate how novelty and familiarity modulates olfactory responses. In our preliminary analysis, we find that neurons in the AON are less odor-selective than in the PCx and that they are stronger modulated by novelty. These differences between AON and PCx are consistent with their different inputs. The AON mainly receives input from fast-responsive tufted cells in the olfactory bulb, whereas the PCx mainly receives slower input from mitral cells, integrating the activity state of sister tufted and mitral cells. Neural responses to novel stimuli rapidly habituate in both AON and PCx during the task. However, since in the PCx, a similar number of neurons was excited and inhibited by odorants, response habituation almost cancels out at the population level. In the AON on the contrary, we find almost exclusively odor-excited neurons, thus rapid response habituation is prominent at the population level. These findings are consistent with a functional segregation of the main olfactory pathway at the level of the olfactory bulb. Additional experiments are needed to further address this hypothesis.

Title: Principles of distributed circuits

Authors: *S. SRINIVASAN[1], K. POSTON[2], M. BROWN[3], C. F. STEVENS[4]
[1]Salk Inst. and KIBM, UCSD, La Jolla, CA; [2]Kavli Inst., San Diego, CA; [3]Brown Univ., San Diego, CA; [4]Salk Inst., La Jolla, CA

Abstract: Distributed circuits are common to olfactory, hippocampal, and cerebellar circuits, and contain sub-circuit components that seem to interconnect randomly, i.e. without any

preference. They present a puzzle as they represent high dimensional information (e.g. faces or odors) with sparse and distributed neuronal ensembles and raise three questions. How is such ensemble activity produced, and how does it encode stimuli? Are circuit design principles conserved across species? and do distributed circuits that handle different functions like olfactory and cerebellar circuits have common organizational principles? To answer these questions, we first examined the olfactory circuit in mice and six mammalian species using stereology techniques and light microscopy. Elegant studies have shown that olfactory bulb input innervates the primary olfactory cortex without any spatial preference and such distributed input and activity is conserved across species. Our explorations yielded two insights. First, with a nearly parameter-free model of the mouse olfactory circuit, we found that the olfactory cortex robustly maintains odor information and discrimination ability present in the olfactory bulb. Second, using anatomical measurements, we show that olfactory circuits across mammalian species share a common organizational principle: the number olfactory neurons n scale with bulb glomeruli g as $n \sim g^{3/2}$. Lastly, to test if this organizational principle might be a common feature of distributed circuits, we examined cerebellar (mammals) and cerebellar-like (teleost fish tectum) circuits, and found that cerebellar granule and Purkinje cells scale similarly.

Title: Functional characterization of odor-driven modulation of olfactory perception by basal forebrain nuclei

Authors: *M. MÜLLER[1], I. SCHWARZ[2], I. PAVLOVA[2], M. MITTAG[1], M. K. SCHWARZ[2], M. FUHRMANN[1]
[1]Neuroimmunology and Imaging, German Ctr. For Neurodegenerative Dis. DZNE, Bonn, Germany; [2]Functional Neuroconnectomics Group, Inst. of Exptl. Epileptology and Cognition Res., Bonn, Germany

Abstract: The olfactory bulb (OB) acts as a gate for olfactory information entering the mammalian brain and is innervated by centrifugal fibers originating in the horizontal limb of the diagonal band of Broca/magnocellular preoptic nucleus (HDB/MCPO), a basal forebrain area. Afferent projections from the HDB/MCPO connect to the granule cell layer as well as the glomerular layer, where they potentially influence olfactory processing within the olfactory bulb.

However, little is known about the top-down modulation provided by the HDB/MCPO. Therefore, we investigated the HDB/MCPO feedback circuit's modulatory influence on odor processing in the OB and on olfactory-driven behaviors.
Modified rabies virus (mRabV) mediated mono-transsynaptic retrograde-tracing revealed an extensive excitatory and inhibitory monosynaptic input from centrifugal fibers originating within the HDB/MCPO. Tetanus toxin (TnTx) light chain mediated silencing of the HDB/MCPO profoundly affected olfactory driven social/sexual behaviors, leaving intact general cognitive abilities.
We employed two-photon *in vivo* Ca^{2+}-imaging to monitor the activity of GCaMP6 expressing HDB axons in the OB in awake mice during odor stimulation. We identified odor-responding axons in the OB originating in the HDB. Furthermore, we found different classes of odor-tuned axons responding to one, both or none of the presented odors. Interestingly, axons with different response properties were spatially intermingled in the OB. Moreover, silencing the HDB by TnTx injections resulted in reduced glomerular odor-responses compared to sham-treated mice. We conclude that the centrifugal projections from the HDB/MCPO innervating the OB are activated specifically by odors and modulate the activity of targeted cells within the olfactory bulb.

Title: Distinct cortical amygdala circuits mediate approach and avoidance behaviors

Authors: *C. CHAN[1], J. H. LEE[1], M. H. BASSETT[1], A. J. FAULKS[1], C. M. ROOT[2]
[2]Biol. Sci., [1]Univ. of California San Diego, La Jolla, CA

Abstract: Olfactory information is critical to survival for most animals, driving innate foraging and defensive behaviors. These behaviors are observed in animals without prior experience and are likely driven by neural circuits that are genetically determined and stereotyped. The cortical amygdala is a part of the olfactory neural circuit that mediates innate appetitive and aversive odor-driven behaviors (Root et al., 2014), but it remains unclear how this structure is organized to drive opposing behavioral responses. Here we anatomically and functionally investigate the organization of this structure and it's outputs to downstream structures.

Within the posterorlateral cortical amygdala, we have identified anterior and posterior domains that appear to mediate aversive and appetitive behavior, respectively. Expression of channelrhodopsin in random ensembles of neurons in these regions, and subsequent optical activation, is sufficient to elicit avoidance or approach responses. We are characterizing the projections from these domains to downstream targets. In a preliminary set of experiments, we have observed that neurons responding to aversive versus attractive odor have distinct projections within the limbic circuits. We expressed Cre-dependent channelrhodopsin (ChR2-eYFP) in odor-responsive neurons using the ArcCreER mouse line and found that neurons responding to aversive odor have projections to structures including the BNST, lateral septum and central amygdala, whereas neurons responding to attractive odor have projections to structures in the ventral striatum. Further, when ChR2 was expressed in the posterior region of the cortical amygdala, axonal projections were observed in the lateral region of the nucleus accumbens. These projections were confirmed by Retrobead injection into the lateral nucleus accumbens, which labeled neurons in the posterior cortical amygdala. Behaviorally, we observed that optogenetic stimulation of these projections from the cortical amygdala to the lateral nucleus accumbens elicited approach behavior. Together, these data suggest a functional organization of the cortical amygdala with small domains projecting to different limbic circuits to generate innate odor-driven behaviors.

Abstract: Olfactory disabilities are one of the early symptoms of neurodegenerative diseases, such as Alzheimer's disease and Parkinson's disease. As current medical services depend on self-report to measure olfactory dysfunction, objective assessment of patients' olfactory function will open up opportunities for precise and earlier diagnosis of neurodegenerative disease. Whereas electroencephalogram (EEG) recorded in the primary auditory and visual sensory cortices are used as objective measures of audition and vision, primary olfactory cortices or the olfactory bulb are located deep inside making it difficult to measure perception-related activities non-invasively. Previous EEG studies have shown the possibility of objective measurement of olfactory perception by recording high-order cortices such as frontal cortex, also implied a limitation that it is difficult to understand electrophysiological activity correlates of olfaction without studying cortical activation in relation to activities of the peripheral olfactory system or the olfactory bulb. Here, we measured local field potentials (LFP) of mouse prefrontal cortex (PFC) simultaneously with the main olfactory epithelium (OE), the peripheral area of which contains olfactory sensory neurons and the main olfactory bulb (OB), the direct receiver of signals from olfactory sensory neurons. For this purpose, we characterized LFP responses of healthy control C57BL/6 mice compared to zinc sulfate treated anosmia model mice, which show specific destruction of mature olfactory neurons. We recorded urethane anesthetized mice LFP with olfactory stimulation under oddball paradigm. In control mice, PFC power showed significant increase at all band from delta (1-4 Hz) to gamma2 (70-90 Hz), which were showed coherence with power increases of OE and OB oscillations. Beta (15-30 Hz) and gamma1 (30-50 Hz) oscillations showed persistent response during stimulation in all regions. Power in response to deviant odor was stronger than that of standard odor in the beginning of the stimulation in PFC, which showed coherence with significant power difference of oscillatory response between deviant and standard stimulation in OE and OB. Compared to control mice, the response of all oscillatory band from delta to gamma2 was weaken in zinc sulfate treated anosmia model mice in all regions. Power difference of standard and deviant odor stimulation was also decreased in zinc sulfate mice. Our results shows that PFC oscillatory response have coherence with the OE and OB, which implies possibility for using PFC activations in EEG as a guidance for human olfactory perception in diagnosis of olfactory deficit.

Title: NMDA spikes mediated amplification of odor pathway information in the piriform cortex

Authors: *A. KUMAR[1], O. SCHIFF[1], E. BARKAI[2], B. MEL[3], A. POLEG-POLSKY[4], J. SCHILLER[1]
[1]Technion, Haifa, Israel; [2]Univ. of Haifa, Haifa, Israel; [3]USC, Los Angeles, CA; [4]Univ. of Colorado Sch. of Med., Aurora, CO

Abstract: The piriform cortex (PCx) is the main cortical station for odor recognition and memory. It receives monosynaptic inputs from Olfactory bulb (OB) via Lateral Olfactory tract (LOT). Pyramidal neurons (PN) in PCx are main integration units within which the information from the OB is remapped to form "odor objects". PN in PCx have "discontinuous" receptive fields, i.e., they respond to multiple chemically diverse odorants, while failing to respond to re-combinations of those odorants' component parts. Formation of these "discontinuous" receptive fields from OB inputs is unexplained. A previous study had analyzed dendritic responses of olfactory PNs and reported that pyramidal neurons in the PCx lack sufficient NMDA (or other) regenerative currents that could provide either the combination selectivity or amplification of LOT inputs. They also reported that PN in PCx, unlike their counterparts in other cortical areas, act as intrinsically linear summing units. Counter to this view that olfactory PNs sum their inputs passively, using glutamate uncaging, focal stimulation and compartmental models, we show for the first time that robust NMDA spikes within individual dendrites can be evoked and can both amplify OB inputs and impose combination selectivity upon them. Using a model, we show that these local spikes may serve to effectively amplify clustered versus distributed LOT input, forming basis for a discontinuous field. Their ability to compartmentalize voltage signals allows different dendrites to represent different glomerular combinations, fulfilling the basic requirements for a discontinuous receptive field. We also show that the LOT and Intra-cortical inputs interact nonlinearly, a finding crucial for understanding the recurrent pattern completion functions of PCx.

