Abstract: Commercial myoelectric prostheses for persons with upper-limb amputations are controlled by residual muscle activity via electromyography (EMG) recorded from the skin surface. These traditional systems are unable to obtain reliable EMG signals for finger-specific motions because the desired signals are either obscured by superficial muscle activity or non-existent due to the level of amputation. Intramuscular recording techniques and Regenerative Peripheral Nerve Interfaces (RPNIs) can potentially resolve each of these issues. RPNIs are created by implanting the end of a severed peripheral nerve into a small free muscle graft and have been demonstrated to produce stable EMG recordings after reinnervation in animal studies (Kung et al., 2014; Vu et al., 2017). To date, two patients with transradial amputations have enrolled in a clinical study where bipolar electrodes were implanted chronically. P1 had RPNIs surgically created on each of the median, ulnar, and radial nerves. P2 had two RPNIs surgically created on the ulnar nerve, which had been subdivided into two fascicles, and one RPNI created on each of the median and radial nerves. Eight pairs of bipolar electrodes (Synapse Biomedical) were implanted into the ulnar and median RPNIs for both subjects as well as six and five residual muscles for P1 and P2, respectively. A Matlab xPC (Mathworks) decoded EMG in real-time and controlled virtual (MuJoCo) and physical prosthetic hands (DEKA, Ossur). We recorded strong motor-specific EMG signals from the implanted electrodes; for example, 2530μV and 650μV mean peak-to-peak motor unit signals from P1 and P2's median RPNIs during thumb flexion trials. Using binned mean absolute value as an input, a Naïve Bayes classifier distinguished 9 individual finger and wrist movements offline with an average accuracy of 92.6% across 50ms time bins. Performance did not greatly improve with additional features or alternate classifiers. P1 and P2 completed an online virtual posture matching task distinguishing all 9 movements and rest with an average success rate of 93.6%. To reduce decoder latency, we implemented a Hidden Markov Model (Kemere et al., 2008) which P1 and P2 used to classify 4 functional grasps and rest with average decoding latencies of 92 and 224ms. P1 also used the DEKA hand to complete a functional reach and place activity requiring multiple grasps. These results indicate that implanted intramuscular electrodes can record high-quality signals from RPNIs and residual muscles to provide users with intuitive multi-grasp control. Future work includes integrating a functional prosthesis for P2 and exploring techniques to add wrist activation to our control scheme.

Title: A chronic neuro-myoelectric sensorimotor interface improves dexterous use of a bionic arm

Authors: *J. A. GEORGE[1], T. S. DAVIS[2], M. R. BRITON[1], M. D. PASKETT[1], C. C. DUNCAN[3], D. T. HUTCHINSON[4], G. A. CLARK[1];
[1]Biomed. Engin., [2]Neurosurg., [3]Physical Med. & Rehabil., [4]Orthopaedics, Univ. of Utah, Salt Lake City, UT

Abstract: The long-term goal of these studies is to provide amputees with intuitive control of, and natural sensory feedback from, multiarticulate sensorized bionic arms. Here we 1) report on a chronic sensorimotor interface consisting of implanted Utah Slanted Electrode Arrays (USEAs; Blackrock Microsystems) and intramuscular electromyographic recoding leads (iEMG; Ripple LLC); and 2) quantify improved control of bionic arms via an optimized modified Kalman filter (mKF). We implanted 2-3 USEAs and a 32-channel iEMG into the residual arm nerves and forearm muscles of 2 transradial amputees. Amputee S6 received implants 13 years after a traumatic amputation. Amputee S7 received implants during an elective amputation that followed 25 years of prior complex regional pain syndrome (CRPS) and hand disuse. Sensory feedback was evoked by stimulating through USEA electrodes, triggered by the experimenter or by sensors on a bionic arm. Both amputees reported functional proprioceptive and cutaneous percepts. For S7 there was a narrow window between detection and discomfort, hinting at a central contributing mechanism for CRPS. S6 experienced up to 119 different percepts that were localized, well-distributed across the hand, and perceived as enjoyable. Sensory feedback improved grip precision and reduced the coefficient of variation ($p < 0.05$). Sensory percepts were stable within sessions and most were stable (mean: 71%) when retested at 1-to-2-month intervals. After the first month post-implantation, there were no significant changes in median detection thresholds (52 µA) or electrode impedance (64 kΩ). Simultaneous proportional motor control was provided by a mKF using both EMG and neural recordings. EMG provided a robust

measure of motor intent across the 14-month (S6) and 17-month (S7) study durations. For S7, neural recordings further improved control ($p < 0.001$) and were also viable over time, with 26 electrodes providing neural signals (signal-to-noise ratio of 7.69) at 503 days after implantation. Modifications for the mKF (optimized offline) included ad-hoc thresholds that reduced unintended movement ($p < 0.001$) and gains that improved intended movement ($p < 0.001$). The mKF also improved sustained grasping ($p < 0.001$) in real-time and allowed both amputees to successfully complete activities of daily living (e.g., eating, using tools, etc.) with the DEKA "LUKE" arm. S7 also completed a supervised take-home trial with the "LUKE" arm using the mKF deployed onto a portable wireless processor (Brinton et al., SfN 2019), demonstrating the translational impact of and improved dexterity afforded by chronic sensorimotor interfaces and multiarticulate bionic arms.

Title: Sensory consequences of electrical stimulation of individual fascicles within peripheral nerve

Authors: *C. K. OVERSTREET[1], J. CHENG[2], E. W. KEEFER, III[1];
[1]Nerves Inc., Dallas, TX; [2]Plastic Surgery, UTSW Med. Ctr., Dallas, TX

Abstract: As part of the DARPA HAPTIX program, we are engaged in the development of a bidirectional peripheral nerve interface to provide intuitive motor control and robust sensory feedback for upper extremity prosthetic devices. Electrical stimulation of peripheral nerves can be used to evoke a wide range of sensations. The quality, location, and size of these percepts is dependent on the population of nerve fibers that are activated by a stimulation pulse train. Developing electrodes and methods of selectively activating specific portions of the nerve, so as to maximize the number of distinct stimulation-induced sensory percepts, has been a major focus of peripheral interfacing research.

Our approach involves implanting longitudinal electrode arrays *into* individual fascicles within peripheral nerve and additionally placing cuff electrodes *around* each fascicle. This method is designed to exploit the natural somatotopic organization and functional separation of fibers into fascicular groups within peripheral nerve. Interfacing at both the intra- and extra-fascicular levels also results in a high level of redundancy to mitigate the effects of electrode damage common in chronic peripheral nerve interfaces.
To date, we have implanted chronic electrodes of this design in the forearms of five human subjects with upper extremity amputations. Here we report on the sensory percepts reported by these subjects during stimulation of individual fascicles within the median or ulnar nerve. During the implantation procedure, intraoperative functional testing was used to broadly classify each fascicle of interest as being comprised of primarily sensory, primarily motor, or mixed sensory and motor fibers. Throughout the implant period, stimulation of sensory fascicles primarily produced cutaneous sensations, including light touch, pressure, and vibration. Stimulation of motor fascicles often produced proprioceptive sensations referring to muscle contraction, joint position, or movement. The size and location of these percepts within the hand also varied consistently based on the fiber type contained in the stimulated fascicle.
The ability to form redundant, chronic interfaces with individual fascicles of peripheral nerve provides unique opportunities to selectively activate the nervous system. This methodology has broad application to both stimulation and recording in peripheral and cranial nerves.

Title: Vns enhances thalamic information transmission through control of noradrenergic and cholinergic systems

Authors: *C. RODENKIRCH, Q. WANG;
Dept. of Biomed. Engin., Columbia Univ., New York, NY

Abstract: Vagus nerve stimulation (VNS) has long been used to modulate brain circuit dynamics to treat seizure and depression in clinical settings. Previous work has also suggested that VNS can facilitate rehabilitation through its effects on neural plasticity. Further, VNS has been shown to enhance memory and learning via its effects on the acetylcholine and locus coeruleus-norepinephrine (LC-NE) systems. However, little is known about the effect of VNS on

sensory processing. Here, we examined the effect of VNS on thalamic feature selectivity and information transmission in the rodent vibrissa system. We recorded single-unit activity in the ventral posteromedial (VPm) nucleus of the thalamus, an early stage of the rat's vibrissa pathway, in response to repeated presentations of a 15 s block of frozen white gaussian noise whisker stimulation. During these recordings, we randomly cycled through varying VNS patterns (off, 30 Hz for 30 seconds followed by 90 seconds off, 30 Hz for 3 seconds followed by 7 seconds off, and 10 Hz continuous). Each stimulation condition period lasted for 180 seconds and was repeated multiple times (2-6 repetitions). 75 seconds of deadtime followed any stimulation condition to allow for the system to reset. The feature selectivity of each recorded neuron was then estimated separately for each of the VNS activation conditions using spike-trigged reverse correlation analysis. Our preliminary data showed that VNS produced similar effects on thalamic sensory processing as the effects we observed with direct LC activation. In particular, VNS caused a dramatic reduction in the occurrence of bursting activity within the VPm, indicating decreased calcium T-channel activity. Using information theory to quantify the information VPm spikes transmit about the absence/presence of features in the received stimulus, we found that VNS dramatically increased both information transmission efficiency (bits/spike) and rate (bits/second). Pharmacological manipulations were performed to tease apart the role of the noradrenergic and cholinergic systems in this VNS-induced enhancement. Taken together, our preliminary results suggest that certain patterns of VNS can be used to improve sensory-related information transmission via optimizing the coding properties of neurons in the early stage of sensory pathways.
The authors would like to thank Kilgard and Kronoer Labs for sharing their VNS electrode design. This project was supported by NSF Award 1847315.

Biomed. Microtechnology, IMTEK-Dept Microsystems Eng, Univ. of Freiburg, Freiburg, Germany; [4]Orthopaedic Surgery Dept., Sch. of Med. Univ. of Belgrade, Belgrade, Serbia

Abstract: Leg amputation destroys the sensory-motor communication between the central nervous system and the environment during standing and walking. Lower-limb amputees rely on very limited and uncomfortable haptic feedback from the stump-socket interaction to monitor ground and obstacles contact, climb stairs, or walk in uneven terrains. The lack of sensory feedback causes several impairments to patients that risk falls, have decreased mobility, increased cognitive load during walking, do not perceive the prosthesis as part of their body (low embodiment) resulting often in prosthesis rejection. In upper-limb amputees, neural interfaces allowed to restore somatotopic sensations, thanks to the direct nerve stimulation and to the connection between nervous structures and robotic hand prosthesis. Considering the highly-disabling clinical condition of trans-femoral amputees, we decided to translate this approach overcoming many scientific and technological barriers. Indeed, it has never been proved that the neural stimulation by implantable neural interfaces can evoke sensations from missing leg and foot, also exploitable in a bionic leg in real-time. In this work, we developed a lower-limb prosthesis restoring sensory feedback by means of neural stimulation injected through Transversal Intraneural Multichannel Electrodes (TIME) implanted in the sciatic nerve. The stimulation was driven by the readout of pressure sensors positioned under the prosthetic foot in a sensorized insole, and an encoder embedded in the prosthetic knee. Two trans-femoral amputees were involved in this study performing motor tasks where their mobility was investigated. We perform the biomechanical and signal analysis of kinematic and dynamic data acquired with wearable sensors. Very promising results showed the clinical and functional benefits provided by restoring neural sensory feedback to lower limb amputees. Our findings indicate a clear path towards the development of a new sensory-enhanced leg neuroprostheses to improve life of people with amputations.

Title: Bi-directional control and sensory restoration solution for amputees

Authors: *E. W. KEEFER, III[1], C. OVERSTREET[1], J. CHENG[2], Q. ZHAO[3], Z. YANG[3]; [1]Nerves Inc., Dallas, TX; [2]Plastic Surgery, UTSW Med. Ctr., Dallas, TX; [3]Univ. of Minnesota Twin Cities, Edina, MN

Abstract: We have accumulated 3+ years of human amputee data from 6 subjects to date in the DARPA HAPTIX program using electrodes surgically targeted to specific fascicles of the ulnar and median nerves. Using our unique electronics and deep learning-based decoding strategy, we have for the first time allowed amputees completely intuitive control of individual prosthetic digits. The amputee-machine interface is truly bi-directional, in that the computer uses the neural signal to interpret the intent of the amputee to move individual fingers or make gestures, and the amputee selects between different AI models to personalize and tune his experience while controlling the prosthetic digits based upon the "feel" of the model response to his movement intent. The major focus of our sensory stimulation work has been to develop methods of providing functionally-relevant feedback of interactions between the prosthesis and the external environment. This is a multi-faceted challenge, requiring innovations in stimulation technique, sensorization of prosthetic devices, and understanding of the psychophysics of artificial sensation. Effective multichannel stimulation is critical for sensory-capable prosthetic hands with multiple degrees of freedom. The sensations induced by interleaved multichannel stimulation can differ wildly from the sum of the sensations evoked by discrete stimulation on a single electrode; however, little attention has previously been devoted to understanding the sensory effects of multichannel stimulation.

We have developed a comprehensive system containing the following interdependent components: (1) Motor control derived from a novel peripheral nervous system (PNS) interface for individual digit control obtained through surgically targeting specific fascicles of forearm nerves. (2) Neural decoding based on a novel machine learning algorithm that critically reduces the amount of patient effort and training time yet provides high decoding performance. (3) Sensory feedback by closed-loop stimulation through selective and specific surgical targeting of neural interfaces to discrete tactile and proprioceptive neural components. The result is a robust, reliable, and intuitive interface for dexterous prosthetic control with tactile and proprioceptive sensory feedback where the human subjects provide cognitive functions, which are supplemented and enhanced by the great computational power provided by the AI. The human subjects adapt to the AI algorithm for better performance, and new data are generated to allow the AI to better support the human subject (true man-machine interactive learning).

Title: Closed-loop stimulation of cervical spinal cord and dorsal roots in upper-limb amputees to enable sensory discrimination

Authors: *S. CHANDRASEKARAN[1], A. C. NANIVADEKAR[2], D. M. WEIR[1], E. R. HELM[1], M. L. BONINGER[1], J. L. COLLINGER[1], R. A. GAUNT[3], L. E. FISHER[3];
[2]Bioengineering, [3]Physical Med. and Rehabil., [1]Univ. of Pittsburgh, Pittsburgh, PA

Abstract: In an effort to provide meaningful sensory feedback in upper-limb amputees, we electrically stimulated the dorsal spinal cord and roots (DSCR) using FDA-cleared spinal cord stimulation (SCS) leads. Three 16-contact SCS leads were placed percutaneously into the lateral epidural space targeting the C6-C8 roots. Stimulation was delivered through the SCS leads using a custom stimulator for up to 4 weeks following implant, after which the electrodes were removed. Here we show the receptive fields, detection thresholds and just-noticeable differences (JNDs) measured using a structured reporting system from two upper-limb amputees. In both subjects, increasing stimulation amplitude and frequency evoked a linear increase in the perceived intensity within the ranges tested (1-6 mA and 20-300 Hz) while increasing pulse width showed an asymptotic change in perceived intensity. JNDs showed a strong dependence on the stimulus amplitude in accordance with Weber's law. We also carried out closed-loop experiments, where the subjects were asked to interact with an object using a sensorized DEKA hand or a virtual hand in MuJoCo and determine its size or compliance. Stimulation amplitude was mapped either linearly or exponentially to force data from the sensorized prosthesis. One subject used a DataGlove worn on her contralateral intact hand to control the prosthesis in a proportional fashion while the other subject used EMG signals from the residual limb to control grasp closing at constant velocity. With DataGlove control, the subject was consistently more adept at determining object size (62% and 74% mean accuracy in the real and virtual world task scenarios, respectively) than object hardness (46% mean accuracy in MuJoCo). With constant velocity myoelectric control, the other subject achieved a higher accuracy level in determining object hardness (72% and 53% mean accuracy in the two scenarios, respectively) but could not perform better than chance (33% accuracy) for determining object size in either of the task scenarios. Thus, DSCR stimulation can provide information for both contact detection and object

compliance but it might be important to design the right control strategy to achieve maximal accuracy in functional tasks. In conclusion, stimulation of the DSCR can evoke sensory percepts in the missing limb which could be utilized with minimal training by the subject for control of a prosthesis.

Title: Retinal implants with vertically aligned carbon nanotube pillar arrays for *in vivo* retinal studies

Authors: *K. ZAPPITELLI[1], J. STODDARD[2], R. TAYLOR[1], T. MCGILL[2], B. ALEMÁN[1]; [1]Univ. of Oregon, Eugene, OR; [2]Oregon Hlth. and Sci. Univ., Portland, OR

Abstract: Microelectrode array (MEA)-based retinal implants provide a valuable means to counteract vision loss due to retinal degenerative diseases. Penetrating electrodes—micrometer-scale, needle-like electrodes that penetrate deep into the retinal tissue—promise to improve MEA implants because they allow for closer proximity to the target neurons, thereby decreasing the stimulation threshold and alleviating inflammation. Vertically aligned carbon nanotubes (VACNTs) are an attractive material for penetrating electrodes because of their excellent biocompatibility and neural stimulation properties, and their intrinsic ability to form mechanically stable, high-aspect-ratio structures. Despite their promise, retinal implants with VACNTs have not been assessed *in vivo*. A key obstacle to *in vivo* work has been to create implants that simultaneously satisfy the physical size requirements (sub-millimeter) for surgical implantation into rodents and the synthesis constraints of high-aspect-ratio VACNT structures, which, although strong, are also mechanically flexible and delicate. Therefore, many fundamental questions remain about the *in vivo* structural integrity and chemical viability of VACNT electrodes and the corresponding *in vivo* physiological response. In this work, we develop a robust procedure to build passive silicon implants with patterned VACNTs for *in vivo* retinal studies. We make implants with lateral dimensions below a millimeter, and we use high-temperature chemical vapor deposition (CVD) to grow VACNT “forests” (which largely cover

the implant surface) and penetrating electrode structures by patterning VACNT pillar arrays of various heights, diameters, and spacing. We then surgically insert the VACNT and bare silicon control implants into the subretinal space of an anesthetized rat. Post-surgery, we use high-resolution optical coherence tomography to image the fundus to confirm implant placement and lack of adverse surgical events (e.g. subretinal hemorrhaging) and to quantify the degree to which the different VACNT structures remained intact. This work makes the crucial first step towards assessing the viability of VACNTs as an electrode material in MEA-based retinal implants. In the future, we aim to use this approach to identify the optimal pillar penetration depth that simultaneously maximizes electrode stability and minimizes structural reorganization and immune response of the retina post-implantation.

Title: Neural stimulation eliciting sensation activates reflex pathways in lower-limb amputees

Authors: *H. CHARKHKAR[1,2], K. H. CHENG[1,2], N. S. MAKOWSKI[3,2], R. J. TRIOLO[1,2]; [1]Case Western Reserve Univ., Cleveland, OH; [2]Louis Stokes Cleveland VA Med. Ctr., Cleveland, OH; [3]MetroHealth Med. Ctr., Cleveland, OH

Abstract: Sensory feedback including cutaneous and proprioceptive inputs from the foot and ankle plays an important role in locomotion and stability. Compared to able-bodied individuals, lower-limb amputees (LLAs) have a higher fall risk and exhibit gait abnormalities which may result in part from lack of proper sensory feedback from the missing limb. Electrical stimulation of peripheral nerves in the residual limb elicit sensations referred to the missing limb and could provide LLAs with feedback about plantar pressure of the prosthetic foot. However, it is unknown whether neural stimulation to elicit sensation activates reflex pathways. This study investigated the activation of such pathways by examining changes in activity of selected muscles in the intact and residual limbs during peripheral nerve sensory stimulation in a LLA. Electrical stimulation was delivered via nerve cuff electrodes implanted in the residual limb of a transtibial amputee on pre-branch sciatic and post-branch tibial nerves. Stimulation elicited tactile sensation or proprioception. The reported proprioception included sensation of residual muscle movement or movement at the ankle. Surface electromyograms (EMG) were collected in

both legs from tibialis anterior (TA), medial gastrocnemius (MG), bicep femoris longus (BF), and vastus medialis (VM) muscles. The participant was instructed to either stand straight or flex his knee about 20 degrees to stretch the quadriceps. Each trial consisted of 2s of pre-stimulation baseline followed by 3s of stimulation. EMG signals were amplified, digitized, and then filtered to remove artifacts. EMG Mean absolute value (MAV) was calculated for baseline and stimulation phases of each trial; statistical significance was determined by a two-tailed paired t-test.
Compared to baseline, MAVs for BF and VM on the affected side were increased ($p<0.05$) with no changes in MAV on the intact limb during standing straight. However, when the same stimuli were applied during a flexed stance, EMG decreased for BF and MG on the intact side ($p<0.01$). Findings suggest activation of crossed extensor circuitry during nerve stimulation while quadricep muscles are slightly stretched. Repetition will determine if these results generalize, but preliminary results indicate direct-nerve interface for sensory restoration in a LLA activates reflex circuitry that could bilaterally affect locomotion dynamics.

Title: Explicit adjustment of step timing during split-belt walking reveals interdependent recalibration of movements in space and time

Authors: *M. GONZALEZ-RUBIO, N. F. VELASQUEZ, G. TORRES-OVIEDO;
Dept. of Bioengineering, Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Several studies have shown that spatiotemporal features of walking can be adapted by interacting with novel environments, such as walking with the legs moving at different speeds (i.e., split-belt walking). It is unclear the degree to which such recalibration of walking movements in the spatial and temporal domains is interdependent. In this study we aimed to determine the interdependence between the spatial and temporal control of the limbs during walking. We hypothesized that spatial and temporal inter-limb features are controlled independently based on previous studies demonstrating their dissociation. To test this hypothesis, subjects walked on a split-belt treadmill, which requires the adaptation of spatial and temporal

gait features. We further altered the adaptation of one domain and observed the impact on the adaptation of the other domain. We used visual feedback to manipulate either "where" (spatial feedback group) or "when" (temporal feedback group) subjects landed their feet as they walked in the split-belt condition. The steady state during split-belt walking and subsequent after-effects of spatial and temporal features in the feedback groups were contrasted with those of a control group, who walked in the split-belt condition without any specific instruction (n=7 in each group). We computed step time and step position, which are gait parameters known to quantify adaptation and after-effects of the spatial and temporal control of the limb. Separate two-way repeated measures ANOVAs were used to contrast outcome measurements for the control group to each feedback group. We confirmed that explicit adjustments of step position had a domain-specific effect (i.e., reduced steady state: $p<0.01$ and after-effects: $p<0.01$ of step position compared to controls, but not the step time's steady state: $p=0.39$; after-effects: $p=0.9$). Surprisingly, this dissociation was not maintained when step time was explicitly altered. In other words, the temporal feedback group had reduced steady state ($p<0.01$) and after-effects ($p<0.01$) in step position and step time compared to the control group. In sum, we observed that motor adaptation in the spatial domain was susceptible to changes in the temporal domain, whereas motor adaptation in the temporal domain was resilient to adjustments in the spatial domain. Our results suggest a hierarchical organization such that explicit changes to temporal deficits cannot occur without modifying the spatial control of the limb, which informs the treatment of patients with spatial and/or temporal asymmetries.

Title: Interaction between healthy aging and walking speed on the generalization of locomotor adaptation

Authors: *D. M. MARISCAL, C. J. SOMBRIC, H. M. HARKER, G. TORRES-OVIEDO; Dept. of Bioengineering, Univ. of Pittsburgh, Pittsburgh, PA

Abstract: We have previously shown that older adults have greater after-effects overground following split-belt walking compared to young individuals (Sombric et al., 2017), suggesting

that healthy aging increases the generalization of recalibrated movements across walking conditions. However, in the aforementioned study old and young participants walked at relatively slow speeds, which could influence the generalization of after-effects overground, as it does on the treadmill (Vasudevan and Bastian, 2010). Thus, in this study we investigated the extent to which healthy aging and walking speed regulated the generalization of adapted movements across different walking situations. We hypothesized that subjects would generalize more if they were adapted around their preferred walking speed. This hypothesis was formulated on the basis that unnatural speeds would be used as context-specific cues that will reduce generalization. To test this hypothesis, we compared the magnitude of after-effects overground following split-belt walking when older (n=16, age: 73.13±5.40 yrs.) and younger (n=16, age: 20.81±6.02 yrs.) adults walked on a split-belt treadmill at either faster or slower speeds than their self-selected speed. All groups experienced a gradual split-belt perturbation (i.e., gradual change from 1:1 to 2:1 speed ratio) because this type of adaptation favors generalization (Torres-Oviedo and Bastian, 2012). To assess generalization subjects walked overground following a split-belt adaptation paradigm. Kinematic data were recorded to characterize the after-effects of step position and step time (Finley et al., 2015), which are spatial and temporal asymmetry measures known to generalize differently (Sombric et al., 2017). Two-way ANOVA was used to compare overground after-effects across groups. We found that older adults generalized more step position (spatial parameter) when they were adapted at slower speeds, whereas young adults generalized more this gait parameter when adapted at faster speeds (interaction: p=0.001). In contrast, in the temporal domain (step time) older adults generalized more than young adults, regardless of the walking speed at which they were adapted (Age: p=0.007). Our results indicated that healthy aging and walking speed affect the generalization of split-belt walking patterns across environments. Therefore, treadmill-assisted rehabilitation would be more effective in older populations if they are adapted at slower speeds, whereas younger adults need to be adapted at faster speeds.

Title: Human perception of walking speed asymmetry and its adaptation over the course of split-belt walking

Authors: *P. A. ITURRALDE[1], G. TORRES-OVIEDO[2];
[2]Dept. of Bioengineering, [1]Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Mismatch between predicted and actual sensory information is thought to drive the recalibration of internal models for motor control, and perceptual adaptation has been used as a proxy to assess this recalibration process [Synofzik et al. 2008, Izawa et al. 2012]. Split-belt walking with one leg moving faster than the other has been shown to change subjects' perception of this speed asymmetry. However, it remains unclear what is the human ability to detect such asymmetry, and thus, how it changes as a result of sensorimotor adaptation. To address these questions we combined a two-alternative forced-choice and a belt-speed matching tasks [Vazquez et al. 2015]. In experiment 1 (N=9), we characterized the baseline accuracy of belt-speed difference perception in a cohort of young, healthy subjects. We found that humans can detect speed differences as small as 25mm/s (<2.5% of mean walking speed) with above chance levels (64% accuracy, p=0.018). Also, differences of 100mm/s and higher were detected with >80% accuracy. Moreover, subjects' reaction time was predictive of response accuracy even after accounting for task difficulty (p=1.2e-5), suggesting that reaction time could be used as a proxy for confidence in the participant's response. Computational modeling of the active perceptual task through a drift-diffusion model was unable to characterize this relation between accuracy, reaction time, and task difficulty. We also observed that in the belt-speed matching component of the perceptual task, subjects were able to reduce the initial speed differences by about 85%, regardless of the initial speed asymmetry. In experiment 2 (N=10), we tracked the adaptation of speed difference perception throughout a split-belt walking adaptation and deadaptation protocol. Subjects were exposed to a split-belt walking environment (905 strides at 1300 & 800 mm/s). At periodical intervals, the same task of experiment 1 was performed. Results show the evolution of perception of belt-speed differences throughout the adaptation and deadaptation periods. We observed perceptual aftereffects during post-adaptation of at least 200mm/s (population median), which decayed exponentially with a time constant of approximately 93 strides. We conclude that humans are able to perceive very accurately speed differences between their legs of much smaller magnitude than previously reported [Lauziere et al. 2014, Hoogkamer et al. 2015]. Further, our speed matching task enabled us to confirm the perceptual aftereffects following split-belt walking and revealed their temporal dynamics during adaptation and deadaptation.

Title: Using electrically-evoked ankle pain to study gait adaptations to fixed versus movement-dependent pain duration: A model of musculoskeletal lower limb pain

Authors: *R. JEFFREY-GAUTHIER[1], M. BERTRAND-CHARETTE[1], C. MERCIER[1], J.-S. ROY[1], L. J. BOUYER[2];
[1]Rehabil. Dept - CIRRIS, [2]Rehabil. Dept- CIRRIS, Univ. Laval Fac Med., Quebec, QC, Canada

Abstract: INTRODUCTION: Following musculoskeletal (MSK) injuries, pain avoidance strategies modify movement execution, including gait. It has been proposed that such modifications may lead to maladaptive behaviors and to pain chronicization. To study this theory, a better understanding of the physiological basis of movement adaptation to pain is needed. The first aim of this study was therefore to develop an experimental paradigm that simulate MSK pain during gait. A second aim was to assess the effect of fixed versus movement-dependent pain duration, to better understand the consequences of a mismatch between gait adaptation and pain relief. Our hypotheses were that 1) phasic pain would alter the gait pattern (temporal and EMG parameters) and 2) gait adaptation would differ for fixed versus movement-dependent pain.
METHODS: Six healthy participants took part in a single experiment. They had to walk normally on a treadmill at 4 km/h for 6 bouts of 3-min duration. EMG activity from flexor (rectus femoris, biceps femoris, tibialis anterior) and extensor (vastus lateralis, gastrocnemius medialis, soleus) muscles of both lower limbs were recorded and right and left foot load distributions were measured with insole force sensors matrices. Painful trains of electrical stimulations (intensity of 2-4/10), were delivered to the right lateral malleolus during bouts 3 and 5. Pain conditions (matched or unmatched duration to right heel loading) were presented in randomized order. Repeated-measure ANOVAs were used to examine foot pressure distribution and EMG activity changes between pain conditions and baseline.
RESULTS: Stimuli intensity ranged between 9.5 to 13.5 mA, and were described as a electrical, sharp or stabbing pain in the malleolus area. Regardless of the pain condition, pain altered gait in all participants. The foot load distribution pattern was modified: right heel load duration and right heel load peak were significantly decreased during both pain bouts compared to baseline.

Step duration was decreased and cadence, increased. Extensor muscles activation was prolonged during late stance. Flexor muscles activation was not altered.
DISCUSSION: These results suggest that electrical stimulation can be used as a model for investigating movement adaptation to musculoskeletal-like pain. Electrically-evoked phasic pain alters gait, regardless if pain duration was dependent or not on heel loading.
These findings are relevant to the understanding of movement adaptation to pain and will be used to investigate mechanisms underlying motor adaptation to MSK pain.

Title: Effect of over-actuation on neuromechanical model of rat hindlimb with biarticular muscles

Authors: *K. DENG[1], A. J. HUNT[2], R. D. QUINN[1];
[1]Mechanical and Aerospace Engin., Case Western Reserve Univ., Cleveland, OH; [2]Portland State Univ., Portland, OR

Abstract: This work compares two neuromechanical models of rat hind-limb sagittal walking. One model uses antagonistic muscle pairs (extensor and flexor) actuating each joint in the sagittal plane, and the second introduces biarticular muscles into the biomechanical body. The muscle number of each limb increased from 6 to 8 in the second model, and 3 of them are biarticular muscles, BFP (biceps femoris Posterior), RF (Rectus femoris), and GA (Gastrocnemii). Each model is controlled by a synthetic nervous system composed of a two-level central pattern generator. In order to test the stability of the models, different perturbations were applied to the network. These include inhibitory tonic stimuluses to the synthetic nervous system and forces applied to the limb. Results show that the neuromechanical model with biarticular muscles exhibit more robustness than the monoarticular model when external force was applied to the body, and there is no significant difference when a stimulus is applied to the synthetic nervous system. In addition, the biarticular muscle model shows better kinematic matching when compared to animal data. It turns out over-actuating the model not only reifies the biomechanical body, but also makes it more stable for several reasons. In the monoarticular model, the joint coordination is only relying on proprioceptor feedback to mediate the phase of walking rhythm,

so the stability of the model is dependent on the robustness of the synthetic nervous system. However, in the biarticular muscle model, the biarticular muscles link related joint motions during walking. When joints are linked together through muscles, rejection of a perturbation at one joint can be distributed through the whole leg. Additionally, biarticulate muscles can serve multiple purposes through the course of a step. For example, at the start of stance, the BFP provides hip extensor force, however when switching from stance to swing, the BFP also produces flexion in the knee, assisting in lifting the leg from the ground.

Title: Balance impairment investigation of pediatric medulloblastoma patients with wearable motion capture system

Authors: *M. B. KILICOGLU[1], M. TANRIVERDI[2], F. B. CAKIR[2], H. ARGUNSAH BAYRAM[1];
[1]Acibadem Mehmet Ali Aydinlar Univ., Istanbul, Turkey; [2]Bezmialem Vakif Univ., Istanbul, Turkey

Abstract: Objective: The goal of this study was to assess balance impairment of pediatric medulloblastoma patients based on kinematic data, which has been collected with wearable motion capture (WMC) system and compare the results with current assessment tools used by physical therapists. This study hypothesized that these patients have balance impairment at concerning degrees, which cannot be detected only by commonly used subjective forms.
Methods: 25 children with brain tumor were recruited with the exclusion of the ones who had communication problems. Patients and their families were informed about the study protocol and signed the informed consent form that has been approved by the Institutional Review Board. The kinematic data was collected with Xsens MVN (Xsens Technologies BV ® (Netherlands)), which allows an unrestricted, 3D and spontaneous gait analysis. WMC sensors were placed on participant's body as described by the manufacturer. After calibrating the WMC system, data collected during standard 10-meter walk test at self-selected walking speed for 2 minutes and single leg stance assessment tests.
Results: According to the preliminary results, sternum orientation degree values showed that patients had foot drop during the late-stance phase due to improper and insufficient ankle joint dorsiflexion and knee joint flexion/extension. Additionally, stance phase knee joint flexion, which is critical for efficient energy flow in lower extremity, was not observed. Paired t-test

analysis revealed that the patient's knee joint range of motion was significantly asymmetrical throughout the data collection session when the walking pattern was compared with the control group (61.995 ± 3.497 SD vs. 54.810 ± 1.661 SD; t (0.05,29) = 10.172, $p<0.001$).
Conclusion: The ability to provide stability and balance is critical for the neurological and orthopedic diseases rehabilitation, because the goal is to achieve functional independence during ambulation. Pediatric brain tumor patients have difficulties in coordination and balance problems while performing daily life activities, and these not only affect their motivation, but also limit their motor abilities in daily life. The absence of gait symmetry, which is the ratio of kinetic and kinematic parameters between right and left extremities, results in differences in muscle contraction, balance and biomechanical parameters during mobilization. Accurate knowledge of static and dynamic proprioception is essential to maintain proper body weight and sustain normal ambulation and in order to achieve this information innovative engineering techniques should be integrated to conventional physical therapy practices.

Title: Optogenetic activation and silencing of leg motor neurons and proprioceptors alters walking dynamics in *Drosophila melanogaster*

Authors: *E. S. DICKINSON, J. C. TUTHILL;
Univ. of Washington, Seattle, WA

Abstract: Locomotion requires rapid integration of proprioceptive sensory cues with ongoing motor rhythms. However, it has been challenging to assess the role of specific sensory and motor neurons in the coordination of locomotor behaviors like walking. In this study, we combined optogenetics and quantitative analysis of walking behavior to test the function of genetically-defined populations of leg proprioceptors and motor neurons in the fruit fly, *Drosophila melanogaster*. Walking in the fly is fast and complex, requiring the coordination of five leg segments across six legs with step cycles of just 30 ms. Each fly leg is controlled by 52 motor neurons and monitored by 135 proprioceptors. We used visual stimuli to elicit forward running

and turning in tethered flies on a frictionless spherical treadmill. We measured the walking dynamics of flies while optogenetically manipulating the activity of tibial proprioceptors and motor neurons with a 532nm laser focused on the fly's front left leg. We activated genetically-defined neurons using a red-shifted channelrhodopsin, CsChrimson, and silenced neurons using an anion channelrhodopsin, GtACR1. We found that sustained activation or inhibition of specific leg proprioceptors interrupted all locomotion, leaving the fly unable to run or turn. In contrast, activating or silencing specific motor neurons led to subtle changes in forward walking and turning. Thus, flies appear to overcome perturbations to motor output but not proprioceptive feedback. These results reveal the critical role of sensory feedback in coordinating walking behavior and suggest that there exists a high level of redundancy within the leg motor control system.

Title: Enhanced variation in lateral pelvis assistance force during walking may facilitate weight shifting in individuals post-stroke

Authors: *M. WU[1,2], C.-J. HSU[3], J.-T. LIN[3], W. DEE[3];
[1]Shirley Ryan Ability Lab- Chicago, Chicago, IL; [2]Bioengneering, Univ. of Illinois at Chicago, Chicago, IL; [3]Legs and Walking Lab., Shirley Ryan Ability Lab., Chicago, IL

Abstract: Individuals post stroke often show insufficient weight shifting toward their paretic side during walking due to the weakness of the paretic leg muscles. Insufficient weight shifting has been shown to be correlated to impairment in walking function in individuals post stroke. Previous studies indicated that increased variability of training may improve motor learning. The goal of this study was to determine whether applying varied assistance force to the pelvis was effective in facilitating weight shifting toward the paretic side in individuals post-stroke. We hypothesized that compared to abrupt pelvis assistance force, applying varied pelvis assistance force would be more effective in facilitating weight shifting toward the paretic side during walking in individuals post-stroke. Five individuals with chronic (> 6 months) stroke participated in 2 testing sessions. In session 1 (varied condition), participants walked on a treadmill at their comfortable speed without force for 1 minute (baseline), and then a controlled lateral pelvis assistance force was applied to the pelvis toward the paretic side during early stance phase of gait

for 10 minutes (adaptation). Afterward, the force was removed and participants continued to walk on the treadmill for another 1 minute (post-adaptation). The magnitude of force was set at ~8% of body weight, and varied from step to step (variation of peak force ranged from 30% - 100%). In session 2 (abrupt condition), a protocol was similar to session 1 was used except the magnitude of pelvis assistance force was the same from step to step. The order of testing condition was randomized across subjects. The displacement of the pelvis and leg was measured using custom designed position sensors. The primary outcome measure was the maximum pelvis lateral displacement during stance phase. During early adaptation period, increased pelvis displacement toward the paretic side was observed for both conditions, suggesting an improved weight shifting toward the paretic side when the pelvis assistance force was applied. During the late adaptation period, participants gradually reduced their pelvis displacement toward the paretic side for the abrupt force condition, suggesting the weight shifting toward the paretic side was reduced. For the varied condition, the increased pelvis displacement toward the paretic side was still partially retained, suggesting improved weight shifting toward the paretic side was partially retained. This preliminary study indicated that increased variability in the magnitude of lateral pelvis assistance force may enhance motor learning of weight shifting toward the paretic side in individuals post stroke.

Title: Development of a wearable balance sensor that provides real-time tactile biofeedback and preliminary test results on pediatric brain tumor patient

Authors: *B. YALCIN[1], M. TANRIVERDI[2], F. B. CAKIR[2], M. B. BAYRAM[1], H. ARGUNSAH BAYRAM[1];
[1]Acibadem Mehmet Ali Aydinlar Univ., Istanbul, Turkey; [2]Bezmialem Vakif Univ., Istanbul, Turkey

Abstract: Objective: This study aimed to develop an innovative wearable balance sensor, capable of providing real-time stimulus for maintaining balance and postural control, and investigate the biomechanical and physiological changes of a pediatric brain tumor patient in response to tactile biofeedback.
Methods: A wearable tactile real-time balance biological feedback mechanism was developed, which is intended to be used during the neurological, orthopedic and neuromuscular disease rehabilitation practices and its accuracy and sensitivity were validated with Xsens MVN Awinda

wearable motion capture system. Real-time balance was monitored with Motion Processor Unit 9250, which was placed on patient's sternum. All motors and the MPU were controlled by Raspberry Pi. The innovative real-time balance sensor device is composed of a motion processor unit, microprocessor and four vibration motors. Vibration motors -for front-back-left-right directions, were located between the participant`s under bust and natural waist line with an adjustable strap. Accurate positioning of the motors was obtained by using ergonomic 3D printed cases attached to the participant's body. A 16 year old brain tumor (medulloblastoma) patient, who has undergone surgical intervention, participated in this study. 16 year old healthy subject participated as the control subject. 10 meter walking and single leg stance assessment tests were examined with and without vibrobalance biological feedback device.
Results: IBM SPSS Statistics v21.0 was used to perform the statistical analyses. Paired t-test analysis (two-tailed) revealed that the patient's knee joint range of motion was significantly symmetrical throughout the data collection session when real-time tactile biofeedback was provided to the patient (61.995 ± 3.497 SD vs. 54.810 ± 1.661 SD; $t_{(0.05,29)} = 10.172$, $p<0.001$). Statistically, the effect of the sensor was not found to be significant with the healthy control (71.987 ± 2.178 SD vs. 72.774 ± 0.906 SD; $t_{(0.05,29)} = -1.814$, $p=0.08$).
Conclusions: According to the results, there are significant improvements when haptic and visiual biological feedback is provided during all exercises in the data collection sessions, especially in data of the medulloblastoma patient. Biofeedback is a method of providing real-time feedback to the patient using auditory, visual, and tactile stimulus. Additionally, physician and/or physical therapist can utilize biofeedback mechanisms in order to regulate the gait pattern, correct balance/posture, and thus create personalized physical therapy programs for the patients while regulating the physiological, kinetic and kinematic variables.

Title: Intermittent linearity of foot force direction vs center of pressure in quiet standing

Authors: K. NICHOLS, A. LEFRANC, J. BARTLOFF, ***K. G. GRUBEN**;
Univ. Wisconsin, Madison, WI

Abstract: Humans maintain quiet standing by modulating lower limb joint torques to maintain translational and rotational balance in the sagittal plane. Mechanically, joint torque coordination directly maps to the force of the ground on the feet (*F*). Previous research has shown that quiet standing can be characterized as a series of frequency dependent intersection points (*IP*) of *F* (Boehm et al, J Biomechanics 2019). These *IPs* arise from the linearity of band-passed time signals of force direction (approximately *Fx/Fz*) and center of pressure (*xCP*) where *F* tended to intersect above the center of mass (*zCM)* for slow frequencies (below 2Hz) and below *zCM* for fast frequencies. This frequency method was limited as it displayed the average characteristics of *F* behavior over time periods generally longer than 15 seconds. To investigate the presence of *IPs* at shorter time scales, we analyzed short time windows (~0.1 to 1 s) of force direction and *xCP*. We hypothesized that *xCP* and force direction will be modulated so as to have an *IP* and that the height of the *IP* (*zIP*) will correlate with some measure of the amount of or rate of change of *xCP*. Kinetic and kinematic data for quiet standing was analyzed from a public data set of 27 quietly standing humans (Santos & Duarte, PeerJ 2016). Time windows were selected between time points where *xCP* velocity was 0. The principal component of the force direction vs *xCP* was used to calculate the *zIP*. Interestingly, the results showed increases of *zIP* with window duration and *xCP* range. This relationship is similar to the previous results (Boehm et al, J Biomechanics 2019) where window duration correlates with the inverse of frequency (low *zIP* with short duration or high frequency). Using *zIP* as a metric to evaluate balance can be helpful because it reduces the dimensionality of torque coordination from 3+ variables (hip, knee, ankle + vertebral) to one variable, *zIP*. Coordination, expressed as an *IP*, relates to the translational and rotational requirements of balance and can be useful for powered prostheses and biomimetic robotic control, and for accessing and improving rehabilitation of neuromuscular balance problems.

Title: Cognition relates to motor output complexity during a challenging locomotor task in young adults

Authors: S. A. BRINKERHOFF, R. T. FAWCETT, *J. A. ROPER;
Auburn Univ., Auburn, AL

Abstract: Muscle activity during gait can be organized into motor modules, and can increase as task complexity or expertise in movement control increases. We sought to examine the influence of expertise in movement control and cognition on number of motor modules during flat walking and three gait tasks. Sedentary adults (n=11, 2 males), active adults (n=12, 6 males), and 'expert' adults participating in dance or tennis (n=7, 3 males) participated. Three cognitive tests were administered: the Mini-Mental State Exam (MMSE), the Digit Span test, and the Trails Making test. Participants completed four walking tasks: normal walking (GAIT), tandem walking (TANDEM), tandem walking on an 8-foot beam on the floor (BEAM), and walking over stepping stones of various surface area and height (TARGET). Electromyography was recorded unilaterally from the gluteus medius, tibialis anterior, soleus, gastrocnemius, vastus medialis, rectus femoris, and the medial and lateral hamstring of the dominant leg. Non-negative matrix factorization calculated the number of modules needed to account for at least 90% of the total variance in muscle activity. Higher scores on the MMSE were related to a higher number of modules used during GAIT and TARGET. We observed differences in the proportions of sedentary, active and expert adults displaying varying number of modules in TANDEM. Specifically, 46% of sedentary individuals used 4 modules, 58% of active used 3 modules, and 43% of experts used 3 modules. A 3(group) x 4(task) ANOVA resulted in no interaction between group and condition and no effect of group, but there was an effect of condition such that participants used more motor modules when walking over the stepping stones (4.2) than walking over flat ground (3.5), tandem walking (3.5), and beam walking (3.1). This confirmatory study signifies that individuals, regardless of expertise, have higher muscular coordination during step-targeting tasks and heightened muscular coordination is related to high global cognition. We surmise that an important association exists between neural structures governing both movement control and cognitive performance. The precise role and interplay of cognition and movement control remains to be elucidated, and should be explored in further research.

Univ., College Station, TX; [3]Biol. Sci., [4]Georgia Inst. of Technol., Atlanta, GA; [5]Georgia Hand, Shoulder & Elbow, Atlanta, GA; [6]Col. of Engin. and Applied Science,, Lehigh Univ., Bethlehem, PA; [7]Tufts Univ. Sch. of Med., Boston, MA; [8]Poly-Orth Intl., Sharon, MA

Abstract: Despite the availability of the modern multi-degree of freedom powered limb prostheses, their users often are dissatisfied with them due to complex, non-intuitive control and lack of sensory feedback (Ostlie et al. 2012). Recent case studies of bidirectional control of powered prostheses in individuals with upper and lower limb loss have demonstrated drastic improvements in quality of movements (Ortiz-Catalan et al. 2014). We recently developed a sensing powered transtibial prosthesis for the cat (Park et al. 2018) to investigate effects of bidirectional prosthetic control on locomotor mechanics. Here we present results obtained on one cat that had this prosthesis for 20 months. The prosthesis is attached to a percutaneous porous titanium pylon (Pitkin, et al., 2012) implanted into the distal tibia marrow canal. The pylon has a channel inside through which leads of EMG electrodes in implanted residual soleus and tibialis anterior and of a cuff electrode on the residual distal tibial nerve are passed through to connect to a linear actuator and onboard nerve stimulator. Nerve stimulation was triggered when a pressure sensor on the bottom of the prosthetic foot recorded contact with the ground. Three Modes of prosthetic operation were investigated: (1) pressure Mode, in which the linear actuator extended the prosthetic ankle during contact with the ground and flexed it during swing; (2) EMG Mode without stimulation, in which soleus EMG signal was used to control ankle extension during stance while ankle flexion was performed during swing; and (3) EMG Mode with nerve stimulation, in which in addition to Mode 2 the residual distal tibial nerve was stimulated during prosthesis contact with the ground. In total we recorded 346 cycles of overground prosthetic walking. We found that the duty factor of the prosthetic hindlimb was longer for Mode 2 than for Mode 1 or Mode 3 ($p=0.004$-0.050). The relative duration of the double hindlimb support phase with the contralateral hindlimb being the trailing limb was shorter in Modes 1 and 3 than in Mode 2 ($p=0.016$-0.041). We found no difference in peak of vertical ground reaction force of the prosthetic limb between Modes. We concluded that bidirectional control of the transtibial prosthesis modulates locomotor kinematics.

Title: Kinematics of simultaneous bidirectional hindlimbs locomotion in decerebrate cats

Authors: V. LYAKHOVETSKII[1,2], N. MERKULYEVA[1,2,3], O. GORSKII[1], ***P. MUSIENKO**[3,1,2];
[1]Pavlov Inst. of Physiology, Russian Acad. of Sci., Saint-Petersburg, Russian Federation; [2]Russian Res. Ctr. of Radiology and Surgical Technologies, Ministry of Healthcare of the RF, Saint-Petersburg, Russian Federation; [3]Inst. of Translational Biomedicine, Saint-Petersburg State Univ., Saint-Petersburg, Russian Federation

Abstract: The bidirectional (BIDI) locomotion, when one limb moves forward while other simultaneously moves backward, is a highly specific locomotor mode demanding during rotation in stepping or swimming in intact animals (Field, Stein, 1997) and healthy humans, either adults (Choi, Bastian, 2008) or children (Yang et al., 2005). Whether solely the spinal cord and brainstem circuitry may induce BIDI locomotion or the conscious control by the forebrain is necessary for this task? To solve this question, the model of cat (n=6) decerebrated at the precollicular-postmamilar level was used. The hindlimb locomotion was elicited by epidural stimulation of the dorsal surface of the spinal cord. For every animal, the same point of dorsal surface (L6-L7 segments) was used to elicit unilateral forward (FW), unilateral backward (BW), and BIDI stepping. The direction of the hindlimb movements was determined by the direction of movement of the treadmill belts. The kinematics of movements were recorded with the help of reflecting markers.All animals were able not only to unidirectional FW and BW stepping, but also to coordinated BIDI stepping, characterized by a high coefficient of stability of trajectories and low asymmetry of the period of stepping. During BIDI stepping, the hindlimb moving forward (FW-BIDI) was located more rostral than the hindlimb moving backward (BW-BIDI), that is coincided with the hind limbs position during corresponding unidirectional stepping. The angle range in the ankle and hip joints at unidirectional FW walking for both hindlimbs was significantly higher than for unidirectional BW walking. For BIDI walking, the angle ranges of two hindlimbs were differed significantly: the kinematic characteristics of the FW-BIDI hindlimb and BW-BIDI hindlimb were similar to the features of the corresponding unidirectional FW and unidirectional BW stepping. Despite these significant differences in kinematics, both hindlimbs had similar stepping periods. An ability of the decerebrate animals to the BIDI locomotion means that the neuronal circuitries of the spinal cord, brainstem, and cerebellum are enough to control such highly coordinated and extraordinary locomotor task.

Title: The HoloLens augmented reality system provides valid measures of gait performance in healthy adults

Authors: *M. MILLER KOOP[1], A. B. ROSENFELDT[1], J. D. JOHNSTON[1], J. QU[1], M. C. STREICHER[1], J. L. ALBERTS[2];

Abstract: Biomechanical measures are the gold standard in the assessment of gait in healthy and neurological populations. Augmented reality systems represent an opportunity to evaluate human movement under more realistic and interactive conditions. A barrier to integrating augmented reality into healthcare is the unknown accuracy in quantification of human movement. This project aimed to determine the accuracy of the HoloLens relative to 3D motion capture in quantifying gait. Ten healthy adults completed nine walking trials (n=3 for slow, medium, and fast speed). Outcome measures included: cumulative walking distance, number of steps, step length and speed. Statistical equivalence testing, using an a-priori threshold of five percent, confirmed biomechanical measures derived from the HoloLens were equivalent to motion capture. Cumulative walking distance from the HoloLens was within 1.5- 2.1% of the motion capture system for all walking speeds. Difference between systems in terms of movement accuracy was less than 3.7 cm across trials. Equivalence in outcomes make the HoloLens appropriate for the quantification of frequently used gait variables to characterize walking performance. Future augmented reality applications have the potential to deliver digital therapeutics to patient populations under more real-world conditions in which movement performance can be quantified.

Title: A novel approach to the spatiotemporal quantification of gait in the common marmoset

Authors: A. BRADFIELD[1], N. SCHULTZ-DARKEN[2], K. MALICKI[2], K. K. AUSDERAU[1], M. E. EMBORG[2], *K. A. PICKETT[1];

Abstract: In humans, gait evaluation is used as a predictive disability outcome measure as well as an indicator for intervention effectiveness. Parallel methods of gait analysis in nonhuman primate models are essential for clinical translation. The goal of this study was to first assess whether gait data could be reliably collected from common marmosets in a Noldus CatWalk XT10.6 and second, establish a testing protocol to assess gait and the intraindividual variability during repeated testing. **Method:** The CatWalk system was modified and used to assess gait in eight adult common marmoset monkeys across multiple days and trials. Experiment one focused on the refinement of the methological approach and experiment two applied these techniques to a second group of subjects. Data were first analyzed to identify valid runs based on the established criteria. A further analysis examined mean base of support, average stride length, average swing time, and average stance time. **Results**: Raters had a high level of concurrence of usable data across all trials with successful trials including four consecutive hindfoot footfalls, during a continuous, uninterrupted segment of walking. A significant main effect of time ($p<0.001$) but not rater ($p=0.98$) was present with significant interactions for time by subject ($p<0.001$), but not rater per subject ($p=0.538$), time ($p=0.186$), or three-way interaction ($p=0.297$). **Discussion:** The CatWalk system allowed for reproducible, automated and translational locomotor data to be collected at multiple time points with detailed analyses. **Conclusions:** The CatWalk system, similar to those used in humans, can be effectively used to quantify spatiotemporal characteristics of gait in the common marmoset.

Title: Influences of peripheral visual field loss on sensory reweighting system during quiet standing in virtual reality environment

Authors: ***K. TANEDA**[1], H. MANI[2], N. KATO[4], S. KOMIZUNAI[3], K. ISHIKAWA[1], T. MARUYA[1], Y. TAKAMATSU[2], T. ASAKA[2];
[1]Grad. Sch. of Hlth. Sci., [2]Dept. of Rehabil. Science, Fac. of Hlth. Sci., [3]Grad. Sch. of Information Sci. and Technol., Hokkaido Univ., Sapporo, Japan; [4]Dept. of Physical Therapy, Fac. of Hlth. Sci., Hokkaido Univ. of Sci., Sapporo, Japan

Abstract: Visual, vestibular, and proprioceptive senses clearly contribute to postural control, so that individuals with peripheral visual field loss such as glaucoma have serious postural instability because of reduced visual sensory input. Some studies have proposed a hypothesis, which is called functional sensitivity hypothesis, that the peripheral or central visual field is specifically responsible for postural control in the anteroposterior (AP) or mediolateral (ML) direction, respectively. However, the hypothesis is not consistent in several other studies. In addition, no studies have investigated the relationship between postural instability due to peripheral visual field loss and reweighting of sensory input. Therefore, the purpose of this study was to investigate the influences of peripheral visual field loss on postural control. Fifteen healthy young adults participated in this study. The participants were asked to conduct quiet standing on a foam surface. Three conditions of virtual visual field loss (90 deg, 45 deg, and 15 deg) were given by a head mounted display. The ground reaction forces were recorded using by a force plate to calculate the displacements of center of pressure (COP) during quiet standing. As a result, the smaller the visual field was, the more the 95% ellipse area, root mean square (RMS), and mean velocity of COP displacements in the horizontal plane were increased. Analyzed by direction of COP displacements, the RMS in the AP direction was maintained even under the smallest visual field condition. On the other hand, the RMS in the ML direction and the mean velocity in each direction were increased according to the peripheral visual field loss. Furthermore, in the AP direction, the power spectral density of the low frequency band (0-0.3 Hz) which depends on the visual sense, was decreased. In addition, that of the middle frequency band (0.3-1 Hz) which depends on the vestibular sense, was increased. However, the power spectral density was remained in any frequency band in the ML direction. These results suggest that the functional sensitivity hypothesis is rejected in the quiet standing task, and the appropriate reweighting of sensory input contributes to maintain the postural stability in individuals with peripheral visual field loss.

Title: Learning effects of visual and auditory feedback training on voluntarily postural control

Authors: *N. HASEGAWA[1], M. MANTINI[2], L. A. KING[2], F. B. HORAK[2], T. ASAKA[1]; [1]Dept. of Rehabil. Sci., Hokkaido Univ., Sapporo, Japan; [2]Dept. of Neurol., Oregon Hlth. and Sci. Univ., Portland, OR

Abstract: Introduction Augmented feedback (AF) training to enhance sensory information is often used to improve postural control. Our previous study showed that motor learning using continuous auditory AF was more effective compared with continuous visual AF. However, it is unknown whether similar learning effects would be present using discrete, rather than continuous, AF. Therefore, this study aimed to investigate the learning effects using discrete auditory versus visual AF training to improve postural control. Our hypothesis was that both auditory and visual AF would similarly induce the motor learning of voluntarily postural control. Methods Twenty-two healthy young adults were randomly assigned to either visual or auditory AF. Participants were asked to shift their center of pressure (COP) in line with a hidden target, which moved a sine curves, by voluntarily swaying in the sagittal plane. In the training sessions with either visual or auditory AF, participants were required to change the magnitude of a visual circle or a sound according to the distance between the COP and the target in order to reach the target, respectively. AF was given only when the target reached the inflection points of the sine curves (discrete AF). Participants performed 80 trials for two consecutive days consisting of 5 time points: before and after first training (pre-1 and post-1), before and after second training (pre-2 and post-2), and 48 hours after the second training session (retention). The average and standard deviation of the distances between the COP and the target (D_{Ave} and D_{SD}) and the coherence between the COP and the target signals were calculated to determine the learning effects on spatial (D_{Ave} and D_{SD}) and temporal domains (coherence), respectively. Two-way mixed-design ANOVA was used with factors Group and Test session for the statistical analysis. Results D_{Ave} and $D_{SD,}$ our measure of spatial domains showed a significant improvement at both post-tests ($p < 0.01$), and retention ($p < 0.01$) in each group. On the other hand, the temporal measure of coherence improved significantly at both of the post-tests and at the retention in the auditory AF group ($p < 0.01$), but not the visual AF group. Furthermore, the coherence of the auditory AF group showed a significant improvement compared with that of the visual AF group at retention ($p = 0.02$). Discussion Our findings suggest that motor learning of postural control is improved by discrete auditory AF training, and not by discrete visual AF training, particularly for temporal measures. It may be explained that auditory information is relayed faster than visual information which may improve such aspects of motor learning for postural control.

Title: Role of ventricle volume in the association between cognitive status and mobility metrics in Parkinsonian disorders: A mediation analysis

Authors: *A. RAGOTHAMAN[1], O. MIRANDA DOMINGUEZ[2], N. HASEGAWA[4], J. G. NUTT[5], M. MANCINI[3], D. A. FAIR[6], F. B. HORAK[7];

Abstract: Besides gait and balance disturbances, cognitive problems are also common in movement disorders, such as Parkinson's disease (PD) and frontal gait disorder (FGD). While several brain areas and functional systems have been associated with such domains in isolation, the neuroanatomical reasons for the close relationships between cognition, mobility, and aging, however, is unclear. In this study, we aimed to determine if the relationship between mobility metrics and cognitive impairments is mediated by increased ventricular volume.
Ninetyseven people with idiopathic PD, 12 people with FGD parkinsonism, and 50 control subjects (age 68.7 $\pm$ 8.3 years) were recruited. Brain and ventricular size were measured using structural MRI (T1w) and Freesurfer. Total ventricular volume was computed as a percentage of intracranial volume. Wearable inertial sensors quantified the following domains of gait and balance: spatiotemporal gait, anticipatory postural adjustments (APA), automatic postural responses (APR), and standing postural sway. Cognitive status was assessed using the Montreal Cognitive Assessment score (MoCA). Mediation analysis was used to predict the balance and gait measures given MoCA using total ventricle volume as the mediator using R. Subjects were sex matched and all variables were controlled for age. Bootstrapping with 500 simulations and correction for multiple comparisons was performed.
Ventricle volume significantly mediated the association between MoCA and spatio-temporal gait measures (foot angle at toe off ($p<1e-5$), gait speed ($p=0.0080$), foot angle at heel strike ($p=0.043$), trunk sagittal range of motion while walking ($p=0.036$)); and postural sway measures (mediolateral and anteroposterior root mean square of sway with eyes open on foam surface, $p=0.028$), and as shown in figure.
Our findings suggest that increased ventricular volume mediates the association between cognitive decline and gait and standing balance dysfunctions by 28 - 43%; thus, confirming that cognition and specific mobility outcomes may share common neuroanatomical structures.

Hlth. Solutions, Arizona State Univ., Phoenix, AZ; [5]Dept. of Rehabil. Med., Seoul Natl. Univ. Boramae Med. Ctr., Seoul, Korea, Republic of

Abstract: Background: Gait and balance is impaired in Parkinson's disease (PD) and has been associated with cognitive deficits. We designed an Agility Boot Camp with Cognitive challenges (ABC-C) rehabilitation program to see if improvements could be made in gait and balance (King et al 2015). **Objective:** To investigate the effects of a 6-week cognitively challenging exercise intervention in people with Parkinson's disease (PD) on objective measures of gait and balance. We hypothesized that exercise training will improve gait and anticipatory postural adjustments (APA). **Methods:** We used a randomized, single-blinded, cross-over design, in 93 people with idiopathic PD (68±8 years, MDS-UPDRS III, Off medication 42±12; mean±SD), Forty seven subjects had freezing of gait (FoG). Subjects completed 6-weeks of ABC-C exercise program and 6-weeks of education classes (placebo), with intervention order randomized. Outcome measures (Off medication) included clinical, perceived and objective measures of balance and gait (24 metrics of gait, sway, APA, and APR; single- and dual-task (ST,DT)). We used a linear mixed-model that included fixed effects (treatment and order) and random effects (subjects). **Results:** Postural instability and gait disorder score and the PDQ ADL section improved after ABC-C program but not after education ($p=0.002$), while the MDS-UPDRS III ($p=0.25$) and total Mini-BESTest ($p=0.08$) did not change. For objective measures, the gait metrics arm range of motion (RoM), trunk coronal RoM, and foot strike angle, as well as the APA metrics first step RoM and peak medial-lateral APA were improved after exercise, while Sway and Anticipatory postural responses (APR) metrics did not improve. Dual-task cost on gait speed significantly improved after ABC-C program but not after education ($p=0.001$). For the subjects with FoG, worse baseline Motor UPDRS (>67 Off) and Mini-BESTest (<20) scores showed significant improvement ($p=.01$-$.04$). Among gait and balance measures, the spatio-temporal gait parameters significantly improved after the ABC-C program but not after education ($p<0.00001$). Postural sway with eyes open on foam showed a trend for improvement after the ABC-C program ($p=0.03$), while APR to a Push and Release test did not change. Also, for subjects who had lower baseline exercise levels, more improvements were seen following exercise intervention. **Conclusions:** A 6-week cognitively challenging exercise program improved specific characteristics of gait and balance. Spatio-temporal parameters of gait, dual-task cost of gait, and perceived functional independence, were the most sensitive to change after exercise compared to after education intervention.

Title: Multiple domains of postural control in Parkinson's disease; feature selection of mobility measures

Authors: *L. A. KING[1], N. HASEGAWA[2], V. SHAH[1], P. CARLSON-KUHTA[1], M. MANCINI[1], F. HORAK[1];
[1]Neurol., Oregon Hlth. and Sci. Univ. Dept. of Neurol., Portland, OR; [2]Dept. of Rehabil. Sci., Hokkaido Univ., Sapporo, Japan

Abstract: Introduction: There are distinct domains of postural control that may be impaired in people with Parkinson disease (PD) including: 1) postural control during quiet stance (Sway), 2) reactive postural reactions (APR), 3) anticipatory postural adjustments (APA), 4) dynamic balance during walking (Gait), and limits of stability (LOS). This study aimed to determine the most sensitive objective measures of postural control that may differ between people with PD and healthy control subjects (HC), and investigate the association between those metrics with clinical measures of balance confidence, quality of life, and disease severity.
Methods: We recruited 144 subjects with PD (age: 68±8 yrs.) and 79 HC (age: 68±8 yrs.). All participants wore 8 inertial sensors (Opals, APDM), while performing various mobility tasks (PD in their practical *off* state), which measured performance in all 5 postural control domains; Sway, APR, APA, Gait, and LOS. All metrics were computed from inertial sensors. We first calculated the Standardized Mean Difference (SMD) and kept metrics that had SMD value greater than 0.5. Next, we computed a correlation matrix and removed highly dependent metrics ($r > 0.70$) to avoid the problem of multi-collinearity. Spearman's rho correlation was then used to determine the correlations between the most sensitive metrics and the ABC scale, PDQ-39 (total and Mobility), and MDS-UPDRS (total, part 2 and 3).
Results: We started from a comprehensive set of 93 metrics from all mobility tasks. After applying an imputation method (for missing data) and a threshold on SMD (>0.5), we were left with 44 metrics. After reducing highly correlated metrics, we were left with 24 metrics from 4 of the 5 postural domains (all except LOS). The most sensitive objective metrics were in the dynamic balance domain including turn velocity, foot strike angle at initial contact, arm range of motion and gait speed during a walk with a cognitive task. Metrics from the Gait domain also correlated most strongly with clinical measures of balance confidence (Foot strike angle and Gait speed with ABC scale; $r = 0.49$), and quality of life (Stance time with PDQ-39 total; $r = 0.35$).

Finally, dynamic turning velocity correlated most strongly with disease severity (MDS-UPDRS part 3; r = 0.51).
Conclusions: The proposed procedure reduced the objective measures of mobility while still capturing 4 of the 5 domains of postural control. From a comprehensive set of 93, we identified 24 metrics from the Sway, APR, APA and Gait domains. Our results indicate the importance of assessing multiple postural control domains and will help guide data reduction and outcome measure selection in clinical trials for people with PD.

Title: Turning features in people with Parkinson's disease, spinocerebellar ataxia, and healthy control subjects

Authors: *V. V. SHAH[1], M. MANCINI[1], N. HASEGAWA[2], P. CARLSON-KUHTA[1], J. G. NUTT[1], C. GOMEZ[3], H. L. CASEY[3], M. EL GOHARY[4], F. B. HORAK[1];
[1]Oregon Hlth. and Sci. Univ., Portland, OR; [2]Hokkaido Univ., Sapporo, Japan; [3]The Univ. of Chicago, Chicago, IL; [4]APDM, Portland, OR

Abstract: Objective: We investigated whether objective features of turning are different among healthy controls (HC), patients with Parkinson's disease (PD) and Spinocerebellar Ataxia (SCA). **Background:** Ability to turn during walking is a complex motor skill that can be greatly impaired in both PD and SCA. However, turning features such as smoothness of turn or velocity profile have not been well-studied. We hypothesized that turning in HC will be similar to a ballistic trajectory with a single smooth peak and a bell-shaped velocity profile unlike PD and SCA. **Methods:** One hundred and forty-three people with a mild-moderate idiopathic PD (UPDRS III score: 40.60 ± 12.60), 79 age-matched HC subjects, and 52 people with SCA (SCA-1 (n=6); SCA-2 (13); SCA-3 (12); SCA-6 (21); and SARA score: 10.8 ± 4.44) participated in this study. All subjects wore 6 inertial sensors (Opals, APDM) attached to both feet, shanks, wrists

and the lumbar region, and subjects were asked to walk 7 meters back-and-forth for 2 minutes (PD in their practical *off* state). From the lumbar sensor, we detected a start and an end of the turn, and derived a total 6 measures of turning: Turn duration, Turn angle, Turn velocity, Turn peak velocity, Medio-lateral (ML) range, and ML Jerk (smoothness measure). Non-parametric ANOVA was performed using the Kruskal-Wallis Test, and post-hoc analysis was performed using the Mann-Whitney U test. **Results:** All six turning features showed a statistically significant difference among the groups. Post-doc analysis revealed that all turning features were statistically significant between Control and PD. Turn duration for completing 180° turn was longer in PD and SCA compared to HC, but very similar between PD and SCA (p=0.373). Although, PD and SCA both showed slowness during turning (e.g. longer turn duration) compared to HC, turn smoothness was significantly different between PD and SCA. Specifically, ML jerk was the lowest in PD and the highest in SCA (p=0.001). Similarly, the ML range was the lowest in PD and the highest in SCA (p=0.000). **Conclusions:** Our preliminary findings suggest that although both PD and SCA showed slowness during turning, turn smoothness was impaired in opposite ways for PD and SCA compared to HC. PD showed the smallest ML jerk indicating the more axial rigidity, and SCA showed the largest ML jerk indicating less rigidity compared to HC. Future work on exploring the velocity profile during turning will provide more information about brain circuitry involved during turning.

Abstract: Step length asymmetry asymmetries after stroke are commonly associated with balance impairments and may increase the risk of falls. This increase in fall risk may result, in part, from abnormal recovery responses following unexpected perturbations. Reactive recovery responses during perturbed walking are commonly characterized by measures of whole-body angular momentum (WBAM), which reflect the net contribution of all body segments to the body's rotation about a given axis. Recent work has shown that people with spatiotemporal gait asymmetry have higher peak-to-peak ranges of WBAM during walking. However, while this may suggest that spatiotemporal asymmetries impair balance during walking, no studies have quantified how reductions in asymmetry influence the reactive control of balance post-stroke. Here, we tested the hypothesis that reducing step length asymmetry would improve reactive control of WBAM in stroke survivors. Fourteen individuals post-stroke walked on a dual-belt treadmill at their self-selected speed and followed instructions to use visual feedback to either match their natural step length asymmetry or to adopt steps of equal length. During each trial, we randomly applied ten accelerations to the treadmill belts on the paretic and non-paretic sides at foot-strike. Each perturbation was characterized by a trapezoidal speed profile in which the speed increased by 0.2 m/s at an acceleration of 1.6 m/s^2, was held for 0.6 s and then decelerated back to the self-selected speed during the swing phase of the perturbed leg. We recorded full body motion capture and used these data to compute the integrated WBAM during the perturbation steps to capture the magnitude of body rotation in response to the perturbation. We found that the integrated WBAM during the perturbation step was greater on the paretic side than the non-paretic side ($p<0.001$). Also, there was a significant interaction between step length asymmetry magnitude and the direction of baseline asymmetry on WBAM ($p=0.01$) such that for people who took shorter paretic steps, reductions in asymmetry were associated with an increase in integrated WBAM. In contrast, for people who took longer paretic steps, there was no significant relationship between the magnitude of step length asymmetry and integrated WBAM. These results suggest that reducing step length asymmetry may impair the reactive control of stability for some stroke survivors, particularly those who take shorter steps with their paretic limb.

Title: Impact of modifying spatiotemporal asymmetry on frontal plane whole-body angular momentum during walking post-stroke

Authors: *U. S. P. PARK[1], C. LIU[1], S. NATALIA[1], J. K. TILSON[1], S. J. MULROY[2], J. M. FINLEY[1];
[1]USC, Los Angeles, CA; [2]Rancho Los Amigos Natl. Rehabil. Ctr., Downey, CA

Abstract: Neurological impairments such as stroke, often result in asymmetric walking patterns and increased instability in the frontal plane. Because spatiotemporal gait asymmetries are associated with balance impairments post-stroke, researchers and clinicians often aim to create interventions to reduce asymmetry in these individuals. However, the acute effects of changing asymmetry on balance during walking have yet to be examined. These effects may also depend on the direction of asymmetry as some individuals take longer steps with the paretic limb and others taking longer steps with the non-paretic limb. Here, we determined how the manipulation of step length asymmetry using explicit instruction influences measures of dynamic balance in the frontal plane during walking post-stroke. When increasing step length to reduce asymmetry, we expected that people would increase frontal plane whole-body angular momentum (WBAM) and shift their center of mass toward the contralateral stance limb to advance the swing limb. A total of 15 chronic, post-stroke individuals participated in this study. Participants walked on a treadmill using visual feedback in three conditions presented in a randomized order. These conditions included walking at their natural step length asymmetry, walking with instruction to take steps of equal length, and walking with exaggerated asymmetry. Dynamic balance was characterized by measures of WBAM in the frontal plane with respect to the body's center of mass. We measured the peak-to-peak range of WBAM over the gait cycle as a metric of dynamic balance. We used mixed-effect regression models to determine if measures of WBAM were associated with step length asymmetry magnitude and the direction of asymmetry. Participants successfully modified step length asymmetry through use of visual feedback in both the symmetry and exaggerated asymmetry conditions. There was a significant association between step length asymmetry magnitude and the peak to peak range of WBAM over a stride ($F = 10.38$, $p = 0.001$) with a significant interaction between asymmetry magnitude and direction (*rpar=0.007, rnonpar=-0.011* , both $p < 0.001$). Thus, improving symmetry acutely decreased the range of angular momentum for people who have longer paretic steps, and increased the range for those who have longer non-paretic steps. These results suggest that the direction of asymmetry influences the functional consequences of instructing people post-stroke to walk more symmetrically and this may be an important consideration during rehabilitation.

Title: Differences in response to auditory cues across movement types in people with Parkinson's disease with and without freezing of gait

Authors: *A. P. HORIN[1], E. C. HARRISON[2,4], K. S. RAWSON[1], G. M. EARHART[1,2,3]; [1]Program in Physical Therapy, [2]Dept. of Neurol., [3]Dept. of Neurosci., Washington Univ. Sch. of Med., St. Louis, MO; [4]Dept. of Dance, Washington Univ. in St. Louis, St. Louis, MO

Abstract: Parkinson disease (PD) is a neurodegenerative movement disorder characterized by gait impairments that reduce mobility and increase fall risk. A common gait deficit is freezing of gait (FOG), a delay in initiation or pause in locomotion. One form of gait rehabilitation is rhythmic auditory cueing, in which a person matches their footfalls to the beat of an auditory cue. Our previous research has indicated different outcomes for externally-generated (e.g., music) and self-generated (e.g., mental singing) cues, such that both music and mental singing improved velocity and stride length, but music also negatively affected temporal stability whereas mental singing did not. Gait differences, in response to cueing, have also been shown in people with PD without FOG (PD-FOG) and with FOG (PD+FOG). We expect these differences are due to underlying neural mechanisms, however, studying gait with neuroimaging is difficult. Thus simpler movements such as finger tapping or foot tapping may be useful surrogates. Here we compared the responses of gait, finger tapping, and foot tapping to externally-generated and self-generated cues in healthy older adults (Control, n=24), PD-FOG (n=17), and PD+FOG (n=16). Temporal stability of movement was assessed via coefficient of variation (CV) for gait (inter-step interval) and finger tapping (inter-tap interval). For all cued trials, participants were cued at 100% of the tempo of their uncued, preferred pace movement (UNCUED). For externally-cued trials (MUSIC), participants matched the pace of the movement to the beat of the song. For self-generated cued trials (MENTAL), participants matched the pace of the movement to the beat of them mentally singing. Repeated measures ANOVAs were used to determine differences between group, condition, and movement on CV. There was a main effect of condition ($p<.0001$) and no main effects of group or movement. There was an interaction effect of condition and movement ($p<.0001$) with pairwise comparisons (Bonferroni corrected) indicating MUSIC trials had the highest CV compared to MENTAL across all movements and groups. These results show that self-generated cues elicit greater temporal stability across movements and groups than externally-generated cues. This provides evidence for using finger

tapping as a proxy for gait in neuroimaging studies to investigate differences in neural mechanisms underlying externally and self-generated cues in people with PD with and without FOG.

Title: Can stroke survivors learn and retain a new walking pattern through explicit, strategic locomotor learning?

Authors: *M. FRENCH[1], D. S. REISMAN[2];
[1]Univ. of Delaware, Newark, DE; [2]Physical Therapy, Univ. Delaware, Newark, DE

Abstract: Background: Locomotor learning, specifically sensorimotor adaptation, has been studied extensively using the split belt treadmill. Sensorimotor adaptation, in this context, is implicit, automatic, and requires few cognitive resources. Explicit, strategic learning, on the other hand, has been minimally studied during locomotion and requires cognitive resources. Due to the differences in these forms of learning, it is important to understand whether stroke survivors can learn through explicit, strategic locomotor learning. Thus, the purpose of this study was to evaluate the ability of stroke survivors to learn and recall a new walking pattern through an explicit, strategic learning paradigm.
Methods: Stroke survivors and age-matched healthy adults were recruited to participate in a treadmill walking study. On Day 1, subjects walked for Baseline, Learning, and Learning Test phases. On Day 2, subjects walked for a Retention phase. During Baseline, step length (SL) was calculated and the leg with the shorter SL (SSL) and longer SL (LSL) were identified. During Learning, a bar graph with a target line for each leg displayed real time information about subjects' SL. Subjects were asked to match both bars to the target line; however, the bar representing the SSL was distorted resulting in subjects learning a new walking pattern to make the bars to hit the target line. During Learning Test on Day 1 and Retention on Day 2, subjects were asked to recreate the pattern they learned without the visual feedback. Step symmetry [SS, $(SL_{SSL}-SL_{LSL})/(SL_{SSL}+SL_{LSL})$] was calculated and used to quantify learning and retention. Learning was measured by Absolute Error (AE), which was the absolute difference between SS

at the end of Learning and the target SS (i.e. the SS that would result from hitting both target lines). Retention was measured by the Magnitude of Retention (MR), which was the absolute difference between the average SS during Learning Test and during Retention. A Mann-Whitney U test was used to compare AE and MR between the two groups.
Results: AE was not different between the stroke survivors (n=12; 66.08 ±10.6) and age-matched healthy adults (n=6; 69 ±7.1) (p=0.083). There was also no difference in MR between groups (p=0.417).
Discussion: Based on our results, it appears that stroke survivors learn and retain a new walking pattern through explicit, strategic learning as well as age-matched healthy adults. These results suggest that stroke survivors maintain the capacity to learn and retain new walking patterns through an explicit, strategic locomotor learning, despite the added cognitive resources required for this form of motor learning compared to sensorimotor adaptation.

Title: The characteristic of gait in children with motor coordination problems during dual cognitive and locomotor tasks

Authors: *C. W. CHAU, N. RIPIC, A. STEKL, N. WHITE, B. MALLABER, M. DONAHUE; Nazareth Col., Rochester, NY

Abstract: Previous results from our laboratory have shown gait decrement (reduced velocity, cadence, step length, swing duration and increased stance and cycle duration) in 5 and 6 year old (yo) typically developing (TD) children while walking and performing concurrent cognitive tasks. This study investigates changes of locomotion in children with motor coordination problems (MCP) during similar concurrent cognitive tasks. Children with MCP are at risk of developing developmental Coordination Disorder (DCD) and scored ≤ 46 on the Developmental Coordination Disorder Questionnaire 2007© (DCDQ) (Wilson et al, 2009). TD group has DCDQ score >47. Fifteen kindergartners (11 male and 4 females), divided into TD (N=9) and MCP (N=6) group based on DCDQ score, performed two cognitive tasks, a verbal counting backwards (VCB) task where they count backwards from 10 to 1, and a verbal sound recognition (VSR) task where they identify different familiar sounds played. Then, subjects walked on the GAITRite® (CIR System Inc. NJ), a portable carpeted walkway (2X14ft) embedded with electronic pressure sensors that record footprints and allowing us to measure spatiotemporal gait

parameters. Each subject completed 3 trials of walking without a concurrent task (Single-Task (ST)) or with a concurrent cognitive task (Dual-Task (DT)), either DT-VCB or DT-VSR in a randomized order. Each dual-task trial lasts 1-1.5 minute. The only constraint for all walking tasks is that the child may not stop on the GAITRite®. There was no statistical significance in gait parameters during all walking tasks between TD and MCP groups except for gait variability which was increased in all walking tasks from children with MCP. The step length stride to stride variability significantly increased in children with MCP (17.4%) as compared to TD children (6.5%) during DT-VSR. Similar to TD group, children with MCP showed a significant decrease in velocity (-53.9cm/s), step length (-14cm) and cadence (-34 steps/min) during DT-VSR as compared to ST. More children with MCP than TD made errors during DT-VCB (TD:11%; MCP:50%), but not during DT-VSR (TD: 44%; MCP:33%). A significant negative correlation between cadence and DCDQ score was found during DT-VCB in TD group (r=-0.83) but not in children with MCP (r=-0.49). Our results suggest that gait decrement during DT are similar between children with MCP and TD children. Children with MCP have more difficulty with DT-VCB than TD children suggesting increased difficulty in children with MCP with an internal-cued cognitive task. It is possible that children with MCP may use alternative strategy to compensate for increased cognitive demands during gait when compared to TD children.

Title: The contribution of use dependent plasticity to locomotor learning

Authors: *J. M. WOOD[1], H. E. KIM[3], D. S. REISMAN[4], S. M. MORTON[2];
[2]Physical Therapy, [1]Univ. of Delaware, Newark, DE; [3]Dept. of Psychology, Univ. of California, Berkeley, Berkeley, CA; [4]Physical Therapy, Univ. Delaware, Newark, DE

Abstract: Motor learning of locomotor patterns has been studied primarily in the form of sensorimotor adaptation (SMA). SMA refers to the trial-by-trial updating of motor commands in response to sensory prediction errors elicited during perturbed movements. Despite the extensive study of different forms of motor learning in upper extremity reaching tasks, it is unclear if these forms of motor learning also exist for locomotion. For example, use-dependent plasticity (UDP), which results in the biasing of future movements towards previously repeated movement patterns, has never been examined in locomotion. We sought to assess the contribution of UDP

to visually-guided locomotor learning. Young, healthy adults walked on a treadmill while watching real-time visual feedback of their step lengths on a computer screen. Step lengths were represented as two different colored bars which increased in size as the foot advanced during the swing phase of gait and then 'held' on the screen when heel strike occurred. Subjects were instructed to make the bars hit a target line during each step. The walking paradigm consisted of three phases: a baseline phase, where subjects were familiarized with the task, a learning phase (22 minutes), where subjects were taught a new walking asymmetry, and a washout phase (22 minutes), where subjects were instructed to walk normally and no visual feedback was provided. Subjects were randomly assigned to one of two groups. Subjects in the SMA+UDP group learned the new asymmetry by viewing erroneous visual feedback with a gain perturbation. Subjects in the UDP only group learned the new asymmetry by viewing veridical feedback with adjusted target lines, thus no sensory prediction error occurred. The primary outcome was step asymmetry index, measured as [(long leg step length - short leg step length)/stride length]. To assess the contribution of UDP to learning, we compared mean step asymmetry indices between groups at late baseline, late learning and early washout phases. We found no differences between groups during any of these phases, indicating that both groups were able to learn to walk asymmetrically to the same degree and, importantly, the associated aftereffects from visually-driven learning of an asymmetric locomotor pattern through combined SMA and UDP may be explained by UDP alone. Given the prevalence of repetition during nearly all locomotor learning studies, these findings may have broad implications for our understanding of how newly acquired locomotor patterns are shaped by prior recent experience.

Title: Walking humans regulate lateral stepping in a redundant, multi-objective, and adaptable way

Authors: ***J. B. DINGWELL**[1], J. P. CUSUMANO[2], M. E. KAZANSKI[3], A. C. RENDER[3]; [1]Kinesiology, Pennsylvania State Univ. Univ. Park, University Park, PA; [2]Engin. Sci. & Mechanics, Penn State Univ., University Park, PA; [3]Kinesiology, Pennsylvania State Univ., University Park, PA

Abstract: When humans walk, we are inherently more unstable side-to-side (laterally). Additionally, humans most often walk on paths (sidewalks, store aisles, etc.) with finite width that may be narrow or wide, straight or curved, etc. It is important to determine how people regulate lateral stepping movements in such contexts. Due to biomechanical redundancy, there are infinite choices for where to place each foot at each step. We recently extended a computational framework (Dingwell et al., PLoS Comput. Biol., 2010) to determine how humans exploit available redundancies to regulate lateral stepping movements while they walk (Dingwell & Cusumano, PLoS Comput. Biol., 2019). In general, to walk successfully on nearly any defined path, lateral stepping can be regulated to achieve various goals equating to different combinations of lateral position (z_B), heading (Δz_B), and/or step width (w) control. We then showed that during normal straight-ahead walking, humans adopt a multi-objective strategy that weighs strong (~95%) w-control against weaker z_B-control (~5%) (Dingwell & Cusumano, 2019). Here, we present results of 2 new experiments that manipulated the task of walking to elicit changes in step-to-step regulation of lateral stepping. In experiment 1, healthy adults were subjected to continuous pseudo-random lateral perturbations of either the walking surface or the visual field (e.g., as in McAndrew et al., J. Biomech., 2010). In response to these perturbations, all participants exhibited increased variability of all stepping variables. However, relevant time series analyses of step-to-step dynamics showed that participants also (and independently) more strongly corrected deviations in both z_B and w simultaneously. In experiment 2, healthy adults were given direct step-to-step visual feedback of z_B, or Δz_B, or w. Participants were asked to minimize errors relative to the desired values of each. Here, participants successfully reduced the variability of each feedback variable presented, relative to no-feedback (normal walking). Relevant time series analyses of step-to-step dynamics again showed that participants also adapted / modified the degree to which they regulated each stepping variable, according to each feedback condition and in ways generally consistent with the predictions of our computational framework. Together, these results demonstrate that regulation of lateral stepping in walking is redundant and multi-objective, and that humans adapt their step-to-step regulation in appropriate ways given relevant changes in task demands and environmental context.

Title: Center-of-mass predictions of foot placement may reflect passive dynamics and not control

Authors: *N. S. PATIL[1], J. B. DINGWELL[1], J. P. CUSUMANO[2];
[1]Kinesiology, The Pennsylvania State Univ., University Park, PA; [2]Dept. of Engin. Sci. & Mechanics, Penn State Univ., University Park, PA

Abstract: Humans stay upright during walking in part by choosing appropriate stepping locations on the ground. Exactly how this is accomplished from each walking step to the next in an active manner is the topic of much current research. Recent experimental studies of humans walking on a treadmill have shown that during an individual step, the pelvis or Center-of-Mass (CoM) state is a good predictor of the next foot placement, as perturbations to the upper body are consistently mapped to and, hence, successfully corrected by "appropriately chosen" foot placements. This has been interpreted by some to imply that the nervous system uses the CoM state at or near mid-stance to actively control subsequent foot placement. However, correlations of CoM state to subsequent foot placement could also, perhaps strongly, arise from passive dynamics, especially as movements of the feet are mechanically coupled to those of the rest of the body. This important alternative hypothesis has, however, not been directly tested. Here, we used a simple passive, open-loop-stable (i.e., without any active feedback) 2D walking model to show that one cannot take this ability to predict the foot placement from a CoM state in the preceding step, by itself, as evidence of active control. We simulated our uncontrolled model by adding "motor" noise. We also incorporated measurement errors in the regression variables to qualitatively replicate human walking data. In our simulations, we too found high correlations between the CoM state and the subsequent foot placement, but here, these were entirely due to intrinsic passive dynamics as our system, by design, has no control. Our simulations thus suggest that much of the aforementioned predictability in humans can perhaps be attributed to the passive or "ballistic" nature of trajectories between consecutive heel-strikes. Furthermore, they suggest that the observed correlations may, in addition, be strongly affected by even small amounts of noise in the experimental measurements. This finding does not mean the nervous system does not use CoM state to control subsequent foot placement at all. However, it does mean that such statistics should be used to characterize within-step active control in human walking only with great caution. Any conclusions about control require supporting evidence beyond the experimental correlations alone. The extent to which correlations of CoM state to foot placement in human walking reflect the effects of active control, or likely those of passive dynamics, or of some combination of both, thus remains an important and still open question.

Title: Effects of concurrent cognitive task difficulty on cortical activation and network in a cognitive-[editor1]postural dual task: A functional near-infrared spectroscopic study

Authors: *M. MIHARA[1], S. INAZUMI[2], H. OTOMUNE[3], I. MIYAI[3], Y. SUNADA[1];
[1]Dept. of Neurol., [2]Kawasaki Med. Sch., Kurashiki, Japan; [3]Neurorehabilitaion Res. Inst., Morinomiya Hosp., Osaka, Japan

Abstract: Background: It is well-known that a concurrent cognitive task often leads to impaired performance of postural or gait task (dual-task cost). Recent studies have revealed prefrontal involvement in cognitive-postural dual task, but a precise neural mechanism is still unclear. Objective: We investigated the effect of cognitive task difficulty on postural stability against a dynamic perturbation task and cortical activation using functional near-infrared spectroscopy (fNIRS).
Methods: We recruited 18 healthy young subjects (26.4 ± 9.5 y.o., 11 males). The subjects completed three postural-cognitive dual-task sessions. As cognitive task, they asked to sum all the numbers appeared every 2 s on the screen with three different task difficulties included simple counting (COUNT: using 0 or 1), easy calculation (EASY: using −9 to 9), and complex calculation (COMPLEX: using −99 to 99). Calculation results were checked for every 20 numbers (three times in one session). Concurrent with the calculation task, we applied brisk forward and backward translations of a platform as the postural perturbation, and evaluated the center of pressure (COP) and EMG activation of bilateral TA and GC muscle during perturbation. To measure postural task-related cortical activation, we used Oxy-Hb based signal measured by the fNIRS (FIORE-3000, Shimadzu Corp). We also evaluated effective connectivity in motor-related cortical areas during the postural task using Granger causality analysis.
Results: Normalized COP displacement (perturbation/rest) was significantly smaller in COUNT than in EASY and COMPLEX (COUNT: 2.19 ± 1.02, EASY: 2.13 ± 1.00, and COMPLEX: 2.57 ± 0.89). The normalized EMG activation (perturbation/rest) was also smaller in COUNT than in COMPLEX. Postural task-related cortical activation was most significant in COUNT, and there was significant reduction in the supplementary motor area activation (SMA) in COMPLEX than COUNT. There was also a significant correlation between cortical activation changes and COP displacement changes (Dual-task cost) in the right prefrontal cortex (PFC), SMA, and the medial sensorimotor cortex. Granger causality analysis revealed that effective connectivity from right PFC to SMA was significantly reduced in COMPLEX than that in COUNT.

Conclusion and interpretation: Our findings revealed dynamic changes in the postural task-related cortical activation and networks, suggesting an important role of the right PFC in cortical resource allocation to the SMA, which is one of the main hubs of the postural control network in cognitive-postural dual task.

Title: Larger visual perturbations affect the foot placement but not the ankle roll or push-off mechanism for balance control during walking

Authors: *H. REIMANN[1], T. D. FETTROW[1], M. ARCODIA[1], E. KAYE[1], D. GRENET[1], J. J. JEKA[2];
[2]Kinesiology & Applied Physiol., [1]Univ. of Delaware, Newark, DE

Abstract: Humans must continuously regulate upright posture during walking, to prevent losing balance. We have previously identified three separate mechanisms for balance control in the frontal plane, that are available at different points during the gait cycle. 1) In single stance, humans use lateral ankle musculature to roll their stance foot ankle. 2) At heel-strike, they shift the location of the foot placement. 3) During double stance, they shift weight between the two feet by pushing off more or less strongly with the trailing foot. Here we investigate how these three different mechanisms are flexibly recruited depending on the strength of a sensory perturbation. Ten healthy, young subjects (5 female) walked on a self-paced, instrumented treadmill, surrounded by a virtual reality scene projected onto a curved dome covering almost their complete field of view. To provide a visual fall stimulus, the scene was rotated around the sagittal axis at floor level with a constant acceleration for 600ms, then kept at a constant angle for 2,000ms, then reset at constant speed over 1,000ms. The initial acceleration was either 45 deg/s^2 (LOW) or 90 deg/s^2 (HIGH), or no movement (control), randomized. Stimuli were triggered on heel-strike of either foot, with a randomized inter-stimulus interval of 10-12 steps. Direction of the fall stimulus was towards the triggering foot, and we merged all data assuming body symmetry. The maximal average lateral CoM shift was significantly higher for HIGH (6.0cm) vs. LOW (3.9cm), representing the overall balance response to the visual stimulus. 1) The stance leg subtalar angle change at heelstrike was not significantly higher for HIGH (1.7deg)

vs. LOW (1.4deg). 2) The foot placement change in response to the stimulus was significantly higher for HIGH (0.57cm) vs. LOW (0.38cm). 3) The maximal trailing leg plantarflexion change was not significantly higher for HIGH (0.7deg) vs. LOW (0.7deg). We expected the relative contribution of the three mechanisms to change, but were surprised that this change came almost exclusively from the foot placement mechanism, which was about 50% higher for HIGH vs. LOW, very similar to the 54% increase in CoM shift.

Title: Individual neurons in macaque deep mesencephalic nucleus display both vestibular and locomotor modulation

Authors: *O. R. STANLEY, E. GUGIG, K. E. CULLEN;
Biomed. Engin., Johns Hopkins Univ., Baltimore, MD

Abstract: The deep mesencephalic nucleus (DpMe) is a relatively large midbrain area implicated in a wide variety of behaviors and functions, including sensory modulation, motivation, sleep, attention, eye movements, and locomotion. Its diverse connections include spinal, cortical, and basal ganglia inputs as well as outputs to thalamic nuclei and reticulospinal nuclei and tracts, and its potential clinical significance is a subject of active investigation, as demonstrated by recent human trials for Parkinson's disease symptoms using deep brain stimulation in DpMe. Specific areas within DpMe have long been known to be related to locomotion, posture, and gait. Additionally, studies across species and modalities have suggested the region plays a role in vestibular information processing. However, to date, studies of DpMe neuronal activity have predominantly focused on either motor activity or individual sensory modalities. Here, we present the first analysis of single-unit extracellular recordings from rhesus macaque DpMe during both passive vestibular stimulation recorded using a head-mounted accelerometer, and a head-fixed treadmill walking task (i.e. in the absence of vestibular input) during which we extracted animal posture using a deep-learning computer-vision tool. In particular, we demonstrate that there exist individual cells in this region which modulate their responses during both paradigms. Focusing on cells without eye movement sensitivity, we analyzed fifteen cells in macaque DpMe responsive to vestibular input, finding sensitivities

consistent with previous reports. Furthermore, the vast majority (14 of 15) of these cells' responses were also modulated by ongoing locomotion during head-fixed treadmill walking. Specifically, we find firing changes both as a function of gait phase and as a function of specific aspects of dynamic 3D posture, and we identified an increase in the power spectra of firing activity at the same frequency as the animal's step cycle. These results provide evidence that single cells in primate DpMe may be involved simultaneously in processing information from converging multimodal information streams for the purpose of complex sensorimotor processes, shedding light on a clinically relevant and intensely interconnected deep brain area.

Title: Motor adaptation to cognitive challenges and walking perturbations

Authors: *P.-C. KAO, M. A. PIERRO;
Univ. of Massachusetts Lowell, Lowell, MA

Abstract: Walking is not a fully automated motor task but requires sufficient cognitive capacity to control walking stability and adapt to environmental complexity. When performing a cognitive task during walking (i.e., dual-task walking), a competition for information processing resources and attention would lead to a compromised performance of either or both tasks. However, majority of the dual-task walking paradigms utilized in the previous studies were focused on posing a cognitive challenge by adding a secondary cognitive task. When encountering walking perturbations (e.g., destabilizing walking environment), it is not clear whether people would still use similar task prioritization strategies. The purpose of this ongoing study is to investigate how people adjust motor responses when both cognitive and walking challenges are presented, and if the task prioritization strategies are differed when receiving cognitive tasks that challenge different sub-components of the executive function. We recorded kinematic data as subjects walked on a treadmill 1) under two walking conditions: walking with and without continuous random-amplitude treadmill platform sways (Perturbed vs. No-perturbed walking); and 2) with and without each of the four cognitive tasks: Paced Auditory Serial Addition test (PASAT), clock test, visual color-word incongruent test (V-stroop), and auditory pitch-word incongruent test (A-stroop). We quantified walking stability by computing dynamic margins of stability (MOS), gait variability, and short-term local divergence exponent (LDE) of the trunk motion (local stability). The preliminary data of five healthy younger subjects show that cognitive performance in general is significantly lower in PASAT and clock test compared

to V-stroop and A-stroop ($p<0.05$). During the perturbed walking, subjects had significantly lower cognitive performance, more walking instability, and greater gait variability compared to no-perturbed walking. Under dual-task conditions, subjects walked with lower joint angle variability and significantly larger mean MOS compared to walking only. Subjects also showed a trend to walk with more local instability during V-stroop than during other cognitive tasks. These preliminary data suggest that healthy younger individuals tend to prioritize walking over cognitive tasks when encountering walking perturbations. However, during a cognitive task with a lower difficulty level or taxing visual attention, subjects tend to prioritize the cognitive task with a cost of compromising walking stability.

Title: Link of white matter tract integrity & dual-task costs on gait parameters in mild cognitive impairment and normal aging

Authors: M. M. GORECKA[1], S. CASTRO-CHAVIRA[1], T. R. VANGBERG[2], O. VASYLENKO[1], K. WATERLOO[1], ***C. RODRIGUEZ-ARANDA**[1];

Abstract: Persons with MCI experience cognitive and motor deteriorations that affect gait. These declines are assessed via dual-tasks paradigms where a cognitive task is performed during walking. Degree of change on gait parameters can be calculated by dual-task costs, i.e., the difference between single walking and dual-task performance. Because gait changes in MCI are thought to rely in part on cognitive decline and brain degeneration, the present study aims to evaluate the link between white matter tract integrity and dual-task costs on spatio-temporal gait parameters in persons with MCI and age-matched controls.
Method: 16 right-handed MCI patients (*mean* age 70.4 y, 10 women) and 20 right-handed healthy older adults (mean age 70.4 y, 13 women) were evaluated during single-task walking and on three dual-task conditions varying in difficulty. The cognitive task employed was dichotic listening which consists of simultaneous pairs of syllables presented differently for each ear on each trial. In the 3 conditions, subjects are asked to walk while a) report freely best-perceived stimulus, b) report stimuli from right-ear and c) report stimuli from left-ear. Means and

coefficients of variation were measured for gait speed, step length, and step width with the Optogait©-system. Dual-task costs (DTC) by condition for all gait parameters were calculated and analyzed with repeated-measures ANOVAs. Anatomical and diffusion-weighed (DW) images were acquired in a 3T MR scanner. The anatomical images were processed using FreeSurfer and utilized as reference for processing the DW images with the TRACULA software. Fractional anisotropy (FA) and mean diffusivity (MD) were estimated using global probabilistic tractography for the 18 major brain tracts. Then, FA and MD for each tract were entered into hierarchical regression models to predict DTCs on each dual-task condition. Age and gender were entered in Step 1 of the analyses. Statistical analyses were run on transformed z-scores.
Behavioral Results: A main effect for condition ($p < .0001$) and group ($p < .01$) were found only for mean step length with no significant interactions. *MRI Results*: Forceps minor (MD), cingular angular bundle (FA) and corticospinal tract (MD) explained 31% of the variance on DTC for mean step length ($R = 0.61$, $R^2 = 0.37$; $R^2\Delta = 0.31$, $p = 0.01$; beta = -0.61).
Conclusions: In MCI, the mean DCT of step length was nearly twice as that as the control group. The shortening in steps length as well as deterioration of forceps minor and cingular angular bundle are typical of MCI patients. The present finding linking decline on step length to white matter tracts known to deteriorate in MCI needs to be confirmed in larger samples.

Title: Dual-task costs in highly aged residents of primary care settings

Authors: J. RUDISCH[1], A. KRAMER[1], *C. VOELCKER-REHAGE[1], B. WOLLESEN[2];
[1]Inst. of Human Movement Sci. and Hlth., Chemnitz Univ. of Technol., Chemnitz, Germany;
[2]Fac. of Psychology and Human Movement, Univ. of Hamburg, Hamburg, Germany

Abstract: Introduction: In addition to the effects of normal aging, immobilization and sedentary behavior may further exacerbate the deterioration of locomotor function in residents of primary care setting facilities. Therefore, more cognitive resources are required to control gait. In motor-cognitive dual-task (DT) situations, attention may be directed to one of the tasks (either the cognitive or motor task) resulting in either so called dual-task costs (DTC). As a result, risk of

falling increases these situations. In this exploratory study, we investigated cognitive and motor performance in DT of varying complexity in highly aged primary care residents to explore the impact of secondary cognitive tasks on motor function.
Methods: Twenty-one multimorbid residents (17 females; 86.9 +/- 7.2 years old) in 2 primary care facilities in Chemnitz, Germany participated in this study. Subjects walked at a self-selected speed and performed three cognitive tasks in single- or dual-task scenarios, presented in randomized order. Cognitive tasks comprised serial number tasks (counting backwards by 1 [serial1] and 3 [serial3]) and verbal fluency (naming words beginning with a specified letter). Gait parameters were measured using an Optogait system (Microgate, Bolzona-Bozen, Italy). Mean and coefficient of variation of stride-time and step-length were calculated as primary outcomes.
Results: Motor DTC, i.e., a reduction in step-length and stride-time, were found in the serial3 and verbal fluency DT, however not in serial1. Gait variability, on the other hand, increased in all three DT scenarios as compared to single-task condition . No significant positive or negative DTC were found for cognitive performance. Data, however, showed a trend level relationship between cognitive performance and DTC. That is, individuals with more correct answers showed less DTC.
Discussion: Changing cognitive load of secondary task can affect motor DTC. Intraindividual differences, however, need consideration: Better cognitive function may reduce the amount of executive control needed to perform the motor and/or cognitive task (and therefore reduce DTC). On the other hand, individuals with lower cognitive function may disregard the cognitive task and therefore prioritize the motor task (likewise reducing DTC). Larger samples are required in future studies to include both, cognitive performance and cognitive DTC as predictors of motor DTC.

Title: Age differences in a combined walking and grasping task

Authors: *A. H. MASON[1], K. A. PICKETT[1], B. TRAVERS[2], A. PADILLA[1];
[1]Univ. of Wisconsin - Madison, Madison, WI; [2]Univ. of Wisconsin-Madison, Madison, WI

Abstract: Previous studies have examined the synchronous performance of locomotion and grasping in young adults, however, it is unclear how the coordination of these two tasks changes

with age. The purpose of this study was to investigate differences in the combined control of upper and lower limbs in young adults and adolescents. ***Method:*** Twenty-one right-handed young adults (8 males, mean age 21.2 ± 1.0 years) and 23 adolescents (14 males, mean age 11.2 ± 2.0 years) participated in the study. Three-dimensional kinematic data of the torso and right upper limb was collected via infrared motion capture (VisualEyez, PTI Phoenix, inc.). Gait characteristics were collected using a six meter GAITRite instrumented walkway. Participants were asked to walk the length of the gait mat and grasp a small or large object that was positioned on a height-adjusted table mid-way along the mat. These combined walking and grasping tasks were compared to conditions where participants walked without grasping or grasped without walking. We also compared spatio-temporal gait and grasp measures across key time points such as the approach phase (steps prior to the moment of grasp) and grasp phase. ***Results:*** For normalized step length during the approach phase there were significant main effects of Group ($F_{1,42}$=8.518, p=0.006) and Condition ($F_{2, 84}$=25.011, p<0.001). Normalized step length was longer for the children than for the young adults and was longer in the forward walking condition than both the grasp small and grasp large conditions. For normalized step length during the grasp phase, there were significant main effects of Group ($F_{1,42}$=4.444, p=0.041) and Condition ($F_{1.683,70.668}$=96.040, p<0.001). Final normalized step length was longer for the children than for the young adults and was longer in the forward walking condition than both the grasp small and grasp large conditions. When comparing grasp aperture (maximum distance between the index finger and thumb) for the walking and grasping conditions and the standing and grasping conditions, there were main effects of Condition ($F_{1,41}$=39.4, p<.001) and Object Size ($F_{1,41}$=792.5, p<.001). Peak aperture was larger when participants walked and grasped compared to when they stood still and grasped. Apertures were also larger when grasping the large object when compared to the small object. There were no group differences for peak aperture. ***Conclusion:*** Although there were main effects of group across most variables, the lack of interaction effects provides preliminary evidence that adolescents and young adults coordinate the complex task of walking and grasping similarly.

Title: Deep brain stimulation of the mesencephalic locomotor region acutely enhances locomotion in a large animal model of incomplete spinal cord injury

Authors: *S. J. CHANG[1,4], A. J. SANTAMARIA[1], F. J. SANCHEZ[1], P. M. P. SARAIVA[1], L. M. VILLAMIL[1], Y. NUNEZ-GOMEZ[1], I. OPRIS[1], J. P. SOLANO[2], J. D. GUEST[1,3], B. R. NOGA[1,3];

Abstract: Background: The mesencephalic locomotor region (MLR) is a region of the midbrain where electrical stimulation can elicit fictive/overground locomotion in decerebrate/intact small animal models, and enhance locomotion in small animal models of incomplete spinal cord injury (SCI). Assessing the effect of MLR deep brain stimulation (DBS) in a freely moving large animal model of SCI is a major step in determining the feasibility of using MLR DBS to augment gait clinically for gait disorders (i.e. SCI, Parkinson's disease).
Hypothesis: We hypothesized that DBS of putative MLR sites in awake and freely moving Yucatan micropigs would augment locomotion parameters after SCI.
Methods: Medtronic 3389 DBS electrodes were chronically implanted into putative MLR sites of Yucatan micropigs using MRI-guided stereotactic targeting. Intraoperative stimulation was used to evoke locomotor-like activity and confirm our stereotactic targeting. The ability to initiate and augment locomotion with MLR DBS was confirmed in freely moving, intact animals before they received an incomplete T9 contusive SCI by weight drop. EMG electrodes were implanted intramuscularly to record patterns of muscle activation in agonist/antagonist muscles of all four limbs during locomotion with and without MLR DBS. Kinematics data was collected using a Vicon motion capture system.
Results: We demonstrate that in addition to initiating and augmenting locomotion in the intact micropig, MLR DBS can be used after SCI to augment hindlimb EMG amplitudes, increase hindlimb frequency, and enhance coordination of limbs during locomotion.
Conclusions: Electrode location and stimulation parameters are crucial to eliciting specific locomotor outputs in the intact Yucatan micropig. Discovering these optimal electrode position and stimulation parameters allowed us to effectively evaluate the acute locomotor effects of MLR DBS in this animal model of SCI. Our research results have direct translation potential to clinical DBS trials targeting this region, and may partly explain why previous studies in Parkinson's disease patients to alleviate gait dysfunction did not produce more significant outcomes. Further research is required to ascertain the chronic effects of MLR DBS on locomotor function in this large animal model of SCI.

Title: Adaptive locomotor trajectory planning in consistent and unpredictable environments

Authors: *M. A. BUCKLIN[1,2], J. DEOL[1,3], M. WU[1], G. BROWN[1], K. E. GORDON[1,4]; [1]Physical Therapy and Human Movement Sci., [2]Biomed. Engin., Northwestern Univ., Chicago, IL; [3]Shirley Ryan Ability Lab., Chicago, IL; [4]Edward Hines Jr. Admin. Hopsital, Hines, IL

Abstract: To aid in successful execution of goal-directed walking (discrete movement from a start location to an end target) the nervous system forms a motor plan that must be adapted in response to environmental changes. Despite motor planning being inherent to goal-directed walking, it is not understood how the nervous system adapts these plans to interact with novel environments. Our purpose is to understand how people adapt motor plans of center-of-mass (COM) trajectory during goal-directed walking amid consistent or unpredictable changes in the environment. We hypothesized that participants would modify an internal model to control movement in a consistent environment and would use a high-impedance strategy in an unpredictable environment. Healthy adults performed repetitions of a discrete walking task, moving from static standing to a target located 1.5 leg lengths ahead. During some trials, a cable-driven robot applied a laterally-directed force to the participant's COM. This force field was proportional in magnitude to forward walking velocity. Participants performed 110 total trials of the task: 20 Baseline trials (no applied forces), 70 Field trials (in the force field), and 20 Washout trials (no applied forces). Trials 45, 60, 75, and 90 were Catch trials (no applied forces) to evaluate neural control strategies. Two groups of participants (n=5 per group) performed the experiment. For group one, the force field direction was consistent, always applied to the right. For group two, the force field was unpredictable, randomly applied to the right or left. We quantified Signed Deviation - deviation of COM trajectory relative to a straight line in the sagittal direction. Changes in COM trajectory were evaluated by comparing Signed Deviation between Baseline and Catch trials with a two-tailed t-test and significance set at $p < 0.05$. We observed a significant difference between Baseline and Catch for group one ($p < 0.05$) and no significant difference for group two ($p = 0.85$). During catch trials in the consistent environment, participant's trajectories deviated in the opposite direction of the force field, suggesting the use of an internal model. During Catch trials in the unpredictable environment, trajectories were

similar to Baseline, suggesting the use of a high-impedance strategy. These results support our hypothesis that people form an internal model of their COM trajectory amid a consistent environment and utilize a high-impedance strategy amid an unpredictable environment. The ability to adapt different whole-body control strategies in response to varying environments provides the nervous system flexibility to consider competing costs of walking.

Title: Effects of environments on the dual tasking timed up and go test: A pilot study

Authors: *R. ALMAJID, A. MAKAREMI, A. HENSLEY;
West Coast Univ., Los Angeles, CA

Abstract: The Timed Up & Go (TUG) Test is a clinical measure to assess the probability of an individual having a fall [1]. Dual-task (DT) TUG test has shown to be more sensitive in detecting those who are at high risk of fall compared to standard TUG test [2]. One limitation of the DT TUG, however, is that it is performed in a controlled laboratory setting. Little is known about the effect of DT on TUG activities in an outdoor environment. Thus, the objective of this study is to evaluate the effects of the environment (indoor vs. outdoor) on the DT TUG test. Two young adults (age 27.5 ± 0.7, 1 Female) completed five conditions that were presented in a randomized order: 1. TUG, 2. TUG while carrying a cup of water (TUG_m), 3. TUG with a mental calculation task (TUG_{MCT}), 4. TUG with a verbal fluency task (TUG_{VF}), 5. TUG while texting ($TUG_{Texting}$). These conditions were performed in two environments: 1. Indoor: which was the research/biomechanics lab at West Coast University (WCU), 2. Outdoor: which was a sidewalk within a walking distance from WCU. The dependent variables include the dual tasking cost (DTC) of the time, step count, and cadence. The DTC is a calculation that reflects the change in a motor behavior occurring under high attention-demand conditions; a lower DTC would reflect poorer motor performance [3]. Environment did not alter the DTC of time, cadence, or step count. The DTC of the walking time in $TUG_{Texting}$ was lower in the outdoor environment compared to the indoor environment; however, this did not reach a significant level ($p=0.09$). Our pilot data suggest that texting might add an additional cost to motor performance in the outdoor environment compared to the indoor environment. A clearer conclusion will be drawn from this data as we enroll more participants across ages. The results from this project may help in developing an ecologically valid measure for fall risk assessment or intervention in the elderly.

Title: Muscle synergies identified from step-to-step variations of muscle activations during treadmill locomotion in rats

Authors: *J. J. WALLNER[1], C. ALESSANDRO[2], M. C. TRESCH[3];
[1]Physiol., [2]Physiol. Dept., [3]Biomed. Eng, Physical Med. and Rehab, Physiol., Northwestern Univ., Chicago, IL

Abstract: It has been proposed that muscles are controlled as parts of coordinated groups, referred to as *motor primitives* or *muscle synergies*. In this hypothesis, each muscle synergy specifies a particular balance of activation amongst a set of muscles and complex behaviors are produced from a simple combination of these synergies. Dimensionality reduction techniques have demonstrated a lower-dimension latent space of muscle activations underlying a range of behaviors in a number of species, providing evidence for this muscle synergy hypothesis. However, it is currently unclear whether the identified synergies arise centrally from neural control or simply reflect the constrained requirements of individual tasks. As a step towards evaluating these issues, it has been proposed that the trial-to-trial variations in muscle activation across repetitions of a behavior might better reflect the structure of neural control. This approach assumes that muscle activations that are consistent across repetitions of a behavior reflect the consistent influence of task constraints on muscle activation. Although this assumption is likely to be a simplification, this approach might allow investigators to evaluate whether identified muscle synergies reflect neural control strategies or task constraints. We are examining these issues in the context of hindlimb muscle activations produced by rats during locomotion. We recorded the simultaneous EMG activity in up to 15 hindlimb muscles while animals walked

across a range of treadmill speeds and inclines. For each behavioral condition, we divided the EMGs into distinct steps defined by foot contact and calculated the step-averaged activation for each muscle. We subtracted this average from the observed EMG to obtain the residual EMG reflecting the trial-to-trial variations of muscle activation. We then identified the dimensionality of the latent space and muscle synergies underlying either these residual activations or underlying the total activations. In initial results we have found that the identified latent space is very similar whether analyzing either the total or the residual activations, suggesting that the observation of muscle synergies is not strictly determined by task constraints. Additionally, although the dimensionality of the residual activations was higher than that of the total activations, the synergies identified from the residual activations predicted the total activations very well. We are currently evaluating the robustness of these findings across task conditions and across animals, in order to better understand the role of task constraints in determining muscle synergies observed during behavior.

Title: Older adults demonstrate sustained adaptation to frequent perturbations in recumbent stepping

Authors: *T. SHAFFER[1], S. SHIRAZI[2], H. J. HUANG[2];
[1]Electrical and Computer Engin. Dept., [2]Mechanical and Aerospace Engin. Dept., Univ. of Central Florida, Orlando, FL

Abstract: Perturbations applied during treadmill walking often result in adapted walking patterns and balance control. Applying perturbations during locomotor tasks such as recumbent stepping could lead to adapted stepping patterns and arm and leg coordination that improve walking; this allows individuals with balance or walking difficulties, such as older adults, to benefit from perturbation-based training on a recumbent stepper. The purpose of this study was to quantify stepping adaptation of older adults in response to frequent mechanical perturbations during recumbent stepping. We hypothesized that older adults would adapt to the perturbations and minimize stepping errors to return to the unperturbed kinematic profile. Subjects (n=6, age: 60-75) stepped on a robotic recumbent stepper that created brief 0.2 s perturbations on every stride. Each subject performed four 10-minute stepping trials. The first and last two minutes of

each trial had no perturbations (i.e. unperturbed baseline and post), while the middle six minutes had perturbations that were applied at the onset or middle of leg extension (2 legs * 2 time-window = 4 trials). We instructed subjects to step smoothly and to maintain a stepping pace equal to 60 steps-per-minute following a visual cue. We excluded the first minute of the baseline and the last minute of the post from our analyses and quantified stepping error as the maximum difference of the time-normalized stepper position for each stride from the averaged baseline profile. The stepping error for baseline was always less than 5 degrees. During the 6 minutes of perturbed stepping, there was a significant increase in stepping error, but the error decreased with adaptation from the first perturbed stride to the last. This decrease was only significant for mid-extension perturbations (rAnova & LSD, post-hoc $p<0.05$). Stepping error decreased in the post period but remained significantly greater than the baseline error for all perturbations (rAnova & LSD, post-hoc $p<0.05$). We found that older adults adapted to the brief, frequent perturbations applied during recumbent stepping. However, adaptation did not return to the unperturbed kinematic profile; this suggests that subjects sustained the adapted stepping patterns, which may be beneficial for rehabilitation.