Title: Coding of odor mixtures in cortical feedback projections to the olfactory bulb

Authors: *J. D. ZAK, V. N. MURTHY
Mol. & Cell. Biol., Harvard Univ., Cambridge, MA

Abstract: The olfactory bulb not only integrates bottom-up information from the sensory periphery, but also receives dense top-down modulation from other areas of the brain, including the piriform cortex. The piriform cortex is thought to be involved in computations related to odor identity, quality, and predictive coding; however, it is unknown to what degree, if at all, the cognitive aspects of odor processing are transmitted back to the olfactory bulb. Recent studies have demonstrated that projections from the piriform cortex play a critical role in decorrelating the output from olfactory bulb projection neurons for monomolecular odors. We have begun to investigate how cortical feedback projections respond to odor mixtures, especially when individual components have distinct behavioral context. We used multiphoton microscopy to visualize odor responses from cortical axon terminals expressing the calcium indicator GCaMP6f. Individual boutons had diverse responses to monomolecular odorants as well as to complex odor mixtures. For individual odors, across >700 boutons and >11000 bouton-odor pairs, we observed both enhanced and suppressed responses to odor stimulation, as well as diverse temporal structure. The mean lifetime sparseness (a measure of stimulus selectivity) for all boutons was 0.39 ± 0.27, with ~20% of all boutons showing no response to any of the 16 odors in our panel. We next considered how these same feedback projections would respond to odor mixtures. First, we generated binary mixtures over a wide range of dilutions. We observed a strong concentration dependence to the responses, with the highest odor concentration (10%) eliciting the largest positive as well as negative signals. Individual boutons that responded to a particular concentration with a positive response, also exhibited positive responses to all other concentrations (if responses were detected). We also occasionally observed responses that were present for only a subset of the dilutions. Lastly, we delivered odor mixtures containing up to 12 components, and our initial analysis indicate highly non-linear mixture interactions. In summary, complex information about odor composition is broadcast to the olfactory bulb, and ongoing experiments are aimed at dissecting the nature of this information.

Title: Odor processing by distinct classes of principal neurons in piriform cortex

Authors: *S. NAGAPPAN, B.-X. HAN, F. WANG, K. M. FRANKS
Neurobio., Duke Univ., Durham, NC

Abstract: Odor information is encoded by the activity of dispersed populations of principal neurons in piriform cortex (PCx). PCx is a trilaminar structure with principal neurons largely concentrated within Layer II (LII). LII further subdivides into a superficial layer containing a class of excitatory neurons known as semilunar cells (SLs), and a deep layer containing a morphologically and electrically distinct class of excitatory neurons, superficial pyramidal cells (SPs). SLs have extensive apical dendrites but no basal dendrites and receive afferent inputs predominantly from olfactory bulb (OB). In contrast, SPs have extensive apical as well as basal dendrites and receive both OB and intracortical inputs. These differences in morphology and connectivity between SLs and SPs determined in mouse brain slices suggest a two-stage model for odor processing in PCx, where SLs pre-process afferent, OB inputs, and then transmit this information to SPs. But, does this model hold in awake animals?

To compare how SLs and SPs process odor information *in vivo*, we generated a Netrin-G1-cre knock-in mouse line that selectively expresses Cre recombinase in a subset of PCx neurons. The morphology and laminar properties of these neurons indicate broad and selective labeling of SLs, but not SPs. We then used cre-dependent AAVs to express archaeorhodopsin (Arch) in Netrin-G1-expressing SLs and recorded both light- and odor-evoked spiking in large populations of LII neurons in awake, head-fixed mice. Cells whose spontaneous spiking was rapidly and robustly suppressed by light were determined to be Arch+ SLs, while Arch- cells were determined to be presumptive SPs.

Spontaneous firing in SLs were significantly higher than SPs and SLs were more broadly tuned than SPs. SLs also exhibit a prominent biphasic response, with brief excitation followed by substantial suppression, that was not observed in SPs. Latencies to response peak were equivalent in SLs and SPs. Additionally, optical suppression of SL cells markedly decreased spontaneous firing in SPs, indicating that SPs are, at least, partially driven by SPs. However, interestingly, SL suppression did not abolish the biphasic odor responses in SPs. In fact, if anything, the signal-to-noise ratio of SPs increased in the absence of SLs. Together, these findings suggest that odor processing by SLs may not unambiguously precede and influence odor processing by SPs as proposed in the model. Rather, the independent differences in response properties between these two main classes of PCx principal neurons imply parallel sensory processing streams, potentially serving distinctive higher order functions.

Title: Pattern completion and separation via modulation of synchrony in the interplay between olfactory bulb and cortex

Authors: *G. TAVONI, D. KERSEN, V. BALASUBRAMANIAN
Univ. of Pennsylvania, Philadelphia, PA

Abstract: How can contextual information change the perception of sensory stimuli? In the olfactory system, we propose a model for this process where descending feedback from the central brain modulates synchrony in peripheral responses during odor discrimination tasks. Our model consists of pyramidal neurons in the piriform cortex receiving input from overlapping "modules" of mitral cells in the the olfactory bulb (OB). Modules are assumed to have different degrees of intrinsic temporal synchrony, and drive their cortical targets through a sigmoid-like transfer function. We propose that feedback from the central brain about the context of odors acts to manipulate the synchrony of mitral cell responses in the OB. The feedback can affect a random, odor-independent subset of modules, but must act so that alternative contexts have opposite effects on synchrony in the affected modules. We argue that this modulation of synchrony can be achieved by the known descending inputs to granule cells, via their widespread connections with mitral cells. Within this model we demonstrate that association of two odors with the same context leads to *pattern completion* in cortex where responses to the two odors become more similar. Meanwhile association with opposite contexts leads to decorrelation of odor responses in cortex, i.e., *pattern separation*.
The model reproduces two striking experimental effects (Chapuis and Wilson, Nat. Neuro., 2012; Shakhawat et al., J. Neurosci, 2014): (1) Pattern completion induced by similar contexts is greater for already similar odors, (2) Pattern separation induced by opposite contexts is larger for previously similar odors. This increased pattern completion and separation for initially more similar odors is greater when cortical units have steeper response functions and higher thresholds that match measurements. We show that alternative response functions can actually produce the *opposite* effects, suggesting that response properties of cortical neurons are tuned to maximally promote the experimentally measured forms of pattern completion and separation.

Abstract: The olfactory piriform cortex is thought to participate in olfactory associative memory. Like the hippocampus, which is essential for episodic memory, it belongs to an evolutionally conserved paleocortex and comprises a three-layered cortical structure. During slow-wave sleep (SWS), the olfactory piriform cortex becomes less responsive to external odor stimuli and instead displays sharp wave (SPW) activity similar to that observed in the hippocampus. Neural activity patterns during hippocampal SPW have been extensively studied in terms of memory consolidation; however, little is known about activity patterns of olfactory cortical neurons during olfactory cortex sharp waves (OC-SPWs). In this study, we simultaneously recorded multiple neuronal activity in the anterior piriform cortex in urethane-anesthetized mice. We found that activity pattern of olfactory cortical neurons during OC-SPWs was non-randomly organized. OC-SPWs recruited the discharges of the subsets of olfactory cortical neurons. Individual olfactory cortical neurons varied in the timings of the peak firing rates during an OC-SPW event, constituting sequential neuronal activation as a whole. Moreover, specific pairs of olfactory cortical neurons were more frequently activated than expected by statistical chance. Based on these observations, we speculate that coordinated and sequential activation of specific subsets of olfactory cortical neurons repeats during OC-SPWs, thereby facilitating synaptic plasticity underlying consolidation of olfactory associative memories.

Title: An integrated model linking structural and dynamical properties of local cortical circuits

Authors: *P. GONG, Y. GU
The Univ. of Sydney, Sydney, Australia

Abstract: Experimental studies have begun revealing essential properties of the structural connectivity and the spatiotemporal activity dynamics of cortical circuits. To integrate these properties from anatomy and physiology, and to elucidate the mechanistic links between them, we develop a local cortical circuit model that captures a range of realistic features of synaptic connectivity. We show that the model accounts for the emergence of higher-order connectivity structures, including overrepresented three-neuron motifs and highly connected hub neurons that form an interconnected rich-club. The circuit model exhibits a rich repertoire of activity states, ranging from asynchronous to localized and global propagating wave states. We find that around the transition between asynchronous and localized propagating wave states, our model quantitatively reproduces a variety of major empirical recordings regarding neural spatiotemporal dynamics, which otherwise remain disjointed in existing studies. These dynamics include diverse coupling (correlation) between spiking activity of individual neurons and the population, propagating wave patterns with variable speeds and precise temporal structures of neural spikes. We further illustrate how these neural dynamics are mechanistically linked to the structural connectivity properties by analyzing the contributions of connectivity to neural spiking dynamics and by showing that the rich-club structure is fundamentally related to the emergence of the diverse population coupling. These findings establish an integrated account of structural connectivity and activity dynamics of local cortical circuits, and provide novel experimentally testable predictions.

Title: Building and simulating a biophysically detailed network model of the mouse primary visual cortex

Authors: *Y. N. BILLEH, S. L. GRATIY, K. DAI, R. IYER, N. W. GOUWENS, S. MIHALAS, C. KOCH, A. ARKHIPOV
Allen Inst., Seattle, WA

Abstract: Rapid advancement in neuroscientific tools is yielding an extraordinary amount of data regarding the structural and dynamical properties of cortical circuits. In parallel, there has been vast progress in parallel computing and software to allow for unprecedented simulation capabilities. Herein we describe our efforts in combing these two exciting advances to develop, in a data-driven manner, a model of the mouse primary visual cortex (area V1) comprising ~230,000 neurons from all cortical layers.
For developing our cortical model, we used the Brain Modeling ToolKit (BMTK), a python API developed by the Allen Institute (github.com/AllenInstitute/bmtk). BMTK allowed us to construct our network and integrate seamlessly with NEURON [Hines and Carnevale, 1997] to enable parallel simulations. Approximately 51,000 neurons in our model are biophysically detailed, pooled from >100 models of individual neurons from the Allen Cell Types database (celltypes.brain-map.org). The network receives spike-train inputs from filter models representing a variety of functional cell types from the Lateral Geniculate Nucleus (LGN). The LGN filter models were based on spatiotemporal fits from experimental recordings *in vivo*. The thalamocortical projection architecture and magnitude of excitatory post-synaptic current that V1 neurons receive was based on experimental literature.
After optimizing the LGN input to the column, the recurrent connectivity between cell-types and layers was introduced. The probability of connections, strength of connections (unitary PSP), functional connectivity rules, and synaptic placement between all cell-types was obtained via a thorough literature search, resulting in a knowledge graph that combines the connectivity information with the records of literature sources; assumptions were used where data was not available. As the next critical step, the synaptic weights were optimized to produce irregular network activity in response to visual stimulation.
We will describe the construction and simulations of the V1 model and discuss how available or hypothesized information about properties of cell types, feedforward connectivity from LGN, and recurrent connectivity has resulted in certain functional properties - such as, for example, orientation and direction selectivity. The model represents a milestone in the development of

data-driven simulations of brain activity and computations and should provide a valuable resource for the computational neuroscience community, in conjunction with the standardized model construction and simulation interfaces of the Brain Modeling ToolKit.

Abstract: Transgenic mouse technology enables the selective labeling of cell populations and, along with genetically encoded calcium sensors, has provided an immensely powerful tool for probing the function of cells and circuits in the mouse brain. However, Cre transgenes, which often involve modifications or disruptions of endogenous genes, and the genetically encoded calcium sensors (which can potentially alter calcium buffering or interfere with gating and signaling of L-type calcium channels), can each result in undesirable abnormal phenotypes in mice. The Allen Brain Observatory is the online portal for a two-photon calcium imaging pipeline that generates functional physiology data in a variety of transgenic mice (www.brain-map.org/visualcoding). Cre-defined cell populations in mouse visual cortex were labeled with GCaMP6 calcium sensor by crosses between 13 Cre lines driven by various promoters(Cux2, Dlx5, Emx1, Fezf2, Ntsr1, Pvalb, Rbp4, Rorb, Scnn1a, Slc17a7, Sst, Tlx3, Vip) and various GCaMP6 reporters (Ai93, Ai94, Ai148, Ai162). Prior to inclusion in our experiments, these transgenic crosses were thoroughly characterized to identify the lines best suited for functional physiology. Animals were assessed for observable phenotypes in appearance, weight, in-cage behavior and locomotor activity. Additionally, the GCaMP6 reporter expression was evaluated in each line; for some Cre driver lines, Ai148 was preferred over Ai93 to achieve greater selectivity of expression. Intrinsic signal imaging was used to assess basic visual function and targetability

of higher visual areas; in one case, abnormal retinotopic maps specific to a particular cross contraindicated that line for use in vision-dependent experiments. Finally, calcium imaging of lines was evaluated for response properties in response to visual stimuli, as well as to assess the frequency of interictal events that might indicate epileptic-like abnormal brain activity. Overall this data set provides a useful reference for experimentalists seeking to identify appropriate lines for functional imaging experiments.