Title: Task-specific modulation of the functional field of view during locomotion

Authors: *V. MIYASIKE-DASILVA[1], J. J. BANKS[2], Y. R. RAWAL[1], B. SHARAFI[3], J. V. JACOBS[4];
[1]Fac. of Kinesiology & Recreation Mgmt., Univ. of Manitoba, Winnipeg, MB, Canada; [2]Dept. of Kinesiology, Univ. of Massachusetts, Amherst, MA; [3]Celect Inc., Boston, MA; [4]Rehabil. and Movement Sci., Univ. of Vermont, Burlington, VT

Abstract: During locomotion, vision plays a crucial role in the ability to identify obstacles and environmental features to guide appropriate gait changes. Relevant visual information about the environment can be extracted via the functional field of view, which is the area in the peripheral visual field within which visual stimuli can be detected while central vision is engaged in a concurrent visual task. Although it is well established that increased cognitive load in the central task causes an overall reduction in the functional field of view, the present study investigated the effect of locomotor activity on the extent of the lower and upper functional field of views.

Healthy young adults (n=14) performed a reaction-time task requiring them to discriminate letters appearing in their central visual field. Concurrently, participants detected visual stimuli appearing randomly in their upper and lower peripheral visual fields at varying eccentricities (25, 35, and 45 degrees). Central and peripheral vision stimuli were presented on a projection screen. Participants performed the visual tasks under 3 postural conditions: sitting, standing, and walking on a treadmill. For the central vision task, there were no differences in reaction times and errors across the 3 postural conditions. However, the ability to detect peripheral visual stimuli was influenced by posture. Specifically, participants missed more peripheral stimuli during walking (11.0±0.06%) than during sitting (3.00±0.044%) or standing (3.00±0.043%). Interestingly during walking, there was a higher rate of misses for peripheral stimuli presented in the upper field of view than in the lower field of view, especially for stimuli at 45 degrees. For sitting and standing, the rate of misses was balanced between upper and lower fields of view. These findings suggest that the capacity to extract visual information from the lower visual field is preserved during locomotion. This study presents evidence for a task-specific modulation of the functional field of view which likely plays an important role in the control of locomotion during daily activities such as distracted walking.

Title: Evaluating optimization principles in bipedal locomotion using dynamical movement primitives

Authors: *P. NOZARI PORSHOKOUHI[1], J. M. FINLEY[2];
[1]Biomed. Engin., [2]Biomed. Engineering, Div. of Biokinesiology and Physical Therapy, USC, Los Angeles, CA

Abstract: Despite the many possible ways that one could walk, humans often choose stereotypical features of their gait pattern that vary systematically as a function of performance objectives and environmental constraints. The selection of these features can often be explained as arising from the optimization of one or more objectives such as energetic cost and stability. Testing hypotheses about the objective functions underlying the selection of gait features often requires models that capture the key dynamics of locomotion. Optimization of bipedal walking

models, however, is computationally challenging due to the high-dimensionality of the state and action space. One potential biologically-inspired optimization approach during locomotion is to systematically constrain the action space to a lower-dimensional manifold. Here we present a framework for evaluating optimization principles during walking through the use of dynamical movement primitives (DMPs) in simulations of bipedal gait. DMPs are low-dimensional control policies that can be extracted from demonstration by fitting a set of basis functions to observed trajectories.

We fit DMPs onto kinematic data of human walking on treadmill. These DMPs produced time-varying trajectories for lower-extremity joint angles via a small set of free parameters. We also developed a simulation of an anthropometric biped with nine degree-of-freedom and six controllable joints walking on a treadmill in Matlab SimScape. Foot-ground interactions between the biped and treadmill were modeled via viscoelastic elements. Since the biped has fewer controlled degrees of freedom than available ones, we added a feedback controller that updated the DMP amplitudes and timing to stabilize the biped's pitch and position on the treadmill.

The extracted DMPs fit the human demonstrations successfully. The controllers efficiently stabilized the biped walking on the treadmill producing a high negative correlation between the update in step length and the error in biped position ($r = -0.92$ for left and $r = -0.79$ for right leg) such that when the biped fell behind the center of the treadmill the controller produced longer steps to move back toward the set point and vice versa. In the absence of feedback control, the biped was unable to walk a full stride. The mechanical power consumed by the biped was 2.82 $W.kg^{-1}$, which is comparable to the cost of transport of ~2.38 W.kg-1 for human walking at matched speeds. Having a control policy that mimics the behavior of human walking, we now have a framework that can be used in predictive simulations to explore plausible ways in which the neuromotor system adapts to unexpected disturbances or novel environments.

Title: Lighten up! Postural instructions affect static and dynamic postural control in healthy older adults

Authors: *R. G. COHEN[1], C. G. BILLINGS[1], J. L. BAER[2], D. KRAL[1], R. RAVICHANDRA[1], C. P. MCGOWAN[2], T. W. CACCIATORE[3];
[1]Dept. of Psychology & Communication, [2]Dept. of Biol. Sci., Univ. of Idaho, Moscow, ID; [3]Neurol., Univ. Col. London, London, United Kingdom

Abstract: Background: Aging is associated with declines in static and dynamic postural control, which may lead to falls. Previous work showed that brief postural instructions can affect steadiness and step initiation in older adults with Parkinson's disease. Here, we compared the effects of different instructions on postural control in a group of healthy older adults. **Method:** Twenty participants practiced three sets of instructions, then attempted to implement each instructional set during (1) 30-second eyes-open quiet standing on foam; (2) a three-second foot-lift. The 'Light' instructions relied on principles of reducing excess tension while encouraging length. The 'Effortful' instructions relied on popular concepts of effortful posture correction. The 'Relax' instructions encouraged minimization of effort. We measured kinematics and muscle activity. **Results:** During quiet stance, the Effortful instructions increased mediolateral jerk and path length of the center of mass. In the foot-lift task, the Light instructions led to the longest foot-in-air duration and the smallest anteroposterior variability of the center of mass, the Relax instructions led to the farthest forward head position, and the Effortful instructions led to the most activity in torso muscles. **Conclusion:** Maintaining postural intentions based on the idea of effortlessly "lightening up" may reduce excessive co-contraction and increase postural stability. This effect may partly account for the reported benefits of embodied mindfulness practices such as Tai Chi and Alexander technique on balance in older adults.

Title: Corticomuscular coherence in alpha band differentiates active and passive stepping

Authors: *S. M. BRUNSON[1], H. J. HUANG[2];
[1]Dept. of Biomed. Sci., [2]Mechanical and Aerospace Engin. Department, Biomed. Engin. Area, Univ. of Central Florida, Orlando, FL

Abstract: Previous studies have shown that active effort tends to improve recovery of walking ability compared to passive movements. This could be due to increased corticomuscular coherence, which is the determination of whether cortical impulses are synchronous with muscle activation. The purpose of this study is to analyze brain activity using electroencephalography (EEG) and muscle activity using electromyography (EMG) from both active and passive recumbent stepping for corticomuscular coherence. We analyzed EMG data from the tibialis anterior for the right leg only. We outfitted seventeen healthy young adults with a 256-channel EEG system, and they performed stepping on a robotic recumbent stepper using either active or passive effort. For active effort, subjects used their arms and legs to drive the stepper, while for passive effort, subjects relaxed and allowed the stepper to move their limbs. We performed independent component analysis and source estimation using DIPFIT. We identified four clusters for use in coherence calculations: the right parietal, right premotor, posterior cingulate, and right motor cortices. We analyzed the coherence spectra using the FieldTrip toolbox for MATLAB. Current results show small increases in coherence for active stepping in certain regions of the brain. Subjects showed increased coherence during active stepping in the right motor cortex from 10-15 Hz and within the beta band around 22 Hz. The right premotor and posterior cingulate showed higher coherence in active stepping within the alpha band (8-13 Hz). The right parietal, however, showed higher coherence during passive stepping in the alpha band. These results suggest that the brain and muscles may be communicating slightly more during active stepping than passive stepping. Beta band coherence is especially tied to conscious control of motor movements, while the alpha band is often linked to onset of dynamic movements. This provides greater evidence that active stepping is more dynamic than passive stepping. However, the high values of passive coherence in many subjects may show that cortical control persists even in passive movement. Another consideration is the difference between the biomechanics of treadmill walking and recumbent stepping, as the tibialis anterior plays a smaller role during recumbent stepping. Overall, these results indicate that active stepping has greater corticomuscular coherence than in passive stepping, though this may vary depending on the individual and the region of interest in the brain.

Title: Walking speeds can be predicted from electroencephalography after dimension reduction

Authors: A. S. RAHROOH[1], H.-H. HUANG[2], *H. J. HUANG[1];
[1]Dept. of Mechanical and Aerospace Engin., [2]Dept. of Statistics, Univ. of Central Florida, Orlando, FL

Abstract: Electroencephalography (EEG) is being used to more and more to record electrical brain activity from the scalp during walking and dynamic movements. Several studies have shown that electrocortical activity is coupled with walking dynamics and more recently, that electrocortical activity is also modulated with walking speed. The purpose of this study was to determine whether common classification methods could predict walking speeds from reduced temporal dimension EEG data. Subjects (n = 7) walked with five different walking speeds (0.5 m/s, 0.75 m/s, 1.0 m/s, 1.25 m/s, and self-paced) on an instrumented treadmill while wearing a 128-channel EEG cap to record scalp EEG data. For each speed, subjects walked for 5 minutes for a total of 25 minutes. The EEG system had a sampling rate of 512 Hz. To reduce the temporal dimension, we used spatial Independent Component Analysis prior to classification on a training data set and validation on a testing data set. On the training data set, we applied seven classification methods (Bagging, Boosting, Random Forest, Naive Bayes, Logistic Regression, and Support Vector Machines with a linear and radial basis function kernel). On the test data set, we calculated and compared overall classification rate, precision, sensitivity, and specificity for each classifier. The Logistic Regression classifier had the highest overall classification rate (mean +/- standard deviation, 76.6% +/- 13.9%), the highest precision (86.3% +/- 11.7%), and highest sensitivity (88.7% +/- 8.7%). The Support Vector Machine with a radial basis function kernel had the greatest specificity, 60.7% +/- 39.1%. The overall performance was relatively good, considering that the EEG data was minimally processed or "cleaned" as we only high-pass filtered the EEG with a 1 Hz cutoff frequency. We recently performed a similar study but applied this procedure of using spatial Independent Component Analysis to reduce dimension to an isolated EEG motion artifact data set recorded as subjects walked with different speeds (0.4 m/s, 0.8 m/s, 1.2 m/s, and 1.6 m/s). The results of our previous study were similar to this study in that the Logistic Regression performed the best out of four classifiers evaluated in the previous study (K-nn, Naïve Bayes, Logistic Regression, and Support Vector Machine with a linear kernel). Together, these results indicated that walking speeds can be predicted from EEG data after the temporal dimension of EEG was reduced using spatial Independent Component Analysis.

Title: Transfer of the perceptual and motor components of treadmill learning to natural walking

Authors: *C. ROSSI[1], A. J. BASTIAN[2];
[1]Johns Hopkins Univ., Baltimore, MD; [2]KKI & Johns Hopkins, Baltimore, MD

Abstract: Motor adaptation is an error driven learning process that recalibrates motor commands in response to predictable changes in the environment. This learning process also changes the perception of the adapted movement. For example, when people walk on a split belt treadmill, they learn a new gait pattern that accounts for the fact that the belts are moving at different speeds. They also develop the perception that that their legs are moving at more similar speeds than they actually are during split belt walking. People exhibit aftereffects in both the motor and perceptual domain when the treadmill belts are returned to equal speeds. However, the perceptual recalibration is incomplete compared to the motor recalibration. This has led to the idea that the perceptual changes may represent one component of the overall learning process. Split belt adaptation can partially transfer to natural over ground walking. This finding is also suggestive that more than one learning process may be at play: one component that generalizes and another that is context specific. It is not known if the perceptual recalibration transfers to over ground walking. Here we asked whether the recalibration of leg speed perception could be a marker of a) context specific learning, and therefore does not transfer to over ground walking or b) generalizable learning, and hence transfers and is fully washed out by natural walking. Participants adapted on the split belt treadmill and then were tested for both motor and perceptual aftereffects, before and after a bout of over ground walking. As expected, participants exhibited both motor and perceptual treadmill aftereffects following adaptation. Motor aftereffects partially transferred to over ground walking, washed out rapidly, and were reduced when subjects returned to the treadmill. Perceptual aftereffects also transferred to natural walking and were reduced upon subsequent return to the treadmill. Thus, both motor and perceptual effects transfer incompletely. This clearly demonstrates that the perceptual recalibration is not a marker of either context specific or generalizable components of adaptation. An interesting alternative is that both types of recalibrations are context specific, but the nervous system is slow to switch between walking patterns based on environmental cues. This could explain the transient over ground transfer and the resulting washout of the adapted motor and perceptual calibrations.

Title: A walk to remember: People learn and store new locomotor memories despite competing cognitive involvement

Authors: *K. A. LEECH[1], A. J. BASTIAN[2];
[1]Johns Hopkins Univ., Baltimore, MD; [2]KKI & Johns Hopkins, Baltimore, MD

Abstract: Savings, or faster relearning after initial learning, is a phenomenon observed across motor adaptation paradigms. Evidence suggests that cognitive processes interact with error-based learning to account for savings in arm and hand movements. For example, savings of an adapted reaching movement has been attributed to the use of aiming strategies. Specifically, upon re-exposure to the perturbation participants consciously aim their reaches toward the previously learned target location. We have previously demonstrated that savings of a recently adapted walking pattern is related to the ability to explicitly recall the perturbation. Yet, the contribution of cognitive processes to savings during walking remains unclear. Here we investigated how engagement in a cognitive task while simultaneously learning a new walking pattern may influence re-learning. We collected data from healthy young and older adult participants while they walked on a split-belt treadmill. All participants initially adapted to a split-belt perturbation, de-adapted with tied belt speeds, and adapted again to the same split-perturbation. To investigate the effects of increased cognitive demand during initial learning, participants either performed the split-belt paradigm alone or simultaneously completed cognitive tasks with varying degrees of difficulty (e.g. Simple Reaction Time Task, 3-Back Task). We found that dual-task performance did not change initial motor learning behavior in either age group. Despite simultaneously engaging in cognitive tasks, participants in the dual task groups learned the new walking pattern at the same rate as participants that performed the split-belt paradigm alone. While the motor behavior was similar across groups, dual-task interference was evident in the cognitive domain. Specifically, performance in the cognitive domain was poorer early in adaptation. Importantly, we found that increasing the cognitive load during initial learning did not interfere with the formation of a motor memory or savings of the new walking pattern. These findings suggest that adaptation-based learning may be a useful treatment approach in persons with cognitive deficits. However, more work is necessary to delineate the impact of cognitive deficits on the feasibility and efficacy of motor learning mechanisms. R37-NS090601 to AJB

Title: Learning a new walking pattern: The roles of movement and model formation

Authors: P. PADMANABHAN[1], V. S. CHIB[2], *R. T. ROEMMICH[3];
[1]Dept. of Neurosci., [2]Dept. of Biomed. Engin., Johns Hopkins Univ. Sch. of Med., Baltimore, MD; [3]Kennedy Krieger Inst., Baltimore, MD

Abstract: The nervous system exhibits remarkable plasticity for learning new walking patterns to navigate through novel environments. This learning is mediated by a constantly updated internal model driven by sensory prediction error. These new patterns are then committed to memory for faster re-learning in the future – a phenomenon called "savings". Here we asked if humans learn and save the new walking pattern itself or, alternatively, an internal model of the pattern.

In this study, we perturbed walking in healthy adults but prevented them from adopting a walking pattern suited to a novel environment. We hypothesised that learning and savings would be affected if these processes rely on behavioral expression of the new pattern, but not if they rely solely on the formation of a new internal model (which could form with or without changes in movement). We used a split-belt treadmill to perturb walking by making the two legs move at different speeds simultaneously. Here, people initially demonstrate a large limp (e.g., right step longer than left) but eventually restore symmetric walking. This type of locomotor learning (termed "adaptation") is signified by an "aftereffect", or limp in the opposite direction upon removal of the perturbation.

During adaptation, one treadmill belt moved twice as fast as the other. In the clamped group, participants used visual feedback to maintain their initial limp throughout adaptation. This caused their step length asymmetry to remain unchanged and asymmetric throughout the trial. The control group adapted to the same perturbation without visual feedback. In both groups, we measured learning aftereffects with both belts moving at tied speeds. Savings was assessed by re-exposure to the same perturbation without visual feedback. The clamped group showed diminished learning compared to controls as evidenced by a markedly reduced aftereffect. Furthermore, the clamped group showed a complete lack of savings. These results suggest that inhibiting expression of the intended pattern is detrimental to learning and saving new gait patterns.

We then investigated whether learning may have been impacted by physiological factors that underlie locomotor control and could have been affected in the clamped group. Specifically, energy optimisation is thought to be fundamental to healthy walking. Indeed, energy cost was significantly higher throughout adaptation in the clamped group compared to controls. Thus, we prevented both symmetric walking and energy optimisation in the clamped group, revealing a need to dissociate the causal roles of expression of intended movement and energy optimisation in learning and savings of new walking patterns.

Title: Unsupervised classification of open field mouse behavior

Authors: *U. KLIBAITE[1], J. VERPEUT[2], M. KISLIN[3], S. S.-H. WANG[4], J. W. SHAEVITZ[1]; [2]Princeton Neurosci. Inst. and Dept. of Mol. Biol., [3]Neurosci. Inst., [4]Princeton Neurosci. Inst., [1]Princeton Univ., Princeton, NJ

Abstract: Advances in computer vision and deep learning have made it possible to explore animal behavior at fine temporal and spatial scales. In particular, new advances in automated pose detection make it possible to track fine-scale movements in mice, a model system for the study of many aspects of neural function, from locomotion and coordination to complex neurodevelopmental disorders such as autism. We combined the use of a deep-learning-based approach called LEAP (LEAP Estimates Animal Pose), which produces estimates of joint coordinates, with unsupervised classification in order to discover distinct behavioral bouts in 72 wild-type mice in an open field arena over five subsequent days. We used the resulting behavioral phenotypes to explore the evolution of behavior in individuals over minutes and across days. We also identified behavioral differences among individuals and between wild-type mice and models of neurodevelopmental disease. This method can be used to capture a broader behavioral repertoire with fewer experimental constraints than traditional low-dimensional, high-throughput behavioral assays.

Title: Behavioral effects of the DREADD agonist clozapine-N-oxide (CNO) revealed by computational analysis of free animal movement

Authors: *J. L. VERPEUT[1], M. KISLIN[1], U. KLIBAITE[1], J. W. SHAEVITZ[2,3,1], S. S.-H. WANG[1];
[1]Neurosci., [2]Lewis-Sigler Inst., [3]Physics, Princeton Univ., Princeton, NJ

Abstract: Chemogenetic activation of ectopically-expressed receptors is now commonly used to perturb the function of specific brain circuitry. However, receptor activators may have their own effects independent of neural circuit-specific effects. To probe the effects of the DREADD (designer receptor exclusively activated by designer drugs) activator clozapine-N-oxide (CNO) on mouse behavior, we used a neural network-based approach to classify detailed body-part positions and pose transitions (see accompanying abstract by Klibaite et al.). We monitored mice for 10-20 minutes per day, up to 5 days in a row, to capture detailed movements as well as adaptations to the arena.
We analyzed the distribution of behaviors across days in untreated mice and in mice treated, either acutely or over 5 weeks of juvenile development, with CNO (1 mg/kg, PND 21-56). In the absence of perturbation, adult mice demonstrated a high degree of fast locomotion on day 1. Mice acclimated over days, as evidenced by a shift away from locomotory and toward grooming behaviors. In mice treated in juvenile life, this multiday acclimation was not observed. In already-acclimated adult mice, acute treatment with CNO, we did not detect a change in the locomotory/grooming ratio. These results show that CNO can influence mouse behavior even in the absence of its intended receptor target.

Title: Effects of the first dose of levodopa on multi-muscle synergies stabilizing vertical posture in drug-naive Parkinson patients

Authors: *S. M. FREITAS[1], P. B. DE FREITAS, JR[2], A. FALAKI[3], T. CORSON[4], M. M. LEWIS[4], X. HUANG[4], M. L. LATASH[3];
[1]Univ. Cidade De Sao Paulo, Sao Paulo, Brazil; [2]Inst. de Ciencias da Atividade Fisica e Esporte, Univ. Cruzeiro Do Sul, Rio Claro, Brazil; [3]Dept. of Kinesiology, Pennsylvania State Univ., University Park, PA; [4]Dept. of Neurol., Pennsylvania State Univ., Hershey, PA

Abstract: Indices of multi-muscle synergies stabilizing center of pressure (COP) coordinates, assessed within the uncontrolled manifold (UCM) framework, are reduced in patients with Parkinson's disease (PD) compared to age-matched controls. Within the UCM approach, inter-trial variance is quantified in the space of activations of muscle groups with proportional activation scaling (M-modes) in two spaces, one affecting (V_{ORT}) and the other not affecting (V_{UCM}) the COP coordinates. A synergy index (ΔV) is computed as the normalized difference (V_{UCM} - V_{ORT}). In previous studies, we have demonstrated that PD patients on chronic antiparkinsonian medication show low ΔV in the "off" state (overnight withdrawal from medication) and an increase on ΔV due to greater V_{UCM} (good variability) without any changes in V_{ORT} (bad variability) after medication administration. Our goal was to disambiguate possible effects of long-term drug exposure and PD *per se* on the index of COP-stabilizing synergy. We tested a group of 11 drug-naïve PD patients and 11 healthy controls. PD patients had no clinical postural instability, recent falls, or positive scores on the pull-back test of the UPDRS-III. Participants performed three trials of whole-body voluntary sway followed by 25 trials of a self-initiated load-releasing task during standing on a force plate. Surface electromyographic activity in 13 muscles on the right side of the body was recorded to quantify M-modes. Data were collected both before ("off") and approximately 60 min after ("on") the first dose of carbidopa/levodopa (25/100) in eight PD patients. Drug-naïve PD patients showed negative ΔV magnitudes (lack of COP-stabilizing synergy) "off" medication, whereas controls showed posture-stabilizing multi-muscle synergy ($\Delta V > 0$). After taking the first dose of levodopa, PD patients demonstrated a significant reduction in V_{ORT} with no effect on V_{UCM}, leading to higher ΔV. The results suggest that de novo, drug-naïve PD patients already show impaired posture-stabilizing multi-muscle synergies. Moreover, levodopa modifies synergy metrics differently in de novo, drug-naïve PD patients (V_{ORT}) compared to PD patients on chronic antiparkinsonian medications (V_{UCM}). These data suggest that indices of multi-muscle synergies are promising behavioral biomarkers of early-stage PD.

Title: The relationship between speed and spatiotemporal gait metrics of overground and treadmill walking in Parkinson's disease

Authors: *C. LU[1], K. H. LOUIE[2], S. E. COOPER[1];
[1]Neurol., [2]Biomed. Engin., Univ. of Minnesota, Minneapolis, MN

Abstract: Gait disorders are one of the most disabling symptoms of Parkinson's disease (PD) and one of the most refractory to treatment. While treadmill provides a convenient way to study gait, it remains equivocal whether the gait varies between overground and treadmill. Therefore, the aim of this study is to investigate how the relationship between gait metrics and walking speed vary between overground and treadmill walking in people with PD and healthy controls. We compared 29 healthy controls to 27 PD patients in the off-medication state. Participants were asked to walk continuously on an instrumented mat for at least 30 valid steps at a self-paced speed. After a resting break, participants were instructed to walk at their measured overground walking speed on an instrumented treadmill for 2 minutes. Average stride length and average cadence were computed for each participant in both overground and treadmill walking. Multiple linear regression analysis was employed for overground and treadmill walking separately for each dependent variable. The predictor variables selected for the analyses were the following: age, walking speed, group, and interaction between speed and group.
Regressions of log-transformed stride length and cadence on log-transformed gait speed showed the previously reported linear relationship for both overground and treadmill [1]. Furthermore, Parkinsonian gait was associated with shorter stride length regardless of whether stride length was normalized by leg length (leg lengths did not differ significantly between PD and control) compared to controls under both conditions. Stride length difference between PD and control was slightly greater in more severely affected PD patients with lower gait speeds. On the other hand, the cadence was faster in PD than controls under both conditions and the difference in cadence between PD and control was markedly greater in more severely affected PD patients with lower gait speed. In addition, we found both stride length and cadence were marginally

different between overground and treadmill.
The results demonstrate the relationships between specific gait metrics and gait speed are very similar between overground and treadmill walking. We conclude that our treadmill protocol is suitable for laboratory use to approximate natural overground walking scenario.

Abstract: The field of locomotor rehabilitation robotics developed to alleviate the heavy demands imposed by manual gait training, in which one or more therapists provide assistance by pushing and pulling on a patient's legs from a kneeling or squatting position. Although numerous robotic locomotor training algorithms have been developed and tested, such as assist-as-needed algorithms, outcomes are often below expectations. A better understanding of how human locomotor facilitators (LFs) help patients achieve locomotor goals may advance robotic algorithms. LFs are defined as individuals that apply assistive forces to improve patient gait characteristics (commonly physical therapists). However, human LF performance is usually constrained by heavy physical demands and awkward positioning, which makes it difficult to extract the "unencumbered" sensorimotor control strategy of a human LF. We, therefore, developed a new telerobotics approach that allowed LFs to provide locomotor assistance to patients with minimal sensorimotor encumbrances. Two human LFs (one experienced and one novice) used coupled robotic interfaces to provide manual assistance to a chronic stroke survivor walking on a treadmill (the LFs performed separately on different days). The LFs sat comfortably at a table while holding onto a small robotic manipulandum that provided haptic feedback about the stroke survivor's locomotor behavior, and the LFs saw a visual display of

information about the on-going sensorimotor interaction with the stroke survivor. The LFs assisted by applying light forces to the manipulandum, which were amplified and transferred to the stroke survivor's affected leg by a robotic arm. The goal was to increase step length by 25%. The training was performed once per week for five weeks, including about 20 min of assisted treadmill locomotion each session. Results indicated that both LFs were able to effectively manipulate the gait of the stroke survivor using the robotic interface. The novice LF applied forces that tended to lift the stroke survivor's leg upwards during push-off and swing, which was associated with improved retention of step length increases. Notably, poorer retention was observed for the experienced LF who applied assistive forces that more directly pushed the leg forward during swing. As expected, there was significant variation of LF assistance strategies and patient adaptation, even within the same LF. These results support the feasibility of minimizing therapist sensorimotor encumbrances using therapist-in-the-loop robotic gait training, which may inform customized robotic locomotor training algorithms for improved therapy outcomes.

Title: Children with idiopathic toe walking showed differences in areas of tactile and vestibular processing

Authors: *V. W. CHU[1], G. L. GIROLAMI[2], R. SOANGRA[3], R. BEUTTLER[4], C. HOLLANDSWORTH[3], S. CHHEDA[3], M. GRANT-BEUTTLER[3];

[1]Virginia Commonwealth Univ., Richmond, VA; [2]Physical Therapy, Univ. of Illinois at Chicago, Chicago, IL; [3]Crean Col. of Behavioral Sci., [4]Sch. of Pharm., Chapman Univ., Irvine, CA

Abstract: Idiopathic toe walking (ITW) is characterized by the absence of heel contact during gait that cannot be attributed to a known medical cause. It has been suggested that ITW may be related to impaired sensory processing, but to date, there is limited research examining this relationship. Areas of sensory processing that potentially relate to ITW include: sensory seeking, tactile defensiveness, poor proprioception, vestibular dysfunction and difficulties with sensory modulation (Sobel et. al., 1997, Williams et. al., 2014, Wick & Zanni, 2010). There is also evidence that children with ITW has difficulty with balance (Williams, et al, 2013). To test the relationship between ITW and sensory processing, we examined balance, sensory processing, and motor function in individuals with ITW at 2 sites in the US.

At Virginia Commonwealth University, we recruited 9 children with ITW between the ages of 4 to 10 years (mean=6.6, 6M/3F) , and 1 young adult with ITW (20.8 y, F), along with age-matched subjects without gait deviations. Participants completed a set of activities: balance, ankle proprioception, sensory modulation response to tactile and vestibular stimuli, tactile sensitivity (detection threshold), gait, and gross motor skills to examine sensory processing related to walking. Children with ITW have difficulty using vestibular and vision information and ineffective use of ankle strategies for balance. They also showed increased difficulty with sensory modulation of vestibular stimuli and had tactile sensitivity on the extreme ends of the spectrum.

At Chapman University, we recruited 20 children with ITW between the ages of 4 and 14 years (mean=9.6, 12M/8F). Participants completed the Sensory Organization Test (SOT) and the Balance subtest on the Bruinicks-Oseretsky Test of Motor Proficiency (BOT-2). 17 of 20 participants demonstrated more than 1 fall on the SOT with a mean standard score of -2.6. BOT-2 balance subtest mean standard score was -1.5.

At our 2 research sites, we showed that children with ITW has challenges with balance and differences in tactile and vestibular processing. This research will advance our understanding of ITW by providing a framework to detect and analyze underlying sensory differences that can be present in some children with ITW. This framework may also allow the identification of subtypes of ITW related to sensory processing differences. Our research strives to better understand the causes of ITW, so that we can develop effective interventions to guide earlier treatment and prevent long-term consequences associated with persistent toe walking.

Title: Persistent deficits in hindlimb locomotion following infarct in the hindlimb motor cortex of rats

Authors: *S. B. FROST[1], J. A. BORRELL[2], S. BARBAY[1], E. HOOVER[1], B. J. LAMB[3], R. J. NUDO[1];
[1]Rehabil. Med., [2]Bioengineering Program, [3]Mol. & Integrative Med., Univ. of Kansas Med. Ctr., Kansas City, KS

Abstract: The purpose of this study was to examine deficits in hindlimb locomotion and changes in ambulatory behavior following infarct in the hindlimb representation area (HLA) of primary motor cortex. Adult, male, Sprague Dawley rats were randomly assigned to one of two groups: Infarct or Surgical Control. Intracortical microstimulation (ICMS) using standard procedures was conducted to identify the origin of corticospinal projections mediating movement of the hindlimbs in each rat. At the completion of mapping, an ischemic lesion of the HLA was made in the infarct group. To induce cortical ischemia, endothelin-1 (ET-1; Bachem Laboratories, 0.3mg/mL) was injected at a depth of 1.5mm from the cortical surface, through a micropipette attached to a Hamilton syringe using a micro syringe injector. Surgical control rats were mapped using ICMS but did not receive an infarct. Behavioral testing included Ledged Beam walking, Horizontal Ladder walking, Treadmill Gait Analysis via the DigiGait and TreadScan system, and Open Field Walking using OptiTrack (NaturalPoint, Inc.) kinematic analysis. Motor performance of each rat was evaluated on each test before surgery, and once a week for 4-10 weeks post-surgery. RESULTS: Foot fault scores for the contralateral hindlimb revealed greater deficits in animals with HLA infarct than pre-infarct or control rats on the Ledged Beam and Horizontal Ladder tests, up to 8-10 weeks after surgery. Additionally, persistent differences in some gait measurements of stride were observed in HLA infarct rats. These results demonstrate prolonged, measurable deficits following infarct in the HLA of motor cortex of rats, that suggests, contrary to current dogma, that HLA plays an important role in hindlimb locomotion in rats.

Title: Neck muscle activation latency in older adults

Authors: *J. J. SOSNOFF, T. WOOD;
Kinesiology and Community Hlth., Univ. of Illinois at Urbana-Champaign, Urbana, IL

Abstract: Traumatic brain injuries (TBI) are a major cause in morbidity and mortality in older adults, with upwards of 80% of TBIs resulting from head impact during a fall. Recently it was observed that older adults are 3-times more likely than young adults to impact their head during an experimentally induced fall. Based in part on the observation that neck muscle latency is associated with mild TBIs in athletes, it was of interest to determine how aging impacts neck muscle activation latency in response to perturbation. It was hypothesized that old-old would have the largest muscle latencies. A total of 57 volunteers participated in the investigation and were divided into groups based on age (20 young (10 male, 22.3±3.8 yrs), 23 young-old (13 male, 67.2±3.8 yrs) and 14 old-old (4 male, 81.1±5.3 yrs). To examine muscle activation latency, participants underwent postural perturbations while muscle activation of the sternocleidomastoid (SCM), upper trapezius, and splenius capitis (Trigno wireless system, Delsys Inc, Natick MA) was recorded. Participants stood with their feet shoulder width with arms at their side staring straight ahead. The platform translated anteriorly or posteriorly 6.35 cm at a velocity of 20 cm/sec in a random fashion. Participants underwent three trials in each direction (randomized). Muscle activation latency was calculated as the onset of EMG signal subtracted from the onset of the translation. A Kruskal-Wallis nonparametric test was used to assess group differences. For anterior perturbations, a significant group effect for muscle latency of the right ($X^2(2) = 7.033$, $p = 0.030$) and left upper trapezius ($X^2(2)=12.2$, $p<0.05$) was observed. The young displayed shorter muscle activation latency (~175 ms) in comparison to young-old (~220 ms) and Old-Old groups (~230 ms). For posterior perturbations, a significant group effect for the right ($X^2(2)=9.0$, $p<0.05$), and left SCM ($X^2(2)=11.9, p<0.05$), the right upper trapezius ($X^2(2) = 7.326$, $p = 0.026$) were observed. The Young group (~150 ms) displayed quicker muscle activation latency compared to the Young-Old (~180 ms) and Old-Old groups (~215 ms). The current study revealed that there are greater neck muscle activation latencies in response to translations as a function of age. Given that neck muscle activation delays of 40 ms increase TBI risk by 20-25%, the functional importance of these observations are paramount. Future research examining the association between aging, head control and fall-related TBI is warranted.

Title: Dual-task cognitive motor interference exacerbates turn deficits in fragile X-associated tremor/ataxia syndrome (FXTAS)

Authors: *J. GUAN[1], J. A. O'KEEFE[2];
[1]Rush Univ. Med. Ctr., Chicago, IL; [2]Anat. and Cell Biol., Rush Univ. Col. of Med., Chicago, IL

Abstract: Individuals with a 55-200 CGG repeat expansion in the fragile X mental retardation 1 gene are at risk for developing FXTAS, a neurodegenerative disorder characterized by cerebellar ataxia and cognitive dysfunction. Balance and gait deficits are a major problem in FXTAS that lead to falls and progressive mobility disability. The impact of dual task (DT) cognitive motor interference or fast paced gait which are real life/challenging conditions has never been studied in FXTAS. We hypothesized that these gait "stress tests" would exacerbate gait and turn deficits and increase fall risk. Thirty individuals with FXTAS (age 66.9 ± 8.8 yrs.) and 35 controls (age 65.5 ± 8.3 yrs.) performed gait analysis using an inertial sensor based 25-meter two-minute walk test (APDMTM) under self-selected (SS) typical pace, fast as possible (FAP) pace and, DT cognitive interference condition asking subjects to perform a concurrent verbal memory task while walking at their normal speed. The dual task cost (DTC) for gait and turn parameters was calculated as (ST-DT/ST x 100). Linear regression analyses were performed to assess the association between FXTAS diagnosis on gait and turn outcomes under the three different gait conditions, controlling for age and sex. FXTAS subjects had marked reductions in stride length and velocity, increased double support and reduced swing phase times, and slower turn velocity and greater number of steps to turn compared to controls ($0.0001 > p < 0.039$) under all 3 test conditions. Under fast paced gait, FXTAS individuals displayed increased gait variability ($p = 0.025$) which is associated with instability and falls. Men participants with FXTAS had significantly elevated DTC for turning speed ($p = 0.036$), indicating cognitive interference for turning, which requires greater motor control compared to straight walking. There were no elevated DTC for spatiotemporal aspects of gait during straight walking, suggesting that men and women with FXTAS prioritized gait over cognition during the DT walking. This was supported by the finding that FXTAS individuals had greater DTC for the cognitive verbal fluency task ($p = 0.004$). The use of DT gait paradigms to cognitively challenge subjects significantly exacerbates turn function in men with FXTAS. Gait stress testing paradigms and associated gait and cognitive markers may be useful in future studies to: 1) help determine fall risk in FXTAS,

2) determine effective treatment interventions for both cognitive and motor deficits to improve cognition, gait and turning and thereby reduce fall risk and 3) provide clinically relevant outcome measures for clinical research.

Title: Ageing brain shows less gait-phase-related modulation of midline sensorimotor cortex

Authors: *H. YOKOYAMA[1], T. YOSHIDA[2], K. MASANI[3];
[1]Tokyo Univ. of Agr. and Technol., Koganei-shi, Japan; [2]Univ. Med. Ctr. Göttingen, Göttingen, Germany; [3]Toronto Rehab Inst., Toronto, ON, Canada

Abstract: Introduction: The elderly tend to show instability during walking compared to the young. Recent studies suggest that the cortical activity plays an important role in the dynamic balance during walking. For example, the modulation of the cortical activity is coupled to gait cycle phases. However, this has been shown only in the young. As ageing is associated with structural and functional changes in the brain, the cortical contribution to the dynamic balance during walking may be also affected by ageing. Here, we tested the hypothesis that the elderly exhibit a different cortical activity during walking competed to the young.
Methods: Fourteen young and nine older men participated in this study. The participants walked straight on a path 40 times. We measured electroencephalographic (EEG) signals using 20 electrodes and lower limb kinematics for 80−120 strides data in each participant. The event related spectral perturbations (intra-stride changes in the spectral power) were calculated for three electrodes: Fz, Cz and Pz.
Results: We found significant spectral power modulations ($p<0.05$) relative to the gait cycle phases in a wide frequency band (10–40 Hz) at Cz in the young group. The power increased during 0−25% and 50−75% of the gait cycle and decreased during 25−50% and 75−100% of the gait cycle. On the other hand, there were no clear spectral power modulations at the other electrodes in the young group and all electrodes in the elderly group. A comparison between the spectral power modulations at Cz between the two groups showed significantly larger power modulations ($p<0.05$) in the gamma band (25–40 Hz) in the young group.
Discussion: The clear gait-related spectral power modulations at Cz (i.e., leg sensorimotor area) in the young group agree with previous studies. We found that the gait-related spectral power is attenuated in the elderly. This agrees with previous studies that showed the attenuation of motor-related cortical activity due to ageing in other motor tasks. Given that the gamma band activity

may be involved in muscle control and perception binding, the significant attenuation in the gamma band activity in the elderly may be related to their gait instability.

Title: Individuals with an ACL reconstruction adopt a more rigid coordination pattern during dynamic movement

Authors: *C. N. ARMITANO, S. MORRISON, D. M. RUSSELL;
Physical Therapy and Athletic Training, Old Dominion Univ., Norfolk, VA

Abstract: The anterior cruciate ligament (ACL) is the most commonly injured ligament in the knee accounting for approximately 200,000 injuries in the United States each year. While the majority of research on individuals with and ACL reconstruction has focused on the local mechanical implications of this surgery, increased attention has been directed towards understanding the impact this injury (and subsequent surgery) could have on neuromuscular function. The aim of the current study was to examine if persons post-ACL reconstruction exhibit slower reaction times under postural conditions. Further, it was also of interest to assess whether there were difference in muscle recruitment patterns and/or movement strategies for persons with an ACL reconstruction compared to healthy controls. Sixteen adults with unilateral ACL reconstruction and 16 age-matched healthy controls participated in this study. Participants stood facing a reaction time light panel where they performed both simple and choice reaction time tasks under postural conditions. When the light source from the reaction time device turned on, participants were instructed to step forward as quickly as possible. Muscle activation of the lower extremity was assessed bilaterally using surface EMG on the gastrocnemius, soleus, vastus medialis, rectus femoris, biceps femoris, and gluteus medius. In addition, accelerometers were placed on the lower trunk, neck, and head to compare upper body acceleration patterns during a dynamic task. The reaction time device as well as the EMG and accelerometers were synced to capture the onset of the light stimulus as well as the onset of movement. The results revealed that the ACL reconstructed group were slower to initiate a step under the postural reaction time conditions. This slowing was seen irrespective of the limb used to initiate the step (i.e. unaffected or surgically repaired). In addition, persons with a reconstructed ACL also exhibited tighter coupling between the upper and lower body while taking a step compared to the controls. The muscle activation patterns of the ACL group revealed increased co-contraction of both lower limbs, possibly in an effort to increases stabilization of the body prior to taking a step. Overall,

these findings indicate that persons who have had an ACL reconstruction adopted a more rigid, coordination pattern during the dynamic stepping tasks that may account for their slower movement responses.

Title: Sonic Hedgehog expression by pyramidal tract neurons is critical for quadrupedal gait coordination

Authors: A. SAJAN[1], **J. SHEN**[2], L. STARIKOV[2], *A. H. KOTTMANN[2];
[1]SUNY Downstate Med. Sch., New York, NY; [2]Molecular, Cell. and Biomed. Sci., City Univ. of New York Sch. of Med., New York, NY

Abstract: Restoring the corticospinal tract (CST) after spinal injury is an unmet need. Recently, seminal studies demonstrated that forced neuronal activity greatly improves functional outcomes in rodent paradigms that are based on partial CST transection. The mechanisms by which electrical activity facilitates restorative and compensatory neuronal growth and synaptogenesis is not well understood. Layer 5 pyramidal tract (PT) neurons express multiple signaling factors throughout life in addition to glutamate including the cell signaling factor Sonic Hedgehog (Shh) (Harwell et al., 2012). In the adult CNS, Shh can be released from nerve terminals by neuronal burst firing. During spinal cord development, Shh is well known for regulating differentiation and congruent growth of neuronal and glial cell populations. In addition Shh signaling is critical for neuronal growth cone guidance of commissural neurons and synaptogenesis. Whether Shh signaling takes part in neuronal repair upon spinal cord injury in the adult is not well understood. We found that pyramidotomy increases up to 5 fold the expression of Shh in the soma of injured PT neurons (PT_{Shh}), indicating that Shh expression might be repressed by negative feedback signaling originating distal to the injury site. These results are reminiscent to the up-regulation of Shh expression in motor neurons and in dopamine neurons by motor neuron axotomy (Akazawa et al., 2003) or neurotoxin induced degeneration of striatal dopamine neuron targets (Gonzales Reyes et al., 2012), resp.. Together these observations suggest that increased Shh signaling is an acute response of projection neurons to their injury. We further find that animals with conditional ablation of Shh from PT neurons incompletely adapt to a complex running wheel: while control litter mates progressively improve running on a wheel in which random rungs were removed, mutants selectively improve placement of front limbs but not hind limbs. These observations suggest that Shh expression by PT neurons is critical for the coordination of

brachial and lumbar motor activity. One mechanism by which PT_{Shh} could influence quadrupedal coordination is by influencing structural plasticity of long distance intra spinal projection neurons. These neurons are critical for transmitting gait cycle status information from the brachial to lumbar spinal cord. We are currently identifying the neuronal subtypes in the spinal projection fields of PT neurons that express the Shh receptor Patched using gene expression tracer alleles. Further, we will test the degree of functional recovery to hemi-section of the spinal cord in animals with Shh ablation from PT neurons and controls.

Title: Influence of neural electrode implant in the median nerve of rhesus monkey on gait parameters of quadruped locomotion

Authors: *J. WON, J. PARK, J. SEO, Y.-J. AHN, H.-G. YEO, K. KIM, C.-Y. JEON, Y. LEE; Natl. Primate Res. Ctr., Korea Res. Inst. of Biosci. & Biotech., Cheongju, Korea, Republic of

Abstract: The aim of this study was to evaluate the gait parameters of rhesus monkeys after implantation of neural electrode. A total of six adult female rhesus monkeys (Macaca mulatta) were used in this study. Three of the monkeys were implanted with fork-type sieve electrode in the median nerve of right upper limb for 4 weeks while the other three were used as a normal control group. We characterized the spatio-temporal and kinetic parameters of quadrupedal gait of rhesus monkeys using a pressure-sensing walkway. In addition, we compared the longitudinal changes in gait parameters and symmetry index to baseline data that acquired prior to surgical implantation. All parameters for gait analysis following neural electrode implant showed significant difference. The laterality of symmetry index was progressively recovered over the course of 4 weeks after surgical implantation. These results indicated that peripheral nerve injury following neural electrode implant could be improved during the post-recovery period. These findings highlighted the features of neural electrode implant for monkey and process of peripheral nerve injury characteristics, providing a basis for the assessment of quadruped locomotion.

Title: Post-concussion recovery timeline of postural stability in a division 1 baseball athlete

Authors: *S. J. CHAVEZ[1], S. M. SORIA[2], K. MANYAK[3], A. J. KOVACS[5], D. J. GOBLE[6], H. S. BAWEJA[4];
[2]Sch. of Exercise and Nutritional Sci., [3]Dept. of Athletics, [4]Sch. of Exercise and Nutritional Sciences, Col. of Hlth. and Human Services, [1]San Diego State Univ., San Diego, CA; [5]Univ. of Wisconsin, La Crosse, WI; [6]Oakland Univ., Rochester, MI

Abstract: Concussions are traumatic brain injuries that alter brain functions such as balance and coordination. Sport-related concussions are critical to assess to avoid further permanent brain damage. The American Medical Society for Sport Medicine advises the use of postural control assessments to detect concussion-related abnormalities. Most of these assessments subjectively quantify balance errors, and these test scores tend to resolve within 72 hours post concussive incident; this may be problematic for athletes. We have recently shown that the use of Balance Tracking System (BTrackS) to assess balance is twice as sensitive as some of the subjective assessments immediately following a concussion. The BTrackS quantifies body sway control from total center of pressure excursion created by foot forces using a gold-standard balance measurement technology. In the current case study, we report the recovery timeline for postural sway from a 20-year-old male Division-I baseball catcher who suffered a concussion due to a direct foul ball hit to his helmet. BTrackS Balance Tests (BBT) were administered during pre-season and again 48 hours, 7, 14, and 21 days post-concussion. Testing consisted of three, 20 second trials where the athlete stood still on the BTrackS Balance Plate with eyes closed, hands on hips and feet shoulder width apart. BBT score was calculated as the average COP excursion across the testing trials. COP excursion is a proxy for total body's sway control. Larger BBT values indicate postural instability and worse balance. Recovery was quantified as the COP values returning to baseline within the Minimum Detectable Change (MDC; 5 cm) criterion for the test. Following the concussion, the athlete exhibit a significant balance decline. His immediate post-concussion sway was over 4 times larger than baseline, which is indicative of significant postural instability. There were two stages of recovery noted. An acute phase where balance improved to 4x MDC by day 7. A second recovery occurred from days 14-21 where the athlete tested within the criterion from baseline. In this report we show that it took more than 72 hours for recovery. While not all concussions cause balance deficits, those that do must be evaluated with sensitive objective tools to ensure complete recovery prior to return to play. A

premature return significantly increases the chances of a second impact in athletes and would have devastating effects on neurological function.

Title: Wearable sensor system to monitor PD gait in activities of daily living

Authors: B. SHIWANI[1], S. H. ROY[1], M. M. SAINT-HILAIRE[2], C. A. THOMAS[2], P. CONTESSA[1], G. DE LUCA[1], *J. C. KLINE[1];
[1]Delsys Inc. and Altec Inc., Natick, MA; [2]Dept. of Neurol., Boston Univ. Sch. of Med., Boston, MA

Abstract: Current technologies to track the quality of gait for monitoring the presence and progression of neurodegenerative diseases such as Parkinson's disease (PD) are limited to instrumented lab setups or can track only a few basic gait parameters with portable settings. Consequently, monitoring clinically relevant metrics of gait in daily living activities remains a challenge. To satisfy this need, our group has developed a system of wearable sensors and automated detection algorithms that can automatically detect the gait activity and quality of gait within each cycle during activities of daily living. We tested this system during a pre/post L-dopa medication protocol among n=6 patients (age: 60.8 ± 11 y) with Parkinson's disease (Hoehn & Yahr 1-3) where gait deviations associated with medication wearing-off was tracked during 3-hours of unscripted activities of daily living in a simulated home environment. Two wearable

sensors were placed on the Extensor Digitorum (ED) and Tibialis Anterior (TA) muscles, respectively, on their most symptomatic side to record surface electromyography (sEMG) and inertial measurement (IMU) signals. Algorithms were designed to autonomously detect and monitor, in real-time, 4 key characteristics of PD gait: 1) angular range of arm movement - to assess degree of arm swing; 2) angular velocity of leg movement- to assess gait velocity; 3) EMG RMS - to analyze the muscle activation patterns during different phases of gait cycle; and 4) heel strike and toe-off dynamics - to analyze landing and propulsive phases of gait. We successfully detected instances of gait amidst other unscripted activities with 99.5% accuracy. All four gait metrics were significantly different ($p<0.05$) between the medication ON and OFF periods (based on expert video annotation). These results demonstrate that our wearable monitoring system can objectively characterize PD gait impairments in non-clinical settings.

Title: Cognitive load does not impact gaze behavior during walking in a real-world environment in older adult fallers and non-fallers

Authors: *L. A. ZUKOWSKI[1], C. A. GIULIANI[2,3], P. PLUMMER[2,3];
[1]Dept. of Physical Therapy, High Point Univ., High Point, NC; [2]Div. of Physical Therapy, Dept. of Allied Hlth. Sci., [3]Human Movement Sci. Curriculum, Univ. of North Carolina at Chapel Hill, Chapel Hill, NC

Abstract: Everyday walking often involves simultaneous performance of a cognitive task in environments with competing auditory and visual stimuli. Previous research has not evaluated task performance in these situations, where older adults are known to fall, limiting our understanding of how older adults adjust their gait, visual scanning (gaze), and cognitive processing to avoid falls (or not). The purpose of this study was to examine the effect of dual-

task walking in a high-distraction real-world environment on cognitive performance, gait performance, and gaze behavior in older adult fallers relative to non-fallers. **METHODS:** Fourteen older adult fallers (76±9 years of age, 11 females, 17±3 years of education) and 15 older adult non-fallers (77±8 years of age, 11 females, 17±2 years of education) participated. Participants performed single-task walking, single-task cognitive (seated category naming), and dual-task walking (category naming + walking) trials for 1 minute each in a real-world environment (busy hospital lobby). Gait speed, gaze fixation duration on 6 areas of interest (AOIs), and percentage of time fixating on 6 AOIs were recorded during single- and dual-task walking trials. Number of correct responses, time to first response, and mean subsequent response time (measure of rate of decline of response retrieval throughout trial) were determined for single-task cognitive and dual-task walking trials. Two-factor mixed MANOVAs (Group x Task) compared cognitive and gait variables for fallers and non-fallers during single- and dual-task trials. A 3-factor mixed MANOVA (Group x Task x AOI) analyzed the gaze variables. **RESULTS:** Compared to single-task trials, during dual tasks, participants walked 0.2 m/s slower ($p<0.01$), had 1.5 fewer responses ($p=0.03$), and a 2823 ms shorter mean subsequent response time ($p<0.01$), indicating a faster declining rate of retrieval. Fallers walked 0.2 m/s slower than non-fallers ($p=0.01$). They also had 3.8 fewer responses than non-fallers during the single-task trial ($p=0.03$) and were 759 ms slower for the first response than non-fallers during dual tasking ($p=0.05$). Gaze behavior (fixation patterns) did not differ by group or condition. **CONCLUSIONS:** Older adult fallers and non-fallers exhibited dual-task decreases in gait and cognitive performance, but they did not change their gaze behavior, which may signify prioritization of visual scanning over gait and cognition. The apparent prioritization by fallers of cognitive performance over gait in a real-world environment, as evidenced by the slowed gait speed during single- and dual-task trials but less consistent cognitive decreases, may be contributing to fall risk.

Title: Hand2 transcription factor enhances NMJ organization and function in old mice

Authors: *A. RODRIGUES[1], H. BONILLA[1], M. MESSI[1], Z.-M. WANG[1], W. M. FREEMAN[2], O. DELBONO[3];
[1]Gerontology-Internal Med., Wake Forest Univ., Winston-Salem, NC; [2]Physiol., Oklahoma Univ. Hlth. Sci. Ctr., Oklahoma City, OK; [3]Intrnl. Medicine, Gerontology, Wake Forest Sch. Med., Winston Salem, NC

Abstract: Over time, declining muscle force and power leads to mobility disability and impaired quality of life. In aging rodents and humans, a denervation and reinnervation process is strongly implicated in *sarcopenia*: the progressive decline of skeletal muscle mass, composition, and function. We propose that the concomitant decline in expression of Hand2, a key transcription factor (TF) for sympathetic neuron maintenance, induces motor pre- and postsynaptic neuromuscular junction (NMJ) instability and disorganization. To counter the deleterious effect of sympathetic denervation, we developed a novel viral vector (AAV9-Hand2-eGFP, Hand2) carrying Hand2 expression exclusively to sympathetic neurons. Male and female, 16-month-old mice, were examined for signs of muscle denervation and sarcopenia 6 months after IV injection with either Hand2 or control empty virus (AAV9-eGFP, EV). We found that Hand2 increased preterminal synaptic vesicle release, neurofilament phosphorylation (Neurite length: Hand2: 3732±496 µm, EV: 2674±165 µm; P <0.01), NMJ pre/postterminal co-localization, hindlimb muscle mass (EDL: 25%, soleus: 14%, tibialis anterior: 17% and gastrocnemius: 25%; n = 6-8 muscles per treatment group; P < 0.01), myofiber cross-sectional area, and protein kinase-A RIIα/RIα ratio (EV, RIIα:1.05±0.03, RIα:0.93±0.04, ratio: 1.13; Hand2, RIIα:1.81±0.03, RIα:0.94±0.03, ratio: 1.94; P<0.001) which contributes to stability of the NMJ. We also examined Hand2 gene methylation, and RNA-sequencing, muscle metabolomics, and whole body and muscle function with aging in EV and Hand2 injected mice. Our data indicate that expression of Hand2 significantly enhances skeletal muscle adrenergic receptor signaling through the canonical pathway, and prevents in NMJ transmission, and muscle mass and function decline with aging.

Title: Open-eyed one leg stand test predicts cognitive function, grey matter volume and white matter volume in healthy older people

Authors: *R. HORIE[1], R. NOUCHI[2], H. TAKEUCHI[2], K. SAKAKI[2,3], S. YOKOTA[4], K. IIZUKA[5], H. C. LEE[2], R. KAWASHIMA[2];

Abstract: Relationships between motor functions and brain structures have been mainly investigated in patient studies. Previous studies showed the association between balance performance and hippocampal volume loss in patients with Alzheimer's disease (AD) and mild cognitive impairment (MCI). However, they focused on specific brain regions such as medial temporal lobe using Region of Interest (ROI) analysis. In addition, they focused on either grey or white matter volumes in patients with AD and MCI. In the present study, we investigated the association between balance performance and both regional grey matter volume (rGMV) and white matter volume (rWMV) using whole brain analysis in healthy older people. Cognitively healthy 109 participants (62 females, mean age = 66.99) performed open-eyed one leg stand test to measure balance performance and 17 cognitive function tests to measure general cognitive function, processing speed, executive function and memory. Regional brain volume was measured by T-1 weighted MRI. The rGMV analysis revealed that the performance of the open-eyed one leg stand test was significantly positively correlated with rGMVs in the hippocampus, the nucleus accumbens, ($p<0.0125$, FWE, TFCE). The rWMV analysis also revealed that the performance of the open-eyed one leg stand test was significantly positively correlated with rWMVs in the superior frontal gyrus, the middle frontal gyrus, the hippocampus ($p<0.0125$, FWE, TFCE). In cognitive function results, the performance of the open-eyed one leg stand test was correlated with the performance of Trail Making Test B ($r=0.28$, $p=0.004$) and that of verbal fluency test ($r=0.21$, $p=0.028$). Consistent with the previous studies in AD and MCI, rGMV and rWMV in hippocampus was significantly correlated with the balance performance in the healthy subjects. On the other hand, we firstly found significant correlations between rWMV in the frontal region. Hippocampus and nucleus accumbens are important for spatial memory, which is associated with the vestibular system. Superior and middle frontal gyri are important for executive function and are related to balance control. Furthermore, this study revealed that open-eyed one leg stand is related to executive function. For older people, open-eyed one leg stand demands somatosensory inputs from the whole body and then they have to adjust the muscle strength or the center of gravity. Therefore one leg stand is associated with these brain regions.

Title: Effect of dopaminergic medication on balance automaticity in Parkinson's disease

Authors: *R. MISHRA[1], C. WORKMAN[2], A. THRASHER[1];
[1]Hlth. and Human Performance, Univ. of Houston, Houston, TX; [2]Healthy and Human Physiol., Univ. of Iowa, Iowa City, IA

Abstract: Background: Dual-tasking is an integral part of every-day life. Despite advances in pharmacological treatments, the problem of impaired dual-tasking persists in patients with Parkinson's disease (PD). Impaired dual-tasking can exaggerate balance dysfunction and increase the risk of falling. Loss of motor automaticity is considered a major reason for impaired dual-tasking in individuals with PD. There is a need to understand the influence of current dopaminergic medication on balance automaticity in PD. Furthermore, studies have shown non-analyses can provide another perspective about balance control, i.e., regularity in the body sway. An increased regularity in body sway indicate an improved and more efficient postural control. Along with conventional measures, non-linear parameters can facilitate to understand better the changes in postural control dynamics in patients with PD.
Research objective: To investigate the effect of dopaminergic medication on standing balance automaticity during a phoneme monitoring dual-task in PD.
Methods: Sixteen individuals with PD participated in a cross-over study involving single- and dual-task upright standing for 3 min, off and on dopaminergic medication, with eyes open and eyes closed (4 trials total). Linear and non-linear analyses were used to evaluate balance performance. The linear measures consisted of 95% confidence ellipse area, anterior-posterior (AP) sway velocity, medial-lateral (ML) sway velocity, and integrated time to boundary (iTTB). The non-linear measure involved percentage of determinism (%DET) based on recurrence quantification analysis.
Results: Compared to medication-off state body sway was more regular during medication-on state indicated by increase in %DET (p=0.007), but only during eyes open condition. Furthermore, medication caused significant increase in ellipse area (p= 0.002) and decrease in the performance on the secondary task (p= 0.004). In addition, different eyes conditions (open vs. closed) significantly increased both sway velocities (AP = $p < 0.001$, ML = $p < 0.001$) and increased iTTB ($p < 0.001$). There was also task by eyes condition interaction effect for AP velocity and iTTB (p= 0.015 and p= 0.009, respectively.
Conclusion: Conventionally, an increase in sway velocity and area is interpreted as poorer balance performance. However, the regularity in body sway increased indicated by increase in %DET. Therefore, in the context of stability, an alternate interpretation for medication-induced balance changes in PD suggest an increase in maneuverability without sacrificing the stability.

Title: Changes in lumbar BDNF gene methylation and locomotor behavior following spinal cord transection in developing rats

Authors: A. L. BOZEMAN[1], T. S. DOHERTY[3], T. L. ROTH[4], *M. R. BRUMLEY[2];
[2]Dept. of Psychology, [1]Idaho State Univ., Pocatello, ID; [4]Psychology, [3]Univ. of Delaware, Newark, DE

Abstract: Although epigenetic activity in the brain is now well documented, relatively little is known about epigenetic regulation of genes in the spinal cord, and how it contributes to neural plasticity and behavioral potential in this part of the CNS. In the brain, methylation of the brain-derived neurotrophic factor (BDNF) gene is implicated in behavioral development and neural plasticity. BDNF is known to play an important role in spinal plasticity, including neural changes that occur following a spinal cord injury and improvements in stepping behavior that are induced by exercise. Therefore, here we examined if DNA methylation of the BDNF gene in the spinal cord is related to development of hindlimb weight-bearing locomotion, in both intact rats and those that received a neonatal spinal cord transection. Neonatal male rats received a low-thoracic spinal cord transection or sham operation on postnatal day 1 (P1). On P10, subjects were behaviorally tested in an open field to measure spontaneous locomotion. Spinal cords were later dissected, and global levels of methylation and exon-specific methylation were measured on the BDNF gene in the lumbar spinal cord. Compared to shams, spinal-transected rats showed significantly less partial- and full-weight bearing locomotion on P10. Global methylation (global 5-mC) levels in the lumbar cord were significantly higher in spinal-transected rats. Bisulfate sequencing PCR was used to measure group differences in BDNF methylation at exons I and IV. Spinal-transected subjects showed significantly higher levels of methylated BDNF at exon I, whereas they showed significantly lower levels of methylated BDNF at exon IX. These data provide evidence that epigenetic alterations are associated with the development of locomotor behavior and following a spinal cord injury, and suggest that environmental influences may have exon-specific effects.

Title: Corticospinal drive is reduced with age during split-belt treadmill walking

Authors: S. SATO, *J. T. CHOI;
Univ. of Massachusetts Amherst, Amherst, MA

Abstract: INTRODUCTION: Older adults are known to have difficulty adapting their gait to environmental challenges (e.g. irregular terrain, obstacles) which may lead to falls or otherwise limit their mobility. Recent studies showed reduced corticomuscular and intramuscular coherence in the beta- and low-gamma frequency band (15-45 Hz), a marker for corticospinal drive, in older adults compared to young adults during walking. However, it is unclear how age-related changes in corticospinal drive impact gait adaptability. The objective of this study was to examine age-related changes in tibialis anterior (TA) intramuscular coherence and adaptation in spatiotemporal gait parameters during split-belt treadmill walking in older adults. METHODS: 5 healthy young (Age: 28.6 ± 9.0) and 5 healthy older (Age: 74.4 ± 2.1) participants walked on a split-belt treadmill. Each session consisted of a pre-adaptation, adaptation, and post-adaptation periods. During the pre-adaptation period, participants walked symmetrically at a slow speed (0.6 m/s) for familiarization, fast (1.2 m/s) speed, and slow speed again for 5 mins each. During the adaptation period, walking was challenged by altering the speed of each leg at a 1:2 speed ratio (0.6 m/s for the slow belt, 1.2 m/s for the fast belt) for 10 mins. During the post-adaptation period, participants walked with both legs at 0.6 m/s for 10 mins. Kinematics were recorded with reflective markers on the lower extremity, and EMG was collected using two pairs of surface electrodes placed at the proximal and distal ends of TA. Intramuscular coherence was calculated between the two pairs of EMG during the swing phase of gait. RESULTS: All participants adapted and de-adapted double support (DSsym) and step length symmetry (SLsym). However, DSsym was more asymmetrical in older adults compared to young adults (DSsym: $p = 0.034$, SLsym: $p = 0.200$). Beta and gamma frequency intramuscular coherence was significantly greater in young compared to old in the fast (Beta: $p = 0.014$; Gamma: $p = 0.006$) and slow leg (Beta: $p = 0.009$, Gamma: $p < 0.001$). In young adults, beta- and gamma-band coherence was modulated in the slow leg (Beta-fast: $p = 0.262$; Beta-slow: $p = 0.003$; Gamma-fast: $p = 0.080$; Gamma-slow: $p = 0.010$). In contrast, older adults did not show any modulation in TA coherence with split-belt adaptation and de-adaptation (Beta-fast: $p = 0.059$; Beta-slow: $p = 0.619$; Gamma-fast: $p = 0.364$; Gamma-slow: $p = 0.533$). DISCUSSION: Beta- and gamma-band intramuscular coherence is reduced in amount, and modulation is absent in older adults compared to young

adults. This may reflect age-related differences in corticospinal neural mechanism during split-belt adaptation.

Title: Repeated exposures to environmental-like concentrations of benzene, toluene, ethylbenzene, and xylene (BTEX) in adolescent Swiss-Webster mice results in alterations to locomotor activity

Authors: *C. J. DAVIDSON, D. W. SVENSON, K. HESLIP, M. NADDAF, S. E. BOWEN; Wayne State Univ., Detroit, MI

Abstract: Volatile organic compounds (VOCs) such as benzene, toluene, ethylbenzene, and xylene are widely utilized in combination in both industry and in-home products. Collectively known as BTEX, these VOCs are present in most urban areas. Volatile compounds are present in low concentrations within the environment and readily vaporize from liquid to gas at room temperature. Although VOC levels can vary, there are relatively higher concentrations found in urban-industrial areas, roadways, and parking structures. With no published preclinical investigation of the effects of BTEX exposure, our model was constructed using peer-reviewed publications that reported environmental concentration ratios and occupational maximums set by OSHA. Adolescent male Swiss-Webster mice were exposed Monday - Friday to BTEX concentrations that were modified to mimic human exposure (1.5 hrs/exposure x 2 exposures/day x 3 weeks = 30 total exposures). Four exposure groups were utilized which included three BTEX exposure mixture “groups”. The first two groups represented a 10- (“ENV 1”) and 100-fold (“ENV 2”) increase above previously reported environmental concentrations. The third group was a positive control which was exposed to the maximum concentrations for occupational exposure (OCC). Finally, an “air only” (“AIR”) exposure condition was used as control. Locomotor activity was assessed during exposure (N=32) and behavioral assays were conducted during and following these exposures (N = 40). Preliminary analysis of locomotor behavior show differential patterns of activity with all BTEX exposure groups (ENV 1, ENV 2, and OCC) initially displaying increases in locomotor activity as compared to AIR. Mice in the OCC group showed a reduction in locomotor activation as repeated exposures continued. Our preclinical

model illustrates that acute BTEX exposure may have significant effects on behavioral measures of gait such as locomotor activity. Pending analysis of fecal bolus, rotarod, inverted-screen, and a baited Y-maze outcomes will provide greater insight into the consequences of repeated BTEX exposure.

Title: Online adjustments of foot placement during walking

Authors: *J. B. SMEETS[1], Y. ZHANG[1,2], E. BRENNER[1], J. E. DUYSENS[3], S. VERSCHUEREN[2];
[1]Human Movement Sci., Vrije Univ. Amsterdam, Amsterdam, Netherlands; [2]Dept. of Rehabil. Sci., [3]Dept of Kinesiology, KU Leuven, Leuven, Belgium

Abstract: We know that hand movements are quickly (latency of about 110 ms) adjusted to small changes in target location. Such changes are of a size that corresponds to the precision with which targets can be reached. Therefore, the circuit underlying such adjustments is presumably important for controlling any movement in a dynamic environment (Smeets et al. 2016). With age, the adjustments become less effective because the latency increases and the vigor decreases (Zhang et al. 2018). The aim of the current study was to investigate whether movements of the foot during walking are adjusted in a similar way.
Participants walked at 3 km/h on a treadmill on which rectangular stepping stones (25 x 10 cm) were projected. The distance between the centers of the stepping stones was 20 cm laterally and 50 cm in the walking direction (corresponding to a leg swing duration of about 400 ms). Every 6-9 steps, a stepping stone was displaced by 2.5 cm in the mediolateral direction 120 ms after toe-off (thus, 280 ms before heel-strike).
We found clear fast adjustments of the foot trajectory, with a latency of about 150 ms for young adults. Older adults took about 20 ms longer. The latency was 10 ms shorter for shifts in the

lateral than in the medial direction. For both age-groups, the center of pressure adjusted 30 ms before the kinematics of the foot. The older adults' responses and responses to perturbations in the medial direction were also less vigorous. The increased latency and reduced vigor in the older adults resulted in less complete responses: they corrected for about 50% of the target shift, whereas younger adults corrected for about 70%. The correction was also larger for displacements in the lateral direction (66%) than for those in the medial direction (54%).
We conclude that despite the cyclic nature of walking, the movements of the foot are controlled in a similar way as those of the hand. The effects of aging on these adjustments might explain some of the mobility problems in the elderly.

Title: The relation between falls risk, slowing of movement, and variability in Parkinson's disease

Authors: *J. R. MOXEY[1], R. SIMMONS[2], A. GRUNSFELD[4], K. THOMAS[5], S. MORRISON[3];
[2]Athletic Training and Physical Therapy, [3]Physical Therapy and Athletic Training, [1]Old Dominion Univ., Norfolk, VA; [4]Sentara, Charlottesville, VA; [5]Sentara, Virginia Beach, VA

Abstract: Parkinson's disease (PD) is a neurodegenerative disorder linked to the loss of dopaminergic neurons within the basal ganglia. The consequences of this disease process often result in a range of neuromotor problems resulting in declines in balance control and, subsequently, increased falls risk. Additionally, the movements of individuals with PD are characterized by a general slowing and changes in variability. This study was designed to investigate the relationship between falls risk, balance, and speed of movement for persons with PD compared to age-matched healthy older adults. It was also of interest to assess whether persons with PD also exhibited changes in the pattern of intra-individual variability (IIV) of these selected neuromotor tasks. Falls risk was measured using the Physiological Profile Assessment, a validated tool which includes tests of vision, sensation, balance, and leg strength.

Values from each test are combined to provide an overall risk score with higher scores denoting greater falls risk. The specific movement tasks performed included simple reaction time, finger tapping, and gait. Reaction time was assessed for the hand and foot (20 trials each). Walking ability was assessed using a Protokinetics pressure sensitive walkway. Individuals performed five walking trials at their preferred speed and five at a self-selected fast speed. For finger tapping, persons tapped at both their preferred speed and as fast as possible on two force sensors with their index fingers. As expected, the PD persons had a significantly increased falls risk compared to the healthy older controls. The heightened falls risk was linked to slower reaction times, decreased tapping speeds, and slower walking patterns (i.e. decreased cadence, slower gait velocity). The increased falls risk and slowing of motor responses for the PD group was also associated with increased within-subject variability during the reaction time, finger tapping, and gait assessments compared to healthy older adults. Together these results illustrate that the consequences of this neurological disease are not simply characterized by slowing of motor function, but increased variability of movement responses also emerges. Further, these results highlight the potential for using IIV measures for assessing the widespread implications of this disease.

Title: The negative effects of cognitive interference on mobility in Huntington's disease

Authors: *N. L. PURCELL[1], J. G. GOLDMAN[3], B. BERNARD[2], J. A. O'KEEFE[1]; [1]Cell and Mol. Med., [2]Neurolog. Sci., Rush Univ. Med. Ctr., Chicago, IL; [3]Shirley Ryan Mobility Lab., Chicago, IL

Abstract: Huntington’s disease (HD) is characterized by a triad of motor, cognitive, and psychiatric symptoms. As HD progresses, previously automatic tasks, like walking, require more cognitive resources. By stressing the locomotor system, dual-task (DT) paradigms and fast-paced gait may reveal or exacerbate deficits not seen under single-task (ST), especially during more dynamic movements, like turning. However, how these “stress test” gait paradigms impact the mobility of HD individuals needs further investigation. Therefore, the goals of this study were to assess 1) how cognitive-motor DT paradigms and fast-paced walking impact gait and turning in

HD and 2) whether gait measures from wearable inertial sensors are sensitive to motor symptom severity in HD. Seventeen HD participants (55 ± 9.7 years) and 17 age-matched controls (56.5 ± 9.3 years) underwent quantitative gait and turn analysis via a 25m, two-minute walk test utilizing an inertial sensor system (APDM^{TM}). Gait was assessed under a 1) self-selected (SS) pace, 2) fast-as-possible (FAP) pace and 3) during a cognitive-motor DT, having subjects perform a verbal fluency task during SS walking. The Unified Huntington's disease Rating Scale-total motor score (UHDRS-TMS) was administered. A cognitive test battery was also administered to examine potential associations between cognitive and gait deficits. Significant DT costs were observed exclusively while turning. HD Individuals took more time ($p = 0.013$) and steps to complete their turns ($p = 0.028$) while dual-tasking compared to controls. HD participants demonstrated significantly slower gait speed and shorter stride length, as well as greater lateral step and stride length variability compared to controls ($p<0.00001$ to 0.034) under all gait conditions. Higher UHDRS-TMS scores, reflecting greater disease severity, correlated with greater stride length variability ($p = 0.001$ to 0.046), but unexpectedly were correlated with less time in double support ($p = 0.004$ to 0.012) and more time in swing phase ($p = 0.003$ to 0.013). These results need further investigation, though may be due to characteristics of choreatic gait and a poorly defined "stutter-step". Lower information processing speed was associated with greater gait variability under SS and FAP conditions. HD Individuals exhibited greater cognitive interference while turning. Executing a turn is a less automatic motion than straight walking, requiring inter-limb coordination, anticipatory control, and greater cortical regulation. The complexity of turning, combined with the dysfunctional motor system in HD, likely makes it more susceptible to the negative effects of DT cognitive interference.

Title: Proportional myoelectric control of a powered ankle prosthesis for the enhancement of postural control under expected perturbation: A pilot study

Authors: *A. FLEMING[1], H. HUANG[2];
[1]Biomed. Engin., NC State Univ. & UNC, Raleigh, Chapel Hill, NC; [2]NCSU/UNC Joint Dept. of

Biomed. Engin., North Carolina State Univ. and Univ. of North Carolina-Chapel Hill, Raleigh, NC

Abstract: Under expected perturbation, the body works to maintain balance by employing postural control mechanisms like Anticipatory and Compensatory Postural Adjustments (APAs & CPAs). Post-amputation, transtibial amputees lose active control of their ankle-joint system and are forced to incorporate the use of a passive ankle joint into these postural control mechanisms. Without the ability to change ankle joint mechanics, amputees adopt postural control strategies that rely more heavily on their intact limb. This leads to the potential for decreased medio-lateral (ML) stability and higher risk for overuse injury of the intact limb. Proportional myoelectric control of ankle prostheses has been used to restore active ankle control by using descending neural commands via electromyography (EMG) from residual muscles in transtibial amputees. This control paradigm has been tested in cyclic tasks like walking and tasks that involve a single residual muscle. However, the ability for previously antagonistic residual muscles to generate coordinated contractions for the control of non-cyclic tasks like postural control were unaddressed.
In this pilot study, we investigated the potential for residual antagonistic muscles to generate APAs, and we investigated the potential benefit of proportional myoelectric control of a powered ankle prosthesis to stability under expected perturbation. We used a predictable pendulum drop task with a single transtibial amputee. In two sessions the participant used his prescribed passive device and a powered device controlled by residual Tibialis Anterior (TA) and Lateral Gastrocnemius (GAS) muscle activations. In the powered condition the transtibial amputee generated significantly earlier activations from the residual TA ($p=0.007$), higher anticipatory center of pressure (CoP) excursions ($p=0.017$) and reduced peak center of mass excursions ($p=0.021$). Peak ML CoP excursions were also less in the direction of the intact limb ($p=0.003$). The results from this pilot study demonstrate the promise for transtibial amputees to generate APAs with residual antagonistic muscles. This study provides a basis to further investigate the potential for proportional myoelectric control of a powered ankle prosthesis to improve stability under expected perturbation.

Title: Chronic impairments of postural stability associated with history of concussion

Authors: *N. REILLY, J. PREBOR, J. MOXEY, E. SCHUSSLER;
Sch. of Physical Therapy and Athletic Training, Old Dominion Univ., Norfolk, VA

Abstract: Concussion is a common type of mild traumatic brain injury (mTBI) that results in cognitive, physiological and biomechanical symptoms. Individuals recovering from a concussion display deficits in postural stability during quiet stance such as increases in center of pressure (COP) displacement and a decrease in regularity (i.e. entropy) of postural sway. However, the lack of availability of specialized equipment to assess these measures in concussed individuals is a common limitation for clinicians making return-to-play decisions, increasing the risk of premature return-to-play. This study was designed to assess persisting deficits in postural stability during upright standing in individuals with history of one or multiple previous concussions long after medical clearance in comparison to individuals that have been never sustained a diagnosed concussion. Postural stability was assessed by having participants stand on a force plate under four conditions assessing balance by challenging the vestibular system (bipedal and unipedal stance) and cognitive demand (single and dual task). COP root mean square (RMS), velocity and regularity (i.e. sample entropy) were calculated in both the sagittal and frontal planes. All participants displayed greater COP displacement and velocity in both the sagittal and frontal planes in unipedal stance compared to bipedal. Individuals with a history of multiple concussions displayed significantly increased COP displacement and decreased sample entropy values (more regular) during the dual task conditions compared to those who had suffered a single concussion and those without a history of concussion. In addition, individuals with a history of multiple concussions displayed significantly slower COP velocity in both the sagittal and frontal planes during both the single and dual task conditions compared to those with a history of a single concussion as well as those that have never sustained a concussion. Overall, our findings support the notion that deficits in postural stability persist long after the return-to-play decision is made. There appears to be a cumulative effect of concussions on deficits to integration of sensory information, exemplified by the greatest deficits in stability being seen in individuals that have a history of multiple concussions. Clinically, these findings represent the need for more sensitive measures of impairment following concussion.

Title: Functional impact of white matter aging among adults aged 50 years and above: A cross-sectional study

Authors: *P. NAIR[1], P. BALASUNDARAM[2], D. VIBHA[1], S. DWIVEDI[3], N. KUMAR[4], S. GAIKWAD[2], K. PRASAD[1];
[1]Dept. of Neurol., [2]Dept. of NeuroRadiology, [3]Dept. of Biostatistics, [4]Dept. of Psychiatry, All India Inst. of Med. Sci. (AIIMS), New Delhi, India

Abstract: Background- Cerebral aging is a complex and heterogeneous process. Magnetic resonance imaging (MRI) is used to identify and quantify non-disease-related aging of the cerebral white matter. Increased white matter hyperintensities (WMHs), cerebral atrophy, reduced micro-structural integrity are common findings among older adults and have been associated with cognitive and gait impairment. This study examined the impact of multimodal white matter imaging on mobility and cognitive functions among community dwelling adults aged 50 years and above. **Design:** Cross-sectional sub-study of AIIMS cohort study. **Setting:** Medical Site; AIIMS Cohort Study. **Methods:** 36 participants (50 to 75 years) without any prior history of neurological or orthopedic disorder were included. Neuroimaging measures included volumetry ; WMH; FA & MD; Mobility was evaluated using walkway system with 30 comprehensive spatio-temporal parameters of gait (pace, rhythm, variability etc); Prospective recording of fall assessment was done. Cognitive measures included color tail test A & B for executive functions and MMSE. Depression was also evaluated using the Geriatric depression scale. **Results-** The mean age was 62 (±2.34) years, 44% were male. WMHs were found in 19 out of 36 participants; Fall was recorded in 4 out of 36 participants. WMHs were found to be significantly associated with gait velocity (P value =0.009), stride length (P value =0.025), double stance time (P value =0.036) and body mass index (p = 0.042); Reduced gait velocity was associated with reduced FA and higher MD in corpus callosum. Executive function, MMSE, depression and other vascular risks factors like hypertension, diabetes, and smoking found no significant association. **Conclusions:** The data suggests that in non-clinical aging populations, mobility measures may be sensitive to sub-clinical variance in brain MRI measures. Future studies should incorporate quantitative imaging markers of cerebral perfusion and functional imaging parameters which may offer additional clinically relevant information.

Title: Determine the kinematic differences between healthy controls and patients with unilateral vestibular deafferentation during gait and gaze stability exercises

Authors: *L. WANG, O. ZOBEIRI, J. MILLAR, M. SCHUBERT, K. CULLEN;
Johns Hopkins Univ., Baltimore, MD

Abstract: The vestibular system, which senses head motion, is critical to maintaining balance and stabilizing gaze. Patients with vestibular schwannoma (VS) resection suffer from vestibular hypofunction which significantly affects their daily activities. Clinicians prescribe rehabilitation exercises of gaze and gait stability to regain functional improvement related to vestibular hypofunction. The best exercise should challenge the patients' existing function, while not allowing errors of vestibular signal to become too large. However, the prescriptions of exercise are based on limited observation in the clinic and subjective opinion. In the current study, we aim to determine the appropriate type and dosing of exercises by looking through the kinematic differences between healthy controls and patients during gait and gaze stability exercises. Age-matched healthy controls were tested once. VS patients were tested pre-operatively and during six weekly post-surgical visits. Motion signals were recorded using six-dimensional motion sensors (3-axis linear acceleration and 3-axis gyroscope) from head, back, waist, right and left ankles, and dominant hand while they perform a series of gaze stabilization, balance, and gait exercises. We found that: 1) in most of the gaze stabilization exercises, the velocity and variability of patients' head movements were smaller than controls before surgery, decreased significantly after surgery, and gradually returned to their pre-surgery baseline after 6 weeks. 2) in balance exercises, the patients' head and waist stability was comparable to controls. 3) in gait exercises, patients' gait speed was comparable to controls, whereas their head and waist movements were smaller. While these results confirm the wide-accepted idea that increasing head movements is important for VS patients, it is also suggested that patients would benefit from increasing their waist movements during rehabilitation exercises and daily activities. Therefore, clinicians could prescribe gait exercises that require more head and waist movements and instruct patients to increase the amplitude and variability of these movements with the help of real-time kinematic data. Overall, our data suggest that both patients and clinicians can benefit from an enhanced prescription that addresses multiple aspects of vestibular symptoms by monitoring a wide range of kinematic data.

Title: Transcutaneous spinal cord stimulation facilitates stepping performance in stroke patients

Authors: *Y. GERASIMENKO[1], D. SAYENKO[2], N. SANCHEZ[3], J. M. FINLEY[3], *V. R. EDGERTON[4];
[1]Pavlov Inst. of Physiol, St. Petersburg, Russian Federation; [2]Dept. of Neurosurgery, Ctr. for Neuroregeneration, Houston Methodist Res. Inst., Houston, TX; [3]Div. of Biokinesiology and Physical Therapy, USC, Los Angeles, CA; [4]Dept Integrative Biol. & Physiol., Univ. of California Los Angeles, Los Angeles, CA

Abstract: The loss of joint coordination and gait dysfunction is a typical case in subjects after stroke, and gait recovery is a major objective in the rehabilitation for stroke patients. The aim of this study was to develop neuromodulatory techniques using transcutaneous spinal cord stimulation (tSCS) to improve lower-limb motor function and walking abilities in stroke patients. Our previous findings demonstrated that tSCS can activate spinal locomotor-related neuronal network and facilitate the recovery of voluntary movements in SCI patients. In the present studies we examined the effects of multisite non-invasive tSCS in regulation of stepping movements in people post-stroke. The participants were placed in a special device to suspended legs beyond the edge of a table so they could perform a bilateral oscillating stepping-like motion in the presence or absence of multisite transcutaneous spinal cord stimulation. Stroke participants (n=9 were tested while lying on their side with the upper paretic leg supported in a sling directly at the shank and the lower non-paretic leg placed on a free rotating brace segment attached to a horizontal board supported by vertical ropes secured to hooks in the ceiling. By using this "Zero-G" suspension apparatus, the participant's legs were supported and allowed to move freely in the horizontal plane in a gravity-neutral manner.
Non-invasive spinal cord stimulation at a frequency of 30 Hz using a custom-built constant-current stimulator was delivered transcutaneously at three independent sites, along the midline and between the spinous processes of vertebrae C5-C6, T11–T12, and L1–L2. The intensity (range: 40–90 mA) of tSCS was adjusted sufficiently to generate involuntary rhythmic movements without causing discomfort. EMG activity of leg muscles and limb kinematics were monitored. We have found that tSCS facilitated the limb displacement in 7 of 9 participants. During tSCS bilateral stepping-like oscillations were more symmetrical between paretic and non-paretic legs. Spinal stimulation at three sites was more effective than at one site. The mean joint

displacement for the toe, ankle, knee, and hip of the paretic leg during voluntary stepping-like oscillations in the presence of tSCS was greater by 118%, 123%, 130%, and 124%, respectively, compared to voluntary stepping-like oscillations alone. We suggest that this non-invasive spinal neuromodulation can be a viable clinical approach to improve the control of stepping in stroke patients.

Title: Transcutaneous spinal stimulation modulates overground walking performance in individuals post-stroke

Authors: ***J. M. FINLEY**[1], N. SANCHEZ[1], Y. GERASIMENKO[2,3], D. SAYENKO[4], V. EDGERTON[3];
[1]Div. of Biokinesiology and Physical Therapy, USC, Los Angeles, CA; [2]Pavlov Inst. of Physiol., St. Petersburg, Russian Federation; [3]Dept Integrative Biol. & Physiol., Univ. of California Los Angeles, Los Angeles, CA; [4]Houston Methodist, Houston, TX

Abstract: Walking impairments contribute to post-stroke disability and as a result, improving walking function is a common priority of neurorehabilitation. Although the immediate deficits following stroke result from damage to supraspinal circuits, there is considerable evidence that supraspinal lesions also result in long-term changes in the properties of spinal networks. Recent efforts have demonstrated that transcutaneous spinal stimulation (tSCS) in people with spinal cord injury can lead to improvements in posture and voluntary stepping capacity. However, it remains to be seen if tSCS can overcome the brain-induced disruption of spinal function and improve walking function post-stroke. Here, we explored the use of tSCS to modulate spinal locomotor networks and improve locomotor function in stroke survivors. Our general hypothesis is that noninvasive stimulation of the lumbosacral spinal cord can attenuate the asymmetric motor impairments imposed by supraspinal stroke. Nine individuals in the chronic stage of stroke recovery participated in a study where they walked at their self-selected speed overground with

and without tSCS. Participants completed two walking trials with no stimulation, followed by a set of trials where they walked while receiving tSCS at 30 Hz using a custom constant current stimulator. Stimulation was applied at three sites, between the spinous processes of T11 and T12, T12 and L1, and C7. Stimulation intensity ranged from 60 to 140mA and was individualized based on each participant's tolerance to the stimulation. Finally, participants walked without stimulation to determine if there were any lasting effects of the stimulation. We measured joint kinematics and spatiotemporal features using a 10-system motion capture system. Seven out of nine participants increased their paretic stance and swing times by 0.04 ± 0.05 s (4.33 ± 3.45%) and 0.02± 0.02 s (3.75 ± 3.45%), respectively, when walking with tSCS. After stimulation was turned off, paretic stance time remained 0.05 ± 0.04 s (6.55 ± 5.73%) longer than baseline in eight participants. There were no consistent changes in step lengths or joint ranges of motion. These preliminary results suggest that transcutaneous electrical stimulation has the potential to be applicable in the recovery of gait post-stroke. Increases in paretic stance time following stimulation suggest that upregulation of spinal circuitry may facilitate stabilization and/or propulsion with the paretic limb. Future work is necessary to determine the mechanisms by which tSCS leads to changes in lower extremity function post-stroke.

Title: Elucidating sex specific effects of stress on T helper cell subpopulations

Authors: *G. N. RIVERO BALLON[1], A. P. JOHNSON[3], J. R. RAINVILLE[1], G. E. HODES[2]; [1]Sch. of Neurosci., [2]Neurosci., Virginia Tech., Blacksburg, VA; [3]Virginia Polytechnic Inst. and State Universit, Blacksburg, VA

Abstract: Globally over 300 million people live with depression, but women are almost twice as likely to be diagnosed. Men and women often have different symptoms of depression, and women tend to have more issues with weight gain or loss, feelings of sadness and melancholy,

while men tend to have more difficulty sleeping, feelings of anger and aggressive behaviors. Current treatments for depression fail to adequate relieve symptoms in up to one third of patients, and women are more like to be treatment resistant than men. The mechanism underlying these sex difference are not fully understood, and have not been adequately addressed when developing treatments. Previously, we explored the cytokine profiles of men and women with treatment resistant depression, non- treatment resistant depression and healthy controls. Our analysis of cytokine expression in blood samples from patients undergoing depressive episodes suggests the possibility that T helper cell sub populations may be differentially regulated in men and women with depression, and that treatment resistant women experience the strongest dysregulation in cytokines associated with Th1, natural killer T (NKT) cells, and Th17 associated cytokines. Here we present data using a variable stress model to induce T cell changes and explore their relationship to behavioral responses in male and female mice. Female mice are stress susceptible following 6 and 28 days of variable stress, while males are resilient at following 6 days of variable stress, but susceptible following 28 days of variable stress. Our preliminary findings have shown that T helper cells (CD4+) expressed at a higher percentage of the total white blood cell numbers in female mice, but that neither 6 nor 28 days of stress affects the total percentage of CD4+ T cells. We hypothesize that CD4+ T cell differentiation is affected by stress in females, but not males. We will present data characterizing the effects of 6 and 28 days of stress on T cell differentiation by measuring changes in percentages of different CD4+ T cell subpopulations, including Th1, Th2, Th9, Th17, and NKT cells by flow cytometry. We will discuss the relationship between individual behaviors from a test battery and numbers of T cell subpopulations, in order to determine the contribution of specific T cell subpopulations to susceptibility or resilience to variable stress.

Title: Sex differences in the effects of stress on microglia morphology are region specific

Authors: *M. TSYGLAKOVA[1], J. R. RAINVILLE[2], D. MCDANIEL[1], G. E. HODES[3]; [2]Sch. of Neurosci., [3]Neurosci., [1]Virginia Tech., Blacksburg, VA

Abstract: Depression and anxiety are common and debilitating mood disorders, that are more prevalent in females than males. Stress is a trigger for many mood disorders and has effects on plasticity in the brain's reward circuitry, including Nucleus accumbens (NAc) and Hippocampus (HPC). We previously demonstrated that 6 days of variable stress (SCVS) sex specifically regulates plasticity in NAc. SCVS induced a behavioral stress response in females but not males, whereas 28 days of chronic variable stress (CVS) triggered depression-associated behavior in both sexes.Microglia are implicated in regulating neuronal plasticity during development and in disease states. To characterize the effects of SCVS and CVS on microglial populations we examined microglial number and density in the NAc core and shell sub-regions, as well as CA1 region of HPC of male and female mice. Variable stress consisted of three different stressors: foot shock, restraint tube and tail suspension. Each stressor was administered for one hour, and stressors alternated each day for either 6 (SCVS) or 28 (CVS) days. We then used immunohistochemical analysis for expression of ionized calcium binding adaptor molecule 1 (Iba1) in the NAc core and shell sub-regions and CA1 hippocampal region. We found that following SCVS, when only females were behaviorally susceptible to stress, there was a sex-specific effect on the number of microglial cells and microglial density in the NAc, but not in CA1. Both microglial density and number decreased in the core sub-region in females only, along with a decrease in cell counts in shell. In males, who are stress resilient following SCVS, we did not find any changes in microglia number or density. Following CVS, when both sexes are stress susceptible we found a significant interaction between sex and stress in the microglial density in the shell sub-region, no significant changes were observed in CA1. These data suggest that stress has sex and region-specific effects on microglia morphology and number which potentially modulate sex specific effects of neuronal plasticity and the higher rate of mood disorders in females. To further investigate functional changes of morphological alterations in microglia following stress, and to determine whether mice remain stress susceptible in the absence of microglial activation, we administered minocycline, microglial activation inhibitor in the drinking water to female mice. Our results indicate that following SCVS, minocycline has a behavior specific effect in female mice.

Title: Sex differences in the regulation of braininterleukin 1 beta in response to chronic stress

Authors: *D. F. BARNARD[1], K. M. GABELLA[1], A. C. KULP[1], A. D. PARKER[1], P. B. DUGAN[1], J. D. JOHNSON[2];
[2]Biol Sci. Dept, [1]Kent State Univ., Kent, OH

Abstract: Elevations in brain interleukin-1 beta (IL-1β) during chronic stress exposure have been implicated in behavioral and cognitive impairments associated with depression and anxiety. Two critical regulators of brain IL-1β production during times of stress are glucocorticoids and catecholamines. These hormones work in opposition to one another to inhibit (via glucocorticoid receptors) or stimulate (via beta-adrenergic receptors: β-AR) IL-1β production. While chronic stress often heightens both corticosterone and catecholamine levels, it remains unknown as to how chronic stress may affect the "yin-yang" balance between adrenergic stimulation and glucocorticoid suppression of brain IL-1β. To investigate this further, male and female rats underwent 4 days of stress exposure or served as non-stressed controls. On day 5, animals were administered propranolol (β-AR antagonist), metyrapone (a glucocorticoid synthesis inhibitor), vehicle, or both drugs and brain IL-1β mRNA was measured by rtPCR in limbic brain areas. In males, administration of propranolol had no effect on IL-1β expression in non-stressed controls but significantly reduced IL-1β in the hippocampus and amygdala of chronically stressed animals. In females, propranolol significantly reduced IL-1β in the amygdala and hypothalamus of both control and stressed rats. In male rats, metyrapone treatment significantly increased IL-1β mRNA regardless of stress treatment in all brain areas, while in female rats metyrapone only increased IL-1β in the hypothalamus. Interestingly, propranolol treatment blocked the metyrapone-induced increase in brain IL-1β indicating the increase in brain IL-1β following metyrapone treatment was due to increase β-AR activation. Additional studies revealed that metyrapone significantly increases norepinephrine turnover in the hypothalamus and medial prefrontal cortex in male rats and that microglia appear to be the cell type contributing to the production of IL-1β. Overall, data reveal that stress exposure in male rats affects the regulation of brain IL-1β by the norepinephrine-β-AR pathway, while stress had no effect in the regulation of brain IL-1β in female rats.

Title: Sex differences in corticotropin-releasing factor (CRF) receptor trafficking in the locus coeruleus of mice conditionally overexpressing CRF: Implications for amyloid beta distribution

Authors: *J. A. ROSS[1], B. A. REYES[2], V. B. RISBROUGH[3], E. J. VAN BOCKSTAELE[4]; [1]Pharmacol. and Physiol., Drexel Univ. Col. of Med., Philadelphia, PA; [2]Pharmacol. & Physiol., Drexel Univ., Philadelphia, PA; [3]Dept. Psychiatry, Univ. of California San Diego, La Jolla, CA; [4]Dept. of Pharmacol. & Physiol., Drexel Univ. Col. Of Med., Philadelphia, PA

Abstract: The locus coeruleus (LC)-norepinephrine (NE) system is an underappreciated and understudied area of research in the context of Alzheimer's disease (AD). Clinical studies have correlated stress with increased risk for developing AD, and preclinical studies demonstrate that amplification of the stress system disrupts cellular and molecular processes at the synapse, promoting the production of the amyloid beta (Aβ) peptide. Stress-induced activation of the LC is mediated by corticotropin releasing factor (CRF), and CRF receptor 1 (CRFR1) exhibits sex-biased stress signaling. In previous studies, we examined the cellular substrates for interactions between Aβ and tyrosine hydroxylase (TH) a marker of noradrenergic somatodendritic processes in the LC in mice conditionally overexpressing CRF in the forebrain (CRF OE) under a Doxycycline (DOX) regulated tetO promoter. These studies revealed significant sex differences in Aβ distribution in the coeruleo-cortical pathway of CRFOE mice. We hypothesize that these sex differences may partly be due to the sex-dependent trafficking of CRFR1, because CRFR1 signaling significantly influences the production of Aβ and CRF OE males internalize CRFR1 in response to stress signaling, an adaptive response that is not observed in females. In the present study we sought to determine the subcellular localization of CRFR1 in the LC of CRF OE male and female mice in relation to Aβ and TH using triple labeling immunoelectron microscopy. Some tissues sections were also processed for single immunogold labeling of CRFR1. Semi-quantitative analysis of CRFR1 trafficking was calculated as a ratio of cytoplasmic-to-total silver grains, and showed that male CRF OE have 70% ±1% (96/134) cytoplasmic immunolabeled CRFR1, compared to 47% ±1% (40/85) in male controls. Female CRF OE mice showed 49% ±1.5% (214/433) cytoplasmic CRFR1, compared to female controls that exhibited 59% ±0.5% cytoplasmic CRFR1. Two-way ANOVA indicated that the effect of sex, treatment, and interaction were significant ($p<0.05$). Tukey's post-hoc analysis indicates that CRF OE males were significantly different than CRF OE females, with males showing a greater percentage of internalized CRFR1. CRF OE male mice exhibited 63%, while female CRF OE mice exhibited 64% of TH-immunoreactive (ir) and CRFR1-ir profiles that were also Aβ-ir.Male control mice exhibited 66% while female control mice exhibited 50% of TH-ir and CRFR1-ir profiles that were also Aβ-ir.These findings are consistent with previous CRFR1 trafficking studies in behavioral models of stress, and could have significant implications for Aβ production throughout the coeruleo-cortical pathway.

Title: Androgens mediate sex differences in hypothalamic corticotropin releasing hormone gene expression following adrenalectomy of mice

Authors: *A. L. HECK, R. J. HANDA;
Biomed. Sci., Colorado State Univ., Fort Collins, CO

Abstract: Although prominent sex differences exist in the hypothalamic pituitary adrenal (HPA) axis's response to stressors, few studies of its regulation in the hypothalamic paraventricular nucleus (PVN) have compared both male and female subjects. In this study, we sought to explore sex differences in the acute regulation of PVN neuropeptide expression following glucocorticoid (GC) removal and the underlying role of gonadal hormones. We first examined the effects of short-term adrenalectomy (ADX) on PVN corticotropin releasing hormone *(*CRH*)* and arginine vasopressin (AVP) gene expression in adult mice using *in situ* hybridization. ADX increased PVN CRH mRNA levels by two days after ADX in males only, whereas both sexes showed increases in CRH mRNA after four days. In contrast, PVN AVP mRNA was increased at two and four days after ADX in both sexes. To determine if gonadal hormones contributed to this sex bias, we examined adrenalectomized (ADX'd) and gonadectomized (GDX'd) mice with or without gonadal hormone replacement. Using droplet digital PCR, we found that, unlike the pattern in intact animals, two days following ADX/GDX, PVN CRH mRNA levels did not increase in either sex. When males were given dihydrotestosterone propionate (DHTP), CRH mRNA levels increased in ADX'd/GDX'd males similar to those observed following ADX alone. To determine a potential mechanism, we examined the co-expression of androgen receptor (AR) immunoreactivity and PVN CRH neurons using the *Crh-IRES-Cre;Ai4* transgenic mouse model in which CRH neurons are permanently tagged with a fluorescent protein. Abundant colocalization was found in the anteroventral bed nucleus of the stria terminalis, but it was limited in the PVN. Our findings ultimately reveal a sex difference in PVN *Crh* expression following the removal of GC negative feedback that may depend on indirect AR actions in males. Supported by NIH RO1-DK105826.

Title: Stress effects on impulsive choice depend on sex and time of exposure during development

Authors: *E. ORDOÑES SANCHEZ[1], J. FLOWERS II[2], C. M. ROGERS[2], C. S. ARDEKANI[2], S. B. FLORESCO[4], D. A. BANGASSER[3];
[1]Psychology, [3]Dept. of Psychology and Neurosci. Program, [2]Temple Univ., Philadelphia, PA; [4]Univ. British Columbia, Vancouver, BC, Canada

Abstract: Stress can alter cognition. However, few studies have examined how stressors experienced early life versus in adulthood may affect impulsivity. Adversity early in life is of particular interest because it has lasting effects on health that persist into adulthood, but when it is not overwhelming it can promote resilience. Likewise, repeated stressors experienced in adulthood can aggravate and contribute to symptoms of several disorders. Here we examined how repeated stress either early in life or in adulthood affected impulsive choice on a delayed discounting (DD) task in male and female rats. In DD, rats chose between two levers, one of which provided a small reward immediately, versus another which delivered a larger reward following a delay. Preference for the small, immediate reinforcer served as an index of impulsive choice. Early life adversity was modeled using the limited bedding and nesting (LBN) paradigm, wherein, a dam's access to nesting materials was restricted during the pups first week of life. This manipulation increases maternal care, perhaps as a compensation for the limited resources. Once LBN rats reached adulthood, we compared impulsive choice to controls raised with ample nesting material. In comparison, the effects from moderate stressors in adulthood was probed by exposing rats to a 6-day chronic variable stress (CVS) procedure, consisting of three alternating stressors: restraint (1 hr), predator odor exposure (15 min), and forced swim (15 min). After each stressor exposure (30 min), rats were tested on the DD task and this continued for several days after stressor cessation. Early LBN exposure decreased impulsive choice in adult males relative to control reared males. Interestingly, LBN exposure had no effect on choice in adult female rats. In contrast, preliminary findings suggest that adult CVS exposure increases impulsive choice in males that persisted several days after stressor exposure. However, CVS had no effect in females. Collectively, these results indicate that stress can differentially alter impulsive choice in males in a manner dependent on the developmental timing of stress exposure. Females appear resilient to these stress manipulations and future studies will examine mechanisms that promote

this resilience. These findings also suggest that stress in adulthood may increase impulsivity in males that in turn may contribute to these symptoms observed in certain psychiatric disorders.

Title: Sex specific effects of early life stress on development and steroid hormones

Authors: *C. S. ARDEKANI[1], S. ECK[2], S. LUZ[4], E. KIM[2], M. SALVATORE[5], A. HALL[2], S. FAMULARO[2], S. BHATNAGAR[4], D. A. BANGASSER[3];

Abstract: Early life adversity can alter maturation and development, affecting endpoints such as the timing of puberty and reproductive function. However, these effects seem to differ depending in the type and timing of stressor exposure, and the mechanisms by which this occurs are largely unknown. Here we used limited bedding and nesting (LBN) model of early life adversity in Long Evans rats to examine its effects development and sex steroid hormones. In LBN, dams and pups are exposed to a limited resource environment where the dams lack proper materials to build a nest from the pups' postnatal days 2-9. This manipulation is compared to control housing conditions in which rat dams have access to ample nesting materials and enrichment. We found that the LBN manipulation reduced weight gain in both male and female pups and this effect was observed into adulthood. Additionally, the anal genital distance (AGD) of rats exposed to LBN was smaller in both males and females after LBN, even when controlling for weight. Smaller AGDs result from lower androgen exposure, suggesting that LBN disrupts the efficacy of this class of hormones. In females, LBN had no effect in puberty on the timing of vaginal opening or estrous cycle length in adulthood, suggesting that, in our hands, this manipulation does not have lasting effects on female reproductive function. However, LBN did increase estradiol levels in both adult male and female rats, although this effect was clearly driven by the males. In contrast, testosterone levels were comparable in adult male rats in both the LBN and control nesting condition. Given that testosterone is converted to estradiol by aromatase, these results suggest an increase in aromatase activity in males exposed to LBN. Ongoing studies are exploring whether

LBN males have altered reproductive behavior compared to controls to provide deeper insight into the consequences of early life adversity on male reproductive function. Together, these results suggest that LBN alters development in both males and females, but the effect on steroid hormones is more persistent in males.

Title: Pubertal chronic sleep restriction induces depression-like behavior and alters stress response in a sex-specific manner

Authors: *M. S. MURACK[1], É. MALETTE-GUYON[1], R. CHANDRASEGARAM[2], É. RHÉAUME[1], Z. NANJI[1], S. SEMCHISHEN[3], E. AH-YEN[1], O. LATUS[1], C. MESSIER[1], N. ISMAIL[1];

Abstract: Depression is a highly prevalent and debilitating disorder responsible for decreased quality of life and heightened risk of suicide. The rate of major depression diagnoses increases at pubertal onset, especially in females. Puberty is a critical period of development characterized by increased synaptic pruning and plasticity in the brain. Maladaptive rewiring of neurons allow for increased vulnerability to pubertal and even adult psychiatric disorders. Exposure to chronic stress such as sleep restriction downregulates corticosterone release from the adrenal glands and decreases glucocorticoid receptor (GR) activation in areas associated with depressive behaviour (i.e. hippocampus, hypothalamus and dorsolateral prefrontal cortex). Chronic sleep restriction (CSR) is a natural characteristic of early pubertal development. Yet insomnia is a common symptom of most depressive disorders. Therefore, CSR may increase depressive behaviour via stress - related correlates. To address this possibility, eighty male and female pubertal and adult mice were allowed normal rest or were sleep restricted for eight consecutive days during the first four hours of their sleep cycle. Depressive behaviour was measured with the forced swim test. GR expression and activation via c-Fos protein staining was assessed with immunohistochemistry. Sleep restricted pubertal females displayed greater depressive behaviour

compared to non-sleep restricted controls as well as their adult counterparts. Pubertal females exposed to CSR displayed less GR activation in the hippocampus compared to pubertal males. CSR likely affects the onset of pubertal female depression along established stress pathways. Through manipulation of sleep habits in puberty, we may prevent the early onset and development of depression.

Title: Early life stress effects on microglia function, blood brain barrier gene expression, and sex differences in mood-related behavior

Authors: *A. I. SAULSBERY[1], C. M. DODSON[2], H. D. LICHTENSTEIN[2], S. P. MURPHY[1], K. M. LENZ[2,1,3];
[1]Psychology, [2]Neurosci., [3]Inst. for Behavioral Med. Res., The Ohio State Univ., Columbus, OH

Abstract: In humans, early life stress is associated with increased vulnerability to later-life psychological disorders and cognitive dysfunction. The mechanisms that underlie this increased vulnerability are not fully understood; however, it is possible that early life stress (like adult stress in rodents) induces activation of immune cells, including mast cells and microglia. This activation could alter microglia function, or mast cell degranulation could compromise blood-brain barrier (BBB) integrity, enabling peripheral immune cell infiltration into the brain. We have previously found that daily brief handling stress increases mast cell numbers in the female hippocampus on postnatal day (PD) 11 (Joshi et al., in press). Early life stress may alter the function of microglia, including phagocytosis, which contributes to neurodevelopmental processes such as neurogenesis and synaptic patterning (Nelson et al., 2019). Here, we subjected male and female Sprague-Dawley rat pups to 4hr/day of maternal separation stress (or brief control handling) during the light cycle from PD2-20. Half of the pups were sacrificed at PD21; a randomly chosen hemisphere of each brain was subsequently processed for gene expression

analysis via qPCR. Another cohort was raised to adulthood and tested for anxiety- and depression-like behaviors in the open field (OFT), elevated plus maze (EPM), and forced swim test (FST). Separation stress significantly decreased pup weights at PD 16, 18, and 20. To explore potential mechanisms for early life stress effects on adult behavior and psychiatric vulnerability, we tested the expression of genes related to microglial phagocytosis in the PD21 hippocampus. Stress significantly increased the expression of Tyrobp. Further, we observed a trending stress-induced increase in hippocampal C1q expression. We observed no effects of sex or stress in the expression of Cybb or CD68. Although our group has found sex differences in the expression of Tyrobp, Cybb, and CD68 in the PD2 hippocampus (Nelson et al., 2017), these sex differences were no longer evident at PD21. In ongoing studies, we are assessing phagocytic gene expression in the PD21 amygdala and hypothalamus. No stress or sex effects were observed in hippocampal mRNA expression for the BBB tight junction proteins occludin, claudin-5, TJP1, or TJP2 at PD21. As adults, stressed rats spent significantly less time immobile in the FST than controls, and stressed male rats showed increased anxiety-like behaviors in the OFT. No stress effects were observed in open arm time in the EPM. These results suggest a potential mechanism whereby early life stress programs adult behavior and cognitive function.

Title: Developmental alterations in prefrontal cortex microglial morphology following maternal separation and lipopolysaccharide injection in male and female rats

Authors: *S. PETERZELL, K. R. GILDAWIE, J. A. HONEYCUTT, V. THOMPSON, H. C. BRENHOUSE;
Psychology, Northeastern Univ., Boston, MA

Abstract: Adverse experiences during early life have been shown to increase vulnerability to a multitude of neuropsychiatric disorders. Adversity during critical developmental time periods can have detrimental effects on neural development, particularly in the prefrontal cortex (PFC). Adversity-related aberrations in the PFC have also been found to alter neuroimmune signaling, elevating cytokine levels produced by microglia, the main resident immune cells of the brain. Microglia are reported to have increased neuroimmune activity and subsequent production of

inflammatory molecules in response to homeostasis disruption. Microglia are also capable of provoking long-term changes in brain structure and function, particularly within local microcircuitry. Importantly, they have the ability to become chronically sensitized, or 'primed' to over-activation following insult. However, it is unknown whether maternal separation (MS) early in life followed by a secondary challenge later in life alters microglial reactivity and morphology across development. To investigate the impact of MS on microglial priming in the developing immune system, male and female rat pups were separated from their dams for 4 hours per day from postnatal day (P) 2-20. Rats were then exposed to the endotoxin lipopolysaccharide (LPS) in either juvenility (P20) or adolescence (P40). Four hours after LPS injection, rats were perfused and brains were collected, cryoprotected, and sliced on a freezing microtome to 40 µm slices. Tissue sections containing the prelimbic (PL) and infralimbic (IL) PFC were immunohistochemically stained to visualize Iba1+ microglia. Fluorescent microscopy was used to capture images in three consecutive sections in the PL and IL (6 images per section). Morphological microglial alterations were quantified in ImageJ via the AnalyzeSkeleton macro plugin. Our findings reveal that MS confers sensitization to a secondary LPS insult in a sex- and age-dependent manner. Investigating variances in neuroinflammatory changes at different time points between MS and LPS induced stress can help elucidate the role that early life adversity plays in altering microglia function and pathology in later life.

Title: Developmentally-dependent effects of maternal separation on oxidative stress accumulation in parvalbumin neurons of male and female rats

Authors: *A. R. SOARES[1,2], K. R. GILDAWIE[2], J. A. HONEYCUTT[2], H. C. BRENHOUSE[2]; [1]Interdepartmental Neurosci. Program, Yale Univ., New Haven, CT; [2]Developmental Neuropsychobiology Laboratory, Dept. of Psychology, Northeastern Univ., Boston, MA

Abstract: Early life adversity in humans is linked to the emergence of cognitive deficits and an increased risk of mental illness later in life, including anxiety, depression, bipolar disorder, and

schizophrenia. Developmental insults, such as early adverse experiences, and the subsequent mental illness susceptibility have been associated with abnormalities in the prefrontal cortex (PFC), hippocampus (HPC), and basolateral amygdala (BLA), among others. Modeling early life adversity in rodents using a maternal separation (MS) paradigm shows similar neuropsychological deficits that may partially be driven by dysfunction in inhibitory parvalbumin (PV) interneurons. Research demonstrates that PV interneurons are particularly susceptible to oxidative stress, and that accumulation of oxidative damage may contribute to observed PV dysfunction following MS. Additionally, sex differences have been reported in the timing and severity of neurological and behavioral deficits associated with MS. The goal of the present study was to quantify oxidative stress accumulation over development in PV neurons of both male and female rats exposed to MS. To do this, pups were separated from their dam for 4 hours each day from postnatal day (P)2 to 20 and then sacrificed for neural quantification and analyses in either juvenility (P21) or adolescence (P40). Serial sections from PFC, HPC, and BLA were immunohistochemically tagged with antibodies against PV, as well as 8-oxo-dG, a marker for oxidative DNA damage. Individual and colocalization expression of these targets were measured in the PFC, HPC, and BLA to determine the oxidative effect of MS and establish whether its progression varies as a function of sex. We specifically examined the prelimbic and infralimbic cortices of the PFC, and the CA1 and CA3 fields of the HPC, as well as the dentate gyrus. We present novel and compelling data demonstrating a link between MS and increased oxidative stress in PV neurons, in a sex- and age-dependent manner, as well as sex differences in overall PV cell count. These data identify a potential timepoint at which antioxidant treatment may be administered in order to prevent further neurological dysfunction in individuals subjected to early life adversity, and highlight the importance of sex differences in the treatment of adversity-related dysfunction.

Abstract: Line1—a retrotransposon that comprises ~17% of the human genome and ~23% of the rat genome —is aberrantly expressed in psychiatric disorders such as schizophrenia, bipolar disorder, and Rett syndrome, suggesting it may play an important role in neurodevelopment. Line1 expression was previously thought to be quiescent during typical developmental conditions through epigenetic suppression; however, recent evidence suggests that Line1 levels and DNA copy number may actually be affected by environmental experiences. Specifically, once expressed, Line1 has the ability to self-replicate via reverse transcription of an RNA intermediate and can subsequently reinsert itself throughout the genome. In the current study, we sought to understand whether early life stress (ELS), a known risk factor for the development of later psychiatric disorders, would affect Line1 expression. Our study used a neonatal predator odor exposure (POE) paradigm to model ELS in rats to examine the consequences of experiencing "fear of harm" on brain development. We examined Line1 RNA levels using RT-qPCR at two different timepoints, neonatal postnatal day 3 (PND3) and juvenile (PND33), to assess whether ELS would alter Line1 expression levels in males and females. Our results suggest that Line1 expression is sensitive to ELS and that these changes are sex and region specific. Because we see changes in RNA expression, we are exploring whether this leads to an increase in DNA copy number due to Line1 self-replication. Therefore, we are seeking to understand whether ELS creates somatic mosaicism within the developing brain.

Title: Stress- and gender- dependent changes in locus coeruleus physiology and anxiety-like behavior

Authors: *O. BORODOVITSYNA[1], D. J. CHANDLER[2];
[1]Cell Biol. and Neurosci., Rowan Univ. GSBS, Stratdord, NJ; [2]Cell Biol. and Neurosci., Rowan Univ. Sch. of Osteo. Med., Stratford, NJ

Abstract: The locus coeruleus (LC) is the main source of norepinephrine (NE) in central nervous system. During exposure to a stressor, corticotropin releasing factor (CRF) is released onto LC dendrites and activates CRF receptor 1, depolarizing its neurons and enhancing NE release throughout the forebrain. We have previously demonstrated that a single stressful event produces acute and long-term changes in LC physiology and anxiety-like behavior in adolescent male rats. It is known that the female LC characterized by functional and structural differences compared to male LC, including larger size, more complex dendritic arborization patterns, increased NE biosynthesis in response to estrogen, and differences in CRFR1 trafficking and internalization. In addition to animal studies, female patients are known to be more susceptible to depressive and anxiety disorders than men. Based on these discoveries we hypothesized that the same acute stressor would have different responses in female and male rats.
Female rats (42PND) were exposed to 15 minutes of combined predator odor (TMT) and restraint stress. Immediately after animals were tested in elevated plus maze (EPM) to determine anxiety-like behavior and returned to their home cage. One week later, anxiety-like behavior was assessed in the open field test and whole-cell patch clamp recordings were performed to determine the long-term effects of stressor exposure on LC physiology. To access the endocrine branch of stress response serum was collected at baseline level before stress, 35 minutes after the beginning of stressor exposure or control conditions and a final measurement a week after. Preliminary results indicate that female rats show increased mobility in the mazes compared to males. Females also showed lower endocrine responses to stressor exposure compared to males. These findings will help to determine if and how the sexually dimorphic nature of the mammalian LC contributes to sex-specific behavioral responses to stress and anxiety-like behavior.

Title: Developmental Pb-exposure causes sex-dependent neurobiological changes in cell counts determined by isotropic fractionation and are associated with later life anxiety-like behavioral outcomes: Implications for early onset of emotional dysregulation disorders

Authors: *L. S. NEUWIRTH[1], *J. S. JOSEPH[2], J. C. SKEEN[2], K. P. LYNCH[1], I. AHMED[1], E. KHAIRI[2], E. CABANAS[2], M. A. VASQUEZ[3], G. CRUZ[2], J. R. BONITTO[2], A. CHOE[4], K. GILLENWATER[4], B. HINDI[4], S. PILOUT[4], M. KENT[5], K. G. LAMBERT[4];

[1]Psychology & SUNY Neurosci. Res. Inst., [2]Biol. Sci. & SUNY Neurosci. Res. Inst., [3]Biochem. & SUNY Neurosci. Res. Inst., SUNY Old Westbury, Old Westbury, NY; [4]Psychology, Univ. of Richmond, Richmond, VA; [5]Psychology, Univ. of Richmond, Richomond, VA

Abstract: Lead (Pb) is a well-established neurotoxicant that causes developmental neuropathologies, which result in cognitive and behavioral impairments across the lifespan. The current study assessed the effect of 150ppm and 1,000ppm perinatal Pb-exposed in offspring of Long Evans rat dams on locomotor activity and anxiety-like behaviors associated with neuronal cell counts in the prefrontal cortex (PFC) and hippocampal (HP) brain regions. The perinatal Pb-exposure began 1-month prior to breeder pairing through parturition and ceased at postnatal day (PND) 22. Control rats (0ppm) were used to evaluate the degree of neuropathological changes in behavioral and neurobiological outcomes as a function of Pb dose-response and sex. When assessed in the elevated plus maze (EPM) (PND 35), rats exposed to 150ppm and 1,000ppm of Pb exhibited increased locomotor activity when compared to control rats. Pb-exposed rats at both dose-responses frequented and spent more time active within the open arms of the EPM with females showing more Pb-sensitivity. Encephalization Quotients (EQ) were calculated for all treatment groups as a ratio of brain-to-body weight within a species index. Control females EQs were larger than Control males. However, in response to developmental Pb-exposure the 150ppm males had reduced EQs, whereas the 1,000ppm males had higher EQs, when compared to control males. Contrastingly, both 150ppm and 1,000ppm female had higher EQs when compared to control females. Cell counts are currently being conducted via isotropic fractionation (IF) in the PFC and HP to determine the effect of Pb-exposure on the number of cells (i.e., neuronal and glia) in these brain regions that are Pb-sensitive. Notably, Pb-exposure can cause inverted-U neurotoxicant relationships whereby low-doses may cause increased neurogenesis and high-doses apoptosis through compensatory mechanisms, sex-based susceptibilities remain to be elucidated. Females appear to be more sensitive to the high-doses of Pb-exposure. Given the increased risk for environmental Pb-exposure in children, understanding how Pb can impair neurodevelopment may prove useful in developing psychopharmacological interventions in addressing anxiety-like behaviors across the life span.

Title: Hemispheric and sex-dependent effects of early-life stress on synaptic plasticity, neuronal excitability and NMDAR expression in the rat postweaning basolateral amygdala

Authors: *A. GUADAGNO[1,2], H. LONG[1], T. WONG[1,3], C.-D. WALKER[3,1];
[1]Douglas Mental Hlth. Univ. Inst., Montreal, QC, Canada; [2]Integrated Program in Neurosci., [3]Dept Psychiatry, McGill Univ., Montreal, QC, Canada

Abstract: Early-life stress (ELS) exposure is associated with increased vulnerability to mental disorders. The basolateral amygdala (BLA) - medial prefontal cortex (mPFC) circuit plays an important role in emotional behavior and is extremely sensitive to ELS. Using a naturalistic rodent model of ELS, the limited bedding paradigm (LB) between postnatal days (PND) 1-10, we previously showed that LB male, but not female preweaning pups display increased BLA neuron spine density paralleled with enhanced evoked synaptic responses, in addition to altered male BLA-mPFC functional connectivity. Since ELS effects are often sexually dimorphic, we aimed to examine sex differences in the developing BLA and its relation to the mPFC. We investigated changes in synaptic plasticity and neuronal excitability of BLA neurons *in vitro* in the left and right amygdala of PND25-28 offspring of normal bedding (NB) or LB mothers. Since NMDAR are developmentally regulated and critical for synaptic plasticity, we also examined expression of GluN2A, GluN2B and GluN1 in the BLA and mPFC on PND28. We report that LB conditions enhanced evoked synaptic responses in the right, but not the left, BLA of males. Furthermore, BLA input/output function in LB males was significantly greater than that from LB females. Interestingly, the stress of LB increased long-term potentiation (LTP) formation in the right BLA of males exclusively. Action potentials fired from BLA neurons in the right amygdala of LB animals were of a larger amplitude compared to those from NB animals, and more frequent in LB compared to NB males. With respect to NMDAR, GluN1 levels were elevated only in the right side of the BLA of LB males compared to females, whereas the opposite pattern emerged for GluN2B expression in the mPFC. GluN2A expression was also largely decreased in LB compared to NB pups in the mPFC. Our data suggest that LB modifies synaptic organization and laterality in the BLA-mPFC pathway in postweaning pups, with effects being mostly exacerbated on the right side in males. We propose that increased excitability of BLA neurons might alter the strength of BLA-mPFC projections, potentially affecting NMDAR expression and excitatory/inhibitory neurotransmitter balance in the mPFC. These changes in the BLA-mPFC circuit could underlie the sexually-dimorphic behavioral phenotype we have previously observed as a long-term consequence of ELS exposure.

Title: Variations of early life stress and sex differentially alter hippocampal development and function leading to disruptions in contextual learning

Authors: *J. D. WHITE[1], A. PUGLIESE[1], C. H. LEE[2], T. AREFIN[2], J. ZHANG[2], A. KAFFMAN[1];
[1]Psychiatry, Yale Sch. of Med., New Haven, CT; [2]New York Univ. Langone, New York City, NY

Abstract: Stress has pronounced effects on the brain, and thus behavioral outputs. This is particularly true when the stress occurs during vulnerable points in neural development. In humans, early life stress (ELS) appears to be additive, with the severity in outcomes corresponding with the number of instances or degree of trauma experienced. Due to the wide-ranging and often compounded stressors experienced by humans, the mechanisms underlying ELS-induced changes in brain development and function can be difficult to study. To address these issues, we utilized two animal models of early life stress (ELS), i.e., limited bedding and nesting (LBN) and a modified version of the LBN paradigm that also includes intermittent 1 hr maternal separation sessions and nest disruption on postnatal days (P) 14, 16, 17, 21, 22, & 25 (UPS). We have previously shown that these ELS paradigms differentially affect anxiety behaviors and fronto-limbic connectivity in adulthood, and that these effects are further moderated by sex. In the current study, we focused on how LBN and UPS interacts with sex to affect changes in the developing hippocampus and whether this leads to differential behavioral outcomes in contextual learning in adulthood. Exposure to LBN and UPS differentially stunted hippocampal development across a number of measures, and altered postnatal neurogenesis, corticosterone levels and neuronal activation in a region-specific way within the hippocampus. RNA-seq analysis from hippocampal tissue at P17 indicated striking differences between control and ELS reared animals while also demonstrating significant differences between LBN and UPS paradigms. Our results indicate that, although LBN and UPS are closely related ELS paradigms, they lead to distinct changes in the developing hippocampus, some of which are moderated by sex. The disparate outcomes between the LBN and UPS paradigms highlights the need to further investigate how different forms of postnatal stress can modify the pathophysiology and consequences of ELS across the lifespan.

Title: Exercise effects on activation of dorsal raphe nucleus-projecting neurons during uncontrollable stress

Authors: *K. BONAR;
The Univ. of Colorado Denver, Denver, CO

Abstract: Exercise increases stress resistance, but the neurochemical mechanisms underlying the stress-protective effects of exercise remain unknown. In rats, 6 weeks of voluntary access to running wheels prevents the anxiety- and depression-like behavioral consequences of exposure to an uncontrollable stressor. Hyperactivation and sensitization of serotonin (5-HT) neurons in the dorsal raphe nucleus (DRN) is necessary and sufficient to produce the behavioral consequences of uncontrollable stress, and exercise is thought to prevent these stress-induced behaviors by constraining the activation of DRN 5-HT neurons during uncontrollable stress. The mechanism by which exercise constrains DRN 5-HT neurons during stress is unknown. Identification of this circuitry could contribute to the development of novel targets of stress resilience. Here we used viral neural-tract-tracing to identify neurons that project to the DRN. We then quantified cFos immunoreactivity following uncontrollable stress in DRN afferents in rats allowed 6 weeks of prior wheel running vs. locked wheel conditions. Quantification of cFos expression in DRN-projecting neurons in the striatum, locus coeruleus, habenula, and prefrontal cortex is currently underway. Results could reveal novel stress-resistance neural circuitry that is sensitive to exercise and able to constrain activation of the DRN during exposure to damaging uncontrollable stressors.

Abstract: Women are at a higher risk for developing stress-related neuropsychiatric disorders such as generalized anxiety disorder, post-traumatic stress disorder and depression. The mechanisms underlying these differences are unknown but they may arise from different responses to stress resistance/resilience-inducing factors like physical exercise. In male rodent models, 6 weeks of voluntary wheel running (VWR) prevents exaggerated freezing and social avoidance produced by exposure to an uncontrollable stressor. However, it is unknown if the stress-buffering effects of exercise are present in females as it is in males. Here, we demonstrate that females allowed 6 weeks of access to VWR are protected from the behavioral sequelae of uncontrollable stress. In males, the buffering effects of exercise are partly due to reduced serotonergic output from the dorsal raphe nucleus (DRN). Top-down inhibition of the DRN by the medial prefrontal cortex (mPFC) has been identified as a potential endophenotype across other stress resilience models (e.g. ketamine, stressor controllability). In order to determine if prior VWR leads to the engagement of the mPFC during uncontrollable stress, we examined continuous calcium-mediated activity in the mPFC using fiber photometry in both male and female rats. Understanding the neurobiological mechanisms that mediate the protective effects of exercise, and whether there are sex-based differences, could lead to novel strategies to improve the treatment of neuropsychiatric disorders in women.

Title: Optogenetic activation of SIFamide neurons during adulthood causes sexually dimorphic sleep induction in *drosophila melanogaster*

Authors: *H. HUANG[1], C. G. VECSEY[2];
[2]Neurosci. Program, [1]Skidmore Col., Saratoga Springs, NY

Abstract: SIFamide (SIFa) is a genetically conserved neuropeptide in arthropods, and previous studies have shown that it regulates diverse behaviors, which include sexual behaviors, feeding behaviors, sleep, and rest:activity rhythms. In *Drosophila*¸ SIFa is expressed in four neurons in the pars intercerebralis (PI), and either ablating SIFa neurons or knocking down SIFa expression level shortens time spent asleep, suggesting that SIFa is sleep promoting in *Drosophila.* However, it remains unclear if: 1) acute activation of SIFa neurons during adulthood will also induce sleep, 2) other factors, which include sex, duration of neural activation, and intensity of the activation, will influence the strength of the effect, 3) the activation of SIFa neurons will lead to other behaviors besides sleep. Here, we addressed these issues by utilizing an optogenetic approach to activate SIFa-expressing neurons. By building a fly line with both SIFa-Gal4 and UAS-Chrimson, we were able to activate SIFa-expressing neurons with red-light stimulation. The current study showed that the activation of SIFa neurons when flies were active could significantly decrease flies' activity, suggesting that activity in these neurons promotes sleep. SIFa neuron activation also showed a sexual dimorphism, in that a greater effect on sleep was observed in female flies than in males. An acute study that activated SIFa neurons with a short red-light stimulation (1-5 seconds) showed that a short activation of SIFa neurons was able to induce sleep, and that the duration of sleep was intensity-dependent. In short, the current study showed that an acute activation of SIFa neurons was able to promote sleep in adulthood, and the strength of the sleep-promoting effect depended on sex, the intensity, as well as the length of the activation. Future studies will identify the neurotransmitter that promotes sleep during the activation of SIFa neurons and characterize the sleep-relevant downstream effects of SIFa neuron activity.

Title: Sex differences in hypothalamic-pituitary-adrenal axis response following a single and multiple nights of sleep restriction

Authors: *K. BUBAN[1], E. A. SHUPE[2], S. W. ROTHWELL[1], T.-Y. J. WU[1];
[1]Uniformed Services Univ., Bethesda, MD; [2]Sch. of Neurosci., Virginia Tech., Blacksburg, VA

Abstract: 1 in 3 adults report experiencing inadequate or disrupted sleep throughout the night (Liu et al., 2016), with the incidence being higher in women than in men. Disturbances in nightly sleep result in hormonal, neurochemical and behavioral alterations that contribute to a number of disorders. Sleep is believed to contribute to the pathogenesis of these disorders through its interaction with the hypothalamic pituitary adrenal (HPA) axis. The HPA axis releases corticotropin-releasing factor (CRF) from the paraventricular nucleus of the hypothalamus (PVN) to ultimately result in glucocorticoid (CORT) release from the adrenals. The present study sought to investigate the effect of one and three nights of restricted sleep on HPA axis reactivity. Male and female C57BL/6J mice were sleep-deprived for a 20h period for one night or three consecutive nights using the modified multiple platform method and subjected to 20 minutes of restraint stress after an 8h recovery. Males, at both one and three days of sleep restriction, showed blunted restraint-induced rises in CORT relative to their home cage control (HCC) groups ($p< 0.05$). Similarly in females, following three nights of sleep restriction, mice showed a blunted restraint-induced CORT response ($p<.05$). However, following a single night female mice showed a complete ablation of HPA reactivity (< 0.05). Analysis of pituitary and adrenal mRNA expression revealed significant alterations in peripheral HPA axis regulatory genes. Males, regardless of sleep restriction duration showed increases in proopiomelanocortin expression ($p< 0.05$), while females showed increases after only a single night ($p< 0.05$). In contrast, females showed increases in CRFR1 expression regardless of sleep restriction duration ($p< 0.05$), while males only showed an increase following three nights of sleep restriction ($p< 0.05$). Restricted sleep also significantly increased 11β-hydroxylase mRNA expression and altered 11β-hydroxysteroid dehydrogenase 1 and melanocortin receptor 2 expression in the adrenals. Altogether, these data suggest that both central and peripheral mechanisms are involved in the HPA axis dysregulation observed following the periods of restricted sleep examined in this study. Current efforts are underway to explore the role of central regulatory mechanisms in the

HPA axis response following sleep restriction. These findings suggest there is a sex difference in how the HPA axis responds to sleep loss.

Title: Sex differences of the phosphoproteomic profiles in APP/PS1 mice after chronic unpredictable mild stress

Authors: *S. DOMINGUEZ[1], G. RODRIGUEZ[1], H. FAZELINA[2], H. DING[2], S. SEEHOLZER[2], H. DONG[1];

Abstract: Of the 5.4 million Americans suffering from Alzheimer's Disease (AD), roughly two-thirds are women. While women's longer average lifespan is a plausible explanation for the prevalence gap in AD diagnosis, increasing evidence suggests that there remains an age and risk factor-matched enhanced risk for AD in women. The biological mechanisms underlying this sex divergence in the AD prevalence, however, remains unknown. Previous research has shown sex-specific biochemical differences in central stress responses that bias female mice towards pro-AD signaling on the phosphoproteomic level via Corticotropin Releasing Factor (CRF) Receptor 1 activation after CRF overexpression. In this study, we aimed to determine if these findings could similarly be reproduced under physiological CRF expression following chronic stress. We stressed APP/PS1 mice using a Chronic Unpredictable Mild Stress (CUMS) paradigm for 1 month. CUMS is commonly used in animal models to mimic the daily life stress of humans. In our model, we used a variety of mild to moderate stressors including wet bedding, cage tilt, and acute restraint at differing times of the day. Following CUMS and behavioral assessments, we collected brain tissue and identified and quantified whole protein and phosphoprotein levels in the cortex of stressed and non-stressed APP/PS1 mice using MaxQuant. While there were no significant differences at the total protein and peptide levels, we found 909 statistically significant phosphopeptides between stressed and unstressed females and 841 statistically significant phosphopeptides between stressed and unstressed males using a False Discovery Rate of 5%. Of these significant phosphopeptides, only 301 were the same in males and females. These results indicate that while both males and females undergo protein phosphorylation

changes following stress, the peptides that are phosphorylated differ between sexes. We then compared these significant phosphopeptides using Metacore analysis to determine which biological pathways were affected. We found that several pathways were changed differently between male and female mice including NMDA receptor trafficking, cytoskeleton organization, and Tau pathology. Our next step will be to confirm such changes in statistically significant pathways of interest, specifically those associated with AD-related neuropathogenesis. The differing biological pathways affected between males and females in response to chronic stress may help us understand why women are at a higher risk of AD and what may be causing the link between female-biased, stress associated neuropsychiatric disorders such as major depression disorder with AD.

Title: Irisin injection into the hippocampus suppresses acute stress-induced memory impairment and anxiety-like behavior in a sex dependent manner

Authors: *M. JODEIRI-FARSHBAF, D. CHERKOWSKY, N. MANAL, D. P. MOUSSOUKI, K. ALVIÑA;
Texas Tech. Univ., Lubbock, TX

Abstract: Acute stress can disrupt a variety of neural processes, including reducing levels of brain-derived neurotrophic factor (BDNF) in the hippocampus. Exercise, on the other hand, can increase BDNF levels and has overall beneficial effects for health and brain function. Irisin is a myokine that is released into the peripheral blood during aerobic exercise. Although the main known functions of Irisin, both in human and rodents, are browning white adipose tissue and improving glucose homeostasis, recent findings have shown that Irisin mediates the activation of an exercise-induced BDNF-mediated neuroprotective pathway in the hippocampus. Therefore, in this study we tested the hypothesis that Irisin can counteract the deleterious effects of acute stress when directly injected into the hippocampus. To test our hypothesis, we first established a 3h physical restraint stress in adult mice that resulted in sex-dependent increased anxiety-like behaviors and memory impairment in a combined open field/novel object recognition (OF/NOR) test. Moreover, acute stress also reduced skin temperature and body weight in both female and male mice. We then injected Irisin via bilateral stereotaxic injection and repeated the acute stress paradigm and combined OF/NOR test. We found that Irisin partially blocked stress-induced

anxiety-like behavior and memory impairment in male mice, while also preventing the reduction in skin temperature and body weight. Interestingly, in female mice Irisin only prevented the skin temperature and body weight reduction but showed no beneficial effects on neurobehaviors. Taken together, our results suggest a novel role for Irisin in counteracting acute stress-induced neurobehavioral and physiological abnormalities. Also, our results support the idea that exercise can be a potentially effective tool to promote the maintenance of healthy neural function.

Title: Chronic stress results in sex-specific deficits in behavioral flexibility and changes in gene expression in rat medial prefrontal cortex following a novel stress challenge

Authors: *K. M. MOENCH, M. R. BREACH, C. L. WELLMAN;
Indiana Univ., Bloomington, IN

Abstract: Chronic stress leads to sex-specific changes in the structure and function of rat medial prefrontal cortex (mPFC). Little is known about whether these effects persist following the cessation of chronic stress, or how these initial effects may impact responses to future stressors. We have previously shown that dendritic remodeling in mPFC during the post-stress rest period is dynamic and sex-specific. Additionally, chronically stressed males and females have different patterns of neuronal activation in mPFC in response to a novel stress challenge following a post-chronic stress rest period. Thus, there are sex differences in the lasting effects of chronic stress on mPFC that may contribute to different behavioral outcomes following a novel stress challenge in males and females. Here we examined attentional set-shifting in male and female rats following chronic restraint stress (3 h/d, 10 d), a post-chronic stress rest period, and an acute novel stress challenge (elevated platform stress, 30 min). Chronic stress resulted in a reversible impairment in extradimensional set-shifting in males, but had no effect on attentional set-shifting in females. Surprisingly, chronically stressed female, but not male, rats had impaired extradimensional set-shifting following a novel stress challenge. Alterations in the balance of

excitation and inhibition of mPFC have been implicated in behavioral deficits following chronic stress. Thus, in a separate group of rats, we examined changes in the expression of genes related to glutamatergic (NR1, NR2A, NR2B, GluR1) and GABAergic (Gad67, parvalbumin, somatostatin) neurotransmission in mPFC after acute and chronic stress, rest, and their combination. Stress significantly altered the expression of NR1, GluR1, Gad67, and parvalbumin. Notably, the pattern of stress effects on NR1, Gad67, and parvalbumin expression differed between males and females. In males, these genes were upregulated following the post-chronic stress rest period, while minimal changes were found in females. In contrast, both males and females had greater GluR1 expression following a rest period. These findings suggest that chronic stress leads to sex-specific stress adaptation mechanisms that contribute to sex differences in response to subsequent stress exposure.

Title: Examination of mu-opioid receptors in sexually-dimorphic responses to chronic stress

Authors: *S. N. CASSELLA, L. HORST, S. BAHLS;
Loras Col., Dubuque, IA

Abstract: Sex-differences in the stress response - both behavioral and physiological - are not completely understood, however accumulating data has pointed to the importance of the immune system. This relationship makes sense as we know women suffer from stress-related psychiatric diseases and immune-related disorders at a higher rates than men. Unfortunately, it's still unclear if baseline differences in inflammatory profiles of brain regions are responsible for these sex-specific behaviors, or if stress itself induces sex-specific changes that lead to divergent behaviors. One behavior that differs by sex is ethanol consumption following acute stress - female rodents consume more than males. This compliments the fact that women also need more morphine for anesthesia and points to the role of β-endorphins and μ-opioid receptors on microglia in stress regulation. The current work looks to examine the sex-specific role of the μ-opioid receptor on microglia in sexually-dimorphic stress responses to chronic stress. The results at this point are mystifying - males have an increased preference for ethanol following chronic stress, however, females have increased anxiety-like behavior on the elevated plus maze. Ongoing analysis is examining the expression and function of μ-opioid receptors in this paradigm, specifically those expressed on microglia in the hypothalamus. This project may also offer insights into sex-differences in the areas of pain and addiction.

Abstract: Gulf War Illness (GWI) continues to be a lingering condition for some Operation Desert Shield/Storm Veterans deployed to the Persian Gulf in 1990-1991. Recent reports suggest permanent changes in the brain white matter of those still experiencing symptoms. We hypothesized that repeated exposure to a combination of personnel-issued chemical supplies along with bacterial infection caused persistent neuroinflammation, leading to any one or combination of symptoms associated with GWI. This hypothesis was tested in male and female C57Bl/6 mice. The chemicals tested were the type I pyrethroid insecticide permethrin (PERM) and the nerve-gas prophylactic pyridostigmine bromide (PB). Both have been demonstrated to cause neuroinflammation in rodents at high doses. Lipopolysaccharide (LPS) was used to model the immune response to an infection; LPS has also been demonstrated to cause acute signs of neuroinflammation. The chemicals were applied dermally (PERM) or orally (PB) over 1 month. The LPS was administered 3 times over one week to cause week-long proinflammatory cytokine activity. The LPS was administered either during the first or last week of chemical exposure. Additional chemical-exposure alone and LPS-alone groups served as positive controls to assess the additional role of proinflammatory cytokine activity and combined chemical exposures. Behaviors were assessed 3 months and 6 months later. Motor functioning, as assessed by the rotor-rod test, was significantly impaired in the mice at both time-points only when LPS had been administered during the first week of chemical exposure. There was no evidence of any object-based memory impairment using the object recognition or object placement recognition test. There was no significant difference attributable to Sex in any of the behavioral tests. These results suggest there may be a unique temporal relationship between experiencing a significant infection and being exposed to these chemicals, with the concurrent infection during the early

exposure to the chemicals being more detrimental to motor functioning. Future work will assess whether the brains from early-LPS/chemical exposure mice demonstrate selective white matter expression differences.

Abstract: At least 20% of the service personnel deployed to the Persian Gulf during Operation Desert Storm developed a variety of disorders. Neurological problems are common and significant neurodegeneration over time can be involved. We have been testing neuroprotective transcription factor modulation to improve the outcomes while investigating underlying mechanisms responsible for the symptoms. Previously, we have reported morphological changes to dendritic arbors in the hippocampus induced by the insult and improved by treatment. Here, we tested mice receiving the combined insult of the anti-sarin prophylactic, pyridostigmine bromide, an organophosphate insecticide, chlorpyrifos, and the insect repellent, DEET (N,N-diethyl-m-toluamide) administered subcutaneously by infusion pump. These chemicals have been previously implicated as exposure hazards that could have contributed to Gulf War Illnesses. After 2 weeks of exposure, we examined astrocytes in several brain regions. Astrocytes were counted and astrocyte structures were examined with the aid of automated routines with ImageJ. We found indications of reactive astrocytosis induced by the Gulf War toxins. For example, astrocytes in the dentate gyrus of the hippocampus displayed 50% greater overall process length (P=0.003) per cell and a 45% increase in the number of process endpoints per cell (P=0.004) in the insulted mice (n=9) compared to the vehicle treated mice (n=4). The astrocytic

responses, combined with the structural changes that we have found in neurons in the hippocampal region, raise questions concerning the cell specific regulatory pathways that are dysregulated in Gulf War Illness. Through the identification of cellular interactions and signaling pathways, we hope to uncover therapeutic targets that will lead to improved outcomes for Veterans and others suffering related neurodegenerative disorders.

Title: Autonomic disturbances elicited by stress and pyridostigmine bromide in a rat model of Gulf War illness

Authors: J. L. WOODRUFF[1], J. PECORELLA[2], J. RIVERS[2], C. M. LOMBARD[3], B. MUNIZ[2], V. A. MACHT[6], C. A. GRILLO[4], *L. P. REAGAN[2], S. K. WOOD[5]; [1]Pharmacology, Physiol. and Neurosci., [3]Pharmacology, Physiology, and Neurosci., [4]Dept Pharmacol, Physiol & Neurosci, [5]Pharmacology, Physiol. & Neurosci., [2]Univ. of South Carolina Sch. of Med., Columbia, SC; [6]Bowles Ctr. for Alcohol Studies, Univ. of North Carolina At Chapel Hill, Chapel Hill, NC

Abstract: Pyridostigmine Bromide (PB), an acetylcholinesterase inhibitor used as a prophylactic agent against nerve gas during the Gulf War, has been suggested as a possible cause of the chronic constellation of symptoms suffered by Gulf War Veterans. Under non-stressful laboratory conditions PB was demonstrated to have minimal autonomic consequences, however it is suggested that when combined with repeated stress PB may be deleterious to the autonomic system, contributing to GWI symptomatology. In the present study male rats were treated with either vehicle or PB (1.3 mg/kg) daily for 14 consecutive days. On the final 10 days of treatment, rats were exposed to either restraint stress (RS) or non-stressed control. To identify the dynamic temporal development of autonomic changes, cardiovascular telemetry was used to measure blood pressure (mean arterial pressure; MAP) and heart rate (HR) at a delayed time point (3 months post stress/treatment) to assess the progressive nature of GWI cardiovascular

complications. Since our previous studies determined that PB + stress altered neurochemical and endocrine responses to subsequent challenges, we examined the effects of an acute immune challenge (lipopolysaccharide; LPS, 100μg/kg) and an acute RS challenge on these cardiovascular parameters. Unlike observations at earlier time points, arrhythmic burden was unchanged in PB+RS rats at the delayed time point. However, the arrhythmic burden remained heightened under a novel endotoxin stressor in the late LPS trials. Additionally, LPS induced heightened LF/HF ratio in rats with a history of PB-RRS compared to all other groups, suggesting an imbalance of the autonomic nervous system biased towards reduced vagal tone. Collectively, these data acquired at the delayed timepoint are consistent with studies in GWI patients that demonstrate evidence of deficient vagal acetylcholine tone. Moreover, these studies illustrate the distinct autonomic effects of PB treatment during repeated stress exposure and provide insight into the progressive nature of the cardiovascular complications characteristic of GWI.

Title: Microtubule-based mechanisms and therapies for Gulf War illness using hiPSC-derived neurons

Authors: ***P. YATES**[1], A. PATIL[1], K. A. SULLIVAN[2], P. W. BAAS[1], L. QIANG[1]; [1]Neurobio. and Anat., Drexel Univ. Col. of Med., Philadelphia, PA; [2]Envrn. Hlth., Boston Univ. Sch. of Publ. Hlth., Boston, MA

Abstract: Gulf War Illness (GWI) is a chronic multisystem disorder suffered by at least 25% of the nearly 700,000 U.S. veterans who fought in the 1990-1991 Gulf War. Central nervous system (CNS) symptoms include chronic fatigue, reduced information processing speeds, memory deficits, chronic headaches, and impaired mood and sleep. Evidence suggests that GWI is caused by the combination of the stress of the battlefield and exposure to organophosphate pesticides and nerve agents at concentrations below the threshold that inhibit acetylcholinesterase, thus implicating novel biological targets. We posit there is a constellation of cellular changes in the

central nervous system contributing to the long-lasting symptoms of GWI. We are interested in elucidating these aberrant cellular phenomena, screening potential therapies that can be rushed to suffering veterans, and investigating any cellular differences that might help explain why some veterans suffer from GWI while their similarly exposed mates do not. To tackle these questions, we are using human induced pluripotent stem cells (hiPSCs) derived from veterans of the first Gulf War, both from healthy veterans and from veterans with GWI. We are differentiating the hiPSCs into glutamatergic neurons and then exposing them to the GWI regimen of Cortisol plus Diisopropyl fluorophosphate (DFP), an analog of sarin. In one line of investigation, we are screening microtubule-based therapies that might correct previously documented changes in microtubule (MT) related processes, including alterations in MT stability, axonal transport, and neuronal activity. We are testing inhibitors of the tubulin-specific histone deacetylase 6 (HDAC6), which we have already shown can correct many of these MT-based alterations in primary rodent neurons, and inhibitors of kinesin-5, which we have shown can correct some of the axonal transport deficits. However, a mechanistic explanation for these MT-based alterations is still unclear. We hypothesize that pathology of the microtubule-associated protein tau might contribute to some of the MT-related deficits. Exposure to Cortisol plus DFP dramatically increases total tau and hyperphosphorylated tau, and now we are testing whether tau knockdown can correct the alterations in MT stability, axonal transport of mitochondria, and neuronal activity. This line of investigation opens the door to therapies from the tauopathy field. Lastly, we are growing forebrain cerebral organoids to model GWI in a more complex system to examine alterations in neurogenesis, cortical laminations, synapses, and glial activation.

Title: Modeling the behavioral and metabolic phenotype of mice exposed to Gulf War toxicants

Authors: *E. V. KOZLOVA, B. D. CHINTHIRLA, J. D. TRAN, A. E. BISHAY, G. R. LAMPEL, E. MONARREZ, M. C. CURRAS-COLLAZO;
Univ. of California Riverside, Riverside, CA

Abstract: Gulf War Illness (GWI) is a chronic multi-symptom condition that still affects a third of veterans who served in the 1991 Persian Gulf War (GW). Latently-emerging and persistent

symptoms fall into 5 general domains: neurological/cognition/mood (memory, concentration, anxiety, depression), muscle/joint pain, respiratory, gastrointestinal disturbances and especially chronic fatigue. GWI remains untreated due to lack of potential therapeutics evaluated in preclinical animal studies. The poorly understood etiology of GWI is suggested to be attributed to continuous exposure to GW agents administered to protect military personnel: 1) acetylcholinesterase inhibitor pyridostigmine bromide (PB) taken orally as prophylaxis against nerve agents, 2) topical insecticide permethrin (PER), and 3) topical insect repellent diethyltoluamide (DEET). Although GW agents were administered at safe doses, their chronic and combined use, in addition to stress, a critical component of GW deployment, may produce and/or intensify the pathophysiology of GWI for reasons not fully understood. Additionally, GW veterans report symptoms associated with delayed-onset Type II diabetes mellitus, which may be associated with chronic fatigue. To further investigate the behavioral and metabolic manifestations of GWI pathophysiology, we studied the effects of acute (AE) and chronic (CE) GW toxicant exposure in adult C57Bl6/N males utilizing a repeated measures design. The AE model consisted of 1wk exposure to PB (2 mg/kg/d; ip), PER (200 mg/kg/d in 70% ETOH; top), DEET (40 mg/kg/d in ETOH; top) and 5 min restraint stress/d (n=4-7; PND 118-252). The CE model consisted of 28 days of exposure to PB (1.3 mg/kg/d; po), PER (0.13 mg/kg/d; top) in 70% ETOH, DEET (40 mg/kg/d in ETOH; top) and 5min/d stress 5d/wk (n=6-8; PND 62-122). When compared to pre-treatment, mice exposed to AE or CE paradigms showed depressive-like behavior on forced swim and tail suspension tests. AE produced sensorimotor deficits as measured by an increased number of falls/segments crossed on SUOK beam test, and CE produced increased segments crossed relative to baseline. Increased anxiety in CE was observed as decreased risk assessment on SUOK and in AE as less percent time spent in open arm of an elevated plus maze (not due to decreased mobility). GW agent exposure had no effect on three-chambered sociability test. Both CE and AE groups displayed insulin insensitivity relative to baseline. These results show that GW agents can produce insulin insensitivity along with motor disturbance, anxiety and depressive-like behavior. Our findings will help inform studies that aim to elucidate the etiology and pathophysiology of GWI.

Title: Transcriptome analysis reveals a persistent, dormant neuroinflammatory phenotype revealed by inflammatory challenge in a mouse model of Gulf War illness

Authors: K. A. KELLY[1], L. T. MICHALOVICZ[1], D. B. MILLER[2], *J. P. O'CALLAGHAN[3]; [2]Ctr. Dis. Control & Prevention, [1]CDC-NIOSH, Morgantown, WV; [3]Centers For Dis. Control and Prevention, Morgantown, WV

Abstract: Gulf War Illness (GWI) is a multi-symptom, neuroimmune-based disorder that presents with features similar to sickness behavior. Unfortunately, current treatments for GWI tend to focus on managing symptoms as opposed to addressing the underlying cause of the illness. Using a preclinical mouse model, we have found that GWI is associated with an exacerbated neuroinflammatory response to immune challenge, like lipopolysaccharide (LPS) exposure, and the activation of microglia. In this model, mice are exposed to the stress hormone corticosterone (CORT; 200 mg/L) in the drinking water for 7 days followed by a single injection of diisopropyl fluorophosphate (DFP; 4 mg/kg, i.p.) to model the "in theater" conditions of high physiological stress and potential nerve agent exposure. This is then followed by periodic administration of CORT for 7 days every other week to a total of 5 weeks with a systemic LPS challenge (0.5 mg/kg, s.c.) on the final day. Mice were sacrificed 6 hours after LPS challenge and brain cytokine mRNA expression was evaluated by qPCR and RNAseq. RNAseq analyses revealed 2430 statistically significant genes ±1.5 fold change over saline controls. A PCA plot of these findings illustrate good separation of groups confirming a difference between the GWI (CORT+DFP+LPS) and CORT+LPS groups. Of these genes, 114 were unique to the GWI group. Analysis of the gene list with DAVID revealed inflammatory related GO terms and KEGG pathways. Ingenuity Pathway Analysis of the significant genes reveals many inflammatory canonical pathways across the groups to be depicted in a heat map. Together these findings provide further evidence for the neuroimmune basis for Gulf War Illness. Title: An alpha7 nicotinic acetylcholine receptor modulator ameliorates behavioral performance in Gulf War illness model

Authors: J. REYES-GONZALEZ[1], D. PEREZ[2], P. A. FERCHMIN[2], *N. SABEVA[1];
[1]Neurosci., [2]Biochem., Univ. Central Del Caribe, Bayamon, PR

Abstract: Gulf War Illness (GWI) is a chronic multiorgan condition, which prominently involves the brain. It is characterized by a cognitive deficit associated with neuroinflammation and neuronal loss. GWI causative factors are the simultaneous exposure to pyridostigmine bromide (PB, administered for prophylactic purposes against nerve agents), permethrin (PER) and N, N-diethyl-meta-toluamide (DEET) for insect control along with traces of Sarin. PB, DEET, and Sarin are acetylcholinesterase inhibitors (AChE-I) possibly contributing to the adverse cholinergic activity in GWI veterans. DEET is a weak AChE-I but has other neurotoxic properties. Here, we report the development of a murine GWI model and the testing on this model of a therapeutically promising nicotinic α7nAChR ligand, the 4R-cembranotrienes-diol (4R).To recreate GW conditions, we enhanced an established mouse GWI model (10 days PB + PER) with DEET, traces of DFP (a Sarin surrogate) and moderate stress. After exposure to the GW agents, behavioral testing was conducted every 30 days for 4 months. We assessed the learning abilities using the Barnes maze where control and GWI mice show the same ability to learn to locate the escape box during the 4 days training period. Exploratory nose-poke pattern and time in escape quadrant (EQ) was evaluated after removal of the rewarding escape box. GWI mice showed steady nose-poke exploration and time spent at the escape quadrant (EQ) during testing. Initially, control mice showed intense exploration followed by a 50 % decline at Day 75 and 105 showing that, contrary to GWI mice, controls retain the capability to extinguish obsolete spatial information. To test whether 4R restores extinction in GWI mice 4R was applied 3 times a week for 6 weeks (6mg/kg i.p.) 150 days after exposure to GW agents. The four groups (Control: -vehicle and -4R, and GWI-vehicle and -4R) demonstrated a similar ability to learn the new location of the escape box. However, 24 hrs later when the rewarding escape box was removed the GWI-4R animals had a similar spatial preference as vehicle and 4R controls assessed by time spent in EQ. Inversely, GWI-vehicle group spent 40% less time near the rewarding hole suggesting that 4R can reverse the effect of GWI and restore the memory function. The present work will contribute to the understanding of GWI and will test a promising candidate drug for the treatment for GWI veterans and future victims of similar civilian or military adverse events.

Lauderdale, FL; [7]Sch. of Publ. Hlth., Boston Univ., Boston, MA

Abstract: Medically unexplained illness found in nearly 1/3 of the Gulf War Veterans (GWV) out of approximately 700,000 US troops deployed to the Persian Gulf theater for Operation Desert Storm still presents a major unmet progressive clinical problem, 27 years after the war. The initial concern was exposure to the plumes from the burning oil well, subsequently, the area of concern became the increased rates of multisymptom illnesses. The VA, DoD, EPA, DHHS, along with the task force of the Defense Science Board, reported the possible cause and effect of the differential levels of exposures to chemicals, environmental stressors and pollutants, vaccines, antidotes and endemic biologics. Repetitive exposures to various chemicals, especially organophosphate-related compounds, may inhibit AChE irreversibly, even at non-lethal doses. Prophylactic treatments with reversible AChE inhibitors such as anti-nerve gas pills, and various vaccines can prime the immune system. Paradoxically, it can trigger the CNS-glymphatic system to mount a neuroinflammatory response in some individuals, resulting in subclinical symptoms. There are complex networks of trophic factors that are secreted to maintain the neurons both in the central and peripheral nervous system. Many studies have reported decreased levels in various neuromuscular disorders and our objective in this study is to focus on the plasma levels of Brain-Derived Neurotrophic factor (BDNF). Two monomers of BDNF selectively bind to Trk B, a tyrosine kinase receptor. In coordination with LNGFR/P75NTR, it dimerizes and mediates its action by adding phosphate molecules to regulate cell signaling, providing various supports such as neuronal cell differentiation, growth, migration, survival, dendritic arborization, synaptogenesis, and synaptic plasticity both in developing and mature neurons. Signaling through receptor-specific tyrosine kinases are essential for performing specific functions, as they

regulate axonal growth and regeneration of injured neurons and are directly associated with the formation and modulation of short and long-term memories. We assessed the plasma levels of BDNF in 25 symptomatic GWV who were diagnosed and assessed by the Kansas Scale and CDC case definition. Plasma levels of BDNF in 25 veterans with GWI were compared to the plasma levels of BDNF in 25 non-symptomatic GWV and 25 healthy civilian controls. As our reference-disease control, we compared 25 veterans with Chronic Fatigue Syndrome (CFS) and 25 veterans with PTSD. The overall levels of plasma BDNF were significantly lower in symptomatic GWV, than in non-symptomatic GWV and healthy controls ($p<0.001$), as well as CFS and PTSD ($p<0.02$).

Abstract: The human microbiota is a term that is used to describe the microorganisms (archaea, bacteria, eukaryotes, and viruses) associated with the human body. The past decade has been characterized by a number of landmark surveys of the human microbiome such as the Human Microbiome Project and the American Gut Project. The main objectives of those surveys were to generate a point of reference and to establish large databases of mainly healthy individuals. Nevertheless, in-depth analyses of the human microbiome in association with validated measures

of human general, physical, and mental health are lacking, especially the latter. The main goal of the US Veteran Microbiome project is to serially assess the skin, oral, and fecal microbiomes in association with validated measures of general health, physical health, insomnia, and mental health in a cohort of U.S. Veterans at 6 month intervals. We studied a group of individuals with unique environmental exposures and health outcomes to determine if there were identifiable microbial signatures associated with specific health measures. To date we have recruited over 400 US Veterans who have provided microbiome samples from three anatomical sites (skin, oral, and fecal). We have characterized the microbiome of all three sample types (skin, oral, and fecal) as they relate to metadata collected in three main categories: general and physical health, insomnia, and mental health. Based on preliminary analysis, measures of general and physical health displayed increased alpha diversity of the fecal microbiome in association with "healthy" states. We found that severe insomnia symptoms and multiple measures of mental health were associated with microbial features from the various sampling sites. Further analyses are underway to understand the biological basis of the associations between the skin, oral, and fecal microbiomes and measures of physical health, insomnia, and mental health, and if microbiome-based interventions can be developed in order to improve these health outcomes.

Title: Post-exertional brain activity associated with verbal working memory differentiates Gulf War illness from chronic fatigue syndrome

Authors: *S. D. WASHINGTON[1], R. U. RAYHAN[2], R. GARNER[1], D. PROVENZANO[1], K. ZAJUR[1], J. W. VANMETER[1], J. N. BARANIUK[1];
[1]Georgetown Univ. Med. Ctr., Washington, DC; [2]Howard Univ., Washington, DC

Abstract: Gulf War Illness (GWI) affects a third of veterans of the 1990-1991 Persian Gulf War. Post-exertional malaise with cognitive dysfunction, pain, and fatigue following physical and/or

mental effort typify GWI. These symptoms coincide with those of Chronic Fatigue Syndrome (CFS), fueling debate over whether GWI is a subtype of CFS. However, CFS mostly affects 40 to 50-year-old women, but military demographics dictate that GWI affects mostly men. Here, we modeled post-exertional malaise by assessing changes in functional magnetic resonance imaging at 3T during an N-Back working memory task performed prior to a submaximal bicycle stress test and 24 hr later following a second identical stress test. The subjects in our groups were categorized as healthy controls (HC, N=23), Gulf War Illness (GWI, N=80), and Chronic Fatigue Syndrome (CFS, N=38). After performing a 2-Back>0-Back per subject contrast, we performed a two-sample t-test in SPM12 with age and sex regressed out. Prior to exercise, GWI had significantly greater activation in the right angular gyrus relative to HC and CFS. After exercise, GWI had significantly (cluster-level: $p<0.05$, family-wise error correction) less activation in the cerebellar vermis and right intraparietal sulcus than did HC and CFS. Further, CFS had significantly greater activation in the left Rolandic operculum than HC or GWI, and CFS also had significantly greater activation than GWI in both the periaqueductal gray and right insula. HC had no significant changes in activation before or after exercise. In short, peri-insular neural activity differentiates CFS from GWI and controls whereas medial cerebellar activity differentiates GWI from CFS and controls. These findings suggest qualitatively different neural substrates of post-exertional malaise associated with cognition in GWI and CFS.

Title: Exercise differentially alters ascending arousal network activity associated with verbal working memory in Gulf War illness and chronic fatigue syndrome

Authors: *H. S. PEPERMINTWALA[1], S. D. WASHINGTON[2], F. A. MARTINEZ ADDIEGO[1], R. U. RAYHAN[3], J. N. BARANIUK[2];

[1]Georgetown Univ., Washington, DC; [2]Georgetown Univ. Med. Ctr., Washington, DC; [3]Dept. of Physiol., Howard Univ. Col. of Med., Washington, DC

Abstract: Nearly 30% of the veterans who served in Operation Desert Storm (1990-1991) suffer from Gulf War Illness (GWI), a symptom cluster that includes cognitive impairment, autonomic dysfunction, chronic pain, and debilitating fatigue. Several studies detailing the neurological symptoms of GWI implicate the brainstem, where nuclei associated with arousal and autonomic function largely reside. Few of these studies provide functional neuroimaging or other physiological evidence for brainstem dysfunction in the GWI population. Here, we compared the blood oxygenation level dependent (BOLD) contrast elicited by a 2-Back working memory task (2-Back>0-Back) in veterans with GWI (n = 79) relative to that of sedentary, healthy controls (HC, n=31) and people with chronic fatigue syndrome (CFS, n=36). As GWI and CFS are both characterized by post-exertional malaise, all three groups completed fMRI scans before and after two exercise stress tests. Analyses were restricted to predetermined brainstem ROIs from the Harvard Ascending Arousal Atlas, including the dorsal raphe (DR), locus coeruleus (LC), median raphe (MR), medullary reticular formation (MRF), parabrachial complex (PBC), pedunculopontine nucleus (PPN), periaqueductal gray (PAG), pontine oralis (PO), ventral tegmental area (VTA). Medial structures (DR, MR, PAG, VTA) were maintained as single ROIs whereas lateral structures were divided into left and right hemispheric structures. One-way Analyses of Covariance (ANCOVAs) and paired t-tests were used to compare the activation in the a priori regions between HC, CFS, and GWI. Bonferroni corrections were used to adjust for multiple comparisons and significant regions were reported for regions where $p < 0.05$. Pre-exercise CFS had significantly decreased BOLD activity bilaterally in the PPN compared to HC, while all other brainstem regions were not significantly different. Post-exercise, GWI had significantly lower BOLD activity compared to CFS in most regions (DR, MR, PAG, VTA, R_LC, L_MRF, R_MRF, R_PBC, R_PPN), while HC was non-significant. Delta values were calculated, and it was found that due to the effect of exercise, CFS BOLD activity increased while GWI BOLD activity decreased in the majority of regions evaluated (DR, MR, PAG, VTA, R_LC, R_PBC, L_PO, R_PO, L_PPN, and R_PPN). These results are the first to demonstrate functional brainstem anomalies that corroborate the structural brainstem abnormalities commonly reported in GWI.

Title: A small-molecule that can enhance tripartite synapses is capable of improving mood and cognitive deficits in a mouse model of Gulf War illness

Authors: *X. WANG[1], Z. XU[1], F. ZHAO[1], K. LIN[1], T. XIAO[1], N. KUNG[1], J. FOSTER[1], C. C. ASKWITH[1], K. HODGETTS[2], C.-L. G. LIN[1];

Abstract: Mood and memory deficits are ubiquitous among the various symptoms of Gulf War illness (GWI). It is widely believed that these clinical symptoms are linked to a combination of exposures encountered by the service personnel. Literature has indicated that chronic exposure to GWI-related chemicals and stress results in glutamate dyshomeostasis in the hippocampus, which may contribute to memory and mood deficits. The purpose of this study was to investigate if enhanced structural and functional plasticity of the tripartite synapse by a small molecule LDN/OSU-215111 can improve mood and cognitive deficits in a mouse model of GWI. Three to four months old C57BL/6J mice were exposed to GWI agents, including pyridostigmine bromide, permethrin, and DEET, and unpredictable stress daily for six weeks. At three months post-exposure, mice developed anxiety- and depression-like behaviors and cognitive difficulties. In a study designed to mimic a preventive therapy, mice received compound treatment daily during six-week of GWI conditions and the treatment continued until mice were euthanized. We found that compound treatment almost completely prevented mood abnormalities and cognitive decline. Upon completion of behavioral assessment, a subset of mice was euthanized for electrophysiological studies to assess the integrity of the hippocampal synaptic circuit by measuring long-term potentiation (LTP). Results showed that GWI mice exhibited a substantial reduction of LTP and compound treatment completely restored LTP. In addition, we measured hippocampal extracellular glutamate levels by microdialysis. We found that GWI mice exhibited a significant increase of glutamate levels and compound treatment completely normalized extracellular glutamate levels. Furthermore, in a study designed to mimic treatment after symptoms arise, GWI mice were treated with the compound at five months post-exposure when the deficits have developed. After one month of treatment, behavioral tests were conducted. We found that the compound was still able to improve anxiety- and depression-like behaviors and also cognitive functions. These results indicate that LDN/OSU-215111 has therapeutic potential for GWI. We are currently investigating the underlying molecular mechanisms of compound effects. The results will be presented.

Abstract: Gulf War Illness (GWI) is a multi-symptom illness, which affects approximately 30% of veterans who served in the first Gulf War. Epidemiological studies have suggested that exposure to a combination of chemicals that inhibit acetylcholinesterase activity, and stress, during the war caused GWI. Indeed, concurrent exposure to low doses of chemicals widely used in GW and mild stress for 28 days in rats leads to symptoms seen in veterans with GWI. The central nervous system related symptoms in GWI include cognitive and mood dysfunction in association with chronic neuroinflammation and decreased neurogenesis in the hippocampus. We investigated the efficacy of curcumin encapsulated biodegradable nanosystems (nCUR, a compound having robust antioxidant and anti-inflammatory properties) for improving brain function and modulating neuropathological changes in animals exposed to GWI-related chemicals and stress (GWI rats). We first exposed young rats to low doses of GWI-related chemicals such as the nerve gas prophylactic drug pyridostigmine bromide (PB), mosquito repellant DEET, insecticide permethrin (PM) for 28 days. Two months later, GWI rats received nCUR at 10, 20 or 40 mg/Kg (3 days/week) or empty nanoparticles (vehicle) for eight weeks. A group of age-matched naïve control rats was included as controls. A battery of behavioral tests performed in the last four weeks of treatment revealed cognitive and memory dysfunction, pattern separation deficit, and anhedonia in GWI rats that received empty nanoparticles. Moreover, the hippocampus of these animals displayed activated microglia, hypertrophied astrocytes, decreased neurogenesis and increased expression of genes that encode proteins relevant to mitochondrial electron transport with elevated levels of mitochondrial complex proteins I, II and IV. In contrast, GWI rats that received different doses of nCUR showed better cognitive, memory and pattern separation function and no anhedonia. Besides, the hippocampus of these animals displayed reduced density of activated microglia and hypertrophied astrocytes, increased neurogenesis, and normalized expression of mitochondrial genes and complex proteins

II and IV. Interestingly, a maximal increase in neurogenesis was observed in GWI rats that received the lowest dose of nCUR (10mg/Kg). Thus, eight weeks of low-dose nCUR treatment is sufficient for improving brain function in a model of GWI. Reduced neuroinflammation, enhanced neurogenesis, and normalized mitochondrial activity likely underlie the improved brain function mediated by nCUR treatment.

Title: Efficacy of melatonin for improving cognitive and mood function in a model of Gulf War illness

Authors: *L. N. MADHU, S. ATTALURI, B. SHUAI, M. KODALI, L. MELISSARI, X. RAO, A. K. SHETTY;

Abstract: Gulf War Illness (GWI) affects 30-40% of 700,000 military personnel who served in the first Gulf War (GW). GWI is typified by a lingering cognitive, memory and mood impairments. Animal model studies employing exposures to GWI-related chemicals (GWIR-Cs) and moderate stress have linked these symptoms to persistent neuroinflammation, increased oxidative stress, mitochondrial dysfunction, and decreased hippocampal neurogenesis. These observations have prompted testing of various antioxidant and antiinflammatory compounds for their effectiveness to improve brain function. We investigated the efficacy of different doses of melatonin for improving cognitive and mood function in a rat model of chronic GWI. We also examined whether brain impairments and the associated pathological changes, continue into the middle age in GWI rats. Male SD rats were exposed daily to GW-related chemicals, pyridostigmine bromide, (PB, 2 mg/kg), DEET (60 mg/kg), and permethrin (PM, 0.2 mg/kg), and 15-minutes of restraint stress for 28 days. Six months later, the animals were treated with different doses (5, 10, 20, 40 and 80mg/Kg) of melatonin for eight weeks (5 days/week). Following the treatment regimen, animals were tested for cognitive and mood function through a battery of behavioral tests. The tasks comprised an object location test (OLT), a novel object recognition test (NORT), a pattern separation test (PST), an object in place test (OIPT), and a

sucrose preference test (SPT). GWI rats receiving vehicle displayed impairments in all tests, implying that cognitive and mood impairments seen at earlier time-points persist for prolonged periods. While most doses of melatonin were effective for improving memory function in NORT and OIPT, improvements in more complex behavioral tests in GWI rats required a higher dose of melatonin. Indeed, GWI animals receiving 80mg/Kg melatonin displayed improved cognitive ability for discerning minor changes in the environment as well as better pattern separation function. Doses of melatonin at 20-80 mg/Kg were also effective for reversing anhedonia. Immunostaining analyses of brain tissues revealed the persistence of activated microglia, reactive astrocytes and reduced hippocampal neurogenesis in middle-aged GWI rats. Higher doses of melatonin treatment reduced the percentage of activated microglia in GWI rats. Measurements of the effects of melatonin for modulating the population of reactive astrocytes, and increasing hippocampal neurogenesis, are currently in progress. Thus, melatonin therapy has promise for improving cognitive and mood function in GWI at relatively higher doses.

Title: Anthrax in Gulf War illness (GWI): Evidence from neuroblastoma cultures for the presence of anthrax vaccine antigen in the serum of veterans suffering from GWI

Authors: *P.-E. C. TSILIBARY[1], E. P. SOUTO[1], L. M. JAMES[1,2], B. E. ENGDAHL[1,2], M. G. KRATZKE[1], A. P. GEORGOPOULOS[1,2];

Abstract: After the Persian Gulf War of 1990-91, about one third (more than 200,000) of veterans complained of a variety of chronic physical and neurocognitive symptoms, presently identified as Gulf War Illness (GWI) and traditionally attributed to possible exposures to toxic warfare chemicals (e.g. sarin). In 2016, we identified genetic vulnerability factors in GWI, when we discovered that veterans with GWI lacked one or more of 6 Human Leukocyte Antigen (HLA) class 2 alleles [1] the presence of which was associated with reduced GWI symptom severity in a dose-response fashion. Since these alleles are essential for mounting antibodies to foreign antigens, we hypothesized that veterans lacking those alleles could not make antibodies

to eliminate harmful antigens which would persist and cause GWI. Such antigens could come from exposure to biological and chemical substances. A unique exposure of GW veterans was to anthrax antigen(s) contained in the vaccine [2] they received. Here we tested the hypothesis that persistent, harmful anthrax antigens are involved in GWI. Using specific, recombinant polyclonal antibodies against the PA63 and PA83 anthrax antigens contained in the anthrax vaccine, we obtained evidence for the presence of these antigens in the serum of 15 veterans suffering from GWI (and lacking all 6 HLA protective alleles), causing detrimental effects on brain cultures [3] which were eliminated when anti-anthrax antibodies were added to the serum. These findings demonstrate a direct link between anthrax vaccine and GWI.

Abstract: Gulf War Illness (GWI) is a chronic multisymptom illness that affects veterans of the Persian Gulf War and presents with chronic musculoskeletal pain, fatigue, and cognitive dysfunction. While the exact etiology of GWI is unknown, the onset of GWI is associated with exposure to neurotoxic insecticides, organophosphate (OP) nerve agents, and OP prophylactics. There are currently no pharmacotherapies available for treatment of GWI. The present study

investigated the efficacy of a novel immunomodulatory agent, lacto-N-fucopentaose III (LNFPIII), in treating the persisting neurophysiological and cognitive deficits observed in a GWI mouse model. Male C57BL/6J mice were treated with 2 mg/kg pyridostigmine bromide (s.c.) and 30 mg/kg N,N-diethyl-meta-toluamide (s.c.) once per day for 14 days. On days 8 - 14 mice also received corticosterone in their drinking water (200 mg/L in 1.2% EtOH) to emulate combat-related chronic stress. On day 15, animals received a single injection of a common sarin surrogate, diisopropylfluorophosphate (3.75 mg/kg, i.p.). Control mice received saline vehicle instead of GWI chemicals. Subsets of GWI and saline-treated animals received twice-weekly LNFPIII (GWI-LNFPIII, saline-LNFPIII) or vehicle (GWI-vehicle, saline-vehicle) treatment beginning 7 months after exposure to GWI chemicals. Nine months after GWI chemical exposure, an 8-arm radial arm maze (RAM) foraging task revealed impaired performance in GWI-vehicle animals, an effect that was partially reversed in GWI-LNFPIII animals. Dorsal hippocampus (dH) and ventral hippocampus (vH) slices obtained from GWI-vehicle animals exhibited reduced LTP magnitude 10 months after GWI treatment. GWI-LNFPIII animals displayed dH and vH LTP magnitude that was similar to saline-treated mice. Moreover, a main effect of GWI treatment on LTP was observed in the dH but not the vH, suggesting sector-specific effects of GWI chemical exposure. Basal synaptic transmission was decreased in the dH and the vH of GWI-vehicle animals compared to GWI-LNFPIII, saline-LNFPIII, and saline-vehicle treated mice. Impaired performance in the RAM foraging task suggests deficits in short-term spatial working memory due to GWI chemical exposure. Reduced sector-specific LTP, as well as decreased dH and vH basal synaptic transmission, provides mechanistic insight into such working memory impairments. Importantly, LNFPIII treatment beginning 7 months after GWI chemical exposure partially restored working memory performance and fully restored dH and vH LTP magnitude, suggesting that LNFPIII may be an efficacious treatment for cognitive dysfunction observed in GWI patients.

Title: Gulf War illness and inflammation: Association of symptom severity with c-reactive protein

Authors: *R. JOHNSON[1], L. JAMES[2], B. E. ENGDAHL[2], A. P. GEORGOPOULOS[3]; [1]Cognitive Sci., Univ. of Minnesota, Minneapolis, MN; [2]Brain Sci. Ctr., Univ. of Minnesota/Minneapolis VAHCS, Minneapolis, MN; [3]Neurosci, Univ. Minnesota, Minneapolis, MN

Abstract: Gulf War Illness (GWI) is a chronic multi-system condition that has affected one-third of U.S. veterans who served in the Persian Gulf. Although GWI etiology remains unclear, mounting evidence points to immune system involvement and inflammation, in particular, as underlying the host of symptoms associated with the condition. Here we investigated the association between GWI symptoms and C-reactive protein (CRP), a marker of inflammation, in 76 veterans with GWI. Results indicated a highly significant positive association between CRP and mean GWI symptom severity. At the symptom domain level, CRP was significantly and positively associated with Pain, Neurocognitive/Mood, Fatigue, and Respiratory symptom severity but not with Skin or Gastrointestinal symptom severity. These results support the premise that GWI symptoms, particularly those implicating brain involvement, are a result of neuroinflammation. The cause for inflammation is not known. We have hypothesized that at the root of GWI are harmful persistent antigens stemming from environmental exposures associated with service during the Gulf War that could not be successfully eliminated due to lack of specific immunity. Work is underway in our laboratory to identify and eliminate persistent antigens in veterans with GWI which we anticipate will result in reduced inflammation and reduced GWI symptoms.

Title: Gulf war illness (GWI)-protective HLA DRB1*13:02 allele protects against harmful anthrax vaccine antigen

Authors: *S. CHARONIS[1,2], A. P. GEORGOPOULOS[1,2];
[1]Neurosci., Univ. of Minnesota, Minneapolis, MN; [2]Brain Sci. Ctr., Dept. of Veterans Affairs Hlth. Care Syst., Minneapolis, MN

Abstract: GWI has afflicted many veterans of the 1990-91 Gulf War, affecting the brain, among other organs. Brain network abnormalities [1] resemble those of immune disorders [2], hence GWI's designation as a "neuroimmune" disorder [2]. A deficit in specific, adaptive immunity in GWI was discovered in 2016 [3], namely that GWI veterans lack one or more of 6 HLA class II protective alleles [3]. Since these alleles are necessary for producing antibodies against foreign pathogens/antigens, we hypothesized that such harmful "persistent antigens" are at the root of GWI, namely antigens to which GW veterans were exposed but which could not be eliminated due to lack of HLA protection in those veterans [4]. A unique exposure of GW veterans was to anthrax Protective Antigen (aPA) contained in the vaccine they received (Bio Thrax). We show in a different presentation at this meeting [5] that aPA is indeed harmful to neural cultures, which suggests its possible involvement in causing GWI.
Here we show that aPA is also an excellent target of the HLA class II DRB1*13:02 allele which is one of the 6 GWI protective alleles [3] and which protects against GWI-related brain atrophy [6]. We used the Immune Epitope Database (www.iedb.org) to identify predicted epitopes of class II HLA proteins for aPA and ranked the matched epitopes according to the number of experimental assays they were in. We thus obtained the ranked binding affinities of aPA (UniProtKB ID P13423) of the 6 GWI-protective HLA class II alleles (DRB1*01:01, DRB1*08:11, DRB1*13:02, DQB1*02:02, DPB1*01:01 and DPB1*06:01). Small percentile ranks indicate higher binding affinity and vice versa.
We found that DRB1*13:02 had the highest binding affinity to aPA (minimum percentile rank, MPR = 0.34), closely followed by DRB1*01:01 (MPR = 0.36). The binding affinities of the remaining 4 alleles were 17-54 times lower than that of DRB1*13:02. These results support the hypothesis that the protective role of DRB1*13:02 [3,4] in GWI could be partially mediated through elimination of harmful aPA and are in keeping with the idea that anthrax vaccine containing aPA is involved in developing GWI. (Supported by the Department of Defense Award Number W81XWH-17-1-0677).

Abstract: Gulf War Illness (GWI) is a chronic multi-system condition that has affected one-third of U.S. veterans who served in the Persian Gulf. We reported recently the presence of brain atrophy in GWI [1] and a positive association of GWI symptom severity with the level of C-reactive protein (CRP), an inflammatory marker [2]. Here we investigated the effect of CRP on brain atrophy and fractional anisotropy in 65 GWI veterans. Structural MR and diffusion weighted images were acquired using a 3T Philips magnet and data were analyzed using the Human connectome project pipeline, FreeSurfer and ExploreDTI packages. CRP values were log-transformed to normalize their distribution [2]. We found that higher CRP levels were associated with (a) lower volumes (i.e. higher atrophy) of the brainstem and hippocampi (bilaterally), and (b) lower values of fractional anisotropy in the fornix, the output of the hippocampus to hypothalamus, indicating a disruption in this white matter tract. Altogether, these findings point to an inflammatory basis for brain atrophy and white matter pathology in GWI. The localization of these effects in the brainstem and hippocampi, regions near the most permeable blood brain barrier (BBB), are consistent with our hypothesis [1] that harmful substances (persistent antigens [3]) circulating in the blood of GWI patients [4, 5] gain access to the brain through most vulnerable BBB regions to inflict damage on nearby areas.

Title: Delayed treatment with the immunotherapeutic LNFPIII ameliorates Gulf War illness-related behavioral deficits in a rodent model of the disease

Authors: *J. M. CARPENTER[1], R. L. DOCKMAN[1], H. D. LUDWIG[1], J. J. WAGNER[1], D. A. HARN[2], N. M. FILIPOV[1];
[1]Physiol. and Pharmacol., [2]Infectious Dis., Univ. of Georgia, Athens, GA

Abstract: Nearly 30% of veterans from the 1990-1991 Gulf War (GW) suffer from Gulf War Illness (GWI), a complex illness with many neurological symptoms that might have immunological underpinnings. War-related stress combined with overexposures to GW related chemicals, including a nerve agent prophylactic (pyridostigmine bromide; PB), pesticides (N,N-Diethyl-methylbenzamide; DEET) and, in some cases, exposure to nerve agents (sarin/cyclosarin) have been implicated in GWI. Currently, long-term, efficacious treatment options are unavailable. Here, an established GWI mouse model was utilized to explore the (1) long-term behavioral effects of deployment related GW chemicals exposure and (2) ability of a novel immunotherapeutic, Lacto-N-fucopentaose III (LNFPIII), to modulate GWI behavioral effects when given months post the initial GW exposures. Male C57BL6/J mice (8-9 weeks) were exposed to PB and DEET for 14 days, with the second 7 days also including corticosterone to emulate war-time stress. On day 15, a single injection of the sarin surrogate diisopropylfluorophosphate was given. Seven months post GW exposures, LNFPIII treatment began and continued until study completion. A battery of rodent behavioral tests, assessing memory, mood and motor function were performed beginning 8 months post GW exposures. From the data analyzed to date, in tests of motor function, GWI mice exhibited hyperactivity as evident by more distance traveled in an open field (OF), increased cadence, stride length and interstep distance in a gait test and decreased time to descend the pole in a pole test. Sensorimotor function was impaired by GWI as mice had longer latencies to contact the sticker in a sticker removal test. Grip strength was also decreased in GWI mice. These motor related

deficits, except OF distance, were attenuated by LNFPIII. GWI disrupted short-term memory, as mice approached and spent less time at a novel object in the novel object recognition test and this was not affected by LNFPIII. LNFPIII decreased anxiety-like behavior in GWI mice on the marble burying test (less marbles buried) and elevated zero maze (more open arm time and higher latency to enter the closed arm). In the OF, GWI mice exhibited more anxiety-like behavior (more time and entries into the corners) that was not prevented by LNFPIII. Together, it appears that months after exposure to GW-related chemicals, deficits in motor function, memory and mood are present. Many of these deficits were ameliorated by LNFPIII treatment initiated months following GW exposures, highlighting its therapeutic potential for veterans with GWI.

Title: Using single-cell transcriptomics to study the effects of early-life adversity on the crh-expressing neurons of the paraventricular nucleus (PVN)

Authors: *C. WILCOX[1], A. K. SHORT[3], M. BIRNIE[2], J. L. BOLTON[4], Y. CHEN[1], A. MORTAZAVI[1], T. Z. BARAM[3];
[2]Dept. of Pediatrics, [1]Univ. of California, Irvine, Irvine, CA; [3]Univ. of California Irvine, Irvine, CA; [4]Dept. of Anat. & Neurobio., Univ. of California-Irvine, Irvine, CA

Abstract: Mental and cognitive health as well as vulnerability to neuropsychiatric disorders involve the interplay of genes with the environment during sensitive developmental periods. Genetic and environmental factors contribute to the development and maturation of neurons, synapses and the resulting brain circuits. Within the hypothalamus, early-life adversity causes an increase in the number of excitatory synapses onto corticotropin-releasing hormone (CRH)-expressing neurons in the paraventricular nucleus (PVN). Further, such synaptic changes suffice to induce enduring epigenomic changes within these cells, influencing programs of gene expression. However, the epigenetic mechanisms by which early-life adversity orchestrates epigenetic programs within individual CRH-expressing neurons, with enduring functional consequences, remain unknown.

We utilize animal models of an impoverished environment and unpredictable maternal care (in a limited bedding and nesting [LBN] paradigm), which provokes major alterations in cognitive and emotional outcomes. We are focused on the change in gene expression profile of stress-sensitive CRH-neurons in the PVN following LBN. Initial studies focus on the immediate consequences of adversity, studied in 10-14 day old mice of both sexes. Because of the known heterogeneity of CRH-expressing neuronal populations, we are using single cell RNA sequencing (RNA-seq) to determine differential gene expression associated with early-life adversity and establish the upstream mechanisms and downstream consequences. Specifically, we employ CRH-ires-CRE mice, where a reporter (TdTomato) is expressed in CRH+ cells, enabling FACS selection of CRH expressing neurons. We employ the SmartSeq2 protocol to build single cell RNA-seq libraries and, once sequenced, STAR and RSEM are used to map and quantify the reads, respectively.
Initial analyses confirm the striking heterogeneity of CRH+ cell populations within the hypothalamus. Ongoing studies are delineating the large-scale change in gene expression provoked by early-life adversity.

Title: FKBP5, a depression-associated gene, has a role in autophagy

Authors: *H. PARK[1], S.-Y. JUNG[2], J. CHANG[2], S. LEE[1];
[1]Dept. of Anat. and Hypoxia-related Dis. Res. Center, Col. of Med., Inha Univ., Incheon, Korea, Republic of; [2]Dept. of Biomed. Sci. and Dept. of Brain Sci., Ajou Univ., Suwon, Korea, Republic of

Abstract: Mood disorders are common psychiatric disorders caused by various genetic and environmental factors. There are many antidepressants exist, but these do not work for more than half of the patients. Therefore, genetic factors may contribute to individual variation in antidepressant response. FK506 binding protein 51 (FKBP51, also known as FKBP5) belongs to a family of immunophilins that binds to the immunosuppressants FK506 and rapamycin. The

scaffolding activity of FKBP5 enables it to play a modulatory role in the immune response, tumorigenesis, cell death, and the stress hormone axis. Moreover, single nucleotide polymorphisms in FKBP5, which increase FKBP5 protein levels, are significantly associated with increased recurrence of depressive episode. However, the molecular mechanism for how FKBP5 regulates depression remains unclear. It has been recently reported that FKBP5 not only modulates antidepressant response but also interacts with Beclin1, Akt, and PHLPP, which are critical for autophagy, an intracellular degradation system necessary for the maintenance of cellular homeostasis. To investigate the relationship between FKBP5 and autophagy, we generated FKBP5 knock-out cell lines using a CRISPR/Cas9 system and analyzed them. We found that autophagic flux was impaired by a loss of FKBP5 in both basal and induced autophagy conditions. The detailed mechanisms will be shown in the presentation. We hope these findings will help to understand the molecular mechanism of how autophagy is associated with depression.

Title: Normalizing aberrant DNA methylation associated with maltreatment

Authors: *N. COLLINS, C. ZIMMERMAN, T. S. DOHERTY, N. L. H. PHILLIPS, T. L. ROTH;
Univ. of Delaware, Newark, DE

Abstract: Childhood adversity has negative implications for development, including increased risk for various psychological disorders. One way this may occur is through changes to the epigenome. Using a rodent model, our lab has demonstrated alterations in both adult behavior and the epigenome that are associated with exposure to maltreatment. The present study sought to investigate whether valproic acid (VPA), a histone deacetylase inhibitor (HDACi), can normalize aberrant brain methylation associated with maltreatment. Using a scarcity adversity paradigm of maltreatment outside the home cage, male and female Long-Evans rat pups were exposed to either nurturing care or maltreatment for 30 minutes per day during postnatal days 1-7. Prior to each exposure session, rats were given a systemic injection of vehicle or VPA (200 mg/kg). We replicate our previous observation of a significant effect of infant condition, such that both males and females exposed to maltreatment displayed higher levels of methylation in

the prefrontal cortex. VPA was ineffective at preventing the maltreatment-induced increase in methylation. Current work in the lab is exploring whether other doses of VPA or another HDACi are capable of normalizing the methylation, with future work aimed at determining whether this strategy can also normalize adult behavior associated with maltreatment.

Title: The effects of prenatal testosterone on stress system development

Authors: *E. R. MARTIN[1], H. A. WILSON[2], N. J. MACLUSKY[2], E. CHOLERIS[1];
[1]Psychology, [2]Biomed. Sci., Univ. of Guelph, Guelph, ON, Canada

Abstract: Gonadal hormones, such as testosterone (T), act on the brain during critical periods of development to produce sexually dimorphic changes which result in sex differences in neuroendocrine function and behaviour later in life. Exposure to increased T levels during prenatal development has implications in various disorders such as Autism Spectrum Disorder, which is characterized by impairments in social behaviour and is often associated with anxiety disorders. A recent study assessed the effects of slightly elevated prenatal T exposure in mice and found increased aggression and anxiety-like behaviour as well as deficits in social recognition and social learning. The current study aims to determine the mechanisms underlying the lasting changes in behaviour caused by prenatal T. Prenatal T and glucocorticoid (GC) exposure produce similar effects on offspring behaviour and their transcriptional effects have been shown to interact, so we hypothesize that prenatal T and GC exposure might exert similar effects on brain development and stress responsivity. We assessed the effects of elevated prenatal T and dexamethasone (DEX; a synthetic GC) on the expression of stress sensitive genes and miRNAs during the neonatal period as well as hormone profiles and GC levels in mice in adulthood. Pregnant CD1 dams were subcutaneously injected with sesame oil (vehicle control), 10 μg T propionate, or 0.1mg/kg DEX on embryonic days 12, 14 and 16. The expression of stress sensitive genes and miRNAs were measured in the hippocampus (HPC) on the day of birth. We also measured T levels from 1-6 hours following birth in male pups. Plasma corticosterone (CORT) was measured in adulthood at 10 minutes, 1 hour, or 3 hours following a 30-minute restraint stress. Prenatal treatment had no effect on T levels on the day of birth;

however, miR-124 was selectively down-regulated in the HPC at this time. MiR-124 is a brain specific miRNA that negatively regulates the expression of both the GC receptor and mineralocorticoid receptor, which may result in changes in stress sensitivity. DEX had no effect on CORT responsivity in either sex but prenatal T reduced CORT responsivity to restraint stress in males, but not in females. Thus, low doses of prenatal T may specifically alter stress responsivity in males. These findings have implications for understanding sex differences in the prevalence of ASD.

Title: Surgical disruption of corticotropin releasing hormone neurons in the nucleus of the hippocampal commissure reduces HPA axis activity in birds

Authors: *M. T. KIDD, Jr[1], H. J. KADHIM[2], S. W. KANG[1], W. J. KUENZEL[1];
[1]Poultry Sci., [2]Cell and Mol. Biol., Univ. of Arkansas, Fayetteville, AR

Abstract: The nucleus of the hippocampal commissure (NHpC) in previous studies has been proposed to be part of the hypothalamic-pituitary-adrenal (HPA) axis regarding its role in the neuroendocrine regulation of stress in birds. The objective of this study was to apply electrolytic lesions to the NHpC, effectively disrupting corticotropin releasing hormone (CRH) neurons in that structure, to determine if its disruption affects the normal activity of the HPA axis driven by CRH neurons within the paraventricular hypothalamic nucleus (PVN). Male chicks (BW 300-350g, 10-14 days of age) were used in this experiment and split into two groups; lesioned birds (LES) and sham operation controls (sCON), which are birds subjected to surgery including placement of the electrode within the brain, but with no electrical current applied. On day 5 post surgery, a 2-hour (2 h) food deprivation (FD) stress was applied to all birds. Brain and anterior pituitary (APit) were promptly taken at 2 h of FD. Brain samples from the NHpC and PVN were dissected for qRT-PCR. Gene expression of CRH and CRH receptor 1 (CRHR1) in the NHpC were measured as well as CRH and CRHR1 in the PVN, the major hypothalamic nucleus involved in stress responses of vertebrates. CRHR1 and proopiomelanocortin (POMC) mRNA were measured in the APit. All data were analyzed using a one-way ANOVA. CRH and CRHR1 mRNA in the NHpC were found significantly down due to lesion placement ($p<0.001$) in LES in

comparison to sCON. In the PVN, CRH was found significantly upregulated ($p<0.01$) in LES in comparison to sCON, while its receptor, CRHR1 was significantly downregulated ($p<0.05$) in LES compared to sCON. In the APit, POMC was found significantly downregulated ($p<0.001$) in LES in comparison to sCON while its receptor, CRHR1, was found upregulated ($p<0.001$) in LES. Evidence suggests that lesioning the NHpC including all or some of its CRH neurons disrupts food restriction related HPA stress responses due to APit downregulation of POMC. Although PVN upregulation of CRH is present, the upregulation could be a compensatory response caused by the lack of normal increased NHpC CRH expression due to surgical disruption. Even with upregulated expression of CRH in the PVN, downregulation of POMC and upregulation of CRHR1, illustrate a lack of HPA activation expected from an intact NHpC. Also, diminished POMC expression suggests a neural pathway from the NHpC to median eminence. In conclusion, lesioning NHpC CRH neurons disrupted the expected response of the avian HPA axis during FD stress adding evidence that the NHpC plays a role in the avian HPA axis. (Supported in part by an Arkansas Biosciences Institute Grant).

Title: Vasotocinergic system in septo-hypothalamic structures and anterior pituitary sustains HPA axis response in birds

Authors: *H. J. KADHIM[1], M. T. KIDD, Jr.[2], S. W. KANG[2], W. J. KUENZEL[2];
[1]Cell and Mol. Biol., Univ. of Arkansas Fayetteville, Fayetteville, AR; [2]Poultry Sci., Univ. of Arkansas, Fayetteville, AR

Abstract: Recently, we proposed that CRH neurons in the nucleus of hippocampal commissure (NHpC), located in the septum, functioned as a part of the traditional HPA axis in avian species. A major reason was greater activation of CRH mRNA in the NHpC compared to CRH mRNA in the paraventricular nucleus (PVN) following food deprivation (FD) stress. Therefore, we determined if FD stress also activates arginine vasotocin (AVT) neurons and their receptors, V1aR and V1bR, within HPA axis. AVT mRNA and its receptors were examined in the NHpC, PVN, and medial basal hypothalamus (MBH). Additionally, gene expression of V1aR and V1bR in the anterior pituitary (APit) and plasma corticosterone (CORT) concentration were determined. Male chicks, 14 days of age, were divided into six groups (10 birds/treatment) and

subjected to different times of FD (Control, 1 h, 2 h, 3 h, 4 h, and 8 h). For each bird, blood was first collected for measuring CORT by RIA. Brains and APits were sampled and immediately frozen for each group. Brains were cryosectioned. The NHpC, PVN, and MBH were microdissected for RT-PCR. Data were analyzed using one-way ANOVA followed by Tukey Kramer HSD test with significant level ($p<0.05$). Here, we provide novel evidence that not only AVT ($p<0.001$) and V1aR ($P< 0.001$) mRNA are expressed and increased significantly in the PVN during stress, but V1bR mRNA also appears to be expressed and upregulated ($p<0.001$) in the avian brain, particularly in the MBH. Data showed a positive feedback between AVT and receptors in the PVN starting at 3 h of FD. In contrast, significant downregulation of AVT mRNA occurred in the NHpC ($p< 0.001$) during FD perhaps due to the absence of AVT cell bodies in that structure as shown by immunohistochemistry, whereas its receptors were upregulated significantly after 3 h of FD. On the other hand, AVT mRNA in its nerve terminal fields located in the MBH were upregulated ($p<0.001$) at 2 h and continued throughout the last sampling point (8 h) along with upregulation of V1bR ($p<0.01$) and downregulation of V1aR ($p<0.01$). At the APit level, significant upregulation of V1bR ($p<0.001$) and downregulation V1aR ($p<0.001$) indicated that AVT differentially regulates receptors in the AP to regulate CORT release. Data show that upregulation of AVT mRNA in the PVN and V1bR in the APit sustained the significant increase of plasma CORT ($p<0.001$) at the end of the FD treatment. Taken together, continued FD stress is associated with increasing plasma CORT via upregulation of AVT mRNA not only in the cell bodies within the PVN but also in the terminal field including the MBH and median eminence responsible for differential activation of AVT receptors in brain structures and APit. Title: Exploring the role of Egr1 in regulating hormone-dependent transcriptional programs and anxiety- and depression-related behavior in female mice

Authors: *D. ROCKS[1], I. JARIC[1], H. CHAM[2], A. HERCHEK[1], J. M. GREALLY[3], M. SUZUKI[3], M. KUNDAKOVIC[1];

Abstract: Due to the prevalence of sex-bias in animal research of the brain and behavior, little is known about the mechanisms driving the two-fold increase in risk for anxiety and depression experienced by females. To address this gap in knowledge, we studied the role of ovarian hormone fluctuations and developmental stress in mediating sex-specific vulnerability to anxiety- and depression-like behavior as measured by behavioral tests (open field, elevated plus maze, sucrose preference, forced swim, n=80 females, 40 males). We found that females exposed to early-life stress in the form of maternal separation (MS) showed increased depression-like behavior compared to MS males. Within control females, the high-estrogenic stage of the cycle was associated with decreased anxiety- and depression-like behavior compared to the low-estrogenic stage. This protective effect of estrogen was disrupted by early-life stress, as high- and low-estrogenic MS females exhibited no difference in anxiety-indices in the open-field test. To understand the molecular basis of this phenomenon, we utilized targeted and genome-wide gene expression and epigenetic assays: qRT-PCR & Bisulfite-Pyrosequencing (n=12 females, 8 males), and ATAC-seq (n=12 females, 6 males) in the ventral hippocampus, a brain region relevant for anxiety and depression. Following early-life stress, we observed aberrant gene expression and DNA methylation in psychiatric-risk genes including *Nr3c1* and *Cacna1c*. Additionally, we found that neuronal chromatin organization in this brain region changes dynamically across the estrous cycle. A subsequent motif analysis identified Egr1, an estrogen-responsive transcription factor, as a predicted upstream regulator of genes with differential chromatin accessibility across the estrous cycle. Interestingly, the expression of *Egr1* fluctuates across the estrous cycle in control females and is disrupted by early-life stress in MS females. To validate a direct relationship between estrogen and Egr1 that is implicated in our observed phenotype, we utilized primary mouse hippocampal neurons. Preliminary data from these experiments reveal a dynamic pattern of *Egr1* expression following estradiol treatment that coincides with the expression of anxiety-related Egr1 target genes. Together, our results indicate an important role for sex hormone fluctuations in female-specific susceptibility to depression and anxiety disorders. Further, we present Egr1 as a candidate key regulator in driving transcriptional fluctuations across the estrous cycle which are likely contributors to increased female vulnerability to anxiety- and depression-related phenotypes.

Title: Impaired proteostasis in response to early life stress in the adult and aged hippocampus

Authors: *J. A. SIERRA FONSECA[1], J. N. HAMDAN[2], A. A. COHEN[2,3], S. M. CARDENAS[2], S. SAUCEDO, Jr.[2], G. A. LODOZA[2], K. L. GOSSELINK[2,4];

Abstract: Early-life stress (ELS) can persistently modify neuronal circuits and functions, and increase the expression of misfolded and aggregated proteins that are hallmarks of several neurodegenerative diseases (NDs), including Alzheimer's (AD). In order to maintain proteostasis, the healthy brain clears abnormal proteins through the actions of two main pathways: the autophagy-lysosomal pathway (ALP), which employs autophagosome fusion with the lysosome for recycling of cellular components, and the ubiquitin-proteasome system (UPS), which targets soluble, short-lived proteins with a specific ubiquitin signal for proteasomal degradation. Accumulating evidence indicates that these two systems become impaired in NDs, causing accumulation of abnormal proteins and ultimately leading to neuronal death. ELS is known to impact development and progression of NDs, yet the precise underlying mechanisms remain poorly understood. We therefore hypothesized that ELS disrupts proteostasis in the brain, leading to deficient clearance and the subsequent accumulation of abnormal proteins. Our analyses focused on the hippocampus (HIPP), given its critical roles in mediating the stress response and its involvement in the pathology of AD. Female and male Wistar rats underwent ELS in the form of maternal separation for 3h/d on postnatal days 2-14. Brain tissue was then harvested from adult (3 months) and aged (16 months) animals, and the HIPP was isolated and evaluated for expression of protein markers associated with the ALP (beclin-1, LC3 and p62), the UPS (20S proteasome, PSMC5, and K48-polyubiquitinated proteins), and AD (phosphorylated Tau, amyloid precursor protein and cleaving enzymes BACE1 and IDE) using Western blot. ALP markers in the adult HIPP were significantly increased by ELS in both sexes, whereas UPS marker expression displayed sex differences, with 20S proteasome and K48 polyubiquitinated protein expression increased in females but decreased in males. In the adult HIPP, phospho-Tau was increased significantly after ELS in females but decreased in males, and the cleaving enzymes BACE1 and IDE were increased by ELS in males only. In the aged HIPP, expression of the ALP marker p62 was increased by ELS in females, while the UPS protein PSMC5 was found to be increased in females and decreased in males. Levels of phospho-Tau were found to be decreased in the aged male HIPP, with the enzyme BACE showing decreased levels in ELS males. Collectively, our results indicate that ELS can persistently and selectively modify the proteostasis machinery in the HIPP in a sex- and age-dependent manner, which may consequently impact the development of NDs.

Title: Effect of chronic corticosterone treatment on tryptophan hydroxylase isoform expression and activity in rat adrenal glands

Authors: *N. SAROJ[1], J. TERRÓN SIERRA[1], S. ,,[2];
[1]Pharmacol., CINVESTAV-IPN, Mexico City, Mexico; [2]Pharmacol., Ctr. for Res. and Advanced Studies of the Na, Mexico City, Mexico

Abstract: Chronic stress has been proposed as one of the key factors predisposing to endocrine disruption and the development of stress-related disorders. Recently chronic restraint stress (CRS) was shown to induce sensitization of stress-induced corticosterone (CORT) secretion via ACTH-independent mechanisms involving increased adrenal 5-HT levels and ectopic expression of adrenocortical 5-HT7 receptors. Tryptophan hydroxylase (TPH) is the rate-limiting enzyme in the biosynthesis of 5-HT and two isoforms of this enzyme encoded by different genes, TPH1 and TPH2, have been identified. In the present study we examined the effect of chronic CORT treatment on TPH isoform expression in rat adrenal glands, as determined by immunohistochemistry, Western blot and reverse transcription polymerase chain reaction (RT-PCR), respectively; in addition, TPH activity was also measured by a fluorometric HPLC technique. Male Wistar rats received chronic CORT (20 mg/kg, s.c.) and vehicle (VEH; 1 ml/kg, s.c.) treatments for 14 days. On day 15, animals of each group were anesthetized and perfused or decapitated for collection of tissues. Body weight gain, and relative adrenal and thymus weight were recorded. As compared to VEH, chronic CORT treatment notably increased TPH2 -but not TPH1- expression in the adrenals, as visualized by an increase of TPH2-like immunoreactivity in the adrenocortical zona glomerulosa and inner and outer zona fasciculata, as well as TPH2 protein and mRNA levels in whole adrenal glands. Furthermore, chronic CORT significantly increased adrenal 5-HT levels as compared to chronic VEH treatment. Results support the notion that the increase of adrenocortical levels of 5-HT in chronically stressed animals may be accounted for by ectopic expression and activity of THP2, and that these changes are corticosteroid-dependent.

Title: Profiling m^6A RNA methylation in human postmortem brain tissue in individuals with depression

Authors: *H. MITSUHASHI[1,3], C. NAGY[3], Z. AOUABED[3], G. TURECKI[3,2];
[1]Integrated Program in Neurosci., [2]Dept. of Psychiatry, McGill Univ., Montreal, QC, Canada;
[3]McGill Group for Suicide Studies, Montreal, QC, Canada

Abstract: Introduction: Major Depressive Disorder (MDD) is one of the most common psychiatric disorders worldwide. Mounting evidence suggests there is an alteration of epigenetic mechanisms in response to stressful stimuli and environmental factors in the pathophysiology of MDD, yet little is known about the epitranscriptome in MDD. N6-methyladenosine (m^6A) is the most abundant and reversible RNA modification in mammalian mRNA. Given its high abundance and dynamic regulation in the brain, m^6A has been described to be crucial in brain development. Recent studies have found m^6A to be involved in stress response suggesting its importance in the development of stress-related psychiatric disorders. However, there are no human studies examining m^6A-seq in the brain and its role remains largely undescribed. The aim of this study is to describe the landscape of m^6A in the human brain and to identify changes that may occur in the context of MDD.
Methods: To examine the post-mortem stability of m^6A and the influence of age, RNA Integrity, and pH on m^6A levels, global m^6A levels were quantified using EpiQuik m^6A RNA Methylation Quantification Kit (Epigentek). To assess the small quantity of RNA extracted from post-mortem brain tissue, a low-input m^6A-seq protocol was optimized according to the published protocols and sequenced on the Illumina platform.
Results: Results suggest that PMI does not have a significant influence on global m^6A levels and m^6A is relatively stable in post-mortem brain. A significant number of peaks were detected using the low-input m^6A-seq protocol compared to a high-input m^6A-seq protocol.
Conclusions: The use of human postmortem brain could help us understand the role of m^6A in general brain function as well as provide greater insight into the etiopathogenesis of MDD.

Abstract: Early experiences during perinatal life may be a factor of vulnerability to develop psychiatric disorders such as depression, and substance abuse. Maternal separation (MS) in male rats increase the consumption of alcohol in adulthood. MS also induces decreased expression of cannabinoid receptor 1 (CB1R) in the PFC. On the other hand, high levels of oxytocin are associated with social bonds. The objective of this study is to describe the changes in the oxytocin and endocannabinoid systems and the affective state (anxiety and depression) generated by family and / or social exclusion, in adult male Wistar rats. as well as to analyze the potential environmental protection effect social during adolescence. Four groups of Wistar rats, non-MS /Socialized, non-MS/Isolated, MS (PND2-15)/ Socialized (PND24-60) and MS/ Isolated (PND24-90) were utilized. They were evaluated in the elevated plus maze test. Oxytocin and CB2 receptors were estimated in PFC, Amygdala, NAcc, by means of immunofluorescence. Results. Social isolation facilitated the expression of like-anxiety behaviors. Socialization during adolescence reversed MS effects on the anxiety-like behaviors. Regarding the findings of Oxytocin and CB2R will be discussed. Key words: Cannabinoid receptor 2, oxytocin receptor, maternal separation, socialization

Title: Chronic stress-induced increase of adrenocortical serotonin transporter expression in rats: A glucocorticoid-dependent phenomenon

Authors: S. „[1], J. TERRON SIERRA[2], P. LOPEZ SANCHEZ[2], N. SAROJ[3];
[1]Ctr. For Res. and Advanced Studies of the Na, Mexico City, Mexico; [2]CINVESTAV-IPN, Mexico city, Mexico; [3]Pharmacol., CINVESTAV-IPN, Ciudad DE Mexico, Mexico

Abstract: Chronic restraint stress (CRS) has been shown to magnify acute stress-induced corticosterone (CORT) secretion in rats through a mechanism involving 5-HT7 receptors, and to increase the amount of 5-HT7 receptors and serotonin (5-HT) in the adrenal cortex. Since chronic stress has also been demonstrated to increase the expression of the 5-HT transporter (SERT) in the central nervous system, the purpose of the present study was to investigate whether SERT expression is also increased in the adrenal glands as a result of CRS exposure, specifically at the level of adrenocortical cells involved in glucocorticoid secretion. In addition, we asked the question whether potential CRS-induced changes in adrenocortical SERT expression might be glucocorticoid-dependent. We examined the effects of CRS (20 min/day) as compared to control (CTRL) conditions for 14 days on SERT-like immunoreactivity (SERT-LI) in adrenal gland sections, and SERT mRNA and protein levels in whole adrenal glands as determined by immunohistochemistry, reverse-transcription polymerase chain reaction (RT-PCR) and Western blot assays, respectively. On the other hand, the effects of a chronic 14-day treatment with CORT (20 mg/kg, s.c. per day) as compared to vehicle (20% CBD; 1 mL/kg, s.c. per day) on SERT-LI, SERT mRNA and protein levels in adrenal glands as well as on acute 30 min restraint-induced ACTH and CORT secretion were analyzed. Exposure to CRS augmented SERT expression in adrenal glands as suggested by a remarkable increase of SERT-LI in the adrenal cortex along with a significant increase in the amount of SERT mRNA and protein in whole adrenals. Like CRS, chronic CORT treatment induced an increase of 5-HTT-LI in the adrenal cortex as well as in the amount of SERT mRNA and protein in whole adrenal glands as compared to vehicle. In contrast to the reported changes in acute stress-induced secretion of ACTH (i.e. decrease) and CORT (i.e. magnification) as a result of CRS exposure, chronic CORT treatment produced significant blunting of restraint-induced secretion of ACTH and CORT. The present data reveal an interesting association between chronic stress exposure and SERT expression in adrenocortical cells, which seems to be a glucocorticoid-dependent phenomenon.

Title: Oxidative stress modifies extracellular vesicles in HT22 murine hippocampal cells

Authors: *T. TANABE[1], Y. SHIMOKAWA[2], C. MIYASHITA[1], T. UKAI[3], T. MIZUKI[3], T. NEDACHI[1];
[1]Grad. Sch. of Life Sci., [2]Fac. of Life Sci., Toyo Univ., Laboratory of Animal Cell Engineering, Japan; [3]Toyo Univ., Bio-Nano Electronics Research Centre, Japan

Abstract: It has been well established that neuronal cells secrets several proteins in response to oxidative stressors. For example, we recently identified that the secretions of progranulin (PGRN) and BDNF were increased by hydrogen peroxide (H_2O_2) treatment in HT22 cells or PC12 cells. On the other hand, whether the other secreted factors, such as nucleic acids, lipids, and extracellular vesicles, are also involved in this process has not been well understood. Among these factors, we focused on extracellular vesicles (EVs), which contain proteins and small nucleic acids, and transfer these molecules by fusing with the other cells. EVs seem to play important roles in causing pathological changes that are typically observed in some neurological diseases which are induced by oxidative stress (i.e. Alzheimer disease). In this study, therefore, we investigated whether and how the quantity and quality of EVs are modified by oxidative stress in HT22 cells.Initially, we purified EVs from HT22 cell culture supernatant by the sequential ultracentrifugation method, which were confirmed by electron microscopic analysis, dynamic light scattering (DLS) analysis, and the expression of specific exosome marker proteins assessed by western blotting. We then analyzed the effects of H2O2 on the secretion of EVs. Briefly, HT22 cells are cultured with or without different concentration of H2O2 for 48 hours and the EVs were purified from the collected supernatant, followed by DLS analysis. The amounts of EVs release significantly increased by oxidative stress without affecting the size distribution of EVs. The induction of PGRN gene expression by oxidative stress was tightly correlated with this enhancement of EV release, which is consistent with recent reports; however, exogenous PGRN treatment did not affect the EV release, which suggested the “intracellular” PGRN induction by oxidative stress may control the secretion of EVs. Moreover, we comparatively analyzed the protein profiles in EVs with or without H2O2 treatment, and found that the amounts of three proteins in EVs were significantly reduced by oxidative stress. By utilizing MALDI/TOFMS analysis, we identified two proteins are related to membrane

trafficking.In conclusion, oxidative stress clearly affects the quantity and quality of EVs released from HT22 murine hippocampal cells. We speculate that this modification may alter the EV-dependent cell-cell communications in central nervous system.

Title: Hippocampal regulation of BDNF and Sonic hedgehog- Gli1 signaling cascade via naringenin in a rat model of depressive-like behavior

Authors: *M. TAYYAB[1], S. FARHEEN[1], M. M. P.M[1], N. KHANAM[1], M. M. HOSSAIN[1,2], M. H. SHAHI[1];
[1]Interdisciplinary Brain Res. Ctr., [2]Dept. of Physiology, J.N. Med. Col., Aligarh Muslim Univ., Aligarh, India

Abstract: Background: Brain-derived neurotrophic factor (BDNF) is a highly abundant neurotrophin and one of the principal neural growth factors. It is involved in adult hippocampal neurogenesis, neural plasticity and in various mental disorders including depression. In addition to BDNF, Sonic hedgehog (Shh) is also a powerful regulator of embryonic as well as adult hippocampal neurogenesis. Recently, studies have delineated a significant role of Shh in various neurological diseases including brain tumor and depressive disorders. In our study, we concentrated on antidepressant and neuroprotective effects of naringenin (NAR) pretreatment via BDNF and Shh signaling pathways in a rat model of chronic stress-induced depressive-like behavior.
Method: Twenty-four male Wistar rats were randomized into four groups namely; Control (saline), Naringenin (NAR 50mg/kg), chronic unpredictable mild stress (CUMS) and CUMS+NAR for 28 days including 1-week pre-treatment with NAR. Forced swim test (FST), open field test (OFT) and Morris water maze (MWM) were performed. The rats' brains were harvested for histopathological examination and for the analysis of mRNA expression of BDNF, Shh, its downstream signaling component GLI1 and its homeodomain transcription factors NKX2.2 and PAX6.
Results: We observed that NAR reversed depressive behavior as well as CUMS associated cognitive deficits and morphological anomalies. The mRNA expression of BDNF, Shh, GLI1, NKX2.2 and PAX6 were decreased in CUMS, and these decreased levels were recovered by

NAR. In conclusion, we suggest that BDNF and Shh signaling pathways might play an important role in the pathophysiology of depression and in providing NAR mediated antidepressant effects.

Title: Mouse hippocampal G-protein coupled estrogen receptor (GPER) protein expression and functional signalling is regulated by glucocorticoids

Authors: *K. C. NICHOLSON[1], E. R. MARTIN[2], A. L. MENDELL[1], C. E. CREIGHTON[1], N. J. MACLUSKY[1];
[1]Biomed. Sci. - Ontario Vet. Col., [2]Psychology, Univ. of Guelph, Guelph, ON, Canada

Abstract: Estrogens exert neuroprotective and neurotrophic effects on the hippocampus, modulating hippocampal-dependent learning and memory. The primary female sex steroid 17β-estradiol binds to the G-protein coupled estrogen receptor (GPER), rapidly enhancing hippocampal dendritic spine density, learning, and memory in female rodents via a mechanism involving phosphorylation of c-jun N-terminal kinase (JNK). However, in response to acute behavioural stressors, estradiol-mediated neurotrophic and memory-enhancing effects are dramatically impaired in the female hippocampus. The mechanisms underlying stress-induced impairment of rapid estrogen effects on the brain remains unclear. This study tested the hypothesis that stress-induced glucocorticoid release might affect hippocampal GPER expression and GPER-mediated cellular responses. Novel mHippoE-14 (female-derived) and mHippoE-18 (male-derived) immortalized mouse hippocampal cell lines (Gingerich et al., Neuroscience. 2010;170:54-66) were characterized for mRNA expression of stress hormone, gonadal steroid, and neurotransmitter receptors through conventional PCR (n=10). Amplicons were validated with sequencing. Given the concurrent expression of the glucocorticoid receptor (GR) and GPER, cells were treated with vehicle or the synthetic glucocorticoid dexamethasone (DEX; 10nM) for 10 minutes, 1 hour, 10 hours, 24 hours, and 48 h. GPER protein levels determined using Western blot analysis were significantly downregulated at 24 h after treatment with 10 nM DEX (n=5). To characterize functional GPER responses, cells were treated with 10 nM of the synthetic GPER agonist G-1 for 10 minutes, 1 hour, or 4 hours. To characterize functional GPER

antagonism, cell lines were pretreated with 10 nM of the synthetic GPER antagonist G-15 for 1 hour followed by 10 nM G-1 for 10 minutes, 1 hour, or 4 hours. Western blot analyses show G-1 induced phosphorylation, while G-15 inhibited phosphorylation of both 54 and 46 kDa JNK isoforms (n=4-6). To investigate glucocorticoid regulation of GPER signalling, mHippoE-14s were given a 24-hour 10 nM DEX or vehicle pretreatment, followed by a vehicle or 10 nM G-1 treatment for 10 minutes, 1 hour, or 4 hours. Western blot analyses indicate that G-1 induced phosphorylation of both JNK isoforms was blocked by prior treatment with 10 nM DEX (n=4). Since GPER mediates some of the rapid neurotrophic, neuroprotective and memory enhancing effects of estradiol, these findings may explain why the female hippocampus is particularly vulnerable to the detrimental effects of stress (Supported by NSERC and the Ontario Veterinary College).

Title: Time course of acute surgical stress and the role of testosterone in the post-operative recovery of dendritic morphology in adult male rats

Authors: *L. K. ISAACS, E. M. LAWTON, A. L. MENDELL, N. J. MACLUSKY; Biomed. Sci. - Ontario Vet. Col., Univ. of Guelph, Guelph, ON, Canada

Abstract: Gonadal and stress steroids dramatically alter dendritic morphology in the hippocampus (HC) and medial prefrontal cortex (mPFC). These changes may contribute to altered cognitive function, as well as the development of neuropsychiatric disorders. Our laboratory has shown that orchidectomy (ORCH) results in the rapid expansion of apical dendrites in the cornu ammonis 3 (CA3) subfield of the HC lasting for up to 2-months following surgery. The time-course of the effects of surgical stress following ORCH and the role of testosterone (T) in modulating these effects have yet to be completely elucidated. We hypothesized that even brief surgical stress might result in remodeling of hippocampal and mPFC apical dendrites, while T enhances recovery. To test this hypothesis, we determined the time-course of the effects of surgical stress and glucocorticoid (GC) treatment in young adult male Sprague-Dawley rats (60-70 days old). Rats were given drinking water containing

1.5ug/mL of dexamethasone for 16-hours and sacrificed 1-, 3- and 10-days later. Brains were stained using the Golgi Cox method. Three-days following treatment CA3 apical dendrites showed decreased dendritic branching similar to that seen in rats who received a sham-orchidectomy (SHAM). No effects were seen in CA1 or the mPFC. To determine the role of T in the modulation of dendritic morphology following surgery, young adult male Sprague-Dawley rats received either ORCH with T replacement (ORCH+T), ORCH with cholesterol replacement (ORCH+C), SHAM or left intact and were sacrificed 1- or 2-months later (n=4-5). At 1-month, ORCH+C rats showed similar expansion of CA3 apical dendrites previously seen at 10-days and 2-months. While the ORCH+T and intact rats had similar CA3 apical dendritic branching, SHAM rats displayed decreased CA3 apical branching. At 2-month following surgery, SHAM rats appeared to be almost completely recovered. However, all operated animals had dramatically reduced the maximal apical dendritic length in CA3, even at 1- and 2-months following surgery. No effects were seen in CA1 or the mPFC. These results suggest that surgical stress causes the rapid remodeling of CA3 apical dendrites, which is at least partially mediated by glucocorticoid action, while T may modulate the subsequent recovery of dendritic morphology.

Title: Purine salvage deficiency drives energy deficits and impairs dopaminergic cell development in humans

Authors: *S. C. BELL, H. PENG, M. JEFRI, C. ERNST;
McGill Univ., Montreal, QC, Canada

Abstract: Lesch-Nyhan Syndrome (LNS) is a purine recycling disorder caused by mutations in *HPRT1* and includes features such as dystonia and self-aggressive behaviour. Human studies have repeatedly implicated midbrain dopamine dysfunction in LNS, however, it remains unclear how mutations in *HPRT1* lead to disease. We made isogenic knock-outs of *HPRT1* in human induced pluripotent stem cells and simultaneously differentiated these cells to a forebrain and midbrain fate. HPRT deficient midbrain cells showed a clear deficiency in all markers of dopaminergic development including tyrosine hydroxlase, a result recapitulated in cells derived

from nine different LNS patients. Analysis of glycolytic rate and oxygen consumption showed that HPRT deficient cells have compromised energy dynamics, while midbrain cells show particular deficits in oxidative phosphorylation, a result absent in forebrain cells deficient in HPRT. Metabolomic analyses showed that HPRT-deficient midbrain cells have increased levels of metabolites specific to *de novo* purine synthesis, likely depleting intracellular glucose pools normally used in OXPHOS and glycolysis. Additionally, HPRT deficient midbrain cells show a significant reduction in MTORC1 signalling, a integrator of cell nutritional state and developmental programing. We propose that loss of purine salvage leads to profound loss of ATP required for proper dopaminergic development through an MTOR-mediated mechanism. Our results describe an unexpected link between purine salvage and metabolic rate in human midbrain progenitor cells. We further reveal a surprising need for high energy flux for proper dopaminergic development in humans. These results have important implications for LNS and other disorders of the dopaminergic system, including Parkinson's disease.

Sci., Univ. of Maryland Sch. of Pharm., Baltimore, MD; [6]Psychiatry, Univ. of Pennsylvania Perelman Sch. of Med., Philadelphia, PA; [7]Pharmacol., Univ. of Maryland Baltimore, Baltimore, MD

Abstract: Extracellular vesicles (EVs) are a unique mode of intercellular communication capable of incredible specificity in transmitting signals involved in cellular function. One example of this is the essential role EVs secreted by epithelial cells lining the lumen of the

reproductive tract play in the post-spermatogenic maturation of sperm. EVs released by these epididymal epithelial cells (EECs) transport bioactive cargoes including small non-coding RNA (sncRNA), proteins and lipids that are required for sperm to develop essential properties, including the ability to swim and fuse with the ovum. Here we demonstrate that this fundamental process also plays a causal role in the somatic-to-germline transmission of information regarding paternal stress experience capable of altering fetal development in a preclinical model. In our model, paternal preconception stress produces lasting histone and transcriptomic alterations in mouse EECs, with corresponding persistent changes in the miRNA, proteomic, and lipid composition of secreted EVs. Using the *in vitro* fertilization technique, intracytoplasmic sperm injections, we demonstrate sperm that had been incubated with EVs collected from stress-treated EECs produce offspring with significant changes in neurodevelopment and adult stress reactivity. To determine whether these findings had a potential translational relevance, we developed a broad framework to assess the composition of sperm sncRNAs (including miRNA, piRNA, tRNA, and rRNA) in healthy human subjects. Utilizing within and between subject comparisons of sperm samples and perceived stress reports collected repeatedly over six months, we were able to detect a distinct sncRNA expression pattern that largely grouped subjects according to their recent stress experience, similar to that of our mouse model. In addition, by implementing complex modeling of the relationship between individual sncRNA and perceived stress state in these data, we have identified specific populations of sperm sncRNA that are responsive to the dynamics of stress experience. These studies establish a novel precedent that intergenerational transmission does not require propagation of germ cell epigenetic marks through gametogenesis and provides broad mechanistic insight into the translational importance of parental lifetime stress experiences and exposures on offspring development.

Abstract: A proton magnetic resonance spectroscopy (^{1}H-MRS) has been broadly used in the study for the stress and provide the neurochemical information for the brain of a living animal. The acute stress (AS) response is the complex process that activates the neuroendocrine and metabolic systems for homeostasis. A study on the stress responses is important to understand the process by which an organism adapts to the stress for survival. Up to now, most studies have focused on the chronic stress responses and there are few studies for the AS. They have analyzed the changes of brain metabolites at a particular time after AS. In this study, we explored the temporal variations of the brain metabolites in the hippocampi of mice after receiving AS response using ^{1}H-MRS. We used 24 male C57BL/6N mice from 6-7 weeks that weigh from 18g to 25g and randomly divided into two groups, control group (10 mice) and AS group (12 mice). Two from the control group were removed by the outlier occurring at all times. To evaluate the temporal variability of the AS response, all mice in the AS group were physically restrained for 2 hours in a 50mL conical tube. Then, MRS data for the two groups were acquired with 9.4T Bruker MRI/MRS equipment using PRESS with the following parameters: TR/TE = 4000/10ms, NEX = 512, voxel size = 1.8 x 3.4 x 1.8mm^3. MRS data measurements were repeated four times without inter-scan interval. MRS data were analyzed using LCModel with a simulated basis-set including 17 metabolites. In order to compare and identify the temporal variability between two groups, MRS data for control group and AS group were statistically analyzed using two-way repeated-measure analysis of variance. We found that the effect of time that is a repetition factor for intra-group significantly exists ($P < 0.05$) on the concentration of Glutamate (Glu) and Alanine (Ala). The effect of stress between groups is presented in Ala ($P < 0.05$), but not in Glu ($P = 0.094$). As shown in Figure 1, the concentrations of Glu and Ala in the stress group are higher than those in the control group at all time points and the temporal variability for concentration of Glu and Ala showed a decreasing tendency over time. The decreasing tendency of concentrations of Glu in control group is similar to previous studies. In addition, our study suggests that Ala as well as Glu is related with AS. The result of our study can provide a deeper understanding of AS responses and consider the utility as a biomarker of AS response.

Title: Quantitative micro neurovasculature mapping across the whole brain in young and old mice

Authors: *Y.-T. WU, U. CHON, Y. KIM;
Penn State University, Col. of Med., Hershey, PA

Abstract: The structure of the brain's microvasculature provides the extraordinary surface needed for a high level of energy exchange and clearance of metabolic wastes. Small vessel pathologies are involved in cognitive decline associated with aging and many brain disorders. Mounting evidence suggests that the 3D regional distribution of small vessels is heterogeneous in different circuits, which may undergo differential changes during aging. To quantitatively understand the underlying neurovascular mechanisms affected in health and pathological conditions, we are creating a precise 3D map of micro vessels in the entire mammalian brain using the mouse as a model. We used FITC conjugated fluorescent albumin gel perfusion to label the micro vessel in the whole brain from young (2 months old) and old (18 months old) mice. Then, we used serial two-photon tomography to acquire high resolution 3D brain images at resolution 1 x 1 x 5um (x,y,z), which is sufficient to visualize even smallest micro vessels. We are developing computational pipeline to precisely stitch the terabyte size imaging data, detect and track fluorescently labeled the vasculature information. We used image registration to map our signal in a standard reference brain to quantify vasculature signals (e.g., density, connectivity) in over 200 different anatomical regions across the whole brain. Our preliminary finding suggests significant difference in vascular density and 3D geometry across different brain regions, which can be linked with different vulnerability of brain regions in pathological conditions. We envision that our work provides a foundation for further studies of neurovascular architectures supporting normal cognitive function and their changes in various neuropathologies.

Title: Aroma effects on hemodynamic modulation in the prefrontal lobe measured using fNIRS

Authors: *T. MATSUMOTO[1], T. KOHAMA[1], Y. TAKIKAWA[1], S. KANJIYAMA[2], H. YOSHIDA[2];
[1]Kindai Univ., 930 Nishimitani, Kinokawa, Wakayama, Japan; [2]KIndai Univ., 930 Nishimitani, Kinokawa, Wakayama, Japan

Abstract: Aromatherapy has begun to attract attention as a treatment for depression. In particular, the aroma of lavender is suggested to have a sedative effect (Ueda & Ikeda 2007). Previous studies have shown effects of the perception of smell measured using functional near-infrared spectroscopy (fNIRS) on prefrontal lobe activities. However, the studies had limitations such as those of lengthy stimulation or incomplete removal of skin blood flow artefacts in fNIRS signals. In this study, to objectively evaluate the effects of aroma stimulation on prefrontal activity, we used fNIRS. Four healthy college students (2 men and 2 women) participated in the experiment. We used a block design approach with an aroma stimulation of 2 seconds and an interstimulus interval of 20 seconds. The aroma stimuli were Lilium japonicum, lavender, grapefruit, and the control was odorless air. The stimuli were presented in this order 8 times in each trial. We also examined another condition applying 30 seconds of stimulation and 30 seconds of interval, for comparison with previous studies. An fNIRS device with 22 channels (WOT-100, Hitachi medical Co.) was used to measure the subjects' prefrontal activity. We analyzed the fNIRS signals with the following steps: (1) Separate into brain function and systemic components based on a hemodynamic modality separation method (Yamada et al. 2012); (2) Eliminate long-term trend using a high-pass filter; and (3) Subtract the average during the stimulus presentation section for baseline correction. A difference in the responses of aroma stimuli and odorless air was observed only when the subjects underwent stimulations for 2 seconds. When the aroma stimuli were presented for 30 seconds, no differences between the stimuli and odorless air were found in any subject. However, large individual differences were observed, but no clear differences were seen in the responses of the three aroma stimuli. These results suggest that the perception of smell influences the hemodynamic responses of the prefrontal lobe. Furthermore, it indicates that a short duration of stimulation is effective when measuring the effect of aroma stimuli using fNIRS.