Title: Nonlinear models of mouse visual cortex

Authors: *M. D. OLIVER[1,2], M. A. BUICE[2], P. LEDOCHOWITSCH[2], N. H. CAIN[2], G. K. OCKER[2], S. E. DEVRIES[2], D. MILLMAN[3]
[1]Modeling, Analysis & Theory, Allen Inst. for Brain Sci., Woodinville, WA; [3]Neural Coding Group, [2]Allen Inst. for Brain Sci., Seattle, WA

Abstract: Building predictive models of neural activity is a central aim of computational neuroscience. To better understand the various representations in mouse visual cortex, we aim to build stimulus-response models for neurons in cortical areas VISp, VISl, VISal, VISrl, VISpm, and VISam. Data from these brain areas was collected as part of the Allen Brain Observatory at the Allen Institute for Brain Science. The Allen Brain Observatory dataset includes data from hundreds of animals exposed to a standardized set of visual stimuli while calcium fluorescence was recorded from a cortical visual area. However, despite this large dataset, learning the stimulus-response mapping function for individual neurons is a challenging problem. The chief difficulty is that stimulus-response mapping functions are inherently high-dimensional and nonlinear while response data for a single neuron is limited by experimental demands and intrinsically noisy. One of the most successful approaches for tackling this problem is to linearize the stimulus-response mapping by preprocessing the stimulus with a carefully chosen nonlinear transform. For our model, we constructed linear and non-linear transforms using a pyramid of spatio-temporal Gabor filters to create a set of linear and quadratic filters that densely

tile the stimulus (Nishimoto & Gallant, 2011). We then use regularized regression to find a linear mapping between the transformed stimuli and the estimated responses of each recorded neuron. This regression can be thought of as a regularized version of Spike Triggered Average / Spike Triggered Covariance analysis. Neural responses were estimated from the fluorescence traces using an L0 regularized deconvolution algorithm (Jewell and Witten, 2017). Before fitting the models, we separated the stimuli used in the Allen Brain Observatory into 'natural' and 'artificial' classes. 'Natural' stimuli included natural movies and images. 'Artificial' stimuli included static gratings, drifting gratings and locally sparse noise. We fit models in these two stimulus regimes separately in order to determine which type of stimulus best allows for the construction of predictive stimulus-response models. We find that models fit using natural stimuli both generalize better and are more interpretable. We also find that across all cortical visual areas the fit models tended to utilize far more quadratic regressors than linear regressors. This suggests that neural representations in mouse cortex, even in the first cortical visual area VISp, contain few if any true “simple cells” and may exhibit higher-order tuning earlier in their visual hierarchy than other species, such as cats and primates.

Title: Matching cells across two photon images of multiple optical physiology experiments

Authors: *F. LONG, M. GARRETT, S. DE VRIES, J. LECOQ, L. KUAN, C. THOMPSON, D. FENG, W. WAKEMAN, J. GALBRAITH, L. NG
Allen Inst. for Brain Sci., Seattle, WA

Abstract: To better understand neural activities in different retinotopically mapped areas of visual cortex, cortical layers, and Cre lines during visual stimulation in behaving mice, we collected two photon (2P) time-series of neuron responses as part of the Allen Brain Observatory. The same location within a cortical visual area of each brain was imaged over multiple sessions, between which the animal was removed from the apparatus and then returned to approximately the same position for the next session. Images acquired from each session vary depending on different visual stimuli and inaccuracy in configuring the exact same depth and field of view. Analyzing these experiments invariably requires identifying which regions of interest (ROIs) from multiple imaging sessions correspond to the same physical cell. We therefore developed an automated matching approach that allows us to find ROI correspondence

across any number of optical physiological experimental sessions. The approach involves multiple steps. First, it estimates the affine transformation required to bring each image in the multiple sessions into a common coordinate space based on intensity correlation. This compensates for the translation and rotation errors that occurred when the apparatus is reassembled for each session. Second, it matches ROIs between any two experiments by considering all the possible combinations of pairwise sessions using bipartite graph matching. ROIs in any two sessions are represented by two sets of nodes in the graph, and matches are represented by edges between the two sets. The overall best match is obtained by maximizing the sum of the edge weights defined as a cost function combining overlap and closeness features between ROIs. Third, pairwise matching results are combined to generate the final matching list of ROIs across all sessions. This involves cascading correspondence from pairwise matching results and resolving their conflicts based on the edge weights of each bipartite graph computed in the second step. Our experiments on a pilot dataset show that the approach generates reasonable cell matching results across multiple optical physiology experimental sessions. Our approach and code will be made publicly available for the global brain research community.

Abstract: In 2016, the Allen Institute for Brain Science launched the Allen Brain Observatory: the first tool of its kind to create highly standardized surveys of cellular-level activity in the mouse cortex. The creation of this high throughput data collection pipeline presented a new and unique opportunity: building a true astronomical observatory in systems neuroscience whereby both experimental and theoretical scientists around the world could propose experiments to run on the Allen Brain Observatory. Our hope with this model is to streamline hypothesis testing of cortical function by selecting the most impactful experimental proposals.

Here we present results from our first-year pilot. We evaluated the interest and feasibility of the astronomical observatory model in System Neuroscience. (1) A Request For Proposal (RFP) document was communicated to a selected panel of scientists (Summer Workshop on the Dynamic Brain attendees and Allen Institute scientists). (2) Experimental proposals were selected based on feasibility and scientific impacts. (3) Experiments were piloted and conducted on the Allen Brain Observatory optical physiology pipeline. (4) Data is analyzed by the application teams. We report a high interest in the model (10% RFP response rate), discuss the model incentives and associated operational (scientific review, selection criteria and bias) and technical challenges. We conclude with potential future development of the model.

Title: Functional interrogation of claustrum involvement in a visual change detection task

Authors: *D. R. OLLERENSHAW[1], A. M. SHELTON[1], J. DAVIS[1], Y. WANG[3], H. ZENG[2], S. R. OLSEN[1], C. KOCH[1]
[2]Structured Sci., [1]Allen Inst. for Brain Sci., Seattle, WA; [3]Allen Inst., Seattle, WA

Abstract: The extensive, reciprocal connectivity between the claustrum and the cortex points to possible roles for the claustrum in coordinating activity across cortical regions during perceptually demanding behaviors. Backing this view, recent studies in this structure have pointed to specific roles for the claustrum in signaling salience of sensory events, or coordinating top-down control of attention during sensory-guided tasks. To further probe the function of the claustrum during behavior, the Allen Institute has developed a mouse line with Cre expression under control of the Gnb4 gene, which expresses preferentially in the claustrum. Whole brain, axonal tracing of Gnb4+ claustral neurons demonstrates widespread, bilateral projection patterns, with axons terminating predominantly in midline cortex. To probe the function of these cells, we have performed single-photon fluorescence imaging of the claustrum using implantable gradient index (GRIN) lenses in Gnb4-Cre mice crossed with GCaMP6 reporter mice to measure claustrum function during a psychophysically demanding change detection task, as well as widefield imaging of the cortical surface to measure activity in cortical projections of Gnb4+

cells. Cells in the claustrum appear to signal both stimulus changes and behavioral choice, with the strongest responses occurring when both conditions are coincident. In addition, chemogenetic perturbation of claustrum cells during the same task interferes with task performance, indicating possible causal involvement of the claustrum in the task. Together, these results further indicate the role of the claustrum in coordinating cortical areas during decision making.

Title: Large-scale calcium imaging reveals cell class specific roles in a visual change detection task

Authors: *M. GARRETT[1], P. A. GROBLEWSKI[3], J. KIGGINS[2], D. R. OLLERENSHAW[3], L. CASAL[1], A. CHO[1], A. LEON[1], K. MACE[1], S. MANAVI[1], K. ROLL[1], C. THOMPSON[1], A. WILLIFORD[1], S. R. OLSEN[3]
[2]Neural Coding, [1]Allen Inst. for Brain Sci., Seattle, WA; [3]Allen Inst. For Brain Sci., Seattle, WA

Abstract: Detection of moment-to-moment changes in the visual scene is fundamental to an animal's ability to navigate the world. We have developed a go/no-go change detection task in which images are presented serially and mice must respond to changes in the visual stimulus to earn rewards. We show that head-fixed mice can be trained on this task within a few weeks using an automated training regimen, enabling comparison of behavioral performance across dozens of mice from multiple transgenic lines. Mice can detect changes in a diverse set of visual stimuli (e.g. oriented gratings and natural scenes), permitting a range of experimental questions. Despite variability in training times and engagement patterns, the tendency to detect changes between individual natural scene images is highly consistent between mice, indicating that animals rely on similar perceptual cues to detect changes between natural images. Optogenetic perturbation experiments demonstrate that the visual cortex is necessary for task performance.
To understand how behavioral state influences the representation of natural images, we have begun systematically measuring activity in the visual cortex during performance of this task using a standardized 2-photon imaging pipeline (Allen Brain Observatory: http://observatory.brain-map.org/visualcoding/). Using this approach, we find that excitatory and inhibitory populations differ in their selectivity and in the relationship of population activity with behavioral detectability of specific images. Modulation by task engagement is observed in layer 2/3 excitatory and VIP+ inhibitory populations.

By imaging the activity of populations of single neurons across multiple visual cortical regions, cell classes, and cortical depths, this study will provide a comprehensive survey of information processing in visual cortical circuits during visual behavior in mice. As part of the Allen Institute's commitment to open science, the data generated through this project will be made publicly available for download and use by the neuroscience community to drive progress in understanding the neural basis of perception and behavior.

Title: Ca^{2+} imaging favors bursty neurons

Authors: *P. LEDOCHOWITSCH[1], N. CAIN[1], J. H. SIEGLE[1], X. JIA[2], G. K. OCKER[1], M. D. OLIVER[3], S. R. OLSEN[1], S. E. DEVRIES[1], M. A. BUICE[1]
[1]Allen Inst. for Brain Sci., Seattle, WA; [2]Brain Sci., Allen Inst., Seattle, WA; [3]UC Berkeley, Kirkland, WA

Abstract: To build a bridge between electrophysiology and optical physiology, this work investigated the degree to which spatial receptive fields computed directly from spiking activity could be inferred via models of Ca^{2+}-dependent fluorescence.
(I) We have collected 'ground truth' calibration data by simultaneous juxtacellular patching and 2P imaging *in vivo*. After semi-automated quality control, we identified 15 simultaneous recordings from layer 2/3 pyramidal cells, which expressed GCaMP6f under the pan-excitatory Emx1 promotor, and matched the noise and response profile of the Allen Brain Observatory (BOb). We then calibrated 'MLSpike' [1], a biophysically inspired non-linear model on these data which yielded 15 model parametrizations capturing a spread of relationships between spikes and resulting fluorescence, and allowed simulating fluorescence data for arbitrary spike trains.
(II) We recorded spiking activity in awake, head-fixed mouse, free to run on a wheel 165 mm in diameter. Visual stimuli (locally sparse noise, gratings, natural scenes, and natural movies) were presented on a 24.1" monitor placed 150 mm from the right eye. Six Neuropixels probes [2] were aligned to the center of each of six visual areas: VISam, VISp, VISal, VISl, VISlm, and VISrl. Area maps were obtained via intrinsic signal imaging (ISI) ~2 weeks prior to the experiment. Each probe was inserted approximately 1300 µm into the brain, penetrating through all 6 layers of cortex and down into hippocampus.