Title: Three dimensional imaging reveals exercise induced alteration of vascular morphology in the rat primary motor cortex

Authors: *M. E. STEVENSON[1], C. C. MILLER[1], A. S. NAZARIO[1], B. S. LARSON[1], Y. S. GREENBERG[1], H. A. OWEN[2], R. A. SWAIN[1];
[1]Psychology, [2]Biol. Sci., Univ. of Wisconsin- Milwaukee, Milwaukee, WI

Abstract: Exercise is beneficial to brain health, and, historically, the advantageous effects of exercise on the brain have been attributed to neuronal plasticity. However, it has become clear that the brain vascular system also exhibits plasticity in response to exercise, and these changes contribute to the beneficial health outcomes exercise produces in the brain. Increased blood vessel density following exercise is well replicated in brain regions involved in movement, like the primary motor cortex. Still remaining ambiguous is the form of vascular plasticity that underlies these increases in blood vessel density. Specifically, is increased blood vessel density due to a permanent expansion of existing vessels or sprouting of new vessels (angiogenesis)? This experiment aimed to answer this question by employing vascular corrosion casting and scanning electron microscopy, methods not standardly used to characterize vascular plasticity following exercise. These methods provide a high-resolution, three-dimensional view of vessel architecture that cannot be obtained using traditional light microscopy. In this experiment, one group of rats engaged in five-weeks of voluntary wheel running while a second group remained sedentary. Animals were then euthanized and, during perfusions, a resin was infused into each animal's vascular system. Brains were removed and the surrounding tissue was macerated, leaving only the vascular corrosion cast, a replica of the brain vasculature. The primary motor cortex region on each vascular corrosion cast was imaged on the scanning electron microscope. For each animal, vessel diameters were measured and number of new vessel sprouts was counted. Preliminary data suggest rats that engaged in voluntary exercise had wider microvessels (vessels categorized as less than 20 μm in diameter) and more new capillary sprouts than sedentary controls. This indicates both the expansion of existing vessels and angiogenesis contribute to exercise-induced vessel remodeling.

Title: The contribution of cortical tachykinin receptor 1 inhibitory interneurons to neurovascular coupling

Authors: *C. F. RUFF[1], J. J. COUEY[1], B. M. HOOKS[1], A. L. VAZQUEZ[2], S. E. ROSS[1];
[1]Neurobio., [2]Radiology, Univ. of Pittsburgh, Pittsburgh, PA

Abstract: The brain lacks energy reserves and depends on the blood for a constant supply of oxygen and glucose. To meet energy demands, cerebral blood flow parallels changes in brain activity by a mechanism known as neurovascular coupling (NVC). Although NVC is critical to normal brain function and its dysfunction is reported in many neuropathologies, the underlying neural basis remains unclear. Here, we describe a tachykinin receptor 1 (Tacr1)-CreER knock-in mouse that selectively labels a subset of cortical inhibitory neurons that are ideally suited to regulate cerebral blood flow. Using this genetic tool, in combination with two photon imaging, electrophysiology, optogenetic techniques and in vivo laser Doppler flowmetry we explore the role of Tacr1 neurons in the regulation of cerebral blood flow. Our data suggests that Tacr1 cortical interneurons are a specific population of long-range projecting neurons that receive local excitatory input. Moreover, optogenetic activation of this distinct inhibitory population is sufficient for a local cerebral blood flow response. Together, these findings suggest that Tacr1 cortical inhibitory interneurons act as local integrators of neural activity to mediate NVC, providing important insight into this unique population of long-range projecting neurons and the circuitry of NVC.

Title: Proinflammatory cytokine contributes to the effects of angiotensin II on neurovascular coupling

Authors: *J. YOUWAKIM, D. VALLERAND, H. GIROUARD;
Univ. de Montréal, Montreal, QC, Canada

Abstract: Angiotensin II (Ang II), a hormone involved in the development and maintenance of arterial hypertension, alters neurovascular coupling (NVC). NVC is the dynamic link between neuronal activity and local blood flow supply. NVC impairment induces cerebral homeostasis disruption and have been associated with increased susceptibility to strokes and

neurodegenerative diseases. We have recently demonstrated that Ang II induces brain inflammation. This inflammation can be induced by modulation of T cell activity involving an increase in the production of the proinflammatory cytokine IL-17A. Thus, our hypothesis states that IL-17A is involved in the induction of neurovascular decoupling by Ang II. NVC was tested by monitoring the cerebral blood flow (CBF) response to whiskers stimulation by laser-Doppler flowmetry in anesthetized C57BL/6J mice. Our results show a significant reduction in NVC in mice with chronic Ang II administration by osmotic pump (600 ng / kg / min, for 14 days) compared to the control group (14.4% and 18.6%, $p < 0.01$, $n = 10-12$). The depletion of IL-17A by intraperitoneal injections of a neutralizing antibody, anti IL-17A (0.5 μg / μL) normalizes NVC and demonstrates a response comparable to the values obtained for the control groups (17.6% and 18.6%, $n = 10-12$). Treatment with the IL-17A antibody also reduces Ang II induced oxidative stress in the hippocampus ($p <0.05$, $n = 7-12$) and the somatosensory cortex ($p < 0.05$, $n = 7-12$). Finally, the effects of IL-17A depletion on NVC is accompanied by a partial prevention of about 10 mm Hg of the increase in systolic blood pressure in mice receiving Ang II ($p <0.05$ at day 7 and $p <0.001$ at day 14, $n = 12-20$). These results suggest that IL-17A plays a crucial role in the effects of Ang II on NVC. Therefore, therapy using antibody against IL-17A could prevent cerebrovascular dysfunction in hypertensives patients and reduce the incidence of strokes and neurodegenerative diseases associated with high blood pressure.

Title: Acute brain-wide pericyte ablation leads to rapid neurovascular uncoupling

Authors: *K. KISLER, A. M. NIKOLAKOPOULOU, M. D. SWEENEY, Z. ZHAO, B. V. ZLOKOVIC;
Physiol. and Neurosci. and Zilkha Neurogenetic Inst., Keck Sch. of Med. of the Univ. of Southern California, Los Angeles, CA

Abstract: Pericytes are perivascular mural cells that grow along capillaries. Pericytes help maintain blood brain barrier integrity at the capillary level and play a role in neurovascular coupling (NVC), the regulation of cerebral blood flow (CBF) to match the demands of neuronal functional activity. We have previously shown that congenital loss of pericytes driven by genetic knockout of one copy of PDGFRβ resulted in dysregulation of NVC. However, in this model it remains unclear what the developmental impact of embryonic loss of PDGFRβ signaling may be on the vascular phenotype in the adult brain. To address this, we generated an inducible pericyte-specific Cre line employing a double promoter strategy using both *Pdgfrb* and *Cspg4* promoters, which are genes enriched in pericytes relative to other brain cell types. The resulting pericyte-specific Cre line was crossed to mice carrying Cre-dependent human diphtheria toxin receptor (iDTR). Diphtheria toxin (DT)-induced pericyte ablation in adult mice led to rapid reduction in stimulus-induced CBF response measured with laser Doppler flowmetry and intrinsic optical signal imaging, suggesting defects in NVC. Voltage sensitive dye imaging indicated no neuronal deficit at the time of NVC failure, implicating pericyte dysfunction and loss driving changes to NVC. This has implications in neurodegenerative disorders where pericyte loss and CBF changes are observed such as Alzheimer's disease and stroke.

Title: Pericyte contractility by optogenetics regulates capillary diameter and blood flow

Authors: *A. R. NELSON, M. A. SAGARE, Y. WANG, K. KISLER, Z. ZHAO, B. V. ZLOKOVIC;
USC, Los Angeles, CA

Abstract: Pericytes are vascular mural cells that wrap around capillaries and are essential for blood-brain barrier formation and maintenance, and perform multiple functions at the neurovascular unit including regulation of **a)** BBB permeability and bulk flow fluid transcytosis, **b)** capillary diameter, **c)** cerebral blood flow (CBF) velocity, **d)** angiogenesis, subsequent microvascular stability and network architecture, **e)** clearance of toxic metabolites from the CNS,

f) pro-inflammatory responses, and **g)** multipotent stem cell activity. However, whether or not pericytes are contractile cells has been a continuous debate dating back to 1873 when Rouget first described them. Here, we test the hypothesis that capillary level pericytes are contractile cells, and that their contractility is altered by amyloid-beta. We used a novel pericyte-specific Cre mouse using a double-promoter approach with both the *Pdgfrβ* and *Cspg4* promoters, and crossed to a Cre-dependent channelrhodopsin (ChR2) mouse with a YFP reporter gene, termed *Pericyte-ChR2*, or crossed to a Cre-dependent archaerhodopsin (ArchT) mouse with a YPF reporter gene, termed *Pericyte-ArchT*. Furthermore, we are testing the impact of amyloid-beta on pericyte contractility. First, we confirmed that ChR2 and ArchT are only expressed in pericytes by performing immunofluorescent staining with anti-CD13 antibody and which colocalized with the YFP reporter gene. Using the *Pericyte-ChR2* mice, we performed optogenetics experiments *in vivo* and found that stimulation of ChR2 caused pericytes to contract, the underlying capillary to constrict and restricted blood flow. Using *Pericyte-ArchT* mice, we performed optogenetics experiments *in vivo* and measured changes to pericyte contractility and underlying capillary diameter, and are assessing whether amyloid-beta alters contractility. Pericytes are contractile cells. Discovering the functional role of pericytes will have important implications for pathological conditions and neurodegenerative diseases in which pericytes degenerate including Alzheimer's disease, amyotrophic lateral sclerosis, Parkinson's disease and Huntington's disease.

Abstract: The brain vascular network provides a stable supply of energy and oxygen to support neural activity. To quantify and understand the network through which blood flows, we prepared

whole brains from 2 month old mice in which every vessel lumen was filled with a cross-linked fluorescent gel (Tsai et al, J Neurosci 2009) and imaged with block-face serial two photon microscopy at 0.3 x 0.3 x 1.0 μm^3 voxel resolution (Economo et al, Elife 2016). We implemented a computational pipeline to reconstruct the vascular network and, further, extracted the graphical representation of the network. The reconstruction contains more than 300 meters of interconnected vessel segments. Preliminary analysis suggests that the microvasculature is fully interconnected across the entire brain, i.e., the dominant cluster of the connectivity matrix contains at least 96 % of all microvessels. Interestingly, the density of the microvasculature varies across different regions of the brain, with a mean volume fraction of 0.011 but a range of 0.005 to 0.016 for 95 % of the sample. In agreement with past data on microvasculature in parietal neocortex (Blinder, Tsai et al, Nat Neuro 2013), some topological and geometrical features of the microvascular network across all parts of the brain are rather uniform, i.e., 97% ± 3 % of the nodes are of degree 3, the median number of microvessels that comprise the shortest loops is 8.8 ± 1.5 (mean ± SD), and the median tortuosity of the microvessels, i.e., the ratio of actual length to end-to-end length, is 1.25 ± 0.07. We are working on precise vectorization of the entire brain vascular network with combined experimental and computational approaches.

Abstract: Epilepsy is characterized by recurrent seizures that involve the most dramatic neuronal activation. It has long been known that, following the termination of a seizure, individuals often experience an extended period of behavioral abnormalities from hours to days, such as sensory, cognitive, or motor dysfunction according to brain regions that are affected by the seizure. Recently, it has been suggested that the negative consequences of seizure can be attributed to prolonged hypoxic condition during the post-ictal state which accompanies pathological hypoperfusion. In this realm, hypoperfusion in the post-ictal state could impair proper local network functions, i.e., brain tissue oxygen levels are not normally maintained. Recent studies suggested that the post-ictal hypoxia is mediated by the hypoperfusion due to vasoconstriction and that a structural disruption of neurovascular units during seizure events could affect blood flow regulation. However, a detailed examination of cerebrovascular system has not been carried out yet to clarify what causes the post-ictal hypoperfusion. In this study, we conducted real-time *in vivo* two-photon microscopic imaging with an injection of fluorescence-conjugated dextran for a detailed investigation of functional and structural cerebrovascular changes during the post-ictal state. Acute mouse seizure model induced by a 4-aminopyridine (4-AP) injection was used as we could designate the seizure focus in the experimental setting, mimicking focal seizures in human brain. Around the seizure focus after the cessation of recurrent seizures, resting blood flow was measured by red blood cell (RBC) velocity, and structural changes were assessed by vessel diameter and blood-brain barrier (BBB) function. Our results show changes in the mean RBC flow in capillary beds and BBB permeability, depending on the severity of seizures that were induced. Therefore, epilepsy is not solely a neurological disorder that disrupts neuronal network, but also can result in long-lasting consequences of vascular dynamics and function. Our study can provide insights to better understand the underlying mechanisms of the post-ictal state brain malfunctions and evidence for a potential therapeutic target.

Abstract: Two-photon phosphorescence lifetime microscopy is the new emerging technique for high-resolution measurements of oxygen partial pressure in vessels and tissue of brain and other organs. However, previous studies (including ours: Parpaleix et al. 2013, Lyons et al. 2016) have disregarded that imaging through a cranial window lowers brain temperature, an effect known to change neuronal excitability and susceptible to affect cerebral blood flow, the properties of the oxygen sensors and thus brain PO2. Here, we investigated the relationship between temperature, blood flow parameters and oxygenation in the olfactory bulb of awake and anesthetized mice. We first show that in awake mice chronically implanted with a thermal sensor below the glass window, or a thinned-skull surface, the postsurgical decrease of brain temperature takes several days to recovers. In both animal preparations, imaging with a water immersion objective at room temperature decreases brain temperature by ~ 2-3°C, causing resting capillary blood flow and Po2, hemoglobin saturation and tissue Po2 to drop. These adverse effects are corrected by heating the immersion objective or avoided by imaging through a dry air objective, allowing the establishment of truly physiological values of brain oxygenation in awake mice.

Title: Improvement of vasoactive dysfunction on rat cerebral penetrating arterioles in early vascular injury after subarachnoid hemorrhage

Authors: *T. MURATA[1,2], T. HORIUCHI[1];
[1]Dept. of Neurosurg., Shinshu Univ. Sch. of Med., Matsumoto, Japan; [2]Dept. of Neurosurg. Shinonoi Gen. Hosp., Nagano, Japan

Abstract: Early brain injury (EBI) after rupture of rupture inducing subarachnoid hemorrhage (SAH) represents one of the most important contributors to poor outcome in patients with SAH. EBI is characterized by a severe reduction in cerebral blood flow suggesting alterations on the level of cerebral small vessels. The early vascular injury in small vessels after SAH demonstrated a rapid change in structure, however, vasoactive dysfunction via potassium

channels is unclear. This study was therefore conducted to clarify whether SAH induced immediate potassium channels dysfunction in rat experimental SAH model, and free radical scavenger restored potassium channels dysfunction. The institutional animal ethics committee in Shinshu University School of Medicine approved all experimental protocols for this study. In this study, SAH was induced using a blood injection method into the cisterna magna of male rat, and saline injection models were also made. Sham surgery rats as control received the same surgical procedures except for the injection. Rats were sacrificed at 1 hour after SAH, saline injection and sham surgery. The penetrating arterioles from the middle cerebral artery were isolated, cannulated and pressurized. Vessel diameters were recorded by computer-aided videomicroscopy. After development of vascular tone, to investigate the ATP-sensitive potassium channels function, the activator pinacidil was applied with or without free radical scavenger. The penetrating arterioles from SAH models developed significantly more tone compared with the arterioles from sham. The ATP-sensitive potassium channels activator significantly dilated the penetrating arterioles from sham surgery rats. The vasodilatory responses to the activator were attenuated in SAH rats but not saline injection and sham surgery rats. Free radical scavenger-treated arteriolar dilatory response to ATP-sensitive potassium channels activator was partially restored compared with non-treated arteriolar response. In conclusion, ATP-sensitive potassium channels may inactivate immediately after SAH, and the dysfunction may be induced by free radical due to acute increased intracranial pressure. These results provide a background to understand the early vascular injury after SAH.

Title: Spatial-temporal dynamics of functional hyperemia and mural cell calcium signals from the synapse to the pia

Authors: *R. L. RUNGTA, E. CHAIGNEAU, B. OSMANSKI, S. CHARPAK;
INSERM U1128, Paris, France

Abstract: Objectives: Functional hyperemia, a regional increase of blood flow triggered by local neural activation, is used to map brain activity in health and disease. Despite its vast importance for functional imaging, the spatial-temporal dynamics of functional hyperemia, as well as its site of initiation remain unclear. Furthermore, the dynamics of mural cell (pericyte and

smooth muscle cell) Ca^{2+} signals in different vascular compartments remain elusive. **Methods:** *In vivo* two-photon calcium imaging of neuron, oligodendrocyte precursor cell, pericyte and smooth muscle cell responses to sensory stimulation in combination with vessel diameter and red blood cell velocity measurements in NG2-creERT2;GCaMP6f mice (both anesthetised and awake). First, by exploiting the unique neural-vascular anatomy of the olfactory bulb we are able to map out these responses along the entire vascular arbour, from juxta-synaptic capillaries back to the upstream pia. Second, these dynamics are investigated in the primary somatosensory cortex. **Results:** In the olfactory bulb, we first show that activation of oligodendrocyte precursor cells is a reliable marker of synaptic input and precedes (by ~300 ms) a synchronous Ca^{2+} drop in upstream pericytes and smooth muscle cells enwrapping the vessels that feed the activated synapses. Despite this simultaneous activation of mural cells, the resulting hemodynamics varied dramatically but precisely in terms of timing, amplitude and direction according to the vascular compartment. The most rapid dilation occurs with indistinguishable onset at the parenchymal arteriole and proximal first-order capillary and is paradoxically associated with a local decrease or delayed increase in blood velocity. In contrast, a slower dilation associated with a rapid velocity increase occurs in the upstream pial arteriole and downstream capillaries. Proportionally, the largest velocity increase occurs in juxta-synaptic capillaries. Interesting similarities and differences in these OB dynamics were observed in the somatosensory cortex. **Conclusions:** These results establish the precise temporal and spatial dynamics of blood volume and velocity changes essential for the interpretation of blood flow based imaging techniques such as BOLD-fMRI.

Title: Real time visualization of vascular remodeling in ischemic stroke using visible light optical coherence tomography

Authors: *N. A. NADKARNI[1], L. BECKMANN[2], A. BATRA[1], D. P. SULLIVAN[3], W. A. MULLER[3], X. ZHANG[2], H. ZHANG[2];
[1]Dept. of Neurol., Northwestern Univ. Feinberg Sch. of Med., Chicago, IL; [2]Functional Optical Imaging Lab., Northwestern Univ., Evanston, IL; [3]Pathology, McGaw Med. Ctr. of Northwestern Univ., Chicago, IL

Abstract: Background: Stroke is a leading cause of death in the USA. Angiogenesis, the formation of new capillaries from blood vessels, is a key area of interest in neurorehabilitation. The ability to track microvascular remodeling after stroke *in vivo* is necessary to better understand future therapeutic targets. We have pioneered a system using visible-light optical coherence tomography (vis-OCT), a 3-dimensional anatomical and functional imaging modality with microscopic resolution, integrated with chronic cranial window-embedded microprism to visualize vessels 1mm in depth from the cortical surface *in vivo* for up to 60 days after ischemic stroke. Methods: A Vis-OCT microscope system for brain imaging was developed using a supercontinuum laser with a center wavelength of 560nm and bandwidth of 100nm as the light source. We created cranial windows by attaching a 1-mm right angle aluminum coated microprisms to two concentric coverslips of different diameter. Six wild-type C57Bl/6 mice around 3 months age underwent craniotomy, durotomy, and subsequent insertion of the cranial window apparatus with ultimate adhesive seal. After 15 days for healing, a mouse underwent a transient middle cerebral artery occlusion (tMCAO) for 60 minutes to recreate the ischemic penumbra. Results: The microprism provided a deep view with an additional 1000µm×750µmx250µm cortical volume in addition to standard 250 µm surface view without microprism. After microprism insertion, bleeding was observed on Vis-OCT on day 2 and day 3 but almost completely resorbed by day 7 with no evidence of blood on day 15. By day 60, the window and glue were stable with consistent image quality in optical microscopy. There were no behavioral deficits noted as a result of the microprism surgery. After tMCAO, severe reduction of capillary density was noted in the deep view image on day 1 with minimal capillary density change at the surface view. On day 30 and day 60, vessel diameters were smaller in both views than at the acute stage with a robust increase of vessel density in the deep view. Conclusions: Vis-OCT, in combination with a chronic cranial window embedded-microprism, is a novel modality to longitudinally study *in vivo* vessel changes as a consequence of stroke. Further investigations will focus on better understanding these changes to inform us to new outcome measures for patients with stroke.

Title: Neurovascular coupling in the diabetic brain

Authors: *A. R. NIPPERT, P.-P. CHIANG, E. A. NEWMAN;
Neurosci., Univ. of Minnesota, Minneapolis, MN

Abstract: Diabetes mellitus is associated with vascular pathologies in the periphery and central nervous systems. Decreases in cognitive function have been described in patients with both type 1 and type 2 diabetes. These declines in cognitive function may be due to vascular dysfunction in the brain. Studies in the retina, which is damaged by diabetic retinopathy, demonstrate that functional changes in the vasculature occur before structural damage or overt cellular pathology. Specifically, there is a decrease in neurovascular coupling, the active dilation of vessels in response to increased neuronal activity. While some evidence exists suggesting reduced vessel responses in the brain in diabetes, it is unknown how neurovascular coupling is altered. In this study, simultaneous measurements of neuronal activity and blood flow were taken longitudinally from mice before and after the induction of diabetes with streptozotocin, a within subject design. Due to sex differences in diabetes induction, results are from male mice only. Using a cranial window implanted over the whisker barrel cortex with an implanted electrode, blood flow and neuronal activity were simultaneously measured, with laser Doppler flowmetry and local field potential recordings, respectively. Whisker stimulation with an air puff elicited changes in blood flow and neuronal activity. All measurements were taken from awake, head-fixed mice over a two month period, including a two week period prior to induction of diabetes. Results indicate a reduction in neurovascular coupling after induction of diabetes. A decrease in neurovascular coupling occurred immediately after induction of diabetes and continued to decline over the next two months. Future experiments will examine how acute hyperglycemia alters neurovascular coupling and if the decline in neurovascular coupling seen in diabetes can be reversed with the iNOS inhibitor aminoguanidine, which reverses the loss of neurovascular coupling in the retina.

Title: Exploring the non-linearity of the BOLD response through varied stimulus timing

Authors: *K. B. XI, X. ZOU, J. KIM, D. RESS;
Neurosci., Baylor Col. of Med., Houston, TX

Abstract: Introduction: Functional magnetic imaging (fMRI) is based on the hemodynamic response function (HRF) elicited by a brief (2—4 s) period of neural activation, the stereotypical blood oxygen level dependent (BOLD) response that depends on competition between cerebral blood flow (CBF) and oxygen consumption. The shift-invariant linearity of the BOLD HRF is a critical feature of fMRI. However, for briefer stimuli (<2 s), the HRF exhibits non-linearity that is poorly understood. We measured HRF and CBF responses with high spatiotemporal resolution using BOLD fMRI and arterial spin labeling (ASL), respectively, with variable stimulus durations. We will fit measured HRF and CBF with BOLD models to investigate the non-linearity. **Methods**: A speeded audiovisual sequence-detection task was used to evoke strong HRFs over a large portion of cerebral cortex. On each run, stimulus duration was fixed at one value in the range of 0.33, 0.67, 1.33, or 2.67 s, in a slow event-related design with a 30-s inter-stimulus interval and 12 stimuli/run. HRFs were measured using a SMS-accelerated acquisition that covered the whole brain with 2-mm cubic voxels and TR = 1.25 s on a 3T scanner. Initial analysis was carried out in early visual areas discerned using population receptive field mapping methods applied to separate imaging sessions. **Results**: Strong HRFs were evoked across most of visual cortex by all stimulus durations (Fig **A**). Example HRFs from primary visual cortex (Fig **B**) show the strong non-linearity of the HRFs. In particular, peak amplitude has a sub-linear dependence on stimulus duration, while time-to-peak increases monotonically in a complex fashion. Processing of CBF measurements and BOLD modeling are in progress. **Discussion**: Our variable-duration stimulation approach permits the investigation of BOLD non-linearity in many brain regions. Evoked HRFs show clear non-linearity, which we expect to be the consequence of weak transmural oxygen transport competing with more effective longitudinal oxygen transport by blood flow, as indicated by our previous modeling work (Kim & Ress, 2016).

Title: Impact of common carotid artery compliance on cerebrovascular resistance in amnestic mild cognitive impairment

Authors: ***C. CHILES**, T. TOMOTO, J. SUGAWARA, B. CURTIS, E. PASHA, R. ZHANG; Insitute For Exercise and Envrn. Med., Dallas, TX

Abstract: Objective: Increased cerebrovascular resistance (CVR) associated with brain hypoperfusion is a potential risk factor for the progression of Alzheimer's disease (AD). However, the underlying pathophysiological mechanisms are unknown. Increased arterial stiffness augments cerebral blood flow (CBF) fluctuations which may cause cerebrovascular damage and a subsequent increase in CVR. However, the relation between arterial stiffness and CVR is unclear. This study investigated the correlation between arterial stiffness and CVR for patients with amnestic MCI (aMCI), a prodromal stage of AD.
Methods: Fifty-four amnestic aMCI patients and twenty-four cognitively normal (NC) subjects underwent measurements of CVR and arterial compliance, an inverse index of arterial stiffness. CVR was calculated as the ratio of mean arterial pressure measured via applanation tonometry to total CBF. Total CBF was calculated from CBF velocities and diameters at the bilateral internal carotid and vertebral arteries using Duplex ultrasonography. Arterial compliance at the common

carotid artery was calculated as the ratio of carotid pulse pressure to the vessel diameter changes. **Results:** Compared to the NC, total CBF was lower (MCI = 585 ± 66, NC = 636 ± 66 ml/min) and CVR higher (MCI = 0.156 ± 0.023, NC = 0.143 ± 0.019 mmHg/ml/min, P = 0.015) in aMCI. Arterial compliance (MCI = 8.57 ± 2.10, NC = 9.27 ± 1.64 mm^2/mmHg*100, P = 0.151) was not different between groups. Decreased arterial compliance was correlated with higher CVR in aMCI (R = -0.505, P < .001) but not in NC (R = -0.321, P = 0.126). When controlling for age, sex, and BMI, the correlation maintained in aMCI (R = -0.431, P = 0.002) but not in NC (R = -0.204, P = 0.377).
Conclusions: Patients with aMCI had a higher CVR and lower CBF when compared to cognitively normal adults. Additionally, higher arterial stiffness was associated with higher CVR in aMCI. These results suggest arterial stiffening may contribute to the increased CVR in patients with aMCI.

Title: Simultaneous 2-color imaging of vascular and neural activity using 2-photon microscopy

Authors: *E. M. KLEIN, C. I. MOORE;
Neurosci., Brown Univ., Providence, RI

Abstract: Cerebral blood vessels (CBVs) form a dense and interconnected network that exists in close proximity to neurons. Dynamics across neurovascular networks are functionally interconnected, most notably, as increases in neural activity predict local vascular dilations. The reciprocal impact of vascular dynamics on neurons is, however, a largely under-explored question. To explore cellular activity dynamics between these networks, we have developed a strategy for 2-color calcium imaging of CBV endothelial cells and neurons. Head-bars, and cortical imaging windows were implanted in adult mice (*N*=5 Tie2:CaMP6f, and *N*=5 WT). To explore Ca^{2+} dynamics in primary somatosensory cortex CBVs, we imaged Tie2:GCaMP6f mice using 2-photon microscopy. Imaging of CBV Ca^{2+} activity was tested in pial arteries and supragranular vessels. Vascular dilation and constriction was recorded from these vessels. To observe the cellular activity of CBVs and of perivascular neurons, *N*=3 Tie2:GCaMP6f mice were injected with adeno-associated virus transducing jRGECO1a under control of the hSyn promoter. Tie2:GCaMP6f/hSyn-jRGECO1a mice were imaged during and between tactile vibrissa stimulation to compare spontaneous and functional hyperemia epochs of neurovascular

activity. Imaging data was preprocessed to cancel motion and noise. Vessel walls were traced in images when possible - to record dilation and constriction. Fluorescence data were segmented into spatiotemporal components using constrained non-negative matrix factorization (Pnevmatikakis et al., 2016, Giovannucci et al.,2019) and deconvolved to infer Ca^{2+} transients. Analysis of the data indicates that Ca^{2+} activity in CBVs can be segregated into distinct spatiotemporal components. Transients in these components occurs both during and in absence of vessel motion. Cross correlation and event triggered averages revealed lead-lag relationships where neural activity is synchronized to, leads or lags vascular activity. Ca^{2+} transients occurring during bouts of vascular constriction or dilation indicate that endothelial Ca^{2+} is an important signaling pathway for cerebrovascular regulation. The manifestation of multiple lead-lag temporal dynamics between vascular and neural activity suggests a bi-directional, rather than exclusively feed-forward relationship between perivascular neural, and cerebrovascular activity. These data are consistent with prior and ongoing studies being conducted in our lab in parallel with the imaging described here, in which optogenetic stimulation of vascular elements has been associated with changes in local neural activity.

Title: Somatosensory responses in the deep layers of superior colliculus

Authors: *A. QURESHI[1], R. GOEL[1], J. KIM[1], N. M. DE LA ROSA-RIVERA[2], M. HIMMELBACH[3], G. HAGBERG[4], K. SCHEFFLER[5], D. RESS[1];

Abstract: Introduction: Neurons in the deep layers of superior colliculus (SC) respond during somatosensory input, so we expected that deep-layer responses would be evoked by a somatovisual integration task. Based on animal experiments, we also expected the deep-layer activation to correspond to the retinotopic position of the hands for the subject. Methods: Visual stimuli were 4 square grids of red and green dots, with patterns changing every 0.5 s. Usually, the dot patterns were random. Each grid was 3° on a side, and offset 2.5° in both x and y from fixation. Subjects fixated on a central dot, and were cued to attend to the left or right pair of grids

by tactile stimulation with a train of air puffs delivered alternately to the index and ring fingers of the current hand. Every few seconds, subjects (N = 2) were cued to attend either the upper or lower grid in the current hemifield by a double air puff to one of the two fingers. After a variable delay, the dot pattern took on either a x or + shape. Only occurrences of the rarer + shape were counted by the subject, and reported at the end of each run. The left-right alternation occurred every 30 s and repeated 8 times in each 4-min run. During each run, fMRI data was collected on a 3T scanner using a dual-echo spiral sequence (1.4-mm voxels) on 13 quasi-axial slices that covered SC. Results: We observed two regions of significant responses (Figure attached). Early responses (~3-s lag with respect to right stimulation onset) on the left SC, and later responses (~18-s lag) on the right SC. They are located near the caudo-lateral edges of both SCs. Activations extend ~5 mm within SC, but also include more superficial responses in the same region. Discussion: The somatovisual integration task successfully evoked strong lateralized responses that included the deep layers of SC. The results confirm the expected retinotopic organization of deep layer neuronal responses for hand stimulation: strongly caudal because hand position is at high eccentricity, and at the lateral margins of SC because of their position in the lower visual field. Future experiments are planned at 9.4T to extend these results.

Title: Neural-vascular uncoupling in the hippocampus of multiple sclerosis patients: Could it explain multiple sclerosis-related memory deficits?

Authors: *B. P. RYPMA[1], **D. SIVAKOLUNDU**[4], K. WEST[2], M. D. ZUPPICHINI[3], G. BATCHALLI MARUTHY[5], D. H. ABDELKARIM[6], M. P. TURNER[6], Y. ZHAO[1], R. ROMERO[5], S. RAO[5], D. OKUDA[7];

Ctr., Dallas, TX

Abstract: Introduction:
Cognitive impairment occurs in about 70% of Multiple Sclerosis (MS) patients. Neural-vascular uncoupling, sub-optimal blood flow increases following neural activity have been postulated to explain cognitive impairment in MS. Effective coupling requires coordinated and optimal functioning of the neural, glial, and the vascular system.
Objective:
We sought to assess the integrity of the neural-vascular coupling system in the hippocampus of MS patients. We hypothesized that neural-vascular uncoupling in the hippocampus contributes to memory deficits in MS.
Methods:
We conducted a single-blind case-control study comparing MS patients and healthy controls (HC). We studied neural-vascular coupling under basal and constricted vascular tone using caffeine as a vasoconstrictor. Each participant underwent 2 calibrated fMRI sessions following caffeine and placebo administration. MRI scans were performed on a Philips 3T MRI. A dual-echo MRI sequence permitted measurements of cerebral blood flow (CBF) and blood-oxygen level dependent signal (BOLD). During each session, participants performed two scans. In one scan, participants periodically inhaled room-air and a hypercapnic gas mixture for calculation of cerebral metabolic rate of oxygen ($CMRO_2$). In a second scan, participants learned face-name pairs, while judging whether or not the face and name fit together well or poorly. We calculated task-evoked changes in BOLD, CBF and $CMRO_2$ in the hippocampus following caffeine and placebo intake. The effect of caffeine on the task-evoked changes in BOLD, CBF and $CMRO_2$ was studied by comparing the changes following placebo administration.
Results:
Following caffeine intake, MS patients had significantly lower task-evoked BOLD, CBF and $CMRO_2$ compared to healthy controls in the hippocampus. Neural-vascular coupling ratio was calculated as the ratio of task-evoked CBF to $CMRO_2$. Neural-vascular coupling ratio was significantly lower in the hippocampus of MS patients compared to healthy controls, following caffeine administration.
Conclusion:

Our results suggest that there is neural-vascular uncoupling in the hippocampus of MS patients. Such uncoupling differences becomes more apparent under constricted vascular tone (i.e., following caffeine intake). This result suggests that underlying glial-vascular dysfunction might contribute to neural-vascular uncoupling in the hippocampus and would have implications for cognitive performance in MS.

Title: Traveling waves coordinate brain-wide activity in awake, adult humans

Authors: *R. V. RAUT, A. MITRA, A. Z. SNYDER, M. E. RAICHLE;
Washington Univ. In St. Louis, St Louis, MO

Abstract: Brain function requires communication among functional units at a range of spatial scales. At the macroscale, function is organized into anatomically distributed systems, such as the cortico-subcortical components of the motor and visual systems. It is presently unclear how the activity of such large-scale systems is coordinated. Increasingly slow fluctuations in excitability synchronize neural populations of increasing spatial scale. Thus, infra-slow activity (<0.1 Hz) as measured using resting-state functional magnetic resonance imaging (rsfMRI) signals may shed light on brain-wide coordination. In particular, the global fMRI signal, computed as the mean signal across the brain, is positively correlated across the entire brain; however, this global information is typically discarded to reduce artifact and increase spatial specificity. Here, using a cohort of 1,100 healthy adult humans, we show that latency patterns of the rsfMRI global signal demonstrate the presence of traveling waves within cortex, striatum, thalamus, and cerebellum. In cortex, propagation is topographically organized and results in a temporal sequence of large-scale functional networks that begins with the somatomotor-sensory

system and ends with the distributed regions of the default mode network. Importantly, we find that this network sequence is largely recapitulated separately within the striatum, thalamus, and the cerebellum. We show that the spatial arrangement of functional networks in relation to the motor system, which is roughly consistent within each of these structures, enables such network sequences to arise from traveling waves. Finally, we demonstrate that activity within each functional system begins in the cortex and subsequently appears in the striatum, thalamus, and finally, the cerebellum. Findings were highly consistent across sub-samples of the studied cohort. The observed patterns suggest that infra-slow activity may propagate via cortico-subcortical loops. Moreover, previously demonstrated arousal state-dependence of the global signal suggests that these waves may reflect the widespread broadcasting of motor state. In sum, spontaneous, low-frequency, cortically- and subcortically-organized traveling waves may provide a scaffolding for the ongoing coordination of brain-wide activity.

Title: Using the cross-wavelet transform to measure functional connectivity in BOLD fMRI reveals frequency-specific effects of anesthesia in mice

Authors: *G. DESROSIERS-GRÉGOIRE[1], G. A. DEVENYI[4,2], J. GRANDJEAN[5,6], M. CHAKRAVARTY[4,1,2,3];

Abstract: Introduction
In functional magnetic resonance imaging (fMRI) research, considerable efforts are targeted at understanding how functional connectivity (FC) regulates brain function. While FC is typically computed using temporal correlation in blood oxygen-level dependent (BOLD) signal between regions, electrophysiological recordings suggests that neural communication may operate through frequency-specific oscillatory coherence in activity. We investigated whether similar oscillatory structure is driving BOLD FC using the cross-wavelet transform (xWT), a technique measuring oscillatory coherence.
Methods

We used fMRI data from 100 subjects of the Human Connectome Project (HCP), and a mouse fMRI dataset acquired in a previous study by Grandjean et al., where mice were anesthetized under either isoflurane 1% (Iso group, n=8), medetomidine 0.2 mg/kg/h (Med group, n=6), or a combination of both anesthetics at half dosages (MI group, n=8). Regions of interest (ROI) were defined with independent component analysis (ICA) and timeseries were extracted from 50 (humans) or 46 (mice) components. Each timeseries was decomposed with the wavelet transform to measure oscillations across frequencies (Fig. 1A). FC between two timeseries was assessed across time and frequencies by measuring the "phased xWT" (Fig. 1B).

Results

We found that taking the mean of the phased xWT reproduces a FC matrix essentially identical to the correlation FC matrix (r=0.938) (Fig. 1C). Then, we found that the frequency signature of xWT is strikingly different across mouse groups (Fig1. D), in accordance with differences in the BOLD frequency spectrum previously reported by Grandjean et al. Finally, the differences across anesthetic groups were much greater when measuring temporal variability in FC using xWT than using sliding-window correlations (Fig. 1E).

Conclusion

For the first time, we demonstrate how the xWT can not only recapitulate correlation-derived FC, but also highlight how this technique improves mechanistic interpretability and differentiation between states of brain dynamics.

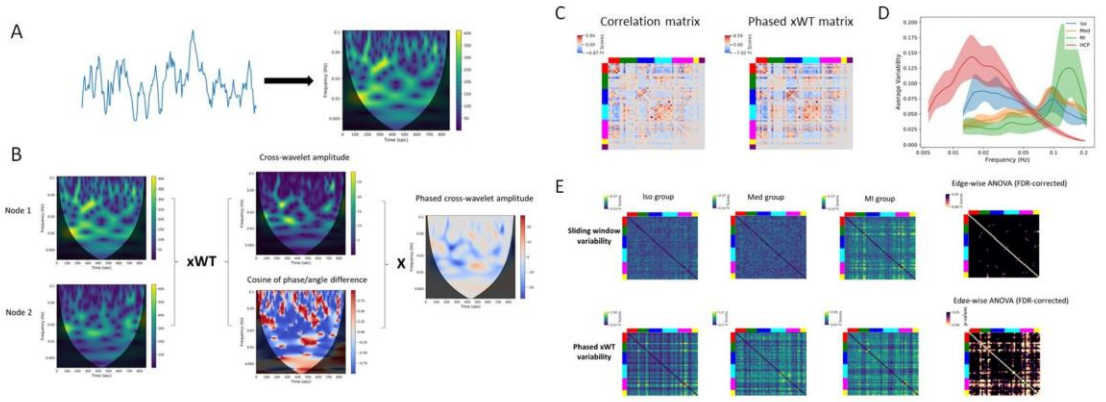

Figure 1: A) Decomposition of a BOLD timeseries (left) using the wavelet transform demonstrates frequency composition of the signal and computes oscillatory amplitude (right) and phase across frequencies (Shading areas represents time windows incompletely captured, due to incomplete phase). **B)** The cross-wavelet transform (xWT) measures oscillatory coherence between two signals decomposed by the wavelet transform (estimates the two signals' shared oscillatory amplitudes and their phase lags). The "phased xWT" is then computed by multiplying xWT amplitude with the cosine of the phase lag to map positive and negative coupling. **C)** Comparison of a brain-wide FC matrix derived from correlations (left) to a FC matrix measured by the phased xWT averaged across time and frequencies (right). ROI order was arranged based on k-means clustering (color labels on the side of the matrices). **D)** Comparison of the frequency profile of FC temporal variability in the phased xWT in humans (HCP) and across mouse anesthesia groups. The anesthesia groups are isoflurane (iso), medetomidine (med), or a combination of the two (MI). The FC variability by the temporal standard deviation, and the average was taken across all ROIs to map which frequencies are dominant for oscillatory coherence. **E)** Comparison between the sliding-window correlations (mapping changes in correlations over time) and the phased xWT in measuring the influence of anesthesia on FC temporal variability. On the right, p-values for group effects on FC was measured with one-way ANOVA and the matrices were corrected for false discovery rate (FDR).

Title: Common neural mechanisms underlie contralateral and ipsilateral negative bold responses in human primary visual cortex

Authors: *N. ETTEHADI[1], Q. RAZLIGHI[2];
[1]Biomed. Engin., Columbia Univ. in the City of New York, New York, NY; [2]Neurol., Columbia Univ. Med. Ctr., New York, NY

Abstract: The task-evoked positive BOLD response (PBR) due to a unilateral visual stimulus is often accompanied by robust and sustained contralateral as well as ipsilateral (relative to the stimulus) negative BOLD responses (NBRs) in the human primary visual cortex. Little is known about the origins and characteristics of these two types of NBRs, their relationship with one another, and with the accompanying PBR. Hence, in this study, we used a unilateral visual task to stimulate human primary visual cortex during fMRI acquisition to investigate the properties of the two task-evoked NBRs. Using 42 healthy and right handed participants, we first demonstrated that the magnitude of both NBRs linearly increase with the stimulus duration, providing evidence of rough linearity. Then, we extracted the shape of the hemodynamic response functions (HRFs) of the two NBRs and demonstrated that the two are very similar in both overall shape and timings (figure 1). However, the amplitude and timing of the HRF for contralateral NBR (cNBR) and ipsilateral NBR (iNBR) were significantly different from the PBR. While both NBRs showed a delayed onset time ($\Delta t=-1.05\pm1.81$ sec, $p<0.0009$), they both reached their peaks faster ($\Delta t=0.42\pm0.72$ sec, $p<0.006$), and also fell back to their baselines quicker ($\Delta t=1.4\pm3.88$ sec, $p<0.0005$) than PBR. Additionally, we showed that the subject-wise amplitude of the cNBR is tightly associated with that of iNBR ($r=0.96$, $p<5.6x10^{-26}$) which is much higher than their relationship with PBR (cNBR: $r=-0.507$, $p<0.00062$; iNBR: $r=-0.364$, $p<0.018$). Furthermore, we showed that unlike the PBR, neither of the NBRs were correlated with task performance. Finally, we demonstrated that unlike the PBR both NBRs are independent of attention. Our findings suggest that the visually evoked cNBR and iNBR are most likely generated through a common underlying neural and/or vascular mechanism(s).

Engin. Sci. and Mechanics, Pennsylvania State Univ., University Park, PA; [6]INSERM 1128 Paris Descartes Univ., Paris cedex 06, France

Abstract: Imaging techniques based on blood flow dynamics are commonly used to study sensory processing in the human brain. However, these techniques do not directly measure neuronal activation, reporting instead functional hyperemia, a delayed increase of blow flow that irrigates a volume larger than that of the activated neurones. This raises the question of how maps of brain activation with a mesoscopic spatial resolution report local cellular and vascular responses measured with microscopic resolution. Using the olfactory bulb as a model, we combined two-photon microscopy and fast ultrasound imaging (fUS) in the same mouse. We computed the transfer functions (TFs) between the cellular and vascular microscopic responses, as well as the TF between microscopic and mesoscopic (fUS) responses. The TF from neuronal calcium and capillary red blood cell (RBC) velocity responses were robust across mice and a large range of odor duration and concentration. However, this TF required fine adjustments to predict correctly responses to brief stimuli (elicited by a single sniff of the odor) or very high odor concentrations. Co-alignment of the fUS and two-photon imaging apparatus enabled us to establish a TF between the fUS signal from single voxel and microscopic responses from the responsive glomerulus comprised in the same voxel. This first “hemodynamic response function” (HRF) for fUS data, was robust with respect to the stimulation duration and intensity, and faster than the canonical BOLD fMRI HRF. When applied to standard statistical mapping analyses (GLM), the TF improved the precision of fUS olfactory bulb activation maps. In conclusion, this new TF provides a new tool to compare quantify neurovascular coupling in control and pathological animal models.

Title: Resting state BOLD signal, functional connectivity, and neural dynamic modeling

Authors: *M. E. ARCHILA-MELENDEZ, C. SORG, C. PREIBISCH;
Dep. of Diag. and Interventional Neuroradiology, Klinikum rechts der Isar, Fakultät für Medizin, Technische Univ. München, Munich, Germany

Abstract: Introduction Blood oxygenation level dependent (BOLD) signal's ability to reflect underlying neuronal activity (NeuA) relies on the assumption of tight coupling between NeuA and vascular-hemodynamic processes. This neurovascular coupling (NC) depends on changes in cerebral blood flow (CBF) and cerebral metabolic rate of oxygen ($CMRO_2$). The precision with which the ongoing NeuA is reflected by the BOLD signal during rest is not completely understood. In this study, we aimed to investigate the influence of CBF and $CMRO_2$ amplitude changes on the BOLD signal and intrinsic functional connectivity (iFC) at rest.
Methods BOLD signals were simulated (S_{BOLD}) using a dynamic model based on the balloon model assuming tight coupling[1,2] for different combinations of normalised CBF and CMRO2 amplitude changes, f1 (1.0-1.75) and m1 (1.0-1.375), respectively. NeuA was modeled as dynamic amplitude-amplitude coupling between gamma, alpha and ultra-slow oscillations[3]. Different SNR levels (1000-125) were modeled by adding random noise to the S_{BOLD}. We calculated correlation coefficients (CC) between S_{BOLD} with different f1 and m1 for all SNR levels to quantify the interaction between vascular components influencing the BOLD signal (Fig1).
Results S_{BOLD} reflected the amplitude modulation in power generated by ultra-slow oscillations. S_{BOLD} evolved from negative responses for all $CMRO_2$ amplitudes (m1=1.0-1.375) at constant CBF, i.e., f1=1.0, to positive responses for all $CMRO_2$ amplitudes at max. CBF change amplitude, f1=1.75 (Fig2). The CC varied between negative and positive values for different SNR levels (Fig3). For SNR between 150 and 250, CC ranged between 0.4 and 0.3, as commonly found in iFC analyses.
Conclusion Accurate modeling of the NC can provide insights on the interplay between vascular-hemodynamic components, which should be considered when estimating iFC, especially in patients with potential vascular pathologies.

Title: Reduced arterial compliance along the cerebrovascular tree predicts cognitive impairment in multiple sclerosis: Evidence for neural-vascular uncoupling hypothesis

Authors: *D. SIVAKOLUNDU[1], K. WEST[3], G. MARUTHY[1], M. D. ZUPPICHINI[4], M. P. TURNER[2], D. H. ABDELKARIM[2], Y. ZHAO[1], J. SPENCE[1], H. LU[6], D. OKUDA[7], B. P. RYPMA[5];
[1]Univ. of Texas at Dallas, Richardson, TX; [2]Sch. of Behavioral and Brain Sci., Univ. of Texas at Dallas, Dallas, TX; [3]Ctr. for BrainHealth, [4]Zuppichini, [5]Behavioral & Brain Sci., Univ. of Texas At Dallas, Dallas, TX; [6]Johns Hopkins Univ., Baltimore, MD; [7]Univ. of Texas Southwestern Med. Ctr., Dallas, TX

Abstract: Background: Cognitive impairment occurs in almost 70% of multiple sclerosis (MS) patients. The pathophysiology of this impairment is unknown. Loss of vascular compliance along the cerebrovascular tree (i.e., vascular network extending from superficial pial arteries to deep penetrating arteries) would result in suboptimal vasodilation upon neural stimulation, providing insufficient nutrients and oxygen to active neurons. This process is called neural-vascular uncoupling and we hypothesized this uncoupling would result in cognitive impairment.
Objective: To assess vascular compliance along the cerebrovascular tree and its relationship to MS-related cognition.
Methods: We conducted a cross sectional study investigating healthy controls, cognitively-normal and -impaired MS patients. Participants were scanned on a Philips 3T MRI scanner using a dual-echo fMRI sequence while they periodically inhaled room-air and hypercapnic gas-mixture (5% CO_2 and 95% room air). We assessed vascular compliance along the cerebrovascular tree by dividing cerebral cortex into nested-layers. Arterial and venous cerebrovascular reactivity (CVR) was calculated from both cerebral blood flow (arterial) and blood-oxygen-level-dependent signal (venous) increases per unit increase in end-tidal CO_2.
Results: Arterial CVR exponentially reduced from the superficial to deep portions of the cerebrovascular tree for healthy controls ($p=0.0014$) and cognitively-normal MS patients ($p=0.0005$). No such reductions were observed in cognitively-impaired MS patients ($p=0.7244$). These arterial CVR changes were fit to exponential functions, the decay-constant (arterial compliance index; ACI) of which was associated with individual subjects' cognitive performance ($p=0.01$) and accounted for 20.3% of variability in their performance in MS patients. Furthermore, ACI significantly explained an additional 11.7% of the cognitive-performance variability in MS after controlling for age, disease duration, lesion volume, EDSS, brain atrophy, and cortical grey and white matter volume ($p=0.003$).
Conclusion: ACI is a novel biomarker reflecting the degree of injury along the cerebrovascular tree. This index might provide a platform for MS disease surveillance, development of targeted cognitive therapies, and a method for distinguishing between MS patients who are prone to develop cognitive impairment and those who are not.

Abstract: Introduction: FMRI relies on a stereotypical response to brief neural activation called the hemodynamic response function (HRF) that largely depends on competition between cerebral blood flow (CBF) and oxygen metabolism. The detailed dynamics of the CBF response are poorly understood. Standard arterial spin labeling (ASL) experiments to measure transient CBF suffer from low temporal sampling (≥5 s). We used a dithering scheme to obtain 1.25-s sampling of the CBF evoked by brief stimulation, as well as baseline CBF. **Methods**: An audiovisual sequence-detection task was used to evoke the HRF broadly across visual cortex in 7 subjects. CBF was measured in 5 runs using ASL with PICORE/Q2TIPS tagging, TR = 2.5 s, and 2-mm voxels. Stimulus onset times were 4:1 dithered, with onset delayed in 1.25-s steps from event-to-event. Dithering was compensated by upsampling and shifting each event time series. The fMRI HRF was measured in 2 runs using SMS-accelerated EPI, TR = 1.25 s, 2-mm voxels, without dithering. Data were transformed into a 0.7-mm MP-RAGE anatomy and analysis restricted to gray matter voxels. Retinotopic mapping was done in separate sessions to discern visual areas V1—3, V3AB, and hV4. CBF and HRF data were averaged across these visual areas to obtain 44 measurements. **Results**: Strong CBF and HRF response were obtained across visual cortex

(Fig A). Stimulation created an initial CBF peak followed by an undershoot (Fig B). Peak was reliable in all measurements and undershoot significant in 33/44 measurements. Peak and undershoot were significant in all HRF measurements. There were significant moderate-to-strong correlations among HRF, CBF responses, and baseline CBF (Fig C). **Discussion**: Our dithering approach allowed detailed characterization of flow dynamics with satisfactory contrast-to-noise ratio. CBF dynamics were similar to HRF dynamics, and the CBF was at least partly responsible for the HRF undershoot. The correlation of CBF and HRF peak responses with baseline CBF indicated that fMRI signals may be strongly modulated by perfusion, a notable nuisance effect for fMRI analysis.

Title: Arousal-state dependence of bilateral hemodynamic signals in the mouse

Authors: *K. L. TURNER[1], P. J. DREW[2];
[1]Dept. Biomed. Engin., [2]Dept. Engin. Sci. and Mechanics, Pennsylvania State Univ., University Park, PA

Abstract: Hemodynamic signals in the brain are used to infer neural activity, and bilateral correlations in hemodynamic signals have been observed in the absence of any overt stimulus or task. However, recent studies have suggested that the nature and strength of hemodynamic signals depend on arousal state. Here, we monitored neural activity and hemodynamic signals in un-anesthetized, head-fixed mice to understand how sleep and wake states impact cerebral hemodynamics. In parallel with electrophysiological recordings, we used intrinsic optical signal imaging to measure bilateral changes in cerebral blood volume (CBV). We concurrently monitored body motion, whisker movement, muscle EMG, and cortical LFP to classify the arousal state of the mouse into awake, NREM sleep, or REM sleep. We found that mice regularly fell asleep for a few minutes at time during imaging. During both NREM and REM sleep, mice showed large increases in CBV relative to the awake state. During NREM sleep, the amplitude of bilateral low-frequency oscillations in CBV increased markedly. Bilateral correlations in neural activity and CBV were highest during NREM sleep, and lowest in the awake state. Our results show that hemodynamic signals in the cortex are strongly modulated by arousal state and emphasize the importance of behavioral monitoring during studies of spontaneous activity.

Title: Simulations of nitric oxide diffusion show spatial dynamics of degradation can drive vasomotion and post-stimulus constriction

Authors: *W. D. HASELDEN[1], R. KEDARASETTI[2], P. J. DREW[3];
[1]The Pennsylvania State Univ., State College, PA; [2]Ctr. for Neural Engin., The Pennsylvania State Univ., University Park, PA; [3]Dept. Engin. Sci. and Mechanics, Pennsylvania State Univ., University Park, PA

Abstract: Nitric oxide (NO) is a gaseous signaling molecule that plays an important role in neurovascular coupling. NO produced by neurons diffuses into smooth muscle surrounding

arterioles, driving vasodilation. However, the rate of NO degradation in hemoglobin is orders of magnitude higher than in brain tissue, though how this might affect NO signaling is not completely understood. Using computer simulations, we investigated how the spatial and temporal patterns of NO generation and degradation impacted arterial dilations. We found that NO production that was localized near the arteriole was markedly more effective than spatially extended NO production. Because of the higher degradation of NO in the blood, the size of the arteriole exerted an effect on NO signaling in our simulations, with smaller vessels being more sensitive to NO than larger ones. When we implemented a model with dynamic NO production, degradation and vasodilation, we found that the increased degradation of NO created by vasodilation drove emergent dynamics. In this dynamic model, large dilations were followed by a post-stimulus constriction, similar to the post-stimulus undershoot seen in fMRI experiments. The dynamic model also generated oscillations in arterial diameter around the 0.1-0.3 Hz range, reminiscent of vasomotion. Vasomotion could also be enhanced by increasing the free hemoglobin in the plasma, as happens with certain diseases. Thus, our simulations suggest that many common arterial dynamics may be emergent phenomenon generated by the dynamics of NO degradation by the blood.

Abstract: Multimodal brain imaging of neuronal and blood flow dynamics in the same animal allows the quantitative analysis of the causal relationship between neuronal activation and functional hyperemia. Given the complexity of the many mechanisms involved during neurovascular coupling (NVC), we adopt a model-free approach, using the transfer function (TF), whose convolution with neuronal signals, will provide an estimation of expected vascular responses. We first established a database of cellular and vascular responses to odor. We measured with microscopic resolution using two-photon imaging, and with a mesoscopic resolution using functional ultrasounds (fUS), in the same mice. A direct approach to determine TFs is the deconvolution, either working on the frequency domain, or calculating the Toeplitz matrix. Both these methods produced estimates that were extremely sensitive to noise, and did not give robust TFs. We then used a machine learning optimization algorithm working on known functions, such as the gamma functions, and were able to build up a set of TFs recapitulating NVC at the microscopic resolution (from neuronal calcium to capillary red blood cell velocity responses) or at the mesoscopic level (from neuronal calcium to single fUS voxel responses). After having evaluated the effect of regularization and cross-validated the robustness of the TFs across mice, we challenged the best TF by modulating the stimulation parameters: this first "hemodynamic response function" for fUS data, was fast and robust over a large range of odor durations and intensities. Our approach sets some guidelines for efficient computations and validations of a TF that can predict NVC in control and pathological animal models.

Title: Arousal state-associated hemodynamic changes occlude stimulus-evoked neurovascular coupling in the somatosensory cortex of the juvenile mouse

Authors: *K. W. GHERES, K. L. TURNER, P. J. DREW;
Pennsylvania State Univ. Univ. Park, University Park, PA

Abstract: In juvenile rodents and humans, neurovascular coupling associated with sensory stimulus can be weak, absent, or inverted. Using Intrinsic Optical Signal (IOS) imaging, two photon microscopy, and in vivo extracellular electrophysiology, we investigated how neurovascular coupling in somatosensory cortex is affected by arousal state throughout the

juvenile period. In adult mammals, the diurnal sleep-wake cycle is characterized by long bouts of wakefulness followed by periods of sleep which is accompanied by large, global, increases in blood volume. However, in juvenile mice, sleep and wake periods occur sporadically and in quick succession on the time scale of seconds to minutes. We find that in juvenile mice, sleep onset is accompanied by a large increase in cerebral blood volume (CBV) in the somatosensory cortex. After eye opening (~P14), whisker stimulation will awaken the mice, resulting in large decreases in blood volume. This arousal state-related change in CBV obscures any sensory-evoked neurovascular relationship. Finally, we use cell type specific optogenetics to investigate how the neurovascular hemodynamic response is affected by sleep state independent of sensory stimuli. These results suggest that careful monitoring of arousal state is essential to prevent confounding of stimulus evoked hemodynamic responses with large global changes in blood volume driven by sleep-wake state transitions.

Title: Regulation by central estrogen receptors of ethanol-induced tachycardia in female rats

Authors: *C.-C. LAI[1,2], J. SITUMORANG[2], H.-H. LIN[3];
[1]Dept. of Pharmacol., [2]Master and PhD Programs in Pharmacol. and Toxicology, [3]Dept. of Physiol., Tzu Chi Univ., Hualien, Taiwan

Abstract: Several ethanol-related diseases are gender-dependent; females are more sensitive than males to the effects of ethanol (alcohol). Our previous study showed that nitric oxide synthase (NOS) and nitric oxide (NO) signaling in the medulla of the brain might play an important role in mediating ethanol-induced tachycardia during ethanol exposure. Studies showed that estrogen or estrogen receptors might regulate NOS/NO signaling in the brain. The role of estrogen receptors in the brain in ethanol-induced tachycardia remains unclear. This study examined the role of central estrogen and estrogen receptors in the changes in blood pressure (BP) and heart rate (HR) induced by acute ethanol administration in ovariectomized (OVX) and sham-control (SHAM) female SD rats weighing 250-300g. The responses of BP and HR in conscious rats were measured by the tail-cuff method. Ethanol (3.2 g/kg) and saline (as control) were given by oral gavage. Oral administration of ethanol increased HR with little changes in BP in both SHAM and OVX rats. Compared to SHAM rats, however, OVX rats showed a

significantly higher HR response in 60, 90, and 120-minute post ethanol administration. Intraperitoneal (IP) injection of Tamoxifen (a selective estrogen receptor modulator) augmented ethanol-induced tachycardia in SHAM rats. Intracerebroventricular (ICV) infusion of estrogen α or β receptor antagonists potentiated ethanol-induced tachycardia effect in SHAM rats. ICV infusion of Estradiol (E2, an estrogen receptor agonist) attenuated the ethanol-induced tachycardia effects in OVX rats. These results suggest that estrogen and estrogen receptors in the CNS play a role in the regulation of ethanol-induced tachycardia in female rats. The changes in the NOS activity and NO contents will be determined in several brain nuclei related to autonomic control to clarify the role of NOS/NO signaling in estrogen regulation of ethanol-induced tachycardia.

Title: Estrogen receptor beta agonists block slow-onset angiotensin II hypertension and reduce NMDA receptor-signaling in paraventricular neurons in female mice at an early stage of accelerated ovarian failure

Authors: *T. A. MILNER[1], N. H. CONTOREGGI[2], F. YU[2], M. A. JOHNSON[2], G. WANG[2], E. M. WATERS[3], B. S. MCEWEN[3], M. J. GLASS[4];

Abstract: Men are more susceptible to hypertension than women from early adulthood to mid-life; however, when women transition to menopause (perimenopause), their risk for hypertension increases and approaches that of men. Animal models suggest that differences in hypertension susceptibility in males and females may involve sex-dependent divergences in estrogen signaling in cardiovascular regulatory brain areas, including the hypothalamic paraventricular nucleus (PVN). Our studies have begun to elucidate the mechanisms for these sex differences using the 4-vinylcyclohexene diepoxide (VCD) mouse model of accelerated ovarian failure (AOF), which recapitulates hormonal changes in peri-menopause (peri-AOF). In peri-AOF mice, slow-pressor angiotensin II (AngII) increases blood pressure. This is accompanied by redistribution of the

GluN1 NMDA receptor subunit from the cytoplasm to the plasmalemma in PVN estrogen receptor beta (ERβ) containing dendrites, a process that would promote sympathoexcitation (Marques-Lopes et al., 2017). Here, we report that cyclic administration of diarylpropionitrile (DPN; 1mg/kg, I.P.), ERB041 (20mg/kg, I.P.), or liquiritigenin (30mg/kg, I.P.), which represent three different classes of ERβ agonists, blocked the increase in blood pressure by AngII in peri-AOF females but not age-matched males. Dual-label electron microscopy revealed that the reduction of blood pressure in DPN-administered peri-AOF females was paralleled by a decrease in GluN1 near the plasmalemma, in the cytoplasm and in total in ERβ-containing dendrites in the PVN. In contrast, the trafficking of GluN1 in ERβ-containing dendrites in DPN-administered hypertensive males was unaltered. Physiological studies are in progress analyzing the NMDA-receptor mediated excitatory signaling in PVN ERβ-expressing neurons from AngII mice with DPN agonists. These results suggest that heightened NMDA receptor signaling in ERβ-expressing PVN neurons contributes to the susceptibility of peri-AOF mice to the hypertensive actions of AngII. These findings provide preclinical evidence supporting a therapeutic window of opportunity for estrogen-based management of hypertension as women transition through menopause.

Title: Estrogen receptor beta activity contributes to a reduction in tumor necrosis factor alpha-induced reactive oxygen production in the hypothalamic paraventricular nucleus and to the resistance to angiotensin II-dependent hypertension in cycling female mice

Authors: *M. J. GLASS, C. WOODS, N. H. CONTOREGGI, T. A. MILNER, G. WANG; Weill Cornell Med., New York, NY

Abstract: Before the start of menopause women have a lower incidence of hypertension when compared to age-matched men. However, the mechanisms influencing sex-differences in hypertension susceptibility are not well understood. Males and females differ with respect to essential processes that affect blood pressure, including neurogenic factors, inflammation, and oxidative stress. In a mouse model of neurogenic hypertension induced by low-dose angiotensin

II (AngII) infusion males show an increase in blood pressure that involves both tumor necrosis factor alpha (TNFα) and reactive oxygen species (ROS) signaling in the hypothalamic paraventricular nucleus (PVN), an important central coordinator of cardiovascular regulation. However, the role of TNFα signaling in reactive oxygen production and blood pressure in response to AngII administration in females is uncertain. These issues were addressed using a combination of *in situ* hybridization, high-resolution electron microscopic immunohistochemistry, and *in vitro* dihydroethidium microfluorography. We found that cycling female mice given chronic (14-day) infusion of AngII did not show an increase in blood pressure, a finding consistent with previous reports. In addition, female mice infused with AngII or vehicle did not differ either in the expression or the subcellular localization of the TNFα receptor type 1 (TNFR1) in the PVN. In contrast to what is typically seen in males, TNFα exposure resulted in only a modest production of Nox2-mediated ROS in isolated PVN neurons. Significantly, blocking estrogen receptor beta (ERß) with the antagonist PHTPP resulted in a robust increase in TNFα-dependent ROS production in isolated PVN cells from female mice. Moreover, administration of PHTPP during chronic AngII infusion was associated with an increase in blood pressure in females. These results indicate that ERß signaling in PVN neurons contributes to the reduced sensitivity of female mice to cytokine-induced free radical production and AngII-dependent hypertension.

Title: Changes in neuropeptide expression, responses, and receptors in parasympathetic neurons following chronic myocardial infarction

Authors: *L. LOISELLE, P. GALVIN, K. HUTTON, J. C. HARDWICK;
Biol., Ithaca Col., Ithaca, NY

Abstract: Myocardial infarction (MI) induces significant remodeling in both cardiac muscle and the neuronal systems that control the heart. Previous studies have demonstrated significant increases in activity of the sympathetic nervous system following MI. The current study looked at changes in postganglionic parasympathetic neurons in the cardiac plexus and autonomic neurons of the nodose and stellate ganglia in guinea pigs 4-6 weeks following a chronic MI. MI

was surgically-induced in both male and female guinea pigs by ligation of coronary vessels branching off the LAD. Animals were then allowed to recover for 4-6 weeks. Intracellular voltage recordings from neurons within whole mounts of the intrinsic cardiac plexus were used to assess physiological changes in parasympathetic neuronal responses to peptide application. Intracardiac neurons from MI animals showed a decrease in sensitivity to NPY. NPY application (in the bath or by local pressure ejection) accelerated the rate of return to resting membrane potential of the afterhyperolarization of a single action potential. A dose response curve (1 nM - 100 nM NPY) of control neurons vs. neurons from MI animals showed a 10-fold increase in the EC_{50} for NPY with MI. Specific agonists for Y1 and Y5 receptors demonstrate that the response in these neurons is due to primarily to activation of Y1 receptors. Western Blot analysis of homogenized cardiac ganglia showed no significant change in Y1R protein at 6 weeks post MI, indicating that the decrease in sensitivity is not due to reduced protein content. In addition to postganglionic neurons, we also examined the neurons that innervate these cells, including the nodose ganglion and the stellate ganglion. Examination of cryostat sections of fixed nodose ganglia showed little to no NPY expression in neurons within the ganglion in control or MI tissues, but did show a significant increase in expression of galanin-immunoreactivity, and nNOS in neurons with MI, along with an increase in neuronal size. Examination of stellate neurons, whose fibers also innervate this cardiac plexus, showed an increase in NPY expression and cell size with MI, consistent with findings in other species. This data demonstrates that chronic heart disease, such as MI, induces phenotypic and functional remodeling in both the sympathetic and parasympathetic neurons innervating the heart.

Title: Participation of brain angiotensin type 1 receptor in the anti-hypertensive effects of catalase blockade in spontaneously hypertensive rats

Authors: *M. R. LAUAR, D. S. A. COLOMBARI, L. A. DE LUCA JR, P. M. DE PAULA, E. COLOMBARI, C. A. F. ANDRADE, J. V. MENANI;
Dept Physiol. and Pathol., Dent. School, UNESP, Araraquara/SP, Brazil

Abstract: The spontaneously hypertensive rat (SHR), a genetic model of neurogenic hypertension, has increased sympathetic activity, a hyperactive brain renin-angiotensin system and high density of angiotensin II (ANG II) type 1 receptors (AT-1r) centrally. Activation of brain AT-1r enhances NAD(P)H oxidase activity and formation of reactive oxygen species, such as the superoxide anion (O_2^-). The O_2^- is dismutated to hydrogen peroxide (H_2O_2) by the enzyme superoxide dismutase. Previous studies have shown that intracerebroventricular (icv) injection of H_2O_2 or the catalase inhibitor 3-amino-1,2,4-triazol (ATZ) reduces the pressor response to icv ANG II in SHR. In addition, the subcutaneous (sc) administration of ATZ acutely reduces mean arterial pressure (MAP) in SHR. In the present study, we evaluated the participation of brain AT-1r in the changes of MAP produced by sc injection of ATZ in SHR. Male SHR (280-350 g, n=4-7/group) with stainless steel guide-cannulas implanted in the lateral ventricle were used. After a baseline period of MAP and heart rate (HR) recording, rats received icv injection of saline (1 µl) or losartan (100 ng/1 µl) 30 min prior to sc injections of ATZ (300 mg/kg of body weight). The sc injection of ATZ reduced MAP (ATZ: 157 ± 6, vs. baseline 186 ± 7 mmHg) and HR (ATZ: 374 ± 24 bpm, vs. baseline: 425 ± 49 bpm) in SHR that received saline icv. Losartan icv abolished the reduction in MAP (185 ± 3 mmHg) and HR (448 ± 15 bpm) produced by sc injection of ATZ. Losartan alone produced no change in MAP and HR. The results suggest that the anti-hypertensive effects of ATZ depend on AT-1r activity which produces O_2^- that is dismutated to H_2O_2 in the brain. Blocking catalase, ATZ might increase the availability of H_2O_2 produced endogenously in the brain, thereby reducing MAP and HR in SHR.

Abstract: Dickkopf3 (Dkk-3) is a secreted glycoprotein known for its proapoptotic and angiogenic activity. We have shown that Dkk-3 induces vascular endothelial growth factor (VEGF) in astrocytes and endothelial cells (Busceti et al., Front. Pharmacol., 2017; Front. Cell. Neurosci., 2018), raising the possibility that Dkk-3 may regulate vascular homeostasis. Here, we report that genetic deletion of Dkk-3 in mice enhanced systolic blood pressure and impaired endothelium-dependent relaxation of mesenteric arteries. Endothelial function in Dkk-3$^{-/-}$ mice was rescued by incubating mesenteric arteries with the human recombinant VEGF peptide. In addition, *i.v.* injection of a lentiviral vector encoding for Dkk-3 caused anti-hypertensive effects in Dkk-3$^{-/-}$ mice, demonstrating a role for Dkk-3 in the systemic control of blood pressure. At CNS level, immunohistochemical analysis showed a high Dkk-3 immunoreactivity in brainstem nuclei that are involved in the baroreceptor reflex, such as the area postrema, the nucleus of the solitary tract, and the nucleus ambiguous. Interestingly, *i.c.v.* infusion of the lentiviral vector encoding for Dkk-3 could also lower blood pressure in Dkk3$^{-/-}$ mice, but did not rescue endothelial function in isolated mesenteric arteries (as opposed to the *i.v.* injection of the vector). Central infusion of the vector encoding for Dkk-3 enhanced VEGF protein levels and increased endothelial nitric oxide synthase (eNOS) phosphorylation in the brainstem of Dkk-3$^{-/-}$ mice, and Dkk-3 overexpression was unable to reduce blood pressure in eNOS$^{-/-}$ mice. We extended the analysis to spontaneously hypertensive rats (SHR) as a genetic model of neurogenic hypertension. Interestingly, Dkk-3 gene maps inside a WKY/SHR (Wistar Kyoto/Spontaneously hypertensive rat) chromosome 1 QTL (Quantitative Trait Locus) included between D1Mit3 and D1Rat57 markers and linked to the hypertensive phenotype. In SHR rats, i.c.v. infusion of the vector encoding for Dkk-3 lowered systolic blood pressure, whereas Dkk-3 silencing produced the opposite effect. Taken together, these findings demonstrate that the molecular Dkk-3/VEGF/eNOS axis acts as peripheral and central regulator of vascular homeostasis under both physiological and pathological conditions.

Title: Heart rate in myalgic encephalomyelitis/chronic fatigue syndrome: A review revisited

Authors: *K. M. KNUTSON;
Behavioral Neurol. Unit, NINDS/NIH, Bethesda, MD

Abstract: ME/CFS is a heterogeneous, medically unexplained illness characterized by fatigue lasting at least 6 months. A recent meta-analysis (1) summarized the data from peer-reviewed journals regarding heart rate (HR) response to exercise in ME/CFS patients. A main conclusion was that "smaller or reduced increases in HR during CPET (cardiopulmonary testing) are consistently observed in ME/CFS" compared to controls. However, a casual review of the data presented in Table 1 suggests that substantially lower mean peak HRs in ME/CFS patients were found mainly in studies that had no control group and generally not seen in studies with one. We conducted a re-analysis of the meta-analysis data to better understand if there were methodological differences between the controlled and uncontrolled studies. First, we used the observed mean peak HR in patients with ME/CFS from the studies listed in the meta-analysis (Table 1), but separated the data depending on whether the study was controlled or not. A significant difference ($p < .001$) in HR was seen in patients in studies without a control group (144+- 8) compared to patients with one (162 +- 14). This strongly suggests that methodological issues rather than disease-specific issues are driving the finding of blunted HR responsiveness. Further, 7 of 34 papers were written by the same group (peak HR 147 vs 157 in other studies), none of which used a control group. Two of these 7 papers (2, 3) state their data were "re-analyzed", making it likely the same data was included more than once in the meta-analysis, further weighing the results toward a low mean patient peak HR. Furthermore, the patients in the 7 studies were 94% women (85% in the other studies), who tend to have slightly lower peak HRs (4). In addition, HR may be affected by anticipation of or actual pain/stress due to invasive drawing of blood (5, 6). We saw that 9 of the 34 studies included invasive blood draws during or immediately after the exercise test and found that mean peak HR in each group (patient and control) was significantly higher when blood was drawn around the time of exercise than when it was not. This suggests another potential confound, as a higher percentage of controls (37%) received blood draws than patients (27%) in the meta-analysis. HR is an important variable in models for exercise tolerance (7) in ME/CFS. While HR is an objective measure, the methods and circumstances around its measurement can affect it and should be taken into account when comparing HR across groups. In addition, while meta-analyses have more statistical power to detect significant effects than do small, individual studies, careful attention must be made to the data that are included and the conclusions drawn.

Title: Effect of exercise timing on sleep duration, sleep quality, and HRV-based recovery for collegiate female athletes

Authors: B. FLEMMING, **N. NARVAEZ**, *R. E. JOHNSON;
Mechanical Engin. and Bioengineering, Valparaiso Univ., Valparaiso, IN

Abstract: The physiological stresses that athletes experience during training must be balanced with adequate recovery. Recovery allows the body to reach a maximum athletic potential, which allows athletes to perform at higher levels. Recovery is affected by many factors, and in this work we focused on the timing of vigorous exercise. Our previous study found that training sessions after 8pm decreased recovery in collegiate women soccer players [1]. We hypothesized that late training sessions negatively affects sleep, but the literature on how timing of exercise affects sleep shows mixed results. This study investigates the relationship between timing of vigorous exercise, sleep, and recovery for collegiate female athletes.
Specifically, we studied how the timing of games affected sleep duration, sleep quality, and recovery for players on an NCAA Division I women's soccer team during the fall 2017 season. Games that started at or after 7pm were considered late, whereas games that started before 7pm were considered normal. Sleep duration and sleep quality were measured using a qualitative survey completed by players each day [as in 2]. Recovery was estimated using heart rate variability (HRV) by having each player record 5 minutes of their heart rate data each day upon waking up. This HRV data was then used to calculate a Recovery Index [3]. Higher HRV generally indicates better recovery, a process governed largely by the autonomic nervous system. We found that sleep duration remained similar for late and normal games (8 hours for both normal and late games); however, sleep quality decreased by 20% for late games (80% for normal games and 60% for late games). The median recovery index decreased by 6.1 percent for days after late games (52.7 % for normal games and 46.6 % for late games). In summary, we found that vigorous activity in the form of in-season games for a collegiate women's soccer team resulted in lower sleep quality and a lower recovery index when games occurred late in the evening as compared to games in the morning or early afternoon.

Central Univ., Taoyuan, Taiwan; [5]Dept. of Anesthesia, Massachusetts Gen. Hosp., Boston, MA

Abstract: Sleep-wake regularity (SWR) is often disrupted in college students and mood disorders are rife at this age. Disrupted SWR can cause repetitive and long-term misalignment between environmental and behavioral cycles and the circadian system which may then have psychological and physical health consequences. We previously showed that SWR was independently associated with mood, as measured using the Beck Depression Inventory (BDI) in a healthy adult cohort. However, it remained unclear whether this was driven by psychological complaints (e.g. guilt, sadness, or satisfaction) versus physical symptoms (e.g. appetite, libido, or tiredness). We studied 42 college students over a 3-week period using daily sleep-wake diaries. Neuropsychiatric wellbeing and mood was assessed weekly using the Beck Depression Inventory-II. Linear mixed effects models were used to account for repeated weekly measures. When we adjusted for age, sex, race, physical activity, chronotype, and mean sleep duration, prior week SWR was strongly predictive of the subsequent week's psychological symptom score component of BDI ($p = 0.0003$), whereas this was weaker for physical symptoms ($p = 0.02$); in fact, this observation was no longer significant once we accounted for the sleep question in BDI ($p = 0.053$). Further work is needed to understand the implications of poor psychological versus physical symptoms in those with low mood and irregular sleep-wake cycles.

Model		Psychological score (BDI)			Physical (BDI)		
		b	95% CI	*P*- value	b	95% CI	*P*- value
1a	SWR	-8.86	(-13.4 to 4.29)	**0.0003*** **	-3.14	(-5.74 to 0.56)	**0.02***
1b	SWR	-7.10	(-12.0 to -2.20)	**0.005** **	-0.06	(-0.14 to 0.02)	0.13
	Chronotype (MEQ)	-0.11	(-0.23 to 0.02)	0.08	0.05	(-0.004 to 0.10)	0.07
1c	SWR	-6.89	(- 12.4 to - 1.33)	**0.016***	-2.28	(-5.45 to 0.89	0.15
	Chronotype (MEQ)	-0.11	(- 0.23 to 0.02)	0.09	-0.03	(- 0.11 to 0.05)	0.49
	Delayed-bedtime	0.008	(- 0.08 to 0.10)	0.86	0.02	(- 0.04 to 0.08)	0.51

Title: Neuropsychiatric wellbeing and the daily/circadian rhythm of autonomic regulation in young adults

Authors: *L. GAO[1,2], H.-W. YANG[3], P. LI[1,4], C. HU[5], P. WONG[6], F. A. J. L. SCHEER[1,4], C. LIN[3], M.-T. LO[3], K. HU[1,4];

Sch., Boston, MA; [5]Div. of Sleep and Circadian Disorders, Brigham and Women's Hosp., Boston, MA; [6]Dept. of Psychology, Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Disruption to sleep/wake regularity is perhaps most significant during college than at any other stage in life, and not surprisingly, mood disorders are rife. Repetitive and long-term misalignment between environmental/behavioral cycles and the circadian rhythm has been suggested as a potential mechanism leading to poor neuropsychiatric wellbeing, as well as

physical health consequences, likely through its influence on autonomic regulation. We hypothesized that the daily/circadian rhythm of high frequency heart rate variability (HF-HRV) was significantly altered in those with reporting poor mood in a healthy adult cohort.
We studied 42 college students over a 3-week period using daily sleep-wake diaries and continuous electrocardiogram (ECG) recordings from which hourly HF-HRV was derived. Neuropsychiatric wellbeing and mood was assessed weekly using the Beck Depression Inventory-II. We quantified the daily/circadian rhythm using cosinor model fitting in which both fundamental 24-h and 1st harmonics were included. We established a clear 24-h rhythm for HF-HRV ($p < 0.01$) across the study period. We found significantly increased HF-HRV across the habitual sleep-wake cycle ($p = 0.0002$) and a 36.7% increase in the 24-h fundamental rhythm ($p = 0.0003$) for those with poor mood (upper half of mean BDI), leading to more pronounced group difference during typical sleep periods (see Figure 1). In addition, the group difference in the daily/circadian rhythm was more pronounced in those with highly irregular sleep/wake cycles ($p = 0.0015$). Further work is needed to understand the implications of elevated daily/circadian HF-HRV rhythm in those with low mood and irregular sleep-wake cycles.

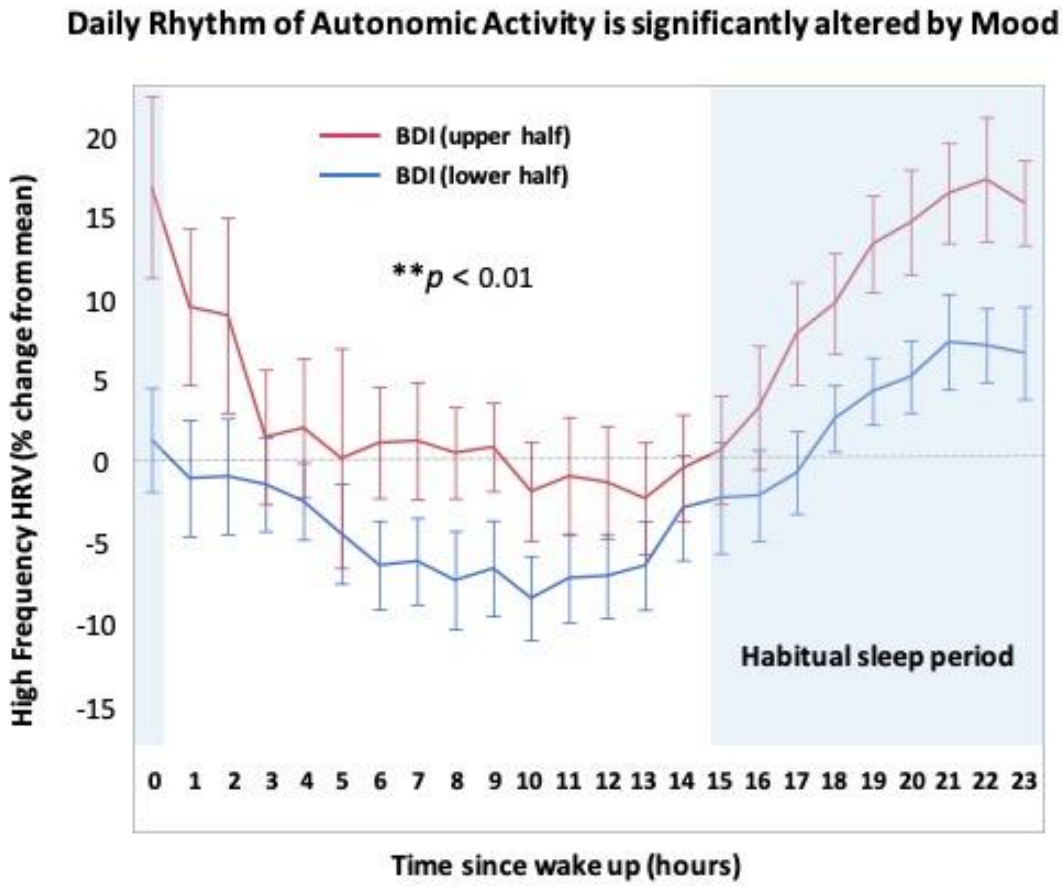

Figure 1. Daily rhythm of high frequency HRV (heart rate variability) is significantly different in those reporting higher weekly BDI (Beck Depression Inventory; upper half) scores versus lower BDI (lower half). Data (mean +/- 95% confidence interval) binned by hourly time since wake up, adjusted for each subject's habitual wake up time

Title: Bioelectronic medicine for cardiovascular state control during spontaneous episodes of high blood pressure and myocardial ischemia

Authors: P. D. GANZER[1], S. ROOF[3], B. TENG[3], D. FRIEDENBERG[4], L. LIN[4], S. COLACHIS[1], R. HAMLIN[3], W. MUIR[3], D. J. WEBER[5], *G. SHARMA[2];

Abstract: Bioelectronic medicine therapies are being developed as new treatments for a wide range of chronic diseases using peripheral nerve stimulation. Bioelectronic medicine can potentially be used to provide therapeutic benefit during many pathological states, including episodes of high blood pressure and myocardial ischemia. Prolonged periods of high blood pressure and myocardial ischemia can be life threatening in individuals with cardiovascular disease, potentially leading to myocardial injury, infarction, and other cardiovascular system damage. We first assessed the hypothesis that non-invasive stimulation of neural circuits can produce a robust and selective reduction in blood pressure without significant side effects. Experiments were performed in anesthetized rats and compared to an implanted cervical vagal nerve stimulation control. We recorded the electrocardiogram (ECG), arterial blood pressure (ABP), and the photoplethysmogram during systematic assessment of stimulation protocols. Our results support the hypothesis that selective control of ABP can be achieved via non-invasive stimulation (significant decreases up to ~35 mmHg), without significant side effects (e.g., no significant effect on heart rate, ECG waveform intervals, or breath rate). These results have potential implications for wearable bioelectronic medicine devices to treat pathological cardiovascular states, including periods of high blood pressure and myocardial ischemia. We next generated a model of spontaneous high blood pressure and myocardial ischemia using clinically relevant injectable cardiovascular agents in anesthetized rats. Agent injections induced prolonged periods of increased blood pressure and significant depression of the ECG S-T segment epoch, therefore modeling the attributes of clinical spontaneous myocardial ischemia.

We will present our results using non-invasive bioelectronic stimulation for reducing blood pressure and correlates of myocardial ischemia. In addition, we will present preliminary findings using machine learning to decode spontaneous episodes of myocardial ischemia at a sufficient prediction accuracy (> 80%, using non-linear support vector machines). These experiments assess the hypothesis that machine learning can be used to decode episodic cardiovascular pathology, and used to rapidly trigger reactive closed-loop neural stimulation for therapeutic benefit. Our eventual goal is to translate these findings to patients suffering from cardiovascular dysfunction, and develop wearable closed-loop bioelectronic medicines for treating an array of debilitating diseases.

Title: Effect of hydrogen sulfide on vascular dysfunction induced by fructose in rat thoracic aorta

Authors: *D. L. SILVA VELASCO[1], E. HONG[2], J. H. BELTRÁN-ORNELAS[1], A. SÁNCHEZ-LÓPEZ[1], C. B. GÓMEZ[1], S. HUERTA DE LA CRUZ[1], D. CENTURION[1]; [1]Pharmacobiology, [2]CINVESTAV, Mexico City, Mexico

Abstract: Hydrogen sulfide (H_2S) is a colorless, flammable and water-soluble gas characterized by a peculiar smell of rotten eggs. H_2S is a gasotransmitter synthetized from L-Cysteine by three enzymatic pathways namely cystathionine-ß-synthase (CBS), cystathionine- γ-lyase (CSE) and the tandem enzymes cysteine aminotransferase (CAT) and 3-mercaptopyruvate sulfurtransferase (3-MST). CSE predominates in the cardiovascular system, especially the myocardium and vascular smooth muscle cells (VSMCs). The aim of this study was to determine the effect of chronic administration of sodium hydrosulfide (NaHS; inorganic H_2S donor), L-Cysteine (L-Cys; H_2S producing enzymes substrate) and DL-Propargylglycine (DL-PAG; CSE inhibitor) on the vascular dysfunction induced by fructose in thoracic aorta obtained from male Wistar rats. For that purpose, animals were divided into two main sets that received for 20 weeks: (1) tap water (Control group; n=6); and (2) 15% p/v fructose in drinking water (Fructose group; n=30). Then, the fructose group were divided into 5 subgroups (n=6 each) which received daily i.p.

injections during 4 weeks of: (1) nothing; (2) vehicle (PBS, 1 ml/kg); (3) NaHS (5.6 mg/kg); (4) L-Cys (300 mg/kg); (5) DL-PAG (10 mg/kg). After 20 weeks, metabolic (oral glucose tolerance test, insulin, and Matsuda index) and hemodynamics variables by tail-cuff method as well as vascular function by *in vitro* experiments were determined. We observed that insulin resistance induced by fructose leads to: (1) an increase in blood pressure (without affecting heart rate); (2) hyperinsulinemia; (3) a decrease in Matsuda index; and (4) a decrease in vasorelaxation to carbachol without effect on the contractile responses to noradrenaline compared to control group. Interestingly, after 4 weeks of treatment, NaHS y L-Cys decreased blood pressure and restored vasorelaxation to carbachol without modifying metabolic variables when compared to vehicle. On the other hand, DL-PAG induced a slightly increase in systolic and median blood pressure with any effect on the contractile to noradrenaline or relaxant responses to carbachol as well as metabolic variables compared to vehicle. Taken together, these results suggest that chronic treatment with NaHS and L-Cys improved vascular dysfunction and reduced hypertension produced by fructose-induced insulin resistance and may have a potential therapeutic application.

Title: Heart rate variability in patients with trigeminal neuralgia

Authors: *G. INBARAJ[1], T. N. SATHYAPRABHA[2], K. UDUPA[3];
[1]Natl. Inst. of Mental Hlth. and Neuroscien, Bangalore, India; [2]Neurophysiol., NIMHANS, Bangalore, India; [3]Neurophysiol., NIMHANS, Bengaluru, India

Abstract: BACKGROUND:
Trigeminal neuralgia (TN) is a common neurological disorder characterized by intermittent events of acute, sharp pain confined to small areas of the face. Numerous studies suggest TN is associated with autonomic dysfunction. Assessing this dysfunction using Heart Rate Variability (HRV) technique is very limited. Hence the aim of the present study is to evaluate the heart rate variability(HRV) in patients with TN and to compare it with healthy controls.
METHODS:
This is a prospective comparative study. Twenty-two (12 males) TN patients and 22 (11 males) healthy controls were included in the study. Short term HRV of time and frequency domain

parameters were assessed by recording resting lead II ECG. Time domain parameters of interest were standard deviation of all RR intervals (SDNN), square root of the mean of the sum of the squares of differences between adjacent RR intervals (RMSSD), the number of pairs of adjacent RR intervals differing by more than 50ms in the entire recording (NN50), the percentage of NN50 counts (pNN50). Frequency domain parameters assessed were Total power (sum of all constituent frequencies), low-frequency power (LF) (0.04 to 0.15 Hz), high-frequency power (HF) (0.15 to 0.4 Hz) and LF/HF ratio. Independent Mann- Whitney U test was used to compare between the groups.

RESULTS:

The mean age (years) of the subjects with TN was 50.36 ± 7.3 and controls was 49.11 ± 5.5. The study results did not show any significant difference in the HRV parameters between groups. The LF power of the TN subjects shows a trend towards high sympathetic activity [Median (Q1-Q3)] of [173.24 (79.87, 248.2)] as compared to healthy controls [150.43 (98.37, 573.20)]. As this is an on-going study we are considering to increase the sample size, include self-perceived pain severity scales and to subgroup the TN patients based on the severity. Extensive statistical analysis will be performed later after including these parameters.

Conclusion:

The results suggest that TN may be linked with autonomic dysfunction by exhibiting a trend towards sympathetic dominance as compared to healthy controls. This altered ANS response observed in TN patients might be a consequence or cause for TN pain. Future studies are required to characterize autonomic dysfunction on pain severity and to describe its pathophysiology in patients with TN.

Title: Effects of match temperature on heart rate for female soccer players

Authors: F. VAZQUEZ[1], ***M. YOUNG**[1], T. WADE[1], A. JOHNSON[1], R. E. JOHNSON[2], K. SCHMITT[1];
[1]Mathematics and Statistics, [2]Mechanical Engin. and Bioengineering, Valparaiso Univ., Valparaiso, IN

Abstract: In athletics, coaches and trainers are increasingly using heart rate data to optimize training and workload. One factor that is not often considered is ambient temperature. We know

that in general, the body works harder in higher temperatures, so heart rate should tend to be higher on those days. However, we do not know if this relationship is consistent enough to use to make real-time decisions on workload for athletes during training and matches. In this study we investigated the relationship between ambient temperature and intensity of a workout, and the effect that temperature has on heart rate. Temperature data was sourced from the National Oceanic and Atmospheric Association (NOAA) and athlete heart rate data was collected by Firstbeat activity trackers. 27 collegiate female soccer players participated in this experiment. Using Python, we created several multiple linear regression models to predict heart rate. Attributes such as intensity of activity, duration, and temperature were included in the models. All results for our study use data starting in the fall of 2017. We conclude that models built on individual players' data is more informative than models on the team as a whole. We made regression equations to produce an average and peak heart rate for each player. These individual models may help us predict if a player is over exerting themselves. If a player's heart rate increased past the average predicted value, then coaches may consider pulling the player from a game or strenuous practice to prevent longer recovery times.

Title: The hypertensive effect of α-MSH in a rat model of metabolic syndrome

Authors: *R. C. SALGADO-DELGADO[1], A. BAEZ-RUIZ[1], R. M. BUIJS[2], N. SADERI[3]; [1]Facultad de Ciencias, UASLP, San Luis Potosí, Mexico; [2]Inst. De Investigacíones Biomedicas, Mexico DF, Mexico; [3]Facultad De Ciencias, UASLP, San Luis Potosí, Mexico

Abstract: Much of the understanding of how the hypothalamus controls body homeostasis regards the physiological properties of the alpha- melanocyte stimulating-hormone (α-MSH) in the Arcuate nucleus (ARC). Blood-borne and neural satiety signals activate α-MSH neurons in order to suppress food intake and stimulate energy expenditure, while the deficit of the melanocortin signaling results in obesity and other metabolic alterations. Previous studies about the hypertensive effects of the hormone leptin indicated that α-MSH might mediate the hyperactivation of the sympathetic nervous system (SNS) in on obese animals and human

subjects. For instance, leptin receptors-expressing cells in the ARC colocalize with the angiotensin II-receptor 1 (AT-1), leading to the hypothesis whether these AT-1-expressing cells are α-MSH neurons. To address this issue, we compared AT-1 and α-MSH immunoreactivity in male Wistar rats (n = 5) fed with a standard chow (controls: CTR) and fed with and high fat diet (HFD) containing about the 30% of fat for 12 weeks. Results showed that HFD promotes AT-1 expression, α-MSH cells activation and the co-localization of AT-1 with α-MSH. Then, to assess the contribution of α-MSH to obesity-related hypertension, we injected either the melanocortin antagonist SHU9119 or saline in the third ventricle of anesthetized CTR and HFD animals and found that it significantly decreases BP specifically in HFD rats. Finally, to identify the anatomical site of the α-MSH hypertensive effect, we evaluated c-Fos expression in the Paraventricular nucleus (PVN), which is one of the main hypothalamic area containing pre-autonomic neurons. We found that HFD increase the number of c-Fos - positive cells in the PVN, while SHU9119 administration decreases it. Finally, among the target of ARC projections to the PVN, we observed that the number of Tyrosine hydroxylase-containing neurons is significantly increased in HFD and these cells received dense α-MSH projections. All together, these results suggest that ARC - α-MSH underlie the abnormal autonomic response in obesity that leads to hypertension.

Title: Mapping of intrinsic cardiac neurons projecting to the sinoatrial node and the left ventricle of rats

Authors: *J. CHEN[1], S. TAPPAN[2], R. VADIGEPALLI[3], J. S. SCHWABER[3], Z. CHENG[1]; [1]Burnett Sch. of Biomed. Sci., Univ. of Central Florida, Orlando, FL; [2]R&D, MBF Biosci. - MicroBrightField Inc., Williston, VT; [3]Dept. of Pathology, Thomas Jefferson Univ., Philadelphia, PA

Abstract: Previously, we showed that multiple intrinsic cardiac ganglionated plexuses (ICGPs) are located on the dorsal surface of the left and right atria. However, it is not clear which populations of the intrinsic cardiac neurons (ICNs) project to the Sinoatrial Node (SAN) and ventricles. Our long-term goal is to determine the topographical organization of ICGPs

projecting to different cardiac targets. In this study, we specifically aimed to determine differential projection of the ICGP to the SAN and left ventricle (LV) of Sprague Dawley rats (male, 3-mo). The SAN and LV were focally injected with fluorescent tracer Fast DiI to retrogradely label ICNs which projected to these regions (2 %; 4-5 µl/SAN injection, 20 µl/ventricle injection; n=5/region). After DiI injection, the animals were returned to their cages for 14 days for tracer transportation. 4-5 days before sacrifice, Fluorogold (FG) was injected intraperitoneally to counterstain all ICNs, and at the end of the time point, animals were perfused and fixed through the heart. The left and right atria were cut open and prepared as whole mounts, and SAN cells were confirmed by immunostaining with HCN4, a pacemaker channel marker. The distribution of tracer-labeled ICNs in the whole mounts of the left and right atria were imaged, overlaid, and analyzed using the Neurolucida Tracing and Digitization System (n=5/region) . Consistent with our previous findings, we found that there are multiple ICGPs, and there is a large ICGP near SAN. DiI injection into the SAN region retrogradely labeled 72.8±17.53 (n=5) ICNs mainly in this large ganglion near the SAN. In contrast, DiI injection into the LV labeled 17.6±5.93 (n=5) ICNs in several spatially-separated ICGPs on the dorsal surface of the atria, with only a few DiI-labeled ICNs in this large ICGP near the SAN, if any. Thus, we propose that there are different populations of ICNs that separately project to the SAN and the LV. Our work contributes to the understanding of the topographical organization of ICN innervation of the heart. Furthermore, a 3-D representation of this topographical mapping in the heart will provide an anatomical substrate to integrate physiological, molecular, and pharmacological data in the future. Abstract: Background: Orthostatic hypotension (OH, i.e. a blood pressure (BP) drop after standing up) is a prevalent condition in older adults and is associated with poor health outcome such as falls. However, its underlying pathophysiological mechanisms are largely unknown. Current clinical assessment based on intermittent blood pressure measurements is insufficient due to lack of sensitivity and presence of compensatory physiological systems. Baroreflex sensitivity (BRS, i.e. increased heart rate as a response to BP drops), cerebral autoregulation (CAR, i.e. cerebral vasodilation as a response BP drops to keep cerebral blood flow constant) and peripheral vasoconstriction are likely to play a key role. There is a need for understanding of above-mentioned mechanisms and their reliability and validity in clinical practice. **Methods:** We used a combination of photoplethysmography (PPG, applied to wrist and finger), ECG, bifrontal near infrared spectroscopy (NIRS) and continuous blood pressure (Finapres) for measurements during postural changes varying in center of mass displacement, speed and leg muscle use in 34 healthy young (median age 25 years, inter quartile range 22-45; 10 female) and 31 healthy older adults (median age 77 years, inter quartile range 74-83; 18 female). Reliability and validity were defined as the correlation between repeats and the correlation with BP, respectively. Peripheral vasoconstriction was assessed using pulse wave velocity (PWV, measured from heart to wrist and finger). **Results:** BRS and CAR had fair to excellent validity in healthy young adults. Pearson correlation of finger PPG with BP during rapid standing up was 0.95 in healthy young adults and 0.55 in healthy older adults. After standing up, PWV showed a significant rise in healthy young adults, but not in healthy older adults. **Conclusion:** Non-invasive measurement of BRS and CAR using PPG-ECG-NIRS signals is reliable in healthy young adults. PPG might be used to estimate BP, but it has a lower correlation with BP in healthy older adults compared to young adults. The upper ertremity arteries demonstrate significant vasoconstriction in healthy young adults after standing up, but not in healthy older adults. The results highlight the potential clinical value of PPG-ECG-NIRS signals to assess BRS, CAR and vasoconstriction in patients with OH.

Title: Pre-competitive physiological state affects performance in snowboard jump competitions

Authors: *S. MATSUMURA, K. WATANABE, N. SAIJO, T. KIMURA, M. KASHINO; NTT Communication Sci. Labs., Kanagawa, Japan

Abstract: An athlete's pre-competitive mental state has a major influence on competitive performance. Several studies have reported that mental state affects the performance of simple motor tasks in experimental environments where mental state control is limited. However, little is known about the relationship between pre-competitive mental state and complex movements requiring high skills in practical situations. We examined the relationship between the pre-competitive physiological state as index of mental state and competitive performance in an actual snowboard jump competition. Forty-four expert snowboarders participated in this competition. There were three sessions, practice, qualifying and final. As in regular professional competitions, three professional snowboarders scored the jump performance in terms of completion. The top twenty jumpers in the qualifying session advanced to the final session and the champion won a prize. During the competition, as physiological indices, electrocardiograms (ECGs) and the electrodermal activity (EDA) of all the participants were measured for 140 seconds during the 10 minutes before the start of each jump. The mean heart rate (HR) and the natural logarithm of the high frequency power (lnHF) of the heart rate variability were calculated from the ECGs as an index of sympatho-vagal balance and parasympathetic nerve activity, respectively. The skin conductance level (SCL) was also acquired from the EDA as an index of sympathetic nerve activity. The twenty finalists were divided into the top and bottom ten, to analyze the dependence of the difference in physiological state on skill level. To compare the physiological indices in the qualifying and final sessions with those in the practice session, they were standardized with those in the practice session. The top group showed a significant increase in mean HR (1.12 ± 0.03, $p = 0.009$) and SCL (1.31 ± 0.11, $p = 0.037$) and a significant decrease in lnHF (0.93 ± 0.02, $p = 0.009$), while the bottom group did not. These results indicate that the sympathetic nerve activity of a skilled snowboarder increases prior to the jump. Since the bottom group did not exhibit such activity changes, highly skilled athletes may appropriately control their mental states to realize high-level performance. Interestingly, additional analysis of the top-group data showed a correlation between the judges' scores and the physiological indices. Since these judgments were related to a complex whole-body movement, this result may indicate that the pre-competitive mental state affects the motor coordination of whole-body movement.

Title: Subjective effects of a gambling challenge in recreational gamblers versus gambling naive individuals

Authors: *L. C. MILLER, A. SÖDERPALM GORDH, B. SÖDERPALM;
Neurosci. and Physiol., Gothenburg Univ., Gothenburg, Sweden

Abstract: Pathological gambling shares many similarities with drug addiction in terms of clinical phenomena (e.g. craving, tolerance, compulsive use and loss of impulse control) plus heritability. Pathological gamblers also show a similar arousal and reward sensitivity during gambling probably mediated by the mesolimbic dopamine system well known to the field of drug addiction. We hypothesize that recreational gamblers show extra sensitivity to the rewarding effects of gambling in comparison to gambling naive individuals.
Eighty-two healthy participants (36 no gamblers, 46 gamblers) were recruited. Self-reported questionnaires as The Profile of Mood States questionnaire (POMS), The Biphasic Alcohol Effects Scale (BAES), The Addiction Research Centre Inventory (ARCI), The Drug Effect Questionnaire (DEQ) and objective measures (cortisol and blood pressure) were used to assess mood states and subjective drug effects described sensitive to the effects of a variety of psychoactive drugs at baseline and post test.
Once participants had completed baseline measures, they gambled for 10 min on a laboratory casino slot machine that was set up on a laptop which gave them 'wins', 'jackpots' and 'loosing streaks. The participants were unaware of the length of time for which they gambled for. No money was paid out to the participants which was disclosed before the trial commenced. Once the gambling had finished each participant answered the post test questions and cortisol and blood pressure was taken a second time.
Our first aim was to study changes in the subjective, neuroendocrine, and physiological responses to an acute gambling situation in recreational gamblers and in those who never gambled before. This study would improve and allow a better understanding of the complexity of an individual's gambling behaviour. We compared recreational gamblers to those who never gambled before.

Title: The across-player correlation of the physiological change reflecting the fight-or-flight response in esports

Authors: *K. WATANABE, N. SAIJO, M. KASHINO;
NTT Communication Sci. Labs., Kanagawa, Japan

Abstract: It is well known that a fight-or-flight response is generated when one has to fight enemies or quickly escape a threat. In fighting sports, for example, it may occur when one player tries to beat or to defend against another. However, the relationship between the responses of two opponents remains unclear. In this study, we observed the changes in the physiological states of two opponents who played an esports fighting game. Nine professional esports players participated in this study. In the fighting game, one player controls a game character and fights an opponent in a virtual world. We measured the electrocardiograms (ECGs) of the participants when they were playing the game. First, the participants were measured when in a resting state. Then, they played against a computer for 5 minutes. After that, the participant competed with other participants until one player had achieved five wins. A group of three men of differing abilities engaged in a round-robin tournament, and a group of six men with comparable abilities also engaged in a round-robin tournament. Heart rate time series were calculated from the ECGs as indices of autonomic nerve activity, and the cross-correlation function (CCF) was calculated from two sets of time-series data obtained from a fighting pair. The results showed that the heart rate increased greatly when the participant played against an actual person, compared with that when the participant was playing the game alone. This indicates that a fight against other participants increases the heart rate.The results for a pair with different abilities showed that the CCF and the change in heart rate of a strong player was smaller than for other pairs, indicating that only the weaker player exhibited the fight-or-flight response. On the other hand, the results for a pair with comparable abilities exhibited a high CCF, indicating that they both exhibited the fight-or-flight response with a similar temporal pattern. These results suggest that the appearance of the fight-or-flight response is related to one's opponent's ability.

Title: The parvalbumin-positive PV2-nucleus of the midbrain PAG

Authors: S. LEHMANN[1], A. BABALIAN[1], F. GIRARD[1,2], F. DAVIS[2], *M. R. CELIO[1];
[1]Sci. and Med., Univ. of Fribourg, Fribourg, Switzerland; [2]Howard Hughes Med. Inst., Janelia Farm, Ashburn, VA

Abstract: The periaqueductal gray (PAG), is known to play a key role in the integration and modulation of autonomic responses. It harbors two of the main terminal fields of the hypothalamic parvafox-nucleus, namely the Su3- and PV2-nuclei. This latter nucleus was yet unknown, leading us to perform diverse studies to characterize its extent, connections, gene expression and function. The PV2-nucleus is an elongated cluster composed of ~500 parvalbumin-expressing neurons, located in the ventromedial region of the distal PAG. Using anterograde-tracing methods, the main projections of the PV2-nucleus were found to innervate the Su3-nucleus of the PAG, the parvafox-nucleus of the lateral hypothalamus, the gemini nuclei of the posterior hypothalamus, the septal region and the diagonal band of the forebrain, as well as various nuclei within the reticular formation in the midbrain and brainstem. The parvafox-nucleus and the lateral orbital cortex also target several of the mentioned regions. Within the brainstem, projections of the PV2-nucleus were discrete, but involved areas implicated in autonomic control. The PV2-nucleus expressed various peptides and receptors, including the receptor for Adcyap, a peptide secreted by one of its main afferences, the parvafox-nucleus. Expression of VGat-1 in a subpopulation of PV2-neurons indicate a partly inhibitory nature of this nucleus. Experiments to determine the possible function of the PV2-nucleus in a circuitry involving the orbitofrontal cortex, the parvafox and the Su3-nucleus are being conducted. These preliminary results suggest an involvement of the PV2-nucleus in the control of the respiratory and the cardiovascular system.

Title: Two roads diverged: Cardiac vagal motor neurons and their role in high fat diet-induced cardiovascular disease pathophysiology

Authors: *L. ESPINOZA, C. R. BOYCHUK;
Univ. of Texas Hlth. San Antonio, San Antonio, TX

Abstract: Cardiovascular disease (CVD) is the leading cause of death world-wide, accounting for 31% of global deaths each year. Obesity can arise from an unhealthy fatty diet, and is an independent risk factor for the development of various forms of CVD including hypertension. One potential conduit to hypertension is tachycardia, and the vagus nerve—one of the primary components of the parasympathetic branch of the autonomic nervous system—regulates heart rate, thereby highlighting vagal motor drive as a promising candidate for novel CVD therapeutics. Cardiac-related vagal innervation originates from two primary neuronal populations: the nucleus ambiguous (NA) and dorsal motor nucleus of the vagus (DMV). Studies have illustrated the therapeutic potential of DMV optogenetic activation in models of CVD. However, little is known about the electrophysiological properties of cardiac-projecting DMV neurons, or how these are altered by high fat diet (HFD) exposure. Our limited understanding comes from recent studies in unlabeled DMV neurons, which have shown that HFD leads to decreased neuronal excitability. However, the mechanism of this inhibited activity remains elusive. Therefore, we hypothesized that HFD-mediated increases in inhibitory current to cardiac-related vagal neurons leads to a decrease in cardiac vagal drive, and ultimately, CVD. In this study, we characterized the differences in the electrophysiological signaling properties and contribution to heart rate modulation between retrogradely labeled NA and DMV neurons, both under control and HFD conditions. Our approach employed retrograde tracing to identify cardiac-related vagal neuron populations; *in vitro* whole-cell patch-clamp electrophysiology to assess their signaling properties; and *in vivo* heart rate telemetry to monitor HFD-induced alterations in heart rate modulation. Tracing studies confirmed that the NA contains significantly more retrogradely labeled neurons from the SA node than the DMV. Whole-cell patch clamp data demonstrate that labeled neurons in the DMV have distinct electrophysiological properties compared to those in the NA. Heart rate telemetry found that mice challenged with HFD for a two-week period had increased heart rate and decreased indices of parasympathetic activity as early as two days following HFD exposure. These changes occurred in the absence of significant changes in fed-state blood glucose levels, food intake, or body weight. Our findings suggest that increasing parasympathetic drive prior and during HFD exposure may be a promising therapeutic target for obesity-induced CVD.

Title: Vagus nerve stimulation activates supramedullary pathways to potentiate activity of nucleus of solitary tract (NTS) neurons

Authors: C. M. COOPER[1], M. C. ANDRESEN[2], R. P. CAMPBELL[3], *E. BEAUMONT[1]; [1]Biomed. Sci., East Tennessee State Univ., Johnson City, TN; [2]Physiol. and Pharmacol., Oregon Hlth. & Sci. Univ., Portland, OR; [3]Emory & Henry Col., Emory, VA

Abstract: **Background:** Vagus nerve stimulation (VNS) is currently used to treat patients with drug resistant epilepsy, depression and, more recently, heart failure. The mild intensities used in chronic VNS suggest activation of a subset of myelinated primary visceral afferents connected directly to NTS neurons. Here we monitored the activity of 2nd and higher order NTS neurons in response to peripheral vagal activation using therapeutic VNS criteria.
Methods: NTS neuronal spike activity was recorded in chloralose anesthetized rats. Controls (n=12) were compared to rats after a mid-collicular knife cut (n=8). The cut severed connections between the brainstem including NTS and supramedullary regions. A bipolar coil electrode was implanted around the left cervical vagus nerve. Single tungsten electrodes were stereotaxically placed in the left caudal medial NTS. Threshold intensity, single or paired shocks established vagal afferent activation of single NTS neurons to determine conduction velocity as well as synaptic order (2nd vs higher). Once vagal connectivity was established, VNS condition stimuli followed clinically styled guidelines using a current intensity that induced a 5% bradycardia.
Results: Our chief findings indicate that a mid-collicular knife cut significantly reduced basal spontaneous activity of 2nd order NTS neurons receiving myelinated vagal input (from 13 ± 1.5 Hz to 2.1 ± 0.31 Hz, $p<0.01$). In these particular NTS neurons, the activity increases associated with acute VNS were similar between control and knife cut animals. Finally, the knife cut eliminated activity increases associated with acute VNS in higher order NTS neurons and also in 2nd order neurons receiving unmyelinated vagal input ($p<0.05$).
Conclusions: Interestingly, higher order NTS neurons and 2nd order NTS neurons receiving unmyelinated vagal input are activated in response to myelinated vagal afferent activation during VNS and this activation is interrupted by the knife cut. Concurrently, the knife cut decreased spontaneous activity in NTS receiving myelinated input, but preserved increased activation with VNS, most likely because VNS directly activated their myelinated axons. Supramedullary descending projections to NTS, in which a proportion of them are coming from the paraventricular nucleus of the hypothalamus (PVN), are needed to amplify the peripheral neuronal signal from VNS. The present study begins to define the pathways activated during VNS and will help to better identify the central nervous system contributions to the therapeutic benefits of VNS therapy.

Title: Intra and extraneural activity in the vagus nerve recorded by platinized graphene fiber electrodes

Authors: *M. A. GONZÁLEZ-GONZÁLEZ[1], R. A. JALLILI[2], G. WALLACE[3], M. I. ROMERO-ORTEGA[1];
[1]Bioengineering, The Univ. of Texas at Dallas, Dallas, TX; [2]RMIT Univ., Melbourne, Australia; [3]Univ. of Wollongong, Wollongong, Australia

Abstract: Neurmodulation of the vagus nerve (VN) is clinically used for the treatment of intractable epilepsy and depression, and currently investigated for the use in morbid obesity, tinnitus and stroke. The VN is the largest autonomic nerve, it connects the periphery organs with different integrative areas in the brain to maintain homeostasis. It has a heterogeneous anatomical composition (~80% afferents and ~20% efferent fibers), resulting in complex functional electrophysiology that responds in a unique way to different physiological stimulus. The requirement of low impedance electrodes with high signal-to-noise ratio (SNR) to allow for sensitive recordings are imperative to understand the VN activity in response to specific physiological stimulus. Conventional electrodes are fabricated with platinum or platinum iridium and have limited sensitivity and low charge injection capacity (Qinj, ~0.05-0.26 mC/cm2), whereas intraneural electrodes fabricated with carbon nanotubes have shown promise (CSC ~372 mC/cm2, 12.5 kΩ). Here we report the use of platinized graphene fiber electrodes for the recording of intra and extra-neural activity in VN. We recently reported the fabrication of high performance platinized graphene fibers (40 µm diameter) obtained form liquid crystalline dispersions of graphene oxide, with excellent electrochemical characteristics (CSC and Qinj ~947 and ~46 mC/cm2 respectively). In this study nine adult male Sprague Dawley rats, were used to record the vagus nerve activity during: i) systemic reduction in Oxygen tension, ii) decreased mean arterial pressure induced by intravenous nitroprusside treatment, and iii) evoked activity in response to proximal vagus nerve stimulation using a platinum hook electrode. In each condition, specific activity waveforms and activity patterns were correlated to the treatments over baseline conditions with high signal to noise ratios (SNR~4.3). The data support the use of these electrodes as autonomic neural interfaces to decode the VN electrical activity. This technology find application in the design of new therapies directed to specific health dysfunctions and for the design of peripheral prosthesis.

Title: Directional biasing of vagal fiber activation using anodal block waveforms

Authors: ***U. AHMED**, Y.-C. CHANG, M. CRACCHIOLO, J. N. TOMAIO, M. F. LOPEZ, L. RIETH, T. ZANOS, S. ZANOS;
Inst. of Bioelectronic Med., Feinstein Inst. For Med. Res., Manhasset, NY

Abstract: One of the challenges in the clinical application of vagus nerve stimulation (VNS) is selection of fiber activation in order to maximize the desired and minimize undesired physiological effects of VNS. In cases where only afferent effects of VNS are sought, efferent effects need to be suppressed, and vice-versa. Anodal block, the suppression of conduction of stimulus-evoked volleys along a hyperpolarized patch of membrane (anode) has been tested in peripheral nerves to achieve directional activation, with varying success. In this study, we tested whether anodal block, with appropriate electrode and stimulus characteristics, can be attained in the context of cervical VNS. In male Sprague-Dawley rats anesthetized with isoflurane, two custom-made, flexible bipolar electrodes (1mm distance between the 2 poles) were placed on left or right vagus, 5mm apart: one electrode was used for stimulation, the other for recording of evoked compound nerve potentials (CNAPs). Stimulation consisted of short trains of rectangular pulses with different polarities, amplitudes and pulse widths. Stimulus-elicited changes in breathing rate and heart rate were used as physiological indices of afferent and efferent fiber activation, respectively. CNAPs and physiological responses to stimuli of different polarities suggested activation of both afferent and efferent fibers, in different proportions. For stimulation pulse waveforms of intermediate intensities and longer pulse widths, cathode caudad polarity was associated with predominantly efferent fiber activation, whereas cathode-cephalad polarity with predominantly afferent fiber activation. The fact that differences in the physiological and CNAP responses to different rectangular waveform polarities can be seen with even short stimulus trains suggests that stimulation polarity can be used to bias current and future VNS-based therapies towards afferent or efferent effects.

Title: Breathing across emotionally-salient states in mice

Authors: *E. C. JANKE[1], A. H. MOBERLY[2], M. MA[1];
[1]Dept. of Neurosci., Univ. of Pennsylvania, Philadelphia, PA; [2]Yale, New Haven, CT

Abstract: Emotional states are associated with distinct autonomic respiration patterns in humans; this observation generated a theory that breathing likely serves as a strong physiological predictor of emotional state. For instance, in panic disorder, breathing abnormalities not only manifest as a result of a panic attack, but cardiorespiratory variability is thought to precede and even trigger the attacks themselves. Thus, understanding the neural mechanisms that drive emotionally-relevant breathing may give insight into dysregulated circuits that exist in some mental disorders. In rodent models, investigation focuses on central pattern generators in the brainstem that control the basic motor output necessary for breathing. However, which neural regions provide top down regulation to these respiratory centers during emotional states remains unknown. While a few studies demonstrate that rodents slow their breathing during freezing, a stereotypical motor response to fear, the relationship between breathing and emotion during frequently used assays is little explored. To address the relationship between breathing and emotional states in mice, we implanted an intranasal cannula into the nasal cavity and used a pressure sensor to monitor breathing in awake, behaving animals. The mice were exposed, in a randomized order, to a range of emotionally-salient stimuli including: an attractive odor, a predator odor, tail suspension test, restraint stress, and fear conditioning. We then used a MATLAB toolbox, BreathMetrics, to rigorously analyze respiration during specific behavioral bouts from these assays such as freezing, sniffing, struggling, or immobility. This analysis revealed that breathing changes reflect specific states such as freezing post fear conditioning or predator odor as well as struggling and immobility in the tail suspension test. These data suggest that respiration patterns may effectively distinguish emotionally-salient states in rodents.

Title: Piezoelectric sensors for noninvasive breath rate tracking in a cage setting

Authors: R. L. BERNAT[1,2], A.-H. LIN[3], A. AGARWAL[1], K. D. DONOHUE[4,1], ***B. F. O'HARA**[2,1];
[1]Signal Solutions LLC, Lexington, KY; [2]Biol., [3]Physiol., [4]Engin., Univ. of Kentucky, Lexington, KY

Abstract: The ability to track respiratory output in rodents provides physiological information relevant to disease states. Noninvasive methods enable longitudinal breath tracking related to disease progression, response to drug treatment, and more rigorous testing of adverse respiratory effects of drugs, such as opioids. Whole body plethysmography is the gold standard for noninvasive monitoring of breathing, and provides accurate measures of rate and tidal volume. However, this method confines the animal to a small space during data collection, requires a period of acclimation, and limits data collection to a few hours. A method to collect breathing data from a home-cage setting would greatly simplify research procedures, and reduce stress to research animals. Piezoelectric sensors are pressure sensors that produce voltage in direct proportion to the pressure applied, and are used in the PiezoSleep system (Signal Solutions LLC) to noninvasively monitor sleep and wake. While the signal resulting from respiration during low activity is used as a feature in the sleep/wake decision statistic for sleep scoring, breathing itself has not been formally investigated. Breath signals are recorded from piezo sensors on the cage floor when animals are sleeping or during periods of low activity. For most research purposes, breath parameters during sleep are highly relevant, when involuntary central respiratory drive is required to maintain breathing. Therefore, a method to continuously monitor breathing during sleep would provide a simpler option. We investigated the accuracy of piezo sensing to track respiratory information in mice of different ages, strains, sex and weight by simultaneously collecting respiratory output by plethysmography and piezo sensors. A plethysmography chamber was fitted with a piezo sensor, and plethysmograph and piezo respiratory output was recorded, along with video. Breath rates are estimated from both the plethysmography and piezo signals over short time intervals using an autocorrelation-based method. All valid estimates are then combined over larger intervals to compute a more robust mean or median breath rate. Graphical representations of raw signals were also overlaid for visual observation, to examine areas of disagreement, and to compare video. During sleep and quiet rest, the two signals

matched well. Areas of disagreement showed brief arousals, twitching, yawning, and repositioning. Initial analysis show a 10% (or .25 Hz) root mean square disagreement between the modalities (90% agreement). Analysis is ongoing for data collected in different strains, sex, ages and weights of mice, along with independent studies in rats.

Title: Hypoventilation in infant rats following orexin receptor blockade

Authors: *R. SPINIELI[1], *K. J. CUMMINGS[2];
[1]Biomed. Sci., Univ. of Missouri, Columbia, MO; [2]Biomed. Sci., Univ. of Missouri, COLUMBIA, MO

Abstract: Orexinergic neurons in the lateral and perifornical hypothalamus project widely to respiratory and regions of the brainstem. Orexin neurons are most active in wakefulness and are mostly silent in sleep. In adult animals, chronic orexin deficiency reduces the respiratory response to CO_2 but has no apparent effect on resting ventilation. The acute effects of orexin on breathing have not been described, either in adult or infant animals. A better understanding of orexin's effects on breathing is important because there is evidence of sleep apnea in narcoleptic patients that have reduced orexin signaling. There is also pathological evidence of orexinergic dysfunction in the Sudden Infant Death Syndrome (SIDS), which occurs in sleep and is associated with reduced ventilation. We hypothesized that orexin receptor blockade would lead to acute hypoventilation in a vigilance state-dependent manner. To test this hypothesis we used whole-body plethysmography to monitor breathing of infant and adult rats treated with

suvorexant, a selective orexin 1 and 2 receptor antagonist. In pups, we determined vigilance state using standard behavioral criteria, confirmed by video. In adults, vigilance state was determined with EEG and EMG. Pups were studied during the light period, and adults were tested at the transition from the dark to light period, when orexin levels peak. Rats cycled through wakefulness (W), quiet sleep (QS, or NREM in adults) and active sleep (AS, or REM in adults) for 1 hr at which point suvorexant (5mg/kg for pups; 20 mg/kg for adults, in 50% DMSO; n=8 pups, n=3 adults) or vehicle alone (n=8 pups) was injected via an intra-abdominal cannula. Rats were monitored for another 1 hr. We analyzed the effects of suvorexant on respiratory frequency (f), tidal volume (V_T), and the ventilatory equivalent (V_E/VO_2) in W, QS/NREM and AS/REM. Significant effects of drug treatment were determined with 2 factor repeated measures ANOVA, and Sidak post-hoc analysis (pups), or paired t-tests (adults). Suvorexant significantly reduced the f of pups, by 18% in W and QS (data were combined; p=0.0003), and by 9% in AS (p=0.02), with no effect on V_T in any state. Due to its effect on f, suvorexant decreased V_E/VO_2 by ~23% in W and QS (p=0.03), with no effect in AS. Vehicle alone had no significant effects on any respiratory variables (treatment x time: $p<0.01$ for both variables). In adults, suvorexant tended to reduce f in W (by 9%; p=0.24). These data suggest that in infant rats, acute orexin blockade reduces respiratory frequency leading to hypoventilation, especially in W and QS.

Title: Trpv1 dependent modulation of synaptic inputs and activity of presympathetic neurons in the rostral ventrolateral medulla

Authors: H. GAO[1], A. ZSOMBOK[2], *A. DERBENEV[3];
[1]Physiol., Dept. of Physiol., New Orleans, LA; [2]Dept Physiol, [3]Tulane Univ., New Orleans, LA

Abstract: Presympathetic neurons in the rostral ventrolateral medulla (RVLM) are best known for determining the level of sympathetic vasomotor tone, and thus blood pressure. Chronic activation of RVLM neurons increases sympathetic output and vasomotor tone. The activity of neurons depends on their intrinsic properties and the balance of inhibitory and excitatory synaptic inputs. Transient receptor potential vanilloid type 1 (TRPV1) channels, non-selective cation channels widely expressed in the central and peripheral nervous system have potent

effects on autonomic motor neurons. TRPV1 was shown to be expressed in the RVLM; therefore, we hypothesized that activation of TRPV1 receptors enhances the excitability of presympathetic RVLM neurons. Whole-cell patch-clamp recordings in brainstem slices were used to determine TRPV1-dependent regulation of presympathetic RVLM neurons identified with the trans-synaptic retrograde viral vector PRV-152. Application of a TRPV1 receptor agonist, capsaicin (1 μM) significantly increased the frequency of miniature inhibitory postsynaptic currents (mIPSCs) from 1.3±0.3 Hz to 3.0±0.6 Hz ($p<0.05$) without changes in amplitude in 6 out of 19 presympathetic RVLM neurons. On the other hand, capsaicin increased the frequency of miniature excitatory postsynaptic currents (mEPSCs) from 2.3±0.9 Hz to 14.8±4.8 Hz ($p<0.05$) without changes in amplitude of mEPSCs in 5 out of 11 presympathetic RVLM neurons. In the presence of tetrodotoxin (TTX), capsaicin application resulted in depolarization (5 out of 16) or hyperpolarization (5 out of 16) of RVLM neurons. In the presence of synaptic blockers (strychnine, gabazine, kynurenic acid, and TTX) the TRPV1-dependent modulation of presympathetic RVLM neurons was lacking. In summary, our data demonstrate that a population of presympathetic neurons receives excitatory or inhibitory TRPV1-expressing inputs and activation of these inputs alter the excitability of presympathetic neurons in the RVLM. These findings suggest that modulation of RVLM neurons by TRPV1 represents a potential means of modulating sympathetic vasomotor tone and control of blood pressure.

Title: Paraventricular nucleus of the hypothalamus mediates the cardioinhibitory responses to activation of the paraventricular nucleus of the thalamus

Authors: *M. PUIGBONET[1], Z. LI[2], J. CIRIELLO[3];
[1]Health, Wellness and Sci., Georgian Col., Barrie, ON, Canada; [2]Dept. Physiol. and Pharmacol., Univ. of Western Ontario, London, ON, Canada; [3]Dept. Physiol. and Pharmacol., Univ. Western Ontario, London, ON, Canada

Abstract: The paraventricular nucleus of the thalamus **(**PVT) is known to function as a site of integration of afferent information from brainstem, limbic and cortical structures involved in visceral and homeostatic regulation, and affective behaviors. We have shown that the sympathoinhibitory effects on arterial pressure (AP), but not heart rate (HR), elicited by PVT are

mediated in part by a pathway involving the central nucleus of the amygdala (ACe). This study investigated whether the HR responses to PVT activation involved a relay within the hypothalamus. In the first series of experiments, cardiovascular responsive sites were identified in the anterior PVT using L-glutamate (Glu; 10 nL, 0.25 M) microinjections in chloralose-anesthetized Wistar rats. Glu elicited decreases in mean AP (MAP, -20 ± 3 mmHg) and HR (-15 ± 5 bpm). In the second series, iontophoretic injections of the anterograde tract tracer PHA-L (2.5%) were made at the cardioinhibitory sites in the anterior PVT in the Wistar rats. Within the hypothalamus, PHA-L labelled fibers and presumptive terminals were found bilaterally in and around the anterior, dorsolateral and the medial parvocellular components of the paraventricular nucleus of the hypothalamus (PVH). A few scattered PHA-L labelled fibers were also observed within the posterior magnocellular component of PVH and the supraoptic nucleus. PHA-L labelling was also found within the lateral and dorsomedial hypothalamic areas, and the area of the tuber cinereum. As PVH is known to play a pivotal role in autonomic regulation, in the final series, bilateral microinjection (100 nL) of either the synaptic blocker $CoCl_2$, the non-specific Glu antagonist kynurenic acid or the selective NMDA receptor antagonists 2-amino-5-phosphonovalerate were made into PVH in chloralose-anesthetized Wistar rats. Although injections of these compounds did not significantly alter the resting level of AP or HR, all compounds attenuated the MAP responses (grouped data; -15 ± 5 mmHg; $p<0.01$) and blocked the HR responses (grouped data, -3 ± 5 bpm; $p<0.01$) to PVT activation (MAP, -25 ± 3 mmHg; HR, -19 ± 7). These data, taken together with our previous findings, suggest that PVT functions to alter cardiac sympathoinhibitory responses associated with arousal, stress, and affective behaviors through a glutamatergic pathway relaying in PVH, while the PVT associated MAP depressor responses are mediated predominantly through a sympathoinhibitory neuronal circuit involving the ACe.

Title: Chronic recording of rat vagal tone with carbon nanotube yarn electrodes

Authors: *J. MARMERSTEIN[1], D. M. DURAND[2];
[1]Biomed. Engin., Case Western Reserve Univ., Cleveland, OH; [2]Dept Biomed. Eng, Case Western Res. Univ., Cleveland, OH

Abstract: The autonomic nervous system governs subconscious control and sensing of visceral organ activity. It has recently become a focus for novel therapeutic technologies, termed “bioelectronic medicine”. The vagus nerve is the largest autonomic nerve, innervating nearly every organ in the body; “vagal tone” is a clinical measure presumed to indicate overall levels of vagal activity. Low vagal tone has been associated with many severe conditions such as diabetes, heart failure and hypertension, yet has so far only been measured indirectly through the heart rate variability (HRV). We have now developed a methodology to directly measure vagal activity in chronic animals, allowing for the first time, true measures of vagal tone. Using microwire electrodes made of carbon nanotube (CNT) yarns implanted inside the vagus nerves of rats, we have recorded vagal tone directly for the first time with simultaneous ECG for measurement of HRV. While the name vagal tone implies a tonic level of baseline activity in the vagus nerve, our results show that baseline neural activity does not correlate with changes in common HRV metrics used for vagal tone, including root mean square of successive differences (RMSSD) and high frequency component of RR-interval (respiratory frequency, 0.5-2.0Hz). It has been hypothesized that HRV may be driven by phasic vagal activity related to respiration. Using changes in RR-interval, we measured average vagal activity during heart rate decreases (presumed expiration) and heart rate increases (presumed inspiration). As expected, vagal activity is *increased* during expiration and decreased during inspiration. The magnitude difference between vagal activity during expiration and inspiration, termed respiratory vagal difference (RVD) was found to have a significant negative correlation with both RMSSD and HF component.
For the first time, we have been able to record vagal tone from the vagus nerve directly, allowing for better understanding of how HRV relates to changes in vagus activity. Unexpectedly, changes in RVD correlated negatively with HRV, suggesting that this metric may not be a direct measure of efferent vagal control of HRV, although this still supports a relationship between HRV and changes in activity in the vagus nerve.

Title: Activation of metabotropic glutamate receptor subtype 5 and protein kinase c pathways in the rostral ventrolateral medulla as a central mechanism for methamphetamine-induced pressor effect in rats

Authors: *H.-H. LIN[1,2], C.-C. LAI[3], C. FANG[2], C.-Y. KUO[2], Y.-W. WU[2];
[1]Dept. of Physiol., [2]Master Program in Med. Physiol., [3]Dept. of Pharmacol., Tzu Chi Univ., Hualien, Taiwan

Abstract: The acute hypertensive effect produced by methamphetamine (MA) has been well known mainly by catecholamines release from peripheral sympathetic terminals. However, the central mechanism of the BBB-penetrating molecule in the pressor effect remains unclear. Since the rostral ventrolateral medulla (RVLM) is the major regulating center of sympathetic and cardiovascular activity in the central nervous system, we hypothesized the RVLM might serve as a central target of MA-induced pressor effect. We monitored the pressor effect on conscious free-moving rats and anesthetized rats by i.p. (2 and 10 mg/kg) or i.c.v. (50, 150 and 500 nmol) injection of MA, respectively. Meanwhile, we evaluated the expression of FOS protein and the phosphorylation state of NMDA receptor subunit GluN1, an index of NMDA receptor activation, in the RVLM. Our data showed that both i.p. and i.c.v. MA induced dose-dependent pressor effects. Besides, MA increased FOS expression, PKC activity, and phosphorylated GluN1-ser 896 (pGluN1-ser 896) in the RVLM. Unilateral microinjection of a potent PKC inhibitor and a specific mGluR5 antagonist into the RVLM dose-dependently attenuated the i.c.v. MA-induced increase in the mean arterial pressure (MAP) and pGluN1-ser 896 in the RVLM. However, we found direct microinjection of MA (2 or 20 nmol) into the RVLM did not change the MAP. By using microdialysis and HPLC, we collected and analyzed dialysate from the RVLM after i.c.v. injection of MA 150 nmol. We found that the concentration of glutamate in the RVLM was significantly increased at first 10 min period after i.c.v. injection of MA. The paraventricular nucleus of the hypothalamus (PVN) has been recognized one of the major origins of glutamatergic innervation to the RVLM, which lead us to reason that the PVN is a logical neural substrate for MA action. Microinjection of MA (2 and 20 nmol) into the unilateral PVN increased the MAP in a dose-dependent manner in anesthetized rats. Administration of MA into the PVN also increased PKC activity, pGluN1-ser 896, and glutamate concentration in the RVLM. We conclude that MA may act on PVN leading to glutamate release in the RVLM further to activation of mGluR5-PKC pathways which will serve as a central mechanism for MA-induced pressor effect in rats.

Title: Chronic administration of sodium hydrosulfide and l cysteine restores the cardiovascular changes induced by high fat diet in rats

Authors: *C. B. GOMEZ, S. HUERTA DE LA CRUZ, G. J. MEDINA-TEROL, J. H. BELTRÁN-ORNELAS, A. SÁNCHEZ-LÓPEZ, D. L. SILVA-VELASCO, D. CENTURIÓN; Pharmacobiology, Cinvestav, Mexico City, Mexico

Abstract: Hydrogen sulfide plays an important role in the regulation of the cardiovascular system, insulin secretion, and glucose homeostasis. The aim of the present study was to examine the effects of chronic administration of sodium hydrosulfide (NaHS), L-Cysteine (L-Cys) and DL-Propargylglycine (DL-PAG) on the changes induced by a high-fat diet (HFD) in zoometric and metabolic variables as well as cardiovascular changes such as hypertension and sympathetic hyperactivity. For this purpose, 200-220 g male Wistar rats were fed a normal fat diet (NFD, n=6) or HFD (n=30) for 12 weeks. Next, the HFD rats were randomly divided into 5 subgroups (n=6 each) which received daily i.p. injections during 4 weeks of: (1) nothing (Control); (2) vehicle (PBS; 1 ml/kg); (3) NaHS (5.6 mg/kg); (4) L-Cys (300 mg/kg); or (5) DL-PAG (1 mg/kg). Then, an oral glucose tolerance test, hormone plasma levels and blood pressure were determined. The cardiovascular responses to stimulation of the vasopressor sympathetic tone or i.v. administration of the agonists noradrenaline ($\alpha_{1/2}$-adrenoceptors), methoxamine (α_1-adrenoceptors) and UK 14,304 (α_2-adrenoceptors) were determined in pithed rats. Then, heart, liver and adipose tissue were obtained and weighted. We found that HFD significantly increased: (1) zoometric variables, which were decreased by NaHS and L-Cys; (2) metabolic variables, ameliorated by DL-PAG; (3) haemodynamic variables, which were totally reversed by NaHS and L-Cys; and (4) the vasopressor responses induced by sympathetic stimulation, which were diminished by NaHS and L-Cys. In conclusion, chronic treatments with NaHS and L-Cys are effective in reducing adipose tissue and ameliorating the cardiovascular changes induced by obesity; meanwhile, DL-PAG ameliorates metabolic variables. These effects could involve a reduction of the sympathetic tone, inviting us to explore deeper into the mechanism underlying this long-term effect.

Title: C1 neuron activation maintains blood pressure during mild hemorrhage

Authors: *G. M. SOUZA, R. L. STORNETTA, D. S. STORNETTA, S. B. ABBOTT, P. G. GUYENET;
Univ. of Virginia, Charlottesville, VA

Abstract: Background: During hemorrhage, BP is initially maintained near normal (compensated phase) by an increase in sympathetic nerve activity (SNA). However, further blood loss (>20-25% blood volume) causes an abrupt and severe BP drop (late or "decompensated" phase) associated with a paradoxical and unexplained reduction of SNA. Under several circumstances (e.g. hypoxia, anesthesia) SNA and BP are largely determined by the level of activity of catecholaminergic presympathetic neurons (C1 neurons) located within the rostral ventrolateral medulla (RVLM). **Goals:** In this study we sought to determine the contribution of the C1 neurons to BP and heart rate during the early and decompensated phases of hemorrhage in non-anesthetized rats. **Methods:** We determined the contribution of the C1 cells to BP by measuring how much this variable drops when the C1 neurons are selectively, briefly (10s) and bilaterally silenced using optogenetics. We transduced the C1 neurons with the inhibitory proton pump Archaerhodopsin by microinjecting AAV2-DIO-ArchT3.0-eYFP bilaterally into the RVLM of adult TH-Cre rats. Four weeks later, C1 neurons were inhibited at regular intervals by delivering green light (532 nm, continuous pulse for 10 s) while the rats (unanesthetized) were subjected to a controlled hypotensive hemorrhage (18 ml/kg of blood withdrawal over 20 minutes). Data were analyzed using one-way ANOVA and results were considered significant when $p<0.05$. **Results:** C1 inhibition produced a much larger BP drop during the early compensated phase of hemorrhage than before hemorrhage (-25 ± 4 vs. -6 ± 2 mmHg, n=4). By contrast, the BP drop elicited by C1 cell inhibition during the decompensated phase of hemorrhage (-3 ± 3 mmHg) was no different from the drop at rest. Before hemorrhage, C1 inhibition caused a slight tachycardia ($+7 \pm 2$ bpm) at rest whereas HR was reduced by C1 inhibition during the early phase of hemorrhage (-20 ± 10 bpm). **Conclusions:** C1 neuron activation contributes to BP stability during the compensated phase of hemorrhage. C1 neurons may be inactive during the decompensated phase and thus may contribute to the paradoxical BP decrease.

Title: Moxibustion reduces blood pressure and heart rate in conscious hypertensive rats

Authors: *Y. GONG, S. MALIK, Z.-L. GUO, L.-W. FU, S. C. TJEN-A-LOOI;
Susan Samueli Integrative Hlth. Inst., Univ. of California, Irvine, Irvine, CA

Abstract: Electroacupuncture (EA) with bilateral stimulation of the acupoints ST36-37 stimulating the deep peroneal nerves attenuates sympathetic outflow and change of blood pressure in reflex hypertension. EA also decreases the elevated blood pressure, but not the heart rate, in cold-induced hypertension through the rostral ventral lateral medulla (rVLM). Moxibustion stimulating the thermosensitive transient receptor potential vanilloid type-1(TRPV1) receptors at ST36 acupoint similarly modulates sympathoexcitatory blood pressure reflexes through the opioid system in the hypothalamus. However, it remains unclear if moxibustion influences hemodynamic parameters including blood pressure and heart rate, in spontaneously hypertensive conscious rats. We hypothesize that moxibustion decreases the elevated blood pressure and heart rate in spontaneous hypertensive rats (SHR). Rats randomly allocated into three groups: moxibustion at ST36, control point G39 twice per week for five weeks, or third group without moxibustion. Another two groups of SHR rats received a 5-week twice a week EA at ST36-37 or sham-EA ST36-37 (no electrical input) treatment. Blood pressure and heart rate were measured in all of the 5 groups of rats. To determine the moxibustion-induced activation of neurons in the medulla, rats subjected to 30 min moxibustion were examined for c-Fos expression in the rVLM and the nucleus tractus solitaries (NTS), a site participating in the regulation of heart rate. We observed that moxibustion in contrast to EA could not display the long-lasting blood pressure lowering effect over the course of 5-week treatment. On the other hand, we observed that the blood pressure accompanied with heart rate were reduced for at least 24 hours and recovered by 48 hours. Heart rate change was not observed in the EA-treated rats. Immunohistochemical staining for c-Fos expression was observed in the rVLM and the NTS implying that moxibustion may include both sympathetic and parasympathetic systems during modification of elevated blood pressure.

Title: Role of potassium channels on the vasopressor sympathetic outflow inhibitioninduced by hydrogen sulfide

Authors: *S. HUERTA DE LA CRUZ, G. J. MEDINA-TEROL, J. H. BELTRÁN-ORNELAS, S. K. MONTIEL-GÓMEZ, C. B. GOMEZ, A. SANCHEZ-LOPEZ, D. CENTURIÓN; Pharmacobiology, Cinvestav Sede Sur, Mexico City, Mexico

Abstract: It is well known that hydrogen sulfide is a novel gasotransmitter with important cardiovascular effects. Indeed, it has been recently demonstrated that a continuous infusion of a H_2S donor, NaHS, is capable to inhibit the sympathetic outflow although the mechanisms remain elusive. This study evaluated the involvement of several potassium channels on the H_2S-induced sympatho-inhibition by using several selective blockers. For this purpose, male Wistar rats were anaesthetized, pithed and cannulated. The left carotid was connected to a pressure transducer to record blood pressure and heart rate meanwhile the right femoral vein was cannulated for gallamine and potassium channels blocker administration and the left femoral vein was cannulated for NaHS i.v. continuous infusion. After that, animals received selective electrical stimulation of the vasopressor sympathetic outflow (T_7-T_9). Animals were divided into 2 main groups. The first one was subdivided into 6 sets to evaluate de effect of K^+ channels blocker on NaHS-induced sympatho-inhibition. Thus, prior to 310 μg/kg min NaHS i.v. continuous infusion animals received: (1) bidistilled water (tetraethylammonium, 4-aminopyridine and barium chloride vehicle; 1 ml/kg); (2) tetraethylammonium (non-selective K^+ channels, 16.5 mg/kg); (3) 4-aminopyridine (non-selective voltage-dependent K^+ channels; 5 mg/kg); (4) $BaCl_2$ (inward rectifier K^+ channels; 65 μg/kg); (5) DMF 5%, glucose 10% and NaOH 0.1N (glibenclamide vehicle; 1 ml/kg); and (6) glibenclamide (ATP-dependent K^+ channels; 10 mg/kg). The second group was divided into 4 subgroups that received: (1) tetraethylammonium (16.5 mg/kg); (2) 4-aminopyridine (5 mg/kg); (3) $BaCl_2$ (65 μg/kg); (4) glibenclamide (10 mg/kg) and did not receive NaHS i.v. continuous infusion in order to evaluate the per se effect of K^+ channels blocker on the vasopressor responses induced by selective electrical stimulation. The NaHS-induced sympatho-inhibition was: (1) unaffected by vehicles; (2) slightly reversed by $BaCl_2$; and (3) abolished by tetraethylammonium, 4-aminopyridine and glibenclamide, meanwhile vasopressor responses induced by selective electrical stimulation remained unaffected by (1) tetraethylammonium; (2) $BaCl_2$; (3) glibenclamide and (4) significantly increased by 4-aminopyridine. Taken together, our results suggest that NaHS-induced sympatho-inhibition is mainly mediated by activation of voltage and ATP-dependent K^+ channels and, to a lesser extent, by inward rectifier K^+ channels.

Title: Afferent bone marrow drive to periaqueductal gray in modulation of blood pressure in the spontaneously hypertensive rat

Authors: *S. KOUTSIKOU[1], D. M. BAEKEY[2], L. F. HAYWARD[3], J. ZUBCEVIC[2]; [1]Medway Sch. of Pharm., Univ. of Kent, Chatham Maritime, United Kingdom; [2]Dept. of Physiological Sci., [3]Dept Physiol Sci., Univ. of Florida, Gainesville, FL

Abstract: Introduction: A range of pathophysiological conditions are characterized by dysfunctional immune and autonomic nervous system (ANS), including cardiovascular, pain, mental and autoimmune disorders. Here, we present new data from a hypertensive rodent model characterized by dysfunctional immune system and ANS suggesting an altered afferent communication between the bone marrow (BM), the main hematopoietic organ, and brainstem autonomic regions. **Methods**: Male adult spontaneously hypertensive rats (SHR) and their normotensive control Wistar-Kyoto (WKY) rats were used in this study. Rats were anesthetized with isoflurane (1.5%), and mean arterial pressure (MAP) and heart rate (HR) were monitored in real time via a femoral arterial catheter and ECG leads. A hole was drilled in the femoral BM of all rats for delivery of electrical impulses (100 square pulses at 20Hz; 5mA, 500us), before and after a unilateral bicuculline (BIC) injection (100nl, 0.4mM) in the dorsolateral, lateral, or ventrolateral periaqueductal gray (PAG). **Results:** Electrical BM stimulation produced an immediate and similar stimulation intensity-dependent drop in MAP and HR in both WKY and SHR. However, the MAP and HR responses to electrical stimulation were significantly enhanced in the SHR following an injection of BIC in PAG regions. **Conclusion:** We propose that an enhanced BM afferent input to the PAG, possibly due to elevated inflammatory events in the SHR BM, will in turn modulate the ANS. This BM-brainstem neuronal circuitry may be important in maintenance of cardiovascular, pain and immune homeostasis.

Title: Impacts of dim light at night and phthalate exposure on circadian locomotor and feeding behaviors and hypothalamic gene expression

Authors: *K. HATCHER[1], Y. PATEL[2], M. M. MAHONEY[3];
[1]Neurosci. Program, [2]Inst. for Genomic Biol., [3]Comparative Biosci., Univ. of Illinois At Urbana-Champaign, Urbana, IL

Abstract: The circadian system synchronizes physiology and behavior with the environment. This timing system is regulated by exogenous and endogenous cues, such as light and hormones, respectively. Neuroendocrine signaling in the hypothalamus controls circadian behaviors such as locomotion and feeding. Phthalates, including di-(2-ethylhexyl) phthalate (DEHP), are ubiquitous endocrine disruptors capable of modifying the endocrine system and its outputs, including metabolism. Further, dim light at night (dLAN, i.e. urban light pollution), alters feeding behavior and metabolism. Despite our knowledge of the impact of DEHP and dLAN on other endocrine systems, the effects of dLAN and phthalate exposure on circadian behaviors, as well as underlying neuroendocrine control of these behaviors, have remained largely unexplored. Here, we tested the hypothesis that dLAN, DEHP, or combined dLAN and DEHP exposure disrupts locomotor activity and feeding behaviors, as well as underlying neuroendocrine regulators of these behaviors. Adult CD-1 male and female intact mice were individually housed with running wheels to measure daily locomotor behavior. Mice (8/sex/group) were treated for 30 days with one of the following: 12h:12h light:dark and corn oil (Control); 12h:12h light:dLAN with 5 lux light during the dark phase and corn oil control (dLAN); 12h:12h light:dark with 50µg/kg/day DEHP (DEHP); or 12:h12:h light:dLAN with 5 lux light during the dark phase and 50µg/kg/day DEHP (DEHP-dLAN). DEHP or corn oil control were administered orally by gently pipetting into the cheek every morning at lights on. Light phase and dark phase food consumption was measured every 12hrs by weighing food in each cage. Males were less active than females, regardless of treatment. DEHP males had significantly reduced total activity compared to control males. Females exhibited reduced nocturnal activity compared to males, and each female treatment group resulting in reduced nocturnal activity compared to control females. Females from all treatment groups were more active during the early part of their light cycle compared to controls, indicating increased diurnal behavior. Although females ate less food overall, no treatment affected food consumption in either males or females. We also aimed to

investigate the effect of DEHP and dLAN on neuropeptide and neuropeptide receptor expression in the arcuate nucleus (ARC) and dorsomedial hypothalamus (DMH). Preliminary data indicates that there was no effect of treatment on gene expression of *Pacap* or its receptor *Pac1r* in the ARC/DMH. Together, these data provide some of the first evidence indicating that dLAN and DEHP result in maladaptive behaviors.

Title: Circadian resonance and entrainment in three spiders (Frontinella communis, Metazygia wittfeldae, and Cyclosa turbinata)

Authors: *R. RAGSDALE, C. SHONE, M. K. MILLER, T. C. JONES, D. MOORE;
Biol. Sci., East Tennessee State Univ., Johnson City, TN

Abstract: Circadian rhythms, endogenous rhythms which typically cycle with a period of approximately 24 hours, are widespread among eukaryotes and organize many internal functions as well as behaviors such as locomotor activity. Previous research indicates these rhythms are advantageous to organisms' survival when they closely match the period of their environment (i.e., exhibit circadian resonance). Desynchrony between internal and environmental periods causes a number of pathological outcomes, including reduced longevity. Additionally, organisms are generally unable to synchronize their internal rhythms with external periods which are very different from their own, suggesting the presence of physiological limits to this system. As some species of spiders exhibit internal periods very different from 24 hours, the question addressed here is if this concept of circadian resonance applies to these spiders as well. The present study compares survivorship within three species of spider (n=166, 135, and 118, respectively, all female) with varying internal periods (*Frontinella communis:* τ=29.05±0.62 hours, *Metazygia wittfeldae*: τ=22.74±0.24h, and *Cyclosa turbinata*: τ=18.54±0.28h) among three light:dark (L:D) cycles with different periods: 19h (9.5h light:9.5h dark), 24h (12:12), or 29h (14.5:14.5). If circadian resonance is relevant to spiders, we expect that spiders in non-resonant L:D cycles should exhibit reduced longevity. Instead, no spider species suffered reduced longevity in non-resonant light cycles. Because non-resonant light cycles have been shown to have little to no effect on the longevity of organisms that are unable to entrain to environmental time cues, a second experiment was designed to evaluate whether these spiders were able to entrain to each L:D cycle. 10-11 spiders of each species were placed into locomotor activity monitors and exposed to one of the three light cycles for 14 days and then transferred to complete darkness for

13 days. These data show that all spider species were able to entrain to all L:D cycles. These results indicate a previously undescribed level of plasticity in spider circadian rhythms and suggest that they are released from selective pressure to maintain a near 24-hour internal period among these species.

Title: Age-related changes in corticosterone circadian rhythm and stress-reactivity

Authors: ***M. G. JACKSON**[1], H. MARSTON[3], S. L. LIGHTMAN[2], E. S. J. ROBINSON[1]; [1]Physiology, Pharmacol. and Neurosci., [2]Dorothy Hodgkin Building, Univ. of Bristol, Bristol, United Kingdom; [3]Eli Lilly and Co., Basingstoke, United Kingdom

Abstract: Aging is associated with many physiological changes, including changes to the circadian clock. This includes significant changes in behaviour, temperature regulation and hormone release. Changes in cortisol (CORT) are of interest as CORT is a key downstream regulator of peripheral clock genes and has a profound effect on behaviour. Previous research in humans has demonstrated age-related changes in the pattern of cortisol including a reduction in circadian amplitude. The use of aged rodents could provide a valuable way to study the underlying neurobiology and behavioral impact of disrupted biological rhythms. The aim of the present study was to (1) assess changes in CORT circadian rhythm in aged rodents and (2) assess stress reactivity using CORT response to a noise stressor. 8 male Sprague-Dawley aged rats (23 mo) and 8 younger sex and strain-matched controls (7 mo) were kindly provided by Eli Lilly & Co. Free-running rats underwent automated blood sampling. Briefly, following intravenous cannulation of the right jugular vein a blood sample was drawn automatically every 10 mins for 28 h. At 26 h a 100 db noise stressor was played. CORT concentration was measured using an in-house radioimmunoassay. A CORT profile of n = 7 younger rats and n = 6 aged rats was obtained. Values for peak and nadir CORT were calculated using area under the curve analysis (AUC). RM two-way ANOVA analysis of plasma CORT in aged and young rats over 26 h show a significant interaction between circadian time and age group, $F(1,11) = 5.263$, $p = 0.042$. Bonferroni post hoc analysis revealed younger rats have a higher peak and nadir CORT than

aged rats (p = 0.027 and 0.011 respectively). There was no difference in CORT peak vs nadir in aged rats (p = 0.261) but there was a difference in CORT peak vs nadir in the younger rats (p = 0.001). AUC analysis of the stress response showed younger rats have a larger CORT response to noise stress compared to aged rats (t(6.761) = 4.993, p = 0.002, unpaired t-test). Overall, this indicates that aged rats have a blunted CORT circadian rhythm and a blunted stress response. Further work will elucidate the molecular underpinnings of this disruption, and how this change may result in changes in behaviour.

Title: Lights clock action circadian rhythms of locomotor activity in larinioides cornutus indicate extreme flexibility in photo-entrainment

Authors: *M. K. MILLER[1], T. C. JONES[2], D. MOORE[2];
[1]Biomed. Sci., [2]Biol. Sci., East Tennessee State Univ., Johnson City, TN

Abstract: Circadian clocks are responsible for scheduling behavioral and physiological processes at the most appropriate times of day. The resulting daily rhythms synchronize (entrain) to external environmental cues (zeitgebers). This phenomenon of entrainment enables organisms to anticipate daily changes in environmental conditions such as sunrise/sunset, temperature variations, availability of prey, etc. Given the critical nature of entrainment to survival, it is no surprise that the mechanism is conserved across taxa. The misalignment of the intrinsic clock with the external environment results in a plethora of negative consequences, made apparent by studies involving shift work and jet lag. The focus of the present study is to investigate the chronobiology of female *Larinioides cornutus* (Araneidae), a nocturnal orb-weaving spider, with an emphasis on entrainment to light:dark (LD) cycles. Locomotor activity of adult female spiders was monitored via infrared sensor as a measure of circadian output. We found that both lights-off and lights-on are influential zeitgeber cues for both activity onset and offset (advance assay n=28, delay assay n=32). Phase shifting experiments reveal that these spiders (n=16) can re-entrain within 2 days to LD phase-shifts of 6 hours, and within 3 days when shifted by 12 hours. These re-entrainment rates are vastly accelerated compared to mammals, which adjust at a rate of around 1 day/ 1 hour of phase shift. In other words, spiders have minimal jet-lag responses, suggesting an increased level of plasticity in the spider circadian clock rarely observed in other organisms. Typical of circadian rhythms in nearly all organisms, activity persisted (free-runs)

under constant conditions. However, in constant darkness (DD), a drastic change in periodicity was revealed in 66% of individuals (n=48), from 23.4 to 25.2 hours, likely indicating the interaction of multiple oscillators. Evidence favoring this interpretation is the consistency in endogenous periods before and after the period shifts among all of the spiders. In contrast, under constant light (LL) conditions, 65% of spiders (n=28) were arrhythmic, suggesting high sensitivity to light. If present, the periods in LL were normally distributed over an unusually broad range, from 16.7 to 34.9 hours. Spiders have received scarce attention with respect to their chronobiology, but due to the atypical rates of re-entrainment to LD phase-shifts, spontaneous changes in free-running period under DD, and arrhythmicity in LL, we propose that spiders provide a valuable comparative model system for elucidating fundamental mechanisms of circadian clocks.

Sci., Univ. of California - Collaborative Mass Spectrometry Innovation Ctr., San Diego, CA

Abstract: Chronic circadian disruption (CDR) is one challenge known to produce negative health consequences, including disrupted sleep and circadian misalignment. Prebiotic nutrients produce favorable changes in gut microbial ecology that can impact physiology and reduce the negative health impacts of challenge. This study tested the hypotheses that ingestion of dietary prebiotics increase the abundance of health-promoting microbes and reduce the negative impacts of CDR on host physiological variables like sleep and core body temperature. Prebiotic-enriched

or caloric-nutrient matched control diets were fed ad libitum to male, Sprague Dawley rats (n = 20-23/group) throughout 8 weeks of CDR (weekly, 12h light/dark reversal). Sleep EEG and core body temperature were recorded via biotelemetry (F40-EET; DSI) in freely moving rats. In order to investigate species level changes, shotgun metagenomics revealed that rats eating prebiotic diet had higher levels of two specific gut microbial species. In order to examine these diet induced gut microbial changes across time we successfully classified these species between the shotgun DNA and 16S rRNA data analyses. The 16S rRNA fecal analysis showed that rats eating prebiotic diet had little change in beta/alpha diversity after 2 days on diet, but after 5 weeks on diet had altered beta/alpha diversity and increases in two specific gut microbial species/genus. CDR had a small effect on evenness of alpha diversity. During exposure to 8 weeks of CDR rats eating prebiotic diet had facilitated re-alignment of the bathyphase of diurnal core body temperature (ClockLab; Actimetrics) scored by an observer blind to treatment of each animal. Rats eating prebiotic diet also returned to normal diurnal NREM sleep faster than those eating control diet at 6 and 8 weeks of CDR. Finally, gut microbial changes were correlated with average number of days to re-entrain at 4 weeks CDR exposure and the time spent in NREM sleep after both 6 and 8 weeks of CDR. These data suggest that prebiotic diet induced alterations in gut microbial ecology are significantly related to improved host outcomes in physiological variables (i.e. core body temperature and the sleep/wake cycle) in rats with a history of CDR. All procedures were approved by the University of Colorado IACUC.

Title: Extended gamma sensory stimulation in cognitively normal individuals

Authors: *B. JACKSON[1,2], D. CHAN[1,3], H.-J. SUK[2], S. BEACH[1], D. STARK[1], V. FERNANDEZ[1], N. MILMAN[1], C. STEARNS[1], E. BOYDEN[2], E. BROWN[1], L.-H. TSAI[1]; [1]Picower Inst. of Learning and Memory, Massachusetts Inst. of Technol., Cambridge, MA; [2]McGovern Inst. for Brain Research, Massachusetts Inst. of Technol., Cambridge, MA; [3]Dept. of Neurology, Massachusetts Gen. Hosp., Boston, MA

Abstract: Recent research into using non-invasive stimulation to alter functional brain frequencies has led to exciting results in both healthy and cognitively impaired individuals. Transcranial alternating current stimulation has been shown to be capable of increasing theta-gamma frequency coupling in the temporal areas of cognitively normal individuals. This stimulation led to increased working memory performance in older adults. Cortex-wide gamma frequency synchronization has been associated with both attention and long-term memory encoding; disruption of this synchronization may also be relevant to Alzheimer's disease. Previous unpublished work in our group has found that we are able to produce robust gamma frequency entrainment in healthy older adults using only external light and sound stimulation. Due to its relevance in cognitive ability, we exposed healthy older individuals to two weeks of one-hour daily, gamma frequency (40 Hz) light and sound and investigated changes in electroencephalography (EEG), functional MRI, and cognitive function using a battery of tests. Both the initial and post-treatment EEG sessions showed significant entrainment at 40 Hz across the cortex; indicating robust, global entrainment with our device. After two weeks of stimulation, we found significant changes in fMRI activation of the hippocampal, parahippocampal, and visual association regions during a face-name association task, which may indicate improvements in associative memory formation during the presentation of novel stimuli. Finally, early results indicate increases in a variety of cognitive abilities quantified through a battery of cognitive tests delivered pre and post intervention. Overall, these results indicate that repeated exposure to gamma sensory stimulation may be cognitively beneficial to healthy older individuals.

Title: Bimodal stimulation in cognitively healthy individuals prompts widespread 40 Hz entrainment and global synchronization: A preliminary study of non-invasive stimulation for treating Alzheimer's disease

Authors: *N. E. P. MILMAN[1], D. CHAN[1,3], H. J. SUK[2,1], B. L. JACKSON[2,1], S. BEACH[1], D. STARK[1], V. FERNANDEZ[1], C. STEARNS[1], E. N. BOYDEN[2], E. S. BROWN[1], L. H. TSAI[1]; [1]Picower Inst. for Learning and Memory, [2]McGovern Inst. for Brain Res., MIT, Cambridge, MA; [3]Neurol., Massachusetts Gen. Hosp., Boston, MA

Abstract: Gamma frequency (25 to 100 Hz) neural oscillations play a vital role in various higher order cognitive functions (Fries, *Ann Rev of Neuroscience*, 2009) and are disrupted in many cognitive diseases, namely Alzheimer's Disease (AD). Previous research in our lab demonstrated that visual and auditory stimulation at 40 Hz could entrain the primary sensory cortices and attenuate AD-related pathology in AD mouse models, showing removal of amyloid-beta, microglia clustering as well as improved cognitive outcomes (Iaccarino et al., *Nature*, 2016; Martorell et al., *Cell, 2019).* With this in mind, we investigated whether non-invasive sensory stimulation could induce 40 Hz entrainment and increase gamma-band synchronization in human subjects, as a preclinical study for using this strategy to treat AD. We developed a device that can concurrently deliver light and sound at 40 Hz, which was used to stimulate cognitively normal subjects (23 males, 23 females; age-range 22-75) over acute and hour-long sessions. Electroencephalogram (EEG) recordings showed that our sensory stimulations could safely entrain the human brain at 40 Hz, with the bimodal stimulation (i.e., concurrent visual and auditory stimulation) inducing the strongest and most widespread entrainment as well as synchronization at 40 Hz. We also found that hour-long bimodal stimulation led to steady entrainment and synchronization throughout the stimulation period without adverse effects. These findings suggest that our sensory stimulation strategy is a safe and effective way of inducing 40 Hz entrainment and synchronization in humans, which may have therapeutic benefits in people suffering from AD.

Title: Investigating the effect of chronic photoperiod shifts on hippocampal-dependent and independent tasks

Authors: *T. T. S. CASSELL[1], J. M. CLEARY[2], M. L. HOUSE-DENINE[1], S. HIGDON[1], S. H. DEIBEL[4], C. M. THORPE[3];

Abstract: The light-dark cycle is the most potent environmental cue in the development of circadian rhythms. Previously it has been shown that rats exposed to a chronic light manipulation (i.e., 64 days) experienced deficits in the acquisition of a hippocampal-dependent (HD) task. The purpose of the current study was to assess whether a 30-day light manipulation was salient enough to result in a deficit in the acquisition of a HD task. First, 32 male Long Evans rats were entrained to a 12:12 light-dark cycle (i.e., 7:00am-7:00pm). Then, 16 of the rats were exposed to a 30-day light manipulation (i.e., LM group). Next, rats were trained on both the hippocampal-independent (HI) and HD tasks. The HD task consisted of a rapid acquisition, massed training, and competition phase of the Morris Water Maze task, each followed by a no-platform probe. There was a significant difference in the rapid acquisition phase of the HD task, with the LM rats taking longer to learn the task than control rats. However, this deficit was not present in the other phases of the HD task or the probes. Additionally, there were no significant differences in performance on the HI task. To conclude, using less than half of the chronic light manipulation resulted in the impairment of the rapid acquisition of the HD task. This implies that 30 days of circadian misalignment can result in detrimental effects in the acquisition of a HD task.

Title: Analysis of circadian behaviour and clock-gene expression after prenatal administration of valproic acid: Implication for autism spectrum disorders

Authors: *S. FERRARO, N. DE ZAVALIA, S. DOBRIC, M. ALONSO-MAYOR, S. AMIR; Concordia Univ., Montreal, QC, Canada

Abstract: Autism Spectrum Disorder (ASD) is a pervasive developmental disorder characterized by restrictive patterns of behaviour and alterations in social interaction and communication. Accompanied by co-morbid disorders, 44-80% ASD patients exhibit sleep-wake cycle disturbances, potentially implicating alterations within the circadian system. Administration of the anti-epileptic drug, valproic acid (VPA), on day 12.5 of gestation results in rodent pups with ASD-like phenotypes. Research has shown that irregular sleep-wake cycles exacerbate ASD symptomology and further impair social performance. While altered sleep-wake cycles have been identified in ASD individuals, little has been done to assess the contribution of the circadian system to these findings. The objective of this study is to characterize circadian behaviour and clock-gene expression in a VPA-induced animal model of autism to highlight perturbations potentially contributing to sleep-wake cycle disturbances. Male offspring introduced to running-wheel apparatuses underwent various circadian challenges, including baseline light-dark cycles, constant dark/light and phase advance/delay protocols. Baseline analysis revealed a significant increase in light phase activity bouts (defined as one count of activity/minute for ten consecutive minutes) in VPA-treated animals (control: 1.1 ± 0.1795, VPA: 1.917 ± 0.2865 $p < 0.05$). Moreover, VPA-treated animals show greater distribution of wheel-running behaviour across light-dark phases, while controls show greater activity confinement to the dark phase (light activity/total activity; control: 0.07550 ± 0.01609, VPA: 0.1724 ± 0.01506. $p < 0.0001$). Further investigation reveals a later running-activity offset in VPA-animals ($p < 0.0005$). Constant light analysis reveals greater running activity in VPA animals ($p < 0.05$), and an increase in the number of days to reach arrhythmicity (control: 12.89 ± 0.5638, VPA: 23.93 ± 2.069. $p < 0.0005$). A 1-hour light pulse (150 lux) at CT 15 after six days of constant dark was used to assess the phase-shifting capacity of the SCN. VPA-treated animals demonstrated a lesser phase-shift when compared to controls (total hours shifted; control: 2.238 ± 0.1688, VPA: 1.495 ± 0.1549 $p<0.005$). Together, these results suggest alterations in photic-entrainment capacity in VPA-treated animals.

Title: Examining the optimal timing for closed loop auditory stimulation of slow wave sleep in young and older adults

Authors: *M. NAVARRETE[1], J. SCHNEIDER[2], H.-V. V. NGO[3], M. VALDERRAMA[4], A. J. CASSON[2], P. A. LEWIS[1];
[1]Cardiff Univ., Cardiff, United Kingdom; [2]Univ. of Manchester, Manchester, United Kingdom; [3]Sch. of Psychology, Univ. of Birmingham, Birmingham, United Kingdom; [4]Univ. of Los Andes, Bogotá, Colombia

Abstract: Slow wave sleep (SWS) is typified by the presence of cortical slow oscillations (SO, < 1Hz), and closed loop auditory stimulation (CLAS) is a method for enhancing SWS. CLAS presents auditory clicks synchronous with the SO, boosting the SO amplitude and phase-locked spindle power (12-15Hz). Still, the optimal timing for click delivery remains unclear. In this study, we took advantage of the inherent variability of click delivery of CLAS to examine the best timing for maximal enhancement of both SO amplitude and spindle likelihood during SWS. Moreover, we evaluated the main factors for sleep spindle odds in an acoustic stimulation condition. For this, we analysed the dynamic reactivity of post-stimuli SO and spindles in young (N = 21, 25.7±4.7 years, 14 females) and older adults (N =17, 55 ±5 years, 9 females) as a function of the phase of stimulation on the ongoing SO (φ_{SO}).
Comparison of CLAS between sham and stimulation conditions revealed that clicks applied anywhere on the positive SO wave increased wave amplitudes and spindle likelihood, although this interval of opportunity was shorter in older people (Welch's t-test $t(35.6) = 3.6$, $P < .001$). However, within condition analysis revealed that for both populations the optimal timing for click delivery is close to the SO peak phase ($\varphi_{SO} = 87.2°$ in young and $\varphi_{SO} = 83.6°$ in older subjects, where 90° is the peak phase of the SO wave and 0° its negative to positive zero crossing). Our work also indicates that spindle likelihood after stimulation is modulated by the phase of the SO in young subjects but not in the older population. A binary logistic regression analysis showed that the main factor determining spindle likelihood in young subjects were SO phase components ($\chi^2 = 24.8$, $P < .001$; *Sin(φ_{SO}), t*(3.12) P = .002; *Cos(φ_{SO}), t*(2.19) P =.028; *Lag, t*(0.48) P > .05), while for older subjects the main factor for spindle odds was the temporal lag since the last spindle ($\chi^2 = 14.3$, $P = .012$; *Lag, t*(-2.35) P = .019; *Sin(φ_{SO}), t*(1.86) P > .05; *Cos(φ_{SO}), t*(0.26) P > .05). Maximal spindle chance occurred after clicks applied on the rising slope of the positive SO half-wave in young adults.
Our data suggest that CLAS can boost SOs and spindles based on the fluctuation of sensory inputs modulated by the thalamocortical networks during the SO. Finally, we speculate that the optimal timing of CLAS is defined within wake-like intervals in which peripheral networks can recruit larger thalamocortical populations.

Title: Short photoperiod exposure reverses ventral subicular lesion-induced affective and cognitive deficits in Wistar rats

Authors: *S. DUTTA GUPTA[1], B. N. SRIKUMAR[1], B. SHANKARANARAYANA RAO[2], B. M. KUTTY[3];
[1]Neurophysiol., [2]Natl. Inst. of Mental Hlth. and Neuro Sci. (NIMHANS), Natl. Inst. of Mental Hlth. and Neuro Scie, Bengaluru, India; [3]Neurophysiol., Natl. Instit Ment Hlt &Neurosci, Bengaluru, India

Abstract: Photoperiod has enduring effects on physiological and behavioral phenotypes such as metabolism, cognition, and affective behavior. Phototherapy has emerged as a safe and effective chronotherapeutic in neurodegenerative conditions such as Alzheimer's and Parkinson's disease, though the underlying mechanism remain elusive. Subiculum, a crucial output structure of the hippocampal formation, mediates a wide range of neurocognitive functions such as learning and memory, motivation, and adaptive behavior. The present study demonstrates the impact of selective bilateral lesioning of the ventral subiculum on behavioral phenotypes such as anxiety, depression and cognitive functions like empathy and sociality, attention and spatial navigation. Ventral subicular lesion (VSL) resulted in heightened anxiety, anhedonia, increased behavioral despair, and decreased self-care. The VSL rats exhibited a considerable degree of impaired social cognition, in terms of altered social preference, social novelty and empathy with altered ultrasonic vocalization. Also, the VSL rats displayed an attentional deficit when tested in a 3 and 5-objects based attention task. We observed a 2-fold increase in plasma corticosterone level in the VSL rats indicating its involvement in the hypothalamo-pituitary-adrenal axis dysfunction. Interestingly, the anxiety- and depressive-like phenotypes were completely ameliorated when VSL rats were exposed to a short photoperiod regime (SPR, 6/18h light-dark cycle) for 21 days. However, exposure to SPR resulted in the recovery of pro-social behavior and social novelty but not the overall sociability of the VSL rats. There was a significant recovery in spatial navigational functions, but SPR could not restore the attentional deficits in the VSL rats. We further observed a decrease in plasma corticosterone level at ZT6 time-point, which might be associated with the behavioral and cognitive recovery. The underlying mechanism is currently been investigated using assessment of adult neurogenesis and glucocorticoid receptors

expression. In summary, the study highlights the efficacy of photoperiod manipulation as a novel, non-pharmacological approach in mitigating the affective and cognitive deficits associated with central nervous system insult.

Title: Dna methylation modulates period aftereffects of circadian entrainment without affecting transient phase shifts

Authors: *S. KIM[1], D. G. MCMAHON[2];
[1]Neurosci. Grad. Program, [2]Dept of Biol. Sci., Vanderbilt Univ., Nashville, TN

Abstract: The suprachiasmatic nucleus (SCN) is a brain region where photic and non-photic inputs reflecting environmental regularities converge onto peptidergic neurons that serve as a central pacemaker of circadian rhythms in the rest of the body. Light inputs can acutely induce a phase shift of circadian rhythms in the SCN and elicit a lasting change in the circadian period that is otherwise genetically determined. Recently, it was reported that DNA methylation mediates circadian period changes in mice entrained to non-24hr light cycles inducing SCN-specific changes in transcription. This suggests that long-term circadian clock plasticity involves epigenetic modifications. However, the mechanism remains largely unknown. To test whether DNA methylation is a mechanism underlying light-induced circadian aftereffects, we investigated the role of DNA methylation in aftereffects of the photoperiod entrainment. Pharmacological inhibition of DNA methyltransferases *in vivo* during entrainment suppressed the circadian period aftereffect and a rhythm amplitude aftereffect, suggesting that DNA methylation is a fundamental mechanism of circadian aftereffects. Since circadian aftereffects are thought to stem from acute changes in a circadian rhythm, we tested whether epigenetic changes in the SCN also play a role in short-term circadian clock plasticity, or acute circadian phase shifts. Pharmacological inhibition of DNA methyltransferases followed by light pulses at night *in vivo* suppressed the period change in the locomotor activity rhythm without affecting an acute phase shift. To confirm that circadian phase shifts take place at the core clock level in the SCN independent of DNA methylation, we performed a Period2::luciferase assay with vasoactive intestinal peptide (VIP), an endogenous neuropeptide mediating light signaling in the

SCN. Consistent with the behavioral experiment, VIP application in the SCN at circadian night produced a comparable phase shift even in the presence of a DNA methylation inhibitor. This shows that transient changes in SCN circadian rhythms do not require DNA methylation. Taken together, our findings suggest that DNA methylation takes part in modulating circadian aftereffect expression of acute circadian phase shifts.

Title: OLM neurons phase lock with type 2 theta in anxiogenic environments

Authors: *J. WINNE[1], R. N. LEAO[3], G. NASCIMENTO[2], K. KULLANDER[4];
[1]Brain Inst., [2]Biomed. Engin. Dept., Federal Univ. of Rio Grande do Norte, Natal, Brazil; [3]Brain Inst., UFRN, Natal, Brazil; [4]Uppsala Univ., Uppsala, Sweden

Abstract: Our group has previously shown that stimulation of oriens-lacunosum moleculare (OLM) neurons in CA1 of the ventral hippocampus increase risk-taking behavior and induce type 2 theta oscillations (theta2). We have also shown that anxiety-like behavior induced by acute tinnitus (salicylate treatment) generates theta2 in the open field test. In this work, we have imaged OLM cell activity using GCamp6F and microendoscopic fluorescente imaging in freely moving mice (Chrna2-cre line) and local field potential recordings in the open-field test. In order to induce anxiety and theta2, animals were pre-treated with salicylate (that induces tinnitus-related anxiety). We found that OLM cells phase-lock to theta2 and show highly coherent activity. In another set of experiments, we tested the hypothesis that OLM cell stimulation prevents anxiety-like behavior in tinnitus. For that purpose, we expressed ChR2 in OLM cells (using a cre-dependent viral vector). We found that OLM stimulation prevented anxiety-like behavior similarly to anxiolytic drugs. These results further demonstrate that OLM neurons are key to circuits that control anxiety and these neurons can be target for the development of anxiolytic therapies. Moreover, OLM cells may also be a target for treatment of mood disorders associated to tinnitus.

Title: A neural circuit for non-photic phase shifting of circadian rhythms by an acute salt load

Authors: *C. GIZOWSKI[1], C. W. BOURQUE[2];
[1]McGill Univ. Hlth. Ctr., Montreal, QC, Canada; [2]McGill Univ., Montreal, QC, Canada

Abstract: While clock time is normally adjusted by daylight onset, it can also be regulated by non-photic stimuli through unknown mechanisms. In this project, we examined if an acute salt load can acutely regulate clock time. The organum vasculosum lamina terminalis (OVLT) is a preoptic nucleus that contains neurons capable of detecting hypernatremia. We therefore examined if OVLT neurons can modulate SCN clock neurons. Histological and tracing experiments showed that salt-sensitive OVLT neurons project to the SCN. Interestingly, SCN VP neurons primarily receive GABAergic synaptic events. Further tracing experiments indicated that sodium-sensitive GABA OVLT neurons project to the SCN. Preliminary results suggest GABA excites SCN VP neurons during wake time, when SCN electrical activity is low. Electrophysiological analysis in slices further revealed that a salt load delivered to the OVLT significantly increases the frequency of spontaneous GABA synaptic currents and triggers an anticipatory shift in the onset of electrical activity in SCN clock neurons. Furthermore, systemic salt load injections during the dark period significantly phase advances circadian locomotor activity in mice. These data show that the SCN not only drives circadian rhythms, but also receives important physiological signals that can mediate non-photic adjustments in clock time and possibly adapt organisms to dynamic environments.

Title: Analysis of learning management system logins identifies interactions between social jetlag, gender, and academic performance

Authors: *A. E. SCHIRMER[1], B. L. SMARR[2], A. ISHAMI[1], M. VUJNOVICH[1];
[1]Northeastern Illinois Univ., Chicago, IL; [2]Univ. of California at Berkeley, Berkeley, CA

Abstract: Misalignments between endogenous circadian rhythms and the built environment (i.e., social jet lag, SJL) result in learning and attention deficits. Currently, there is no way to assess the impact of SJL on learning outcomes of large populations as a response to schedule choices, let alone to assess which individuals are most negatively impacted by these choices. A standard part of most university course work now involves logging into a centralized Learning Management System (LMS) to register for classes, check schedules, turn in homework, and join discussion boards, for example. We hypothesized that these login events would reflect information about the biological rhythms of the students, and could therefore be mined to quantify effects of circadian stability, gender, and social jetlag on academic performance in the real world, covering a large population at the level of the individual. Login data from over 14,000 students were collected from the Northeastern Illinois University learning management system Desire 2 Learn (D2L) and interactions between gender, SJL, and academic performances were explored. The activity profiles revealed that the majority of students experience more than 30 minutes of SJL on average, with greater amplitudes correlating strongly with a significant decrease in academic performance, especially in people with later apparent chronotypes. In addition, login patterns in female students were found to be less variable across the semester and decreased variability correlated with increased academic performance. Understanding these interactions at the individual- and population-level will help guide schedule choice and reduce SJL. This would serve to maximize academic performance to the benefit of individual students and the universities they attend.

Title: Reinforcement of the circadian clock restores alcohol tolerance and decreases toxicity in aged *Drosophila*

Authors: *A. K. DE NOBREGA, L. C. LYONS;
Biol. Science, Program in Neurosci., Florida State Univ., Tallahassee, FL

Abstract: Alcohol consumption and abuse in middle-aged and older adults has become a significant economic and health issue, with more than 75% of the alcohol-induced poisoning deaths occurring in these age groups. Surprisingly, little progress has been made in identifying the cellular mechanisms that underlie alcohol sensitivity and toxicity in middle and old age. One of the factors potentially underlying age-related pathologies is the weakening of the circadian system with age. Previously, we found that the circadian clock modulates alcohol sensitivity and toxicity and that circadian dysfunction significantly increases alcohol sensitivity and mortality. Moreover, we found that age-related increases in alcohol toxicity first occur during early middle age and correlate with a weakening of the circadian system. We hypothesize that age-related weakening of the circadian system can exacerbate alcohol pathologies and increase mortality following alcohol exposure. The similarity in alcohol-induced behaviors across species combined with its comparatively short lifespan and the availability of precise tools to manipulate neuronal gene expression make *Drosophila* a practical model for studies of aging and alcohol neurobiology. In the current studies, we investigated whether strengthening the circadian system in aged flies ameliorates the age-related increases in alcohol sensitivity and mortality. As the *Drosophila* circadian system can be entrained by temperature cycles, we used temperature cycles (25°C:18°C) coupled to the light-dark (12h:12h) cycle to strongly reinforce the circadian system. Circadian reinforcement through the dual entrainment paradigm did not alter mortality in young flies but significantly reduced mortality following repeated alcohol exposures in middle-aged and older flies. We found that temperature reinforcement of clock function significantly decreased the sensitivity to alcohol in young and middle-aged flies (10d and 20d) and restored the development of long-term tolerance (24 h) in middle-aged flies. In older flies under temperature and light entrainment, tolerance was restored only when a longer pre-exposure to alcohol was used. Temperature entrainment alone was sufficient to partially restore functional tolerance in middle-aged flies, although the flies were more sensitive to alcohol than flies entrained by light and temperature cycles. Overall, our results suggest that signaling in the light-entrainment pathway may be disturbed in middle-aged and older flies and that ensuring robust clock function ameliorates age-related changes in alcohol sensitivity.

Abstract: Behavioral ultradian rhythms (URs) are biological rhythms in the 1-6 h range. URs play a role in sleep, food intake, metabolism, and hormone pulsatility, and are understudied relative to circadian rhythms. Challenges to the analysis of URs include circadian harmonic contamination, intrinsic non-stationarity, and defeciencies in traditional chronobiological time series analysis methods in dealing with these problems. Recently, wavelet analysis has emerged as a method for overcoming these issues. Here we used the continuous wavelet transform to examine the roles of sex, gonadal hormones and seasonal changes in day length on the period and power of ultradian rhythms of locomotor activity in C57BL/6 mice. The results identify sex differences in ultradian rhythms and a marked effect of seasonal changes in day length on ultradian period and on the distribution of ultradian power in mice.

Title: Revealing functional brain activity following excitotoxic injury to retinal ganglion cells in a diurnal rodent model

Authors: N. KRAUSE[1], C. BRENNAN[1], J. DYKE[1], G. FOGO[3], *A. J. GALL[2];
[2]Psychology, [1]Hope Col., Holland, MI; [3]Univ. of Michigan, Ann Arbor, MI

Abstract: Intrinsically photosensitive retinal ganglion cells (ipRGCs) transmit light signals to the brain and contribute to non-image forming vision, such as synchronizing circadian rhythms to the light-dark cycle. Our lab recently showed that ipRGCs are resistant to excitotoxic damage and remain functional following N-methyl-D-aspartic acid (NMDA) administration to the retina, in a diurnal rodent, the Nile grass rat (Arvicanthis niloticus). Importantly, whereas non-image forming vision remained functional due to the survivability of ipRGCs, image-forming vision was significantly impaired due to damage to traditional retinal ganglion cells (RGCs). Specifically, RGC damage led to behavioral deficits in the Morris Water Maze, a test that requires rodents to use visual cues in order to find a hidden platform. We hypothesized that brain areas that are critical for image-forming vision in NMDA-treated grass rats would have significantly less neuronal activity than controls. To test this hypothesis, we used cFos, a marker for neuronal cell activation, to visualize neuronal activity in the brains of NMDA-treated grass rats and controls. We predicted that the primary visual cortex (V1), a brain region that is involved in image-forming vision, would exhibit significantly less cFos in NMDA-treated grass rats vs. controls. In contrast, we predicted that the suprachiasmatic nucleus (SCN), intergeniculate leaflet (IGL), and olivary pretectal nucleus (OPT), brain areas that are involved in non-image forming vision, would exhibit no difference in the amount of cFos in NMDA-treated grass rats vs. controls. We found that brain regions that receive projections from ipRGCs and are critically involved in non-image forming vision, such as the SCN, IGL and OPT, did not exhibit a significant change in cFos cells in NMDA-treated grass rats vs. controls. In contrast, V1 expressed significantly less cFos in NMDA-treated grass rats, suggesting that image-forming vision was impaired. Altogether, the present study aims to reveal the functionality of retinorecipient brain regions that are involved in visual functions following excitotoxic injury to RGCs in a diurnal rodent model, the Nile grass rat.

Title: Per1 and c-Fos expression in infralimbic prefrontal cortex (IL) of adult male rats following activation of IL-projecting serotonergic Raphe nucleus neurons at ZT1 or ZT13

Authors: *H. K. STRNAD[1], J. R. RAVENEL[2], S. P. SHARMA[1], M. J. HARTSOCK[3], R. L. SPENCER[1];
[1]Psychology and Neurosci., Univ. of Colorado at Boulder, Boulder, CO; [2]Dept. of Psychology and Neurosci., Univ. of Colorado, Boulder, CO; [3]Univ. of Colorado Boulder, Boulder, CO

Abstract: Circadian rhythms are oscillations in physiology and behavior that optimize organismal function throughout the 24-hour day. Information about daily fluctuations in environmental ambient light is relayed to the suprachiasmatic nucleus (SCN) of the hypothalamus through the retinohypothalamic tract. The SCN aligns its activity to this photic entrainment signal and communicates daily timing information to the rest of the brain and body. However, given a paucity of direct projections from the SCN to extra-hypothalamic brain regions, it is yet unknown how the SCN communicates time of day information to other brain regions. Although glucocorticoid hormone secretion appears to play some role, it is not alone sufficient to drive extra-SCN circadian gene expression independent of SCN activity. Serotonergic neurons from the raphe nucleus (RN) have been shown to be necessary for non-photic entrainment of circadian rhythms, possibly via direct innervation of the SCN. RN neurons project extensively throughout the brain, and serotonin receptor sub-types are localized on a variety of neural cell types (e.g. both pyramidal cells and interneurons). Our lab has previously demonstrated that there is rhythmic clock gene expression in the infralimbic prefrontal cortex (IL), and disruption of IL clock gene expression alters IL-dependent function (conditioned fear extinction learning) (Chun et al, JBR 30:417, 2015; Woodruff et al, eNeuro.0455-18). The current project used Cre-dependent excitatory Designer Receptors Exclusively Activated by Designer Drugs (DREADD) in adult male rats to selectively drive activity of IL-projecting serotonergic neurons of the RN to test whether these inputs contribute time of day information to an extra-SCN brain region. The DREADD activator clozapine-*N*-oxide (5 mg/kg) or vehicle was administered at ZT13 (n = 6-8), approximately one hour before daily peaks in hippocampal and peripheral serotonin levels, or ZT1 (n = 4-7), 12 hours later. Tissue was then extracted and analyzed for changes in *c-Fos* and *Per1* mRNA in the IL via fluorescent and radioactive (S^{35}) *in situ* hybridization.

Title: Indoleamines related to melatonin are secreted from the pineal gland at night and act on melatonin receptors

Authors: *B. LEE[1], D.-S. KOH[1], I. BUSSI[2], H. O. DE LA IGLESIA[2], C. HAGUE[3], B. HILLE[1]; [1]Physiol. and Biophysics, [2]Biol., [3]Pharmacol., Univ. of Washington, Seattle, WA

Abstract: In darkness, melatonin is produced by the pineal gland, a neuroendocrine organ in the brain. Night signals from the retina pass through the suprachiasmatic nucleus (SCN), the master biological clock, and eventually to the superior cervical ganglia, which send postganglionic sympathetic fibers to the pineal that release norepinephrine (NE). Sympathetic NE upregulates the rate-limiting pineal enzyme arylalkylamine N-acetyltransferase (AANAT), which synthesizes N-acetylserotonin (NAS) from serotonin. This precursor is converted to melatonin in one more step. AANAT also converts tryptamine to N-acetyltryptamine (NAT), a structural analog of melatonin. The literature suggests that NAT and NAS are secreted from the pineal gland at night together with melatonin. Do NAT and NAS have similar roles as melatonin? To answer this question, we first tested whether NAT and NAS activate melatonin receptors 1 (MT_1) and 2 (MT_2) using dynamic mass redistribution (DMR), a real-time optical assay. The receptors overexpressed in HEK293 cells were activated by melatonin, NAT, and NAS, but melatonin was more potent than NAT and NAS for both receptors. All effects were blocked by melatonin receptor antagonists. Thus, NAT and NAS are weak partial agonists. We next investigated secretion of the three agonist indoleamines from isolated rat pineal glands with ultra performance liquid chromatography-mass spectrometry (UPLC/MS). NE treatment for 6 hours increased pineal secretion of melatonin, NAT, and NAS by 12, 38, and 41 fold, respectively. Finally, we measured serum levels of the three agonist indoleamines to examine whether NAT and NAS are also night hormones. Serum melatonin increased 32 fold at night, an increase completely abolished after pinealectomy. For NAT and NAS, the basal serum concentrations were already elevated and showed no or weaker circadian rhythms, respectively. The night serum levels of NAT and NAS were several orders of magnitude lower than the EC_{50} for melatonin receptor activation. Taken together, three agonist indoleamines secreted by the pineal gland can activate

melatonin receptors, but in circulating blood only the melatonin concentration is high enough to activate peripheral melatonin receptors. NAT and NAS may still act in a circadian paracrine manner on receptors in or near the pineal gland where they are at higher concentration, or there may be other more sensitive peripheral receptors for them.

Title: Roles for dorsal raphe/periaqueductal gray and retrorubral field dopamine in adaptive fear

Authors: *K. M. WRIGHT, E. LEE, M. A. MCDANNALD;
Dept. of Psychology, Boston Col., Chestnut Hill, MA

Abstract: Fear in the face of certain threat is healthy and adaptive. However, equivalent levels of fear to uncertain threat and certain safety is maladaptive. Disruptions to brain regions underlying successful discrimination of danger and safety may have clinical implications in disordered fear. While considerable research has identified brain regions essential to acquiring fear to certain threats; neural circuits for adaptive fear across a range of uncertain threats are less understood. Dopamine (DA) is widely studied neuromodulator with distinct populations scattered throughout the midbrain. The ventral tegmental area and substantia nigra are canonical sources of midbrain dopamine. Yet many more dopamine populations exist. Here we investigated roles for noncanonical dorsal raphe/ventrolateral periaqueductal gray (vlPAG) and retrorubral field (RRF) dopamine in fear modulation. Male, Long Evans rats were given bilateral 6-hydroxydopamine (6-OHDA) depletions or sham procedures. Following recovery, rats received fear discrimination in which three auditory cues predicted unique foot shock probabilities: danger ($p = 1.00$), uncertainty ($p = 0.25$) and safety ($p = 0.00$). Control rats with DA intact demonstrated excellent discrimination to each of the three cues: high fear to danger, intermediate to uncertainty and low to safety. Depleting vlPAG DA disrupted overall fear discrimination while depleting A8 DA disrupted the temporal emergence of discrimination over cue presentation. The results reveal distinct, but essential roles for vlPAG and RRF DA in adaptive fear.

Title: Dorsal raphe 5-HT updates fear via negative prediction error

Authors: *R. A. WALKER, R. L. SUTHARD, T. PERISON, N. M. SHEEHAN, E. K. ENABULELE, M. H. RAY, A. DILEO, M. A. MCDANNALD;
Boston Col., Chestnut Hill, MA

Abstract: The dorsal raphe nucleus (DRN) contains the largest population of serotonergic neurons in the central nervous system. Serotonin is a widely functioning neuromodulator, but previous research has suggested a possible role for serotonin in fear learning. Here we sought to investigate whether DRN serotonin could be involved in fear updating via prediction error signaling. Using TPH2-cre rats bred on the background of Long-Evans, serotonergic neurons in the DRN were selectively deleted via cre-caspase or labeled with a cre-YFP control fluorophore in experiment 1. Rats underwent 16 sessions of fear discrimination training during which three cues were associated with different probabilities of foot shock: safety p=0.00, uncertainty p=0.375, and danger p=1.00. This task was designed such that it requires the use of prediction errors to demonstrate appropriate fear, specifically for the uncertainty cue. After fear discrimination, rats underwent 8 sessions of selective extinction, during which the uncertainty cue was no longer paired with shock. Results indicated that DRN serotonin is needed to accurately decrease fear to uncertainty during extinction, as rats with serotonin depletion were slower to extinguish fear to the uncertainty cue and did not extinguish to the same extent as YFP controls. In experiment 2, we sought to causally implicate DRN serotonin in prediction error signaling via optogenetics. Again using TPH2-cre rats, cre-dependent halorhodopsin or a cre-YFP control fluorophore was infused into the DRN, and optical ferrules were bilaterally implanted to allow for delivery of 532 nm light. Inhibition of serotonergic neurons was achieved by delivering light at the time of shock omission to the uncertainty cue during selective extinction in order to target the time of negative prediction error. Fear to the uncertainty cue in the halorhodopsin group remained high during the optogenetic manipulation, whereas fear in the control group extinguished normally. Fear to any cue did not change due to light delivery during omission on safety cue trials or during positive prediction error periods for either group, indicating the effects were specific to negative prediction error signaling. Together, experiments

1 and 2 demonstrate a role for DRN serotonergic neurons in fear updating, particularly via negative prediction error signaling.

Title: Cholinergic modulation of learned and innate threat processing

Authors: *P. RAJEBHOSALE[1], L. W. ROLE[2], D. A. TALMAGE[3];
[1]State Univ. of New York At Stony Brook, Stony Brook, NY; [2]Natl. Inst. of Neurolog. Disorders & Stroke, Bethesda, MD; [3]Natl. Inst. of Mental Hlth., Bethesda, MD

Abstract: Threat response behaviors are found virtually in all animal species, and circuits that encode these behaviors in the mammalian brain are evolutionarily conserved. The amygdala, a key region in these circuits, is highly interconnected to various critical nodes in the processing of threat and generation of defensive responses.
The basolateral portion of the amygdala (BLA) is densely innervated by cholinergic axons originating from cholinergic nuclei in the basal forebrain. Neurons in the nucleus basalis/substantia innominata posterior (NBM/SIp) and the ventral pallidum/substantia innominata anterior (VP/SIa) form the major cholinergic input to the BLA, suggesting a potential role for these basal forebrain cholinergic neurons (BFCNs) in the modulation of associative threat processing. In support of this hypothesis we present a few key findings:
We found that in associative threat conditioning, activity of BLA-projecting BFCNs was necessary during both threat acquisition, and retrieval to obtain the typical conditioned response (CR), freezing, as well as activation-induced fos expression in the amygdala. Inhibiting BFCNs of the NBM/SIp only during retrieval was sufficient to ablate the CR, whereas inhibiting VP/SIa BFCNs had no effect on the CR.
NBM/SIp BFCNs were activated during threat memory acquisition and the same neurons were reactivated during memory retrieval. During threat memory retrieval, high responding mice showed greater reactivation of the acquisition-activated pool of cholinergic neurons compared to low responding mice who underwent the same training conditions, or to mice who were not shocked on training day. Thus, the degree of reactivation of these neurons is specific to aversive conditioning and corresponds to the extent of the conditioned response. Based on these

observations we suggest the recruitment of a cholinergic modulatory engram in associative threat memory.
In contrast, during innate threat processing (predator odor exposure), we found that NBM/SIp BFCNs were not activated; however, we observed robust activation of VP/SIa BFCNs, particularly BLA-projecting VP/SIa BFCNs. Inhibition of BLA-projecting BFCNs produced a switch favoring active rather than passive avoidance behaviors.
These results demonstrate the presence of a population of associative threat learning-engraphed cholinergic neurons in the NBM/SI and separate populations in the VP/SI involved in modulating non-associative (innate) threat processing.

Title: A role for the nucleus accumbens core in adaptive fear scaling

Authors: *M. H. RAY[1], A. N. RUSS[1], R. A. WALKER[1], M. A. MCDANNALD[2];
[1]Psychology, [2]Dept. of Psychology, Boston Col., Chestnut Hill, MA

Abstract: Environmental threats exist on a continuum from unlikely to certain. Adaptive behavior requires fear to scale to the level of threat. In two experiments, we determined the role of the nucleus accumbens core (NAcc) in adaptive fear scaling. In experiment 1, male Long Evans rats received bilateral neurotoxic NAcc lesions, permanently ablating NAcc neurons, or sham surgery, leaving NAcc neurons intact. In experiment 2, male Long Evans rats received bilateral NAcc viral infusions of either halorhodopsin (Halo; AAV-hSyn-eNpHR3.0-EYFP) or a control fluorophore (YFP; AAV-hSyn-EYFP) and optical ferrules dorsal to the NAcc. Following recovery, rats were trained to nose poke for food pellets then underwent Pavlovian fear discrimination in which three auditory cues were associated with unique foot shock probabilities: danger ($p = 1.00$), uncertainty ($p = 0.25$), and safety ($p = 0.00$). Fear was measured using suppression of rewarded nose poking. In experiment 1, rats underwent sixteen sessions of Pavlovian fear discrimination. Sham rats acquired excellent fear discrimination, showing high fear to danger, intermediate fear to uncertainty, and low fear to safety. NAcc lesioned rats failed to show the same degree of discrimination, exhibiting decreased fear to danger and increased fear to safety. This pattern was most evident when assessing fear in the first 2-s of cue onset. While shams showed evidence of discrimination in ~600-ms, such discrimination was not

observed in NAcc rats until nearly 2-s. In experiment 2, YFP and Halo rats underwent 10 sessions of Pavlovian fear discrimination, two sessions of cable habituation, and eight sessions of laser illumination. The final eight sessions consisted of alternating two session blocks of cue illumination or ITI illumination (12.5mW – 532 nm light). During habituation and ITI illumination, YFP and Halo rats showed rapid, adaptive discrimination to the three cues. During cue illumination, only YFP rats achieved adaptive fear scaling. NAcc inhibition during cue presentation resulted in increased fear to safety and an inability to discriminate between safety and uncertainty only in Halo rats. Congruent with experiment 1, this pattern was specific to the first 2-s of cue onset. The results demonstrate an integral role for the NAcc in acquisition and expression adaptive fear scaling.

Title: Emotional memory encoding in medial prefrontal cortex: Single unit activity during fear acquisition, extinction, renewal, and sleep

Authors: *M. N. POMPILI[1,2], R. TODOROVA[1], G. MAKDAH[1], E. M. LEROUX[1], T. M. JAY[2], B. P. GODSIL[2], S. I. WIENER[1];
[1]CIRB, Col. De France, Paris, France; [2]IPNP, INSERM U1266, Paris, France

Abstract: A growing literature shows that the medial prefrontal cortex (mPFC) controls fear behavior and modulates emotional memory during fear conditioning and extinction learning. Its sub-regions play distinctive roles, with the dorsal part (dmPFC) implicated in fear expression while the ventral part (vmPFC) modulates fear inhibition and extinction. mPFC immediate early gene expression and synaptic plasticity change in conditioning and extinction learning, suggesting that emotional memory trace storage is controlled there. Recent studies recorded mPFC neurons to characterize the neurophysiological mechanisms underpinning the control of

fear behavior, but the precise neural code to store, retrieve, consolidate, and modulate emotional memory remain obscure. One hypothesis is that the mPFC is a key link in a network forming associations about risky and safe stimuli and contexts. New experiences may modify representations of such emotional valences, and the dorsal and ventral mPFC may have different encoding mechanisms supporting their respective roles in this. However, there is a lack of consensus on these subjects. Moreover, it is unknown whether and how mPFC adapts its coding strategies to support between-days extinction learning and memory consolidation. To answer these questions, we recorded 7866 single units in mPFC in five rats undergoing a 8-15 consecutive days protocol composed of habituation, discriminative auditory fear conditioning, extinction, and within-subject renewal test (ABA scheme) as well as during sleep preceding and following each session (6-8 hours of recording per day). Of these units, 947 were in the anterior cingulate, 702 in medial orbital, 2833 in prelimbic, 1219 in infralimbic, and 465 in dorsal peduncular mPFC sub-regions (up to 257 units recorded simultaneously). Fearful behavior was monitored and quantified with head mounted inertial sensors and multiple cameras. After conditioning, rats increased freezing to both shock-coupled (CS+) and uncoupled (CS-) stimuli and startle reflexes were potentiated. These reactions decreased with extinction training. The analyses characterize the evolution of responses to CS+ and CS- during conditioning, extinction, and renewal in the various regions of mPFC and the differences between rats discriminating and those generalizing their responses to the two stimuli. Moreover, we test whether the reactivation of these units during sleep correlates with memory consolidation. These results will permit a better understanding of mPFC neural coding strategies that support emotional memory.

Title: Somatostatin neurons in the bed nucleus of stria terminalis enhance auditory fear memory formation

Authors: ***B. BRUZSIK**[1], L. BIRO[1], H. SZEBIK[1], K. R. SAROSDI[1], H. ORSOLYA[1], E. SIPOS[2], D. ZELENA[2], V. CSILLAG[3], I. FARKAS[3], E. MIKICS[1], M. TOTH[1];

Abstract: The bed nucleus of stria terminalis (BNST) mediates defensive behaviors to various threats and accordingly hyperactivation of this region is a common phenomenon of anxiety disorders. The involvement of BNST in learned fear responses is less clear, although its anatomical connectivity suggests a potential role in conditioned fear responses. BNST consists of mainly GABAergic neurons (vGAT+) expressing different neuropeptides such as corticotropin-releasing factor (CRF+) and somatostatin (SOM+). These neurons project to various brain regions involved in Pavlovian fear conditioning and anxiety, but it is still unknown how these cells modulate conditioned fear responses. Here, we used chemogenetics to modulate neuronal activity in the BNST during fear memory consolidation. Stimulation of BNST neurons in male vGAT-cre mice selectively impaired fear extinction in conjunction with increased fear recall in safe context (generalization) without affecting freezing in the shock context. Modulation of vGAT neurons in the open field test and predator odor avoidance also confirmed their anxiogenic properties. Activation of SOM+ neurons during fear memory consolidation similarly enhanced cue-dependent fear recall in the safe context. Intriguingly, chemogenetic modulation of CRF+ neurons had no effect on fear recall and anxiety-related behavior. Chemogenetic modulation of the above mentioned cell populations during extinction training had limited effect on freezing response. Our data underlines the importance of anxiety circuits in maladaptive fear memory formation, indicating elevated BNST activity as a potential vulnerability factor to trauma related anxiety disorders.

Title: The fearless paradox

Authors: *T. D. LAPOINTE, M. WOLTER, F. LERI;
Univ. of Guelph, Guelph, ON, Canada

Abstract: Negative reinforcement is said to occur when a response is maintained by the avoidance of an aversive event (unconditioned stimulus such as pain; US). An avoidance response is typically activated by a warning signal (conditioned stimulus; CS) that subjects respond to in order to avoid an aversive stress state. However, observations of subjects trained on two-way signaled active avoidance (SigAA) have indicated that the negative stress reaction produced by the CS dissipates during training. So then, what maintains avoidance behaviour? The goal of the current research was to explore this so called "fearless paradox." Separate groups of male Sprague-Dawley rats were trained for 6 days on SigAA using different foot-shock intensities (0, 0.2, 0.4 and 0.8 mA, n=9 each) and tested for stress-induced analgesia immediately after SigAA sessions. After a 3-day pause, avoidance was re-tested for two consecutive days (7 & 8), and on day 9, the session occurred in the absence of foot-shock. It was found that learning to avoid foot-shock was associated with reduced hot-plate latencies. As well, exposure to the CS in the absence of foot-shock produced significant stress-induced analgesia only in animals that did not acquire the avoidance response. Overall, this study confirms that once learned, avoidance behaviour is not dependent on stress reduction.

Title: NinaA: A novel mediator of pain memory in *drosophila melanogaster*

Authors: *A. CROCKER, G. PIL, K. SARIKAYA, J. MARRIOTT, E. VINTON, K. TABER; Middlebury Col., Middlebury, VT

Abstract: The detection, learning, and recall of pain is crucial to all animals' survival. Dysregulation of these functions can contribute to a number of anxiety disorders. Here we characterize the role of the *NinaA* gene which appears to play a part in painful memory formation and stress behavior in the fly. *NinaA* is known to be important for trafficking Rhodopsin 1 (Rh1) out of the ER in the eye. *Rh1* is also involved in temperature preference. However, our data suggests that the actions of NinaA are independent of *Rh1*. Previously we found that the *NinaA* gene is down-regulated following memory formation. Flies carrying a mutation in the *NinaA* gene fail to form longterm, aversive odor memories. Our preliminary data suggest that these flies fail to centrally integrate the aversive nature of electric shock. This deficit is also seen when trained with noxious heat. Our data suggests that *NinaA* animals generate a stress response to

noxious stimuli, as measured by an increase in wall following behavior, but once that noxious stimuli is removed, the heightened stress response ends. This is in contrast to wild type flies who show enhanced stress responses for at least 10 minutes following painful stimuli exposure. We hypothesize that this failure to maintain a normal stress response to painful stimuli reduces their capacity to maintain long-term memories. We also hypothesize that this is mediated through the DAL neuron. The DAL neuron is important for stress behavior in the fly. Further characterization of both the *NinaA* gene and the DAL neuron will shed light on the role ancient stress pathways play in memory formation in the fly.

Title: Deletion of the prion like domain of CPEB2 in mice impairs long-term memory of one-trial inhibitory avoidance

Authors: *M. L. HUFF[1], B. A. EBNER[2], K. SI[3];
[1]Stowers Inst. For Med. Res., Kansas City, MO; [2]Univ. of Kansas Med. Ctr., Kansas City, KS; [3]Stowers Inst. for Med. Res., Kansas City, MO

Abstract: Memories can last for hours or even years in humans, yet the molecular basis of this memory persistence is still not fully understood. Previous work revealed the specific isoform of neuronal RNA binding protein cytoplasmic polyadenylation element binding protein (CPEB) is required specifically for the persistence of memory in Drosophila. This memory stabilization relies on CPEB's self-sustaining amyloidogenic (prion-like) properties. In mouse and in human two CPEB variants, CPEB3 and CPEB2, have similar properties to Drosophila CPEB. Here we report the consequence of removal of CEPB2 prion-like domain in long-term memory consolidation and stabilization in mice. Wildtype (B6/J) and homozygous prion-like domain deletion ($PD^{-/-}$) littermates were trained on one-trial inhibitory avoidance. On training day, mice received a single, inescapable footshock (0.5mA, 1s) upon fully stepping through from the illuminated to the darkened compartment. Retention was tested days or weeks later and latency to cross from the illuminated to darkened "shock" compartment was recorded. Separate groups of animals were tested at 30 min and 3 h post-footshock to assess short-term memory. Long-term

memory was also tested using an object location task (retention tested at 24 h) and classical fear conditioning (single 1.5mA, 2s footshock; test at 24h). Anxiety was measured in an elevated plus maze. Sessions were recorded and analyzed using EthoVision software. During inhibitory avoidance testing, $PD^{-/-}$ animals show reduced retention latencies compared to matched wildtypes when trained at 1, 3, or 6 months of age. This impairment persisted when retention was repeatedly tested up to 2 months after training. Retention latencies of $PD^{-/-}$ animals at 30 min or 3 h post-training were also decreased compared to wildtype littermates. There was no significant difference in freezing between wildtype and $PD^{-/-}$ animals in classical fear conditioning and no significant difference in the object location task. $PD^{-/-}$ mice enter the open arms more often and spend cumulative time in the open arms of the EPM suggesting reduced basal anxiety. Together, these findings suggest that lack of the CPEB2 prion-like domain disrupts learning and memory. Future studies will examine the temporal nature of CPEB2 effects on learning and memory using conditional $PD^{-/-}$ animals.

Title: Effects of the partial NMDAR agonist D-cycloserine on the acquisition of discriminative safety learning and fear extinction

Authors: *A. ESCOBEDO[1], C. H. L. LEE[2], E. M. SOWINSKI[2], R. HERAKOVICH[2], S. SANGHA[1];

Abstract: Individuals suffering from posttraumatic stress disorder (PTSD) have difficulty maintaining reduced fear levels after extinction-based therapies, as well as reducing fear levels in response to explicit safety cues. Prior research has shown that the partial NMDA receptor agonist, D-Cycloserine (DCS), can facilitate the acquisition and consolidation of fear extinction in humans and rodents. However, it is unclear if this facilitation is limited to non-discriminative fear paradigms, where the subject first learns to fear a cue which is then later extinguished, or if it can also facilitate discrimination between a fear cue and a safety cue. The present study examined the effects of DCS in adult male Long Evans rats during a fear, safety, and reward cue discrimination conditioning task, as well as its effect on subsequent fear extinction. We

hypothesized that DCS would facilitate discrimination learning between a fear cue paired with shock and a combined fear+safety cue presented without a footshock, and this facilitated discrimination would then facilitate subsequent fear extinction. DCS (30.0 mg/kg i.p) was administered during each discrimination learning session, which resulted in marginally greater fear inhibition during the fear+safety cue versus the fear cue; however, this improved discrimination did not facilitate subsequent drug-free fear extinction. In a separate group we tested the hypothesis that DCS would facilitate the acquisition and consolidation of fear extinction in non-discriminative fear learning based on prior research. After fear conditioning to a single fear cue, DCS was administered either directly before fear extinction or directly after, to assess its effect on acquisition versus consolidation. In neither case did we see improved extinction retention one day later. Together, our data indicate that DCS provides mild improvement on inhibiting fear in the presence of a safety cue, but that it does not facilitate the acquisition or consolidation of non-discriminative fear extinction.

Title: Sex dependent influence of gut dysbiosis on defensive behaviors and basolateral amygdala dendritic morphology

Authors: V. WILK, C. GEARY, K. BARTON, P. JEFFERSON, S. ROZENTAL, ***A. L. MOUSLEY**, C. BAKER, D. ESTEBAN, H. BERGSTROM;
Dept. of Psychological Sci., Vassar Col., Poughkeepsie, NY

Abstract: It is now well understood that imbalances in the gut microbiome influence brain function and behavior. Less studied are sex-dependent effects of gut microbiome dysbiosis on defensive behaviors. To determine whether antimicrobial (ATM)-induced gut dysbiosis modulates anxiety-like behaviors and auditory cued fear conditioning, male and female adult (PN70+) C57BL/6N mice voluntarily consumed a non-absorbable ATM cocktail (1.2 mg/mL neomycin, 2 mg/mL bacitracin, and 1.2 µg/mL pimaricin) or tap water control over a 10-day period. Open field behavior, auditory cued fear conditioning, contextual recall and cued recall were tested on days 5-10 of the ATM treatment. Results revealed a significant ATM-induced decrease in anxiety-like behavior in the open field of male (n=20/treatment group), but not female (n=20/treatment group) mice. While there were no effects of ATM treatment on fear conditioning or context fear recall, cued fear memory recall was impaired in female, but not male

mice. Together these data suggest the gut microbiota exerts a sex-dependent influence on anxiety-like behavior and the consolidation of auditory cued fear memory. Considering the essential role for the basolateral amygdala (BLA) in cued fear memory consolidation, studies are underway examining the structure of BLA principal neuron dendritic morphology following ATM-induced gut microbiome dysbiosis in male and female mice. We are also exploring the effects of microbiome dysbiosis on microbiome diversity. DNA extractions will be sequenced for taxonomic identification and relative quantification of bacteria.

Title: Binge alcohol consumption impairs fear extinction retrieval in adolescent C57BL/6N mice

Authors: M. SCARLATA, K. LAWSON, J. BEZEK, A. MOUSLEY, L. LICHTY, C. CHO, C. MANGAN, ***H. C. BERGSTROM**;
Psychological Sci., Vassar Col., Poughkeepsie, NY

Abstract: Deficits in fear extinction recall are thought to contribute to the development of post-traumatic stress disorder (PTSD). Those with PTSD often drink alcohol and drinking tends to increase after trauma exposure. Despite the high co-occurrence of PTSD and alcohol use, the neurobehavioral impact of alcohol on the retrieval of established fear extinction memory is understudied. We recently showed that alcohol impaired extinction retrieval in adult male C57BL/6N mice (Scarlata et al., 2019). An outstanding question is the impact of alcohol on fear extinction retrieval in adolescent and female mice. The primary objective of this research is to study the age- and sex-related neurobehavioral impact of voluntary EtOH exposure on fear extinction memory retrieval. Male and female C57BL/6N mice underwent auditory cued fear conditioning and extinction between postnatal (PN) days 36-40 (mid-adolescent) and PN70+ (adult). Thirty-six hours later, mice were placed in a social “Drinking-in-the-Dark” (sDID) paradigm for 5 consecutive days. In this novel DID procedure, pair housed mice are permitted olfactory, auditory, visual and tactile interactions through perforated dividers while presented with a two-hour exposure to EtOH (20% v/v solution) or tap water three-hours into the natural dark cycle. Seventy-two hours following EtOH or water exposure, mice were tested for fear memory extinction retrieval, contextual renewal, and spontaneous recovery (30 days following extinction training). In adolescent mice, there was greater freezing in the EtOH group relative to controls, indicating impaired extinction retrieval. There were no differences in contextual

renewal, confirming previous findings. Work is currently underway characterizing the adult group. EtOH-induced neuroadaptations following fear extinction retrieval will be identified by mapping neuronal activity across a corticolimbic network using Arc/arg3.1 immunohistochemistry.

Title: The role of the inflammatory response on the aversive learning

Authors: *G. F. ANTUNES, F. VENETUCCI, M. A. KUROKI, C. C. DE OLIVEIRA, L. C. T. DOS SANTOS, M. D. D. SENO, A. P. CAMPOS, R. D. PAGANO, R. C. R. MARTINEZ; Inst. Sirio Libanês De Ensino E Pesquisa, São Paulo, Brazil

Abstract: Impairments in learning, memory and cognitive functions have been suggested to be mediated by inflammatory response, which could be mostly attributed to glial cells. In the two way active avoidance test, two distinct subpopulations are identified based on the number of avoidance responses, the good and poor performers. The goal of our project was to investigate the correlation between glial activation, cytokine release and avoidance response. For that, we evaluated the inflammatory profile of good and poor performers in the prefrontal cortex, hypocampus and amygdala. Our data showed that in the prefrontal cortex, there was a reduction in the levels of IL-1 beta ($F_{(2.45)}$=3.58; P<0.05, followed by Newman-Keuls post hoc test), TNF-alfa ($F_{(2.45)}$=26.48; P<0.001, followed by Newman-Keuls post hoc test) and CINC-1 ($F_{(2.45)}$=17.48; P<0.0010, followed by Newman-Keuls post hoc test) in the good and poor performers in comparison with control animals. The good performers showed higher levels of IL-6 ($F_{(2.45)}$=17.86; P<0.001, followed by Newman-Keuls post hoc test), in comparation with the other groups. The poor performers showed reduction in levels of IL-10 ($F_{(2.45)}$=8.89; P<0.001, followed by Newman-Keuls post hoc test) in comparison with the other groups. The good performers showed higher levels of IL-17 in comparation with poor performers ($F_{(2.45)}$=3.90; P<0.05, followed by Newman-Keuls post hoc test).
In the hippocampus, there was no statistical difference among the groups considering the levels of IL-1 beta ($F_{(2.45)}$=3.23; P>0.05); TNF-alfa ($F_{(2.45)}$=2.39; P>0.05); CINC ($F_{(2.45)}$=1.04; P>0.05); IL-6 ($F_{(2.45)}$=1.06; P>0.05); IL-10 ($F_{(2.45)}$=1.88; P>0.05) and IL-17 ($F_{(2.45)}$=2.55; P>0.05). In the amygdala, good performers showed higher levels of IL-1beta ($F_{(2.45)}$=14.99; P<0.05, followed by Newman-Keuls post hoc test); TNF- alfa ($F_{(2.45)}$=14.00; P<0.05, followed by Newman-Keuls

post hoc test) in comparison with poor performers group. There was no statistical differences considering the levels of CINC-1 ($F_{(2.45)}$=1.63; P>0.05); IL- 6 ($F_{(2.45)}$=0.74; P>0.05); IL-10 $F_{(2.45)}$=0.16; P>0.05) and IL-17 ($F_{(2.45)}$=3.04; P>0.05). The main contributions of our work is to better understand the role of glial cells in the aversive learning and contribute to the development of other therapeutic approaches for cognitive dysfunction.

Title: Stress-induced impairments in fear learning are causally related to increased kynurenic acid formation in the prefrontal cortex

Authors: *A. D. KLAUSING[1], D. J. BUCCI[2], R. SCHWARCZ[1];
[1]Dept. of Psychiatry, MPRC, Univ. of Maryland Sch. of Med., Baltimore, MD; [2]Dept. of Psychological and Brain Sci., Dartmouth Col., Hanover, NH

Abstract: Severe and/or prolonged stress has many detrimental effects and often causes cognitive impairments. Experimental manipulation of kynurenic acid (KYNA) affects learning and memory in animals. However, the link between a stress-induced change in KYNA and a change in cognitive function has yet to be explored. Here we examined whether acute stress increases KYNA levels in the brain and, specifically, if a stress-induced increase in KYNA is causally related to impairments in fear learning. Adult male Sprague-Dawley rats (250-300 g) were tested using three different acute stress models (restraint, exposure to fox urine, or inescapable shocks). Extracellular KYNA levels were determined in the prefrontal cortex by *in vivo* microdialysis (n = 6/group). In rats that received inescapable shocks, extracellular KYNA levels were increased by ~85%. The other two stressors were much less effective (<25% change in KYNA levels compared to baseline). Another cohort of rats (n = 8/group) underwent a fear discrimination procedure immediately after the termination of stress. During training, rats were exposed to two different auditory tones - one paired with a foot shock (CS+) and the other unpaired (CS-). One week later, rats were tested for freezing behavior during re-exposure to both auditory stimuli in a novel context without any shocks delivered. Only rats receiving inescapable

shocks were unable to discriminate between CS+ and CS-. All other groups exhibited greater freezing to CS+ than to CS-. To further examine the impact of KYNA manipulation on behavior, a separate group of animals received a s.c. injection of the irreversible KYNA synthesis (kynurenine aminotransferase II) inhibitor PF-04859989 1 h before initiation of the stress challenge. Application of the KYNA synthesis inhibitor blocked the stress-induced KYNA increase (n = 6-7/group) and normalized the impairment in fear discrimination (n = 12-17/group) in rats that received inescapable shocks. Taken together, these findings indicate a causal relationship between a stress-induced KYNA increase and fear learning impairments. Pharmacological inhibition of KYNA synthesis may therefore be a therapeutic option for treating cognitive dysfunctions in stress-related disorders. (see also Cochran et al., this meeting)

Title: Elevation of kynurenic acid levels impairs the renewal of conditioned fear

Authors: K. B. COCHRAN, M. C. EDDY, M. P. SATURNO, *D. J. BUCCI;
Psychological and Brain Sci., Dartmouth Col., Hanover, NH

Abstract: Kynurenic Acid (KYNA), a product of tryptophan degradation by astroglia, is an antagonist of both NMDA glutamate and alpha-7 nicotinic acetylcholine receptors, both of which are critically involved in fear learning and memory. Recently, we have shown that stress can increase the concentration of KYNA in the prefrontal cortex of rats, causing the generalization of fear to otherwise innocuous stimuli (see Klausing et al, this meeting). The present study extends this work by testing the effects of increased KYNA concentration on the extinction and renewal of conditioned fear. Twenty-four rats received a single session of fear conditioning during which a tone was paired with foot shock in a standard conditioning chamber (Context A). Rats were then divided into three groups (8/group) matched for the levels of freezing behavior observed during the conditioning session. During the next four daily sessions, fear to the tone was extinguished by presenting the tone without foot shock in a different chamber (Context B). Two hours before each of the extinction sessions, the Control and L-KYN REN groups were injected with a vehicle solution and the third group, L-KYN EXT/REN, received an injection of 100mg/kg L-KYN, the precursor of KYNA, to elevate KYNA concentration. Finally, fear to the tone was tested by re-exposing rats to the tone in Contexts A and B. The Control group again

received vehicle treatment before the test sessions, and groups L-KYN REN and L-KYN EXT/REN received L-KYN two hours before the test sessions. As is typically observed, rats in the control group exhibited significantly less fear to the tone in Context B compared to Context A, reflecting the canonical 'renewal' of fear when the extinguished cue is encountered in a context other than the extinction context. Rats in the L-KYN EXT/REN and L-KYN REN groups exhibited a diminished renewal effect. In a prior study, we found that injections of L-KYN during extinction alone also decreased renewal. A subsequent context fear reacquisition session showed that this was not simply due to a KYNA-induced inability to distinguish between the two contexts. Together with the present findings, these data suggest that elevated KYNA levels impair the ability to use contextual information to guide appropriate behavior to fear-conditioned cues. This may have implications for understanding altered fear renewal that is observed in persons with anxiety-related disorders such as PTSD.

Title: Parametric modulators of active conditioned fear responding

Authors: S. S. WASIELEWSKI, M. FANIKOS, E. GOLDEN, *R. M. S. SHANSKY; Northeastern Univ., Boston, MA

Abstract: Post-traumatic stress disorder is twice as likely to develop in women than in men. However, the neurobiological mechanisms underlying this difference are mostly unknown, as conditioned fear responses have traditionally been studied in only male subjects. We have previously shown that darting behavior, an active conditioned fear response, is preferentially utilized by female subjects, but we do not know how the experimental parameters of a fear conditioning protocol influence the prevalence of darting. One possible explanation for this sex difference is that the larger size of males prevents them from engaging active responding in standard testing chambers, so in the first experiment, we examined darting as a factor of space by performing a conditioned fear memory retrieval test in an open field arena. Female and male Sprague Dawley rats underwent a 2-day auditory fear conditioning paradigm. Day 1 presented 5 habituation CS and 7 CS-US pairs inside a typical fear conditioning chamber. On day 2, the subjects were placed in either a large open field arena or a smaller open field insert that was the size of the day 1 fear conditioning chamber. The subjects were then presented with 7 CSs. Darting, freezing, rearing, and grooming were quantified using a combination of automated and

experimenter-observed scoring. We then performed immunohistochemistry for c-fos expression in the prefrontal cortex, periaqueductal gray, basolateral amygdala, and ventral hippocampus. Animals in the open field exhibited more darting than in the smaller space, but females exhibited darting at a 3-fold rate compared to males, suggesting that even with ample room in which to engage escape behavior, darting is still a predominantly female response. In experiment 2, we examined darting as a factor of shock intensity. Male and female rats underwent auditory fear conditioning using either 0.3 or 0.5 mA shock USs. Regardless of shock intensity, darting was observed in approximately 3-4 times as many females as males. In addition, we observed an escalation in response to the shock itself in females but not males, suggesting that shock perception may underlie sex differences in associated fear processing.

Title: Sex specific reversal of context generalization in cued fear conditioning by TRPV1 antagonist

Authors: *M. MEJDELL[1], A. WINTER[1], J. COLOM-LAPETINA[3], M. MORENA[4], A. S. NASTASE[4], M. N. HILL[5], R. SHANSKY[2];

Abstract: Experiencing a traumatic event is twice as likely to cause post-traumatic stress disorder in women as it is in men. Despite this imbalance, the majority of the literature on neural mechanisms that underlie PTSD comes from research in male model animals. The endocannabinoid (eCB) system, which is involved in modulating the stress response, is just beginning to be understood as potentially sexually dimorphic system. A better understanding of sex differences in these processes is critical to progress in developing more personalized therapies for PTSD patients of both sexes. To explore the influence of eCB interactions on fear learning and memory processes, male and female rats were tested in a standard cued fear conditioning and extinction paradigm, after systemic administration of either CB1 receptor antagonist AM251, coupled AM251 with a TRPV1 antagonist Capsazepine, or vehicle. We measured baseline and cue-elicited freezing in all animals, finding that AM251 during fear

conditioning elicited enhanced context generalization the following day and impaired extinction in females only. Capsazepine caused a reversal of this generalization effect and improved extinction in females with no effect in males. Using mass spectrometry, we evaluated anandamide levels immediately post-fear conditioning in the hippocampus, prefrontal cortex, and amygdala in a separate cohort of male and female rats, and found a female-specific increase in hippocampal anandamide. These results demonstrate sex differences in the neural mechanisms related to memory processes and associative learning, and point to a specific role for the endocannabinoid system in modulating context processing in the female brain.

Title: Sex differences in contextual fear learning and generalization

Authors: *J. M. TROTT, R. ADISON, M. S. FANSELOW;
Psychology, UCLA, Los Angeles, CA

Abstract: Contextual fear learning can be used to study the acquisition and generalization of a fear memory. Therefore, it is a useful model to study learning processes relevant to healthy functioning and mental illness, particularly those related to anxiety disorders. Contextual fear generalization is especially relevant to anxiety disorders, which are often defined by expressing fear and/or anxiety in safe contexts. Anxiety disorders are sexually dimorphic with regard to occurrence and severity of episodes such that females tend to experience more frequent and more severe episodes. Presented here are a series of experiments examining contextual fear learning in male and female rats, with a focus on generalization. With some variation, these experiments use a 3-day procedure in which Day 1 consists of pre-exposure to the to-be-shocked context, Day 2 consists of a single context-shock pairing, and Day 3 consists of testing in either the same or a novel environment. Increasing the amount of pre-exposure on Day 1 or time before shock (placement-to-shock-interval; PSI) on Day 2 both lead to enhanced conditioning. It is unknown if these periods use the same process such that they are simply additive or if there are different processes underlying the learning during each period. Historically, male rats tend to show greater contextual fear than females at low PSI's, and this effect can be abolished by a sufficiently long

pre-exposure session. Thus, for these experiments, relatively short pre-exposure and PSI's are used to determine any sex differences in fear learning. With longer pre-exposure periods, female rats show greater contextual fear and more evidence of discrimination. With shorter pre-exposure periods, male rats show more contextual fear and evidence of discrimination, consistent with previous literature. Pre-exposure to a non-shocked safe context prior to conditioning abolished these effects, but did result in increased variability, consistent with the BACON model. The BACON model is a conceptual and computational model of hippocampal contextual learning. One of the major suggestions of the model is that the hippocampus can have two functional modes, one for building a contextual representation (which would mostly happen during pre-exposure) and one for retrieving that representation, prior to shock for example (which would happen during Day 2's PSI). It was found that pre-exposure timing and PSI timing were not equivalent to each other. Animals with 120s of pre-exposure and a 30s PSI show a differential level and time-course of fear expression than animals who received 30s of pre-exposure and a 120s PSI, and this further depended on sex and strain of the rat.

Title: Influences of stress severity and sex on changes in fear learning, anxiety and alcohol consumption following stress exposure

Authors: *S. T. GONZALEZ[1], V. MARTY[2], S. LELE[2], R. VO[2], I. YENOKIAN[2], C. Q. YANG[1], K. AHMED[1], I. SPIGELMAN[2], M. S. FANSELOW[1];
[1]Psychology, [2]Div. of Oral Biology, Sch. of Dent., Univ. of California Los Angeles, Los Angeles, CA

Abstract: Post-traumatic stress disorder (PTSD) develops after exposure to traumatic events and can involve an exaggerated fear response to stimuli that are reminiscent of the original stressor. In addition, PTSD is frequently co-morbid with other disorders including substance abuse. However, not all individuals who experience trauma develop PTSD and the factors that promote

susceptibility versus resilience to the effects of stress are poorly understood, although the disorder occurs more commonly in women than in men. To understand these aspects of the disorder our laboratory has developed a model of stress exposure termed stress-enhanced fear learning (SEFL) that captures many of these features. In this model, exposure to a traumatic stressor (either 4 or 15 unsignalled footshocks) in one context sensitizes fear learning to a mild stressor (1 unsignalled footshock) in a second context. In this study we investigated the extent to which the SEFL model captures the heterogeneity of PTSD and identified potential predictors of susceptibility versus resilience to the effects of stress. In this study both male and female rats received assessments of anxiety and alcohol consumption prior to traumatic stress exposure, and a battery of fear learning, anxiety and alcohol consumption tests following stress exposure. We found that while males and females did not differ on most measures of fear learning following stress, males showed elevated anxiety relative to females. In addition, we found evidence of distinct "susceptible" and "resilient" populations that showed a constellation of behavioral changes relating to fear learning, anxiety and fear extinction. Lastly, we found that baseline levels of anxiety were uniquely predictive of susceptibility to the effects of stress in females, but not in males. These results indicate that the SEFL model is a powerful tool for probing the behavioral and biological factors that promote susceptibility versus resilience to the effects of stress.

Title: Extinction in a Bayesian model of context fear conditioning, with possible implications for exposure therapy

Authors: *F. B. KRASNE, M. S. FANSELOW;
Dept Psychol, UCLA, Los Angeles, CA

Abstract: BACON (Krasne et al, 2015), is a neuro-computational model of context fear conditioning in which contextual representations are formed in the hippocampus and association of fear to them occurs in the amygdala. Representation creation and updating (association of additional contextual attributes on future occasions), as well as fear conditionability and

expression in amygdala, are controlled by degree of confidence that a currently active representation really is that of the current context. Confidence is assessed by the Bayesian Weight of Evidence of representation validity (Brep), computed by comparing currently observed with recalled attributes. The model provides plausible explanations for aspects of context fear conditioning such as the immediate shock deficit, slow onset of conditioned fear, and false conditioning, and also rationalizes seemingly discrepant findings on the role of dentate in recall (Bernier et al, 2017). Here we add extinction to the model (BaconX) by assuming that non-reinforced fear causes inhibition to be conditioned to the same representations that evoke fear. Extinction consolidates only if BaconX is confident that a non-reinforced place is actually where conditioning occurred. These assumptions lead to several interesting design features and predictions; among them: (1) Extinction-causing inhibition must be applied downstream of the conditioning locus (cf. Herry et al 2008, Extinction neurons). (2) Extinction carried out in the conditioning context generalizes better than extinction in a different ("surrogate") context (as done in exposure therapy) (see Fig, I & II). (3) In a novel surrogate context (eg. a virtual reality simulator), the representation of the conditioning context itself will always be activated if sessions are kept too short for a representation of the surrogate context to be created. Therefore extinction will generalize much better than if established in long exposure therapy sessions where a representation of the therapy context would get created.

Title: Dissociation of fear initiation and maintenance by breathing-driven prefrontal oscillations

Authors: *S. BAGUR[1], J. M. LEFORT[1], M. M. LACROIX[1], G. DE LAVILLÉON[1], C. HERRY[2], M. CHOUVAEFF[1], C. BILLAND[1], H. GEOFFROY[1], K. BENCHENANE[1]; [1]MOBs Team, Lab. Abstract: During emotional states, the body undergoes multiple changes which have been suggested to feedback to the brain to influence neural processing. Herewe report that in mice very regular 4Hz breathing mediates such a bodily feedback during fear-related freezing behavior. Both surgical ablation and optogenetic perturbation of the olfactory bulb, the key relay structure for the respiratory related 4Hz oscillation, decrease time spent freezing. More importantly, using probabilistic modelling of behaviour, we show that the two manipulations specifically reduce freezing maintenance without impacting its initiation, dissociating these two phenomena. Finally we show that this oscillation is transmitted to the prefrontal cortex where it organizes neural firing and optogenetic probing of the circuit demonstrates frequency-specific tuning that maximizes prefrontal cortex responsivity at 4Hz, the breathing frequency during freezing. These results point to a brain-body-brain loop in which the initiation of emotional behavior engenders somatic changes which then feedback to the cortex to directly participate in sustaining emotional states.