(III) Using the results of (I), we modeled 15 “calcium” signals, one for each cortically localized spike train from a regular-spiking cell obtained in (II), and computed putative receptive fields via the Allen Brain Observatory data processing pipeline. We found that these receptive fields, when statistically significant, bear a strong resemblance to those computed directly from the electrophysiology using comparable statistical techniques.
The quality of the correspondence was dependent not only on the calcium model parametrization but also on the degree of stimulus-evoked bursting in the observed areas and layers, respectively. Our results from (III) suggest overall that the BOb receptive field fitting provided an accurate characterization of receptive field parameters whenever the presented stimulus effectively drove bursting activity in the chosen combination of area, layer, and cell type.

Title: Stimulus and state-dependence of interactions between vip and sst cells in mouse primary visual cortex

Authors: *D. MILLMAN[1], G. K. OCKER[2], N. H. CAIN[2], P. LEDOCHOWITSCH[2], R. S. LARSEN[3], M. D. OLIVER[4], R. REID[3], M. A. BUICE[2], S. E. DEVRIES[2]
[1]Neural Coding Group, [3]Neural Coding, [2]Allen Inst. for Brain Sci., Seattle, WA; [4]Modeling, Analysis & Theory, Allen Inst. for Brain Sci., Woodinville, WA

Abstract: In cortex, vasoactive intestinal peptide-expressing (Vip) interneurons make strong inhibitory synapses onto somatostatin-expressing (Sst) interneurons and, reciprocally, Sst cells make inhibitory synapses onto Vip cells. This reciprocal connectivity establishes a circuit motif of competitive inhibition with poorly understood effects on cortical processing. Using data from the Allen Brain Observatory, supplemented with follow-up experiments, we investigated the visual stimulus tuning and state-dependent modulation of these two major classes of cortical interneurons in mouse primary visual cortex. On long time scales, behavioral state can have a net correlating effect on these cell types as the activity of both cell classes positively correlates with

the running speed of the mouse. The cells have diverse relationships in their responses to visual stimuli. Full-field gratings drive strong and reliable orientation-tuned responses in Sst cells and reliably suppress activity of Vip cells, consistent with direct inhibition from Sst onto Vip cells. Although previous reports on the relative size tuning of these cells suggest that Sst cells should have much larger receptive fields than Vip cells, we find that Sst and Vip cells both have large receptive fields. Despite this similarity in receptive field size, Sst and Vip cells have distinct spatial frequency tuning. Unexpectedly, Vip and Sst cells are both among the most responsive cell types to natural movie stimuli out of all Cre-lines sampled in the Allen Brain Observatory. We compare the correlation of these cells with natural movies to better understand their functional interactions. These results suggest that the net interaction between these cell types is both stimulus and state-dependent.

Title: Cellular resolution mesoscale study on correlation structure during visual encoding

Authors: *Y. YU, S. L. SMITH
Univ. of North Carolina at Chapel Hill, Chapel Hill, NC

Abstract: In mammalian neocortex, visual information is processed by primary visual cortex (V1) and multiple higher visual areas (HVAs). Neural circuitry can lead to shared variability in spiking responses between neurons. These are called “noise correlations” (NCs), and can be due to shared input and/or direct or indirect connectivity. Thus, NCs provide insight into the functional connectivity of neuronal circuits. In this study, we used subcellular resolution mesoscale field-of-view two-photon calcium imaging to systematically characterize the NCs of layer 2/3 neurons across V1 and four HVAs (LM, LI, AL and PM) of mice. First, we found that the average NCs for pairs of neurons within a cortical area (intra-areal) and pairs of neurons where each neuron is in different cortical area (inter-areal) are orders of magnitude larger than control (e.g., intra-V1: 0.015, shuffled trials: 0.0004; inter-V1-PM: 0.014, shuffled trials:

0.0006). Overall, NCs were higher for neuron pairs with high tuning similarity. Firing rates and receptive field overlap were also positively correlated with NCs in most cases. Second, we found intra-areal NCs declined with distance between neurons, but for inter-areal NCs the distance-dependence was mixed (e.g., V1-LM and V1-LI NCs increased with neuron distance; and LM-LI NCs declined with neuron distance). These trends in NCs provide clues into HVA-specific transformations of visual stimulus representations. Third, to explore tuning-specific NCs in finer detail, we used an unbiased clustering approach to classify neurons based on their responses to orientated grating (8 directions, 3 spatial frequencies, 3 temporal frequencies). This analysis revealed biases in the coverage of spatiotemporal frequency space across HVAs, and relationships between orientation tuning biases and spatiotemporal frequency preferences. Using the resulting functional groupings, we found group-specific intra- and inter-areal patterns of NCs. Thus, there are functionally-specific subnetworks within and among visual cortical areas. Fourth, we analyzed the full covariance matrix to infer network structures that could underlie the measured NCs. We factored the covariance matrix into a low-rank component and a sparse component. The functional networks differed from random networks in the prevalence of well-connected units, whose spatial distribution varied by cortical area. Overall, these results have revealed a comprehensive picture of correlation structure with individual neurons across mesoscale distances and multiple cortical visual areas, which can inform and constrain computational theories of cortical network structure and function.

Title: Detecting information-limiting correlations experimentally

Authors: J. S. MONTIJN[1], R. G. LIU[1], *A. POUGET[1], P. E. LATHAM[2]
[1]Univ. of Geneva, Geneva, Switzerland; [2]Gatsby Computat. Neurosci Unit, London, United Kingdom

Abstract: How does information scale in neural circuits? For most patterns of correlations, information should be proportional to the number of neurons. In contrast, it should saturate to a finite value in the presence of what is known as information-limiting, or differential, correlations. Detecting such differential correlations is important since their presence is required for efficient

computation in neural circuits whenever a large number of neurons are coding for a scalar variable. However, current methods for detecting differential correlations require recording thousands of neurons simultaneously in a small cortical volume, which is not yet feasible. We report here a new method, which requires on the order of hundreds, rather than thousands, of neurons. This method relies on testing whether the 'information' and 'communication' subspaces overlap more than predicted by chance. For a scalar stimulus, the information subspace—where information refers to Fisher information—is a one-dimensional subspace colinear with the **f'** direction, where **f'** is the vector of derivatives of the tuning curves. The communication subspace, on the other hand, is based on the linear predictability of the activity of one neural population given another neural population: the D-dimensional communication subspace is obtained by recording, simultaneously, the responses of two neural populations to multiple presentations of the same stimulus; then using reduced rank regression to find the rank D weight matrix that best predicts the activity of one population based on the other. To test whether the information and communication subspaces overlap, the fraction of information transmitted in the communication channel is compared to the information transmitted in a random subspace of equal dimension. If the former is much higher than the latter, the information and communication spaces overlap. We have found analytically that when the information and communication subspaces overlap with D small (e.g. less than about 10), the neural code is likely to contain differential correlations. Using simulations with a leaky-integrate-and-fire (LIF) neuron model of the LGN-V1-V2 circuits, we confirmed that the method can indeed determine, with 100 neurons or fewer, whether differential correlations are present. This method can be easily applied to existing recordings in primates and rodents.

Title: Unraveling the hidden lamination of the avian visual DVR

Authors: S. FERNANDEZ, C. WEISS, M. D. FERNÁNDEZ, *J. MPODOZIS
Univ. of Chile, Santiago, Chile

Abstract: In birds the most prominent sensory pallial territory is the dorsal ventricular ridge (DVR), which consists of two dorso-ventrally apposed cellular masses: the mesopallium (M) and the nidopallium (N). The internal most aspect of the N contains discrete nuclei receiving

ascending afferents from different sensory modalities. Interestingly, these sensorecipient nuclei are reciprocally connected with dorsally adjacent sublayers of N and M by columnarly organized axonal processes. Recent gene expression studies have shown that these DVR layers differentially express mammalian layer-specific molecular markers. Thus, the neural organization of the DVR has been reinterpreted as following a laminar/columnar arrangement resembling that of mammals and layer-specific equivalences have been proposed. The sensorecipient area of the visual DVR is the Entopallium (E). Based on its connectivity and its molecular profile, E has been considered as the layer 4-like component of the visual DVR, but the existence of a robust projection from E to the underlying subpallium (the lateral striatum, LSt), a feature more consistent with that of neocortical layers 5-6, conflicts this proposal. Here we complemented immunohistochemistry, in situ hybridization essays and neuronal tracing to further characterize the laminar organization of the DVR, focusing on the palliostriatal population "hidden" within E. Tracer injections, both in vivo (pigeon) and in vitro (chicken), confirm that the E's intrapallial efferents mostly originate from its external region (Eex), whereas cells projecting to the LSt define in it a conspicuous internal domain (Ein). This division strikingly coincides with that defined by parvalbumin immunoreactivity, in which Ein exhibits an abundance of densely packed PV+ cells and fibers. ISH assays for the layer 4 specific marker RORß showed that cells of Ein exhibit a lower level of RORß expression than that of Eex. Lastly, anterograde tracer injections revealed that Ein is afferented almost exclusively by the central subdivision of the thalamic nucleus Rotundus (Rt), whereas Eex received fibers from dorsal anterior and posterior Rt. Our results indicate that E contains two superposed sublayers: an external, "layer 4-like" and an internal, "layer 5-like". The former exhibits a higher expression of RORß and exclusively originates intrapallial projections, while the latter lacks RORß expression and originates, mainly but not exclusively, projections to subpallial targets. The results point to the existence of a close relation between the visual flow and subpallial structures, which is more robust and direct than previously illustrated.

Title: Beyond gratings: Flow stimuli reveal ecologically-appropriate responses in mouse visual cortex

Authors: *M. HOSEINI[1], L. DYBALLA[2], M. C. DADARLAT[1], S. ZUCKER[2,3], M. P. STRYKER[1]
[1]Physiol., Univ. of California, San Francisco, CA; [2]Computer Sci., [3]Biomed. Engin., Yale Univ., New Haven, CT

Abstract: The mouse is a widely used model for studying vision because of the molecular, imaging, and genetic tools that are available. Assessments based on spatial frequency analysis imply that the visual capacity of the mouse is of low quality, with few neurons responding to spatial frequencies greater than 0.5 cycles/deg. Visually-mediated behaviors, such as prey capture, suggest that the mouse visual system is more precise. We have used 128-site silicon microelectrodes to measure the simultaneous responses of single neurons in the primary visual cortex (V1) of alert mice with a new stimulus class—visual flow patterns—that is more like what the mouse would encounter in the natural world than are sine-wave gratings but are more tractable for analysis than natural images (Dyballa et al, this meeting). Flows formally approximate natural visual scenes like those that would be seen by a mouse running through grass. Specifically, we have explored a class of drifting patterns of black or white dots that have energy only at higher spatial frequencies than those that produce responses to gratings while holding temporal-frequency content fixed. Flow patterns were displayed to the contralateral eye on a screen subtending 76 deg in azimuth and 58 deg elevation centered in the monocular segment of the visual field. These flow stimuli evoke strong visually-mediated responses well beyond those predicted by spatial frequency analysis. Flow responses predominate in higher spatial-frequency ranges (0.15 - 1.6 cycles/degree); many are orientation- or direction-selective; and flow responses of many neurons depend strongly on sign of contrast. Together these results challenge conventional linear approaches to visual processing and extend the mouse's visual capacity to behaviorally-relevant ranges.
We are grateful to Dr. Sotiris Masmanides of UCLA for supplying the microelectrodes.