Title: Temporally specific dopaminergic control of reward-conditioned movements

Authors: *K. LEE[1], L. D. CLAAR[2], K. I. BAKHURIN[3], A. HACHISUKA[1], S. C. MASMANIDIS[1];
[1]Neurobio., UCLA, Los Angeles, CA; [2]Allen Inst. for Brain Sci., Seattle, WA; [3]Duke Univ., Durham, NC

Abstract: Midbrain dopamine (DA) neurons encode both reward and movement-related events, and are implicated in disorders of reward processing as well as movement. However, disentangling the contribution of DA neurons in reinforcing versus generating movements is challenging and has led to lasting controversy. We dissociated these functions in mice trained on a Pavlovian trace conditioning task, in which presentation of an olfactory cue frequently elicited a conditioned response in the form of anticipatory licking that began prior to reward delivery. In this task, movement generation and reinforcement signals occur at distinct time periods (pre- and post-reward, respectively), and can thus be disentangled with temporally precise optogenetic manipulations. To test the contribution of DA neurons to these processes we virally expressed eNpHR3.0 in lateral ventral tegmental area (VTA) DA neurons (n = 14 eNpHR3.0 and 14 YFP DAT-Cre mice, including medial regions of substantia nigra pars compacta, SNc). We examined behavioral performance across multiple test sessions representing different time periods of optogenetic stimulation. Each session was comprised of three blocks of 40 trials, with the laser activated in the second block. Continuously inhibiting DA neurons for 2 s immediately after reward delivery significantly reduced the probability of anticipatory licking, and this deficit was reversed when the optical stimulation was removed. However, inhibiting neurons for 4 s prior to reward (i.e., in the time period coinciding with cue presentation and the onset of anticipatory licking) had a comparatively smaller effect on licking. A similar bias toward the post-reward period was found for DA neurons in the lateral SNc (n = 9 eNpHR3.0 DAT-Cre mice). In contrast, inhibiting the secondary motor cortex (n = 9 eNpHR3.0 mice) produced a significantly greater effect on behavior in the pre-reward as opposed to the post-reward period. To further deconstruct the behavioral role of post-reward DA signals, we parametrically delayed the timing

(0, 0.25, 0.5, 1 s) of inhibitory optical stimuli relative to the reward (n = 10 eNpHR3.0 and 11 YFP mice). Additionally we performed optogenetic activation of DA neurons during an extinction test (n = 10 Chrimson and 8 YFP DAT-Cre mice). We found that DA activity within about one second of the expected reward time is both necessary and sufficient to sustain conditioned responses on future trials. Together, the results indicate a temporally restricted role of DA neurons primarily related to reinforcing stimulus-reward associations, and suggest that directly generating movements is a comparatively less important function.

Title: Does baldness of attractive male decrease his external and internal power to fascinate female in mice?

Authors: *Y. N. OHNISHI, Y. KAWAHARA, Y. H. OHNISHI, A. NISHI;
Dept. of Pharmacol., Kurume Univ. Sch. of Med., Kurume, Japan

Abstract: Baldness is one of fearful aging phenomenon for men. Complete baldness sometimes enhances masculinity, but partial baldness is believed to decrease sexual attractiveness in most cases. We have previously presented that attractiveness of male mice to female mice is dependent on their appearance and self-confidence, not smell nor voice (SfN 2017, SfN 2018). In those experiments, we used behavior-based measurement with video camera tracking system for female movement in big white box, in which four littermate male mice were placed in four jail transparent boxes set on the corner one by one. The female mouse was allowed to move freely in the big box for 20 minutes. We summed up the total time around each male box for the last ten minutes as preference behavior. Surprisingly, attractive and/or un-attractive male mice were existed despite the same genetic background, suggesting that female mice have a common preference for male attractiveness. This trend of preference disappeared by hiding male mice with four-layered air-permeable filter. Furthermore, genetically blind female mice showed

completely different trend of preference against the same male mice set, indicating that appearance may be one of major factors of male attractiveness. In this report, we focus on the importance of hair appearance. We examined whether hair-cut and whisker trimming of attractive male mouse can affect his attractiveness to female mice. Additionally, we will perform in vivo microdialysis analyses under the experimental conditions, because dopamine levels in the nucleus accumbens of female mice responded to attractive male mice, but not to un-attractive male mice. As internal factor, self-confidence for male attractiveness also seemed to be important as well as external factor like appearance. Because we detected that harem situation of un-attractive male mouse didn't enhance his attractiveness, but isolated situation of attractive male mouse with watching the harem condition of un-attractive male mouse overnight decreased his attractiveness, we will try to examine the effect of the combination of above isolated situation and hair-cut with whisker trimming on his attractiveness. These experiments will reveal preference nature and mesolimbic dopamine reaction of female mice against male attractiveness, and the importance of self-confidence of male mice for male attractiveness.

Title: Stress transforms lateral habenula reward responses into punishment signals

Authors: *S. SHABEL[1], C. WANG[2], B. MONK[3], S. ARONSON[3], R. MALINOW[4];
[1]UT Southwestern Med. Ctr., Dallas, TX; [2]UCSF, San Francisco, CA; [3]UC San Diego, La Jolla, CA; [4]Neurosciences and Biol., UCSD, La Jolla, CA

Abstract: Neuronal activity in the lateral habenula (LHb), a brain region implicated in depression [Proulx CD, Hikosaka O, & Malinow R (2014) Nat Neurosci 17(9):1146-1152], decreases during reward and increases during punishment or reward omission [Matsumoto M & Hikosaka O (2007) Nature 447(7148):1111-1115]. While stress is a major risk factor for depression and strongly impacts the LHb, its effect on LHb reward signals is unknown. Here we image LHb neuronal activity in behaving mice and find that acute stress transforms LHb reward responses into punishment-like neural signals; punishment-like responses to reward omission also increase. These neural changes matched the onset of anhedonic behavior and were specific to LHb neurons that distinguished reward and its omission. Thus, stress distorts LHb responsivity to positive and negative feedback, which could bias individuals towards negative

expectations, a key aspect of the proposed pathogenesis of depression [Beck AT (1967) Depression: clinical, experimental, and theoretical aspects. (Harper & Row, New York) 6th Ed].

Title: Central exendin-4 selectively suppresses cue-evoked phasic dopamine spikes and resultant behavior

Authors: *V. R. KONANUR, T. M. HSU, M. F. ROITMAN;
Dept. of Psychology, Univ. of Illinois at Chicago, Chicago, IL

Abstract: Cues predictive of food reward evoke both phasic increases in mesolimbic dopamine activity and appetitive and consummatory behaviors. We showed previously that the magnitude of cue-evoked dopamine activity scales with hunger or central activation of its hormone mimetics (e.g. ghrelin). Activation of central receptors for glucagon-like peptide 1 (GLP-1) via long-acting analogues (e.g. exendin-4) suppresses food intake but its effects on cue-evoked phasic mesolimbic signaling, a signal critical for reinforcement and goal-directed action, remain unknown. Here, a 1s tone preceded the availability (20s) of a sipper that delivered 0.3M sucrose followed by a randomly selected inter-trial interval (30-60s) for 30 trials. On each trial, the latency to begin licking and the number of licks were measured in food restricted rats that expressed cre-recombinase under the control of the tyrosine hydroxylase promotor (n=5 male and 5 female TH-cre+). After 10 days of training, rats received a virally-mediated vector to express a genetically encoded calcium indicator (GCaMP6f; proxy for neural activity) and a fiber optic implant targeting dopamine neurons of the ventral tegmental area (VTA). Upon recovery, fluorescent calcium transients were measured in dopamine neurons during cue -> sipper sessions. 45 minutes prior to the session, rats received a central infusion of the GLP-1 receptor agonist exendin-4 (0, 0.05 or 0.1μg). Consistent with previous work, exendin-4 suppressed measures of appetitive and consummatory behavior – with stronger suppression observed in females. Exendin-4 had no effect on spontaneous phasic dopamine signaling throughout the session. However, it did selectively and dose-dependently suppress the magnitude of cue-evoked dopamine responses, independent of sex (0.39±0.06, 0.27±0.06, 0.04±0.05 ΔF/F for 0, 0.05 and 0.1μg, respectively; $p<0.05$). We performed linear regression and found, when controlling for

sex and drug dose, an indirect relationship between cue-evoked dopamine activity and latency to begin licking and a direct relationship with number of licks/trial. As cue-evoked dopamine promotes approach behavior, exendin-4 may be of therapeutic value for its ability to suppress neural substrates involved in cognitive and reinforcement related overeating.

Title: The subfornical organ recruits phasic dopamine signaling to water availability via multi-order pathways

Authors: *T. M. HSU, V. R. KONANUR, P. BAZZINO, M. F. ROITMAN;
Psychology, Univ. of Illinois at Chicago, Chicago, IL

Abstract: Changes in physiological state, including hunger, satiety, and body fluid homeostasis, can strongly modulate phasic dopamine signalling and goal-directed behaviors. Here we examine the novel hypothesis that the subfornical organ (SFO), a key central thirst detector, relays need state information to mesolimbic dopamine pathways to regulate thirst-motivated behaviors. To capture phasic dopamine dynamics, we utilized in vivo fiber photometry in rats that express protein-based fluorescent sensors to measure ventral tegmental area (VTA) dopamine neuron activity (Cre-dependent gCaMP6f in TH-Cre+ rats) or dopamine release (dLight1.2) in the nucleus accumbens shell (NAc shell). In water-restricted rats allowed intermittent, cued sipper access, we first demonstrated that VTA dopamine neuron activity and NAc shell dopamine release develop to cues associated with water. After training under water-restriction, we find a lack of cue-evoked VTA and NAc phasic dopamine activity when rats are water-sated. SFO glutamatergic neurons (SFO^{glu}) are engaged during thirsty states and selective activation of SFO^{glu} neurons engages robust water intake in water-sated animals. We found that DREADDs mediated activation of SFO^{glu} neurons mimics thirst in recruiting phasic dopamine activity, as SFO^{glu} activation increases water-cue evoked VTA dopamine responses. To identify potential relay nodes, we find that activation of SFO^{glu} increases c-fos expression not only in the VTA and NAc, but also the lateral hypothalamus (LH). Given previous work demonstrating that activation of a subset of LH neurons that produce neurotensin stimulates thirst, we found that intra-VTA administration of neurotensin dose-dependently increases cue-evoked VTA phasic dopamine activity in water-sated animals - data that suggests LH neurotensin to VTA dopamine neuron

communication mediates thirst-motivated behaviors. Overall, our findings reveal that thirst powerfully influences phasic dopamine signalling and that this occurs via multi-order SFO to VTA pathways.

Title: Distinct subregions of nucleus accumbens shell D2 neurons projections to ventral pallidum drive different movement,valence and reward motivation

Authors: *Y. YAO;
Biomed. engineering, Tsinghua Univ., Beijing, China

Abstract: Nucleus accumbens(NAc) plays an important role in emotion and motivation. Most of the NAc neurons are medium spiny neurons (MSNs), divided into dopamine-expressing receptor 1(D1) neurons and dopamine-expressing receptor 2(D2) neurons. D1 neurons are widely accepted to be associated with positive reinforcement and reward, while the role of D2 neurons are more evasive. D2 neurons transmit messages indirectly via VP and are traditionally associated with negative reinforcement and aversion. However, some reports have attributed movement inhibition or even positive motivational roles to them. Here, we combine optogenetics, Fluorescence in situ hybridization(FISH) and whole-brain mapping of inputs and outputs to demonstrate the anatomical and functional heterogeneity of the NAc shell D2 neurons. D2 neurons in ventral medial nucleus accumbens shell increase movement speed and those in the lateral nucleus accumbens shell decrease movement speeds, while the dorsal medial nucleus accumbens shell has no effect on movement speed. Furthermore, D2 neurons in the dorsomedial zone drive positive preference and increase reward motivation while D2 neurons in the ventromedial and ventrolateral zones are aversive and decrease reward motivation. D2 neurons in different subregions of nucleus accumbens project to overlapping zones in VP but downstream cell targets are of different cell types. Therefore, the finding the heterogeneity in function by anatomical location clears up much of the controversy in the literature surrounding the function of nucleus accumbens D2 neurons.

Title: Effect of sexual behavior on seizures and dopamine levels in male rats

Authors: *M. L. RAMÍREZ-RENTERÍA[1], E. HERNANDEZ-ARTEAGA[2], M. HERNANDEZ[3], M. OLVERA-CORTES[5], M. A. GUEVARA[4], A. AGMO[6];

Mexicano Del Seguro So, Morelia, Mich., Mexico; [6]Univ. of Tromsø, Tromsø, Norway

Abstract: Sexual interaction is a motivated behavior that has been associated with increases in serum testosterone and dopamine levels in the brain of male rats. Various environmental and pathological conditions produce alterations in hormonal and dopaminergic secretions, with seizures being one of the most common neurological disorders, often triggered by neural hyperexcitability. Studies in both humans and animals have reported that the presence of seizures occur in association with alterations in cerebral dopamine levels. Considering that sexual behavior is associated with increases in cerebral dopamine levels (DA) and that this neurotransmitter is involved in inducing seizures, the aim of this study was to determine the effect of sexual behavior on the induction of seizures and the dopamine levels in the prefrontal cortex and amygdala of male rats. For purposes of this study, 46 Wistar rats were classified into four groups: 1) the 3-MPA group (with one i.p. injection of 40mg/kg of 3-mercaptopropionic acid, 3-MPA); 2) the SEX3-MPA group (subjects that had sexual interaction prior to administration of 3-MPA); 3) the SAL group (which received one i.p. injection of saline solution); and 4) the SEXSAL group (subjects that had sexual interaction prior to administering the saline solution). Behavioral recording of seizures was done for 20 minutes post-injection. Dopamine concentrations were determined using the HPLC technique. Results showed that prior performance of sexual behavior decreased the number of subjects that presented seizures (only 39.5%). Also, in the case of the rats that did have seizures, both frequency and duration were lower, accompanied by longer latency and less severity, compared to the 3-MPA group. Regarding DA quantification, the subjects that had seizures showed higher concentrations in both the PFC and the amygdala than the SAL group and the animals that did not present seizures. While the effect of sexual behavior on seizures is not yet fully understood, there is evidence that this type of conduct increases dopaminergic levels in certain brain structures. Moreover, several studies have shown that both increases in DA levels and the administration of DA are associated with lower incidence and severity of seizures. Therefore, these results suggest a possible

neuroprotective effect of sexual behavior on pharmacologically-induced seizures in male rats, likely mediated by increases in dopamine levels.

Title: Temporal evolution of reward prediction error signals during reward and punishment learning

Authors: *M. BROSCH[1], F. W. OHL[1,2,3], M. T. LIPPERT[1,2];
[1]Leibniz-Institute for Neurobio., Magdeburg, Germany; [2]Ctr. for Behavioral Brain Sci. (CBBS), Magdeburg, Germany; [3]Inst. of Biology, Otto-von-Guericke Univ., Magdeburg, Germany

Abstract: Mesolimbic dopamine neurons have long been associated with encoding a universal reward prediction error (RPE) signal necessary for reinforcement learning. Several recent studies have, however, called into question the universality of such a signal, for example by demonstrating that it evolves only gradually during learning (Coddington, L.T. & Dudman, J.T. Nat Neurosci. 2018). Typically, these studies have used conditioning paradigms with appetitive reinforcement. This approach leads to a potential confound of movement-related responses and valence-related responses, obscuring the nature of the dopaminergic signal. Here we investigate how neuronal responses in the medial ventral tegmental area (VTA) of mice evolve during classical Pavlovian conditioning using a paradigm containing both, actively consumed reward as well as passively received punishment. Since it is especially unclear to what degree medial VTA neurons encode RPE signals in the initial phase of learning, faithful tracking of identified dopaminergic cells during this phase of the experiment is a necessity. We have therefore developed a novel optrode drive which combines tetrode unit recordings and optogenetic confirmation of dopamine-cell identity. The construction of the drive prevents electrode tip movements and associated loss of units from the plugging forces of electrical and optogenetic plugs, resulting in a higher yield of identified units over multiple sessions. The drive was implanted in the posterior medial portion of the VTA in DAT-Cre mice. Selective expression of ChR2 in dopaminergic cells from a floxed viral vector allowed the optical identification of

individual dopaminergic units during each session. The mice underwent a head-fixed reward and punishment learning paradigm. In this paradigm, an auditory stimulus preceded either rewarding water delivery or punishing air puffs in a trace conditioning manner. Recording unit activity throughout the VTA then allowed us to evaluate the relationship of dopamine cell firing and RPE coding during the early to late stages of conditioning.

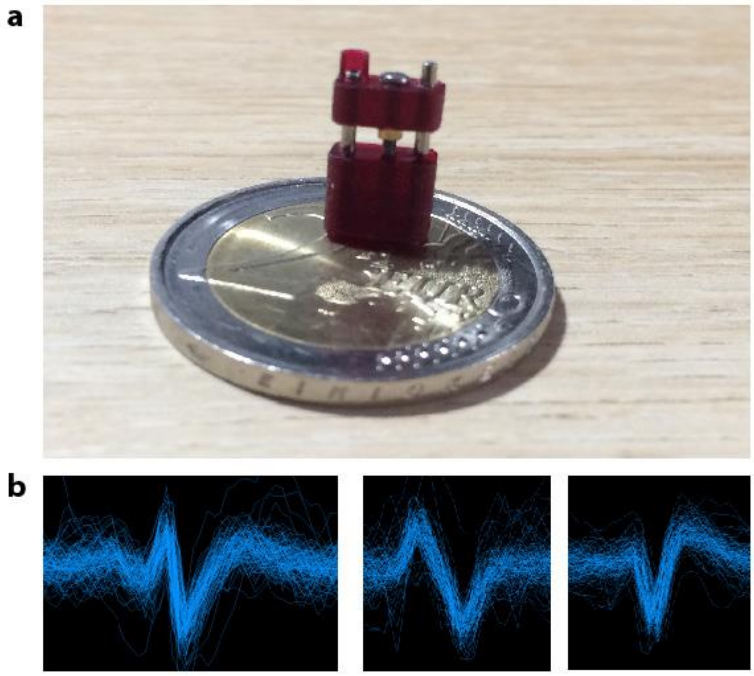

Fig 1 | Newly developed optrode microdrive **(a)** and single trial overlay of different VTA sorted single-units **(b)** exemplary spike traces are overlaid and aligned, recorded in one session of the Pavlovian conditioning paradigm

Title: Overexpression of protein kinase inhibitor alpha in nucleus accumbens increases low voluntary running motivation

Authors: *X. MAO;
Dept. of Biomed. Sci., Univ. of Missouri-Columbia, Columbia, MO

Abstract: Objective and rationale: Physical inactivity is associated with the risk of 40 chronic diseases and has been identified as the fourth leading risk factor for global mortality. Therefore, efforts to increase physical activity level would be beneficial to health. In an effort to reverse the physical inactivity to promote the health, Booth's Lab has developed a low voluntary running (LVR) rat line in order to study the genetic factors contributing to the low physical activity. Therefore, current study attempts to examine the regulatory role of PKIa in determining voluntary wheel running behavior along with the motivation for voluntary running behavior in both WT and LVR male rats. We hypothesize that overexpression of PKIa increases male rats voluntary running distance by increasing the motivation for running. **Methods**: 11 weeks old WT and LVR male Wistar rats were injected with either adeno-associated virus (AAV) expressing an empty-vector (EV) or AAV driving the overexpression of PKIa within the NAc. Following 3 weeks running observation, a running wheel based operant runway test (ORT) was deployed to determine the voluntary running motivation. Endogenous genes expression were then assayed via qRT-PCR. **Results**: WT and LVR male rats following AAV-PKIa overexpression showed no running distance difference compared with their AAV-EV control during the course of 3 weeks. Yet, LVR male rats following overexpression of PKIa spent significantly less time to approach the running wheel than AAV-EV control. **Conclusions**: Overexpression of PKIa did not increase nightly running distance in both WT and LVR male rats; however, the low motivation of LVR males were significantly increased in approaching the running wheel induced by the overexpression of PKIa in NAc. It is possible that the larger body weight of male rats prevents them from increasing the actual running distance following the overexpression of PKIa even under the increased voluntary running motivation. Future study should also investigate the both voluntary running distance and motivation in female rats following the overexpression of PKIa.

Title: Apomorphine as a discriminative stimulus

Authors: *B. L. PACHECO GÓMEZ[1], W. A. ZEPEDA-RUIZ[2], D. N. VELÁZQUEZ-MARTÍNEZ[2];
[1]Univ. Nacional Autónoma De México, Mexico City, Mexico; [2]Univ. Nacional Autónoma de México, Mexico City, Mexico

Abstract: Drug discrimination is a procedure where subjects learn to discriminate between the interoceptive stimulus of a drug and its vehicle. Male Wistar rats were trained to discriminate the dopamine agonist apomorphine (0.1778 mg/kg IP) from saline injection for sucrose reward under a FR10 schedule of reinforcement. When the discrimination was acquired (more than 80% accuracy to both drug or vehicle conditions), generalization gradient to 0.031 mg/kg, 0.056 mg/kg and 0.10 mg/kg doses was obtained. The response rate under apomorphine was depresed in comparison to the response rate of the days when saline was administered. However, lever selection was a dose dependent function: the lowest dose (0.031 mg/kg) showed a similar discrimination index to saline while the dose of 0.10 mg/kg produced a similar discrimination index to the training dose.

Title: Sex differences in cholinergic regulation of nucleus accumbens circuit function controlling motivation

Authors: *L. J. BRADY, M. G. KUTLU, J. E. ZACHRY, E. S. CALIPARI;
Pharmacol., Vanderbilt Univ., Nashville, TN

Abstract: In recent years we have made great strides towards our understanding of psychiatric disease states; however, a majority of these studies have focused almost entirely on male subjects. In a large number of psychiatric disorders, such as anxiety, depression, and addiction, sex is a critical biological variable and women represent a particularly vulnerable population. At the core of these disorders is a dysregulation in reward and motivation, yet there is a disparity between the prevalence and prognosis of these disorders in females. The paucity of data describing the unique neural circuitry underlying these sexual dimorphisms highlight the critical need for preclinical investigation of reward learning and motivation in female subjects. There are a variety of factors that could contribute to these sex differences - including estrous cycle

dependent ovarian hormone fluctuations - but the precise neural circuits and neurobiological mechanisms that underlie these differences in reward and motivation are largely unknown. The mesolimbic dopamine pathway, which connects the ventral tegmental area (VTA) to the nucleus accumbens (NAc), is an essential component of the process that controls motivation and reward-seeking behavior. In the NAc specifically, tonic/phasic dopamine release is known to play a critical role in converting information about environmental reward-predictive cues to anticipated positive outcomes, and is heavily modulated by the activity of cholinergic interneurons signaling through nicotinic acetylcholine receptors (nAChRs). Using fast-scan cyclic voltammetry (FSCV) paired with site-specific pharmacology we measured subsecond dopamine kinetics in male and female mice in either diestrus (low circulating hormones) or estrus (high circulating hormones) and defined sex-differences in local circuit regulation of dopamine release in the NAc. We show that the ability of the cholinergic system to regulate tonic/phasic dopamine activity via nAChRs is enhanced in females. Further, the ratio of phasic-to-tonic evoked dopamine release varied between estrus and diestrus females. Finally, cholinergic regulation of dopamine signaling via nAChRs in the NAc was altered in a way that promotes and enhances dopamine release in estrus females. Together this work will expand our understanding of the sex differences in cholinergic regulation of local NAc circuit function underlying reward learning, aiding in the development of better and more effective pharmacotherapies to counter psychiatric disease states in women.

Title: Dopamine's role in foraging decisions

Authors: *S. STAROSTA[1], S. A. SHUVAEV[1], D. KVITSIANI[2], A. KOULAKOV[1], A. KEPECS[1];
[1]Cold Spring Harbor Lab., Cold Spring Harbor, NY; [2]Mol. Biol. and Genet., Aarhus Univ. / DANDRITE, Aarhus C, Denmark

Abstract: We are continually confronted with decisions about whether to stay engaged in our current behavior or switch to a new course of action. These stay-or-leave decisions have been mostly studied in behavioral ecology as foraging decisions but little is known about their neural basis. Therefore, we set out to study the neural mechanisms underlying stay-or-leave decisions in

a behavioral paradigm inspired by foraging theory from neuroethology.
Optimal choice strategies for foragers facing diminishing returns can be described by the marginal value theorem (MVT), a classic theoretical framework proposed by Charnov (1976). MVT describes how to maximize reward rate on average but it does not address how individual decisions are made. Therefore, we designed a task that allowed us to infer the trial-to-trial choice strategy in a foraging behavior so we could link neural activity with choice behavior.
Mice were allowed to run back and forth between two water ports connected by a variable-height bridge. With each re-entry into the same port the amount of water dispensed decreased according to a preset depletion rate, while switching to the other port reset water to the full amount. Additionally, we manipulated the effort of switching between ports by changing the height of the bridge that had to be crossed between the ports. Using a range of manipulations we show that mouse behavior follows the predictions made by the MVT: both an increase in the average reward rate as well as an increase in harvesting time led animals to leave a depleting port earlier, while increasing the switching effort was associated with staying longer. In addition, the average leaving threshold was similar across ports even when ports were set to deplete at different rates. To describe the observed behavior formally, we constructed a theoretical model that formalizes MVT predictions on a trial-by-trial basis. The model is able to account for the behavioral data described above and suggests that animals use the last ~10 trials to compute the average reward rate proposed by MVT.
Next, we examined the responses of dopaminergic (DA) neurons in the ventral tegmental area (VTA) during foraging because of their key role in reward-guided behavior. We recorded population activity of VTA DA neurons with fiber photometry while mice were foraging for water rewards. We observed that phasic responses in VTA DA neurons reflected the size of reward received and that this reward response was predictive of whether an animal would stay at or leave a port.
We conclude that foraging behavior in mice can be described by an MVT-like decision rule and dopaminergic signaling in the VTA contributes to the decision when to leave a depleting resource.

Title: Restriction and hypercaloric diets modulate the expression of genes related to the dopaminergic system in the ventral tegmental area of mice dams

Authors: *V. FEISTAUER, J. FISH, C. K. D. OLIVEIRA, *M. GIOVENARDI, S. DE ALMEIDA;
UFCSPA, Porto Alegre, Brazil

Abstract: Eating is necessary to maintain physiological processes, but it is also pleasurable. Many individuals are unable to control food intake, leading to an excessive adipose tissue accumulation, long associated with increased morbidity and mortality. Contrary, caloric restriction have been associated with increased life expectancy and reduced incidence of chronic diseases. The dopaminergic system is related to addictive-like behaviors and food reward. Therefore, we aim to evaluate the effects of restrictive and hypercaloric diet during pregnancy and lactation on the expression of dopaminergic system genes in the ventral tegmental area (VTA). We also measured the effect of these diets in locomotor activity and innate fear in the open field (OF) test. BALB/c albino female mice were divided into three dietary groups: control (CONT), restriction (RD) and hypercaloric (HD). Isogenic male mice were used for mating. Dams received their specific diets throughout pregnancy and lactation. On the 9th post-partum day, dams were tested in the OF, and after weaning, dam's VTA was collected. Gene expression was analyzed by reverse transcription real-time polymerase chain reaction. RD and HD dams had increased lateral and central locomotion in the OF. HD had reduced innate fear when compared to RD and CONT dams. RD and HD dams had higher levels of *Th, Slc6a3* and *Drd2* mRNA, and HD dams had increased *Drd1* mRNA, but no significant difference in *Drd3, Comt,* and *Maob* genes. Our results show that restriction and hypercaloric diets modulate the expression of dopaminergic system genes and alter locomotor activity of mice dams.

Title: Roles of midbrain dopamine neurons in relapse

Authors: *Y. LIU, P. JEAN-RICHARD-DIT-BRESSEL, J. YAU, G. D. GIBSON, S. KILLCROSS, G. P. MCNALLY;
Univ. of New South Wales, Sydney, Australia

Abstract: Return to drinking after a period of abstinence remains a key impediment to successful treatment of alcohol use disorders. Dopamine projections from the ventral tegmental area to nucleus accumbens, which comprise the mesolimbic dopamine system, play an important role in motivated behaviors and reinforcement learning, but their role in context-induced reinstatement remain poorly understood. We assessed the roles of ventral tegmental area dopamine neurons (VTA^{Th}) during two different forms of relapse to alcohol-seeking: renewal (context induced reinstatement) and reacquisition in freely moving rats. Using gCaMP fibre photometry, we show that reacquisition, but not renewal, of alcohol-seeking is associated with calcium transients in VTA^{Th} neurons. Then, using dLight fibre photometry, we mapped dopamine transients in nucleus accumbens medial shell, core, and lateral shell during relapse. Calcium transients in VTA^{Th} neurons were temporally specific to behaviors that earned alcohol-associated stimuli and ingestion of alcohol. They were not observed to the same behaviour in the same sessions that did not earn these stimuli or alcohol ingestion. Optogenetic inhibition of VTA^{Th} neurons during the periods in which they showed increased calcium transients reduced reacquisition, but the same silencing at equivalent times had no effect on renewal. Using chemogenetics (KORDs), we confirmed that silencing VTA^{Th} neurons reduced reacquisition but not renewal of alcohol seeking. Taken together, these findings show the role of VTA^{Th} neurons can be dissociated across different forms of relapse in the same animals. Renewal proceeds largely independent of VTA^{Th} neurons whereas the presence of alcohol during reacquisition restores activity (calcium transients) of VTA^{Th} neurons to alcohol-seeking behaviors as well as alcohol-related stimuli and this restoration underpins the rapid return to alcohol-seeking and ingestion.

Title: Involvement of dopamine D1 and D2 receptor-dependent activation of mitogen-activated protein kinase (MAPK) signaling in the nucleus accumbens in stimulus-reward learning and motivation

Authors: *M. SAIFULLAH[1], T. NAGAI[2], K. YAMADA[2];
[1]Nagoya University, Res. Inst. of Envrn. Med., Nagoya, Japan; [2]Nagoya Univ. Grad Sch. Med., Nagoya, Japan

Abstract: Abused drugs, food, and other reward-associated stimuli activate mitogen-activated protein kinase (MAPK) signaling pathway in the mesolimbic dopaminergic system (reward circuit) which projects from the ventral tegmental area to the nucleus accumbens (NAc). NAc is of particular interest because of its role in controlling affective and motivational aspects of behavior. Majority of the neurons in the NAc are GABAergic medium spiny neurons (MSN), which express either dopamine D1- or D2-class receptors. Although mitogen-activated protein kinase (MAPK) signaling plays an important role in several types of learning, the cell type-specific role of MAPK pathway in stimulus-reward learning and motivation remains unclear. In this study, we used adeno-associated virus (AAV)-FLEX mediated conditional transgene expression technology to manipulate MAPK signaling. We expressed wild-type (wt) and constitutively active (ca) MAP2K1 gene exclusively in either D1R- or D2R-MSNs in the NAc and analyzed the effect on methamphetamine-induced conditioned place preference (CPP) as well as on operant behavior for a food reward. The behavioral analyses revealed that D1R-MSN specific expression of caMAP2K1 gene in the NAc potentiated methamphetamine-induced CPP while the D2R-MSN specific expression in the same region did not affect the CPP score. In this test, animals learn to associate the rewarding effect of drug of abuse with the distinct contextual cue. Similar results were observed in Pavlovian conditioning for food reward as well, in which mice learn to associate reward outcome with a predictive cue. Both D1R and D2R mediated caMAP2K1 enhanced motivation to perform an instrumental task. These results suggest that D1R-dependent MAPK signaling pathway in the NAc may play an important role in both natural and drug reward-associated learning and memory, but motivation to perform an instrumental task is modulated by both D1R and D2R mediated MAPK signaling.

Title: Alternative splicing of D2 dopamine receptor mRNA shows little difference between neuronal cell types, but is modulated by nicotine and the sex of the individual

Authors: A. D. HUDSON[1], R. L. MURPHY[2], M. T. PEGLAR[1], *K. J. FRYXELL[1];
[1]Sch. of Systems Biology, and the Interdisciplinary Program in Neurosci., George Mason Univ., Manassas, VA; [2]Dept. of Physiol. and Biophysics, Univ. of Washington, Seattle, WA

Abstract: Alternative splicing of D2 dopamine receptor mRNA produces two protein isoforms ($Drd2_L$ and $Drd2_S$). $Drd2_L$ contains a 29 amino acid segment in the third cytosolic loop, encoded by exon 6, that is absent from $Drd2_S$. $Drd2_S$ receptors are primarily presynaptic, while $Drd2_L$ receptors are primarily postsynaptic. It is unclear whether this pattern of localization is due to differences in transport or synthesis, or at the level of mRNA or protein. What is clear is that significant alterations in the ratio of *Drd2S* to *Drd2L* are associated with schizophrenia, depression, and bipolar disorder. Moreover, SNPs that influence this ratio are associated with increased incidence of cocaine abuse and schizophrenia. Here we developed a novel computational method of analyzing RNA sequencing data, to assess the extent to which alternative splicing of D2 mRNAs differs between brain areas and cell types. In male C57BL/6J mice, samples of the ventral tegmental area (VTA) had a *Drd2L/ Drd2S* mRNA ratio = 5.1, which was somewhat lower than the ratio of 8.6 in the cell bodies of striatal D2 medium spiny neurons (MSN). However, in male FBA/NJ mice, a larger data set from D2 MSN yielded a ratio of 4.9. Overall, there was not any consistent evidence of a much lower *Drd2L/ Drd2S* ratio in VTA, as would have been expected if the presynaptic localization of $Drd2_S$ were regulated at the level of mRNA splicing. We extended these results by qRT-PCR analysis in both male and female C57BL/6J mice, 24 hr after a single injection of either 0.5 mg/kg nicotine or saline. In saline controls, qRT-PCR measurements showed a *Drd2L/ Drd2S* mRNA ratio of 0.7 in male ventral tegmentum (1.0 in females), and 0.8 in male ventral striatum (1.6 in females). Although these two methods differed in their detection sensitivity for the *Drd2S* and *Drd2L* isoforms, both sets of results agreed in finding that the differences between brain areas and cell types were too small to support the hypothesis that the pre-synaptic localization of $Drd2_S$ was regulated at the level of mRNA splicing. We conclude that the predominantly pre-synaptic localization of $Drd2_S$ is likely to be determined at the level of molecular transport and/or stability. On the other hand, we also found that a single nicotine injection significantly altered the *Drd2L/Drd2s* mRNA ratio in all brain areas tested. The effect of nicotine differed between brain areas, sexes, and left/right sides of the brain. Overall, males produced more *Drd2S* than females, and males also showed a greater nicotine effect on the *Drd2L/ Drd2S* ratio. These effects of sex, nicotine, and left/right sides of the brain on the *Drd2L/ Drd2S* ratio have important implications for the etiology of addiction and mental health disorders.

Title: Functional and spatial diversity of dopamine neurons in the substantia nigra for different aspects of behavior

Authors: *M. COSTELLO, D. B. T. MCMAHON, O. HIKOSAKA;
Lab. Sensorimotor Res., Natl. Eye Inst., Bethesda, MD

Abstract: Previous work in our laboratory showed that dopamine (DA) cells show a diverse range of functional properties that vary according to anatomical location within the substantia nigra pars compacta (SNc). The rostral ventromedial region (rvmSNc) contains DA neurons that show the classic dopamine features of reward prediction error signaling and suppressed responses to aversive conditioned stimuli ("Value cells"). Conversely, DA neurons in the caudal dorsolateral region (cdlSNc) show little reward prediction error signaling and respond strongly to both appetitive and aversive conditioned stimuli ("Salience cells") (Matsumoto and Hikosaka 2009). The same axis of the SNc segregates DA neurons with connections to the head and tail regions of the caudate nucleus respectively, and likewise shows a gradient of sensitivity to either the short-term current value of objects ("Update cells" in rvmSNc") or the long-term historical value of objects ("Sustain cells" in cdlSNc) (Kim et al. 2015). To further characterize the functional specialization of dopamine cells within the dorsal and ventral SNc we screened individual neurons with a broad spectrum of behavioral tasks including Pavlovian conditioning, passive viewing of previously conditioned stimuli, and reversal learning tasks. We found Value-Update DA neurons in the rvmSNc that show the "classic" profile of dopamine neurons, namely (1) excitation to reward-predicting but not punishment-predicting stimuli, (2) enhanced responses to unpredicted rewards, (3) no clear spatial selectivity, and (4) cessation of responses to previously learned stimuli in contexts where reward is absent. In contrast the Salience-Sustain DA neurons in cdlSNc show markedly different functional properties, namely (1) brisk responses to both reward- and punishment-predicting stimuli, (2) little sensitivity to the predicted or unpredicted status of rewards, but sensitive to unpredicted airpuff, (3) spatial selectivity for stimuli presented in the contralateral visual field, and (4) sustained responses to historically rewarded stimuli even in tasks where no reward was expected or forthcoming. Taken together, this pattern of results points to a division of labor within the midbrain DA system whereby DA neurons in rvmSNc are specialized for responding to the current expectation of reward and provides new information about motivational value. Conversely, DA neurons in cdlSNc are

specialized for maintaining a long-term historical record of past experience and sending a salience signal marking the significance of upcoming events.

Title: Simultaneous measurement of ventral tegmental area activity and nucleus accumbens dopamine release reveals patterns of neuron firing associated with dopamine release

Authors: *D. F. HILL[1], Z. OLSON[2], M. J. BARTLETT[5], T. FALK[6], M. L. HEIEN[3], S. L. COWEN[4];
[1]Dept. of Physiology, Develop. and Neurosci., Univ. of Cambridge, Camrbridge, United Kingdom; [3]Chem. and Biochem., [4]Dept. of Psychology, [2]Univ. of Arizona, Tucson, AZ; [5]Dept. of Pharmacol., [6]Dept. Of Neurol., Univ. of Arizona Col. of Med., Tucson, AZ

Abstract: Dopamine neuron activity in the ventral tegmental area (VTA) and dopamine release in the nucleus accumbens (NAc) are essential for economic decision making, error-driven learning, and addiction. Though considerable evidence suggests a direct link between VTA neuron activity and dopamine release, little is known about the specific patterns of activity exhibited by midbrain neurons that lead to the release of dopamine in the NAc. Similarly, it is unclear how the activities of cells in proximal nuclei, such as the rostromedial tegmental nucleus (RMTg), known as the master-brake of the VTA, contribute to release. To address this, we developed novel instrumentation capable of measuring dopamine release and single-unit activity simultaneously to elucidate the characteristics of VTA and RMTg activity that give rise to dopamine release. Spontaneous phasic dopamine release was induced pharmacologically in anesthetized male Sprague Dawley rats (n = 22, 3 - 4 months old, 1 - 1.5 % isoflurane) using a dopamine transporter inhibitor GBR-12909 (17.5 mg/kg, *i.p.*) and the dopamine receptor 2-like antagonist eticlopride (0.75 mg/kg, *i.p.*). As predicted, a portion of recorded dopaminergic neurons (15%) exhibited changes in firing at the time of dopamine release onset. Interestingly, many of these cells exhibited changes in firing at both the onsets and the peaks of dopamine release events. These data suggest that the mechanisms involved in the initiation of dopamine release also contribute to the signal that terminates release. We also hypothesized that most non-dopaminergic neurons of the VTA and RMTg, many presumed to be local GABAergic neurons, would decrease firing just prior to dopamine release in order to release dopamine neurons from local inhibition. Instead, we observed that most responsive non-dopaminergic neurons in both regions increased firing at the onset of dopamine release events, suggesting that a more complex

network of inhibitory and excitatory neurons in the VTA and RMTg controls dopamine release than previously thought. These data support a link between VTA neuron activity and dopamine release, but also suggest that VTA-mediated dopamine release in the NAc is not a simple function of dopamine neuron firing activity.

Title: Action-induced inhibition of nigrostriatal dopamine release by goal-directed behavior

Authors: ***N. G. HOLLON**[1], E. W. WILLIAMS[1], H. LI[1], T. I. TRAUT[1], C. D. HOWARD[1,2], X. JIN[1];
[1]Mol. Neurobio. Lab., Salk Inst. for Biol. Studies, La Jolla, CA; [2]Neurosci., Oberlin Col., Oberlin, OH

Abstract: Nigrostriatal dopamine plays critical roles in voluntary movement, motivation, and reinforcement learning, but its exact role in instrumental learning and how it interacts with actions remain poorly understood. Here we examined how self-initiated goal-directed action influences nigrostriatal dopamine transmission during instrumental behavior with minimal overt changes in the external environment. Mice expressing channelrhodopsin in their dopamine neurons learned to press a lever on a continuous reinforcement schedule to deliver blue-light stimulation into their substantia nigra pars compacta (SNc). This free-operant optogenetic self-stimulation of nigrostriatal dopamine was sensitive to changes in the action-outcome contingency, demonstrating that performance was goal-directed. Using fast-scan cyclic voltammetry, we monitored changes in dorsal striatal dopamine concentration during both self-stimulation and subsequent playback of stimulations delivered in the same temporal sequence but not contingent upon any action. Self-stimulated dopamine release was markedly lower than that evoked by non-contingent playback, indicating that self-initiated action causes a robust suppression of dopamine release, even when driven by direct optogenetic depolarization of dopamine neurons themselves. This suppression of the expected neurochemical consequence of one's own action, likely through an efference copy, is consistent with a feedforward inhibition triggered by the goal-directed action. Electrophysiological recordings of optogenetically

identified SNc dopamine neurons provided evidence for inhibition of somatic firing activity contributing to the observed effects on terminal release. Non-reinforced presses of the typically active lever revealed transient dips below baseline dopamine levels. This inhibition was action-specific and was not observed to presses of the inactive lever. Probes with delayed stimulation or varied magnitude demonstrated that the action-induced suppression is precisely timed to counteract the expected consequence of that action. Recordings in mice performing heterogeneous action sequences for nigrostriatal self-stimulation further revealed the sequence-specificity of this inhibition, which was strongest during the sequence element most proximal to outcome delivery. Collectively, these findings demonstrate that nigrostriatal dopamine signals prediction errors in action-outcome associations, and have fundamental implications for instrumental behavior and movement control.

Title: Characterization of the effects of systemically increasing dopamine, serotonin, and noradrenaline levels on the valuation of reward vs. avoidance

Authors: *J. B. ROBERTS[1], O. CHAMAN[1], E. B. OLESON[2];
[1]Biol., [2]Psychology, Univ. of Colorado Denver, Denver, CO

Abstract: Optimal behavior and overall survival require obtaining highly-valued outcomes from our environment. These action-outcome situations are often driven by either the pursuit of reward or the avoidance of harm. The three primary monoamine neurotransmitter systems that modulate such motivated behaviors are dopamine (DA), serotonin (5-HT), and noradrenaline (NA). Here, we are using selective uptake inhibitors GBR-12909, fluoxetine, and desipramine, to block the uptake of DA, 5-HT, and NA respectively. To investigate how these uptake inhibitors influence the value of avoidance vs. reward, we combined operant behavior with behavioral economic theory. In our avoidance task, rats were trained to respond to avoid electrical foot-shock across a range of prices (response requirement/mA shock avoided); in our reward-seeking task, rats were trained to respond for sugar across a range of prices (response requirement/mg sugar received). We then fit data with demand curves and solved for alpha. Demand curves are a

common tool used by economists to measure price sensitivity depicting the relationship between consumption and price. Alpha represents the rate at which demand curves decay and can be used to make inferences regarding the value individuals place on the commodity being consumed. If the slope decays at a faster rate, we would infer that the value to avoid or seek reward is decreased because consumption became more sensitive to price. Conversely, if slope decays at a slower rate, we would infer that the value to avoid or seek reward is increased because consumption become less sensitive to price. Preliminary data suggest that GBR-12909 increased avoidance value; whereas desipramine decreased avoidance value. Investigating whether these pathways produce distinct effects on reward vs. avoidance valuation will provide novel insight into how the brain controls these fundamental aspects of behavior. The implications of this work may also advance our understanding of major psychiatric conditions such as depression and drug addiction. After completing the reward valuation component of this study, we attempt to replicate our findings using chemogenetics to add anatomical specificity to our exploration of this research question.

Title: Dopamine cue salience responses promote associative learning

Authors: J. MORRENS, C. AYDIN, A. JANSE VAN RENSBURG, ***S. HAESLER**;
Neuroelectronics Res. Flanders, Leuven, Belgium

Abstract: Dopamine neurons mediate the association of conditioned stimuli (CS) with reward (unconditioned stimuli, US) by signaling the discrepancy between predicted and actual reward during the US (i.e. reward prediction errors, RPE), a fundamental parameter of reinforcement learning models. Alternative models suggest, learning is influenced by the salience or associability of the CS. A hallmark of CS associability models is that they provide a simple explanation for latent inhibition, i.e. the observation that novel CS are more effectively learned than familiar CS. Novel CS are known to activate dopamine neurons, but whether those CS salience responses affect associative learning has not been investigated. Moreover, pharmacological evidence has implicated the dopamine system in latent inhibition. but the circuit

mechanism by which the activity of dopamine neurons causes a learning bias towards novel stimuli remains unknown. Here, we measured dopamine transients with fiber photometry across the midbrain ventral tegmental area (VTA) and substantia nigra pars compacta (SNc) in a non-associative novelty exposure paradigm, in which animals show spontaneous orienting responses to novel but not familiar stimuli. We found dopamine responses to novel stimuli are graded, with no distinct pattern across SNc and VTA, thus not supporting the notion of a distinct anatomical subpopulation responding to novel stimuli. We then performed olfactory conditioning, using stimulus novelty and familiarity to experimentally manipulate CS salience. With bidirectional optogenetic manipulation of dopamine neurons selectively during the CS period, we demonstrated that dopamine CS salience signals promote associative learning. The function of dopamine in associative learning thus involves stimulus salience signals in addition to US RPE signals. This idea is consistent with dopamine response properties recorded previously in primates and with theoretical models combining stimulus associability and error terms (Lak et al., 2016; Le Pelley, 2004; Schultz, 2016), but it has lacked an experimental confirmation. It has been suggested that latent inhibition results from the reduced associability of stimuli experienced without any consequence. Given our findings, it seems however more plausible it is not the reduced CS associability of familiar stimuli but the increased associability of novel stimuli, which underlie the learning bias towards novel stimuli in latent inhibition. Latent inhibition might thus merely result from the absence of dopamine CS salience responses to familiar stimuli.

Title: Dopamine encodes the state of reward availability in a modified condition inhibition paradigm

Authors: ***A. KALMBACH**[1,2], P. D. BALSAM[3], E. H. SIMPSON[1,2];
[1]Psychiatry, Columbia Univ., New York, NY; [2]Developmental Neurosci., New York State Psychiatric Inst., New York, NY; [3]Barnard Coll Columbia Univ., New York, NY

Abstract: Inhibition of dangerous or wasteful behavior is necessary for allocating energy to situations that are less dangerous or more productive and rewarding. This inhibition requires

observation of environmental cues and adjustment of behavior accordingly. Behavioral inhibition deficits are observed in ADHD, addiction, and schizophrenia. Here, we investigated whether and how dopamine signaling encodes the conditioned stimulus that signals when rewards cannot be earned and the extent to which the dopamine signal correlated with behavioral responses. In our behavior paradigm, the animals pressed a lever to earn a reward on a random interval schedule (RI 20s) but when a prolonged tone was present (3.5kHz; 80s), rewards could not be earned. Animals learned to suppress lever pressing during the tone. Throughout learning, we utilized fast scan cyclic voltammetry to measure extracellular dopamine in the ventral striatum or fiber photometry to monitor calcium dynamics in dopamine neuron cell bodies and axons using GCaMP6f or dopamine release from dopamine axons using dLight. Unexpectedly, we found that, after learning stabilized, both dopamine release and dopamine somatic and axonal activity decreased to a steady state that persisted throughout the duration of the tone. Immediately following tone cessation, dopamine release and neuronal activity rebounded to pre-tone levels. Thus, these measurements of dopamine activity suggest that dopamine encodes reward availability and not proximity to reward. Furthermore, the dynamics of lever pressing during the conditioned tone did not correlate with the dynamics of dopamine release and neuronal activity, which suggests that dopamine activity and behavior are not tightly coupled in this behavioral paradigm. These results also indicate that measurements usually performed to detect phasic changes in dopamine can also be utilized to detect relatively long lasting changes in dopamine.

Title: Electrophysiological analysis of the dynamics of mesocortical circuits during decision making under uncertainty in mice

Authors: *E. BOUSSEYROL, S. DIDIENNE, S. TAKILLAH, C. PRÉVOST-SOLIÉ, J. NAUDÉ, P. FAURE;
Sorbonne Univ., Paris, France

Abstract: The ability to adapt to the unfamiliar or uncertain is fundamental, and entails that animals actively explore their environment. This adaptation requires to balance the exploitation of the best option so far with the exploration of alternative choices (1). Dopaminergic (DA) neurons of the ventral tegmental area (VTA) (2) and frontal cortices such as the orbitofrontal (OFC) (3) and prefrontal (PFC) (4) play crucial roles in this balance. However, little is known about their functional coordination as part of an interconnected mesocortical circuit. In this project, we ask whether specific dynamics in this network (VTA, OFC, and PFC) support decision-making and exploratory behavior in uncertain environments. We used a behavioral paradigm that allows computational modeling of exploratory choices in a decision-making task in mice with simultaneous quantification of electrophysiological activity. Using intracranial self-stimulation of the medial forebrain bundle, mice were trained to obtain rewards on three explicit locations in an open-field. Mice could not obtain two consecutive rewards at the same location, forcing them to navigate between locations. After a learning period, locations were associated with distinct reward probabilities (e.g. 100%, 50% and 25%), offering mice three different binary choices. Local field potentials (LFP) and multi-unit activity were recorded in the OFC and PFC, as well as in VTA DA neurons from mice performing the task. We analyzed transient oscillations from LFPs and neuron firing rate and correlated them with behavior and decision parameters (e.g. reward probability and uncertainty of the available locations). Animals adopted a specific behavioral strategy to deal with the uncertainty of the environment (2). Our results indicate that specific activity patterns emerged in frontal cortices and VTA DA neurons during the learning process, at the time of the decision, when animals engage in a new trial. These activities were temporally organized and locked on specific behaviors. Moreover, we show that this sequence of activities correlates with choices in the probabilistic setting of the task. Finally, in order to disentangle the relative roles of these different structures, we showed that optogenetic manipulation of VTA DA cells biased choices. Our results suggest a specific sequence of activation in the VTA-OFC-PFC network that is related to mouse choices. (1) Cohen et al., Phil. Trans. R. Soc. B 2007 (2) Naudé et al., Nat. Title: Cue encoding patterns of brain stimulation reward compared to sucrose rewards

Authors: *D. N. TAPP, S. M. THOMPSON, M. S. MCMURRAY;
Psychology, Miami Univ., Oxford, OH

Abstract: Dysfunctional reward processing can lead to obesity or psychiatric diseases such as anorexia and addiction.
Thus, it is critical that we understand the neurobiological systems that are responsible for the processing of food rewards. Food rewards recruit complex neural systems responsible for taste reactivity, energy homeostasis, and satiety, in addition to reward processing. Thus, the processing of food rewards is confounded by these other signals, making it challenging to tease apart reward signals from other activators of these circuits. Unlike food rewards, brain stimulation reward (BSR) provides direct electrical stimulation to discrete areas of the mesocorticolimbic reward circuit in a controllable manner. Further, BSR activates dopaminergic cue encoding circuitry in a more direct manner than food rewards. To aid in our understanding of the neural systems responsible for the complex encoding of food rewards, we examined how food rewards activate neural circuitry differently than (BSR), which is free of sensory processes, is more temporally precise, and activates only selected neural circuits. We compared encoding of BSR and food-reward on one critical aspect of reward processing: reward-predictive cue encoding. By combining a classical conditioning paradigm with *in vivo* electrophysiological recordings, we found that the encoding of food-predictive cues by the nucleus accumbens (NAc) is biased by non-reward processes (which BSR is free of). To control for variation in reward intensity, all animals performed behavioral tests after recording to determine reward sensitivity and match subjective reward magnitudes across reward types. By comparing the timescale and intensity of food-evoked cue encoding to BSR, we found that food rewards produce less intense, yet longer-lasting phasic changes in neural activity in the NAc compared to BSR. Such results suggests that food rewards activate neural circuitry for a briefer and less powerful manner than BSR, highlighting how the complex neural encoding of foods may bias reward encoding. These findings shed light on the basic neurobiology controlling both food reward and BSR, which are widely used in reinforcement research.

Title: Sex differences in an effort-related decision making task

Authors: *E. L. ERRANTE[1], M. CHAKKALAMURI[1], O. I. AKINBO[1], S. E. YOHN[2], J. D. SALAMONE[3], L. MATUSZEWICH[1];

[1]Dept. of Psychology, Northern Illinois Univ., Dekalb, IL; [2]Vanderbilt Univ., Nashville, TN; [3]Dept Psychological Sci., Univ. of Connecticut, Storrs Mansfield, CT

Abstract: Major Depressive Disorder (MDD) is characterized by debilitating symptoms, including anxiety, fatigue and anhedonia. Interestingly, there are sex differences in the prevalence rates of MDD with 8.5% of females reporting symptoms compared to 4.8% of males (NIH, 2016). One component of MDD is lowered motivation or interest for pleasurable activities, which can be difficult to treat. An approach previously used to assess motivation is to compare performance on tests of effort-related decision-making, where subjects are presented with a choice between high effort/high reward and low effort/low reward options. Prior research in males has found that dopamine (DA) underlies the motivated behaviors assessed in the effort-related task with antagonism of DA D2 receptors resulting in motivational deficits. However, whether DA antagonism reduces performance in effort-based decision-making tasks in females is not known. The aim of the present study was to investigate motivation for a sucrose reward in an effort-related decision-making task after administration of the DA D2 receptor antagonist haloperidol (HAL). Adult male and female Sprague Dawley rats were randomly assigned to a non-food restricted or a food restricted condition in order to assess sex differences and the motivation for a sucrose reward. A progressive ratio choice procedure was used to assess effort-related decision-making. In this task, rats were trained in operant chambers to either lever press for a highly valued sucrose reward on a progressing fixed ratio schedule or to approach and consume freely available lab chow. Once responding was stable, HAL was administered at varying doses (vehicle, 0.05, 0.1, or 0.2 mg/kg) prior to the test. Our initial findings show that HAL significantly reduced all appropriate parameters in males and females-- lever pressing ($p < 0.05$), highest ratio achieved ($p < 0.05$), and breakpoint ($p < 0.05$)-- without any significant change in chow consumption. There were also significant interactions on lever pressing between drug dose, food restriction and sex ($p < 0.05$) as well as significant interactions on highest ratio achieved between drug dose and sex ($p < 0.05$) and chow consumption between drug dose and food deprivation ($p < 0.05$). Importantly, female rats that were food restricted showed a different pattern of behavior than males in terms of general performance. Overall, these data suggest that DA antagonism produces motivational deficits in both sexes, but that food restriction may not increase responding in female rats as it does in male rats. These findings may provide a better understanding of motivational dysfunction in both sexes and potential treatment targets for MDD.

Title: D2 agonism in the nucleus accumbens, but not the prefrontal cortex, restores reward responsiveness following chronic stress

Authors: *S. J. LAMONTAGNE, S. H. IRWIN, M. C. OLMSTEAD;
Queen's Univ., Kingston, ON, Canada

Abstract: Anhedonia, “a loss of interest or pleasure in previously rewarding activities” (DSM-5, 2013), is characteristically preceded by chronic stress (Hamen, 2005). Recent literature suggests that stress-induced deficits may be alleviated by activating distinct dopaminergic (DA) receptor subtypes. Recently (2019), we showed that chronic mild stress (CMS)-induced reward dysfunction was restored through systemic injections of a D2/3 agonist in rats; however, it remains unclear how this effect is mediated centrally. Although it is well known that the nucleus accumbens (NAcc) and prefrontal cortex (PFC) are sensitive to the effects of chronic stress, their role in mediating reward dysfunction following stress is elusive (Lucas et al., 2004; Chen et al., 2013). Using the rat probabilistic reward task (PRT; Der-Avakian et al., 2013), we investigated the neuroanatomical specificity of D2 agonism on reward learning following CMS.
Eighteen rats were exposed to Willner’s (1992) CMS regime and 18 rats were left undisturbed (no-stress control). Prior to testing in the PRT, animals from each condition received intra-NAcc (n=9 per group) or intra-PFC (n=9 per group) infusions of D2 agonist, quinpirole (QUIN; 1ug/side). We found that both CMS groups showed greater adrenal gland and lower thymus gland weights relative to control groups. There was a strong inverse relationship between adrenal gland weight and reward learning following CMS in the intra-PFC-QUIN group, but not in the intra-NAcc-QUIN group, suggesting that D2 activation in the PFC does not restore reward learning in stress-susceptible animals. Relative to no-stress and CMS animals that received NAcc infusions of QUIN, animals that received PFC infusions showed impaired reward learning with respect to reward response bias, accuracy and reaction time for the rewarding stimulus. CMS animals that received NAcc infusions did not differ from no-stress control animals on any behavioural measure.
Collectively, these findings suggest that the restoration of reward learning following chronic stress is mediated by D2 agonism in the NAcc. Future research should investigate whether other receptor subtypes, such as D1, in the PFC differentially affect reward learning following chronic stress.

Title: Catechol-o-methyltransferase function regulates palatable food consumption in male mice

Authors: *M. NOBACK[1], G. ZHANG[2], N. WHITE[3], G. V. CARR[4], J. C. BARROW[5];
[1]Johns Hopkins Sch. of Med., Baltimore, MD; [2]Drug Discovery Div., [3]Lieber Inst. for Brain Develop., Baltimore, MD; [4]Drug Discovery, Lieber Inst. For Brain Develop., Baltimore, MD; [5]Lieber Inst. for Brain Develop., Lieber Inst., Baltimore, MD

Abstract: Catechol-*O*-methyltransferase (COMT) is a critical enzyme involved in the metabolism of dopamine and other catecholamine neurotransmitters. COMT is a particularly important regulator dopaminergic signaling in regions of the brain with low expression of the dopamine transporter, such as the prefrontal cortex (PFC). Due to this regional specificity, COMT activity is a potent modulator of PFC-dependent cognitive function, including inhibitory control. In humans, expression of the high activity Val isoform is associated with increased risk of obesity, consumption of high-fat food, and craving of self-described “unhealthy” food. In these experiments, we measured palatable food consumption under fixed and progressive ratio schedules of reinforcement in two separate mouse models characterized by increased COMT activity. First we found that wild-type C57BL/6J mice singly housed for two weeks following weaning (postnatal day 21-35) have more COMT protein in the PFC than their littermates who were continuously group housed when measured as adults (postnatal day 63). Additionally, the socially isolated (SI) mice displayed increased consumption of a palatable food (strawberry milk) under an FR1 schedule of reinforcement. The SI mice showed additional signs of increased willingness to work for the palatable food in a progressive ratio task and a continuous performance test (CPT) of vigilance. To determine if the SI phenotype is related to COMT function, we tested transgenic mice that overexpress COMT in the FR1 and CPT. In a preliminary cohort, we found effects similar to those seen in the SI mice. The COMT transgenic mice consumed more strawberry milk on the FR1 schedule and demonstrated increased vigilance in the CPT. These results indicate that COMT activity may regulate palatable food consumption. Future experiments will examine whether the relationship between COMT activity and palatable food consumption can be regulated by acute changes in COMT activity or if it results from long-term adaptations in neurocircuitry.

Title: Time course of D2DR levels in the nucleus accumbens during the development and maintenance of high-fat diet-induced obesity

Authors: M. M. MARCUS, I. BUTZIRUS, D. N. A. OKINE, *A. L. TRACY;
Psychology, Grinnell Col., Grinnell, IA

Abstract: The mesolimbic dopaminergic pathway is implicated in the development and maintenance of obesity. In particular, dopamine (DA) receptor genotype has been shown to affect food reinforcement in humans and food motivation is increased by DA agonism in rats (Epstein et al., 2007; Zhang et al., 2003). Chronic obesity appears to reliably reduce striatal dopamine D2 receptor (D2DR) availability in humans, as well as in high-fat diet (HFD) induced chronically obese rats (Wang et al., 2001; Johnson & Kenny, 2010). However, changes in D2DR during the development of obesity have not yet been studied. The purpose of the present study is to examine the changes in D2DR-positive cells in the nucleus accumbens (NAcc) over an 8-week period of exposure to HFD. Four Long-Evans rats fed a 40% butterfat diet and four rats fed standard chow were euthanized and brain tissue was collected after 0, 7, 14, 21, 28, 35, 42, 49, and 56 days of ad libitum consumption of their respective diet. D2DR positive cells were visualized and quantified in 40 μm slices through the NAcc using immunohistochemical staining. D2DR levels were compared across diet type and duration. In contrast to findings in chronic obesity, our results indicate no difference in D2DR levels between rats consuming the HFD and rats consuming standard chow at early time points following introduction of the HFD (≤ 4 weeks). This finding supports the idea that obesity-induced changes in D2DR are a result of chronic consumption of HFD and/or increases in adiposity, and are not a short-term response to exposure to palatable foods. These changes are consistent with findings that novel food motivation remains similar between diet conditions in the short-term following HFD exposure, dropping off only after chronic intake (> 6 weeks; Tracy et al., 2015), and follow the behavioral pattern of initial binge eating of the HFD, followed by an intake plateau during maintenance of chronic obesity.

Title: Rare rewards drive enhanced dopamine responses and learning

Authors: *K. M. ROTHENHOEFER[1], A. ALIKAYA[1], W. R. STAUFFER[2];
[2]Neurobio., [1]Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Dopamine neurons code reward prediction errors (RPEs), the differences between received and predicted values. However, it is not known how estimated (predicted) uncertainty affects value updating or the neural coding of RPEs. To investigate this, we created two reward size sets represented by two distinct visual cues, with the same expected value but different 'shapes.' One reward set consisted of three reward sizes that were delivered with equal probability (p = 1/3, 1/3, 1/3). The other reward set consisted of the same three reward sizes, but with the middle value more certain to be delivered (p = 2/15, 11/15, 2/15). Thus, the two sets coarsely simulated uniform and normal distributions, respectively. Distinct images predicted the reward sets. Monkeys made choices between one of the reward sets and an alternative option. At un-signaled intervals during a session, we shifted all the reward sizes in a reward set by a constant factor. This manipulation forced animals to learn the shifted mean in order to maximize reward value. The choice behavior indicated monkeys learned faster from RPEs generated by rare rewards drawn from the tails of normal-like distributions - compared to the more frequent, but same magnitude RPEs generated by rewards drawn from uniform-like distributions. We recorded 87 dopamine neurons across two monkeys; 81 were significantly activated by reward ($p < 0.05$, Wilcoxon). Recordings in a Pavlovian task (n = 51 neurons) revealed that dopamine responses, across the population and within single neurons, were magnified by infrequent positive and negative RPEs generated in the normal-like distribution, compared to the identical positive and negative RPEs generates with greater frequency from the uniform-like distribution. Crucially, we observed bi-directional modulations in the same neurons. Therefore, the modulations in the dopamine responses could not be explained by different subjective values assigned to the predictive stimuli. Thus, rare rewards enhance the dopamine RPE responses, even when the conventional RPE is identical. This neuronal effect corresponded to the faster behavioral learning and together these results indicate that reward updating is modulated by estimated uncertainty.

Title: Decoding the influence of dopamine in different NAc subregions on cue-driven behaviors and behavioral inhibition

Authors: *J. W. DE JONG[1], I. CERNIAUSKAS[1], S. OBAYASHI[1], J. P. H. VERHAREN[1], L. TIAN[2], S. LAMMEL[1];
[1]Mol. and Cell Biol. and Helen Wills Neurosci. Inst., UC Berkeley, Berkeley, CA; [2]Biochem. and Mol. Med., Univ. of California, Davis, Davis, CA

Abstract: The mesolimbic dopamine (DA) system, which is comprised of ventral tegmental area (VTA) DA neurons projecting to the nucleus accumbens (NAc), is associated with reward, appetitive motivation, and hedonic processes. Mesolimbic VTA DA neurons signal reward prediction errors (RPEs); they are excited in response to rewards and reward-predicting cues and are inhibited by aversive events. However, we have recently identified a novel subtype of mesolimbic DA neuron projecting to the ventral NAc medial shell (vNAcMed), which is excited by unexpected aversive outcomes and cues that predict them (*de Jong et al., 2019; Neuron*). To further explore the functional role of these non-canonical mesolimbic DA neurons, we performed multi-site fiber photometry recordings in different NAc subregions using the DA sensor dLight during an operant conditioning assay. Specifically, we trained head-fixed mice in an operant reward-seeking task, in which a conditioned stimulus (CS+) predicts the availability of a reward. Consistent with the RPE theory, we find that after conditioning the CS+ evokes transient DA release in the lateral shell of the NAc (NAcLat), whereas reward omission inhibits DA release. In contrast, no changes in DA release were observed in the vNAcMed in direct response to the CS+. Surprisingly, however, DA release in the vNAcMed increased gradually during reward seeking. Furthermore, when we trained mice on a conditioned suppression paradigm to show behavioral restraint and inhibit reward-seeking behavior, which is normally evoked by the CS+, we found that presentation of the CS+ continued to evoke DA release in the NAcLat. However, in this case mice did not initiate reward seeking and there was no increase in DA release in the vNAcMed. Together, these results suggest that while canonical NAcLat-projecting DA neurons signal a reward prediction error, vNAcMed-projecting DA neurons are excited concurrent with reward seeking and possibly reflect either action initiation or the anticipation of a proximal reward. We are currently studying how NAcLat and vNAcMed integrate cortical glutamatergic inputs with

local DA release to mediate cue-driven behavior and behavioral inhibition. Developing a detailed understanding of the role of DA in different NAc subregions underlying cue driven behavior represents an important step towards the identification of clinically relevant targets for treating impulse control disorders such as binge eating disorder and substance use disorder.

Abstract: Maternal care is profoundly important for mammalian survival, and one critical molecular signal for this behavior is oxytocin, released by hypothalamic paraventricular nucleus (PVN) and enabling plasticity within auditory cortex for recognizing infant vocalizations. Maternal behaviors can be expressed by non-biological parents, after experience with infants. To determine how these behaviors can be acquired during natural experience, we continuously monitored homecage behavior of female virgin mice co-housed for days with an experienced mother and litter, synchronized with in vivo recordings from virgin PVN/oxytocin neurons. Mothers engaged virgins in maternal care by directing the virgins toward the nest (shepherding), and demonstrated maternal behavior by self-generating pup retrieval episodes. We found that shepherding led to activation of oxytocin neurons in two stages, first at the start of the physical

social interaction (~ 20% of optogenetically-identified oxytocin neurons), and then when the virgin entered the nest with pups (~ 33% of oxytocin neurons). Similarly, we found that exposure to maternally-executed pup retrievals activated oxytocin neurons in virgin PVN (~30% of oxytocin neurons). This socially triggered increased firing of oxytocin neurons gated behaviorally-relevant cortical plasticity for pup distress calls. Pharmacogenetic suppression of oxytocin neurons delayed the acquisition of pup retrieval behavior via these social interactions. Thus rodent maternal behavior can be learned by social transmission, and our results describe a mechanism for adapting the brains of new parents to infant needs via endogenous oxytocin.

Title: Social transmission of maternal behaviors through observation

Authors: *N. LÓPEZ CARABALLO[1], R. FROEMKE[2];
[1]Sackler Inst. of Biomed. Sciences; Neurosci. Inst., [2]Dept. of Otolaryngology-Head and Neck Surgery; Dept. of Neurosci. and Physiol., New York Univ. Sch. of Med., New York, NY

Abstract: Our laboratory studies the mechanisms by which social experience leads to neuroplasticity to promote learning and pro-social behavioral changes. We focus on maternal care by mice, enabling reliable measurements of various social behaviors combined with experimental approaches such as neural recordings and optogenetics. When mouse pups are out of the nest, they emit vocalizations that prompt the mother to fetch them back to the nest. Virgin females do not initially retrieve pups, but usually begin retrieving after several days of co-housing with an experienced mother and pups.
To understand the social experiences that lead to virgin co-parenting, we first built a new system for combining continuous video-audio-neural recordings from co-housed animals over days. We found that mothers appear to demonstrate maternal behaviors to virgins. To explore the potential for social transmission of maternal behavior, we developed a new paradigm for virgins to learn retrieval through observation. A non-co-housed virgin observes a mother retrieve pups through a transparent barrier that allows visual, odor and auditory cues to go through. Virgin female mice

can learn retrieval through observation. When the visual input was impaired, animals did not learn to retrieve via observation. Also, if the observer was an oxytocin receptor knockout animal, there was also minimal acceleration in time to first retrieval via observational learning (Carcea et al., in review).
We define successful retrieval as a mouse placing the pup safely inside the nest. Although mothers are proficient retrievers, some fail to retrieve accurately, sometimes placing the pups in the outside border of the nest. After observing some virgins mimicked mother's retrieval errors, we developed a setup for virtual simulation of observational learning, consisting of retrieval videos and pup calls audio playback. It allows us to manipulate the sensory stimuli presented to the virgins and further explore experience-related effects on behavior and neural activity. Our data (n=3) shows that virgins can learn to retrieve in the virtual setup. Furthermore, our lab showed that the neuromodulator oxytocin has a role in sensitizing the sensorial cortex promoting learning of pup retrieval (Marlin et al. Nature 2015). Sensory cortices and hypothalamic-oxytocin-releasing regions seem to be activated during observational learning in virgins, as shown by expression of the intermediate-early gene *c-fos* in auditory, visual and piriform cortices and the paraventricular nucleus of the hypothalamus. Our research will help parse out the specific experiences and sensory modalities required for learning of maternal behaviors.

Title: From discriminative to affective touch: A mesoscale perspective of the somatosensory pathway to the primate amygdala

Authors: ***A. B. MARTIN**[1], K. R. ANDERSEN[1], J. K. MORROW[1], E. A. HILLIER[2], M. A. CARDENAS[2], S. LEE[1], S. L. COWEN[3], K. M. GOTHARD[4];

Abstract: The role of the primate amygdala in processing touch has only recently been addressed. The neural processes that transform the objective, discriminatory features of tactile inputs, presumably originating from area 3b, into a representation of emotional significance in the amygdala are unknown. To address this question, we have recorded local field potentials in response to the same tactile stimuli from the primary somatosensory cortex (area 3b), secondary

somatosensory cortex (SII), and the amygdala. The tactile stimuli included 1-s long, non-aversive airflow stimuli and brief sweeping touches by human experimenters. These stimuli were delivered to the face and head of the monkey. The experimenters wore instrumented gloves that signaled the contact force and sweep duration of each touch. In area 3b, the airflow and the touch stimuli elicited similar responses: a brief elevation of power in the 4-30 Hz frequency range, followed by a suppression of the power the 8-30 Hz range, and then a suppression of power in the 4-7 Hz range. As expected, the high-frequency broadband was highly correlated with spiking activity. In the amygdala, the airflow and the touch stimuli also elicited similar responses. However, these responses were different from the responses in 3b and showed stronger modulation in response to touch compared to airflow. Specifically, in response to tactile stimulation we observed an increase in power followed by a suppression in the 4-7 Hz (theta) and 30-70 Hz (gamma) frequency ranges. The most prominent finding was a reliable suppression in the 12-30 Hz (beta) range. None of these responses depended on the presence (airflow) or absence (touch) of stimulus-related spiking activity (see adjacent poster) or the associated high frequency broadband modulations. These features of mesoscale neurophysiology in the amygdala have not been previously reported. We took advantage of the simultaneously recorded LFP's from area 3b and the amygdala to explore the processing flow of tactile signals between these areas. We found a strong correlation in beta modulation at the time of stimulation, especially for human touch. In parallel, we found a weaker correlation in theta between these areas and an associated anti-correlation between cortical theta and amygdalar beta, indicating a temporal link in tactile processing between area 3b and the amygdala. While these findings are preliminary, they suggest that the LFP's in the amygdala map onto the canonical features of sensory information processing found in the cortex.

Abstract: The role of the primate amygdala in processing touch has only recently been addressed. The neural processes that transform the objective, discriminatory features of tactile inputs, presumably originating from area 3b, into a representation of emotional significance in the amygdala are unknown. To address this question, we have recorded neural responses to the same tactile stimuli from the primary somatosensory cortex (area 3b), secondary somatosensory cortex (SII), and amygdala. The tactile stimuli included 1-s long, non-aversive airflow and brief sweeping touches by human experimenters. These stimuli were delivered to the face and head of the monkey. The experimenters wore instrumented gloves that signaled the contact force and sweep duration of each touch. Both the airflow and the human touch reliably activated neurons in area 3b. A large proportion of touch-responsive neurons in 3b (35 of 61) responded to deflections of the whiskers and facial hairs (mainly in the perioral area). A subset of neurons in 3b (approximately 30%) showed significant correlations with the contact forces applied to their receptive fields. In contrast, simultaneously recorded neurons in the amygdala responded reliably to airflow (22 of 110) but failed to respond to human touch delivered to the same area, suggesting a gating mechanism for social touch in the amygdala. To test for the role of social factors, 10 human experimenters, with different levels of familiarity with the subject monkey, delivered similar patterns of touches to the same skin area. Only 2 amygdala neurons of the 151 tested exclusively with human touch responded. These neurons appeared to differentiate between the individuals delivering the touch stimuli. The autonomic state of the animal in response to being touched by different individuals was considered as a factor for the observed gating. Indeed, less familiar individuals caused higher elevations of heart and respiratory rates than more familiar individuals. Compared to human touch, airflow stimuli appeared less arousing. It is possible, therefore, that the autonomic arousal during human touch is related to an intra-amygdala process by which responses to social but not mechanical touch are gated out. This purported gating mechanism may not be universal. In previous studies, we found that 30-40% of the neurons in the amygdala of other monkeys responded to human touch. Ongoing studies will shed light on the sources of the observed individual variation and will determine whether social and non-social tactile stimuli are processed differentially in the amygdala.

Title: Statistically separable components of the local field potential show sensory-modality specific spike-field coherence in the primate amygdala

Authors: *J. K. MORROW[1], M. X. COHEN[2], K. M. GOTHARD[3];
[1]Univ. of Arizona, Tucson, AZ; [2]Univ. Amsterdam, Amsterdam, Netherlands; [3]Univ. Arizona, Col. Med., Tucson, AZ

Abstract: Electrophysiological signals recorded via depth electrodes are often separated into two components: a low-frequency component (often called the local field potential or LFP) produced by the aggregate activity of thousands of nearby cells; and a high-frequency component that reflects action potentials (a.k.a., “spikes”) of individual neurons. Spike-field coherence examines the relationship between these signals to determine if spiking activity is synchronized with, or modulated by, lower frequency oscillations. While numerous studies have found spike-field coherence in well-organized structures like the hippocampus or cortex, next to nothing is known about this important phenomenon in the primate amygdala. To address this issue, we recorded single-unit and LFP activity from 16 sites that spanned the entire dorsal-ventral axis of the amygdala while monkeys received visual, tactile, or auditory stimuli. We then isolated statistically independent sources of LFP signals using a generalized eigendecomposition-based (GED) analysis that has recently been validated using empirical and simulated neural datasets. We found significant spike-field coherence in several low-frequency bands (1-10 Hz) in both the channel-wise and GED-based LFP signals. Visual, tactile, and auditory stimuli often, but not always, elicited spike-field coherence in different frequency bands. The channel-wise LFP showed spike-field coherence at high frequencies (>100 Hz), which is often due to contamination of this frequency range by components of the action potential signal; however, the GED-based signal rarely showed this high-frequency artifact. These results demonstrate that 1) single-unit activity can be synchronized to LFP oscillations within the primate amygdala, 2) spike-field coherence was prominent at low frequencies and appeared to be related to the sensory modality of the stimulus in this particular experiment, and 3) GED-based LFP signals may be more resistant to high-frequency artifacts in spike-field coherence.

Title: Inclusion of dlPFC and vlPFC inputs in cortico-amygdala topography

Authors: *A. C. MCHALE, J. L. FUDGE;
Neurosci., Univ. of Rochester Sch. of Med., Rochester, NY

Abstract: The primate amygdala is a collection of nuclei that work together to interpret a range of salient stimuli, including social cues such as faces and social group hierarchies. The basal nucleus is of particular interest in primates, including humans, because it is disproportionately enlarged and complex. It contains 3 subdivisions: the magnocellular (Bmc), intermediate (Bi,) and parvicellular (Bpc). These subdivisions are distinguished by a gradual dorsal-ventral cellular gradient based on pyramidal cell size and cell-packing density.
In previous work, we found that the topography of projections from "limbic cortex" (orbital and medial prefrontal cortex (omPFC) and insula) to the basal nucleus subdivisions is determined by cortical differentiation rather than lobar assignment. The least differentiated cortices project throughout the basal nucleus, with successively more differentiated cortices overlapping these inputs along a ventral to dorsal gradient.
Our current work seeks to understand whether more highly differentiated "non-limbic" prefrontal cortex, specifically the dorsolateral prefrontal cortex (dlPFC) and ventrolateral prefrontal cortex (vlPFC), fits into this organization. We examined the distribution of labeled cells throughout the dlPFC and vlPFC following small injections of retrograde tracer into different subdivisions of the basal nucleus. We then analyzed them with respect to previous data documenting omPFC and insula inputs. In line with the literature, there is an overall lower density of dlPFC and vlPFC projections into the basal nucleus compared to omPFC and insula projections. However, a topographical pattern of inputs into the basal nucleus was observed. Bpc received few to no projections, Bi received light projections, and Bmc received light to moderate projections from dlPFC and vlPFC regions. The majority of retrogradely labeled cells were in areas 12, 45, and 8A, and there were scattered retrogradely labeled cells in areas 9 and 46. Taken together, the results indicate an overall topography in cortico-amygdala projections wherein relatively more differentiated inputs overlap less differentiated inputs progressing from Bpc to Bi to Bmc.

Title: Specificity of an amygdala-prefrontal projection for integrating emotional and multisensory information in the macaque

Authors: *K. K. SHARMA[1], M. M. DIEHL[3], J. L. FUDGE[4], L. M. ROMANSKI[2];
[1]Dept. of Neurosci., [2]Dept Neurosci., Univ. of Rochester Sch. of Med. and Dent., Rochester, NY; [3]Psychological Sci., Kansas State Univ., Manhattan, KS; [4]Dept of Neurobio. and Anat., Univ. of Rochester Med. Ctr., Rochester, NY

Abstract: The ventrolateral prefrontal cortex (VLPFC) is a site of multisensory integration that is highly responsive to species-specific faces and vocalizations in both monkeys and humans. Face cells and face patches have been found in the macaque VLPFC and studies in humans indicate that a subregion of the VLPFC is critical for the identification of facial expressions. The amygdala is also highly active during the processing of facial and emotional expressions. Within the amygdala, the basal nucleus is a key input to the prefrontal cortex and is massively expanded in primates. In macaques, the basal nucleus has three sub-nuclei with unique and overlapping projections to the prefrontal cortex, thereby participating in distinct but complementary microcircuits. To achieve precise insight into the potential circuit function of amygdala projections to the VLPFC, we injected bidirectional tracers into face and vocalization-responsive regions of the VLPFC and mapped retrogradely labeled cells within the amygdala. In previous electrophysiology experiments, macaques viewed or heard vocalizations, facial gestures, or audiovisual combinations of faces and vocalizations as part of a presentation task or an audiovisual working memory task. Injections of dextran-conjugated tracers were subsequently placed at VLPFC sites with a high concentration of cells responsive to species-specific vocalizations (auditory), faces (visual), or simultaneous presentations of both stimuli (multisensory). 14-21 days post-injection, animals were perfused and the brain was processed for immunocytochemical localization of labelled cells and fibers. In addition to connectivity with auditory association and inferotemporal cortex (previously presented), tracer injections resulted in dense concentrations of retrogradely labeled cells that were consistently found in the basal nucleus and were highly restricted to the intermediate (Bi) and magnocellular (Bmc) subdivisions of the basal nucleus. Our results establish a direct connection between the basal nucleus of the amygdala and VLPFC sites that process and integrate faces and voices. Furthermore, this projection arises from a highly specific portion of the basal nucleus that has established connections to occipital and temporal sensory and association cortices. Our findings illustrate a pathway by which the amygdala may participate in the processing of multisensory, social stimuli in the prefrontal cortex.

Title: Chemogenetic investigation of ventral hippocampus and orbitofrontal cortex interaction in social behavior

Authors: *A. ALIBRO, G. LARYEA, O. ABUBAKARE, Y. CHUDASAMA;
Section on Behavioral Neurosci., NIMH, Bethesda, MD

Abstract: Fronto-temporal interactions are critical for the normal expression of cognitive and socioemotional behaviors. In rats, lesions of the hippocampus have a large impact on social behavior causing disorganized nest building, altered social interactions and abnormal social learning and memory (e.g., Bunsey and Eichenbaum, 1995; Hippocampus, 5: 546-556). Lesions of the orbitofrontal cortex (OFC) also affect social behavior by altering emotional responsiveness towards other rats which in some cases expresses as heightened aggression (e.g., Rudebeck et al., 2007, EJN, 26:2315-2326). The ventral hippocampus (vHC) sends a direct projection to the OFC suggesting that these two regions work closely together in controlling certain aspects of social interactive behavior. To date, the functional interaction between the vHC and OFC with respect to social behavior has not been systemically addressed.
In this study, we used a DREADDs mediated approach to disconnect the interaction between the vHC and OFC. Rats received unilateral injections of the inhibitory DREADDs construct, AAV8-hSyn-hM4D(Gi)-mCherry, in either opposite hemispheres (contralateral, n= 10) or the same hemisphere (ipsilateral, n= 6) while the control group was injected with AAV8-hSyn-GFP (n= 8) in contralateral hemispheres. The animals were first tested on discrimination learning, flexibility and decision-making to assess basic cognitive functions. Subsequently, the animals were tested on a social interaction task to examine how the rats behaved towards familiar or novel conspecifics. Ten minutes prior to the beginning of each tasks, rats were administered clozapine or vehicle (20% DMSO in water) in a counterbalanced design. Preliminary data indicates that although DREADDS mediated inhibition of the vHC and OFC interaction does not impact associative learning and decision-making per se, it appears to influence the degree of social affiliation in rats.

Title: Cingulotomy alters postnatal development of vocalizations in infant marmosets

Authors: *Y. CHUDASAMA, G. NAGARAJAN;
Section on Behavioral Neurosci., Natl. Inst. of Mental Hlth., Bethesda, MD

Abstract: Marmosets have a rich repertoire of vocalizations used to convey positive and negative emotional information to family members. Vocal development is easily modulated by environmental changes such as social interaction. Like all mamammalian species, infant marmosets cry to produce reactions from the mother or care-giver. From a developmental perspective, not responding appropriately to the cries of an infant may have detrimental effects on the animals social behavior when adult. Studies using functional ultrasound in adults (Takahashi et al., 2018) and immediate early gene expression in infants (Neuman, 2016) implicate the cingulate cortex (area 24) in the normal expression of vocal calls. Here we examined changes in vocal calls (acoustics) of infant marmosets (postnatal day 10 - 16) before and after a cingulate lesion (NMDA 0.12 M). Vocalizations were recorded using Sennheiser ME 64 and acoustics analysed using Raven Pro. Vocal calls such as phee, tsik, trill and cry were preserved before and after the lesion. One day after the lesion, the acoustic structure of the calls and preference of call types changed substantially; phee calls became unstructured and longer in duration, cries became more frequent, and the number of tsik and trills were reduced. Five days after the surgery, there was a higher rate of tsik and trill calls. In addition, we found that physical contact with a stuffed toy induced a 90-95% reduction in vocalization. Without physical contact, there was a dramatic increase in the number of calls. These data suggest that physical contact for neonatal infants reduces emotional distress and that cingulate cortex lesion does not eliminate vocalizations but rather influences the call by altering its structure and frequency. This alteration in the overall integrity of the vocalization may influence the information or message conveyed to family members and may also influence how family members interact with the infant during development.

Title: Connections of the medial and lateral septum in the rat: A viral tracing study

Authors: *J. GOODING[1], G. NAGARAJAN[2], Y. CHUDASAMA[1];
[2]Section on Behavioral Neurosci., [1]Natl. Inst. of Mental Hlth., Bethesda, MD

Abstract: The septal region attracts much attention because of its involvement in the control of a variety of motivational, emotional and cognitive behaviors. Many of these studies involved septal lesions that resulted in extensive damage to both medial and lateral septal nuclei. The behavioral effects of large septal lesions may represent a composite phenomenon that reflects the loss of normal, but different functions of the medial and lateral septal regions. The septohippocampal pathway has been best characterised in anatomic and physiological terms but the anatomic localization of the septum makes it an important relay station between brainstem structures and the telencephalon. To date, there have been no systematic analyses of the anatomical
organization of the medial and lateral septal nuclei. Here we used a retrograde viral tracer called pseudorabies (PRV) to determine their major inputs. We injected PRV-614 (DS Red) and PRV-152 (GFP) into the medial and lateral septum, respectively. The preliminary data show that both lateral and medial septal nuclei receive major input from the piriform cortex consistent with previous reports, and both are densely innervated by the entorhinal cortex. The observed differences between these two regions relate to the hippocampus with only the ventral portion projecting to the lateral septum only. In addition, unlike the medial septum, tracer injections in the lateral septum caused extensive retrograde labelling in the ventral regions of the prefrontal cortex, the pre- and postgenual cingulate cortex, as well as the paraventricular and paratenial nulclei of the midline thalamus. Together, these data indicate the medial and lateral septum can be anatomically differentiated on the basis of their selective diencephalic and telencephalic inputs.
Further studies will disentangle the multisynaptic pathways by which the medial and lateral septum are anatomically organized.

Title: Galanin receptor 1 in the ventral prefrontal cortex and ventral hippocampus: Implications for fronto-temporal modulation of impulse control

Authors: *K. E. BERKUN[1], F. MESSANVI[1], H. A. WANG[1], H. TEJEDA[1], R. FIELDS[2], Y. CHUDASAMA[1];
[1]NIMH, [2]NINDS, NIH, Bethesda, MD

Abstract: We recently demonstrated that the neuropeptide galanin modulates ventral prefrontal cortex (vPFC) and ventral hippocampal (vHC) actions on impulse control mechanisms in rats. Specifically, we showed that while local infusion of M617, a selective agonist of the galanin receptor 1 (Gal-R1) in the vPFC made rats impulsive, intra-vHC Gal-R1 stimulation had the opposite effect of making rats more controlled and less impulsive. This finding was in the absence of compulsive perseverative responding suggesting a selective mechanism of Gal-R1 mediated modulation of impulse control in prefrontal-hippocampal circuitry. This prompted us to examine the characteristics of vPFC and vHC neurons expressing the galanin 1 receptor. We first used multiplex fluorescent in situ hybridization to determine the expression of Gal-R1 in vPFC and vHC as well as their co-localization with glutamatergic and GABAergic neuron markers. The preliminary results showed that vPFC Gal-R1 mRNA were mostly found in glutamatergic neurons, whereas vHC Gal-R1 mRNA were located in CA1 pyramidal layer and the subiculum. Some signal was also observed in the dentate gyrus granular layer. We then made an adeno-associated virus (AAV) expressing cre under the promoter of Gal-R1and injected this virus, together with another cre-dependent AAV expressing a fluorescent protein, into the vPFC or the vHC. This analysis will be used to characterize the virus and verify its cellular specificity, which will then allow us to determine connectivity of the infected neurons and later optically stimulate or silence them to assess their functions.

Title: Sexual dimorphic effects of ventral lateral septal lesions on anxiety related vocalization

Authors: *G. NAGARAJAN, J. GOODING, Y. CHUDASAMA;
Natl. Inst. of Mental Hlth., Bethesda, MD

Abstract: Anxiety disorders pose a major health concern in society with an increased prevalence in the female population and are comorbid with other psychiatric illnesses including depression and schizophrenia. According to one prominent view, the expression of anxiety is caused by anomalies in the septo-hippocampal neural connections associated with conflict resolution. In particular, the ventral hippocampus has been implicated in conflict resolution and rats with large septal lesions display anxiolytic behavior. Accordingly, anatomical studies including our own show that the ventral lateral septum (vLS) is densely innervated by the ventral hippocampus in both male and female rats. While these studies implicate an important role for septal-hippocampal interactions, there has been no systematic attempt to establish sex differences in the behavioral expressions of anxiety. In the first of a series of studies, we examined the effect of vLS lesions on standard anxiety tasks in male and female rats and recorded their vocalizations as a potential index of anxiety. The vLS was lesioned bilaterally using NMDA (n=5/group). Soon after recovery, lesioned males were highly aggressive towards their conspecific lesioned cage mate and had to be separated. In the open field test, lesioned-male rats spent more time in the periphery of the box indicating an anxious state whereas the lesioned-females were less anxious as evidenced by spending more time in the center of the box. With respect to vocalization, after receiving the lesion, the males vocalized more than sham males and lesioned females. Together, these data suggest that despite the normal perseveration of the hippocampal-septal projections, lesions to the vLS show clear sexual dimorphic behavioral changes in anxiety.

Title: Alteration of brain connectivity associated with the magnitude of the romantic love in couple

Authors: *J. KIM[1], J. OH[1,2], H. EOM[2], M.-K. KIM[2], J.-J. KIM[1,2];
[1]Yonsei Univ., Seoul, Korea, Republic of; [2]Inst. of Behavioral Sci. in Med., Yonsei Univ. Col. of Med., Seoul, Korea, Republic of

Abstract: Introduction: Romantic love is the evoking one of the most overwhelming affective states and is associated with a desire to enter or maintain a close relationship. Resting state functional magnetic resonance imaging (rsfMRI) studies have found that increased regional homogeneity and functional connectivity (FC) in brain regions involved in the processing of reward, motivation, and emotion regulation network and social cognition network when comparing “in-love” group from “ended-love” and “single” group. However, how the magnitude of the love in the couple is related to the brain, functional structures are not well known. We studied the association between the brain connectivity and the magnitude of the love for one’s partner and from one’s partner. **Method:** rsfMRI and passionate love scale (PLS) were obtained from the 40 couples in the plan of the marriage (Female: N=40, Male: N=40). After standardized preprocessing, region of interest (ROI)-based approach was used to do the ROI to ROI connectivity analysis. The 10 ROIs known as reward, motivation and emotion regulation network [dorsal anterior cingulate cortex (dACC), insula, caudate, amygdala, and nucleus of accumbens] and social cognition network network [temporo-parietal junction (TPJ), posterior cingulate cortex(PCC), medial prefrontal cortex (MPFC), inferior parietal, precuneus] were defined. Correlation analysis was run to explore the association between PLS scores and ROIs’ connectivity. **Results:** 1) One’s PLS score had a positive correlation with the connectivity-strength of ROI to ROI within both insula and dACC but had no correlation with connectivity-strength within the ROI’s of social cognition network. 2) Partner’s PLS score had a positive correlation with connectivity-strength in ROI’s of social cognition network (TPJ and PCC) and reward, motivation and emotion regulation network (dACC, insula and caudate). **Discussion:** This study first provides empirical evidence of the alteration in brain functional architecture associated with the magnitude of love in the couple. Reward, motivation and emotion regulation network is the critical brain region with the degree of love for one’s partner and from one’s partner. Our results may also suggest that partner’s love is more related to social cognition process than one’s love.

Title: Neural reactivity varies with physical and sexual abuse

Authors: ***H. FREEMAN**[1], J. B. PURCELL[2], D. C. KNIGHT[3];
[1]Univ. of Alabama Birmingham, Birmingham, AL; [2]Psychology, Univ. of Alabama at Birmingham, Birmingham, AL; [3]Psychology, Univ. of Alabama-Birmingham, Birmingham, AL

Abstract: Physical and sexual abuse during childhood are widespread issues that have been linked to negative psychological, physical, and behavioral outcomes later in life. Approximately 18% of adolescents in the United States have been physically abused, while 12% have been sexually abused. Dysfunction of emotional processes appear to underlie the stress-related symptoms of those exposed to abuse in childhood. Therefore, it is important to investigate the neural function that supports emotion processes in those who have experienced abuse during childhood to better understand the neural basis of abuse-related emotional dysfunction in adulthood. The current study investigated brain activity using functional magnetic resonance imagining (fMRI) with participants who were physically and/or sexually abused during childhood and compared them to non-abused controls. 301 participants between the ages of 17-23 completed a psychosocial stress task based on the Montreal Imaging Stress Task (MIST; Dedovic et al., 2005) during fMRI. Stress-related brain activity was compared between participants who had experienced abuse and a control group that had not experienced the same type of abuse. Physical abuse was associated with decreased orbitofrontal cortex reactivity to stress. Sexual abuse was linked to decreased neural activation within the ventromedial prefrontal cortex, dorsolateral prefrontal cortex, cingulate cortex, and hippocampus. The present results suggest that childhood physical and sexual abuse alters the stress-related neural function of young adults in brain regions associated with emotion expression and regulation. These findings may lead to better understanding of the adult psychopathology that is associated with adverse childhood events.

Title: Corticotropin-releasing factor in the insular cortex increases social exploration in rats

Authors: *N. S. RIEGER, J. A. VARELA, A. DJERDJAJ, J. P. CHRISTIANSON;
Boston Col., Chestnut Hill, MA

Abstract: Assessing affective state is important to complex social behaviors such as empathy and deficits in these evaluations are implicated in a number of disorders including autism. The insular cortex (IC) is a region with myriad sensory inputs that is important to both social behavior and evaluating the emotional state of others. Corticotropin-releasing factor (CRF) is integral to emotion, valence signaling and social behavior. Importantly, CRFR1 receptors are present in IC but the role of CRF in the IC on social behavior is unknown. In acute whole cell recordings of IC pyramidal neurons, bath application of CRF (50 nM) depolarized the resting potential, reduced action potential amplitude and reduced afterdepolarization without affecting other intrinsic properties (i.e. I/O curve); these effects were evident in cells from male and female rats. In acute recordings on a perforated multielectrode array, CRF (50 and 300nM) increased synaptic fEPSP amplitude. This effect was blocked by both the coapplication of a CRFR1 antagonist (CP154526, 10 µM) and the presence of a GABAa receptor antagonist (SR-95531, 2 µM). In whole cell recordings CRF reduced sIPSC frequency and amplitude further indicating a net excitatory effect of CRF on the IC via CRFR1 mediated inhibition of GABAergic interneurons. We tested for insular CRF induced behavioral changes by giving bilateral infusions of CRF (either 50 or 300 nM) to rats and exposing them to either juvenile (~PN31) or adult (~PN51) conspecifics in a social exploration paradigm. Both 50 nM and 300 nM doses increased the amount of time spent interacting with conspecifics indicating a gain of function role of CRF in the insula in social behavior. Taken together, these results show that CRF increases IC excitability leading to increased social exploration of both juveniles and adults.

Title: Long-term voluntary exercise affected helping behavior mediated by activity of oxytocin neurons in rats

Authors: *Y. LIU, N. KUBOTA, S. AMEMIYA, T. NISHIJIMA, I. KITA;
Tokyo Metropolitan Univ., Tokyo, Japan

Abstract: Several studies have suggested that physical exercise may facilitate prosocial behavior, which is defined as the voluntary behavior intended to be benefit for another, but there are few experimental studies focusing on the effect of exercise on prosocial behavior, conducting in controlled laboratory settings. Hence, whether long-term voluntary exercise affects prosocial behavior and the neural mechanisms underlying the effect of the exercise on prosocial action remain unclear. Previous researches have suggested that empathy is one of the most essential factors for the prosocial behavior and is mediated by activity of oxytocin (OXT) neurons. Thus, it is possible that long-term voluntary exercise may affect the prosocial behavior via the activity of OXT neurons. In the present study, we examined the effect of long-term voluntary exercise for 4 weeks on helping behavior for soaked conspecifics in male rats, and measured neuronal activity of OXT neurons in the hypothalamic paraventricular nucleus (PVN) during helping situation using immunohistochemistry. We also measured neuronal activities in the central nucleus of the amygdala and corticotropin-releasing factor neurons in the PVN in both helping (observer) and soaked (demonstrator) rats in order to evaluate neuronal activities related to empathetic concern in the prosocial behavior. Helping rats were assigned one of two groups to alter the exercise condition; individually housing in the cage with running wheel (EX) or without running wheel (no-EX) for 4 weeks. Then, we observed a helping behavior that a helping rat opens the door for a soaked rat, for 6 consecutive days (maximum for 5 min/day). The time to door-opened and the rate of door-opened were recorded. In addition, the time spent in interaction zone and the duration of grooming were also observed to evaluate helping intention and empathy based on emontional contagion, respectively. Although no significant difference between the groups was obtained in the time to door-opened, the rate of door-opened in EX group was more than that in no-EX group. Furthermore, the time spent in interaction zone and the duration of grooming in the EX group were longer than those in the no-EX group. These results suggest that long-term voluntary exercise may facilitate prosocial behavior by enhancing an ability of empathy. The results of neuronal activity are under consideration.

Title: Prelimbic medial prefrontal cortex disruption during adolescence increases susceptibility to helpless behavior in adult rats

Authors: *D. L. ULIANA, F. V. GOMES, A. A. GRACE;
Neurosci., Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Background: Major depressive disorder (MDD) is a disabling mental disorder worldwide. Several stress animal models have been used to study the neurobiology of this disorder, including learned helplessness (LH), in which susceptible animals show a failure to escape along with a downregulation of ventral tegmental area (VTA) dopamine (DA) system activity. In LH, the prelimbic portion of the prefrontal cortex (plPFC) plays an important role in the modulation of helpless behavior, but so far there is no evidence indicating that its developmental disruption alters susceptibility to this behavior. **Methods:** Male adolescents (PND 31-33) and adult (PND 70-72) Sprague-Dawley rats were submitted to plPFC lesion surgery and during adulthood (>PND 65) or 1 week later were evaluated in the elevated plus maze. Two days following, the rats were submitted to the LH model to evaluate helpless behavior. Electrophysiology recording in the VTA of DA neurons in adult rats was performed after four days of LH. **Results:** Whereas adult plPFC lesion induced neither anxiety responses (% Time and Entries in open arms) nor increased susceptibility to helpless behavior (Number of escape failures and Latency to escape), adolescent plPFC lesions induced an anxiety response. The plPFC lesion increased the proportion of animals showing helpless behavior in LH at adulthood (adolescent plPFC lesion: 92.3% of helplessness; control group: 42.1% of helplessness rats), increasing the latency to escape and the number of escape failures. In the saline-injected group, the latency to escape and the number of escapes failures were significantly different between helpless and nonhelpless rats. plPFC lesions decreased the number of spontaneously active DA neurons compared to the control group in VTA, similar to that observed in other depression models. No effect of condition was found on firing rate and percentage of spikes in burst. Helpless animals with adolescent plPFC lesion showed a decreased DA population activity in VTA compared to naive rats and nonhelpless rats. **Conclusion:** These data suggest that the disruption of plPFC activity during adolescence increases susceptibility to helpless behavior in

adult rats. Therefore, a predisposition or early life adverse events that impair plPFC activity may enhance susceptibility to depression in adulthood. **Financial support:** MH101180.

Title: Development and initial *in vivo* evaluation in monkey brain of [^{11}C]T-1650, a novel positron emission tomography ligand for phosphodiesterase-4 subtype D

Authors: *R. DICK[1], Y. WAKABAYASHI[1], S. TELU[1], M. FUJITA[2], C. MORSE[1], S. S. ZOGHBI[1], R. L. GLADDING[1], R. NUGENT[3], M. GURNEY[3], V. W. PIKE[1], R. B. INNIS[1]; [1]Mol. Imaging Br., Natl. Inst. of Mental Hlth., Bethesda, MD; [2]Hyogo Col. of Med., Nishinomiya, Japan; [3]Tetra Discovery Partners, Grand Rapids, MI

Abstract: Objective: Phosphodiesterase-4 (PDE4) is an enzyme that metabolizes and terminates the actions of the second messenger cyclic adenosine monophosphate (cAMP). Binding of the PDE4 inhibitor [^{11}C](*R*)-rolipram was previously found to be globally decreased in unmedicated subjects with major depressive disorder (MDD) compared to controls, a finding consistent with the cAMP theory of depression. However, rolipram inhibits all four PDE4 subtypes (4A, 4B, 4C, and 4D). Prior research has shown that type D (PDE4D) may play a key role in cognitive function and depression. This study used positron emission tomography (PET) to assess the newly developed PDE4D-selective radioligand [^{11}C]T-1650 in rhesus monkey. **Methods:** Two brain scans were obtained in one monkey using [^{11}C]T-1650. To measure enzyme-specific uptake, one scan was performed after injection with a selective PDE4 inhibitor, rolipram. Concurrent arterial samples were obtained to measure parent radioligand concentrations. **Results:** The tracer readily entered the brain and showed widespread distribution, with lower binding in the cerebellum. Radioactivity concentration in whole brain peaked at 2.65 SUV (standardized uptake value units) at baseline and 4.37 SUV after rolipram administration (1.0 mg/kg). The plasma parent peaked at 12.6 SUV and 11.8 SUV, respectively, and the plasma parent free fraction was estimated at 6.99% and 6.23%, respectively. In the pharmacokinetic analysis, target enzyme density was quantified as total distribution volume (V_T) using the two-tissue compartment model. V_T was well-identified in all brain regions and showed strong time stability. A Lassen plot was used to graphically estimate occupancy of PDE4D by rolipram for several brain regions. PDE4D occupancy was 92.8% and non-displaceable distribution volume

(V_{ND}) was estimated as 3.50 mL/cm^3 (Fig.1). **Conclusions**: [^{11}C]T-1650 was able to successfully image and quantify PDE4D in monkey brain, thus warranting further investigation of this novel radioligand.

Title: Characterization of the long-term effects of inflammatory pain on depressive-like behaviors

Authors: *D. BUREK, N. MASSALY, J. A. MORON-CONCEPCION;
Anesthesiol., Washington Univ. Sch. of Med., St. Louis, MO

Abstract: The rates of suicide and unintentional lethal overdose have doubled in the last 15 years, paralleling increases in reported pain and prescribed opioids. Limited insights into the mechanisms of pain and depression comorbidity underlie inadequate efforts to prevent these fatalities. Both chronic pain and depression involve dynamic recruitment of and allostatic changes to mesolimbic reward circuitry. Emotional responses to pain are associated with activity in the nucleus accumbens (NAcc), which integrates information from multiple brain areas to play a critical role in emotion and motivation, making this structure an ideal candidate for studying pain and depression comorbidity. Interestingly, discrete regions of the NAcc differentially regulate reward and aversion through the kappa opioid receptor (KOR) and its endogenous neuropeptide ligand dynorphin (DYN), by modulating dopamine, glutamate, and serotonin release. Our laboratory recently demonstrated that pain actively recruits this system to drive negative affective states. However, the role of the DYN-KOR system in pain-induced depressive-like behaviors modeled as passivity during acute and inescapable stressors remains to be investigated. Here we demonstrate that persistent inflammatory pain results in longer latency to eat in the novelty-suppressed feeding task, suggesting greater conflict between anxiety and motivation. Persistent inflammatory pain also results in more immobility in the forced swim test but does not impact exploratory behavior in the open field and elevated zero maze, indicating a predominantly depressive-like state. To further uncover NAcc DYN-KOR circuitry, we use retrograde tracing and characterization of KOR-expressing afferents into the NAcc during prolonged inflammatory pain. In parallel, we use the KOR antagonist norBNI directly in the NAcc in an effort to block the effects of pain in the novelty-suppressed feeding, forced swim, and tail suspension tests. This foundation for future studies on specific afferents will elucidate targets to treat pain-induced depressive-like behavior and ultimately improve quality of life for patients and prevent life-threatening episodes.

Title: Streptozotocin-induced hyperglycemia causes depressive-like behaviors with glial alterations in the medial prefrontal cortex

Authors: H. SON, J. BAEK, J. KANG, ***H. KIM**;
Anat. and Convergence Med. Sci., Gyeongsang Natl. Univ. Med. Sch., Jinju, Korea, Republic of

Abstract: Depression is a devastating psychiatric illness that reduces the quality of life and sometimes leads to suicide. The prevalence of depression is more than three times higher in people with diabetes. The global rising prevalence of diabetes could deteriorate the prevalence of depression. However, the nature of the relationship between depression and diabetes remains unclear. In the present study, we investigated the effect of hyperglycemia on depressive behaviors and related brain regions. To induce hyperglycemia, a core symptom of diabetes, we injected streptozotocin (STZ, 100 mg/kg, i.p.) once. We confirmed that the blood glucose levels were two times higher in STZ-injected mice than the control group and the high blood glucose levels were maintained for at least three weeks. We found that preference about novel social interaction decreases in STZ-injected mice, but not in the basal preference of the social interaction, which could represent anhedonic behavior. Thereafter, we measured anhedonic behaviors using the sucrose preference test and female urine sniffing test to confirm anhedonic symptom. We found that sniffing time of STZ-injected mice decreases while sucrose preference does not change. We also found despair behavior in STZ-injected mice by confirming increased immobility during tail suspension test. We found increased expression of glial fibrillary acidic protein and Iba1 in the medial prefrontal cortex (mPFC) of STZ-induced mice. These results suggest that hyperglycemia could induce depressive-like behaviors and it might be due to glial alteration in the mPFC.

Title: Fighting females: Neural and behavioral effects of chronic social defeat stress in female mice

Authors: *E. L. NEWMAN[1], H. E. COVINGTON, III[1], L. CART[1], M. B. BICAKCI[1], K. BURK[1], J. SUH[2], K. J. RESSLER[2], J. F. DEBOLD[1], K. A. MICZEK[1];
[1]Tufts Univ., Medford, MA; [2]McLean Hosp. / Harvard Med. Sch., Belmont, MA

Abstract: Despite the two-fold higher prevalence of mood disorders in females compared to males, most clinical and preclinical research focuses on male subjects. We introduce an ethological murine model to study several cardinal symptoms of affective disorders in the *female targets* of *female aggression*. Housed with a castrated male conspecific, most intact Swiss Webster (CFW) females readily attack unfamiliar C57BL/6J (B6) females, inflicting more than 40 bites/5-min. These highly aggressive CFW females were housed in resident pairs with castrated CFW males and used as stimulus animals for a 10-day female social defeat stress procedure. Daily 5-min defeats occurred in large cages divided by perforated Plexiglas partitions; CFW males were temporarily removed and intruder experimental B6 females were exposed to unfamiliar aggressive CFW females. Following defeats, B6 females were housed opposite the CFW females that defeated them and CFW males were returned to be pair-housed with CFW females. Non-defeated B6 females were housed opposite unfamiliar resident CFW pairs daily, but were never physically attacked. Compared to controls, defeated B6 females exhibited elevated concentrations of plasma corticosterone and increased c-Fos activation in the medial amygdala, ventral lateral septum, ventromedial hypothalamus, and hypothalamic paraventricular nucleus following the final defeat episode. Defeated females also showed vigilance-like behavior and deficits in social interactions, novel object investigation, and nesting as well as greater alcohol intake compared to controls. The duration of social contact increased 24 hrs after defeated females received a single dose of ketamine (20 mg/kg). Ongoing work evaluates the reinforcing strength of aggression in CFW females that work for the opportunity to defeat a submissive female opponent. These novel behavioral methods will encourage further studies of sex-specific neural, physiological, and behavioral adaptations to social stress and on the biological bases for interfemale aggression.

Abstract: Major Depressive Disorder (MDD) is one of the most common mental disorders. Social stressors often increase the incidence of depression in humans, and repeated exposures to social defeat stress in rodents causes a strong depression-like phenotype marked by anhedonia and social-avoidance. One of the fundamental questions arising from these studies in rodents is whether social avoidance could occur due to a loss of social reward. To test this possibility, we measured social conditioned place preference (CPP) in susceptible and resilient mice following chronic social defat stress. Here we show that CSDS, impairs formation of social CPP in susceptible, but not resilient, male and female mice. We next performed a whole brain c-Fos study and found several brain regions showing differential activation of c-Fos expression between susceptible and resilient mice, such as the prelimbic (PL), infralimbic (IL), Nucleus accumbens (NAc), lateral Hypothalamus (LH), supraoptic nucleus (SON) and Periaqueductal gray (PAG). Interestingly, we find different c-Fos expression patterns in the paraventricular hypothalamus (PVH), between susceptible and resilient mice. Our next step is to determine the molecular identity of cell types in the PVH differentially activated by stress and to then to test whether PVH circuitry in causally linked to loss of social reward in susceptible mice. This research may provide a circuit-level framework to understanding deficits in social behavior across a range of stress-related illnesses such as depression and anxiety.

Title: Reduced synaptic inhibition onto CA1 pyramidal neurons induces anti-despair-like behavior in RalBP1 mutant mice

Authors: *S. YOON, W. SONG, S. OH, M.-H. KIM;
Biomed. Sci. and Physiol., Seoul Natl. Univ. Col. of Med., Seoul, Korea, Republic of

Abstract: Balanced excitatory and inhibitory (E/I) neurotransmission is critical for normal brain functions including mood regulation in animals. Here we show that the deficiency of RalBP1 reduces the density of interneurons in the hippocampus and behavioral despair in mice. Mice deficient of RalBP1 ($RalBP1^{-/-}$), a multifunctional protein that interacts with the small GTPase RalA and RalB, displayed fewer interneurons in hippocampal CA1 regions and reduced inhibitory synaptic events in CA1 pyramidal neurons but normal excitatory synaptic transmission. Behaviorally, $RalBP1^{-/-}$ mice were less immobile during both the tail suspension test and the forced swimming test. Bilateral infusion of Muscimol, the $GABA_AR$ agonist, into hippocampal CA1 regions induced despair-like behaviors in WT mice, while knockdown of Gabrg2 in CA1 neurons reduces behavioral despairs. Chemogenetic activation and suppression of interneurons in CA1 areas produced despair-like and anti-depressant behaviors, respectively. Together, these results suggest that the E/I balance in hippocampal CA1 neuron influences behavioral despairs and mood regulation.

Title: Inhibition of the medial prefrontal cortex attenuates symptoms of depression in Long Evans rats

Authors: *J. J. CORTRIGHT, S. ACKERMAN, L. LANDAETA, L. WILLARD;
Univ. of Wisconsin-River Falls, River Falls, WI

Abstract: Self-focus (i.e. the process by which one engages in self-referential processing) is a core issue in the psychopathology of major depression, which affects 350 million people worldwide. Previous studies have used functional neuroimaging to identify that the cortical midline structures, including the medial prefrontal cortex (mPFC), play a key role in self-referential processing in depressed subjects. The current study investigates the hypothesized link between the mPFC and depression using an animal model of learned helplessness to measure self-referential processing. It is hypothesized that a decrease in symptoms of depression will be seen in animals that have undergone inhibition of the mPFC. This research holds significance in that it builds on previous studies, with conflicting results, that have aimed to link specific patterns of activity to the PFC as mediating symptoms of depression. Further examination of the

mPFC is therefore warranted not only as a possible precursor to the implication of its involvement in mediating depression, but also in order to provide support for a theory of dominant pattern of brain activity (inhibition) which interacts with symptoms of depression. The current study utilized female Long Evans rats in order to more accurately generalize findings to the population of women, which make up the majority of depressed individuals in humans. Subjects were exposed to 28 days of randomized stressors during adulthood including forced swim, cage tilt, wet bedding, mild restraint and restriction of food and water. Control animals were housed in pairs, while animals exposed to randomized stress were housed in isolation. Following surgical placement of guide cannula animals were either infused with an inhibitory cocktail (0.3 nmol/0.5µl/side baclofen/0.3 nmol/0.5µl/side muscimol) or sham (artificial cerebrospinal fluid) before being tested for resiliency against learned helplessness. Subjects were tested for latency in a forced swim test and hot plate test, for motivation in a radial arm maze, for lethargy in an open field test, and for anhedonia using sugar pellets. To date, a significant decrease in latency in the forced swim test and hot plate test has been found in stress-exposed animals which had undergone inhibition of the mPFC compared to controls. Currently, attenuation of learned helplessness symptoms in other tests is being analyzed. Collectively, these findings hold significance in that they build on recent research that has aimed to link areas of the PFC to symptoms of depression.

Title: The topography of GABA/glutamate co-release in the rodent and primate lateral habenula

Authors: *L. RIOS, C. TAN, K. GLEASON, C. TAMMINGA, S. SHABEL;
UT Southwestern Med. Ctr., Dallas, TX

Abstract: The lateral habenula (LHb) responds to aversive stimuli, and its hyperactivity is hypothesized to contribute to depression. Recent studies in rodents have shown that inputs from the basal ganglia and ventral tegmental area to the lateral habenula co-release GABA with glutamate; the balance of GABA and glutamate at these synapses may regulate LHb responses to aversive stimuli and mood. In the present study, we investigated whether the magnitude and topography of co-release of GABA and glutamate in the LHb is conserved in primates. Our data indicate substantial co-labeling of GAD (the synthesizing enzyme for GABA) and VGLUT2 (vesicular glutamate transporter) in synaptic terminals in the monkey and human LHb, consistent

with co-release of GABA and glutamate from individual terminals onto primate LHb neurons. Preliminary data suggest that there are differences in the topography of co-release in the primate and rodent LHb, perhaps due to expansion of the LHb in primates. Thus, co-release of GABA with glutamate may be a conserved mechanism for regulation of LHb activity and mood in rodents and primates.

[2]Inst. for Metabolic and Neuropsychiatric Disorders, Binzhou Med. Univ. Hosp., Binzhou, China

Abstract: Chronic stress can cause depression in susceptible individuals, however, the underlying mechanisms remain elusive. Chronic social defeat stress (CSDS) and chronic unpredictable stress (CUS) are the most widely used animal models of depression. Using these two animal models, we examined expression of brain-derived neurotrophic factor (*Bdnf*) exon I, II, III, IV and VI-containing transcripts and histone modifications at individual *Bdnf* promoters in the hippocampus. Both CSDS and CUS mice were separated into stress-susceptible and resilient subgroups based upon their social interaction ratios and sucrose preference ratios, respectively. While CSDS decreased expression of total *Bdnf* mRNA in the hippocampus of both susceptible and resilient groups, only susceptible CUS mice showed reduced total mRNA levels. CSDS and CUS mice displayed distinct patterns of expression of exon-specific *Bdnf* transcripts and histone acetylation and methylation at their corresponding promoters. Furthermore, deletion of *Bdnf* specifically in the hippocampal dentate gyrus increased behavioral susceptibility to subthreshold CUS. These results suggest that histone modifications of the *bdnf* gene may underlie differential expression of exon-specific *Bdnf* transcripts and stress susceptibility in the CSDS and CUS models of depression.

Title: GABAergic entorhinal cortex control of hippocampal function in stress-induced behavior adaptations: Cellular and circuitry mechanisms

Authors: *S. YUN[1,2], F. H. TRAN[1], I. SOLER[1,2], R. P. REYNOLDS[1], M. SUAREZ[1], A. J. EISCH[1,2];
[1]Children's Hosp. of Philadelphia Res. Ctr., Philadelphia, PA; [2]Perelman Med. Center, Univ. of Pennsylvania, Philadelphia, PA

Abstract: Humans with and rodent models for Major Depressive Disorder (MDD) are marked by dysregulated hippocampal circuitry, and several successful antidepressant treatments (antidepressant medication or brain stimulation techniques) ameliorate these hippocampal changes. Thus, a promising framework for discovery of new antidepressants has emerged: find treatments that "recalibrate" depression-linked dysfunctional neural circuits and behavior. Strikingly, while direct stimulation of the hippocampus has generally negative effects, we recently discovered that chronic stimulation of glutamatergic entorhinal cortex [Ent]-DG circuitry is antidepressive in a mouse model for depression (Yun et al., 2018 Nature Med). In addition to Ent-DG glutamateric neurons, it is known that a subset of Ent-hippocampus GABAergic long-range projecting neurons (LRIP) contribute to hippocampal network activity and function (i.e. memory). However, it is unknown if Ent GABAergic LRIPs regulate depressive-like behaviors. Here we used chemogenetics to control the excitability of either Somatostatin (SST) or Parvalbumin (PV) Ent cells via AAV-DIO-hM3Dq or AAV-DIO-mCherry infusion into the Ent of male mice. Repeated stimulation of Ent-CA1/CA3 LRIPs (SST+ or PV+ cells) increased immobility in FST after chronic restraint stress, implying depressive-like behavior. In contrast, stimulation of Ent-DG LRIPs (SST+ cells) decreased FST immobility. Given these data, we now are examining psychosocial stress-induced DG dysfunction (e.g. pattern separation, social and non-social approach behavior, neurogenesis) after stimulation of SST+ Ent-DG projecting LRIPs and neuroanatomical functional complexity of Ent GABAergic LRIPS via monosynaptic tracing and *in vivo* Ca^{2+} imaging. Our study is

revealing the broad implications that Ent-hippocampus projecting GABAergic LRIPs have for understanding MDD and may guide future treatments.

Title: Role of cortical somatostatin and parvalbumin interneurons in the rapid antidepressant actions of scopolamine

Authors: *M. V. FOGAÇA, M. WU, X.-Y. LI, R. S. DUMAN;
Psychiatry, Yale Univ., New Haven, CT

Abstract: Currently available antidepressants have relatively low efficacy and delayed therapeutic responses to alleviate Major Depressive Disorder (MDD) symptoms. A single dose of scopolamine, a nonselective muscarinic acetylcholine receptor antagonist induces rapid antidepressant effects in patients. Scopolamine was shown to act through blockade of M1-type receptors on GABA interneurons, and we have recently found that chemogenic activation of somatostatin (SST) and parvalbumin (PV) interneurons abolishes the antidepressant responses of scopolamine. Using Cre-dependent Design Receptors Exclusively Activated by Designer Drugs

(DREADD), we tested if the inhibition of GABA interneurons in the medial prefrontal cortex (mPFC) could mimic the antidepressant actions of scopolamine, as well as its molecular changes. Using Sst-Cre M1 deletion mice, we also evaluated if scopolamine effects could be mediated by M1 receptors specifically located in SST interneurons and if there are sex differences guiding these responses. Here we used mice that express Cre-recombinase in GABA interneurons (Gad1-Cre) or in specific subpopulations, such as PV (Pv-Cre) and SST (Sst-Cre). The viral vector (pAAV-hSyn-DIO-hM4D(Gi)-mCherry) was infused into mice mPFC to induce Cre-recombinase-dependent expression of Gi-coupled hM4Di receptors, which are sensitive to clozapine-N-oxide (CNO). Two weeks later, mice were tested in three different timepoints, receiving 3 injections of CNO (2.5 mg/kg) with the first administration starting ~24 h before the test, one injection of CNO 4 h before the test or one injection of CNO 30 min before the test. After injections, the mice were subjected to the forced swim test (FST) or to the novelty suppressed feeding test (NSFT). The efficiency of viral infusion was confirmed at the end by histology and electrophysiological recordings. Stimulation of Gad1-, Pv- and Sst-Cre interneurons using the protocol of 3 CNO injections induced antidepressant-like effects, but was ineffective after 4h or 30 min of administration. In addition, the actions of scopolamine in the FST and NSFT were blocked in the Sst-Cre M1 deletion mice in both male and female. Moreover, scopolamine increased levels of the glutamatergic and GABAergic-related proteins in the mPFC. We are currently testing if similar molecular changes could be found in hM4Di animals. The results are consistent with the hypothesis that the initial trigger for the rapid antidepressant action of scopolamine is antagonism of M1 receptors on mPFC GABA interneurons, which then promotes an enhancement in glutamatergic neurotransmission and rapid synaptic changes.

Title: Ultrastructural localization of serotonergic 5-HT3 receptors in the rat locus coeruleus

Authors: *I. HORRILLO[1], B. A. REYES[2], T. LHAMO[3], E. J. VAN BOCKSTAELE[4]; [1]Pharmacol., Univ. of the Basque Country UPV/EHU; Ctr. de Investigación Biomédica en Red de Salud Mental (CIBERSAM), Bilbao, Spain; [2]Pharmacol. & Physiol., [3]Pharmacol. and Physiol., Drexel Univ., Philadelphia, PA; [4]Dept. of Pharmacol. & Physiol., Drexel Univ. Col. Of Med., Philadelphia, PA

Abstract: Deficiency of monoamines, norepinephrine (NE) and serotonin (5-HT) has been implicated in the pathophysiology of depressive disorders. Neurochemical studies show interactions between serotonin and NE systems. Lesioning of the serotonergic nuclei increases LC neuronal firing whereas electrical stimulation of the serotonergic pathways inhibits noradrenergic neurotransmission. Serotonin has been shown to modulate noradrenergic pathways through the involvement of the serotonin receptors. Pharmacological studies have shown that activation of the 5-HT3 receptor (5-HT3) in the locus coeruleus (LC), the primary noradrenergic nucleus in the brain, decreases the firing of LC neurons and release of NE in prefrontal cortex. A recent pharmacological study shows a functional role of 5-HT3 in the LC. However, the cellular substrates for interactions between 5-HT3 and noradrenergic LC has not been elucidated. In the present study, we investigated the cellular sites for interactions between 5-HT3 and noradrenergic neurons in the LC using immunofluorescence and immunoelectron microscopy. Tissue sections were collected through the LC and processed for immunocytochemical detection of tyrosine hydroxylase (TH), a marker for catecholaminergic neurons, and 5-HT3. Immunofluorescence microscopy revealed that TH-containing perikarya and somatodendritic processes exhibited 5-HT3 immunoreactivity. Ultrastructural analysis using immunoperoxidase labeling for TH and immunogold-silver labeling for 5-HT3 confirmed that 5-HT3 are localized within TH-containing somatodendritic processes. Taken together, these results indicate anatomical substrates for proposed interactions between the noradrenergic and serotonergic systems in the LC.

Title: Nucleus accumbens expression of SIRT1 mediates cell-type specific alterations in neuronal morphology in a mouse model of depression

Authors: *T. CALL, H.-D. KIM, A. SUMMERS, N. T. QUINTUS, R. JOHNSON, D. FERGUSON;
Univ. of Arizona Col. of Medicine- Phoenix, Phoenix, AZ

Abstract: Major depressive disorder (MDD) affects over 300 million people worldwide and is the leading cause of lost productivity and workplace disability. The nucleus accumbens (NAc) is

the reward processing center in the brain. Disruption of function in the NAc has been tied to many psychiatric disorders, including MDD and drug addiction. The NAc is comprised mostly of medium spiny neurons (MSNs) which can be divided into two subtypes based on the enrichment of dopamine receptors, D1- or D2- type receptors. While studies have found differing responses between these neuronal subtypes in animal models of MDD, the exact role of these different subtypes in MDD remains elusive. Recent studies have illuminated sirtuin-1 (SIRT1) as a protein of interest affected by chronic social defeat stress that, when elevated in the NAc, results in susceptibility to depressive-like symptoms. Indeed, SIRT1 has been found to play a role in altering neuronal morphology in other brain regions, such as the hippocampus and prefrontal cortex. However, the role and effects that SIRT1 plays in modifying neuronal morphology within the NAc has yet to be established. Here we seek to elucidate the action of SIRT1 on neuronal morphology following overexpression or knock out in D1 or D2 cell-types. To this end, we used transgenic and viral (HSV) approaches to precisely increase or decrease SIRT1 expression in D1 and D2 neurons within the NAc. Morphological changes in these neurons were evaluated via DiOlistic labeling. We found SIRT1-mediated changes in spine densities and dendritic complexities. Understanding the morphology of the NAc in models of MDD will facilitate the generation of novel targeted treatments and the next generation of antidepressant interventions.

Title: The measurement of motivational level by using a modified version of the Brinkman board test in monkeys

Authors: *S. NAKAMURA, K.-I. TSUTSUI;
Lab. of Systems Neurosci., Grad. Sch. of Life Sciences, Tohoku Univ., Sendai, Japan

Abstract: In this study, we aimed to quantify the motivational level of monkeys by introducing a modified version of the Brinkman board test, which was originally developed to test manual dexterity. We required monkeys to grasp a piece of food reward placed in vertically and

horizontally oriented wells on the board. The board consisted of 50 slots, and the food pieces were randomly placed in 12 slots per session. Two types of boards were used to change the difficulty of the test: one had narrow (difficult) and the other had wide (easy) wells. Multiple sessions were continued until the monkeys spontaneously stopped performing. Two parameters were quantified: the number of sessions the monkey performed as an index of the motivational level and the average time the monkey spent to finish a single session as an index of the motor ability. In order to validate this paradigm, we examined how a decrease in the motivational level of the monkeys would affect the performance of the behavioral test. To lower their motivational level to the behavioral test, we gave the monkeys a moderate amount of the same food reward before the behavioral test. As a result, we found a significant decrease in the number of sessions the monkey performed in difficult condition, compared with the baseline level. However, such change was not observed in easy condition. The average time consumption did not change in both conditions. We further examined how the inhibition of the activity of the ventral medial frontal cortex (MFC) including the rostroventral area of the anterior cingulate cortex (ACC), which has long been implicated in motivational behavior, would affect the performance of the behavioral test by applying low-frequency repetitive transcranial magnetic stimulation (LF-rTMS). The LF-rTMS (1 Hz, 1200 pulses in total) targeting this brain region induced a significant decrease in the number of sessions in the difficult condition, but not in the easy condition, whereas the average time consumption per session did not change. In contrast, such change was not observed following the LF-rTMS to the other MFC regions. Together, these results indicate the importance of the ventral MFC including the rostroventral part of the ACC in motivational control, and show the validity of this behavioral test as the measurement of the motivational level in monkeys.

Abstract: Major depressive disorder is a leading cause of disease burden globally. Studies have shown that the prefrontal cortex (PFC) plays an important role in the resilience and susceptibility to depression, but the underlying mechanisms remain unknown. In the present study, we found that an extracellular matrix structure, perineuronal nets (PNNs), that is localized on parvalbumin-positive (PV+) interneurons in the PFC mediated the vulnerability to stress. The maturation of PNNs alleviated the vulnerability to stress. Adolescent rats exhibited a lower level of PNNs in the medial PFC (mPFC) compared with adult rats and also exhibited greater vulnerability to chronic stress. The degradation of PNNs in the mPFC promoted vulnerability to stress in adult rats and impaired GABAergic transmission in the mPFC. Administration of the noncompetitive N-methyl-D-aspartate receptor antagonist ketamine exerted rapid antidepressant-like effects in rats and promoted the structural recovery of PNNs. A single administration of ketamine also reversed the changes in PV+ interneuron activity following chronic stress. These findings indicate that PNNs are important structures in the susceptibility and resilience to stress and highlight a possible neuron-specific target for the antidepressant effect of ketamine.

Title: Orexinergic projection to the dorsal raphe regulates affective behaviors in an animal model of SAD

Authors: *F. SAMAD[1], H. XIONG[1], S. DAOUD[1], K. LINNING-DUFFY[1], F. P. MANFREDSSON[2], J. S. LONSTEIN[3], L. YAN[3];
[1]Psychology, Michigan State Univ., East Lansing, MI; [2]Neurosci. Program, Michigan State Univ., Grand Rapids, MI; [3]Psychology, Neurosci. Program, Michigan State Univ., East Lansing, MI

Abstract: The neuropeptide orexin/hypocretin has been implicated in many functions including wakefulness, reward, and mood. The objective of the present study was to probe the role of hypothalamic orexinergic projections to the midbrain dorsal raphe nucleus (DRN) in regulating anxiety- and depression-like behavior in an animal model of Seasonal Affective Disorder (SAD). SAD is a major depressive disorder recurring in winter when there is lower intensity of sunlight. Our group has developed an animal model of SAD utilizing the diurnal Nile grass rat (*Arvicanthis niloticus*), which shows increased depression- and anxiety-like behaviors when housed in a 12:12 hr light:dark (LD) cycle but with a winter-like low daylight intensity (dimLD) compared to those housed in a 12:12 hr LD cycle involving bright, summer-like daylight intensity (brLD). We also found that the depressive behaviors were accompanied by a reduction in central orexin in grass rats. In this study, we tested the hypothesis that light modulates affective behaviors through an orexin receptor 1 (OX1R) pathway from the hypothalamus to the DRN. Grass rats were injected with an AAV expressing OX1R-shRNA or scrambled control (SC)-shRNA into the DRN, followed by 4 weeks of brLD housing prior to behavioral assessment in an open field test (OFT) and forced swim test (FST). During the OFT, animals injected with OX1R-shRNA into the DRN spent less time in the center of the OFT arena and deposited more fecal boli compared to either a group of DRN-missed OX1R-shRNA controls or scrambled shRNA controls. During the FST, the DRN OX1R-shRNA group spent less time climbing the wall (escape behavior) and more time immobile (behavioral despair), compared to the control groups. These results revealed that AAV-mediated knockdown of OX1R within the DRN leads to increase depression- and anxiety- like behaviors in grass rats housed in the summer-like brLD. The results suggest that the antidepressant/mood-lifting effects of bright sunny days are partly mediated by orexinergic pathways, particularly the orexinergic input to the serotonin-rich DRN.

Title: Manipulation of resilient key drivers alters susceptibility to chronic social defeat stress

Authors: *T. M. GYLES[1], Z. S. LORSCH[2], E. PARISE[3], E. J. NESTLER[4];
[1]Morehouse Col., Atlanta, GA; [2]Neurosci. and Friedman Brain Inst., Icahn Sch. of Med. At Mount Sinai, New York, NY; [3]Icahn Sch. of Med., New York, NY; [4]Icahn Sch. Med. At Mount Sinai, New York, NY

Abstract: Major depressive disorder (MDD) is a significant public health problem. Though MDD incidence varies with ethnicity, as many as 18% of Americans will experience MDD during their lifetime. Genetics and environmental factors like chronic social stress play a role in the development of MDD. Chronic social defeat currently serves as the best animal model stress paradigm to study depressive like behaviors. Using a Weighted Gene Co-expression Network Analysis (WGCNA) on mice resilient to social defeat determined a unique enrichment of gene expression within the brown module. A undirected key driver analysis was then conducted using ARACNE (algorithm for reconstruction of accurate cellular networks) based on gene-gene correlations, GPRIN1 was found to be one of 3 key drivers within the module. The expression of key drivers within the resilient specific brown module were manipulated in order to determine the role of resilient-specific modules in preventing depression like behavior in animal models of MDD. To accomplish this, GPRIN1 was overexpressed using a Herpes Simplex Virus (HSV) in 20 mice. As a control a group of 20 mice were given the same HSV virus with Green Florescent protein (GFP). To test the effect of viral overexpression mice were exposed to four days of accelerated social defeat, along with a social interaction test. It was determined that the viral overexpression of GPRIN1 promotes resiliency to social defeat stress.

Abstract: Depressive disorders affect a significant portion of the world's population. In the United States, for example, 16.2% of inhabitants will experience at least one depressive episode during their lifetime. In addition, according to WHO, depressive disorders are the leading cause of disability in the world, which also highlights the economic relevance associated with

depression. Social defeat stress (SDS), which involves a resident intruder paradigm, has been widely used to induce negative affective states that model symptomatology of depression. Previous studies demonstrate that increased levels of BDNF from the ventral tegmental area (VTA) to the nucleus accumbens (NAc) mediates susceptible behavior to SDS. While it is known that BDNF acts on NAc medium spiny neurons (MSNs) it is unclear if it is acting through dopamine receptor 1 or 2 (D1 or D2) expressing MSNs. To provide insight into this we generated a Cre-inducible adenoassociated virus (AAV) expressing truncated TrkB (Trkb.T1), which lacks the kinase domain thus preventing downstream TrkB signaling. We infused this virus into the NAc of D1-Cre or A2A-Cre mice. Following viral expression we performed SDS followed by social interaction, the splash test, sucrose preference, and the forced swim test. Our data demonstrate that blocking BDNF-TrkB signaling, through TrkB.T1 overexpression, in D2-MSNs prevents stress susceptibility and causes resilient behavior to SDS. In contrast TrkB.T1 expression in D1-MSNs causes a susceptible outcome to a subthreshold (S)SDS. Our studies implicate D2-MSNs as mediating the BDNF-TrkB effects of stress susceptibility, while BDNF acting on D1-MSNs has a protective role in stress.

Title: Antidepressant effects and underlying mechanisms of roman chamomile essential oil in depressive rats

Authors: *D. MA[1], G. ZHU[2], Q. ZHUANG[1], T. WANG[1,3], S. LI[1];
[1]Shanghai Jiao Tong Univ., Shanghai, China; [2]Shanghai Univ. of Med. & Hlth. Sci., Shanghai, China; [3]Kao (China) Res. Ctr., Shanghai, China

Abstract: Depression is called ‘the common cold of mental illness’, which is easy to be neglected, and the pathogenesis of depression remains unclear. Essential oils have long been used as a means of helping people fall asleep and alleviating anxiety, and are considered as a possible antidepressant treatment. At present, our understanding on the mechanism of action of essential oils is scarce; despite their widespread use in alleviating depression no study existed reporting the underlying mechanisms of how essential oils may alleviate depression. In this

study, we aimed to investigate the antidepressant effects and possible underlying mechanisms of Roman chamomile essential oil (RCEO) on depressive-like behaviors in Wistar-Kyoto (WKY) rats. We found that the inhalation of RCEO, or α-pinene, one of the main components of RCEO, for two weeks considerably attenuated the depressive-like behaviors, as witnessed by open-field test, sucrose preference test, and forced swim test. We used isobaric tags for relative and absolute quantitation analysis (iTRAQ), quantitative polymerase chain reaction (qPCR), and western blot (WB) to measure the changes in different mRNA/protein expression levels before and after the inhalation of α-pinene in WKY rats, and compared their expression levels in the hippocampus and prefrontal cortex (PFC) with control Wistar rats. Our iTRAQ analysis showed that inhalation of α-pinene increased the expression of proteins that are involved in oxidative phosphorylation, such as cytochrome c oxidase subunit 6C-2, cytochrome c oxidase subunit 7A2, and ATPase inhibitor in the hippocampus. iTRAQ analysis also revealed an upregulation of the calcium-binding protein, parvalbumin (PV, 2.8-fold upregulation in the hippocampus), which is known to regulate animal behavior, following α-pinene treatment. Upregulation of PV at its transcriptional and translational levels following α-pinene treatment were also confirmed by qPCR (Vehicle, 1±0.06, n=3; α-pinene, 1.28±0.06, n=3; P=0.013) and WB (Vehicle, 1±0.09, n=4; WKY, 0.86±0.03, n=4; P<0.01, one-way ANOVA). However, it had no effect on the number of PV^+ neurons in the hippocampus of WKY rats. Taken together, our results suggest that inhalation of RCEO relieves depression-like behaviors in WKY rats possibly via modifying the oxidative phosphorylation-related pathways and by increasing the level of PV. By overexpression or knockdown of PV in the hippocampus or PFC, the involvement of PV in depression is investigated.

Title: Molecular neurobiology of enrichment loss

Authors: *M. A. SMAIL[1], B. L. SMITH[1], R. SHUKLA[2], J. REIGLE[3], K. ALGANEM[2], A. FUNK[2], R. MORANO[1], J. P. HERMAN[1], R. E. MCCULLUMSMITH[2];

Abstract: Psychological loss impacts nearly all of our lives, yet little is known about what happens in the brain during this experience. Loss occurs when one is deprived of something perceived as important, such as a loved one, home, or job, and its symptomology resembles depression. We can simulate loss in rats by removing environmental enrichment, producing a unique phenotype of depression-like behaviors. Here we probe the molecular neurobiology of enrichment loss with a multidimensional approach that spans big data techniques, brain regions, and sex.

Male and female rats were divided into 3 groups: environmentally enriched (EE), enrichment removed (ER), and control (CON). EE and ER animals were housed in groups of 10 in large, multi-level cages with toys. CON animals were pair-housed. ER animals were removed from enriched housing after 4 weeks and moved to single-housing. Two weeks after removal, brains were collected. Bilateral micropunches were taken of regions implicated in loss by c-fos expression, including the infralimbic prefrontal cortex, basolateral amygdala, and medial amygdala. These regions were run on parallel RNAseq, shotgun proteomics, and kinomics platforms. A series of bioinformatics analyses were then used to derive molecular signatures of loss that span RNA, protein, and kinase activity levels. Tools used include GSEA, iLINCS, OmiClust, and KRSA. The resulting multi-level signatures yield in-depth information about the proteins and pathways that are altered in loss.

The ER group exhibited differential expression in several pathways that may contribute to loss. At the RNA level, we observed modulation of pathways associated with synaptic transmission, neuroinflammation, cytoskeletal organization, lipid homeostasis, and angiogenesis. Sex-specific changes were present within each of these categories. Continued bioinformatic analyses at the protein and activity levels will build upon these results to generate more detailed region- and sex-specific signatures for ER.

Taken together, these results allow us to start to understand what is happening in a rat's brain during enrichment loss, offering insight into the mechanisms that could underlie psychological loss in humans. They also point to potential therapies that may offer relief to people experiencing loss.

Title: NMDA receptor GluN2B tyrosine phosphorylation invoved in depression related behaviour

Authors: *X. SHI[1], J. LUO[1], W. YANG[1], Q. ZHANG[2];
[1]Dept. of Neurobiology, Zhejiang Univ., Hangzhou, China; [2]Sch. of Medicine, Zhejiang Univ., Hangzhou, China

Abstract: Abstract
NMDA receptors mediate various physiological and pathological functions, and studies have shown that phosphorylation of different subunits of NMDA receptors can regulate the processes of receptor membrane trafficking and channal gating.In recent years, it has been found that GluN2 subunit has multiple tyrosine phosphorylation sites. Our previous study reported that the phosphorylation at Tyr-1070 of GluN2B can change the expression of receptor on cell membrane by coordinating the phosphorylation at Tyr-1472, but the in vivo function of this site on NMDA receptor-mediated function remains unclear. In this study, we first prepared GluN2B subunit mice with NMDAR receptor c-terminal tyrosine 1070 mutation mice (hereinafter referred to as 1070 KI mice),Behavioral tests showed that the mutant mice did not affect hippocampal related behaviors, but showed an antidepressant like phenotype. 1070 KI mice after chronic restraint stress model still exist antidepressant phenotypic stability, show in forced swimming test the immobile time significantly shorter than WT mice, anhedonia in sucrose preference test . It is suggested that phosphorylation of GluN2B Tyr-1070 is involved in and regulates the process related to depression. Biochemical results showed that at the basic level, the mutant mice reduced the phosphorylation level at Tyr-1472 only in the mPFC region. the phosphorylation Tyr-1070 of WT mPFC region is increased after CRS,but Tyr-1472 phosphorylation level without any change, it also suggests that tyrosine phosphorylation in regulating at baseline and after the stress is very different. we found that After the mutation at Tyr-1070, the function of NMDARs was not affected on the synapses of pyramidal neurons at layer 5-6 in this brain region, but the function of extrasynaptic GluN2B-containing NMDAR receptor is down-regulated, the number of functional synapses is increased and the excitatory synaptic transmission is enhanced, which was directly related to the enhanced activity of mTORC1 after the mutation at site Tyr-1070.Combined with the above data, we reveals a new mechanism of NMDAR receptor tyrosine phosphorylation in mPFC region in the regulation of depression and provides a new way to elucidate the NMDA receptor-mediated MDD disease.

Abstract: Depression is a serious disorder intrinsically related to stressful events, with an enormous impact on individual wellbeing and public health services worldwide. However, we are still seeking to understand how stress experience impacts the brain and develop more effective treatments for depression. Recent studies using the animal model of social defeat stress demonstrate an important role of the nucleus accumbens (NAcc) and ventral pallidum (VP), key brain areas in motivated behaviors, in the etiology of depression. Considering the extensive and reciprocal connections that exist between these regions, VP projections to NAcc could be interesting targets related to the susceptibility to stress. To address this question, we used a chemogenetic approach to activate or inactivate VP Npas1 neurons, which heavily projects to NAcc, during a subthreshold protocol of social defeat stress. Male Npas1-Cre-2A-tdTomato mice (n = 44) stereotaxically received AAV2-hSyn-DIO-hM3Dq (excitatory Designer Receptor Exclusively Activated by Designer Drugs - DREAAD), AAV2-hSyn-DIO-hM4Di (inhibitory DREADD) or AAV2-hSyn-DIO-eYFP (control groups) into the VP (0.3 uL infused over 15 min) 2 weeks before being exposed to a subthreshold social defeat stress (SSDS) protocol. Briefly, in the SSDS protocol animals were defeated for 2.5 min by three different aggressors (CD1 retired breeders) on a single day, each session separated by 15 min of sensory interaction. Thirty minutes before the SSDS, animals received Clozapine N-Oxide (CNO) i.p. at a dose of 1 mg/kg. Twenty-four hours later the animals underwent a social interaction test (SI) and a forced swim test (FST). Chemogenetic activation of Npas1 neurons during SSDS decreased time spent in the interaction zone and increased the time spent in the corners in the SIT when a social target was presented. It also increased immobility time in the FST. In contrast, inactivation of Npas1 neurons had no effect on such behaviors. Our results demonstrate that increased activity of Npas1 neurons during stressful events induces susceptibility to social defeat stress.

Title: Asparagus extract ameliorates menopausal depression in ovariectomized rats under chronic unpredictable mild stress

Authors: *M. KA, H. KIM, Y. LEE, E. JANG;
Korea Inst. of Toxicology, Daejeon, Korea, Republic of

Abstract: Depression is a serious illness and one of the most prevalent psychiatric disorders. Women are more vulnerable to depression than men. Moreover, a woman's risk of developing depression increases with age, likely due to hormonal fluctuations associated with menopause. To investigate the effects of asparagus extract on menopausal depression, we induced menopause in rats via ovariectomy and exposed them to chronic unpredictable mild stress (CUMS) for 4 weeks. After 2 weeks of initial CUMS exposure, asparagus extract (1000 mg/kg, 2000 mg/kg, PO) and imipramine (IMI, 10 mg/kg, IP) were administered for 4 weeks. Thereafter we measured depression-associated behaviors using the sucrose preference test (SPT), elevated plus maze (EPM) and forced swim test (FST). We then measured the levels of corticosterone and inflammatory cytokines using ELISA. We report that CUMS promoted depression-like behavior and significantly increased corticosterone and inflammatory cytokines levels in ovariectomized (OVX) rats. Treatment with asparagus extract, however, effectively rescued the CUMS induced depression-like behavior and corticosterone levels in OVX rats. Furthermore, we found that CUMS down-regulates the expression levels of brain-derived neurotrophic factor (BDNF) and its primary receptor, tropomyosin receptor kinase B (TrkB), in OVX rats. Treatment with asparagus extract also rescues the expression levels of BDNF and TrkB. These results suggest that asparagus extract exerts antidepressant effects by modulating the BDNF-TrkB signaling pathway in a rat model of menopausal depression.

Title: Activation of CB1 receptors and quantification of the cnr1 gene in a depression model

Authors: A. VILLARREAL ZUÑIGA[1], D. MONTIEL CONDADO[2], A. GONZALEZ HORTA[2], M. BERMUDEZ DE LEON[3], *B. GONZALEZ HERNANDEZ[2];

Abstract: It is estimated that about 300 million people suffer from unipolar major depression, which in the worst case can lead to suicide; also is one of the major causes of ill-health and economic burden worldwide. Besides, after half a century of intensive research since antidepressant drugs were introduced into clinical practice, their efficacy remains low, at around 70% (compared with a no-treatment recovery rate of around 50%); and the onset of action remains slow, at around 4-6 weeks; Recently the CB1 cannabinoid receptors (RCB1) have been explored, because preclinical studies suggest that, agonists for RCB1 possess antidepressant properties and the antagonist are pro-depressant. The objective of this work is to study the participation of CB1 receptors and the cnr1 gene in a depression model. Young male Sprague-Dawley rats (200-250g) were used. The model of depression used was the forced swimming test combined with a "time-sampling" analysis, which consists in forcing the rats to swim individually on two occasions: 1) pre-session of 15 minutes and 24 hours later, 2) experimental session of 5 minutes, in which three behaviors are recorded in intervals of 5 seconds (or counts): climbing, swimming and immobility. The following drugs were administered intraperitoneally: 1) ACEA (3mg/mL/kg), agonist for RCB1; and 2) imipramine, tricyclic antidepressant (30mg/10mL/kg). For the analysis of the cnr1 gene, an RT-PCR of the following nuclei was performed: pre-frontal cortex and hippocampus. The administration of imipramine had the expected antidepressant effect, reducing the immobility behavior, increasing the swimming behavior (no change in climbing) and increase expression of the cnr1 in the hippocampus and pre-frontal cortex. Interestingly, the application of ACEA presented a similar effect, decreasing the immobility and increasing the swim (no change in climbing). Besides was observed, increase expression of the cnr1 in pre-frontal cortex, but in hippocampus was high significative. These results indicate that the activation of CB1 receptors have an antidepressant effect, which may be due to an increase in

expression of the cnr1 gene. Suggesting they have a very important role in the pathophysiology of depression and be a new pharmacological target for its treatment.

Title: Social defeat affects transcription of nociceptin peptide and Oprl1 receptor in reward-processing brain areas

Authors: B. ROMOLI[1], N. PRAKASH[1], S. BERRETTA[2], A. DER-AVAKIAN[1], D. A. PIZZAGALLI[2], ***D. DULCIS**[1];
[1]Psychiatry, Univ. of California San Diego, San Diego, CA; [2]Translational Neurosci. Lab., McLean Hosp., Belmont, MA

Abstract: Anhedonia, the reduced ability to experience pleasure, is a core symptom of depression and other mood disorders often triggered by chronic stress. Nociceptin/orphanin FQ peptide (pNoc) has been classically thought to be involved in pain processing, but its role in stress and depression has recently gained attention. Altered levels of pNoc and its receptor Oprl1 have been associated with stress-induced deficits, including blunted reward learning (Der-Avakian et al., 2017). Here, we investigated whether chronic social defeat induced changes in pNoc/Oprl1 transcription in rats that were either susceptible or resilient to stress-induced anhedonia.
Adult male Wistar rats (n=12) underwent 21 days of social defeat and anhedonia was assessed using the intracranial self-stimulation (ICSS) procedure. Stress-exposed animals clustered into susceptible or resilient subgroups (n=6 each) based on their ICSS reward thresholds (unbiased k-means method). Brain sections of ventral tegmental area (VTA), dorsal striatum (CPu) and prefrontal cortex (PFC) were processed for RNA-scope *in-situ* hybridization (ISH) to detect mRNA levels of pNoc, Oprl1, cFos, and neurotransmitter (NT) markers for dopamine (tyrosine hydroxylase, TH), glutamate (vesicular glutamate transporter1, VGLUT1), and GABA (vesicular GABA transporter, VGAT).
Quantification of ISH-reactive cells in stress- and reward-related brain regions revealed that

stress significantly reduced pNoc-expressing cells in VTA, CPu and PFC, while no significant changes were detected in the number of Oprl1-expressing cells. When stressed animals were clustered into susceptible and resilient subgroups, analyses revealed that pNoc transcriptional reduction in all 3 brain regions was driven by the resilient group, while Oprl1 expression was differentially regulated in specific brain regions and conditions. Susceptible rats had significantly fewer VTA Oprl1-expressing cells than resilient rats, while resilient rats had significantly fewer CPu Oprl1-expressing cells than susceptible rats.
We are currently implementing multiple RNAscope NT markers (TH, VGAT, VGLUT1) in combination with activity gene, cFos, to quantify such pNoc/Oprl1 transcriptional changes in specific neuronal subtypes differentially cFos-activated by stress in susceptible and resilient rats, when compared to non-stressed animals (n=6).
Given the heterogeneity of regulation displayed by different brain regions in response to chronic stress, a region- and cell-specific analysis of pNoc/Oprl1 expression patterns is fundamental to begin to understand its function and generate new targets with a potential translational value.

Abstract: Background: Depression is characterized by disrupted gene expression in cortical brain regions. Such genes are involved in GABAergic and glutamatergic signaling, neurotrophic support, oxidative stress, and other functions. Similar changes occur in UCMS, a depression-

relevant mouse model. Currently, the coordinated changes occurring within and across cell-types of the cortical microcircuitry (CM) are unknown.
Methods: We examined the transcriptomic changes occurring in the principal 4 cell-types comprising the CM of UCMS-exposed C57Bl/6J male mice versus controls (n=10/group). Depressive-like behaviour (emotionality) was assessed through a battery of 7 behavioural tests after 5-weeks of UCMS. Pyramidal (PYR)-cells and GABAergic interneurons expressing somatostatin (SST), parvalbumin (PV), or vasoactive-intestinal-peptide (VIP) were collected using fluorescent in-situ hybridization and laser-capture microdissection. Gene expression was determined by RNA sequencing. Differential expression, biological pathway enrichment, and co-expression network analyses were performed.
Results: UCMS-exposed mice exhibited elevated emotionality versus controls (p=0.002). Differentially expressed genes were largely unique to each cell-type. UCMS induced an upregulation of synapse structure and neurotransmission-related genes in PYR-cells and a dysregulation (up/down-regulation) in SST-cells. UCMS increased co-expression between PYR-cells and both PV (p=0.00048) and SST-cells (p=0.0026) and decreased co-expression between VIP and SST-cells (p=0.014). A co-expression hub module of 1048 genes in PYR-cells, enriched in axon guidance-related genes, correlated with emotionality in UCMS-exposed mice (r=0.78, p=0.010).
Conclusions: CM cell-types undergo different responses to chronic stress. Synaptic changes in between PYR-cells and both SST and PV-cells may underlie the long-term neurobiological adaptations to UCMS. In vivo pharmacological validation studies targeting key disrupted pathways are warranted.

Title: Chemogenetic activation of medial prefrontal cortex excitatory neurons improves chronic corticosterone-induced behavioral deficits

Authors: *A. DIETERICH[1], K. STECH[2], B. A. SAMUELS[2];
[1]Grad. Program in Neurosci., [2]Psychology, Rutgers Univ., Piscataway, NJ

Abstract: The medial prefrontal cortex (mPFC) is less active in individuals with major depressive disorder and acute optogenetic activation of all mPFC neurons has antidepressant-like effects in mice that are susceptible to chronic social defeat stress (Covington et al., 2010). Here we take a chemogenetic approach to specifically target excitatory neurons in the mPFC. To this end, we exposed C57BL/6J mice to chronic treatment with corticosterone (CORT; 5 mg/kg/day), which mimics chronic stress and induces several negative valence behaviors and bilaterally injected AAV-CaMKIIa-hM3-Gq-DREADD into the mPFC. We hypothesized that excitatory neuronal activation in the mPFC would ameliorate the negative valence behaviors induced by chronic CORT administration. We found that acute chemogenetic activation of mPFC excitatory neurons reduced both latency to eat in novelty suppressed feeding and immobility in the forced swim test, while not impacting overall locomotor activity. Taken together, excitatory neuronal activation of the mPFC reverses the behavioral effects of chronic CORT administration, a well-validated chronic stress paradigm. These data suggest that mPFC excitatory neurons are a potential therapeutic target for antidepressant development.

Title: Inhibition of NRG1-ErbB4 signaling in midbrain dopamine neurons attenuated chronic social defeat-induced depressive phenotypes

Authors: *H. WANG[1], W. CUI[1], W. CHEN[1], Z. DONG[1], F. LIU[2], W.-C. XIONG[1], L. MEI[1]; [1]Dept. of Neurosciences, Case Western Reserve Univ., Cleveland, OH; [2]DNRM, Augusta Univ., Augusta, GA

Abstract: Genetic studies including genome wide association studies (GWAS) suggest the involvement of NRG1-ErbB4 signaling in major depressive disorder (MDD), but the underlying mechanism is not known. Mesolimbic dopaminergic system plays a crucial role in chronic stress-induced depression in animal studies. ErbB4 is expressed in midbrain dopaminergic neurons and NRG1-ErbB4 signaling was suggested to promote dopaminergic transmission. We investigated whether and how impaired NRG1-ErbB4 signaling in midbrain dopamine (DA) neurons contributes to depression. ErbB4 deletion from DA neurons caused resilience to depression in a chronic social defeat model. AAV-Cre virus-mediated local deletion of ErbB4 in VTA or local pharmacological inhibition of ErbB4 kinase recapitulated the resilience phenotype. Mechanism

study with in vivo fast scan cyclic voltammetry (FSCV) or ex vivo electrophysiological recording showed NRG1-ErbB4 signaling at soma of VTA DA neurons increases DA neurons' excitability and promotes both DA and BDNF release in nucleus accumbens (NAc), perhaps through MAPK/ERK-mediated phosphorylation of K+ channels and suppressed I_A current. Interestingly, selective inhibition of ErbB4 kinase with 1NMPP1 infusion after development of depression attenuated depressive phenotypes. Similar antidepressant effects were observed with Afatinib, an inhibitor of ErbB4. These results suggest ErbB4 in midbrain DA neurons mediates susceptibility to social defeat stress-induced depression-like phenotypes and might be a potential treatment target of MDD.

Title: Blm-s, a BCL-2 family member, functions in mood control

Authors: T.-Y. YANG[1], C.-W. CHOU[2], ***P.-H. HUANG**[3];
[1]Col. of Medicine, Natl. Taiwan Univ., Grad. Inst. Pathology, Taipei, Taiwan; [2]Col. of Medicine, Natl. Taiwan Univ., Grad. Inst. of Pathology, Taipei, Taiwan; [3]Grad. Inst. of Pathology, Natl. Taiwan Univer, Taipei, Taiwan

Abstract: Mood disorders such as depression and anxiety are common public health problems and both together rank among the top ten causes of disability. Mood disorders are heterogeneous diseases, involving multiple factors including neural circuits, neuromodulators, immune function, and genetic factors. Although highly penetrant genetic variants that cause depression and anxiety have not yet been reported, past studies clearly indicate that mutations in certain 'risk genes' enhance the probability to develop mood disorders, pointing to a genetic component in the etiology of mental illnesses. In line with such view, we recently uncover that deficit of a BCL-2 pro-apoptotic family member- BLM-s (BCL-2 like molecule, small form) causes *Blm*-s-null mice with increased susceptibility to depression- and anxiety-like behaviors, as probed by elevated plus maze, open field, forced swim, and tail suspension tests. However, *Blm-s*$^{-/-}$mice have no alteration in learning and memory as assessed by Morris water maze and novel object recognition test. Using immunohistochemistry and RNA *in situ* hybridization, we found that BLM-s is expressed in cells located close to the subgranular zone (SGZ) of hippocampal dentate

gyrus, in which adult hippocampal neural stem/progenitor cells proliferate and differentiate into functionally integrated dentate granule neurons. To test whether BLM-s regulates adult hippocampal neurogenesis, BrdU-labeling and Ki-67 immunohistochemistry were used to quantify neurogenesis in the SGZ. *Blm-s*$^{-/-}$mice examined at age of 2- and 5-month show much decreased number of BrdU- or Ki-67-labeled cells in close proximity to the SGZ. Further, via Golgi stain, the granule neurons in the DG of the *Blm-s*$^{-/-}$mice demonstrate reduced spine density and reduced complexity of the dendrites evident by decreased number of dendritic node, end, segment, and spine density.Electron microscopic analysis of the synapses over the dendrites of the granule neurons in the DG revealed reduced number and size of excitatory synapse.The decreased branching complexity of dendrites with reduced spine density in granular cells of DG implicates physically altered circuit connectivity in *Blm-s*$^{-/-}$mice, which could provide long-lasting traces underlying depression and anxiety.

Title: Molecular players of depressogenic phenotype induced by hippocampal FGF-AS overexpression identified with proteomic analysis

Authors: *B. UZAY, T. DALKARA, E. EREN-KOCAK;
Neurosci., Hacettepe Univ. Inst. of Neurolog. Sci. and Psychiatry, Ankara, Turkey

Abstract: Background: FGF-antisense (FGF-AS), the natural antisense transcript of fibroblast growth factor-2 (FGF2) is indicated in the regulation of FGF2 expression. Hippocampal overexpression of FGF-AS increased depression-like behaviors and, impaired learning and memory without changing FGF2 expression. Clarifying the molecular mechanisms underlying the depressogenic effects of FGF-AS will help to better understand the pathophysiology of affective disorders. We aimed to determine the proteins, whose expressions were changed by hippocampal FGF-AS overexpression.
Methods: FGF-AS expressing AAV (FGF-AS-AAV) (n=5) or blank AAV (n=6) was injected bilaterally into the hippocampi of male Sprague-Dawley rats. Rats were sacrificed 8 weeks later. Hippocampal protein was analyzed using Liquid Chromatography Tandem Mass Spectrometry. Raw data was processed and compared between groups; proteins with significant expression

differences were determined by principal component analysis. To further delineate possible interacting proteins, network and pathway analyses were performed. The activated or inhibited proteins were determined by their relative activation z-scores.
Results: Proteomic analyses revealed 34 proteins, whose expressions were different between groups. Out of 34 proteins, 31 were upregulated and 3 were downregulated by hippocampal overexpression of FGF-AS when compared to the controls ($p<0.05$). Interestingly S100 calcium binding protein A9 (S100A9) increased 32-fold while chloride intracellular channel 6 (CLIC6) protein increased 46-fold in the FGF-AS-AAV group. Pathway and interaction analyses identified possible involvement of 4 pathways, namely inflammation, growth and proliferation, injury and abnormalities and mitochondrial dysfunction. S100A9 was found to be linked to other inflammatory molecules, including NF-KB, on the other hand, CLIC6 was linked to various hub proteins namely NFkB, CREB, Akt, TP53 and ERK1/2. Interaction analyses revealed activation of IL-6 and MeCP2, and inhibition of PP2A. Other proteins with possible change in the activity in response to FGF-AS overexpression were TGFB1, TNF, HNF4A, PPARG, EGF, STAT3, PRDM1, SMARCA4 and PP2A.
Conclusion: The depressogenic effects of FGF-AS in the hippocampus may be mediated by proteins involved in growth factor and inflammatory signaling, and in mitochondrial function, which is in line with both neurotropic and inflammatory hypotheses of depression. Further molecular analysis is necessary to provide evidence for the players of the aforementioned pathways as the downstream effectors of FGF-AS in the development of depression-like behavior in rats.

Title: Integrative analysis of Gata1 associated transcriptome and epigenome in the cortical neuron

Authors: *K. CHOI, J. PARK, H. KANG;
Dept. of Life Sci., Chung-Ang Univ., Seoul, Korea, Republic of

Abstract: Gata1, a member of the GATA transcription factor family, has been considered as an important factor in the hematopoietic system. As a transcriptional regulator, Gata1 has a crucial

role in blood cell differentiation such as erythrocytes, megakaryocytes, eosinophils, and dendritic cells. Recently, a novel function of Gata1 in the central nervous system was demonstrated. Gata1 showed increased expression in the dorsolateral prefrontal cortex (dlPFC) of patients with depression and functioned as a transcriptional repressor of synapse-related genes. In this study, we examined the global alteration in gene expression by Gata1 overexpression of using Chromatin immunoprecipitation followed by sequencing (ChIPseq), mRNAseq, and smallRNAseq. From the result of ChIPseq for histone marks H3K4me3 and H3K27me3, we have identified 1127 and 4881 unique peaks marking H3K4me3 and H3K27me3 in the gene promoter region, respectively, in the cultured cortical neuron overexpressed with Gata1 compared to control. Gene ontology analysis revealed that Gata1 might be involved in transcriptional activation of genes related to development, differentiation, and immune-related functions. On the other hands, it might act as a transcriptional repressor of genes related to macromolecule processing, synapse-related functions, and signal transduction. In addition, we identified 113 differentially expressed genes and 82 miRNAs in cultured neuron transfected with Gata1 through the mRNAseq and smallRNAseq analysis. Among the differentially expressed genes, down-regulated genes showed a higher correlation with the ChIPseq result than the upregulated genes. Subsequently, we performed target prediction for differentially expressed miRNAs using several online databases. Gene ontology analysis indicated that predicted target genes of up-regulated miRNAs in cultured neuron overexpressed Gata1 associated with synapse-related function, development, and regulation of gene expression. Interestingly, target genes, which are predicted to be decreased in expression by up-regulated miRNAs showed a higher correlation with the ChIPseq result. These results will provide a further understanding that Gata1 can act as a transcriptional regulator that affects the pathophysiological condition such as depression.

Title: Mechanisms contributing to the sustained antidepressant-like response of L-655,708

Authors: *F. R. CARRENO[1], V. BUGAY[1], A. FRAZER[1,2], D. J. LODGE[1], R. BRENNER[1]; [1]UT Hlth. San Antonio, San Antonio, TX; [2]South Texas Veterans Hlth. Care Syst., San Antonio, TX

Abstract: Selective modulation of hippocampal transmission by systemic administration of α5-GABAA receptor negative allosteric modulator, namely L-655,708, is capable of producing a sustained antidepressant-like effect in the absence of any psychotomimetic or abuse-related effects. We utilized conventional pharmacological, electrophysiological (whole-cell, patch clamp), and behavioral approaches to examine the mechanisms by which L-655,708 produces plasticity within the hippocampus to account for its sustained antidepressant-like effect. We found that unlike ketamine, L-655,708 did not cause an increase in the phosphorylation of TrkB in the ventral hippocampus (vHipp) 30 or 60 min after its administration nor did vHipp administration of TrkB inhibitor, K252a, block the sustained antidepressant-like effect of L-655,708. Moreover, acute L-655,708 activation of CamKII does not mediate its sustained antidepressant-like effects, as vHipp administration of KN-93, a CamKII inhibitor, did not block the sustained antidepressant-like effect of L-655,708. Recording of vHipp CA1 pyramidal cells 24h after a single administration of L-655,708 revealed a significant increase of input resistance, which resulted in an approximately two fold increase in action potential frequency. In addition, we found a reduced IPSC half-width. These results are consistent with reduced tonic and evoked chloride currents in ventral CA1 neurons as a consequence of L-655,708, indicating that the sustained antidepressant-like effects of L-655,708 may be mediated by changes in GABA receptor gating properties, with resultant enduring changes in ventral CA1 neuronal excitability. By identifying the mechanisms by which systemic administration of α5-GABAA receptors negative allosteric modulators recapitulate the therapeutic effects of ketamine without its psychotomimetic and abuse-related effects, it should be possible to provide novel, safe, and effective approaches for treating patients suffering from refractory depression.

Title: Fast acting antidepressant potential of reelin in a preclinical animal model of depression: Mechanisms and avenues for future research

Authors: *K. J. BRYMER[1], J. J. BOTTERILL[2], R. ROMAY-TALLON[3], J. T. ALLEN[3], H. J. CARUNCHO[3], L. E. KALYNCHUK[3];
[1]Psychology, Univ. of Saskatchewan, Saskatoon, SK, Canada; [2]Ctr. for Dementia Res., Nathan Kline Inst., Orangeburg, NY; [3]Div. of Med. Sci., Univ. of Victoria, Victoria, BC, Canada

Abstract: Reelin is an extracellular matrix protein involved in the regulation of synaptogenesis, learning and memory, promoting contacts onto dendritic spines, and hippocampal neurogenesis. Work by our lab and others have shown that repeated injections of the stress hormone corticosterone (CORT) decreases hippocampal reelin expression, and this decrease is accompanied by the development of depressive-like behavior. This led us to hypothesize that reelin supplementation would produce an antidepressant effect in a preclinical rodent model of depression. We set out to test this hypothesis through a series of experiments. First, we conducted stereotaxic surgery on male rats to implant an indwelling cannula into the left dorsal hippocampus. A subset of rats received either a single intrahippocampal reelin infusion or repeated intrahippocampal reelin infusions during 21 days of CORT injections. We then assessed depressive-like behavior using the forced-swim test (FST), hippocampal-dependent memory using the object-location memory test (OBL), and examined hippocampal neurogenesis and markers of GABA and glutamate activity. In the second experiment, we tested the involvement of AMPA in the fast-acting antidepressant effects of reelin by infusing the AMPA antagonist CNQX after a single intrahippocampal reelin infusion during CORT treatment in male rats. We then assessed depressive-like behavior using the FST, and examined hippocampal neurogenesis. CORT injections increased time spent immobile on the FST and impaired performance on the OBL, and reelin infusions restored these measures to control levels. A single intrahippocampal CNQX infusion blocked reelin's antidepressant effects on the FST. CORT decreased hippocampal neurogenesis, and reelin infusions restored this back to control levels. CNQX did not block reelin's effects on hippocampal neurogenesis. These novel results demonstrate that reelin has antidepressant effects, and that part of the mechanism behind this effect may be AMPA receptor signaling. Future directions can explore the potential of reelin to reverse depressive-like behavior when infused into regions other than the hippocampus (amygdala and medial prefrontal cortex)

Abstract: Depression risk is determined by both genetic and environmental factors. Recently, it has been proposed that epigenetic mechanisms may also be a contributing factor. Studies show that the offspring of male mice that have been exposed to stress show anxiety- and depression-like phenotypes. We tested the hypothesis that epigenetic alterations in sperm during chronic social defeat stress (CSDS) transmit increased susceptibility to stress phenotypes to both F1 and F2 generations. Male C57BL/6J mice were exposed to 10 days of CSDS and subjected to social interaction testing to assess paternal phenotype. Males classified as resilient or susceptible to CSDS and control F0 males were allowed to mate with non-stressed females 30 days after the stress, to allow the sperm exposed to the stress to mature. One week following natural mating, those same F0 males were euthanized and their sperm was collected for artificial insemination. At ~P60, 1 male and 1 female from each litter was exposed to sub-threshold unpredictable stress and depression- and anxiety-like behaviors were assessed. Each animal was compared to an unstressed littermate of the same sex to control for litter effects. Preliminary evidence suggests that F1 offspring of defeated fathers produced by natural mating or by artificial insemination display altered phenotypes, with reverse effects seen in male and female offspring. Paternal stress enhances stress susceptibility of F1 males, while diminishing it in F1 females. These data suggest that there are changes in sperm during CSDS that encode altered depressive- and anxiety-like phenotypes in their offspring. To identify the molecular mechanisms of this paternal transmission, RNA sequencing was conducted for the sperm of a separate cohort of F0 susceptible and resilient males. Two sperm samples were collected from each animal: 1) ~10 days prior to and 2) 30 days post-CSDS to determine how RNA profiles within the sperm might change due to stress exposure in susceptible and resilient males. Preliminary data suggest that substantial changes in the transcriptomic profiles occur after exposure to stress in susceptible and resilient mice. Current studies are focused on exploring if similar transcriptomic differences are maintained in various tissues of offspring mice.

Title: Taking the fun out of psilocybin: Can psilocybin's rapid antidepressant action be preserved in the absence of hallucinations?

Authors: *N. HESSELGRAVE[1], J. M. FISCHELL[2], S. M. THOMPSON[2];
[1]Program in Neuroscience, Dept. of Physiol., [2]Dept. of Physiol., Univ. of Maryland Baltimore, Baltimore, MD

Abstract: Major depression is a debilitating illness and one of the leading causes of disability world-wide. First line pharmacotherapies targeting the serotonin system, such as selective serotonin reuptake inhibitors (SSRIs) like fluoxetine, are effective in ~60% of patients. Typically, patients must take SSRIs for 4-8 weeks to experience relief of depressive symptoms. More effective and faster acting medications are needed. Recently, psilocybin, a hallucinogenic plant-derived pan-serotonergic agonist, was shown to produce a rapid antidepressant response in humans with treatment resistant depression. However, the hallucinations pose a significant barrier to its widespread use. Antagonists of serotonin2A receptor (5-HT2AR), such as ketanserin, can be used to block hallucinations in humans. Can a combination of psilocybin plus ketanserin provide rapid relief of depressive symptoms without hallucinations? In rodents, chronic administration of fluoxetine reverses anhedonic deficits in reward behavior produced by chronic multimodal stress (CMS). Fluoxetine also restores the strength of temporoammonic (TA) - CA1 synapses in the hippocampus. Here, we test the hypothesis that psilocybin can exert a rapid anti-anhedonic effect in rodents subjected to CMS and ask whether this effect is independent of 5-HT2ARs. Using 10-21 days of CMS, we induced an anhedonic phenotype in rodents, as assessed by loss of sucrose preference. Sucrose preference was restored within 48 hours of a single acute dose of psilocybin (1mg/kg). Experiments with psilocybin and ketanserin are in progress. Ketanserin did not impair the ability of fluoxetine to restore sucrose preference and to strengthen TA-CA1 synapses, suggesting that psilocybin’s antidepressant effect may also be independent of 5-HT2ARs. Blocking the hallucinogenic side effect of psilocybin, but not the rapid acting antidepressant effect, by co-administering psilocybin and ketanserin could provide a novel and viable approach for safe and effective rapid relief of depression.

Title: The $GABA_AR$ α5 subunit is required for the fast antidepressant-like actions of MRK-016 on stress-induced anhedonia and weakened synaptic function

Authors: *T. TROPPOLI[1], P. ZANOS[2], P. GEORGIOU[2], U. RUDOLPH[3], T. D. GOULD[4], S. M. THOMPSON[1];
[1]Physiol., [2]Psychiatry, Univ. of Maryland Baltimore, Baltimore, MD; [3]Dept. of Comparative Biosci., Univ. of Illinois At Urbana-Champaign, Urbana, IL; [4]Psychiatry, Anat. and Neurobiology, Pharmacol., Univ. of Maryland Sch. of Med., Baltimore, MD

Abstract: Major depression is a common debilitating psychological disorder. Current clinical treatment options primarily involve reuptake inhibition of monoamine neurotransmitters, but these therapeutics are only effective in half of patients and have a delayed onset of therapeutic action. Negative allosteric modulators of $GABA_A$ receptors containing α5 subunits (GABA-NAMs), such as MRK-016, exhibit rapid antidepressant-like properties in preclinical models of stress-induced anhedonia and restore stress-weakened glutamatergic excitation at hippocampal temporoammonic-CA1 synapses (TA-CA1). These behavioral outcomes are dependent on the activity of the benzodiazepine site of the $GABA_A$ as they can be blocked via pretreatment with the selective $GABA_A$ competitive antagonist flumazenil. Here we test the prediction that the anti-anhedonic and synaptic responses to these compounds specifically require the $GABA_AR$ α5 subunit. Eight-week old, male C57BL/6J mice were subjected to a 10-day chronic multimodal stress paradigm, sufficient to induce anhedonia, as measured with sucrose and female urine sniffing preference tests. Strength of TA-CA1 synaptic transmission was compared between $GABA_AR$ α5 KO and wild-type animals treated with either MRK-016 or vehicle, as quantified via fEPSP AMPA:NMDA ratios. Additionally, we posit that an increase in cortical quantitative electroencephalogram (qEEG) gamma-power is associated with the persistent antidepressant-like activity of rapid-acting antidepressants. A single IP injection of MRK-016 (3 mg/kg) significantly reversed deficits in these reward behaviors in wild-type animals with intact $GABA_A$ α5 subunits. C57BL/6J mice lacking the α5 subunit ($GABA_AR$ α5 KO) showed no significant improvement in post-stress anhedonic state following MRK-016 treatment. MRK-016 induced significant increases in gamma-power in wild-type, but not in $GABA_AR$ α5 KO animals. Significant increases in gamma-power over baseline were achieved in both strains of animals

following a single IP injection of 10 mg/kg (*R,S*) ketamine, confirming that the absence of the $GABA_A$ α5 subunit does not preclude increases in gamma-power in response to a different rapid-acting antidepressant. We conclude that GABA-NAMs act via the benzodiazepine binding site of α5-containing $GABA_A$Rs to produce a transient increase in correlated neuronal discharge at gamma frequencies, thereby inducing intrinsic activity-dependent synaptic strengthening in critical reward circuits, which may be responsible for its anti-anhedonic actions. α5 selective GABA-NAMs thus have potential as novel, fast-acting antidepressants.

Title: Blood microRNAs as biomarkers for stress susceptibility or resiliency and treatment response

Authors: *Y. Y. VAN DER ZEE[1], O. ISSLER[2], D. M. WALKER[3], A. TORRES-BERRÍO[4], E. M. PARISE[5], A. RAMAKRISHNAN[6], J. W. MURROUGH[6], B. P. RUTTEN[7], E. J. NESTLER[8]; [1]Maastricht Univ., Maastricht University, Netherlands; [3]Neurosci., [2]Icahn Sch. of Med. at Mount Sinai, New York, NY; [4]Neurosci., Icahn Sch. of Med. At Mount Sinai, New York, NY; [5]Dept. of Neurosci., Ichan Sch. of Med. At Mount Sinai, New York, NY; [6]Icahn Sch. of Med., New York, NY; [7]Maastricht Univ. Med. Ctr., Maastricht, Netherlands; [8]Icahn Sch. Med. at Mount Sinai, New York, NY

Abstract: Major depressive disorder (MDD) is an episodic form of mental illness that is characterized by mood disturbances, anhedonia, and alterations in cognitive function. There is a great need for objective biological indicators for the diagnosis of MDD, for prediction of treatment response and for assessment of treatment efficacy. In recent years, small noncoding RNAs known as microRNAs (miRNAs) have been acknowledged as key actors in numerous diseases including mental disorders such as MDD. These molecules act as potent epigenetic post-transcriptional regulators of gene expression. Interestingly, miRNAs can be detected in the circulation and there is evidence for correlations between specific circulating miRNA levels and disease states, suggesting a potential use for these molecules as biomarkers. The present study explored the potential use of miRNAs as biomarkers for MDD and for prediction and assessment

of treatment response. To that end, we performed Nanostring analysis on miRNAs from whole blood of mice that was collected before and after exposure to the chronic social defeat stress (CSDS), as well as after antidepressant treatment (*i.e.*, imipramine or ketamine). This allowed us to profile the expression levels of approximately 600 circulating miRNAs and explore whether they can predict behavioral response to CSDS or antidepressant treatment. Our results demonstrate widespread changes in miRNA expression after stress and antidepressant treatment. Both resilient and susceptible mice demonstrate strong regulatory changes in miRNA expression levels directly after CSDS when compared to control mice. Interestingly, more miRNAs are regulated in susceptible mice treated with ketamine as opposed to mice treated with imipramine. As a result, we have identified a subset of miRNAs that might serve as candidate biomarkers to aid diagnosis and predict treatment response. To probe the involvement of these miRNAs in human drug response, we are conducting qRT-PCR on the blood of treatment resistant depressed patients compared to controls before and after treatment with ketamine. Taken together, this study enhances our understanding of epigenetics changes in response to stress and provides a potentially actionable set of biomarkers for use in clinical settings.

Title: Genetic and pharmacological inhibition of two-pore domain potassium channel TREK-1 alters depression-related behaviors and neuronal plasticity in the hippocampus in mice

Authors: *F. WU, Z. ZHANG;
Dept. of Neurology, Affiliated ZhongDa Hosp., Sch. of Medicine, Southeast Univ., Nanjing, China

Abstract: The two-pore domain potassium channel TREK-1 is a member of background K^+ channels that are thought to provide baseline regulation of membrane excitability. Recent studies have highlighted the putative role of TREK-1 in the action of antidepressants, and its antagonists might be potential effective antidepressants. However, the mechanisms underlying the actions of TREK-1 are not yet fully understood. Here, we demonstrated that chronic unpredictable mild stress (CUMS) increased TREK-1 expression in the mouse hippocampus. Knockdown of TREK-

1 in hippocampal neurons significantly attenuated depressive-like behaviors and prevented the decrease of CUMS-induced synaptic proteins and dendritic spines in mice. Further examination indicated that neuron-specific knockdown of TREK-1 in the hippocampus prevented stress-induced impairment of α-amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid-mediated synaptic transmission in the CA1 region. Moreover, chronic TREK-1 inhibition protected against CUMS-induced depressive-like behaviors and impairment of synaptogenesis in the hippocampus. Taken together, our results indicate a role for TREK-1 in the modulation of synaptic plasticity in a mouse model of depression. These findings will provide insight into the pathological mechanism of depression and further evidence for a novel target for antidepressant treatment.

Title: Astrocyte-specific expression of the extracellular matrix gene Htra1 regulates susceptibility to stress in a sex specific manner

Authors: *E. M. PARISE[1], A. TORRES-BERRÍO[1], C. J. BROWNE[1], T. M. GYLES[2], L. F. PARISE[1], Y. VAN DER ZEE[1], Z. S. LORSCH[1], P. J. HAMILTON[3], B. LABONTÉ[4], S. J. RUSSO[1], E. J. NESTLER[1];

Abstract: Major Depressive Disorder (MDD) is a highly debilitating and costly mental disorder affecting more than 300 million people worldwide. While the underlying pathophysiology is poorly understood, convergent evidence from pre-clinical and clinical research supports the idea that MDD is related to impaired structural plasticity in key limbic brain areas. However, how these structural brain abnormalities contribute to MDD pathology is unknown. The extracellular matrix (ECM) of the brain represents a novel avenue for study and potential therapeutics as it not only provides structural support but is intimately involved in regulating synaptic plasticity and remodeling. We hypothesized that alterations to this complex network of proteins surrounding

neurons and glial cells could regulate morphological processes that may be involved in MDD. To that end, we analyzed transcriptional profiles of ECM-related genes from the nucleus accumbens (NAc) in postmortem brain tissue of humans with MDD as well as in mice that exhibit depression-like behavioral abnormalities after exposure to chronic variable stress (CVS). A large number of ECM-specific genes were identified as being differentially expressed, however, only those that were similarly dysregulated across species were selected for downstream manipulations. In particular, we identified *Htra1*, an astrocyte-enriched secreted serine protease, as being significantly and consistently down-regulated in males and significantly up-regulated in females in both species. Using a combination of viral and transgenic tools, we show that selective manipulation of the *Htra1* gene in astrocytes within the mouse NAc increases susceptibility to stress in a sex-specific manner. Taken together, our findings reveal a pivotal role of astroglia as well as the brain's ECM in mediating stress vulnerability that is impacted in a sex-specific manner.

Abstract: Major Depressive Disorder (MDD) is the most prevalent psychiatric disorder in the world, representing a high level of global economic burden. Despite decades of research, the treatments for MDD remain inadequately effective for roughly half of patients due to the heterogeneity of depressive symptoms and our limited understanding of the molecular

mechanisms associated with treatment response. Fluoxetine (FLX), a selective serotonin reuptake inhibitor (SSRI), has been widely used to treat MDD; however, a majority of patients do not achieve full remission. As an alternative, ketamine (KET), an antagonist of the glutamate N-methyl-D-aspartate (NMDA) receptor among other actions, induces a rapid antidepressant response thus providing a novel therapeutic approach. Importantly, KET has been shown to be effective in ~50% of patients who fail to show full responses to FLX or other SSRI antidepressants. However, the molecular mechanisms underlying this effect are poorly understood. This study was aimed at characterizing the transcriptional profile of successful response to KET in FLX-treatment resistant mice. We exposed adult male mice to chronic social defeat stress (CSDS), a validated mouse model for the study of depression that differentiates between resilient and susceptible mouse populations based on a social interaction test (SIT). Mice exhibiting reduced social interaction were classified as susceptible and underwent antidepressant treatment with FLX in their drinking water for 28 days. After FLX treatment, we identified a subset of mice that continued to show reduced social interaction despite treatment (non-responders). FLX non-responder mice were subsequently given a single injection of KET and assessed in the SIT. We found that FLX treatment primed successful antidepressant response to a single KET injection in comparison to non-responder mice treated with water. We present RNA-seq transcriptional profiling of key neural circuits implicated in MDD, including the prefrontal cortex, nucleus accumbens, ventral hippocampus, and ventral tegmental area of responder and non-responder mice to FLX and KET treatments.

Title: Role of adult hippocampal neurogenesis in the antidepressant effects of lactate

Authors: *A. CARRARD[1], F. CASSÉ[1], S. BURLET-GODINOT[1], N. TONI[1], P. J. MAGISTRETTI[2], J.-L. MARTIN[1];

Abstract: Astrocytes are key players in energy metabolism and glutamate transport. In particular, astrocytes respond to glutamate by increasing the rate of glucose utilization and the release of lactate (Magistretti and Allaman, Nat Rev Neurosci. 2018). Growing evidence indicates that astrocytes are also involved in the pathophysiology and treatment of depression. For instance, SSRIs stimulate lactate release from cortical astrocytes. Recently, we showed that acute lactate administration increased lactate concentration in the hippocampus and reduced immobility in the forced swim test (Carrard et al, Mol Psychiatry 2018). We further investigated the antidepressant-like behavioral effects of lactate in two animal models of depression that respond to chronic antidepressant treatment; the corticosterone model of depression and the open-space forced swim model of depression. We found that chronic administration of lactate improved depressive-like behavior (Carrard et al, Mol Psychiatry 2018). In particular, chronic lactate injection reversed the corticosterone-induced anhedonia-like behavior and partially restored mobility in the open-space forced swim model of depression, in a manner similar to desipramine. The antidepressant effects of lactate are associated with changes in the expression of specific target genes of which Hes5 is involved in adult hippocampal neurogenesis. These findings led us to investigate the role of adult hippocampal neurogenesis in the antidepressant effects of lactate.The involvement of hippocampal neurogenesis in the antidepressant effects of lactate was assessed in the corticosterone model of depression. We found that chronic peripheral injections of lactate counteracted the decreased neural progenitor proliferation and survival induced by chronic corticosterone treatment. In contrast, chronic administration of pyruvate did not produce antidepressant effects and did not prevent the inhibition of neural progenitor proliferation and survival induced by chronic corticosterone injections. Furthermore, depletion of adult hippocampal neurogenesis by administration of the antimitotic drug temozolomide suppressed the antidepressant-like effects of lactate in the chronic corticosterone paradigm. Collectively, these data emphasize the importance of adult hippocampal neurogenesis in the antidepressant effects of lactate.

Title: Subcutaneous administration of beta-hydroxybutyrate produces antidepressant like effects in a rodent model of depression caused by interferon-α

Authors: *R. MATSUO, M. IWATA, N. KAJITANI, T. YAMANASHI, K. TSUNETOMI, M. SHIBUSHITA, A. MIURA, T. NISHIGUCHI, K. KANEKO;
Tottori Univ., Tottori, Japan

Abstract: Interferon-α (IFN-α) is a potent pro-inflammatory cytokine, which is used for the treatment of chronic hepatitis C and some types of leukemia or cancer. While there are many beneficial aspects, IFN-α therapy causes numerous side effects such as fever, fatigue, anorexia, and depression. Amongst the various side effects of IFN-α, depression is a severe side effect which may result in the termination of IFN-α therapy. Although it is unclear how IFN-α causes depression, recent studies demonstrate a role for the involvement of intracerebral inflammation, including evidence that the interleukin-1β (IL-1β) causes depressive behavior. Previously we had reported that stress increases ATP, which activates the Nucleotide-binding protein, Leucine-rich repeat, Pyrin domain containing 3 (NLRP3) inflammasome, which in turn promotes the formation of mature IL-1β in the rat brain. Also, it is well known that IFN-α induces pro-inflammatory cytokines such as IL-1β and tumor necrosis factor α (TNF-α). Thus, we propose a hypothesis that the inhibition of the NLRP3 inflammasome will produce an antidepressant effect by preventing IL-1β production caused by IFN-α therapy. Recently, it has been reported that beta hydroxybutyrate (BHB), a ketone body that supports mammalian cell metabolism during states of energy deficiency, such as fasting or exercise, reduces NLRP3 inflammasome mediated production of IL-1β. We have found that peripheral BHB administration suppressed NLRP3 activation and reduced pro-inflammatory cytokines such as IL-1β and TNF-α, which improved anxious and depressive behaviors in a rodent chronic unpredictable stress (CUS) model of depression. In this study, we aimed to evaluate the possible beneficial effects of BHB in rat depression model caused by IFN-α. The model was made administrating IFN-α daily for seven days, as other groups have already published. Here we show that BHB administration twice a day for fourteen days after making depression model produces antidepressant effects in evaluated elevated plus maze (EPM) test and forced swim test (FST). These findings suggest that BHB may be a therapeutic candidate for the treatment of depression caused by IFN-α.

Title: Acoustic range electromagnetic stimulation reduces anxiety degree in depressed rats

Authors: *N. BUKIA[1], L. MACHAVARIANI[1], M. SVANIDZE[1], M. BUTSKHRIKIDZE[1], N. JOJUA[2];

Abstract: Depression is one of the most common disorders. Despite the fact that it is possible to treat depression using pharmacological substances, about 35-40% of the patients are resistant to such treatment. The electric-magnetic stimulation (EMS) is a noninvasive treatment method, it is used as a complementary to the drugs, for treating different neurodegenerative diseases. Neonatal administration of clomipramine (25 mg/kg) produces physiological, neuroendocrinal and behavioral abnormalities in rats which are similar to those observed in animal models of depression. So, the goal of this study was to explore the impact of EMS on the ECoG activity and anxiety degree in clomipramine -induced depressed rats. Parameters of EMS which full or partially depressed EEG and behavior manifestation of depression, were established during pilot experiments. The forced swim test (FST) and open field test were chose. Experimental group of rats received EMS before testing. Data reliability was assessed using parametric and non-parametric techniques, with the use of one- way layout of factorial analysis. We have obtained the optimal parameters of repeated EMS (10000 -15000 Hz frequency, 1,5 m/Tesla, during 15 min, 10 days), which full or partially Inhibited depressive-like behavior in rats. In depressed rats domination of delta-wave were registrated. Besides, separate, low amplitude beta waves were recorded. Predominance of delta-waves were in positive correlation with the level of rat immobilization in the FST and open field test. On the background of EMS restoration of Beta waves and reduction of the Delta-waves were detected. The EMS reduced immobility time in the FST ($p < 0.05$) in depressed rats compared to nonstimulated one's. Besides, the EMS increased struggling behavior ($p < 0.05$) and swimming in the FST ($p < 0.05$). EMS have no effect on time spent under the water. On the background of EMS in depressed rats, the number of crossed squares ($P \leq 0.01$), hole reflex ($P \leq 0.01$) and head lifts ($P \leq 0.05$) were increased in the Open field test. The number of vertical stands ($P \leq 0.05$), duration ($P \leq 0.05$) and the number of grooming episodes ($P \leq 0.01$), as well as the number of fecal boluses and the frequency of urination were decreased. The present study identified a positive effects of EMS on the treatment of depression-like activity in rats. The acoustic range EMS decreases fear and anxiety degree and consequently, increases the escape activity in FST and exploratory activity in open field test. Therefore, findings of this study will promote the development of new approaches to the treatment of depression.

Title: The affective bias test: A refined and translational method for assessment of novel antidepressants

Authors: *J. K. HINCHCLIFFE, E. S. J. ROBINSON;
Sch. of Physiology, Pharmacol. and Neurosci., Univ. of Bristol, Bristol, United Kingdom

Abstract: For more than 40 years the pre-clinical methods for research into antidepressants has been the forced swim test and tail suspension test. Whilst these assays have been very useful in the development of many of the antidepressant treatments used today, it is now becoming apparent that they only really work for drugs acting through a specific neurochemical system and they show a much poorer ability to predict clinical outcomes. We sought to develop an alternative method to study depression-related biology in rodents which would also avoid the need to use aversive methods and have better translational validity. The affective bias test (ABT) is a bowl digging task based on associative learning and memory. Translated from clinical observations in patients with mood disorders and evidence that they experience impairments in reward-related learning and memory, the task requires animals to learn two independent cue-reward associations (digging in specific substrate to obtain food reward). The value of each experience is the same but affective state can be manipulated prior to one of the experiences. Using a choice test the animal is then 'asked' which do you prefer? We have been able to establish that treatments which cause depression in humans will induce negative biases in this task i.e. the animal is less likely to choose the cue-reward association learnt following treatment. The opposite is seen with treatments which are antidepressant with animals showing a positive bias towards these cue-reward associations. Because the absolute value of the reward is kept constant, these biases can be attributed to the animal's affective state at the time of learning. We have shown that delayed vs rapid onset antidepressants differentially modulate biases in this assay and that animals exposed to early life adversity show increased vulnerability to negative biases. We suggest that the ABT demonstrates face, predictive, construct and translational validity. The ABT has a medium to large effect sizes across different rodent strains and is effective in males and females.

Title: The effect of Galanin N-terminal fragment (1-15) in anhedonia: Involvement of the dopaminergic mesolimbic system

Authors: *C. MILLÓN[1], A. FLORES-BURGESS[1], B. GAGO[1], L. GARCÍA-DURÁN[1], N. CANTERO-GARCÍA[1], F. ALÉN[2], L. ORIO[2], J. NARVÁEZ[1], K. FUXE[3], L. SANTÍN[4], Z. DÍAZ-CABIALE[1];
[1]Univ. of Málaga. Dept. of Human Physiol., Málaga, Spain; [2]Facultad de Psicología, Univ. Complutense de Madrid, Madrid., Madrid, Spain; [3]Karolinska Institute, Stockholm, Sweden, Stockholm, Sweden; [4]Univ. of Málaga. Dept. of Psychobiology, Málaga, Spain, Málaga, Spain

Abstract: The Galanin N-terminal fragment (1-15) [GAL(1-15)] induces depressant- and anxiogenic-like actions in behavioral tests and these effects were significantly stronger than the ones induced by Galanin. Since anhedonia is a core feature of depression, we have analyzed GAL(1-15) actions in two anhedonic-like behavior tests: saccharin Self-administration and Sucrose Preference test (SPT). In order to investigate whether the effect of GAL(1-15) was associated with the reward circuit, we have studied the GAL(1-15) actions over the mesolimbic system by the expression of the C-Fos, Dat, Vmat2 and Dopamine and GAL receptors genes in VTA and NAc. Three sets of experiments were conducted in the saccharin Self-administration test. In the first, a dose-response curve of GAL(1-15) 1nmol, 3nmol or vehicle was performed. We have also compared the effects in the number of saccharine reinforcements of GAL 3nmol and GAL(1-15) 3nmol. In the last experiments, rats received i.c.v. GAL(1-15) 3nmol and the GALR2 antagonist M871 3nmol. In SPT, we have analyzed the effects of GAL(1-15) 3nmol in the sucrose intake and preference after 2, 8 and 24 h. In the qPCR experiments, groups of rats were killed 1h after i.c.v. GAL(1-15) 3nmol or vehicle. The VTA and NAc were dissected and the mRNA expression of C-Fos, Dat, Vmat2 and D1, D2, D3, D5, GALR1, and GALR2 receptors were measured. GAL(1-15) 3nmol significantly decreased the number of reinforcement of saccharin self-administer ($p<0.01$), while 1nmol lacked effect. GAL(1-15) also significantly reduced the number of reinforcement ($p<0.01$) compared with GAL. The GALR2 antagonist M871 significantly blocked ($p<0.05$) the decrease in the number of saccharin reinforcements induced by GAL(1-15). In the SPT, GAL(1-15) decreased the sucrose intake 8 ($p<0.05$) and 24 hours ($p<0.01$) after administration. GAL(1-15) at a dose of 3 nmol produced a significant

decrease in the mRNA levels of Dat and Vmat2 ($p<0.05$) and an increase in the D3 receptor ($p<0.05$) in VTA. In the NAc, GAL(1-15) induced a significant decrease in the expression of C-Fos ($p<0.05$) mRNA and a significantly increased the mRNA expression of D1 ($p<0.05$), D2 ($p<0.05$) and D3 ($p<0.05$). In the current study, we described for the first time that GAL(1-15) induced a strong anhedonia-like phenotype in several behavioral tests, confirming an important role of this neuropeptide in anhedonia, moreover, the dopaminergic mesolimbic system was described as a key region in GAL(1-15)-mediated action on anhedonia. These results may give the basis for the development of novel therapeutic strategies using GAL(1-15) for treatment of depression and reward-related diseases.

Abstract: Major Depressive Disorder (MDD) is a chronic and debilitating disease with poor treatment outcomes. Although significant achievements have been yielded in the field, there is

still a need for identifying mechanisms underlying MDD. Compelling evidence from animal models and human studies suggest a crucial role of the anterior cingulate cortex (ACC) and the anterior part of the basolateral amygdaloid nucleus (BLA) in the development of MDD. Moreover, track-tracing analysis conducted by our team, highlighted a strong reciprocal connection between areas 24a/24b of the ACC and the BLA, making this pathway a good candidate to begin the dissection of the ACC connectome in mood disorders. In order to manipulate the BLA-ACC pathway in C57BL/6J naive mice we used an optogenetic approach. An AAV5 coding for the channelrhodopsine was injected in the BLA and repeated blue light pulses were delivered in areas24a/24b of the ACC to activate the pathway. Using a battery of behavioural tests we showed that chronic activation of the BLA-ACC pathway induced depressive but not anxiety-like behaviours. The need for repeated stimulation strongly suggests the setting up of plasticity mechanisms.In parallel we also assessed the impact of BLA-ACC pathway activation on whole brain connectivity using resting-state functional magnetic resonance imaging. We observed altered connectivity between ACC and amygdala and mesolimbic pathway as well as between BLA and brain structures coding aversive states. Thus, BLA-ACC activation seems to alter global brain connectivity and mimic some of the changes observed in other animal model of depression and patients.To go further, we tested if the inhibition of the BLA-ACC connection could alleviate the anxiodepressive-like behaviours in a chronic pain-induced depression model. A polyethylene cuff was inserted around the principal branch of the sciatic nerve to induce an immediate and long-lasting allodynia, along with anxiodepressive-like behaviours emerging 6 weeks after the surgery. We injected an AAV5 coding for the archaerhodopsine in the BLA and delivered green light in the ACC during behavioral testing to inhibit the BLA-ACC connection. This manipulation resulted in an improvement of the depressive but not anxiety-like behaviour without affecting the mechanical allodynia, consistent with data obtained when activating this pathway in naive mice.Altogether these data reveal the importance of the BLA-ACC pathway in emotional regulation and highlight the need of dissecting circuits rather than single structure to deepen our understanding of mechanisms underlying mood disorders.

Title: FGF-AS overexpression in medial prefrontal cortex is depressogenic

Authors: *F. Ö. HÖKELEKLI, H. KARATAS-KURSUN, M. YEMISCI, T. DALKARA, E. EREN-KOÇAK;
Hacettepe Univ. Inst. of Neurolog. Sci. and Psychiatry, Ankara, Turkey

Abstract: Background: The natural antisense transcripts (NATs) are widespread in a great range of organisms, from prokaryotes and viruses to humans. NATs are shown to regulate protein synthesis in prokaryotes and viruses, however, their role in eukaryotes is poorly understood. Most NATs are not translated into a protein and are thought to control their sense partners' expression. Fibroblast growth factor antisense (FGF-AS) is a NAT, transcribed from the opposite strand of fibroblast growth factor 2 (FGF2) gene. We previously showed the role of hippocampal FGF-AS on depression- and anxiety-like behaviors in rats. We also reported that FGF-AS overexpression in medial prefrontal cortex (mPFC), a region known to be involved in the pathophysiology of the affective disorders, increased anxiety-like behavior. In this study we aimed to investigate the effects of increased expression of FGF-AS in mPFC on depression-like behavior.
Methods: FGF-AS expressing adeno-associated virus 2 (AAV2) (n=16) or a blank control AAV2 (n=13) was injected into both prelimbic and infralimbic regions in mPFC of 8-10 week-old male wild type Sprague Dawley rats. Four weeks later, sucrose preference test (SPT) and forced swim test (FST) were performed to evaluate depression-like behavior, anhedonia and behavioral despair, respectively. Depending on the distribution of the data, Student T-test or Mann Whitney U test was used to compare groups.
Results: FGF-AS overexpression did not change the preference of rats for sucrose ($p=0.694$) but it increased time spent immobile ($p= 0.095$) and decreased time spent swimming in FST ($p= 0.093$).
Conclusion: We reported an increase in behavioral despair by FGF-AS overexpression in mPFC, in parallel with its previously reported anxiogenic effects. Our findings indicate the role of medial prefrontal FGF-AS in some but not in all depressogenic behaviors. Since SPT and FST model different symptomatic aspects of depression, which may be mediated by different brain networks, effects of manipulations of FGF-AS expression in other brain regions on different symptomatic aspects of depression should be studied further.

Abstract: Despite the familial prevalence of adult-onset psychiatric disorders, only a handful of genetic variants have been shown to dramatically increase the risk for these conditions. Previously, we conducted linkage analyses of 972 multiply affected pedigrees with bipolar disorder and found evidence that large-effect variants may exist in a subset of these pedigrees. However, causal variants have yet to be identified. To address this, we conducted whole-genome sequencing in 40 of the 972 pedigrees to identify pedigree-specific large-effect risk variants. By analyzing these genomes together with exome and genome sequences from an additional 2,536 psychiatric cases and 198,840 controls, including population reference datasets, we identified an ultra-rare nonsynonymous variant (G131V) in the *DAO* gene that co-segregated with bipolar disorder in a four-generation pedigree and was significantly associated with risk for psychotic disorders across the combined dataset (p-value = 4.5×10^{-14}). *DAO* encodes D-amino acid oxidase, which has been shown previously to modulate anxiety-like behavior in mice via degradation of the *N*-methyl-D-aspartate receptor (NMDAR) co-agonist, D-serine. Convergent evidence supports a role for aberrant NMDAR neurotransmission in psychiatric disease. In

addition, structural modeling predictions indicate that the G131V substitution could destabilize DAO protein. Thus, we hypothesized that impaired function of DAO via the G131V mutation confers risk for the onset of bipolar disorder. To test this hypothesis, we used site-directed mutagenesis to introduce the DAO G131V variant into HEK293T cells *in vitro.* We found that DAO G131V led to a ~50% reduction in DAO protein levels. Moreover, DAO enzymatic activity was essentially ablated due to the G131V mutation. To further characterize DAO G131V, we generated a new knock-in mouse, using Cas9 genome editing to introduce the precise mutation observed in patients at the endogenous *Dao* locus. Ongoing studies are characterizing the molecular, cellular, and behavioral changes that are associated with the DAO G131V variant in the mouse line *in vivo*.

Title: Ginkgo biloba extract reduces oxidative stress and inflammation while restores 5-HT_{1A} serotonin receptor levels in hippocampus of ovariectomized rats

Authors: *M. M. MACHADO[1], F. M. THOMAZ[2], I. S. DE ANDRADE[3], V. T. BOLDARINE[3], E. B. RIBEIRO[3], R. M. BANIN[2], M. M. TELLES[2];

Abstract: Menopause is associated with the development of physical and psychological alterations related to reduction of estrogen levels. In cerebral structures involved in cognition and memory such as the hippocampus, hypoestrogenism may impair synaptic signaling, contributing to the emergence of cognitive disturbances. Furthermore, cognitive impairment is also associated with the accumulation of oxidative damages to different cells compounds. *Ginkgo biloba* extract (GbE), a widely used herbal supplement, is recognized as an antioxidant and anti-inflammatory agent. We previously demonstrated a stimulatory effect of GbE on the hypothalamic serotonergic system of ovariectomized rats. Therefore, the aim of this study was to evaluate GbE action on oxidative stress, inflammation and 5-HT receptors levels in hippocampus of ovariectomized rats.

Two-month-old female Wistar rats were ovariectomized (OVX) or not (SHAM). Sixty days after surgery, OVX rats were given 500mg/kg of GbE (OVX+GbE) daily by intragastric gavage, while SHAM and OVX groups received saline 0.9% (vehicle) for 14 days. After treatment, rats were euthanized and their hippocampi were removed. Both 5-HT_{1A} (-52.4%; $p<0.001$) and 5-HT_{1B} (-43.8%; $p=0.044$) levels were significantly reduced in OVX rats in comparison to SHAM rats, while GbE partially reversed the effect of OVX on 5-HT_{1A} (38.8%; $p=0.013$). Superoxide dismutase activity was 98% higher in OVX rats in relation to SHAM rats ($p=0.027$), while no differences were observed between SHAM and OVX+GbE groups. Additionally, OVX+GbE rats also presented a significant reduction in phospho-NF-κBp50 levels in comparison to SHAM (-29%; $p=0.006$) and OVX groups (-24%; $p=0.025$), as well as a reduction of 36% phospho-ERK/ERK ratio in comparison to SHAM group ($p=0.034$). In summary, the present data shows that GbE improves oxidative stress and inflammation markers and restores 5-HT_{1A} levels in hippocampus of OVX rats. Since the development of psychological diseases are common features of estrogen depletion, these findings indicate a promising therapeutic use of GbE for menopausal women.

Title: The role of developmental and environmental factors in a mouse model of high emotional reactivity

Authors: *D. MURRA, K. L. HILDE, Q. WEI, L. ZHANG, E. K. HEBDA-BAUER, Z. FREEMAN, S. J. WATSON, Jr., H. AKIL;
Univ. of Michigan, Ann Arbor, MI

Abstract: Early life adversity and genetic factors both influence the development and expression of mood disorders and future emotional reactivities to stress. Although numerous studies have sought to describe individual factors that predispose adults to depression, anxiety, and

other psychiatric disorders, the interplay and hierarchy of these individual factors and their combinations are not fully understood. In this study, we sought to incorporate a genetic mouse model of predisposition to emotional lability, multiple environmental stress models, and various behavioral outcomes to untangle the many factors that influence the propensity of developing adult anxiety and depression-like behavior. Genetically, we have previously shown that constitutive overexpression of the glucocorticoid receptor (GRov) in the forebrain during only the first 3 weeks of life resulted in long-lasting gene-expression changes and increased anxiety-like behavior in adulthood. Because of their role in the transduction of the stress responses, glucocorticoid hormones and their receptors serve as both genetic factors and mediators environmental influences, and thus the extent of emotional reactivity. Moreover, we compared two models of early life stress: maternal separation and developmental enrichment to ask what environmental manipulations change the genetic and control susceptibility to subsequent adulthood anxiety-like behavior. We used those individual factors and their combinations, that when expressed during a critical period of development(P1-P21), to induce future vulnerability or resilience to anxiety-like behavior. Moreover, we were able to further manipulate those factors in adulthood with group and single housing to test the stability of each factor to carry on its behavioral phenotype. Finally, this then allowed us to create a hierarchy model of environmental and genetic interactions that influence emotional reactivity.

Abstract: Depression is a common, chronic and debilitating disorder. Women are twice as likely to suffer from depression as men, yet the molecular mechanisms contributing to this sex difference remain poorly understood. Long non-coding RNAs (lncRNAs) are a recently discovered class of regulatory transcripts which represent a substantial portion of the human genome. To explore the role of lncRNAs in depression we utilized a comprehensive genome-wide profile of RNAs in six brain regions from both male and female post-mortem depressed and control human subjects. Overall, lncRNAs represent about one-third of the differentially expressed genes in depressed subjects compared to controls, and displayed complex region- and sex-specific patterns of regulation. Furthermore, we identified specific targets lncRNAs with potential sex-specific roles in depression. One of these targets is the neuronal gene linc00473, which is downregulated in prefrontal cortex (PFC) and several other brain regions in depressed females, but not males. To explore the causal role for linc00473 in depression, we virally expressed it in mouse PFC neurons. This approach mirrored the human sex-specific phenotype, as expressing linc00473 consequently induced stress resilience in females only. Furthermore, electrophysiological recordings from PFC pyramidal neurons expressing linc00473 compared to control indicated changes in synaptic properties in female mice only. To analyze the molecular mechanism of action of this lncRNA, we performed RNA sequencing on PFC infected with the linc00473 or control viruses either at baseline or following exposure to chronic stress. We found that expressing the linc00473 blunted the normal transcriptional changes in response to stress that was observed in control mice. Furthermore, CREB and cAMP signaling were predicted as upstream regulators of the genes whose levels were altered in mice expressing linc00473. Finally, we utilized Chromatin Isolation by RNA Purification (ChIRP) assay to identify direct DNA biding sites of linc00473 in human neuroblastoma cells either at baseline or following treatment with forskolin, an activator of adenylyl cyclase. Notably, in the forskolin group linc00473 bound genes enriched for those implicated in brain activity in general, and in anxiety and depression in particular. Taken together our studies identify linc00473 as a female pro-resilient effector of CREB signaling that is aberrant in female depression. These studies provide a fundamentally new view of molecular adaptations in brain that contribute to sex-specific stress resilience and may lead to the identification of novel targets for treatment.

Title: Cannabinoid CB1 receptors blockade, decreases food intake and anxiety events in rats with metabolic syndrome

Authors: *M. MUNOZ ARENAS, B. VÁZQUEZ-GONZÁLEZ, A. DÍAZ;
Farmacia, Facultad De Ciencias Químicas, BUAP, Puebla, Mexico

Abstract: Metabolic syndrome (MS) is characterized by insulin resistance, hyperglycemia, hypertension etc. Insulin resistance consist in a poor activation of insulin receptor and this event decreases glucose uptake and storage; in compensation, beta pancreatic cells increase production and secretion of insulin. It has been demonstrated that CB1 receptor activation, produce an increment in glucose concentration in blood, while blocked of these receptors decrease the zoometric measure and the insulin resistance in diabetic rats. The objective of this work was to evaluate the anxiety and depression behavior in rats with metabolic syndrome and to evaluate oxidative stress in brain areas implicated in anxiety. 32 wistar male rats were divided in two groups: Normocaloric (n= 16) and Hypercaloric/hyperglycemic diet (n= 16). Rats were alimented during 90 days for to stablish MS. After to induce MS, rats were divided again in four groups: SSI (1 mL/kg), ACEA (0.25 mg/kg), AM251 (0.1 mg/kg) and ACEA+AM251. All drugs were administrated intraperitoneally during 15 days. We evaluated anxiety in the open field test and the depression in the tail suspension test. CB1 receptors activation increase hyperglycemia and increase depression in rats with MS, while antagonism of these receptors produce contrary effect but increase anxiety in the rats. Diary administration of AM251decreases insulin concentration and food intake. We propose that blocked of CB1 receptors could be an important terapy in the treatment of metabolic syndrome.

Title: Hypervigilant responses to a novel environment in a rodent model of epilepsy and depression comorbidity

Authors: *S. A. EPPS, S. D. HUGHES, F. N. MARTIN, A. E. KELLY, R. B. KREGER, E. L. RANSOM, S. K. RYAN-COATS;
Psychology, Whitworth Univ., Spokane, WA

Abstract: A strong bi-directional comorbidity between epilepsy and depression exists in the clinical population. Both conditions have interacting relationships with stress and are comorbid with anxiety; thus, an understanding of the effects of stress on this comorbidity may provide important insights for treatment and quality of life.
The SwLo rat is a valid animal model of comorbid depression and epilepsy. These rats are selectively bred for low activity in the Porsolt Swim Test, reflective of depression-related behaviors. Additionally, they demonstrate enhanced susceptibility to chemically- and electrically-induced seizures and pilocarpine-induced epileptogenesis. Their counterpart, the SwHi rat, is selectively bred for high activity in Porsolt Swim Test and is resistant to seizures and epileptogenesis.
The current study therefore hypothesized that SwLo rats would show increased anxiety-like behaviors in a novel environment compared to their depression- and epilepsy-resistant counterparts, the SwHi rat. SwLo and SwHi rats (n=12-13 rats per group, equal numbers of males and females) were tested for anxiety-related behaviors in the open field test (OFT), elevated plus maze (EPM) and light-dark chamber (LD). SwLo rats showed a significant increase in number of entries into the inner ($F(1,23)=26.201$, $p<0.0001$) and outer ($F(1,23)=13.189$, $p=0.001$) squares of the OFT compared to SwHi rats. They also showed a significant increase in rearing behaviors when in the inner area of the OFT ($F(1,23)=10.876$, $p=0.003$), the closed arms of the EPM ($F(1,23)=6.64$, $p=0.017$), and the dark area of the LD chamber ($F(1,20)=11.793$, $p=0.003$) compared to SwHi rats. When in the LD box, SwLo rats spent significantly more time in the light compartment of the LD box than SwHi rats ($F(1,20)=4.863$, $p=0.039$). Ongoing studies are assessing the response of these behaviors to a mild restraint stress prior to novel environment exposure.
Contrary to our original hypothesis, SwLo rats exhibited increased locomotor responses and rearing behaviors during novel environment tests when compared to SwHi rats. This may best be

interpreted as either stress-related hypervigilance or attention-deficit hyperactivity (ADHD)-related behavior. Rearing has been associated with hypervigilant information gathering, which could suggest stress-related associations. Alternatively, the increase in exploratory behaviors may be associated with ADHD-related behaviors, suggesting the utility of SwLo rats for assessing underlying mechanisms and treatment possibilities for this comorbidity as well.

Title: A detailed analysis of voluntary wheel running in OBX mice reveals multiple behavioral changes

Authors: *R. P. WATERS[1], A. M. RINKO[1], W. D. STAHLMAN[2], D. M. COPPOLA[3]; [1]Biol., [2]Psychological Sci., Univ. of Mary Washington, Fredericksburg, VA; [3]Randolph-Macon Col., Ashland, VA

Abstract: Bulbectomized mice are a leading model of human major depressive disorder. A primary characteristic of bulbectomy is hyperactivity, which is robustly displayed when bulbectomized mice are housed with a running wheel. Reports of this behavioral phenotype demonstrate a positive effect of bulbectomy on wheel running activity. We performed a detailed analysis of individual voluntary wheel running activity in bulbectomized mice living in social colonies. We incorporated radio frequency identification (RFID) tags to assign wheel running activity to individual mice and to limit access of animals to the running wheel. Our data suggest that olfactory bulbectomy increases wheel running with free access to the wheel; however, delaying access to the running wheel reduces voluntary wheel running. Bulbectomy may also decrease the rewarding properties of running on the wheel. Finally, this surgical procedure disrupts the circadian pattern that is typically observed with voluntary wheel running. These data further characterize this premier model of major depressive disorder, which allows us to better understand the etiology of the disorder.

Title: Fetal programming of the brain structure in the development of behaviors like to depression-anhedonia

Authors: *L. A. TRUJILLO VILLARREAL[1], V. ROMERO-DÍAZ[2], I. A. MARINO MARTÍNEZ[2], L. FUENTES MERA[3], A. CAMACHO[3], M. CHAKRAVARTY[4], E. GARZA-VILLARREAL[5];

Abstract: Exposure to selective nutritional formula during development programs behavioral changes in later stages of life, an event known as fetal programming. Anhedonia-like behavior integrates a macro and microstructural deficit of the mesocorticolimbic circuit including the medial prefrontal cortex (mPFC), hippocampus (Hpp) and the nucleus accumbens (NAc) and defective glutamatergic plasticity. However, it is unknown if nutritional programming contributes to the anhedonia-like behavior phenotype by promoting aberrant macro and micro glutamatergic plasticity of the mesocorticolimbic circuit in the offspring. Here, we characterized macro and microstructural plasticity changes of the mesocorticolimbic circuit in the offspring induced by maternal caloric food exposure, and if these changes reproduce the anhedonia-like behavior phenotype. We use female Wistar rats exposed to a cafeteria diet (high in fat-sugar) for 9 weeks including pre-pregnancy, pregnancy and lactation, a protocol known as fetal programming. Motivating behavior to obtain natural rewards was characterized in male offspring (n= 93) as follow: Operational Conditioning (protocols in the Skinner box), preference to sucrose, open field and novel suppressed feeding. Changes in macro and microstructural plasticity were identified by Magnetic Resonance Imaging (MRI), Western blot (NMDA and AMPA receptor markers) and immunohistochemistry (synaptophysin and Glial fibrillary acidic protein (GFAP)), respectively. We found that the offspring of mothers exposed to cafeteria diet shows less motivation to obtain natural rewards, evidenced by: decrease in the protocols FR1, FR5 and PR, decrease in preference to sucrose, and longer time in the suppressed feeding test. MRI analyzes showed volume decrease in regions including the NAc, Hpp and mPFC. On the other hand, the microstructural analysis reveals anatomical changes in the regions of the Hpp and

NAc, which correlates with an increase in the GluR2 subunit of the AMPA receptor in the Hpp and a decrease in the NAc. Also, offspring exposed to cafeteria show positive hippocampal astrogliosis evidenced by an increase in the GFAP marker when compare with control. Our findings reveal that programming to mothers by caloric diet leads to anhedonia-like behavior phenotype in the offspring, which correlates with macrostructural defects and defective glutamatergic plasticity, and astrogliosis in the mesocorticolimbic circuit.

Title: 3-dimensional analysis of mice habenula in lipopolysaccharide depression model

Authors: *E. YANG, J. KIM, S. YANG, H. LEE, H. KIM;
Korea Univ., Seoul, Korea, Republic of

Abstract: Habenula is known to act as a central mechanism of depression related monoamine neuronal circuit in the brain, hence, it has become an important target for the treatment of depression. The the expression of few markers has been reported in tissue sections of habenula and several volumetric or three-dimensional (3D) analysis of human Hb have been performed. But three-dimensional analysis of mice habenula is still not to be conducted.
In this study, we set up 3D reconstruction methods for mice habenula, and performed volumetric analysis and gene expression analysis of LPS depression model habenula. As a results, we found that LPS injected mice showed smaller habenula volume than vehicle injected control mice. Interestingly, this volume reduction was prominent in MHb(medial habenula) but not in LHb(lateral habenula). Furthermore, the expression of Tac1 (dMHb specific marker) was decreased in all parts of dMHb, ChAT (vMHb specific marker) was decreased in rostral and middle part of vMHb, and Tacr1 (Hb marker) was decreased in rostral and middle part of MHb and LHb.
These results suggest that medial habenula plays important role in LPS depression model and our three-dimensional analysis method (volumetry and gene expression) for habenula will be useful for further investigation of the role of habenula in pathophysiology of depression.

Title: The CAPS2 (calcium-dependent secretion activator 2) knock-down in the medial habenula induces despair-like behavior

Authors: *H. YOO, J. KIM, S. YANG, E. YANG, K. SONG, H. PARK, H. LEE, H. KIM; Korea Univ., Seoul, Korea, Republic of

Abstract: In the central nervous system, calcium-dependent secretion activator 2 (CAPS2 also known as CADPS2) regulates trafficking and exocytosis of large dense core vesicles (LDCV), which is essential in releasing neuropeptides. The medial habenula (MHb) in epithalamus is an important structure related to various neuropsychiatric diseases including anxiety, nicotine withdrawal, addiction, and depression.
In this study, we characterized CAPS2 cell in MHb by *in situ* hybridization and analyzed habenular CAPS2 mRNA level with qPCR in depression animal models. To test the relationship of CAPS2 and depression, we performed depression-related behavior tests and immunohistochemistry after knocking down CAPS2 in MHb by stereotaxic injection of AAV-sh-CAPS2 virus.
In situ hybridization showed that CAPS2 is highly expressed in MHb, both in the substance P-ergic neurons of dorsal MHb (MHbD) and the cholinergic neurons of ventral MHb (MHbV). The mRNA level of CAPS2 in MHb is decreased in rat chronic depression stress (CRS) model and learned helplessness (LH) model, implicating that CAPS2 would play a role in MHb mediated depressive symptoms. CAPS2 knockdown in mouse MHb resulted in despair-like behavior in tail suspension test (TST) and forced swim test (FST), but not anhedonia-like behavior in sucrose preference test (SPT). In the open field test (OFT), the latency to center area was increased, but the frequency and the duration in the center were not changed. The CAPS2 knockdown showed increased p-ERK expression in the interpeduncular nucleus (IPN) and decreased c-fos expression in the ventral tegmental area (VTA).
The results suggest that the reduced CAPS2 expression would have changed neuronal activity in IPN and VTA, leading to induction of despair-like behavior, and the MHb CAPS2 is related to depression.

Abstract: Genetic polymorphisms of the L-type voltage-gated calcium channel (VGCC) are associated with psychiatric disorders including major depressive disorder. Alterations of S100A10 (p11) level are also implicated in the etiology of major depressive disorder. However, the existence of an endogenous regulator in the brain regulating p11, L-type VGCC, and depressive behavior has not been known. Here we report that Ahnak, whose function in the brain has been obscure, stabilizes p11 and Anxa2 proteins in the hippocampus and prefrontal cortex in the rodent brain. Protein levels of Ahnak, p11, and Anxa2 are highly and positively correlated in the brain. Together these data suggest the existence of an Ahnak/p11/Anxa2 protein complex. Ahnak is expressed in p11-positive as well as p11-negative neurons. Ahnak, through its N-terminal region, scaffolds the L-type pore-forming α1 subunit and, through its C-terminal region, scaffolds the β subunit of VGCC and the p11/Anxa2 complex. Cell surface expression of the α1 subunits and L-type calcium current are significantly reduced in primary cultures of Ahnak knockout (KO) neurons compared to wild-type controls. A decrease in the L-type calcium influx is observed in both glutamatergic neurons and parvalbumin (PV) GABAergic interneurons of Ahnak KO mice. Constitutive Ahnak KO mice or forebrain glutamatergic neuron-selective Ahnak KO mice display a depression-like behavioral phenotype similar to that of constitutive p11 KO mice. In contrast, PV interneuron-selective Ahnak KO mice display an antidepressant like behavioral phenotype. Our results demonstrate L-type VGCC as an effector of the Ahnak/p11/Anxa2 complex, revealing a novel molecular connection involved in the control of depressive behavior.

Title: Hyper-excitable neurons produce hypo-functional neuronal networks that predict psychiatric disease: Evidence from modeling CRMP2 in bipolar disorder

Authors: *C. D. PERNIA[1], Y. GOSHIMA[3], E. Y. SNYDER[2];
[2]Stem Cell and Regenerative Biol. Program, [1]Sanford Burnham Prebys Med. Discovery Inst., La Jolla, CA; [3]Yokohama City Univ. Sch. Med., Yokohama, Japan

Abstract: Bipolar disorder (BPD) is a neuropsychiatric disease in 2.6% of the adult population, and is characterized by oscillations in depressive and manic behavior. BPD is the most fatal psychiatric disease due to a high suicide rate, and little is known regarding its underlying pathology. Currently there is no reliably safe or predictably efficacious therapy for treating BPD. Recently, through a combinatorial approach taking advantage of hiPSC-derived neurons, animal models and human tissues, we demonstrated that the “lithium-response pathway” in BPD governs the phosphorylation and activation of collapsin response mediator protein 2 (CRMP2), a key cytoskeleton regulator, particularly for dendrites and dendritic spines. How CRMP2 mediates BPD has yet to be determined. Comparing transgenic mice with endogenous, absent, and constitutively active CRMP2, we have discovered CRMP2 activity impacts neuronal signaling kinetics and neurite proteomics. Specifically, BD-like transgenic CRMP2 neurons have hyperactive calcium activity, while having hypofunctional neuronal-network signaling, implying BPD is a disorder more of "neurodevelopment" than "mood", as was previously categorized in the DSM-IV. Furthermore, a machine learning classifier trained on BPD neuronal calcium data can successfully diagnose if an individual has BPD, and can determine if they will respond clinically to lithium. Collectively, this work illuminates long sought-after findings in BPD pathology, insights into brain function at large, novel targets for future neuropsychiatric therapeutics, and the first ever *in vitro* diagnostic BPD assay.

Title: Intranasal delivery to rats of [D^{26}His]NPY prevents traumatic stress triggered prolonged anxiety and depressive-like symptoms

Authors: *E. L. SABBAN, C. NWOKAFOR, L. I. SEROVA;
Biochem. and Mol. Biol., New York Med. Col., Valhalla, NY

Abstract: Considerable evidence from animal and human studies indicates that in the brain, neuropeptide Y (NPY) can attenuate the response to stress, and has therapeutic potential to prevent stress-triggered impairments such as PTSD, depression etc. We have shown that intranasal infusion of NPY to rats leads to widespread delivery to the brain without significantly changing plasma NPY concentrations. The biological effects of NPY are mediated by at least four G-protein coupled receptor subtypes: Y1R, Y2R, Y4R, Y5R. The anxiolytic effects of NPY are proposed to involve Y1R and possibly also Y2R and Y5R. Most studies have used [Leu^{31}Pro^{34}]NPY as a Y1 preferred agonist that also can activate Y5R. [D^{26}-His] NPY is reported to reduce development of anxiety. However, it was delivered by ICV injection and anxiety was reduced one hour later. Long term effects were not examined.
Here we examined the long-term effectiveness of intranasal administration of NPY and Y1R agonists. In a series of experiments, Sprague Dawley male rats were exposed to the single prolonged stress (SPS) model of PTSD. While still under the influence of ether (the last SPS stressor) they were given intranasal infusion of NPY or Y1R agonists [Leu^{31}-Pro^{34}]NPY, or [D^{26}His]NPY. One or two weeks later they were tested for anxiety on the Elevated Plus Maze (EPM) or depressive/despair behavior on the Forced Swim Test (FST). SPS led to anxiolytic behavior on the EPM. The vehicle infused animals (SPS/V) had less entries into the open arms and higher anxiety index than the unstressed controls, or the NPY infused rats (SPS/NPY). The Y1R agonist [D^{26}His]NPY was exceptionally effective to prevent development of anxiety, while [Leu^{31}-Pro^{34}]NPY was not. SPS also led to greater immobility time in the FST and this was reduced with NPY or [Leu^{31}-Pro^{34}]NPY. [D^{26}His]NPY was significantly more effective than NPY to prevent development of the immobility on the FST.
To study the ability to reverse the anxiety and depressive-like symptoms, SPS treated rats were given intranasal NPY, one or two weeks after the traumatic stress. A high concentration of NPY was able to reverse symptoms of anxiety, depressive-like behavior and hyperarousal. However, when [D^{26}His]NPY was given at the same concentration, in contrast to NPY, it was not effective

to reverse the behavioral impairments.
These data demonstrate therapeutic potential of Y1R agonists, such as[D^{26}His]NPY as early intervention to prevent development of PTSD associated behavioral impairments. It indicates that activation of the Y1R is sufficient to prevent the traumatic stress elicited impairments in anxiety and depressive behaviors, while NPY is able to also reverse these effects.

Title: Developmental photoperiod alters TREK-1 and SK currents in dorsal raphe serotonergic neurons

Authors: *M. A. GIANNONI GUZMÁN[1], T. N. MALIK[2], J. K. SIEMANN[1], D. G. MCMAHON[1];
[1]Dept. of Biol. Sci., [2]Neurosci. Training Program Vanderbilt Univ., Vanderbilt Univ., Nashville, TN

Abstract: Environmental factors can have profound effects on development and physiology. Seasonal changes in circadian day length during fetal development have been linked with the prevalence of mood disorders in adulthood. Among the different depression disorders, seasonal affective disorder manifests in people around the same time every year, most commonly in the winter months when light exposure is lowest during the year. Our laboratory has shown that developmental exposure to seasonal photoperiods has enduring effects on the excitability of dorsal raphe serotonergic neurons, their response to noradrenergic stimulation, intrinsic electrical properties, as well as on depression and anxiety-related behaviors. Here we extend this work by focusing on the twin-pore K+ channels TREK-1 and TASK-1, and the small conductance calcium-activated K+ channels (SK) as possible ionic mechanisms that underlie photoperiodic changes in the DRN. Using multielectrode array recordings, we examined the effects of pharmacological inhibition of these channels on the spike rate of serotonergic neurons in DR slices from mice exposed to different photoperiods. TREK-1, but not TASK-1 currents were modulated by photoperiod. In equinox slices, inhibition of TREK-1 via two independent

inhibitors, low dose amlodipine, and spadin, increased spike rate in a dose-dependent manner, however, in long and short slices TREK-1 inhibition had no effect on spike rate. In contrast, inhibition of TASK-1 resulted in increases in firing rate across all photoperiods. SK channel inhibition with apamin increased spike rates of short neurons, but not equinox or long. These results suggest a combinatorial mechanism in which the high spike rates of long neurons are mediated by reductions in both TREK-1 and SK currents, while the lower spike rates of short neurons are due to increased SK current, and the lower spike rates of equinox are due to increased TREK-1 current. Consistent with this, preliminary RT-PCR data, reveals significant reductions in the expression of TREK-1 expression in both long and short vs. equinox. This data provides evidence of how circadian light input during early life results in enduring changes in neural function.

Title: Determining the impact of photoperiod during sensitive pre & postnatal developmental periods for dorsal raphe serotonin neuronal physiology and serotonergic signaling

Authors: *J. K. SIEMANN[1], D. G. MCMAHON[2];
[2]Dept of Biol. Sci., [1]Vanderbilt Univ., Nashville, TN

Abstract: Early life experiences during sensitive developmental periods have been linked to increased risk for neuropsychiatric disorders later in life. The serotonin system is implicated in mood disorders and is impacted by the duration of daylight or photoperiod. Human epidemiological work has now demonstrated that high magnitude photoperiodic changes during the second trimester of gestation result in a decreased risk for depression in the adult offspring. Recently, we found that, in mice, Long photoperiods program dorsal raphe (DRN) serotonin (5-HT) neuronal firing rate *prenatally*, resembling the firing rate of animals maintained under Long photoperiods throughout development. We also observed that Long summer-like photoperiod exposure during postnatal development results in elevated monoamine content along with reduced mood-related behavior compared to mice exposed to Short winter-like photoperiods. We

are now systematically investigating when during *prenatal* development do Long photoperiods impact DRN 5-HT neuronal firing rate and identifying the sensitive periods in postnatal development responsible for changes to midbrain monoamine signaling and mood-related behaviors. For our prenatal experiments, we switched mice from either Long to Short or Short to Long photoperiods at E14.5 as this is after 5-HT neuronal gestation, when 5-HT switches from a maternal to a fetal source, and represents the approximate equivalent of second trimester human brain development. Surprisingly, we found that mice exposed only to Long photoperiods before E14.5 demonstrated 5-HT neuronal firing rates (1.13 ± 0.12 Hz) similar to animals exposed to Long photoperiods during the entirety of prenatal development (1.18 ± 0.08 Hz) as well as mice maintained under Long photoperiods throughout prenatal and postnatal development (1.24 ± 0.10 Hz). Interestingly, we observed that mice exposed to Long photoperiods after E14.5 demonstrated adult 5-HT firing rates (1.69 ± 0.17 Hz) similar to mice exposed to these conditions throughout the entirety of prenatal development and measured in early adolescence (1.86 ± 0.19 Hz), potentially representing a juvenile state. For our postnatal experiments, we measured midbrain monoamine content in mice developed continuously under either Long or Short photoperiods at P8, P18, and P35. We found elevated levels of 5-HT ($p = 0.0001$), 5-HIAA ($p = 0.0001$), DA ($p = 0.0060$) and DOPAC ($p = 0.0120$) content for Long compared to Short photoperiod mice arising at P18 and P35. We are continuing to investigate developmental sensitive periods impacted by photoperiod with the goal that this may lead to novel insights into the etiology for mood disorders.