Title: Flow stimuli reveal hidden dimensions in mouse visual cortex

Authors: *L. DYBALLA[1], M. HOSEINI[3], M. P. STRYKER[3], S. W. ZUCKER[1,2]
[1]Dept. of Computer Sci., [2]Dept. of Biomed. Engin., Yale Univ., New Haven, CT; [3]Ctr. for Integrative Neurosci., Univ. of California, San Francisco, San Francisco, CA

Abstract: We have analyzed responses of single neurons in primary visual cortex of alert mice to conventional and novel visual stimuli (Hoseini et al., this meeting). Repeated presentations of a given stimulus, or of stimuli drawn from related families, evoke an ensemble of spike trains. We work with gratings and flow patterns, a class of naturalistic visual stimuli that span spatial frequency, contrast, orientation and directionality, and ask: What are the significant commonalities and differences among responses to them? Conventional receptive-field or spatial-frequency analyses yield little insight into flow-stimuli responses. Instead, we have performed a purely data-driven analysis applied to spike-train data from the full stimulus ensemble. Our unsupervised approach organizes cells' responses—at individual and population levels—into meaningful classes, while making no assumption about spike encoding strategies or stimulus classes. Novel dimensionality reduction techniques reveal that (i) diffusion map embeddings of neural data can be clustered to infer the stimulus; (ii) diffusion map embeddings can remain invariant across brain state. (iii) Although raw PSTHs are high-dimensional, they contain only about 8 significant dimensions; (iv) when projected into these dimensions, PSTHs organize into about 12 clusters. (v) Each of these clusters indicates a different type of processing, from the expected simple-type cells to more complex and transient responses. (vi) Some clusters contain mostly flow responses, many of which are delayed. Such delays seem likely to result from feedback originating in other visual areas. The majority of clusters challenge the widely-deployed 'receptive field' model of visual cortex suggesting, instead, much richer networking models.

Title: A hallucinogenic serotonin-2A receptor agonist reduces visual response gain and alters temporal dynamics in awake mouse V1 neurons

Authors: *A. MICHAIEL, P. R. L. PARKER, C. M. NIELL
Inst. of Neurosci., Univ. of Oregon, Eugene, OR

Abstract: Sensory perception arises from the integration of externally and internally driven representations of the world. Disrupted balance of these representations leads to perceptual deficits and hallucinations. The serotonin-2A receptor (5-HT2A) is known to create conditions under which such perceptual alterations occur, as in schizophrenia and after psychedelic drug administration. Despite its drastic influence on perception, almost nothing is known about how activation of 5-HT2A influences sensory processing in the neocortex. Using widefield/two-photon calcium imaging and single unit electrophysiology in awake mice, we found that administration of the selective 5-HT2A agonist DOI (2,5-Dimethoxy-4-iodoamphetamine) drastically altered temporal and spatial processing of visual stimuli in primary visual cortex while leaving basic retinotopic maps, tuning properties, and receptive field structure intact. The net result of DOI-induced changes was a signficant decrease in sensory drive and reduced contextual modulation in visual cortex. Our results are consistent with models of hallucination in which reduced bottom-up sensory drive is a key factor leading to altered perception.

Title: Impact of behavioral sources of noise correlation on population coding across the mouse visual system

Authors: *G. K. OCKER[1], N. H. CAIN[1], P. LEDOCHOWITSCH[1], D. MILLMAN[2], M. D. OLIVER[3], S. E. DEVRIES[1], M. A. BUICE[1]
[2]Neural Coding Group, [1]Allen Inst. for Brain Sci., Seattle, WA; [3]Modeling, Analysis & Theory, Allen Inst. for Brain Sci., Woodinville, WA

Abstract: The visual system encodes during different behavioral states which modulate neurons and neural circuits and impact the structure of visual stimuli. Diverse neuronal populations, of different cell types and in different brain areas and cortical layers, encode and transform visual stimuli with state-specific modulations or computations that have only begun to be revealed. The Allen Brain Observatory contains 2P calcium imaging from simultaneously recorded populations of hundreds of neurons in awake, passively viewing mice on a running wheel. Its recordings together span layers 2-5 in areas V1 and the secondary areas LM, AL RL, AM and PM and are in response to both synthetic and naturalistic stimuli. Locomotion and arousal provide low-

dimensional sources of variability to networks in murine primary visual cortex, but the impact of these low-dimensional fluctuations and other intrinsic sources of joint variability on information coding in higher cortices and across different genetic neural populations remains to be understood. We classify the mouse's behavior during image presentations by a Gaussian mixture model of the running speed. We observe low-dimensional trial-by-trial noise correlations across all examined locations in the mouse brain. This low dimensionality remains when restricting the responses to non-locomotion trials. To measure information coding, we decode the visual stimulus from the single-trial population responses. We see that locomotion improves decoding performance in a location-specific fashion, with differential impacts due to its modulation of single-neuron response properties and joint variability in different visual areas, layers and cre lines. Shuffling trials to destroy noise correlations generally improves stimulus decoding, suggesting that noise correlations negatively impact population coding. However, restricting to non-running trials reveals that, in certain locations, this impact is due to the behavioral modulation of noise correlations - and that noise correlations actually improve decoding performance during a single behavioral state. Together, our results show the differential impact of different sources of joint variability on population coding, highlighting the importance of behavioral context for a population stimulus code.

Abstract: Sensory perception is fundamentally limited by the coding accuracy of sensory neural ensembles. A substantial body of theoretical and experimental research suggests that populations of sensory cortical neurons exhibit positively correlated noise fluctuations that may bound the

precision of cortical neural coding and sensory discrimination. However, due to the limited size of past datasets, it has generally not been possible to examine how noise correlations vary across sensory cortical areas and over time during sensory decision-making. Here we analyzed the signaling and noise correlation properties of neural ensemble dynamics monitored by large-scale neural calcium imaging in the neocortex of behaving mice performing a GO/NO-GO visual decision-making task. Multiple neocortical areas accurately encoded the visual stimulus, as well as the animal's discriminative response. Our analysis also revealed positively correlated noise fluctuations across neural populations in multiple neocortical areas. The mean strength of these noise correlations varied as a function of time across the visual stimulus presentation, delay period and response period of our decision-making assay. Notably, sensory cortical neurons generally exhibited noise fluctuations that were more positively correlated at the start of visual stimulation, but then less so as a decision-making trial proceeded. Neural populations lying within the same visual cortical area and those spanning distinct cortical areas both exhibited this time-dependent modulation in noise correlation strength. These results show the widespread presence of positively correlated neural noise across the cortex and suggest that sensory cortical noise patterns may reflect a time-dependent gating of signal flow between cortical areas.

Title: Registration of multiple cortical layers across individuals improves the relative positioning of neurons

Authors: *C. LEE[1], R. DALLEY[2], A. MUKORA[2], D. SANDMAN[2], G. WILLIAMS[2], S. KEBEDE[2], S. SORENSEN[2], U. SÜMBÜL[1]

Abstract: Laminar organization is a hallmark of cortical tissue. Cell classes are typically defined with respect to their laminar position, which plays an important role in the study of canonical cortical circuits. However, neuronal arbors typically occupy large fractions of the laminar axis, potentially obscuring finer laminar organization. Here, we reconstruct the arbors of cortical neurons from the mouse visual cortex (adult P45-P70 mice), and annotate the corresponding laminar borders together with the pial surface and the white matter boundary using the DAPI and brightfield 20x images. We propose a nonlinear registration algorithm to represent all the neurons in a common laminar axis to account for the variability in laminar thickness across

individuals. We generate cortical depth profiles of individual neurons and compare these profiles with the ones obtained from classical pia/white matter based scaling. Our approach produces narrower depth profiles for individual neurons in the common axis, as measured by the Crest factor, the ratio of the peak value to the root-mean-squared value (Figure 1). These results emphasize the potential role of laminar positioning in the definition of cell types and their organization into canonical circuits.

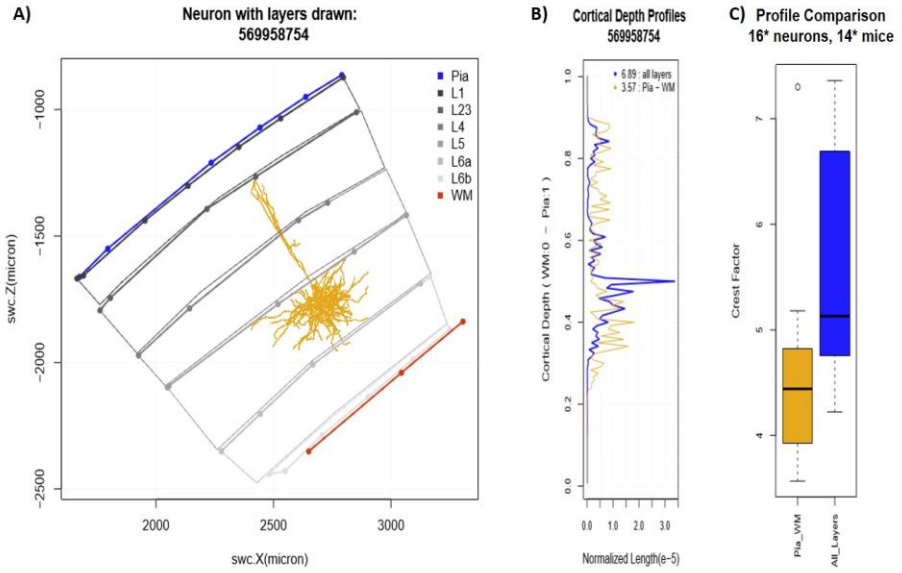

Figure 1. A) A representative neuron with the arbor trace and the cortical layers identified, B) The classical cortical depth profile for the neuron in A is calculated based pia and white matter boundaries (yellow). The depth profile obtained by a nonlinear registration using all the cortical layers (blue) occupies a smaller fraction of the common cortical depth axis. C) Summary of the Crest factors of the cortical depth profiles of a population of neurons obtained by the two methods. The Crest factor indicates how extreme the peak is in a given profile (the higher the better for identifiability). *Many more neurons are to be added.

Title: Eye movement information in V1 is carried through feedback projections

Authors: *S. MIURA[1], M. SCANZIANI[2]
[1]Univ. of California San Francisco, San Francisco, CA; [2]Univ. of California, San Francisco, San Francisco, CA

Abstract: Saccades have a profound impact on vision, both perceptually and physiologically. Using mouse primary visual cortex (V1) as a model system, we have begun to dissect the circuit that carries saccade information to cortex. Similar to previous reports in cats and monkeys, we find that saccades modulate activity in mouse V1. This activity is caused by input of extra-retinal origin that persists even under suppression of all neuronal activity in the eyes. Who provides this saccade information to V1? To address this question, we took a candidate approach in which we silenced different brain regions while recording saccade-related activity in V1. First, we considered the possibility that this activity is inherited from the dorsal lateral geniculate nucleus (dLGN) in thalamus, as this is the major driver of V1 activity. Indeed, recording in the dLGN showed that its activity is also modulated by saccades. However, silencing the dLGN did not eliminate the modulation in V1. In contrast, silencing V1 eliminated saccade-related activity in the dLGN, suggesting that V1 is the source of saccade-information input in the dLGN and not vice-versa. Upon further exploration, we identified the latero-posterior (LP) nucleus in the thalamus as the source of saccade information in V1. LP is a higher order thalamic nucleus that receives inputs not only from visual cortical areas but also from other brain regions including the superior colliculus, a midbrain structure responsible for generating saccades. In turn, V1 receives projections from LP. Consistent with previous studies in monkeys, neurons in mouse LP are also modulated by saccades. When LP was silenced pharmacologically, V1 was no longer modulated in response to saccades. From our analyses, we suggest that saccade information flows from LP through V1 to the dLGN through the feedback pathway. The identification of the source of saccade information in V1 now enables us to explore the precise circuit mechanisms by which the saccade-related activity impacts different cell types within V1. This will allow us to understand the interaction of saccade information with visual information, and how this affects perception of the animals.

Title: Parvalbumin-positive interneuron ensemble dynamics in the primary visual cortex during mouse visual detection

Authors: *A. I. MORE[1,2], C. A. DEISTER[1,2], C. I. MOORE[1,2]
[1]Brown Univ. Neurosci., Brown Univ., Providence, RI; [2]Carney Inst. for Brain Sci., Providence, RI

Abstract: Neocortical computations emerge from the functioning of, and interactions between, neural circuit motifs. While the key components of such motifs are still being determined, there is consensus that tightly regulated interactions between excitatory and inhibitory neurons are key to normal circuit function, and that neocortical activity can be dynamically regulated to enhance information processing. Parvalbumin-expressing fast-spiking interneurons (PV/FS) are hypothesized to be a key mediator of this dynamic balance.
We recently showed that trial-to-trial variation in PV/FS activity in primary somatosensory neocortex (SI) predicts task success during tactile detection of threshold-level stimuli. Specifically, subgroups of PV/FS fire either more or less on a 'hit' than a 'miss' trial (Deister et al., under review). Computational modeling indicates that these subgroups may be key to dynamic implementation of a basic motif, including an ensemble of pyramidal neurons that predict detection with rate increases and decorrelation in the broader population that does not show rate modulation. To test the generality of these task-predictive PV/FS dynamics and related pyramidal behavior, we have begun to image PV/FS in visual cortex during simple visual detection and discrimination. After using wide-field imaging to localize specific sub-domains responsive to discrete retinotopic positions, we have conducted 2-photon microscopy in head-posted mice during behavior. We have to date obtained sigmoidal contrast detection psychometric curves in multiple animals, and mapped PV/FS orientation, contrast, and direction tuning curves (N = 3 mice). We are now obtaining task dependent-activity in PV/FS and surrounding pyramidal networks to test whether parallel dynamics are observed to those found in SI.

Title: Representation of concurrent stimuli by population activity in mouse primary visual cortex

Authors: *D. L. RINGACH
Neurobio. & Psychology, UCLA, Los Angeles, CA

Abstract: It has previously been shown that, in cat primary visual cortex, the responses to two superimposed gratings are the weighted sums of the individual grating responses (Busse et al, *Neuron*, 2009). The relative weights of the responses are explained very well by a contrast normalization model. We studied the same phenomenon in mouse primary visual cortex. We presented two individual visual stimuli *A* and *B*, and their superposition, *A+B*. We measured the corresponding mean population vector responses *r(A)*, *r(B)* and *r(A+B)*. Finally, we measured the angle between *r(A+B)* and the plane spanned by the individual responses *r(A)* and *r(B)*. If *r(A+B)* can be represented as a linear combination of *r(A)* and *r(B)*, as previously reported, the angular deviation is expected to be near zero. Surprisingly, we found this is not the case in mouse primary visual cortex. The population responses to plaid stimuli are far from ***any*** linear combination of the individual granting components. This result is due, in part, to the fact that some cells in mouse V1 respond to *A+B*, but not to *A* or *B*. Thus, in mouse primary visual cortex, the population response to the superposition of two visual stimuli cannot be predicted by a linear combination of the individual population responses.

Title: All-optical interrogation of functional connectivity in mouse visual cortex during behaviour

Authors: *L. E. RUSSELL[1], A. M. PACKER[2], M. HAUSSER[3]
[1]Wolfson Inst. for Biomed. Res., [2]Univ. Col. London, London, United Kingdom; [3]UCL, London, United Kingdom

Abstract: Understanding how the structure of connectivity underlies the processing carried out by cortical circuits is a fundamental problem in neuroscience. Layer 2/3 of mouse visual cortex consists of functionally distinct subnetworks of recurrently connected neurons. Neurons sharing similar stimulus response properties (i.e. cotuned to the same stimuli) preferentially share monosynaptic connections. This specific synaptic connectivity rule may facilitate and maintain robust representations of visual stimuli even under situations when those stimuli are weak or

degraded. Here we have trained mice on a visual detection task and used simultaneous two-photon calcium imaging and two-photon optogenetics to ask: 1. How does this pattern of paired connectivity extend to, and influence, activity at the population level in vivo? and 2. How does the functional signature of subnetworks impact upon the neural representation, and ultimately the behavioural salience, of weak or ambiguous stimuli? To address these questions, we performed targeted photostimulation of ensembles of either cotuned, non-cotuned or non-stimulus responsive L2/3 visual cortex neurons and observed the response of the local network as well as the animal's performance in reporting the current visual stimulus. Our preliminary results show that when a sufficient number of cells are photostimulated during reduced contrast visual stimulus presentation, the behavioural response rate to that stimulus is enhanced. We are currently dissecting how enhancing the behavioural response to a sensory stimulus depends on the functional identity of the photostimulated ensembles and their engagement of the local network. These results provide a bridge between connectomics, sensory stimulus coding and behaviour.

Title: Somatostatin interneurons exhibit divisive inhibitory influence on nonlinear synaptic integration in layer 2/3 pyramidal neurons of the visual cortex

Authors: *C. DORSETT[1], I. T. SMITH[2], S. L. SMITH[2]
[1]Univ. of North Carolina - Chapel Hill, Chapel Hill, NC; [2]UNC Sch. of Med., Chapel Hill, NC

Abstract: Active mechanisms (voltage-gated Ca^{2+} and Na^{+} channels, and NMDA receptors) on the dendrites of cortical pyramidal neurons support dendritic spike generation. Dendritic spikes are a key component of synaptic integration that can enhance stimulus selectivity in visual cortex. Thus, modulation of dendritic spiking would have a powerful influence on cortical circuitry. Somatostatin (SOM) interneurons send a portion of their projections to distal dendritic compartments, and could exert a specialized influence on dendritic spiking. We investigated the role of SOM interneuron-mediated inhibition on dendritic excitability in layer 2/3 pyramidal cells from slices of mouse visual cortex using patch clamp electrophysiology and optogenetics. SOM cells expressing channelrhodopsin-2 (ChR2), responded to trains of light pulses with reliable depolarizations (mean ± SEM: 8.73 ± 0.27 mV, n = 16) to each pulse, but typically only

fired action potentials in response to the first pulse. Application of a GABA antagonist resulted in SOM cells reliably firing action potentials in response to every pulse of light up to 20Hz (n = 4). Thus, ChR2 stimulation likely causes direct release of GABA from SOM cell axons, and SOM cells mutually inhibit each other. We next recorded electrically-evoked synaptic potentials from pyramidal cells. Synaptic potentials increased in a supra-linear fashion above a cell-dependent stimulus intensity, indicating the recruitment of voltage-gated mechanisms on the dendrites. The frequency of non-linear increases was reduced in the presence of an NMDA receptor antagonist, although not abolished in every cell, thus both NMDA receptors and other voltage-gated channels can contribute to nonlinear synaptic integration. Optogenetic stimulation of SOM cells resulted in a mild hyperpolarization of pyramidal neurons (-2.31 ± 0.31 mV, from a baseline of -78.81 ± 1.46 mV, n = 23). Optogenetic SOM cell activation resulted in a reduction in the magnitude of electrically evoked synaptic potentials, especially at higher stimulus intensities, consistent with divisive inhibition (~75% of cells). Of cells with non-linear responses (n = 17), nonlinearities persisted during SOM cell activation (14 of 17), although the magnitude of the non-linearity was reduced or shifted by SOM cell activation. These results argue against a simple model in which SOM cells powerfully inhibit dendritic excitability. Instead, the effects of SOM cell activity appear to be more subtle. SOM cells can often affect the gain of pyramidal neurons, and in some cases modulate nonlinear dendritic integration, and either modulation affects the processing of synaptic input in visual cortex.

Title: A sparse unreliable distributed code underlies the limits of behavioral discrimination

Authors: *B. SRIRAM[1], L. LI[2], A. CRUZ-MARTIN[3], A. GHOSH[1]
[1]Biogen, Cambridge, MA; [2]Div. of Biol. Sciences, Neurobio., Univ. of California San Diego Section of Neurobio., La Jolla, CA; [3]Boston Univ., Cambridge, MA

Abstract: The nature of cortical code must enable subjects to perceive the world at the timescale most relevant for behavior. In rodents, we verify that visually directed orientation discrimination behavior is dependent on activity in the primary visual cortex (V1). Yet, the nature of the activity in V1 has only been characterized on timescales that last many hundreds to many thousands of milliseconds. To test if this is the relevant timescale, we measured the timescale of visual

integration in rodents performing an orientation discrimination task. We find that mice can integrate visual stimuli very quickly (<100 ms) to reach plateau performance. We recorded the activity of neurons across all layers of cortex to such short stimuli in both naïve mice as well as mice that have been trained in the orientation discrimination task. While significant differences exist across layers, such stimuli drive extremely sparse and unreliable responses in V1 such that the activity of no individual neuron is sufficient to decode the stimulus. Integrating information across neurons, however, quickly improved performance. Using a linear decoding model, we estimate that the animal integrates over ~100 neurons to perform the orientation discrimination task. We further find that for such short stimuli, prior training in an orientation discrimination task did not change the population requirements. Thus, visually guided behavior at the limits of perception relies on effective integration of information across units with sparse and unreliable responses to stimuli.

Title: Synaptic mechanism of orientation selectivity in layer 4 of mouse visual cortex

Authors: *Y. CHEN, T. SATO, B. SONG, A. KONNERTH
Inst. of Neuroscience, TUM, Munich, Germany

Abstract: Classical work by Hubel and Wiesel has established that in several mammalian species, including cats and non-human primates, orientation selectivity of the primary visual cortex (V1) is determined by the specific arrangement of non-tuned thalamic lateral geniculate nucleus (LGN) inputs at the cortical entry stage in layer 4 (L4). Such inputs would produce non-tuned synaptic potentials at individual spines at dendrites of L4 neurons and contribute through various mechanisms to the eventually orientation selective output response. While evidence from different laboratories supports a similar model also for mouse V1, several studies revealed an orientation-tuned thalamo-cortical pathway, with axons projecting to multiple layers of V1, including L1 to L4. Thus, the synaptic and circuit mechanisms contributing to orientation selectivity in mouse V1 may be more complex than initially assumed. In the present study, we established methods for single spine imaging in L4 of mouse V1 involving the use of

genetically-encoded calcium indicators. We performed a two-step experiment to achieve sparse labeling of functionally defined V1 neurons. We first performed population imaging with a red-shifted synthetic indicator (Cal-590) and then delivered plasmids of GCaMP6s, GCaMP7b or GCaMP7s to selected individual neurons via targeted single-cell electroporation. This protocol allowed us to chronically monitor calcium signaling in spiny dendrites of such L4 neurons over several days. We found that GCaMP7b was best suited for imaging spines in deep cortical layers. By combining *in vivo* spine calcium imaging and electrophysiology, we determined the specific properties of visual stimulation-evoked synaptic signals as opposed to calcium signals evoked by back-propagating action potentials. Our results demonstrate that in orientation-tuned L4 neurons the vast majority (about 70 - 80%) of responsive single spine inputs were tuned to the same orientation as that of the neuron's output response. Only a small fraction of L4 spines (< 5%) showed non-tuned calcium transients, a property that is expected for a Hubel-Wiesel type synaptic mechanism. Thus, our results demonstrate that the by far dominating factor underlying orientation-selective action potential firing in mouse L4 neurons is the synaptic drive provided by tuned axonal inputs, which are likely to be arising from LGN. In conclusion, we elucidated the synaptic mechanism of orientation selectivity of L4 neurons in mouse V1. The results are not consistent with the Hubel and Wiesel model and suggest an additional, distinctly different mechanism of cortical orientation selectivity in the mammalian visual system.

Title: Predicting excitatory-inhibitory dynamics in the corticothalamic network

Authors: *I.-C. LIN[1], M. OKUN[2], M. CARANDINI[1], K. D. HARRIS[1]
[1]Univ. Col. London, London, United Kingdom; [2]Dept. of Neuroscience, Psychology & Behaviour, Univ. of Leicester, Leicester, United Kingdom

Abstract: Although cortical circuits are highly complex, their global dynamics are often approximated by simple mean-field models involving interactions between the average activity of excitatory (E) and inhibitory (I) populations. How accurately can such models predict cortical dynamics? More generally, can such models treat a cortical region as an isolated system, or must

they include interactions with other brain regions such as the thalamus?
To address these questions, we used dichromatic optogenetics to independently stimulate pyramidal and parvalbumin-inhibitory neurons in the primary visual cortex (V1) of quietly awake mice, while using multisite silicon probes to record the dynamics of E and I populations in V1, and of neurons in the lateral geniculate nucleus (LGN).
Stimulating E neurons strongly but transiently activated first E then I neurons. This activation was followed by a prolonged suppression of both neural populations, and a recovery above baseline (rebound) >100 ms later. Similar events were observed when presenting brief visual flashes to awake mice. These events could not be explained by I activity alone: stimulating I neurons caused a shorter, less visible suppression of both populations without incurring a rebound.
These observations could be well captured by a mean-field model, but not a model of cortex alone. The classical Wilson-Cowan (1972) model was insufficient, as it failed to predict prolonged suppression. Adding a term for cortical slow GABAergic inhibition captured the effects of I but not E stimulation. We were able to account for the latter with a corticothalamic network model including both reticular inhibition and rebound bursting.
To investigate the role of thalamus in responses to optical stimulation on V1, we paired stimulation of cortical E and I neurons with LGN recordings. Stimulating cortical E neurons affected LGN neurons similarly to V1 neurons: initial activation, prolonged suppression, and a rebound. By contrast, stimulating cortical I neurons had only minimal effects. These findings are consistent with the behavior of the corticothalamic mean-field model.
To further validate the model, we tested its ability to predict responses to pairs of optical stimuli. We found that the corticothalamic mean-field model was able to account for responses to pairs of E and I stimuli, in either order, using a single set of parameters fit for each recording.
We conclude that cortical dynamics can be well approximated by mean-field models, but not by mean-field models of cortex alone.

Title: The effect of basal forebrain activation on the trial to trial variability of neuron’s subthreshold response in mice primary visual cortex (v1)

Authors: *P. GHADERI, S. ROSTAMI, M.-S. SAFARI
Neurosci. Res. Ctr., Tehran, Iran, Islamic Republic of

Abstract: Literature and Purpose: Acetylcholine is released from neurons projecting to a broad range of cortical and subcortical sites. These projections can be split into two groups: the basal forebrain (BF) cholinergic system and the brainstem cholinergic systems. In this study, we have investigated the effect of BF stimulation on the subthreshold response variability of a single neuron in v1 area of the mice visual cortex. **Material and Method:** Whole-cell patch clamp recordings in the current clamp mode were obtained from neurons from the V1 of the mice visual cortex. Whole-cell current-clamp recordings were performed using the bridge mode (Manually Tuning series resistance and compensate capacitor) of an Axoclamp 200B amplifier. Electrical stimulation was delivered to the Nucleus Basalis of Meynert(NBM) in Basal Forebrain. A custom-made Matlab code was used to display drifting sine wave grating for 7 level of stimulus contrast at preferred orientation. Recording for each group war repeated 3 times. We investigated both the effect of sensory input and BF stimulation on Trial to Trial variability of subthreshold activity of neurons. **Result:** the experiment and our analysis were performed on 29 neurons. The overall average of trial to trial variability (n=29) is declined during visually evoked activity compared to spontaneous activity (Pvalue<0.05, paired t-test). And also it has been shown that this effect is not significant on different layers. We investigated the effect of visual input on trial to trial variability for a different level of contrast. There is a decrease in trial to trial variability in evoked activity in comparison to spontaneous activity for all level of contrast (Low, Medium and High Contrast).in addition, we investigated the effect of BF stimulation on trial to trial variability. It has been shown that BF stimulation decreases the Trial to Trial variability (pvalue<0.05, paired t-test). Ach effect on trial to trial variability was observed significant on the layer 2/3 but not significant for layer1. BF stimulation decrease trial to trial variability for all level of contrast but the effect was observed statistically significant in medium level of contrast (pvalue <0.05). **Conclusion:** in this study, we investigated the BF stimulation effect on the variability of subthreshold activity of neurons in mice V1. It has been shown that BF stimulation decreases the variability of neurons response, in other words, it made neurons response more reliable. Also, the visual input from LGN to V1 decreases the trial to trial variability of neurons response.

Title: Cell-class-specific census of synapses in mouse visual cortex

Authors: *F. C. COLLMAN[1], M. M. NAUGLE[2], S. SESHAMANI[2], R. SERAFIN[2], O. GLIKO[2], J. SCHARDT[2], S. DAVIS[2], L. ELABBADY[2], H. ZENG[3], S. J. SMITH[2]
[2]Synapse Biol., [3]Structured Sci., [1]Allen Inst. for Brain Sci., Seattle, WA

Abstract: Modern molecular neuroscience has described an increasing number of distinct neuron types, particularly in the visual cortex (Tasic B, et al., bioRxiv. doi.org/10.1101/229542), but a description of how these types interconnect is incomplete. Inventories of neuron-class-specific synaptic connections in transgenic mice offer the prospect of improved models of cortical synaptic network connectivity. Toward this end, we have developed methods for quantitatively characterizing the laminar distribution of synapses to and from Cre-driver-defined neuron classes using conjugate fluorescence/electron array tomography. Using manual annotation of 1023 EM identified synapses from Layer 4 and layer 2/3, we have trained a convolutional neural network (CNN) to identify synapses with at least 85% precision and 85% recall, using 803 EM identified synapses in layer 5 as a validation set. This CNN was then deployed to detect 1,192,731 synapses across all cortical layers of VISp cortex of a mouse derived from crossing a Rorb-Cre driver line into a TdTomato reporter line. Furthermore, synapses can be classified into 4 types based upon the transgenic TdTomato labelling of their pre and post-synaptic compartments. This allows us to systematically measure the density of synapses to, from and between transgenically defined neuronal subtypes. In addition, we can further subdivide synapses based upon analysis of their molecular composition using the multiplexed immunofluorescence labelling, including GABA, synapsin1, GAD2, VGluT1, PSD95, GluN1 and gephyrin. Repetition of these measurements will enable a census of synaptic types as a function of neocortical depth.

Title: Does CNN explain the properties of the middle face patch area of primate?

Authors: *R. RAMAN, H. HOSOYA
Dynamic Brain Imaging, Advanced Telecommunications Res. Inst. Int, Kyoto, Japan

Abstract: In recent computational studies, convolutional neural networks (CNN) optimized for image classification have been found to be highly predictive of neural responses in the primate inferotemporal (IT) cortex. However, these predictions have been made in terms of linear regression of the responses of model units onto those of IT neurons, which leaves a potential computational gap between CNN and IT. One approach that can directly investigate similarity between these two in a unit-to-unit manner would be to compare their tuning properties. Since currently known tuning properties in IT are mostly concentrated on the face processing system, we study here the tuning properties of CNN's related to face stimuli in comparison to those of face-selective neurons.
Specifically, we took two state-of-the-art deep CNN's: VGG-face, trained on face images and Alexnet, trained on Imagenet. We chose two experimental protocols used in past physiological studies on the face-processing middle lateral (ML) area, namely, Freiwald et al. (2009) using cartoon faces stimuli with controllable facial feature parameters and Freiwald and Tsao (2010) using natural faces at various positions and sizes. While simulating these experiments on each CNN, we recorded the responses of the face-selective units in different layers and compared their tuning properties with the experimental data. As a result, we made the following observations consistently for both CNN's. First, across all the layers, the tunings were mostly ramp-shaped and their amplitude depended on the presence of a whole upright face, similar to physiological results. Second, though higher (fully connected) layers captured the position and size invariance properties similar to ML neurons, the units in these layers were typically tuned to higher feature dimensions, quantitively dissimilar to the reported lower feature dimensions (on average three). Third, contrary to the experimental results, which showed that the ML population mainly focused on a small number of features related to eye and facial geometry, these higher layers put nearly equal focus to almost all the features. Fourth, lower-middle layers had smaller tuning dimensions (similar to physiological results), but these layers failed to capture the invariance properties. Thus, we could find no layer which captured all the investigated response properties simultaneously. Taken together, these results indicate that the CNN's capture only partial properties of the ML and require a more comprehensive model to fully explain it.

Title: Perceptual and mnemonic mechanisms underlying the other-race effect

Authors: *J. YAROS, ESQ[1,2], D. A. SALAMA[2], B. A. MIRADA[2], M. S. LARSON[2], M. A. YASSA[2]

Abstract: The Other-Race Effect (ORE) is a social phenomenon in which people are better at recognizing individuals within their own race, relative to other races. While behavioral research suggests the ORE is due to extensive experience with one's own race group, the neural mechanisms underlying the effect remain unclear. The locus of the ORE is subject to ongoing debate; Some believe the ORE is entirely dependent upon differential visual processing mechanisms for same and other-race faces. We show data consistent with the alternative view that both visual and memory processing mechanisms give rise to the effect. More specifically, in addition to visual representational differences, same-race (SR) and other-race (OR) recognition disparities may be dependent on differential mnemonic discrimination (MD) profiles. MD is the ability to discriminate among similar experiences to encode new events as distinct from familiar events. This process requires pattern separation - a neurocomputational process by which overlapping experiences are stored using distinct neural codes.
We therefore investigated the ORE using an MD task with computer-morphed faces, which afforded us a more nuanced picture of the phenomenon than standard recognition tasks have previously provided. MD tasks are similar to standard old/new face recognition paradigms, with the exception of the use of lure stimuli varying in similarity to previously presented stimuli. This gave us the opportunity to characterize recognition accuracy in terms of the ability to resolve interference between prior experiences and new experiences of faces.
Specifically, we found that face recognition performance is modulated by race and similarity (or interference) among stimuli. Subjects demonstrate enhanced recognition accuracy for SR over OR stimuli even when distractor faces were highly similar to the originals. In fact, SR recognition was significantly better than OR recognition at all but the lowest similarity level. Subjects only performed equally on SR and OR faces when morphed pairs were maximally distinct (50% morph). In contrast, no ORE was found in a match-to-sample (MTS) task using the same stimuli and parameters but without a mnemonic load. Taken together, our data identifies a critical component of the ORE that is mnemonic and not perceptual in nature.

Title: Effect of familiarity on neural dynamics of face selective cells in monkey inferior temporal cortex during a demanding face discrimination task

Authors: *W. DANG, D. L. SHEINBERG
Brown Univ., Providence, RI

Abstract: It is well known that visual familiarity can profoundly impact human visual perceptual experience. Monkey studies similarly shown that neural responses can be systematically altered as a function of stimulus familiarity at multiple visual processing stages in neocortex, including the inferior temporal cortex (ITC). However, most previous non-human primate studies have used a passive viewing paradigm to probe these effects, so it remains unclear how neural signatures of familiarity affect behavior. Furthermore, most previous studies of long term familiarity have used visual stimuli taken from different categories, which are highly variable in terms of underlying image statistics. Little is known about how individual neurons respond to familiar exemplars vs. unfamiliar exemplars within a highly familiar, visually homogeneous, category. In the current study, we used computer generated realistic human face images as test stimuli. We trained a macaque monkey to discriminate familiar and novel faces from highly similar perturbations using a successive same-different task. During the task, we recorded single-unit responses from face selective cells in ITC. We found that 1) There is an asymmetry in animal performance: the discrimination accuracy is highest when the original familiar faces was shown as the sample, but lowest when a perturbed familiar faces was the sample. This suggests a possible attractor dynamic, wherein ITC cells may respond to stimuli close to familiar ones as they would to well-known exemplars; 2) Neural responses during the sample period, as well as behavioral performance, changed over several hundreds of trials, but the changes in neural response occur in different temporal epochs for familiar and novel stimuli sets; and 3) In contrast to previous reports of an overall suppression across all time epochs of neural response in the test period of a delayed match to sample test, we found small suppression in early epochs, and strong facilitation in late epochs of test period response. Together, these data deepen our understanding of how long- and short-term experience can affect high order visual processing in the brain and how these changes may affect behavior.

Title: Human MT+ is sensitive to the dynamics of motion of a single dot representing or violating the biological motion of real human walkers

Authors: *J. V. DUARTE[1], B. ARAGÃO[2], J. A. SANTOS[2], M. CASTELO-BRANCO[1]

Abstract: Perception of biological motion is important for daily life activities, such as non-verbal communication. Understanding how the visual system perceives biological motion, even from point-light displays depicting human activity, remains a neuroscientific challenge. The mechanisms that allow us to interpret biological motion from the local motion of individual dots, which is characteristic for the local motion of parts of living beings and can be defined as *life motion*, are largely unknown. The functional separation into distinct neural stages of the correlates of the perception of *life motion* from perception of global motion of a coherent body bearing multiple articulated joints remains to be achieved. We hypothesized that *life motion* processing can be separated, by using a single dot motion paradigm featuring the biomechanical details of local realistic motion of a single joint. Equipped with such a paradigm, we studied the neural correlates of *life motion* perception. Low level visual areas, such as the human hMT+ complex, are known to respond to simple and variable motion patterns. To investigate if this region also responds to biological motion paths that a given center of gravity undergoes through space, we manipulated the constraints imposed by gravity and inertial forces on acceleration/deceleration patterns of foot motion, by mapping realistic foot movement on a single dot motion stimulus. We therefore developed an event-related fMRI experiment to study the neural basis of *life motion* perception from a single moving dot embedding the kinematic properties of local feet motion that only contained local properties. We could isolate more low-level (*life motion*) aspects of biological motion processing from aspects related to social perception of animated shapes. We hypothesized that such local biological motion computation is achieved in hMT+ by assessing, using BOLD fMRI, the neural correlates underlying the decision the decision whether local instantaneous acceleration patterns were truly biological or

not. We found that hMT+ is sensitive to signals that encode *life motion* (local biological motion), which places this region in the initial biological motion processing network.

Title: Color responses of face cells in alert macaque monkey

Authors: I. ROSENTHAL[1], J. FULLER-DEETS[1], T. HAILE[1], S. C. EASTMAN[1], T. GRUEN[1], L. TELLO[1], *B. R. CONWAY[1,2]

Abstract: Consistent with a role in face perception, face-selective cells in the temporal lobe are sensitive to luminance contrast in a face and are thought to be insensitive to color. But although color is not needed for face recognition, it is an important social signal, prompting us to ask: are face cells color tuned? We measured the responses to hue, saturation, and lightness of neurons in the middle face patch of three male macaque monkeys using fMRI-guided microelectrode recording. Responses were recorded to a set of monochromatic photographs of faces (38 images, monkey and human), body parts (17 images), and fruits (16 images). Stimuli were flashed in pseudorandom order on a computer monitor while animals maintained fixation for a juice reward. Each photograph was rendered in 16 hues evenly sampling the maximum gamut of DKL cone-opponent color space, in versions depicting normal luminance contrast and no luminance contrast (pure color). Responses were also measured to normal-contrast images rendered in 8 hues at 3 lightness levels, at intermediate saturation. Here we present results on the population of clearly isolated single units. Consistent with prior work, we found that most neurons were strongly face selective [$(R_{face}-R_{body})/(R_{face+}R_{body})$, = 0.36, STD = 0.13, R_{face}= mean face response, R_{body}= mean body response], and sensitive to lightness ($p<0.05$). But surprisingly, many face-selective neurons also showed broad color tuning [$(R_{best}-R_{worst})/ (R_{best}+R_{worst})$ = 0.34, STD= 0.22; R_{best} = mean response to best color; FWHM = 150°, STD = 108°). Moreover, when using face stimuli, the population showed a consistent color bias (1-way ANOVA, p= 0.02), towards the intermediate L+S color direction (47°; 95% CIs [13°, 90°]), appearing pink. Responses to non-

face stimuli were significant (>2.5*STD baseline) in most cells (86%) but showed no obvious color bias (mean=127°; CIs [21°, 321°]). The average response to faces using stimuli with luminance contrast (4.2*baseline spikes/s, SEM=1.2) was much stronger than the average response to faces defined by pure color (1.54*baseline spikes/s; SEM=.6; t-test, p=0.0001); and only a quarter of face cells showed color tuning that was tolerant (< 60°) to changes in saturation and lightness. These results show that color responses are substantially weaker for face cells than for cells in fMRI-identified color-biased regions of nearby cortex (Bohon et al, eNeuro, 2016), supporting the parallel-processing model of face and color (Lafer-Sousa and Conway, Nat. Neurosci., 2013). The subtle color bias of face cells suggests these cells encode a prior about the likely color of faces, which may hint at a role in color-dependent social signaling.

Title: Neural responses to internal versus contextual face information in two anterior face patches

Authors: *E. WAIDMANN[1], K. W. KOYANO[1], J. J. HONG[1], B. E. RUSS[2,1], D. A. LEOPOLD[1]

Abstract: The fMRI-defined face patches of the macaque inferotemporal cortex contain neurons that respond preferentially to faces. Previous studies have investigated the tuning of neurons in several face patches to a range of internal facial features. Here we investigate the relative contribution to single-unit responses of internal and contextual aspects of face images in the anterior medial (AM) and anterior fundus (AF) face patches. We used a stimulus paradigm in which we swapped image parts to investigate the relative influence of internal facial features, the surrounding head and hair, the attached bodies, and realistic background scenes. Each test stimulus was a photorealistic composite image containing a combination of face and body parts excised from ten original full body images of individual macaques. The two subject monkeys viewed the briefly presented images during a passive task requiring strict fixation. We recorded local neural populations in areas AM and AF longitudinally across sessions using chronically-

implanted microwire bundles, whose electrode tips typically span < 1mm^3. Stimulus images were in four combinatorial categories: (1) inner faces, with upper and lower portions of the face exchanged, (2) heads, with internal and external facial features exchanged, (3) whole monkeys, with heads and bodies exchanged, and (4) scenes, with whole monkeys and backgrounds exchanged. All component image parts (e.g. upper face or uncombined external head alone) were also shown. We found that most neurons in the AM face patch were strongly modulated by either internal or external facial features, but not both. Nearly all AM neurons sensitive to internal features responded selectively to variations of the upper, but not the lower, face. By contrast, many AF neurons were sensitive to details of the outer head and hair, but not to inner facial features. A small subset of AF neurons were strongly modulated by variation in bodies. None of the neurons in either area were strongly modulated by background scene. In sum, while neurons in both AM and AF are face selective, our parts-swapping paradigm demonstrates separate neural populations specialized for internal and external facial features within AM, and a comparatively higher sensitivity for external facial features and body context in AF.

Title: Examining the content of neural representations of faces and voices: Which brain regions represent perceptual and social information?

Authors: *M. S. TSANTANI[1], N. KRIEGESKORTE[2], A. WILLIAMS[1], C. MCGETTIGAN[3], L. GARRIDO[1]
[1]Brunel Univ. London, Uxbridge, United Kingdom; [2]Zuckerman Mind Brain Behavior Institute, Columbia Univ., New York, NY; [3]Royal Holloway, Univ. of London, Egham, United Kingdom

Abstract: We perceive a wealth of information from faces and voices, such as whether we recognise, trust, and like them. Previous studies have shown a number of brain regions that respond more to faces (such as the FFA and OFA) or to voices (such as regions in STS/STG) compared to control visual or auditory stimuli. There are also a number of multimodal brain regions that respond to both faces and voices (such as the pSTS). However, there is limited information on the type of face and voice information that is represented in these different face-responsive, voice-responsive, and multimodal brain regions. Here, we aimed to shed light on

what is the *content* of the representations of faces and voices in these regions by (1) comparing neural representations with perceptual and social judgments of the same stimuli, and (2) comparing the similarity of neural representations across different brain regions. In an event-related fMRI study with 30 participants, we measured brain activity patterns while participants viewed the faces and listened to the voices of 12 famous people. We defined multimodal, face-, and voice-responsive brain regions with independent localisers. In a separate behavioural session, participants rated the same faces and voices on pairwise visual (for faces) and auditory (for voices) similarity, and on perceived trustworthiness, dominance, attractiveness, and positive-negative valence. We used representational similarity analysis (RSA) and computed neural representational distance matrices (RDMs) for each brain region and modality. These RDMs showed the pairwise neural discriminabilty between the faces or the voices of all 12 people. Our first analysis compared the neural RDMs for faces and voices with RDMs based on the behavioural judgments, separately for each participant and modality. Our results showed that the perceived visual similarity of faces was correlated with the neural discriminability of faces in the OFA, and the perceived auditory similarity of voices was correlated with the neural discriminability of voices in several regions along the STS/STG. No significant correlations were found between neural RDMs and behavioural RDMs for trustworthiness, dominance, attractiveness, and positive-negative valence. These findings suggest that the OFA represents perceptual characteristics of faces, and regions of the STS/STG represent perceptual characteristics of voices. We will also present results of the analysis correlating neural RDMs across different brain regions to assess the similarity of neural representations across difference face-responsive, voice-responsive, and multimodal regions.