Title: Social context modulates depressive-like behavior and dopamine deficit induced by early pup removal in late postpartum rats

Authors: *M. RINCÓN-CORTÉS[1], A. A. GRACE[2];
[1]Neurosci., [2]Neuroscience, Psychology, Psychiatry, Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Maternal mood during the postpartum can be dependent on offspring exposure (Feldman et al. 1999). In humans, the loss of a child can lead to severe grief and depression in mothers (Badenhorst and Hughes, 2006). In rodents, repeated long separations from pups impair

maternal behavior and alter emotionality in late postpartum rats (Boccia and Pedersen, 2001). Both repeated long separations and pup removal shortly (<24-hours) after birth increase immobility duration in the forced swim test (FST) in rat dams, which is interpreted as increased depressive-like behavior (Pawluski et al., 2009; Boccia et al., 2007). However, the use of the FST as a measure of depressive-like behavior has recently been questioned (Molendjik and de Kloet, 2019); and, other measures of depressive-like behavior in rat dams following pup removal remain unexplored. Here we evaluated long-lasting effects of pup removal and social context on maternal affect and dopamine (DA) activity. 3 groups: i) dams with pups, ii) dams with no pups, single-housed, iii) dams with pups removed and co-housed with another dam, underwent a behavioral test battery including: sucrose consumption, forced swim, elevated plus maze, and social approach tests during postpartum days (PD) 21-23. In vivo electrophysiological recordings of ventral tegmental area (VTA) DA neurons were performed (PD22-23) in subset of animals used for behavioral testing (EPM, social approach) to measure 3 parameters: number of spontaneously active DA neurons (i.e. population activity), firing rate, and firing pattern (i.e. burst firing). Dams that underwent pup removal and postpartum single-housing exhibited increased depression-like phenotypes (i.e. reduced sucrose intake, increased FST immobility, decreased social motivation) compared with co-housed dams or control dams kept with pups (one-way ANOVA: $p < 0.05$; n=8-10). Furthermore, single-housed dams that underwent pup removal exhibited an attenuation in VTA DA activity (i.e. reduced number of active DA cells) compared with dams that were co-housed or control dams kept with pups (one-way ANOVA: $p < 0.05$; n=7-9). These data indicate that disruption of social relationships during the postpartum period induces long-lasting alterations in depression-related behaviors and decreased VTA DA activity.

Title: Low effort bias induced by the dopamine depleting agent tetrabenazine in an effort-related decision making task using mouse touchscreen procedures

Authors: *J.-H. YANG[1], A. SHAH[1], T. QUILES[1], R. PRESBY[1], R. A. ROTOLO[1], R. FITCH[1], M. CORREA[2], J. D. SALAMONE[1];

Abstract: Tetrabenazine (TBZ) is a vesicular monoamine transport type-2 inhibitor that blocks striatal dopamine (DA) storage and depletes DA. TBZ is used to treat Huntington's disease, but studies report that TBZ induces side effects such as motivation dysfunction and depression. In animal research, effort-based decision making has emerged as a commonly used experimental approach for evaluating activational aspects of motivation. Typically, effort-related choice tasks offer the organism the option of choosing between a preferred reinforcer that requires high effort to obtain vs. a concurrently available but less preferred food. TBZ has been shown to reliably induce a low-effort bias in rats, characterized as a shift of preference from choosing high effort/high reward option toward low effort/low reward one. While the neural mechanisms of effort-based choice have been widely studied in rats, fewer studies have been performed in mice. The present studies used previously established touchscreen procedures to assess the effort-related effects of TBZ in C57BL6 mice. Mice were trained to choose either rearing up to press an elevated lit panel on the touchscreen in order to receive Ensure strawberry milkshake as the reinforcer, or approaching and consuming a concurrently available but less preferred choice food pellets (Bio-serv). C57BL6 mice were tested on a fixed ratio 1/choice schedule, and injections of the DA depleting agent TBZ (2.0 - 8.0 mg/kg IP) produced a dose-related decrease in panel pressing but an increase in the choice food pellet intake. In contrast, reinforcer devaluation by pre-feeding substantially decreased both panel pressing and pellet intake. In free-feeding choice tests, mice strongly preferred the Ensure vs. the pellets, and TBZ had no effect on milkshake intake or preference, suggesting that the TBZ-induced low effort bias is not due to change in primary food motivation or preference. This work provides cross-species evidence of the ability of the DA depleting agent TBZ to induce motivational dysfunction in mice, and it may have clinical relevance for assessing novel drug targets for their potential use as therapeutic agents in patients with motivation impairments.

Title: Novel atypical dopamine transport inhibitors and chemogenetic activation of mesolimbic dopamine neurons induce effort-related motivational changes in rats

Authors: *R. A. ROTOLO[1], R. SCHWARTZ[1], S. SAMELS[1], E. M. ROBERTSON[1], R. E. PRESBY[1], J.-H. YANG[1], V. DRAGACEVIC[2], P. KALABA[2], M. PISTIS[3], M. A. DE LUCA[3], F. CARIA[3], M. CORREA[4], G. LUBEC[2], J. D. SALAMONE[1];

Abstract: Individuals diagnosed with depression and other psychiatric disorders often suffer from fatigue, anergia, and motivational dysfunctions, which are among the most difficult symptoms to treat. Animal studies have been developed to measure effort-related decision making, offering animals a choice between high effort instrumental actions leading to highly valued reinforcers, or low effort/low reward options. Previous studies have shown that dopamine (DA) transport inhibitors, including GBR12909, lisdexamfetamine, methylphenidate, and PRX-14040, can reverse the effort-related effects of the vesicular monoamine transport inhibitor tetrabenazine. Because many drugs that block DA transport (DAT) act as major stimulants and produce a number of undesirable side effects, there is a need to develop and characterize novel atypical DAT inhibitors with unique and selective binding profiles. A recently synthesized analog of modafinil, (S)-CE-123, is highly selective for DAT, with biochemical characteristics of atypical DAT blockers. Studies from our lab have shown that (S)-CE-123 (24.0 mg/kg) significantly but partially reverses the effort-related effects of tetrabenazine (1.0 mg/kg) when co-administered during a fixed ratio 5/chow feeding choice test, and significantly increases lever pressing on a progressive ratio (PROG)/chow feeding choice test. Microdialysis results indicate a significant increase in nucleus accumbens core DA, which remains stable 40 to 180-minutes after injection. Additional studies have examined a newly synthesized and more potent compound, CE-158 (3.0-8.0 mg/kg), which is being assessed for its ability to reverse the effort-related effects of tetrabenazine, and to increase lever pressing in a high-effort task when administered alone. Increases in high-effort responding induced by selective DAT inhibitors are consistent with the behavioral effects of chemogenetic stimulation of mesolimbic DA neurons observed in our lab. TH-Cre rats were trained on the PROG/chow feeding choice task and injected with pAAV-hSyn-DIO-hM3D(Gq)-mCherry into the ventral tegmental area (VTA). Activation of mesolimbic DA neurons in the VTA significantly increased selection of PROG lever pressing in male and female rats, supported by clear immunohistochemical visualization of mCherry in the VTA. In summary, enhancement of DA transmission by (S)-CE-123 and CE-158, and by chemogenetic activation of DA neurons, is able to reverse the effort-related effects of tetrabenazine and/or increase high-effort responding. It is possible that atypical DAT blockers could be useful as treatments for effort-related motivational dysfunction in humans.

Title: Behavioral and dopaminergic correlates of individual differences in the selection of effortful and vigorous behaviors in rodents

Authors: *M. CORREA[1], A. MARTINEZ-VERDU[1], P. IBANEZ-MARIN[1], C. CARRATALA-ROS[1], S. PORRU[1], E. ARIAS-SANDOVAL[1], P. MATAS-NAVARRO[1], J. HIDALGO-CORTES[1], J. SALAMONE[2];
[1]Psicobiologia. Univ. Jaume I, Castello, Spain; [2]Univ. of Connecticut, Storrs, CT

Abstract: Nucleus Accumbens (NAcb) dopamine (DA), plays an important role in effort-related processes and behavioral activation, and individual differences in effort-based decision-making are related to DA activity markers in NAcb. In the present studies, individual differences in the selection of effortful and vigorous behavioral options were studied in rats and mice, as well as their relation to markers of DA activity in the Nacb. Sprague Dawley adult male rats were assessed using an operant progressive ratio task (PROG) in which animals can either lever press on a PROG schedule for a preferred high-sucrose concentrated (5%) solution, or approach and consume a less-preferred (0.3%) solution that is freely available. Before operant training started, animals were tested for anxiety in the Dark and Light box, novelty-induced exploration in the Open Field, voluntary locomotion in running wheel (RW), and free sucrose preference (0.3% vs 5%). Using the two extreme quartiles in PROG performance, animals were divided into high-responders (HR), and low-responders (LR). HR rats had higher voluntary RW locomotion, but were not different in sucrose preference, anxiety, or locomotion compared to LR. DARPP-32 expression was also different between groups. In CD1 male mice we evaluated the relationship between individual differences in running on a voluntary wheel (RW), and the selection of reinforcers with different vigor requirements. Mice were allowed to run in a RW for two hours a day, 5 days a week, for 4 weeks. Using the two extreme quartiles of RW activity, animals were separated into high (HR) and low (LR) runners. Before training, mice were tested for anxiety, sociability, sucrose consumption and general exploration. After training, mice were evaluated in a T-maze where they interacted freely with 3 reinforcers: a RW, sucrose pellets, or a neutral smell. HR showed higher relative preference for the RW compared to LR, and spent less time

eating and sniffing. HR explored less the T-maze, and were also less sociable, although they did not show differences in anxiety or sucrose consumption. Phosphorylation of the DARPP-32-Thr34 protein was lower among HR. Identifying behavioral and neural correlates of individual differences in effort-based decision-making and selection of vigorous behavioral options could promote an understanding of the factors underlying vulnerability to symptoms such as anergia and fatigue common in many neurological and psychiatric disorders.

Title: Bupropion reverses the effort-related and depression-like effects of the VMAT-2 inhibitor tetrabenazine and increases selection of high-effort running wheel activity in mice

Authors: *J. D. SALAMONE[1], C. CARRATALÁ-ROS[2], A. MARTINEZ-VERDU[2], E. ARIAS-SANDOVAL[2], M. CORREA[2];
[1]Psychological Sci., Univ. of Connecticut, Storrs, CT; [2]Univ. Jaume I, Castellon DE LA Plana/Castello DE LA Pla, Spain

Abstract: Vigor, persistence, and work output are fundamental features of normal motivation. Nucleus Accumbens (Nacb) dopamine (DA) regulates behavioral activation and effort-related decision-making in motivated behavior, and DA depletion has been shown to induce anergia and fatigue in effort-based decision tasks in animals. These motivational symptoms are seen in pathologies such as depression and are highly resistant to treatment. In the present work, we evaluated the antidepressant effect of the catecholamine uptake blocker bupropion (BUP) on its own and also its impact after the administration of tetrabenazine (TBZ), a VMAT2 blocker that has been reported to induce depression in humans, and to deplete DA. The effect of these drugs was assessed on a new 3-choice-T-maze task developed to assess preference between a reinforcer that requires voluntary behavioral activation (running wheel, RW), and other more sedentary reinforcers (sweet food pellets and a neutral non-social odor) in male CD1 mice. We also studied the effects of BUP and TBZ on the forced swim test (FST), which measures behavioral activation in a stressful setting. In addition, anxiety was also studied after the administration of these drugs in the dark-light box (DL), and in the elevated plus maze (EPM). In

the T-maze, BUP alone increased selection of RW activity in animals tested on the T-maze as well as time spent climbing in the FST. TBZ reduced time running, but increased time-consuming sucrose, indicating an induction of fatigue but not an effect on primary sucrose reinforcement. In the FST, TBZ decreased time performing the most active behavior (climbing) and increased passive behaviors (immobility). TBZ did not affect anxiety-related behavior in any of the tests. BUP reversed the effects of TBZ in mice tested on the FST and on the T-maze, and also attenuated the effects of TBZ on pDARPP32-Thr34 expression in Nacb as assessed with immunohistochemistry. These results indicate that BUP shows antidepressant properties in traditional test of depression like the FST, and also in the T-maze task, which could be useful for assessing preferences based on effort requirements. The T-maze task could be a suitable test for the evaluation of antidepressant effects of drugs under non-stressful conditions.

Abstract: In the central nervous system (CNS), insulin plays a critical role in the formation of neural circuits and synaptic connections from the earliest stages of development and facilitates and promotes neuroplasticity in the adult brain. Conversely, CNS insulin resistance contributes to the neurological complications of metabolic disorders, including decreases in cognitive function. Indeed, we have previously reported that induction of hippocampal-specific insulin resistance elicits neuroplasticity deficits in the rat hippocampus that include reduction of stimulus-evoked long term potentiation, granule neuron dendritic atrophy and deficits in spatial learning and memory. Since clinical and preclinical studies demonstrate that patients with

metabolic disorders that include insulin resistance have an increased risk of developing neuropsychiatric disorders like depressive illness, the goal of the current study was to determine whether rats with hippocampal-specific insulin resistance exhibit depressive-like behaviors. In agreement with our previous studies, rats with hippocampal-specific insulin resistance did not exhibit significant differences in body weight or body composition compared to control rats. In the sucrose preference test, rats with hippocampal-specific insulin resistance did not exhibit anhedonia as they consumed similar amounts of sucrose compared to control rats. In the forced swim test, rats with hippocampal-specific insulin resistance exhibited similar immobility, swimming and climbing behaviors as control rats. However, rats with hippocampal-specific insulin resistance exhibited significant decreases in the latency to float in the forced swim test, illustrating that these rats are exhibiting behavioral despair. These behavioral differences observed in rats with hippocampal-specific insulin resistance were accompanied by decreases in plasma BDNF levels. Collectively, these data demonstrate that hippocampal-specific insulin resistance elicits depressive-like behaviors and provide insight into the mechanistic basis for comorbid depressive illness in insulin resistance states like type 2 diabetes, obesity and Alzheimer's disease.

Title: Role of the mu opioid receptor in the antidepressant action of tianeptine

Authors: *J. HAN[1], V. ANDREU[1], J. E. PINTAR[3], B. L. KIEFFER[4], A. HARRIS[1], R. HEN[2], K. M. NAUTIYAL[5];

Abstract: Depression is widely thought to arise from an imbalance of monoamine neurotransmitters, particularly serotonin. However, this hypothesis cannot fully explain the

pathophysiology of the disease: most depressed patients do not have reduced monoamine levels, and only a fraction achieve remission with monoaminergic drugs such as selective serotonin reuptake inhibitors (SSRIs). The discovery that the atypical antidepressant tianeptine is a mu opioid receptor (MOR) agonist has provided a potential avenue for expanding our understanding of depression beyond the monoamine hypothesis. Thus, our studies aim to understand the neural circuits underlying tianeptine's antidepressant effects. By administering tianeptine to MOR KO mice, we showed that MOR is required for the antidepressant behavioral effects of tianeptine, following both acute (forced swim test) and chronic (novelty suppressed feeding) administration. Using tissue-specific MOR knockout (via a floxed MOR mouse) we further show that MOR expression on GABAergic cells is necessary for the acute antidepressant response. Preliminary evidence suggests that this can be localized to SST+ neurons. Moreover, we were able to show a double dissociation of the antidepressant phenotype from other opioid-like phenotypes resulting from acute tianpetine administration. Specifically, while mice lacking MOR expression on GABAergic neurons failed to show the antidepressant-like effect, these mice still showed acute hyperlocomotion, analgesia, and conditioned place preference. Furthermore, knockdown of MOR expression on other neuronal subsets resulted in an absence of typical opioid-like phenotypes, with an intact antidepressant phenotype. Finally, using two different stress-induced depression paradigms, we showed that tianeptine also has MOR-dependent chronic antidepressant effects. Notably, these behavioral effects are present after just one week of treatment, suggesting that tianeptine may be more rapid-acting than SSRIs. Taken together, these results suggest a novel entry point for understanding what circuit dysregulations occur in depression, and possible targets for the development of new classes of antidepressant drugs.

Title: Is a high fat diet always bad and a low fat diet always good? The effects of a low and high fat diet and the selective serotonin reuptake inhibitor, fluoxetine (prozac), in an animal model of depression

Authors: *I. C. SUMAYA, M. MUSQUEZ, A. ALVARADO, L. HERRERA, I. CABANILLAS;
Psychology, California State University, Bakersfield, Bakersfield, CA

Abstract: The overwhelming consensus in both human and animal studies is that high fat intake leads to negative outcomes and a risk factor for many health concerns including diabetes, heart disease, and stroke. Counterintuitive, there is emerging preclinical evidence that a high fat diet may not always have negative consequences in the context of the psychological domain. Recently it was reported that feeding rats a high fat diet (32% fat, isocaloric) served to decrease immobility in the Forced Swim Test thus showing anti-depressive effects. The aim of the present study was to further investigate the previously reported anti-depressive effects of a high fat diet and to provide an animal model of food intake more closely mimicking that found in humans, a 45% non-isocaloric fat diet (Western Diet). Additionally, previous work used as a control diet, standard chow containing unmatched amounts of major macronutrients. To rule out the effects of the major macronutrients, protein and sugar, used in the current experiment was a low-fat diet (10% fat) and a the high-fat diet (45%) with similar amounts of protein and sugar. Also, rats (male, Sprague Dawley) were treated with the selective serotonin reuptake inhibitor, fluoxetine (10 mg/kg ip). Results showed no significant differences in weight between the low (n = 17) and high fat (n = 18) groups or differences in muscle strength as measured by the hanging wire test after a 7 day food regime. In the groups not treated with fluoxetine, the rats fed the high fat diet (45%) showed the least amount of depressive-like symptom (n = 9, immobility: 17.95 $\pm$ 4.79 sec) as compared to their low fat controls (n = 9, immobility: 37.98 $\pm$ 14.64 sec). For the rats treated with fluoxetine, the same pattern was found. Rats on the high fat diet treated with fluoxetine experienced greater antidepressive-like effects (n = 9, immobility: 55.15, $\pm$ 10.96 sec) as compared to their low fat counterparts (n = 8, immobility: 84.09 $\pm$ 16.05 sec). These data provide support for an antidepressive-like effect of the high fat Western Diet (45%) as reported previously in a lower fat content diet (32% fat, isocaloric). Unexpected, and providing first time data, low fat had a depressive-like effect in this animal model of depression.

Title: Galanin(1-15) reverses the impaired long-term memory effect of fluoxetine in the novel object recognition test. Role of 5-HT1A receptor in medial prefrontal cortex

Authors: A. FLORES-BURGESS[1], C. MILLÓN[1], B. GAGO[1], L. GARCÍA-DURÁN[1], N. CANTERO-GARCÍA[1], R. COVEÑAS[2], J. NARVÁEZ[1], K. FUXE[3], L. SANTÍN[1], ***Z. DIAZ-CABIALE**[1];

Abstract: Galanin(1-15) [GAL(1-15)] enhances the antidepressant effects induced by Fluoxetine (FLX) in the forced swimming test through an interaction between GALR1-GALR2 and 5-HT1A receptors in the hippocampus. In this work, we have studied the effects of GAL(1-15) on FLX-mediated effects on the Novel Object Recognition (NOR) and the Object Location Memory (OLM), two tasks where FLX treatment impaired long-term memories 24h post-training. Since the medial prefrontal cortex (mPFC) is a core region for the interaction between emotional processing and cognition with a high density of 5-HT1AR and GALR1 and GALR2, we have also analyzed the binding characteristics and mRNA levels of 5-HT1AR in the mPFC after GAL(1-15)-FLX administration in rats. Groups of male rats (n=5-6) received three injections of FLX(10mg/Kg) between the training and test phases of the NOR and OLM tasks, and a single intracerebroventricular (icv) injection of a threshold dose of GAL(1-15)(1nmol) alone or in combination with the GALR2 antagonist M871(3nmol) 15´ before the test phase. A discrimination index (DI) was calculated as: DI=(N-F)/(N+F), and represent the difference in exploration time expressed as a proportion of the total time spent exploring the two objects. To analyze the binding characteristics and mRNA levels of 5-HT1AR, group of animals (n=6) were injected with FLX(10mg/kg) and GAL(1-15)(1nmol) alone or in combination and coronal sections of the mPFC were obtained to perform a quantitative autoradiography and in situ hybridization experiments In the NOR task, GAL(1-15)+FLX reversed the impairment memory effect induced by FLX(10mg/Kg) ($p<0.05$). This effect was blocked by the GALR2 antagonist M871. On the contrary, GAL(1-15) did not reverse the effect of FLX in the OLM task. In the autoradiographic experiments, GAL(1-15)+FLX increased the Kd ($p<0.01$) and the Bmax ($p<0.05$) values of the agonist radioligand [3H]-8-OH-DPAT compared with FLX in the mPFC. The coadministration also increased the 5-HT1AR mRNA levels ($p<0.01$) compared with the FLX group. Our results describe an interactions between GAL(1-15) and FLX in the mPFC involving interactions at the 5-HT1AR receptor level with implications also at functional level. The GALR1-GALR2-5-HT1A heteroreceptor could be used to reverse some of the adverse effects of FLX on memory processes.

Title: Evaluation of fluoxetine effects in depressive-like behavior in high and low yawning rats

Authors: *D. BRAVO DURÁN[1], J. EGUIBAR[2], C. CORTES[3], A. FERNÁNDEZ-GUASTI[4]; [1]Inst. de Fisiología, Benemerita Univ. Autonoma De Puebla, Puebla, Mexico; [2]Benemerita Univ. Autonoma De Puebla, Puebla, Pue., Mexico; [3]B. Univ. Autonoma de Puebla, Puebla, Mexico; [4]CINVESTAV SUR, Mexico D.F, Mexico

Abstract: In our laboratory, we selectively inbred two sublines from Sprague-Dawley (SD) rats, the high-yawning (HY) with 22 yawns/h and low-yawning (LY) with just 2 yawns/h. These sublines have shown different behaviors in anxiety and stress-related tests where the LY rats are more emotional reactive than HY and SD subjects (Ss). High levels of stress have been linked to more susceptibility to develop anxiety and depression. The aim of this study is to evaluate the depression-like behavior in the forced swimming test (FST) of HY, LY and SD and the effects of FLUO (2.5, 5 and 10 mg/Kg). Adult HY, LY and SD male rats (n = 6 per dose), were housed in standard room conditions with free access to rodent pellets and water. We used an acrylic cylinder filled with warm water (24 ± 1°C) for the FST. All Ss had two swim sessions in two consecutive days, the first 15 min and, 24 h later, a second session of 5 min test. The Ss received, at 23.5, 5 and 1 h before the second test, three i.p. injections of FLUO with 2.5, 5 or 10 mg/Kg or vehicle. We scored the following behaviors: immobility, swimming, climbing and diving. With a fluoxetine 10 mg/Kg dose there was a significantly enhanced swimming and decreased immobility duration in all three groups of rats ($P<0.05$). Importantly, the HY had stronger effects under FLUO with respect to LY and SD rats. We conclude that LY rats exhibit more depressive-like behavior and FLUO is less effective, supporting as a model with higher susceptibility and HY being resilient.

Title: The effects of thyroid hormone manipulation on performance in the saccharin preference test, the elevated plus maze, and novel object placement task in male C57BL/6J mice

Authors: H. OVADIA, *A. L. PEHRSON;
Psychology, Montclair State Univ., Montclair, NJ

Abstract: There is abundant evidence suggesting that Major Depressive Disorder (MDD) is related to thyroid hormone (TH) function, but the exact nature of this relationship is poorly defined in the literature. The present study examined whether hypothyroidism could viably model symptoms of MDD in mice using established behavioral paradigms to measure anhedonia, anxiety, and spatial memory. We hypothesized that hypothyroidism would produce anhedonia-like behavior in the saccharin preference test, elevated anxiety-like behavior in the elevated plus maze, and impaired spatial memory, as assessed in the novel object placement task. 45 male C57BL/6J mice were randomly assigned to one of three groups, which received either control diet, diet infused with 6-propyl-2-thiouracil (hypothyroid group), or 6-propyl-2-thiouracil and thyroxine (hyperthyroid group). Each group had ad libitum access to their food for four weeks prior to behavioral assessment. Contrary to our hypothesis, hypothyroid mice did not exhibit anhedonia-like behavior or spatial memory impairments compared to controls. However, they did spend a significantly lower percentage of time in the open arms of the elevated plus-maze compared to both the control and hyperthyroid groups. These data suggest that hypothyroidism may be related to anxiety, but is not clearly related to anhedonia or spatial memory impairment. Hypothyroid mice also had a lower travel distance in the elevated plus maze, which may be consistent with the fatigue, slowed metabolism, or lower body temperature associated with hypothyroidism in humans. Additionally, the hyperthyroid mice had a greater preference for sweetened water than the other groups in the saccharin preference test, and consumed more liquid volume overall. TH over-stimulation therefore induced behaviors in opposition to a depression-like phenotype. These findings suggest a complex relationship between TH function and mood, and contributing to a large body of research aiming to elucidate the disorder's underlying mechanisms.

Title: Selective serotonin reuptake inhibitor dosing and receptor occupancy: A systematic review and analysis of the mouse forced swim task

Authors: *D. T. ROBERTS, A. FOMIN, L. SANTOS, A. L. PEHRSON;
Dept. of Psychology, Montclair State Univ., Montclair, NJ

Abstract: Traditional approaches used in preclinical behavioral pharmacology studies dictate the administration of increasingly high doses until a behavioral effect is observed. Historically, this practice was used due to methodological constraints, including an inability to empirically estimate occupancy of a drug's mechanistic targets. Recent technological advances allow empirical target occupancy determinations, obviating the need for blind dosing methods, but these techniques are seldom used in preclinical research to determine mechanistically-relevant doses. This may result in the use of inappropriately low or high doses, limiting our ability to draw accurate mechanistic conclusions based on available data. We conducted a systematic review and meta-analysis of preclinical studies testing selective serotonin reuptake inhibitors (SSRIs) in the mouse forced swim test (FST). A random effects model examined the effect of SSRI administration on FST immobility time. Paroxetine and fluoxetine administration had significant, medium to large effects on immobility time compared to placebo. Evidence of publication bias and high heterogeneity were observed. SERT occupancy was estimated for each SSRI using ex vivo autoradiography. Clinically-relevant doses were calculated based on clinical target occupancy data, which indicate that 80% SERT occupancy is required for clinical SSRI efficacy. A metaregression revealed that heterogeneity was only partly explained by SERT occupancy. We found substantial variation in dosing practice across drugs. Fluoxetine doses were generally close to clinical relevance, while the majority of paroxetine study arms used supra-mechanistic doses 20 or more times the clinically-relevant dose. These data suggest that acute SSRIs administration is effective in FST, but acute SSRI administration shows little evidence of antidepressant efficacy in humans. Furthermore, supra-mechanistic doses are commonly used in preclinical studies, which may skew mechanistic interpretations of data. Thus, these data call into question the validity of some common preclinical methodologies and suggests that a lack of access to dose-target occupancy data is a critical weakness in neuropharmacology methods.

Title: Lithium partially restores presynaptic GABAergic signaling deficits in the Ank3 W1989R mouse model

Authors: *R. N. CABALLERO[1], A. D. NELSON[1], J. PHILIPPE[3], P. M. JENKINS[2];
[2]Dept. of Pharmacology, Dept. of Psychiatry, [1]Univ. of Michigan, Ann Arbor, MI; [3]Univ. of Michigan Med. Sch., Ann Arbor, MI

Abstract: Multiple genome-wide association studies (GWAS) have shown that the *ANK3* gene is one of the most significant risk loci for bipolar disorder (BD). The *ANK3*gene encodes ankyrin-G, an adaptor protein that is involved in the formation of the axon initial segment (AIS), nodes of Ranvier, and GABAergic synapses. Recently, we have generated a mouse model with a W1989R mutation in *Ank3,* which abolishes the interaction between ankyrin-G and GABARAP necessary for ankyrin-G-¬dependent stabilization of postsynaptic $GABA_A$ receptors. We have shown that the *Ank3* W1989R mice have striking reductions in inhibitory currents in cortex and hippocampus compared to control mice resulting in increases in the intrinsic excitability of pyramidal neurons. Importantly alterations in inhibitory signaling have also been seen in BD patients. Consistent with this idea, we recently identified a BD family carrying the *ANK3* W1989R variant in our patient cohort in the Heinz C. Prechter Bipolar Research Program at the University of Michigan. The proband is a Caucasian male with type I BD characterized by recurrent mania and depression with a successful treatment with lithium. In these studies, we have treated *Ank3* W1989R mice for 21 days with chow containing lithium carbonate until serum levels reach the therapeutic range and used voltage clamp and current clamp whole cell electrophysiology recordings to measure inhibitory postsynaptic currents in cortical and hippocampal pyramidal neurons. Our results showed a 21 day lithium treatment partially reverses the defect in spontaneous inhibitory post-synaptic current (sIPSC) frequency, while not significantly affecting sIPSC amplitude. Since sIPSC frequency is a measure of presynaptic GABA release probability, we hypothesize that lithium is increasing activity of parvalbumin-positive GABAergic interneurons. In summary, these results suggest that the *ANK3* has an important role in the control of cortical and hippocampal neuronal excitability and dysfunction of this pathway may contribute to the imbalance of circuits seen in BD patients. In addition, our

work suggests that lithium may act to increase the presynaptic GABA release in our model, perhaps resulting from increased excitability of parvalbumin-positive interneurons.

Title: Roles of p11 and serotonin in depression and antidepressant action

Authors: *Y. SAGI[1], L. MEDRIHAN[4], J. CHENG[2], G. UMSCHWEIF[3], P. GREENGARD[2]; [1]Lab. of Mol. and Cell. Neurosci., [3]Lab. for Mol. and Cell. Neurosci., [2]Rockefeller Univ., New York, NY; [4]The Rockefeller Univ., New York, NY

Abstract: Major depressive disorder is a debilitating disease affecting millions of people worldwide. A role for the protein p11, a member of the s100a family of calcium sensors, has been established in attenuating depressive-like behaviors as well as in mediating the action of antidepressants. We elucidated the cellular and molecular functions of p11 in three classes of neurons: GABAergic cholecystokinin (CCK)-expressing neurons of the dentate gyrus, GABAergic parvalbumin-expressing neurons of the dentate gyrus, and cholinergic neurons of the nucleus accumbens. In these neuronal populations, p11 regulates ion channels and serotonergic receptors in a cell-type specific manner. p11 regulates basal cell activity, cellular response to serotonin (5-HT), and adaptation in cell activity in response to chronic antidepressant treatment. The mechanisms underlying these functions include regulation of transcription and regulation of endocytosis. The different roles of p11 in preventing depressive-like behavior or in mediating the action of antidepressants will be discussed.

Title: Fluoxetine effect on chronic unpredictable stress into a depression-epilepsy comorbidity model

Authors: *J. GONZALEZ-GOMEZ, I. ROMERO-ELIZALDE, C. GARCIA-CABALLERO, A. VALDES-CRUZ, S. ALMAZAN-ALVARADO, D. MARTINEZ-VARGAS;
Inst. Nacional De Psiquiatria Ramon De La Fuente, Mexico City, Mexico

Abstract: Chronic unpredictable stress (CUS) and electrical amygdala kindling (EAK) subsequently applied may be a depression-epilepsy comorbidity model, present in a high incidence in the population. The aim was to analyze the effect of the fluoxetine (FLX) on CUS and the seizures induced by the EAK. Nineteen adult male Wistar rats were used; CUS was made with 9 different stressful stimuli during 21 days. The FLX (10 mg/kg) was applied subcutaneously every 24 h in the course of CUS. In all animals, a tripolar stainless steel electrode was placed stereotaxically in the left temporal lobe amygdala (AM), and both prefrontal cortex (PFC). The EEG coherence was recorded and analyzed with an analogical-digital system (ADQCH8). EAK was performed as follow: Daily electrical stimulations of 60 Hz monophasic square-wave pulses, 1 ms width pulses, with a current intensity between 150-300 μA. When the animals exhibited three consecutive stage 5 seizures according to Racine's scale, they were regarded as fully kindled, 24 h later a seizure susceptibility test was performed. Animals were submitted to forced swim test 5 minutes duration to assess the depressive-like behaviors before to start EAK and after the seizure susceptibility test, animals were divided in three groups: CUS+FLX+EAK (n = 7), CUS+EAK (n = 6), and EAK(n = 6). The results showed that CUS+FLX+EAK group had a less frequency of spikes during generalized seizures, a depressive-like behaviors (immobility) diminution after the seizure susceptibility test, and a decrease of the EEG coherence power was observed. Higher susceptibility to evoked focal seizures was observed in CUS+EAK group. Results suggest that the FLX could induce a decrease of propensity to generate focal seizures, as well as, temporal lobule generalized seizures severity into the depression-epilepsy comorbidity, with no effects on antidepressant efficacy. These changes may be associated to decrease of the EEG coherence.

Title: Effect of unpredictable chronic stress and fluoxetine on pentyneletetrazole induced seizures in rats

Authors: *J. ROMERO-ELIZALDE, J. GONZALEZ-GOMEZ, A. VALDÉS-CRUZ;
Inst. Nacional De Psiquiatria Ramon De La Fuente, Mexico City, Mexico

Abstract: The chronic unpredictable stress (CUS) model of depression, in this model, rats or mice are exposed chronically to a constant bombardment of unpredictable micro-stressors, resulting in the development of a plethora of behavioural changes, including decreased response to rewards, a behavioural correlate of the clinical core symptom of depression. The fluoxetine (FLX) is a selective serotonin reuptake inhibitor used for the treatment of depression. Despite of the efficacy of FLX in depressive disorders, its effect on epilepsy remains controversial. Experimental models have shown that FLX affects excitability in short time scales which may lead to changes in epilepsy severity. Pentylenetetrazol (PTZ) is a $GABA_A$ receptor antagonist commonly used as a convulsing drug in experimental studies. The aim of the study was to analyze the effect of the FLX administration on epileptic seizures induced with PTZ in rats submitted to CUS. Experiments were performed using 26 Wistar male rats, with electrodes stereotaxically implanted in dorsal hippocampus (dentate gyrus) bilaterally and epidural electrodes in both prefrontal cortices for EEG recording. The rats were classified as follows: ECI-PTZ, ECI-FLX-PTZ, FLX and PTZ. ECI was applied for 21 days, using 9 different stressors stimuli. FLX (10 mg/kg in 2 ml 0.9% NaCl), was applied every 24 h during the ECI. One day after CUS was ended, animals were submitted to forced swimming test (FST) 5 minutes duration to quantify depressive-like behavior. Induction of convulsive seizures activity was done 24 h after to FST, this was performed as follow: Initial PTZ 20 mg/Kg dose, followed by subsequent PTZ 10 mg/Kg doses every 10 minutes, until status epilepticus was observed. The EEG recording was done during all experiment. The results were showed a depressive-like behaviors decrease in FLX-PTZ group. In the same group also was observed an increase in accumulated and average duration of the seizures, as well as a reduction in the number of seizures. ECI-PTZ group was showed a decrease of accumulated duration and number of seizures. In ECI-FLX-PTZ was observed an increase in the acumulative duration of the seizures. Altought, that FLX administration in patients with comorbid depression-epilepsy has been common and considered safe, our results suggest that its use should be careful due to differential effects on seizures in some kinds of epilepsy.

Title: Motivational dysfunction induced by the SSRI fluoxetine (Prozac) in rats: Possible involvement of 5-HT1B receptors

Authors: *S. M. FERRIGNO[1], R. A. ROTOLO[1], R. PRESBY[1], J.-H. YANG[1], M. CORREA[2], J. D. SALAMONE[1];
[1]Psychological Sci., Univ. of Connecticut, Storrs, CT; [2]Psicobiologia. Univ. Jaume I, Castello, Spain

Abstract: Selective serotonin reuptake inhibitors (SSRIs) such as fluoxetine (Prozac) are the most commonly prescribed treatments for depression. Although efficacious for many symptoms of depression, motivational impairments such as psychomotor retardation, anergia, fatigue and amotivation are relatively resistant to SSRI treatment. Furthermore, in clinical studies SSRIs have been reported to exacerbate these deficits in some people. In order to study motivational dysfunctions in animal models, procedures have been developed to measure effort-related decision making, which offer animals a choice between high effort instrumental actions leading to highly valued reinforcers, or low effort/low reward options. Fluoxetine fails to reverse the effort-related effects of the VMAT-2 inhibitor tetrabenazine in rodent studies, and also has been shown to suppress high effort activities such as wheel running and lever pressing on fixed ratio or progressive ratio choice tasks. Because fluoxetine blocks 5-HT uptake, it is likely that fluoxetine-induced motivational dysfunctions are due to overstimulation of one or more 5-HT receptors. Several experiments have been conducted to characterize the 5-HT receptors that may be associated with the fluoxetine-induced suppression of lever pressing. Co-administration of antagonists of either the 5-HT_{2A} or 5-HT_{2C} receptor have failed to reverse the effects of fluoxetine. Recent studies have focused on the 5-HT_{1B} receptor. For these experiments, the selective 5-HT_{1B} receptor antagonist, NAS-181, was co-administered with fluoxetine to determine if suppression of high effort behavior could be attenuated. There were considerable individual differences in the suppression of fixed ratio 5 lever pressing induced by fluoxetine. Thus, animals were divided into two groups (i.e., high suppression and low suppression). NAS-181 partially reversed the effects of fluoxetine in rats that showed a higher fluoxetine-induced

suppression of lever pressing, with moderate doses of NAS-181 increasing lever pressing in fluoxetine-treated rats. Future directions involve intracranial administration and investigation of the potential role of other 5-HT receptors on effort-related behaviors.

Title: Modeling selection of voluntary physical activity in psychiatric disorders: Effects of the SSRI fluoxetine in rodents

Authors: *R. E. PRESBY[1], F. KUPERWASSER[2], E. ZORDA[2], O. DIMARCO[2], R. A. ROTOLO[1], J.-H. YANG[1], C. CARRATALÁ-ROS[4], M. CORREA[5], J. D. SALAMONE[3]; [1]Psychological Sci., [2]Univ. of Connecticut, Storrs, CT; [3]Dept Psychological Sci., Univ. of Connecticut, Storrs Mansfield, CT; [4]Univ. Jaume I, Castellon DE LA Plana/Castello DE LA Pla, Spain; [5]Psicobiologia. Univ. Jaume I, Castello, Spain

Abstract: It is important to characterize the factors that influence physical activities such as voluntary exercise in people with psychiatric disorders. Depressed people, on average, show reduced levels of locomotor activity, and it has been suggested that increased physical activity could be a useful therapeutic intervention for some people. Furthermore, many people with major depressive disorder show motivational/psychomotor symptoms such as psychomotor retardation, fatigue, and anergia. Drugs that inhibit the serotonin transporter (SERT inhibitors, also known as SSRIs) are the most commonly used class of antidepressants, however, these drugs have been reported to be relatively poor at treating motivational/psychomotor symptoms, and in some people they can induce or worsen fatigue. In view of this, it is important to develop animal models that assess the factors regulating the selection of voluntary physical activities. The present studies focused on the development of a novel choice procedure that allows animals to choose between physical activity (running in a running wheel; RW) vs. intake of food (standard laboratory chow). Male and female Sprague Dawley rats were placed in the task daily for 30 minutes and were able to go back and forth between the two options. Results show a significant difference between the amount of RW activity and chow intake between the two sexes, with the females running more and consuming less, and males showing the opposite. When examining the effects of the SSRI fluoxetine (Prozac), a common treatment for depression that also reduces

appetite, a drug-induced reduction in both RW activity and chow intake in both sexes was observed. These results are similar to those obtained from mouse studies showing that fluoxetine also suppresses selection of running wheel activity. It is possible that this line of research will contribute to an understanding of the neurochemical factors regulating selection of voluntary physical activity vs. sedentary behaviors, which could be relevant for understanding the role of physical activity in psychiatric disorders.

Title: Fluoxetine induces morphological rearrangements of serotonergic fibers in the hippocampus

Authors: S. NAZZI, G. MADDALONI, M. PRATELLI, ***M. PASQUALETTI**;
Univ. of Pisa, Pisa, Italy

Abstract: Serotonin (5-HT)-releasing fibers show substantial structural plasticity in response to genetically-induced changes in 5-HT content. However, whether 5-HT fibers appear malleable also following clinically-relevant variations of 5-HT levels that may occur throughout an individual's life has not been investigated. Here, using confocal imaging and 3D modeling analysis in *Tph2*^{GFP} knock-in mice, we show that chronic administration of the antidepressant fluoxetine dramatically affects the morphology of 5-HT fibers innervating the hippocampus resulting in a reduced density of fibers. Importantly, GFP fluorescence levels appeared unaffected in the somata of both dorsal and median *raphe* 5-HT neurons, arguing against potential fluoxetine-mediated down-regulation of the *Tph2* promoter driving GFP expression in the *Tph2*^{GFP} mouse model. In keeping this notion, mice bearing the pan-serotonergic driver *Pet1-Cre* partnered with a Cre-responsive tdTomato allele also showed similar morphological alterations in hippocampal 5-HT circuitry following chronic fluoxetine treatment. Moreover 5-HT fibers innervating the cortex showed proper density and no overt morphological disorganization, indicating that the reported fluoxetine-induced rearrangements were hippocampus specific. On the whole, these data suggest that 5-HT fibers are shaped in response

to subtle changes of 5-HT homeostasis, and may provide a structural basis by which antidepressants exert their therapeutic effect.

Title: A visual circuit related to habenula underlies the antidepressive effects of light therapy

Authors: ***H. LU**[1], Y. XI[1], X. HUANG[1], F. XU[2], T. XUE[3], M. LUO[4], K.-F. KWOK-FAI SO[1], C. REN[1];

Abstract: Light stimulation of the retina is a powerful modulator of non-visual functions such as affective behavior. Clinical evidence supports an anti-depressive effect of light therapy. However, the precise circuits that mediate the impact of light on depressive-like behaviors remain elusive. In the present study, by combining conventional neurotracer and transneuronal virus tracing techniques, we identified a di-synaptic visual circuit connecting the retina and lateral habenula (LHb) in the mouse. We show that a subset of M4-type retinal ganglion cells (RGCs) innervate GABA neurons in the ventral lateral geniculate nucleus and intergeniculate leaflet (vLGN/IGL), which in turn inhibit the neural activity of the LHb. Specific activation of LHb-projecting vLGN/IGL neurons, activation of LHb-projecting vLGN/IGL neurons, or inhibition of postsynaptic LHb neurons is sufficient to decrease the depressive-like behaviors and reduce the aberrant LHb neuronal activity evoked by long-term exposure to aversive stimuli or chronic social defeat stress. Furthermore, we demonstrate that the anti-depressive effects of bright light therapy are dependent on the activation of the retina-vLGN/IGL-LHb pathway. These results reveal a dedicated subcortical visual circuit that regulates depressive-like behaviors and may shed light on our current understanding of the mechanisms of light therapy.

Title: Effect of low frequency electromagnetic stimulation on the blood quantitative indices in clomipramine-induced depressed rats

Authors: *M. J. SVANIDZE[1], M. BUTSKHRIKIDZE[1], N. JOJUA[2], N. BUKIA[1], L. MACHAVARIANI[1];
[1]Neurophysiol., LEPL Ivane Beritashvili Ctr. of Exptl. Bio, Tbilisi, Georgia; [2]Biochem., European Univ., Tbilisi, Georgia

Abstract: Depression is a common medical illness that negatively effects on living organism. Despite the fact that it is possible to treat depression using pharmacological substances, about 30-40% of the patients are resistant to such treatment and so, their recovery is impossible. In 2008 repetitive electromagnetic stimulation (EMS), was approved by the FDA for the treatment of moderate depression. The content of blood can be changed as a result of depression and also as a repeated exposure of EMS. So, the goal of this investigation was to study the quantitative characteristics of blood cells in depressed and intact albino rats on the background of EMS. In implementation of the project the depressed rats and albino intact rats (250-450 g) were used (n=20). For each task two groups of animal were conducted: experimental group (with EMS) and control group (without EMS). For repetitive (10-days) EMS, the following parameters were used: 10000 -15000 Hz frequency, 1,5 m/Tesla, during 15 min. An animal model of depression was received by subcutaneous injection of Clomipramine from 8 to 21 days of neonatal development. The control group received saline injection in the same period of life. The determination of depression and anxiety reaction of rats were performed 2 months later after clomipramine injection. For hematological analysis of blood HumaCount 30 TS were used. This analyzer allows to quantify the number of red blood cells, leukocytes, platelets, hemoglobin, the hematocrit in 1 ml blood of rats. Determination of these parameters is very important because of EMS affected whole body, including the bone marrow, which is main place blood cells genesis. The blood was collected from the tail lateral vein. Hematological analysis was performed 2 weeks later after EMS. The EMS did not change the main characteristics of blood content during two weeks. In depressed rat's important changes of blood cells was detected. Particularly, the amount of monocytes and mean platelet volume (MPV) was increased, the number of Platelets was decreased. low platelet counts and a high MPV level, suggested that the bone marrow is rapidly producing platelets. This may be because older platelets are being destroyed, so the bone

marrow is trying to compensate. In depressed rats on the background of EMS, the number of monocytes and MPV decreased, but its level was remained high. The number of platelets was increased. In depressive rats, the content of erythrocytes increased. We suggested, that EMS might effected on bone marrow and potentiate erythropoiesis. EMS is non-invasive treatment method without side effects on the blood cell count. In depressed rats the EMS can restore the blood cells imbalance.

Title: TRH and TRH-like peptides participate in the therapeutic effects of metformin

Authors: *A. E. PEKARY[1], A. SATTIN[2];
[1]Res., VA Greater Los Angeles Hlthcare Syst, Los Angeles, CA; [2]Res., VA Greater Los Angeles Hlth., Los Angeles, CA

Abstract: Major depression, heart disease, obesity, and type 2 diabetes are increasingly common comorbidities in aging populations due, in part, to the adoption of Western diets which alter the gut microbiome. Co-administration of metformin (MF) and ascorbic acid (AA) have recently been reported to effectively treat these disorders. The present studies explore the acute, chronic and withdrawal effects of oral MF, which binds copper, to explore how it perturbs the rate-limiting, copper- and ascorbate-dependent processes controlling the expression of the neuro- and gut-protective TRH and TRH-like peptides. These endogenous tripeptides, like MF, have beneficial metabolic, gastrointestinal, cardiac, and neuroprotective effects which may counter some of the pathophysiological effects of Western culture and aging. Sixteen young, adult, male Sprague-Dawley rats, were divided into 4 equal groups. Controls received only tap water. The acute group was provided with tap water for 9 days and then 6 mg MF/ml tap water for 1 day. Chronic animals received MF in tap water for 10 days. The withdrawal rats drank MF-containing water for 8 days and then regular tap water for 2 days. TRH and TRH-like peptide levels were measured in 12 brain and 7 peripheral tissues. The pattern of acute, chronic and withdrawal effects of MF on the expression of each TRH and TRH-like peptide in brain and peripheral tissues tended to increase (↑), or decrease (↓), monotonically in proportion to the total time of exposure to MF. The withdrawal of MF appeared to be too short a period for a return toward control levels to be detected for any peptide. MF-induced acute, chronic, and withdrawal changes in TRH and TRH-like peptide levels, in decreasing order of number of significant changes were:

frontal cortex (21↓), hippocampus (18↓), nucleus accumbens (2↑,14↓), striatum (3↑,12↓), medulla oblongata (2↑,9↓), piriform cortex (2↑,9↓), hypothalamus (2↑,7↓), entorhinal cortex (7↓), amygdala (1↑,6↓), cerebellum (2↑,4↓), posterior cingulate (1↑,3↓), anterior cingulate (2↑,2↓), testis (19↑), adrenals (15↓). Metformin mimics the effects of caloric restriction (CR) which increases health and life spans. CR suppresses central TRH activity resulting in bradycardia and suppression of energy expenditure. The observed persistence of MF effects on TRH and TRH-like peptide levels in the brain and peripheral tissues during MF withdrawal is consistent with a lag in the return of the gut microbiome to its pretreatment composition. We conclude that TRH and TRH-like peptides participate in the therapeutic effects of MF primarily via its sustained alterations in the gut microbiome.

Title: SUVN-D4010, a 5-HT4 receptor partial agonist with antidepressant properties: Behavioral and neurochemical studies in mice and rats

Authors: A. MOHAMMED, N. BOGARAJU, R. PALACHARLA, *S. DARIPELLI, S. GANDIPUDI, P. JAYARAJAN, R. NIROGI;
Suven Life Sci. Ltd., Hyderabad, India

Abstract: SUVN-D4010 is a potent, selective and orally bioavailable 5-HT_4 receptor partial agonist. SUVN-D4010 is a phase-2 ready clinical candidate. Literature indicates involvement of 5-HT_4 receptor in behavioral features of depression, since the deletion of or pharmacological blockade of 5-HT_4 receptor results in depressive and anxiety-like behaviors in rodents. Based on this, potential antidepressant-like properties of SUVN-D4010 were investigated in animal models of depression. Compound was evaluated in dominant submissive model in Wistar rats where the dominance and submissive level was scored for 5 minutes daily for 5 days in a week, 1 hour after the treatment SUVN-D4010. Compared to the control group, the dominance levels of SUVN-D4010 treated group decreased significantly, thus confirming its anti-depressant activity. Additionally, SUVN-D4010 in combination with serotonin re-uptake inhibitor (SSRI) paroxetine produced synergistic effects on serotonin levels in ventral hippocampus of Wistar rats. Results from these preclinical studies provide strong evidence for SUVN-D4010 in alleviating depressive symptoms by complementary mechanism with existing anti-depressants.

Title: The use of transcranial direct current stimulation and paroxetine to treat depressive-like behaviours in olfactory bulbectomized adolescent rats

Authors: *S. WAYE[1], F. BAMBICO[1,2], J. NOBREGA[2], R. RAYMOND[2];
[1]Mem. Univ. of Newfoundland, St. John's, NL, Canada; [2]Ctr. for Addiction and Mental Hlth., Toronto, ON, Canada

Abstract: Adolescent depression is a complex condition that proves difficult to treat, as current treatments have been shown to produce paradoxical effects that worsen depressive symptoms, such as suicidality risk or anxiety. Therefore, we tested if a non-invasive brain stimulation technique known as transcranial direct current stimulation (tDCS) could be used either by itself or in combination with selective serotonin reuptake inhibitor (SSRI) drug therapy to safely and effectively treat adolescent depression. We induced a depressive-like phenotype in adolescent Sprague-Dawley rats (PND 28, n= 90) using olfactory bulbectomy (OBX), a rodent model of depression that results in behavioural and neurochemical changes that are reversed by antidepressant treatment. We examined if two weeks of tDCS treatment (50 μA, 15 minute sessions) was sufficient to reverse OBX-induced depressive-like behavioural symptoms, including hyperlocomotion in an open field chamber, immobility in a forced swim test, and deceased sucrose consumption. We tested if these effects were achievable with tDCS alone or with adjunct Paroxetine treatment (20mg/kg, IP). We found that tDCS, but not Paroxetine, was able to successfully reverse the OBX-induced hyperlocomotion in the open field test, however there were no significant differences in swimming behaviour in the forced swim test. Additionally, acute administration of Paroxetine caused a significant reduction in sucrose

preference, an effect that was completely blocked by concurrent tDCS stimulation. Sucrose preference was normalized after chronic treatment of Paroxetine, with no additional benefit of concurrent tDCS at this point. These findings support the idea that SSRI treatment results in the worsening of depressive symptoms, particularly at the start of treatment. They also suggest that tDCS is an effective intervention for adolescent depression and can be used to treat the disorder in place of, or in addition to, SSRI administration.

Title: Nicotine mediates the positive effects of water pipe tobacco smoking on resilience to chronic social defeat stress by increasing hippocampal BDNF levels, but does not mediate its negative effects on anxiety

Authors: *S. SLEIMAN[1], M. KHALIFEH[2], R. HOBEIKA[2], J. S. STEPHAN[3], R. KHNAYZER[2], C. KHALIL[2];
[1]LAU Sch. of Arts and Sci., Byblos, Lebanon; [3]Sch. of Med., [2]Lebanese American Univ., Byblos, Lebanon

Abstract: The main purpose of this study was to investigate the effects of waterpipe tobacco smoking (WTS) and nicotine on depression and anxiety-like behaviors associated with chronic social defeat stress (CSDS). Male C57BL/6 were exposed to WTS for thirty days, then subjected to CSDS for ten days. Twenty-four hours after the last defeat session, the social interaction test was used to assess social avoidance behavior associated with CSDS and to classify animals as resilient or susceptible to stress. The open-field test was used to evaluate the anxiety-like behavior of the mice. After behavioral testing, the mice continued to be exposed to WTS or were subjected to WTS withdrawal and their behavior was reexamined using the social interaction and open-field tests after ten days. Nicotine (1 mg/kg), Nicotine+Ana-12 (a TRKB inhibitor) or saline were given intraperitoneally after each defeat session for the duration of the CSDS experiments and behavioral testing was also performed. We found that WTS promotes resilience to chronic stress, as well as rescues social avoidance and anxiety-like behaviors associated with CSDS. We also found that continued exposure to WTS after CSDS increases resilience to stress and promotes social interaction, whereas smoking withdrawal did not have significant effects. Interestingly, even though exposure to WTS initially rescued anxiety-like behaviors, prolonged

exposure after the completion of the CSDS paradigm significantly enhanced anxiety-like behaviors. Finally, we showed that nicotine mediates the effects of WTS on resilience to stress, and social interaction behaviors by increasing hippocampal BDNF levels and signaling. Our results show that WTS and nicotine have positive effects on social behavior after CSDS by activating hippocampal BDNF signaling. Furthermore, they also suggest that even though WTS is initially anxiolytic, prolonged exposure to WTS promotes anxiety-like behaviors. Interestingly, nicotine does not modulate anxiety-like behavior suggesting that the effects of WTS on anxiety is mediated by other components of the waterpipe tobacco.

Title: Electroconvulsive seizure alleviates MPTP-induced motor deficits and promotes AMPK-related autophagy signaling in mice

Authors: *Y. KIM[1], S. KIM[2], H. YU[2];
[1]Dongguk Univ. Med. Sch., Goyang-Si, Gyeonggi-Do, Korea, Republic of; [2]Seoul Natl. Univ. Hosp., Seoul, Korea, Republic of

Abstract: Electroconvulsive seizure (ECS) is an animal model of electroconvulsive therapy (ECT), which has been used in the treatment of psychiatric disorders, including depression, bipolar disorder, and schizophrenia, as well as Parkinson's disease. The clinical beneficial effect of ECT on Parkinson's disease has been demonstrated, however, underlying mechanisms of ECS on Parkinson's disease have not been studied yet. In this study, the effects of repeated ECS treatments on a mouse model of Parkinson's disease (PD) induced by neurotoxin 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) on behavioral and neurochemical aspects have been investigated. Firstly, the stimulation protocol of ECS for C57Bl/6J mice has been confirmed, and, for repeated treatments, ECS was applied three times per week during two weeks (total 6 times; E6X). E6X treatments significantly ameliorated the MPTP-induced motor deficits of mice as measuring rotarod and pole test, which were normalized to control level. In mice frontal cortex and striatum, AMP-activated protein kinase (AMPK) and related autophagy signaling molecules were examined. E6x increased the phosphorylation level of AMPKalpha at Thr172,

and phosphorylation of its down-stream molecules, including unc-51-like kinase (ULK1) (Ser317) and Beclin1 (Ser93), was increased concurrently. In MPTP-treated mice, the phosphorylation of AMPK, ULK1, and Beclin1 was reduced in frontal cortex and that of AMPK and ULK1 was decreased in striatum, which were all normalized to the control level by E6X treatments. At the same time, E6X treatments increased the immunoreactivity of LC3-II and ATG5-ATG12 conjugate indicating the activation of autophagy signaling, and E6X restored the MPTP-induced decrease in the level of LC3-II and ATG5-ATG12 conjugate. Taken together, our results show that repeated treatments of ECS activated AMPK-related autophagy signaling which could mediate the beneficial effects of ECS on the mouse model of Parkinson's disease induced by MPTP.

Title: Differential effects of low and high frequencies of rTMS on depressive and anxiety-like behaviors in chronic unpredictable mild stress rat model

Authors: *J. ARROYO-PÉREZ[1], B. L. GARCÍA-QUINTERO[1], E. RUIZ-HERNÁNDEZ[2], D. ELÍAS-VIÑAS[2], L. VERDUGO-DIAZ[1];
[1]Dept. of Phisiology, Sch. of Med., Univ. Nacional Autónoma De México, Mexico City, Mexico; [2]Dept. of Electric Engin., CINVESTAV, IPN, Mexico City, Mexico

Abstract: Repetitive Transcranial Magnetic Stimulation (rTMS), has proven to be an effective alternative for treatment-resistant depression. A variety of frequencies ranging from 1Hz to 25Hz have been used on animal and human research. It’s urgent to clarify each frequency efficacy not only to have a reliable method for treating patients, but also to bring about specific treatment designs suitable for each patient. The objective of the current study was to differentiate behavioral effects using low (1Hz) and high (10 Hz) frequencies on a Chronic Umpredictable Mild Stress (CUMS) induced rat depression model. To apply rTMS we used an In-House Electronic System (EMAGPRO 12). This system was designed and developed by engineers at the Center of Research and Advanced Studies, IPN (Mexico City). The rTMS system consisted of a figure-eight coil and the frequency could range from 1 to 10Hz. We applied 10 minute sessions of 1 and 10Hz rTMS for 15 days on Wistar male rats (n=30) that were exposed to CUMS 20 days before rTMS and 15 days during treatment. We used different measures to

evaluate locomotor activity, anxiety and depressive-like behaviors. Forced Swim Test (FST) was used before and after rTMS treatment to assess the extent of 1 and 10 Hz antidepressant effect. Anxiety was assessed by duration and frequency of entries through closed and open arms of an elevated plus maze (EPM). Locomotor activity as well as other depressive and anxiety related measures (e.g. time spent grooming, rearing and immobility) were assessed using an open field test (OFT). Control rats differed in weight and sucrose consumption from CUMS, CUMS+1 Hz rTMS and CUMS+10 Hz rTMS. Compared to control and SHAM animals, CUMS, CUMS+1 Hz rTMS and CUMS+10 Hz rTMS animals showed significant differences in time spent on close arms of EPM, distance traveled in OPF center and time of immobility in FST. Further research is required to measure other frequencies effects and neurobiochemical markers are still needed to correlate with behavioral outcomes.

Abstract: Dysregulation of cognitive function, including deficits in reward sensitivity and cognitive control, is a common feature of virtually all neuropsychiatric disorders. While perturbations in cognitive control have been studied extensively in humans, it has been challenging to examine these complex processes in laboratory animals. In turn, stagnation in the development of translationally-relevant tasks to assess these processes in laboratory animals and humans has impeded the development of innovative treatments for neuropsychiatric disorders. As part of an NIMH initiative to create reliable and valid cross-species assays of cognitive function, we have developed a touchscreen-based version of the Eriksen Flanker Task to assess cognitive control in rats. Here we examine the effect of modafinil on behavioral performance, as well as event-related potentials (ERPs) and oscillations in the Flanker Task.

Using fading and correction procedures combined with touch-sensitive response technology, we trained male and female Long-Evans rats to discriminate between detailed photographic stimuli (green leaf/violet flower). Discrimination was deemed successful when the criterion of 70% response accuracy during the session was recorded on two consecutive days. Following training, rats underwent stereotaxic surgery for implantation of surface and depth electrodes for neurophysiology data collection. Using a within-subjects design, five 300-trial Flanker Task test sessions subsequently were conducted during which rats received saline, vehicle (100% DMSO), or modafinil (16, 32, and 64 mg/kg IP, 30-minute pretreatment time); continuous EEG and LFP data were collected throughout test sessions.
Early data indicate no effect of modafinil treatment on overall or post-error accuracy. However, preliminary analyses suggest that modafinil decreases the magnitude of the difference between incorrect and correct responses on incongruent trial types, a negative deflection that shares qualitative features with the human error-related negativity (ERN) component of the ERP. These data raise the possibility that modafinil reduces the impact of incorrect responses, which can affect performance in people with psychiatric illness. The analysis of data from additional subjects will aid in evaluating the reliability of this effect and, also, modafinil's possible modulation of expected, task-specific changes in spectral power. Comparing results from rats and human subjects in the same task will indicate whether modafinil-induced changes in behavior and/or neurophysiology are consistent across species.

Title: Antidepressant effects of fear extinction, an animal model of exposure therapy

Authors: *J. LIU[1], A. D. RIGODANZO[1], D. A. MORILAK[2];
[2]Pharmacol. and Ctr. for Biomed. Neurosci., [1]Univ. of Texas Hlth. Sci. Ctr. at San Antonio, San Antonio, TX

Abstract: Depression is a serious mental disorder and the leading cause of disability worldwide. Current treatment includes antidepressant drugs, psychotherapy, or a combination of both. Unfortunately, treatment-resistance and relapse are still high. In recent years, exposure-based therapies, which are among the most effective treatments for anxiety and trauma-related disorders (e.g., PTSD), have been used in the context of depression, by adding principles of exposure and emotional processing to improve cognitive-behavioral therapies for treating depression. In clinical studies, exposure-based therapy has been demonstrated to be associated with significant reductions in depressive symptoms, which is comparable with other cognitive behavioral therapies. Recently, our lab established a model of cognitive behavioral intervention in rats, namely extinction therapy, which resembles exposure-based therapy in the clinic. We found that extinction therapy ameliorated chronic unpredictable stress (CUS)-induced deficits in cognitive flexibility and active coping behavior that mimic symptom dimensions of cognitive inflexibility and avoidance behavior shared by PTSD and depression. In the current study, the potential antidepressant effects of extinction therapy are examined. We found that extinction therapy reduced immobility and increased active coping behaviors in the forced swim test (FST), a widely used animal model to screen for potential antidepressant efficacy. The antidepressant effects of extinction therapy were further demonstrated in reversing CUS-induced anhedonia, a core symptom of depression. Since medial prefrontal cortex (mPFC) is involved in extinction learning in rats, the inhibitory Gi-coupled designer receptor exclusively activated by designer drug CaMKIIα-hM4Di was expressed in vmPFC. vmPFC projection neurons were then inhibited during extinction by administering clozapine-N-oxide. FST was performed 24 h later. We found that inhibiting vmPFC during extinction blocked the antidepressant effects of extinction in the FST. In sum, we have generalized the utility of extinction as a model of cognitive-behavioral psychotherapy in rats, extending our previous findings of beneficial effects on cognitive flexibility and stress coping behavior to other core depressive-like behaviors on the forced swim test and sucrose preference test.

Title: Antidepressant effect of Buddleja cordata extract in a mice model of chronic stress

Authors: G. GARCIA-ALONSO[1], A. MONROY[2], G. FLORES[3], M. MIRANDA-MORALES[4], A. RANGEL[1], R. D. CUEVAS OLGUIN[1], *M. ATZORI[5];

[1]UASLP, San Luis Potosi, Mexico; [2]UAEM, Cuernavaca, Mexico; [3]Univ. Autonoma de Puebla / Inst. de Fisiologia, Puebla, Mexico; [4]Facultad de Ciencias, Univ. Autonoma De San Luis Potosi, San Luis Potosi, Mexico; [5]Univ. Autónoma de San Luis Potosí, San Luis Potosi, Mexico

Abstract: *Buddleja cordata* is a medicinal plant with wide use in traditional Mexican pharmacopeia with the name of tepozan. It is used as remedy for spasms, muscle contracture, as well as for respiratory and skin inflammatory conditions. Some of its identified active compounds are principally verbascosides (fenilpropanoids, esters and terpenoids). The methanolic extract of B.cordata has shown antioxidant and neuroprotecting activity *in vitro* as well as Parkinson disease animal model. Previous biochemical studies indicated suggested that Hydroxityrosol-one of its verbascoside metabolites may be the active compound of tepozan. We tested the antidepressant effect of tepozan using a chronic stress-based mice model of depression. Four groups (n= 8-12 per group) of C57BL/6 were submitted to chronic stress protocol (CS) consisting of early maternal separation (Postnatal Day, PND 2-21) plus restriction (PN week 10-12). The four groups were submitted to different treatments during 4 weeks (8-12 weeks PN). Group 1 was subject only to CS, group 2 was subject to CS plus oral intake of vehicle, group 3 to intake of fluoxetine (20 mg/kg/d) and group 4 to intake of tepozan hydroethanolic extract (100 mg/kg/day). Behavioral tests were conducted during the weeks immediately after each treatment. One-way ANOVA indicated between groups differences ($p < 0.005$, $F= 6.25$). Post hoc Tukey test indicated that group 2 (vehicle: inactivity 32.8% ± 6.7%) did not differ from group 1 (control: inactivity 45.4% ± 7.8%), group 3 (fluoxetine: inactivity 20.3% ± 4.5%) differed both from group 1 and 2, and group 4 (tepozan: inactivity 8.2% ± 3.6%) was significantly lower vs. all other groups. Our experiments suggest that tepozan extract has a potential as antidepressant, even on top of the well described effects of fluoxetine.

Title: Acute administration of propofol in mice pre-treated with fluoxetine does not improve performance on the FST

Authors: N. G. J. DANIEL[1], D. T. G. DANIEL[2], ***D. G. DANIEL**[3], L. C. FLYNN[4], M. ALLEN[5];
[1]Dartmouth Col., Hanover, NH; [2]Brown Univ., Providence, RI; [3]Bioniche Global Development,

LLC, McLean, VA; [4]LCF Consulting, LLC, Lake Forest, IL; [5]Univ. of Colorado Sch. of Med., Aurora, CO

Abstract: Objective:*Acute*intraperitoneal injection of fluoxetine 30 minutes prior to administration of the FST in C57Bl/6 micehas previously been shown to significantly improve performance on the Forced Swimmimg Test (FST) a rodent model of depression. [1] Propofol (2,6-diisopropylphenol) is a GABA-A agonist intravenous anesthetic agent. Based on anecdotal reports of improved mood in humans following propofol (a GABA-A agonist) induced anesthesia, we tested the effect of acute propofol treatment alone or in combination with sub-chronic fluoxetine dosing on FST performance.
Design:72 adult male mice (C57/BL6, CRL-provided) were pre-treated daily with saline or fluoxetine (20 mg/kg, i.p.) (21 days for cohort 1; 24 days for cohort 2). 24 hours after the last pre-treatment injection, mice received saline or propofol (35-50 mg/kg, i.p.) treatment. 45 minutes later, mice underwent a 5-min FST. Immobility time was quantified and evaluated with a custom video-analysis software. Experiments were performed at Charles River Laboratories (SF, CA). The Grubb's test identified statistically significant outliers which were excluded from data analysis.
Results: A two-way ANOVA indicated that pre-treatment with fluoxetine affected immobility time independently of treatment. Further Dunnett's post hoc comparison revealed that fluoxetine-treated mice spent more time immobile than the saline groups.
Discussion: *Acute*intraperitoneal (IP) injection of fluoxetine 30 minutes prior to administration of the FST in C57Bl/6 micehas previously been shown to significantly improve FST performance. [Jin et al, 2017] In contrast, *subchronic and chronic*adminstration of fluoxetine are more problematic to interpret. Mouse strain influences in responsivity to chronic and subchronic oral fluoxetine treatment have previously been reported by Dulawa, et al 2014. [2] In their experiment, chronic oral fluoxetine treatment failed to decrease immobility time in the FST in C57Bl/6 mice. [2] In our experiment subchronic intraperitoneal administration of fluoxetine to C57Bl/6 mice alone or combination with acute IP administration of propofol in did not decrease immobility time on the FST.

Title: Combined treatment with aripiprazole and sertraline increases extracellular dopamine levels in the nucleus accumbens of rats more than sertraline alone

Authors: *Y. OYANAGI, Y. KITAICHI, Y. AN, I. KUSUMI;
Dept. of Psychiatry, Hokkaido Univ. Grad, Sapporo/Hokkaido, Japan

Abstract: Combined treatment with aripiprazole and selective serotonin reuptake inhibitors has been used as augmentation therapy of depression. However, the augmentation mechanism of aripiprazole remains unclear. This study was designed to investigate abilities of systemically administered aripiprazole and sertraline to increase the extracellular levels of monoamines acutely in two brain regions of male Sprague Dawley rats. We examined effects of aripiprazole and sertraline on extracellular serotonin, dopamine, and noradrenaline levels in the nucleus accumbens (Nacc) and the medial prefrontal cortex (mPFC) using *in vivo* microdialysis. The Hokkaido University School of Medicine Animal Care and Use Committee approved all procedures. The aripiprazole alone (0.3, 3 and 9 mg/kg) had no effect on extracellular monoamine levels. However, co-administration of high dose aripiprazole (3 and 9 mg/kg) and sertraline increased extracellular dopamine levels in the Nacc more than sertraline alone. There were no differences in extracellular serotonin and noradrenaline levels in the Nacc between the sertraline with aripiprazole group and the sertraline alone group. There were no differences in all three monoamines in the mPFC between all groups. These results suggest that co-administration of high dose of aripiprazole and sertraline increased extracellular dopamine levels in the Nacc more than sertraline alone, though aripiprazole is a dopamine partial agonist. Antidepressant effects of aripiprazole may be mediated by the reinforcement of dopamine neurotransmission in the Nacc.

Title: Valeriana fauriei exerts antidepressant-like effects through anti-inflammatory and anti-oxidant activities by inhibiting brain-derived neurotrophic factor associated in chronic restrained stress

Authors: *J. OH, J. CHOI, Y. CHANG, B. CHEON, I.-H. CHO;
Kyung Hee Univ., Seoul, Korea, Republic of

Abstract: Background: Depression is the most common psychiatric disorder, but its pharmacological properties are not well-known. Although *Valeriana fauriei* (VF) extract has been reported to exert beneficial effects in several neurological studies, little information is available regarding its antidepressant activity.
Methods: In present study, we demonstrated the antidepressant activity and its underlying mechanism of VF extract in a chronic restraint stress (CRS)-induced depression model in mice.
Results: Oral treatment of VF extract for 14 days significantly ameliorated depression-like behaviors (immobility time) in tail suspended and forced swim tests following CRS induction, in accordance with decrease of the levels of serum corticosterone. VF extract ameliorated c-Fos expression, microglial activation and phosphorylated p38 expression, and inflammatory response (the level of protein expression of cyclooxygenase-2 and inducible nitric oxide) in the hippocampus and amygdala of mice after CRS induction. However, VF extract enhanced the stimulation of the nuclear factor erythroid 2 related factor 2 pathways, which correspondence with the up-regulation in protein expression of brain-derived neurotrophic factor (BDNF).
Conclusion: Collectively, our findings provide that VF extract has antidepressant-like activity against CRS-induced depression through anti-inflammatory and antioxidant effects via inhibiting BDNF expression. Further studies are warranted to investigate the possibility of VF extract's fraction and components as future antidepressant.

Title: Comparison of delayed and rapid onset antidepressants in a rodent probabilistic reversal learning task

Authors: *M. P. WILKINSON, J. R. MELLOR, E. S. J. ROBINSON;
Univ. of Bristol, Bristol, United Kingdom

Abstract: Patients with major depressive disorder exhibit deficits in reward processing and have altered feedback sensitivity in probabilistic reward learning tasks (Murphy et al., 2003; Pizzagalli et al., 2008). One of the most exciting discoveries in modern psychiatry is the rapid antidepressant action of compounds such as ketamine or scopolamine (Zarate et al, 2006; Jaffe et al, 2013). We have utilised a translational probabilistic reward learning task (PRLT, Bari et al, 2010) to compare the effects of conventional and rapid-onset antidepressants on reward learning. Reinforcement learning models allow probing of the underlying computational substrates of reward learning therefore we utilised a Q-learning model to further explain the effects of these drugs on behaviour.
Twelve adult male rats were trained in a PRLT. Rats learnt to spatially bias responses to receive food reward with stimuli being probabilistically rewarded so that there was a rich stimulus and a lean stimulus rewarded 80% and 20% of the time respectively. After 8 consecutive rich stimulus choices the reward contingencies switched. Rats were treated before testing (experimenter blind to treatment, within subject randomised) with either a delayed onset antidepressant (citalopram, venlafaxine or reboxetine) or a rapid onset antidepressant (ketamine or scopolamine). A Qlearn model, utilising a single learning rate for positive and negative information, was fitted using vehicle data and then used to analyse data from each drug dose and animal individually. Citalopram treatment increased positive feedback sensitivity and improved reward learning ability while reboxetine had the opposite effect. Venlafaxine had no effect on any parameter tested. Both ketamine and scopolamine reduced reward learning, positive feedback sensitivity and motivation. The reinforcement learning model suggested that reboxetine caused a decrease in accuracy compared to a model predicted perfect strategy and ketamine significantly decreased the model-based learning rate. Although all the tested drugs have well characterised antidepressant efficacy the incongruity of results in this study suggest that modification of probabilistic reward learning, as measured by this task, is not a key part of their mechanism of action.

Title: Antidepressant efficacy of L-655,708 following infusions into the medial prefrontal cortex

Authors: *A. M. BAILEY, B. STEINHOFF, K. ROBEY;
St. Mary's Col. of Maryland, St. Mary's City, MD

Abstract: Major Depressive Disorder (MDD) is a serious and widespread mental health condition that has a significant negative impact on overall quality of life. Current treatments for depression such as selective serotonin reuptake inhibitors (SSRIs) are slow to take effect, have negative side effects, and fail to achieve remission in a large number of patients. The recent success of ketamine as a fast-acting antidepressant has led to research using other pharmaceutical compounds, with the goal to discover a safe, fast-acting antidepressant without the addictive and psychotomimetic effects of ketamine. L-655,708, a negative allosteric modulator of GABA-A receptors (GABA-NAMs) with an alpha5 subunit, has been shown to produce an antidepressant-like effect when injected systemically and when infused directly into the hippocampus in rodent models of depression. The present study evaluated the effects of the direct infusion of L-655,708 (5ng/0.2 µL) via bilateral guide cannula insertion directly into the medial prefrontal of male rats exposed to a chronic unpredictable stress (CUS) paradigm. Depressive-like behaviors, including anhedonia, were quantified using the sucrose preference test, social interaction test, and the novelty suppressed feeding test. Direct infusions of L-655,708 in the mPFC improved anhedonic measures of sucrose preference and sucrose intake (η^2= .21) although not significantly. Additionally, direct infusions in the mPFC increased latency to interact in the social interaction test but failed to reach statistical significance (η^2= .24). Our data compliments other studies reporting the antidepressant-like effects of GABA-NAMs.

Ctr. at Houston, Houston, TX

Abstract: Introduction: Anxiety, depression and post-traumatic stress disorder may develop in sepsis survivors and have a profound effect on their everyday functioning.
Objective: To study the incidence and predictors of anxiety, depression and post-traumatic stress symptoms in severe sepsis and septic shock survivors 24h and 1-year post ICU discharge.
Methods: A prospective study of 33 patients who survived severe sepsis or septic shock and completed the PTSD Checklist-Civilian Version, Beck Depression Inventory-II and Beck Anxiety Inventory at 24h and 1year after ICU discharge. Demographic and clinical data where measured during ICU stay and laboratory, including HMGB1, BDNF, S100B and NSE, performed 24h and 1-year after ICU discharge. Difference in psychiatric symptoms over time, controlling for possible confounding factors, and the influence of the variables on these symptoms were calculated with marginal models.
Results: The prevalence of clinically meaningful symptoms of anxiety, depression and PTSD 24h after ICU discharge was 67%, 49% and 46%, respectively, and among patients re-evaluated 1 year after ICU discharge the prevalence was 38%, 50% and 31%, respectively. Factors associated with symptoms of PTSD in a multivariate model included serum S100B (OR 1.12, 95% CI 1.01 to 1.23), age (OR 0.56, 95% CI 0.33 to 0.96) and IQCODE (OR 0.22, 95% CI 0.08 to 0.63). Factors associated with depression symptoms included patient age (OR 0.44, 95% CI 0.24 to 0.79) and dobutamine accumulated dose during ICU stay (OR 2.48, 95% CI 1.08 to 5.68). The multivariate model also identified IQCODE score (OR 0.28, 95% CI 0.10 to 0.75) and accumulated dose of haloperidol in ICU (OR 0.12, 95% CI 0.03 to 0.50) associated with

symptoms of anxiety after discharge from ICU.
Conclusion: More than three quarters of the patients exhibited clinically meaningful psychiatric symptoms during the follow-up period. IQCODE score was strongly associated with post-traumatic stress and anxiety symptoms; while accumulated dose of dobutamine and haloperidol was also strongly associated with depression and anxiety, respectively.

Title: Multimodal structural brain imaging of recently traumatized individuals

Authors: *N. G. HARNETT[1,2], J. S. STEVENS[3], N. FANI[3], T. JOVANOVIC[3,4], S. J. H. VAN ROOIJ[3], T. D. ELY[3], L. D. NICKERSON[5], K. J. RESSLER[1,2];
[1]Div. of Depression and Anxiety, McLean Hosp., Belmont, MA; [2]Dept. of Psychiatry, Harvard Med. Sch., Boston, MA; [3]Dept. of Psychiatry and Behavioral Sci., Emory Univ., Atlanta, GA; [4]Dept. of Psychiatry and Behavioral Neurosci., Wayne State Univ., Detroit, MI; [5]Applied Neuroimaging Statistics Lab., Mclean Hosp., Belmont, MA

Abstract: Exposure to traumatic events can have adverse effects on cognitive and affective functions. However, traumatized individuals vary in their individual susceptibility to posttraumatic stress disorder (PTSD) development. Although prior research has suggested the structural morphology of the brain may partially underlie this susceptibility, minimal research to date has sought to combine different measures of brain structure to elucidate multivariate structural profiles in recently (~1-2 months) traumatized individuals. Multimodal brain structure profiles acquired acutely following trauma may better help characterize the neurobiology that underlies future development of PTSD. In the present study, we utilized multimodal magnetic resonance imaging (MRI) to investigate brain structure in recently traumatized (~1-2 month) individuals (n = 78). Participants were recruited in a Level-I trauma center within 24 hours of trauma exposure and completed a series of questionnaires on demographics and past-trauma

history. Participants returned to the lab to report on their PTSD symptom severity over the next year, completing the PTSD Symptom Scale (PSS) 1, 3, 6, and 12 months post-trauma. MRI scans were completed to assess brain grey matter characteristics (T1-weighted anatomical scans) and white matter integrity (via diffusion tensor imaging). Linked independent component analysis (LICA) was completed to perform multimodal data fusion on structural brain features derived from the MRI data and correlated with participant questionnaires. The LICA features included grey matter density, cortical surface area and thickness , and fractional anisotropy/mean diffusivity/diffusion tensor mode of the white matter skeleton. We identified several multimodal components that were stable across different LICA dimensionalities, including components reported previously to be associated with aging ($r = 0.55$, $p < 0.001$). Further, we also identified a multimodal structural profile that was associated with variation in PSS scores, assessed 1-month post-trauma ($r = -0.27$, $p = 0.016$). The structural profile reflected lower grey matter density within a structural covariance network comprised of prefrontal cortex, insula, and hippocampus, lower cortical thickness within the cingulate gyrus, and greater FA within the cingulum. These findings suggest that variability in brain structure is associated with acute expression of PTSD symptoms. Further, these data provide an initial, data-driven characterization of multimodal structural profiles in recently traumatized individuals.

Title: Influence of anhedonic symptom severity on reward circuit connectivity in PTSD

Authors: *S. PESSIN, C. L. PHILIPPI, S. E. BRUCE;
Univ. of Missouri - St. Louis, Saint Louis, MO

Abstract: Anhedonia, marked by deficits in the consummatory and motivational reward processing phases, is a prominent symptom of several psychiatric conditions and has been shown to influence functional connectivity between reward-relation regions. However, the unique neural mechanisms of the reward circuit in posttraumatic stress disorder (PTSD) as influenced by anhedonia severity remain unclear. To address this, we examined resting-state functional connectivity (rsFC) of the ventral striatum as a function of anhedonia for individuals with PTSD.

Resting-state functional MRI scans and behavioral assessments were collected for 71 women diagnosed with PTSD (M_{age} = 31.93, SD_{age} = 9.39) as part of a larger R01 funded study. Standard seed-based rsFC analyses for left and right nucleus accumbens seed regions of interest were performed. Regression analyses were conducted to examine the relationship between anhedonia severity and the standardized rsFC correlations. All rsFC analyses were family-wise error (FWE) cluster-corrected at the whole brain level ($p_{FWE} < .05$). Results indicated that anhedonia severity correlated with reduced rsFC between the left nucleus accumbens and left caudate extending to the thalamus. These findings support reward circuit dysfunction at rest associated with anhedonia in PTSD. This association furthermore contributes to a better understanding of the neural correlates of consummatory anhedonia.

Psychology, Inst. for Psychology and Educ., Univ. of Ulm, Ulm, Germany; [5]Neurobio. and Behavior, Ctr. for the Neurobio. of Learning and Memory, Univ. of California, Irvine, Irvine, CA

Abstract: We have recently shown that an epigenetic modification of the glucocorticoid receptor (GR) gene is linked to traumatic memories and PTSD risk in genocide survivors as well as recognition memory in healthy individuals. In the current study, we aimed to uncover further GR-related epigenetic markers of memory and PTSD by focusing on the GR signaling pathway in two independent African cohorts of heavily traumatized individuals: Survivors of the rebel war in Northern Uganda (N=473) and Survivors of the 1994 Rwandan civil war (N=380). Additionally, we assessed recognition memory and functional brain activity using fMRI in a

sample of healthy Swiss individuals (N=568). DNA was isolated from saliva or blood in African and European cohorts, respectively. Gene pathway analysis revealed that DNA methylation of the glucocorticoid receptor signaling pathway was significantly associated with lifetime post-traumatic diagnostic scale sum scores, with 4 nominally associated pathway members (*NR3C1, KCNH3, PER1*, and *NTRK2*). After applying Bonferroni correction, one gene (*NTRK2*) remained significant. NTRK2 encodes the transmembrane receptor tropomyosin-related kinase B, which binds brain-derived neurotrophic factor (BDNF), and has been shown to play an important role in memory formation. *NTRK2* methylation was negatively associated with intrusion and avoidance symptoms in both Rwandan and Ugandan samples, independent of trauma load. Furthermore, methylation of *NTKR2* was also negatively associated with PTSD risk in both samples. Analysis of *NTRK2* methylation in the healthy sample revealed a significant negative association with recognition memory performance, independent of valence. Furthermore, independent component analysis (ICA) revealed NTRK2 methylation-dependent differences in brain activity in various networks relevant for correct recognition of previously seen pictures. Differential methylation was specific to the enhancer region of *NTRK2*, which has been previously shown as relevant for functional control of *NTRK2* expression. NTRK2 DNA methylation in the two traumatized cohorts was not associated with trauma load and had independent effects on PTSD symptoms, suggesting that methylation differences pre-existed the trauma. The current study replicates our previous GR findings and demonstrates that epigenetic differences in *NTRK2* are also related to traumatic memories and PTSD risk in genocide survivors and memory functions in healthy subjects. Thus, epigenetic modifications of the GR signaling pathway contribute to PTSD symptomatology and might provide novel biomarkers or drug targets.

Title: A multi-domain objective classification of recent post-traumatic stress disorder

Authors: Z. BEN-ZION[1], Y. ZEEVI[1], J. N. KEYNAN[1], R. ADMON[2], H. SHARON[1], P. HALPERIN[1], I. LIBERZON[3], A. Y. SHALEV[4], Y. BENJAMINI[1], *T. HENDLER[1]; [1]Tel-Aviv Univ., Tel-Aviv, Israel; [2]Haifa Univ., Haifa, Israel; [3]Psychiatry, Texas A&M Hlth. Sci. Ctr., Bryan, TX; [4]NYU Langone Med. Ctr., New-York, Israel

Abstract: Introduction: Contemporary symptom-based diagnosis of Post Traumatic Stress Disorder (PTSD) largely overlooks related neurobehavioral findings, possibly explaining the limited efficacy of treatments. Extant neurobehavioral measurements, however, may objectively depict the neurobiology and neuropsychology underlying PTSD phenotype. Here, we evaluated the feasibility and accuracy of a multi-domain objective classification of PTSD in a cohort of recent trauma survivors, using a newly developed semi-unsupervised bioinformatics approach.
Methods: Our 3-staged methodology combines a ***c****ategorization* using the Diagnostic and Statistical Manual of Mental Disorders (DSM) diagnostic criteria with ***c****lustering* and ***c****lassification* using psychometric tools and neurobehavioral measurements (alias a "3C" method). We used this approach to classify 101 adult civilian trauma survivors (age=34.80±11.95, 51 females), evaluated one month after their traumatic experiences. Measurements obtained simultaneously at one month included: total scores of a PTSD diagnostic instrument (the Clinician-Administered PTSD Scale), self-reported rating scales measuring depression and anxiety, participants' performance in eleven neurogognitive domains (a WebNeuro battery), structural MRI indices (volumes and thickness of cortical and subcortical areas); and functional MRI indices of activity and connectivity during emotional face matching task.
Results: Measurements of traumatic stress symptoms, depression, anxiety and general clinical status best explained PTSD severity according to total CAPS scores *(FDR-adjusted p<0.2).* Unsupervised clustering performed based on these four clinical variables, divided the group into two clusters of high and low "disease load". The objecive variables that best differentiated between the clusters were entorhinal and rostral
anterior cingulate cortices volumes (brain structure domain); amygdala functional connectivity with the caudate/thalamus during emotional face matching task (brain function domain); and cognitive flexibility (neurocognitive domain) *(Importance=0.88, 0.43, 0.42, 0.49, respectively).*
Discussion: The 3C classification yielded an objective categorization of PTSD in recent trauma survivors. As such it provides an alternative case-identification model based on objective indicators from neural and neurocognitive domains, all theoretically related to PTSD pathogenic (pathophysiological) mechanism. Biomarkers identified by our classification may generate novel hypotheses and new targets for neurobehavioral, mechanism-driven interventions for PTSD.

Title: Neural substrates of rumination in women with PTSD

Authors: *C. L. PHILIPPI, S. E. BRUCE;
Psychological Sci., Univ. of Missouri, St. Louis, Saint Louis, MO

Abstract: Elevated rumination, characterized by repetitive negative thoughts about oneself, is common in posttraumatic stress disorder (PTSD) and has been shown to predict the onset of the disorder. In healthy and depressed participants, cortical midline brain structures, including the rostral anterior cingulate cortex (rACC), posterior cingulate cortex (PCC), and isthmus cingulate (IsthC), have been frequently implicated in self-focused thought, including rumination. Past research has revealed dysfunction in cortical midline regions in PTSD. However, no studies have investigated the neural substrates of rumination in women with PTSD using both structural and functional MRI. In the current study, we used structural MRI and resting-state functional MRI to examine relationships between rumination and brain volume as well as resting-state functional connectivity (rsFC) of cortical midline structures in women with PTSD due to interpersonal trauma (n = 71; mean age = 31.9, s.d. = 9.4). We performed multiple linear regression analyses to relate brain volume in rACC, PCC, and IsthC regions to self-reported rumination, after controlling for age and intracranial volume. We also conducted standard seed-based voxelwise rsFC analyses for significant regions identified in the structural analysis. All rsFC results were family-wise error (FWE) cluster-corrected for multiple comparisons at the whole brain level ($p_{FWE} < .01$). We found a significant relationship between greater rumination and volume in the left IsthC (p = .025) and trend-level relationships between rumination and volume in the right rACC (p = .087) and right PCC (p = .061). Results from the rsFC analyses revealed a significant relationship between greater rumination and diminished rsFC between the left IsthC and left precuneus ($p_{FWE} < .01$). Together, these findings provide support for alterations in structural and functional neural substrates of rumination in women with PTSD. More broadly, our results extend previous research on aberrant cortical midline structures in PTSD.

Center; Jerusalem Israel, Jerusalem, Israel; [3]Hadassah, Jerusalem, Israel; [4]Dept. of Mental Healthy. Israel Def. Forces., Jerusalem, Israel., Jerusalem, Israel

Abstract: Background: Early adversity (EA) has been previously implicated with lifelong altered stress reactivity. Maladaptive stress reactivity may result in compromised neurocognitive and emotional regulation aptitudes and may lead to acute and chronic post traumatic stress disorder and depression. The current study explores the predictive value of EA associated DNA methylation patterns in genes coding key neuroendocrine regulators and their correlation with neuroendocrine stress reactivity for identifying individual stress related vulnerability.
Methods: Several hundred adolescent trainees undergoing combat military training were screened for exposure to early childhood trauma. An extremes case control sample compared those with high and low childhood trauma for prospective anxiety depressive and post traumatic symptoms, neuropsychological measures, and saliva and blood sampling, at rest and during exposure to extreme stress under simulated combat training conditions. Premorbid characteristics and neuropsychological and biological measures were employed to predict mal/adaptive outcomes following simulated combat.
Results: The correlations of EA associated patterns DNA methylation patterns in the glucocorticoid receptor gene and additional neuroendocrine regulators with baseline and reactive hormonal profiles will be described. Methylation related differential reactivity to acute stress exposure among adolescents reporting EA, and psychological measures mark stress vulnerability and may help predict longer term outcomes before and immediately following exposure to

trauma.
Conclusion: Distinct neuroendocrine signatures may help focus preventive and interceptive efforts on vulnerable subjects during stress exposure and at its immediate aftermath, before chronic Posttraumatic Stress Disorder (PTSD) or depression develop. Results may further shed light on the role of neuro endocrine reactivity in mediating the transduction of stress into long term maladaptive neuropsychiatric outcomes.

Title: Emotion dysregulation mediates the association between acute sleep disturbance and PTSD symptoms in trauma exposed patients

Authors: *M. MCDANIEL[1], N. CHRIST[1], H. XIE[1], M. T. TULL[1], J. ELHAI[1], J. J. MATHEWS[1], R. V. N. BODDAPATI[1], I. LIBERZON[2], X. WANG[1];

Abstract: Sleep disturbances are common within days after experiencing a traumatic event, and may exacerbate the development of posttraumatic stress disorder (PTSD) symptoms. However, the mechanisms between acute sleep disturbances and PTSD symptom development remain unclear. Sleep disturbances have been associated with emotion dysregulation, and emotion dysregulation has been identified as a factor that underlies the development and maintenance of PTSD. Therefore, it is plausible that acute sleep disturbances following a traumatic event interfere with emotion regulation abilities which contributes to the development of PTSD symptoms.

To test this hypothesis, the current study examined relations between acute sleep disturbance [Pittsburg Sleep Quality Index PTSD Addendum (PSQI-A)] and emotion dysregulation [Difficulty in Emotion Regulation Scale (DERS)] within 2 weeks after trauma, and the severity of PTSD symptoms [PTSD Checklist Stressor Specific (PCL)] 3 months later.
Preliminary analyses revealed that trauma survivors with acute sleep disturbances (PSQI-A $\geq$ 4) reported worse PCL, DERS scores at 2 weeks and PCL scores at 3 months after trauma (all p's < 0.01). Multiple regression analyses demonstrates overall model fit (X^2=2.51, p=0.29; RMSEA=0.04; CFI=0.99; TLI=0.96; SRMR=0.03). There was a significant mediating effect of DERS total scores (β=0.13, p<0.01) on the relationship between sleep disturbance and PTSD symptoms after adjusting for age and gender. When individually modeled as mediators, DERS subscales of non-acceptance (β=0.13, p<0.05), inability to engage in goal-directed behavior (β=0.14, p<0.05), and lack of strategies (β=0.19, p<0.01) explained significant amounts of variance in the relationship. However, in a full model adjusting for multivariate effects of other DERS subscales, only the strategies scale (β=0.19, p<0.01) remained significant.
Our findings suggest that while acute sleep disturbances are associated with the development and severity of PTSD symptoms over weeks to months, acute emotion dysregulation explains part of this association. Those with limited emotion regulation strategies, non-acceptance of emotions and inability to engage in goal-directed behavior are at particular risk for developing elevated PTSD symptoms.MM and NC contributed equally

Title: Cortical and subcortical brain volume vary with acute posttraumatic stress symptoms after a medical trauma

Authors: *H. E. DARK[1], N. G. HARNETT[2], A. J. KNIGHT[3], D. C. KNIGHT[4];
[1]Psychology, Univ. of Alabama Birmingham, Birmingham, AL; [2]McLean Hosp., Belmont, MA; [3]Dept. of Physical Med. and Rehabil., [4]Psychology, Univ. of Alabama at Birmingham, Birmingham, AL

Abstract: Posttraumatic stress disorder (PTSD) is characterized by a combination of re-experiencing, avoidance, and hyperarousal symptoms that are associated with stimuli linked to a traumatic event. The amygdala, hippocampus, and anterior cingulate cortex (ACC) play an important role in the pathophysiology of PTSD. Smaller amygdala, hippocampal, and ACC volumes have been linked to greater PTSD symptom severity. However, few studies have assessed the brain volume of patients recently exposed to a traumatic event to determine the relationship with symptom expression over time. The present study examined the relationship between brain volume and posttraumatic stress symptoms at ≤1 and 3 months post-trauma to determine whether brain volume was associated with PTSD symptom expression. Thirty-seven participants (Age: M=27.0; SD=7.4) were recruited for the present study; 19 trauma exposed (TE) participants and 18 non-trauma exposed (NTE) controls. TE participants were recruited from University of Alabama at Birmingham Hospital within 30 days of trauma exposure. There were no differences in race, sex, or estimated IQ between groups. TE participants were slightly older (~5 years) than NTE participants. All participants completed a T1 weighted magnetic resonance imaging (MRI) scan on a 3T Siemens Allegra scanner. A volumetric analysis was performed to determine bilateral amygdala, hippocampal, and rostral ACC (rACC) volumes, as well as the total intracranial volume for each participant. The Posttraumatic Diagnostic Scale (PDS) was used to assess PTSD symptoms at ≤1 and 3 months after the event. Pearson correlations and linear mixed effects models were used to examine the relationship between posttraumatic stress symptoms and brain volume (assessed <1 month post-trauma). Within the TE group, hippocampal volume varied negatively, while rACC volume varied positively with PDS scores at <1 month ($p<.05$). Hippocampal and amygdala volume (assessed <1 month post-trauma) varied negatively with PDS scores at the 3 month follow-up assessment ($p<.05$). Changes in PTSD symptoms from <1 to 3 months did not vary with brain volume. Findings from the present study suggest brain volume may be an important correlate of acute PTSD symptom severity in adults exposed to a traumatic event.

Langone Med. Ctr., New York, NY

Abstract: Neurobiological processes that take place following a traumatic event may determine who will develop posttraumatic stress disorder (PTSD) and who will not. Such processes might be reflected in resting-state functional connectivity (rsFC), which was found to be altered in PTSD. In this project, we study the progression of these alterations as trauma survivors either recover from early PTSD symptoms, or develop sustained PTSD symptomology. This report focuses on the association between these alterations and early PTSD symptoms severity, as well as with change in symptom severity over time. Data were collected from adult civilians within 30 days (T1; *n*=151; 47.6% male; mean age = 33.7 years), 6 months (T2; *n*=107; 46.7% male; mean age = 35.3 years) and 14 months (*n*=91; 46.1% male; mean age = 34.1 years) of admission to an emergency department following a traumatic event. Functional magnetic resonance imaging was used to assess intrinsic connectivity during a resting-state scan and CAPS-5 was used to assess symptom severity. We followed a seed-based approach, using seeds from salience network (SN) and default-mode network (DMN), where alterations have been previously reported in PTSD. All analyses controlled for sex, age and motion. Results show that connectivity between insula and precuneus correlated with PTSD symptoms at T1 and T2, and connectivity between vmPFC, insula and regions within the dorsal attention network (DAN) correlated with symptoms at T2. Additionally, we found that connectivity between PCC, insula and DAN correlated with change in symptoms over time. Connectivity between vmPFC and parahippocampus also predicted greater improvement in symptoms (all $p < .050$, FWE corrected). In sum, this study demonstrates greater functional connectivity between DMN, SN and DAN (i.e., greater desegregation) in individuals with early PTSD symptoms, and suggests that specific connectivity patterns between and within these three networks can be used as potential biomarkers to predict change in PTSD symptoms after a traumatic event.
YL and JS contributed equally to this work.

Title: The effects of psilocybin assisted group therapy on demoralization, depression, and PTSD symptoms in older long-term AIDS survivors

Authors: B. T. ANDERSON[1], A. L. DANFORTH[1], R. B. DAROFF[1], C. S. STAUFFER[1], J. W. DILLEY[1], ***J. M. MITCHELL**[2], J. D. WOOLLEY[1];
[1]UCSF: Dept. of Psychiatry, San Francisco, CA; [2]UCSF: Departments of Neurol. and Psychiatry, San Francisco, CA

Abstract: Demoralization is a syndrome characterized by a sense of hopelessness, helplessness, and a loss of meaning in life, and it is highly prevalent among patients with serious medical illness.[1] Older Long-term AIDS Survivors (OLTAS) are a subset of older people living with the human immunodeficiency virus (OPLWH) who were diagnosed prior to the advent of combined antiretroviral therapy and have lived to be >50 years of age. OPLWH suffer high rates of depression, anxiety, PTSD, social isolation and loneliness.[2,3] OLTAS suffered high rates of traumatic loss during the AIDS epidemic, and many now endorse symptoms of significant demoralization. Psilocybin is a tryptamine psychedelic[4] that acts primarily as a 5HT2A/1A receptor agonist and can diminish the subjective pain of interpersonal loss.[5] Previous clinical data suggest that psilocybin might be effective at improving treatment-resistant depression and that the extent of this improvement correlates with decreased cortical blood flow in the amygdala.[6] **Methods:** Here we conducted an open-label pilot study to assess the safety and efficacy of single dose psilocybin in conjunction with group psychotherapy on demoralization, depression, and PTSD symptoms in a group of 18 male OLTAS. Single dose psilocybin (4-phosphoryloxy-N,N-dimethyltryptamine) was administered once (0.3mg/kg or 0.36mg/kg po) during an individual medication visit. Patients additionally underwent 10 group psychotherapy sessions (4 prior to the medication visit; 6 subjects per group). **Results:** There was a significant attenuation in demoralization (DS-II; n = 18; Hedge's g = 0.99; p = .0004), depression (CESD; n = 18; Hedge's g = 0.76; p = .02), and PTSD (PCL-5; n = 18; Hedge's g = 0.74; p = .004) related symptoms at baseline versus endpoint (1-month post drug). There were no treatment-emergent serious adverse events. **Conclusions:** These data provide preliminary evidence to suggest that psilocybin is a safe and potentially advantageous therapeutic to treat demoralization, depression, and PTSD in certain subject populations. Further studies are needed to determine the durability of these effects and CNS mechanisms by which they are exerted.

Abstract: Neural mechanisms underlying hypervigilance and an enhanced fear state in posttraumatic stress disorder (PTSD) patients remain largely unknown. There is mounting evidence that the circuitry implicated in fear conditioning involves the basolateral amygdala (BLA), medial prefrontal cortex (mPFC), and hippocampus (HPC). Namely, that theta synchrony has been suggested as a mechanism that coordinates activity in these regions leading to the expression or suppression of fear.
In a rare opportunity, we recorded the activity of these regions in a PTSD patient implanted with depth electrodes, while performing an International Affective Picture System (IAPS) task. We found a significant—sustained—increase in right BLA theta and, in contrast, a decrease in mPFC theta after presentation of aversive stimuli (but not neutral or positive stimuli). BLA theta also significantly interacted with BLA and HPC gamma oscillations further corroborating the framework that the regulation of emotional states is mediated by specific oscillatory patterns within the BLA, mPFC and HPC. We were able to replicate the results in another patient who completed the IAPS task while implanted with foramen ovale electrodes for the work-up of possible seizures. This second patient had also been diagnosed with severe generalized anxiety disorder (GAD) and panic disorder. Here, too, the right BLA exhibited significantly higher theta power after negative stimuli. As a control, we recorded the activity of right BLA and HPC in an epilepsy patient implanted with the NeuroPace RNS® System (for epilepsy treatment) who performed the IAPS task. This patient was not suffering from an anxiety disorder, and we did not find any significant differences in either the BLA or HPC theta power after the negative versus positive/neutral stimuli.
Taken together, our results suggest that the activity of the right BLA—in particular the pattern of theta oscillations—after aversive stimuli may be unique or perhaps triggered at a lower threshold in anxiety disorders such as PTSD or GAD such that it is conducive to the coordination of an enhanced fear and a hypervigilance state.

Title: Decoding stress levels from fMRI data obtained in a virtual reality environment

Authors: ***T. TSE**[1], R. GOEL[1], A. FLOREN[3], B. NAYLOR[1], C. PAO[4,5], D. RESS[1], W. WILLIAMS[5], R. SALAS[2,5,1];
[1]Neurosci., [2]Psychiatry, Baylor Col. of Med., Houston, TX; [3]Univ. of Texas at Austin, Austin, TX; [4]Psychological, Health, and Learning Sci., Univ. of Houston, Houston, TX; [5]Michael E. DeBakey VA Med. Ctr., Houston, TX

Abstract: Introduction:
The ability to decode stress levels from functional magnetic resonance imaging (fMRI) would open up exciting avenues for the treatment of post-traumatic stress disorder (PTSD). Virtual reality (VR) exposure therapy has been used to treat PTSD in veterans. VR settings are ideal as they can be presented in the scanner. We are combining VR, fMRI, and machine-learning to investigate new treatment options for PTSD.
Methods:
A therapist first worked with two participants (a veteran with PTSD and a healthy participant) to create an in-vivo hierarchy, a ranked list of stimuli that evoke fear or anxiety in the participant. For the veteran with PTSD, we used a VR environment called Bravemind (developed by Albert Rizzo and his team) as a realistic stimulus to elicit stress responses. For the healthy subject, we used a variety of video clips to evoke stress. Using each participant's in-vivo hierarchy, individualized videos were created to evoke varying levels of stress. The two participants were asked to lie in an MRI scanner while viewing the videos and rate their subjective stress levels every 15 seconds on a scale of 1-8 via a button box. Participants underwent five 8-min runs each of these experiments. The data were collected using SMS EPI (1.5-s TR, 2-mm voxels, 60 slices) on a 3T scanner. Standard motion compensation and slice timing correction were applied to the fMRI data along with a Wiener filter to mitigate hemodynamic delay. Support vector regression (SVR) and support vector classification (SVC) were used to predict the stress levels of the participants from their cortical fMRI data.

Results:
The veteran participant reported stress levels ranging from 1-7, whereas the healthy participant reported levels ranging from 1-8. For the veteran participant, we were able to achieve a classification accuracy of 40% (well above a chance level of 14.3%) using SVC, and a root-mean-squared error (RMSE) of 1.47 using SVR. For the healthy participant, we achieved a classification accuracy of 36% (chance is 12.5%) using SVC and a RMSE of 1.05 using SVR.
Discussion:
Using machine learning techniques, we were able to decode the subjective stress levels of the two participants at well above chance levels. The low RMSE for SVR is very promising for applying our methods to both extinction and biofeedback therapy. Future work will add pulse, respiration rate, and sub-cortical fMRI inputs to the machine-learning computations to further improve performance. We also plan to apply the machine learning to see if the performance holds across sessions and in real time.

Title: Periaqueductal gray resting state functional connectivity prospectively predicts post traumatic stress symptom severity

Authors: *E. WEBB[1], A. HUGGINS[1], E. BELLEAU[2], L. TAUBITZ[3], J. HANSON[1], T. DEROON-CASSINI[4], C. L. LARSON[1];
[1]Univ. of Wisconsin Milwaukee, Milwaukee, WI; [2]McLean Hospital/Harvard Med. Sch., Belmont, MA; [3]Rogers Mem. Hosp., Minneapolis, MN; [4]Dept. of Surgery, Div. of Trauma & Critical Care, Med. Col. of Wisconsin, Milwaukee, WI

Abstract: Introduction: The periaqueductal gray (PAG) plays a central role in generating behavioral responses to physical and psychological stressors. Posttraumatic stress disorder (PTSD) is characterized by avoidance, hyperarousal, and intrusive/re-experiencing symptoms. Distinct columns of the PAG elicit opposing reactions to threatening or stressful stimuli; the ventrolateral PAG evokes passive coping strategies (e.g. analgesia) and the dorsolateral PAG promotes active responses (e.g. fight or flight). We investigated whether altered resting state

functional connectivity of PAG sub-regions prospectively predicted PTSD symptom severity. **Methods:** Trauma exposed participants (*n* = 46; 70% female; age 33 ± 12.2 years) were recruited from the emergency department. Participants underwent a resting state fMRI scan two-weeks post-trauma. Self-report measures of PTSD (Impact of Event Scale; IES) and Pain (Visual Analogue Scale for Pain) were collected during the two-week visit and six-months post-trauma. The effect of six-month IES scores, adjusted for self-reported pain, on whole brain seed-to-voxel functional connectivity of the PAG was analyzed. **Results:** Greater PAG-frontal pole connectivity predicted an increase in total PTSD symptoms as well as hyperarousal and intrusion symptoms. Greater PAG-posterior cingulate connectivity predicted increased hyperarousal symptoms. PAG-inferior parietal lobule connectivity was negatively correlated with total PTSD symptoms, hyperarousal and intrusions symptoms. **Conclusions:** Altered PAG connectivity two-weeks post-trauma prospectively predicted total PTSD, hyperarousal, and intrusion, symptom severity. These findings suggest altered PAG function may serve as a marker of risk for chronic PTSD symptoms, possibly by driving hyperarousal and more broadly, that connectivity of specific brain regions may underlie specific symptom profiles.

Title: Early findings of enhanced eyeblink conditioning in individuals with high levels of manifest anxiety support a learning diathesis model of PTSD

Authors: *T. ALLEN;
Univ. of Northern Colorado, Greeley, CO

Abstract: Classical eyeblink conditioning has a long history of study in humans and several mammalian species with application to the study of the neural and learning mechanisms underlying psychopathologies such as PTSD. While recent eyeblink conditioning studies have focused more so on rabbits, rats, and mice, human eyeblink conditioning preceded the development of the non-human animal paradigms in that human eyeblink conditioning was the dominant conditioning paradigm in the 1950s. Many studies in the 1950s and 1960s by Kenneth Spence and colleagues used the Manifest Anxiety Scale (MAS), developed by Janet Taylor

Spence, to group undergraduates as high or low manifest anxiety. These studies consistently revealed that individuals with high levels of manifest anxiety exhibited enhanced acquisition of conditioned eyeblinks. In addition, females had higher MAS scores and faster acquisition of conditioned eyeblinks than males. While Spence used MAS scores as a measure of drive based on Hull's theory of learning, Taylor hypothesized that MAS scores signified the presence or lack of various personality traits. More recently, the exploration of personality effects on eyeblink conditioning has continued in studies in humans and rats that investigated inhibited personality temperaments such as behavioral inhibition (BI) as risk factors for the development of PTSD. Much like the findings with MAS, individuals expressing BI exhibit enhanced acquisition of conditioned eyeblinks. In addition, current theories hypothesize that BI and female gender interact as vulnerability factors to increase the risk for anxiety disorders and PTSD. Overall, there is a high degree of consistency between findings of enhanced conditioning and gender effects from early human eyeblink studies and current work which support the theory that inhibited personality temperaments are associated with enhanced associative learning as a mechanism for the development of PTSD. This review indicates how early findings can serve as a foundation for the development of current theories and empirical studies.

Title: Post-traumatic stress disorder: Quantitative EEG biomarkers and treatment via the reconsolidation of traumatic memories (RTM) protocol

Authors: *J. D. LEWINE[1], R. GRAY[2], D. BUDDEN-POTTS[2], N. GOODREAU[1], K. PAULSON[1], N. BANGERA[1], J. DAVIS[1], W. MURRAY[2], F. BOURKE[2];
[1]Mind Res. Network, Albuquerque, NM; [2]Res. and Recognition Project, Corning, NY

Abstract: Post-Traumatic Stress Disorder (PTSD) is a potentially debilitating disorder that is triggered by exposure to a significantly stressful traumatic event threatening death or physical injury to oneself or others. Core features of PTSD include intrusive re-experiencing (nightmares and flashbacks), avoidance, negative cognition and mood, and disturbances in arousal and reactivity. Multiple treatment approaches are used for PTSD, including pharmacotherapy and a range of cognitive and behavioral approaches including exposure therapy, cognitive processing therapy, mindfulness and EMDR therapy, but available data suggest that these various approaches generally provide significant relief of PTSD symptoms in only 25-50% of patients. Given the current situation, there is mounting hope that a better understanding of the

neurobiology of PTSD will lead to the development of better and more efficient therapies. This study evaluated how quantitative electroencephalography (qEEG) and clinical measures (PCL and PSSI) from subjects with PTSD were modulated by a novel treatment approach, the Reconsolidation of Traumatic Memories (RTM) protocol. RTM uses a dissociative reimaging procedure that renders reconsolidated memories of the trauma to be less emotionally impactful and intrusive. Twelve PTSD subjects underwent qEEG and clinical assessments at baseline and 1 month after three 90-minute RTM treatment sessions (administered over the course of 1 week). Ten additional PTSD subjects were evaluated at baseline and 1-month following a no-treatment waiting period. qEEG data were evaluated with respect to a normative database. Baseline EEG data were also evaluated from twenty-two age and sex matched neurotypical control subjects. At baseline, 3/22 control subjects, but 15/22 PTSD subjects, showed excessive power in the high-beta range (Chi-square = 13.6, $p<0.0005$). Waitlist PTSD subjects showed minimal clinical or EEG changes between baseline and follow-up evaluations, whereas RTM subjects showed highly significant ($p<0.001$) reductions in PCL and PSSI scores, along with normalization of excessive high-beta activity. Source modelling (LORETA) showed that the baseline abnormalities in high-beta were mostly generated in mesial temporal (hippocampus and amygdala), insular, frontal, and parietal regions. Post-treatment normalization mostly reflected changes in mesial temporal areas. High-beta activity may be a useful biomarker of PTSD that can be used to objectively track the neurobiological impact of behavioral therapies. The RTM protocol appears to be efficacious in reducing the clinical symptoms of PTSD and in normalizing brain activity.

Title: Frontal emotion regulation capacity predicts acute cortisol-responses as well as long-term resilience to post-traumatic stress: Evidence from a prospective longitudinal study

Authors: *R. KALDEWAIJ[1,2], S. B. J. KOCH[1,2], W. ZHANG[1,2], M. M. HASHEMI[1,2], F. KLUMPERS[1,2], K. ROELOFS[1,2];
[1]Donders Ctr. For Cognitive Neuroimaging, [2]Behavioural Sci. Inst., Radboud Univ. Nijmegen, Nijmegen, Netherlands

Abstract: Regulating social emotional actions is essential for coping with daily life stressors and depends largely on the anterior prefrontal cortex (aPFC) and its connections to downstream regions including the amygdala. However, it remains unclear to what extent frontal emotion regulation capacities contribute to resilience for effects of long-term trauma exposure.
We addressed this question in a large longitudinal study among 226 police officers (176 males, age range 18-43), who were tested before and after trauma exposure as part of a 15-month lasting stressful period in their training. At baseline, they performed a well-established fMRI approach-avoidance task, mapping impulsive and controlled emotional actions. This was immediately followed by a formal stress-induction (social evaluative cold pressure task) and the measurement of cortisol, alpha-amylase and subjective stress-responses. Post-Traumatic Stress Disorder (PTSD) symptoms were assessed with the PTSD-checklist (PCL-5) at baseline and at 15-months follow-up.
For the approach-avoidance-task, the typical neural and behavioural emotion-control effects were replicated, including increased aPFC activation, longer reaction times and more errors during approach-avoidance trials that required control over emotional actions. At baseline, relatively high emotion control-related bilateral aPFC activity predicted relatively low reactivity on all stress-measures (all $p < .05$). For the long-term prediction analyses, 178 officers (136 males) who experienced their core traumatic event in the line of duty between the assessment waves were selected. PTSD symptoms increased after exposure to traumatic events. Critically, higher activation of the left aPFC during emotion regulation at baseline was associated with less increase in PTSD symptoms at 15 months follow-up ($T = 4.59$, p(FWE) < .002, small-volume corrected).
These findings implicate that neural emotion regulation capabilities are not only predictive of reduced acute stress-responses, but are also linked to increased resilience to developing post-traumatic stress symptoms. This adds to our understanding of neurobiological vulnerability factors for the development of stress- and trauma-related disorders, which may ultimately contribute to novel prevention and treatment strategies in high risk populations and professions.

Title: Sex-specific transcriptomic alterations in posttraumatic stress disorder across multiple regions of human frontal cortex

Authors: *M. J. GIRGENTI[1], J. WANG[2], D. JI[2], D. CRUZ[3], D. WILLIAMSON[4], M. FRIEDMAN[5], H. ZHAO[2], J. H. KRYSTAL[1], T. STUDY GROUP[6], R. S. DUMAN[7]; [1]Yale Univ. Sch. of Med., New Haven, CT; [2]Yale Sch. of Med., New Haven, CT; [3]Duke Univ. Sch. of Med., Durham, NC; [4]Dure Univ. Sch. of Med., Durham, NC; [5]Dartmouth Sch. of Med., Hanover, NH; [6]Veterans Admin. Natl. Ctr. for PTSD, West Haven, CT; [7]Dept. of Psychiatry, Yale Univ. Sch. Med., New Haven, CT

Abstract: Posttraumatic stress disorder (PTSD) is a maladaptive and debilitating psychiatric disorder characterized by an extreme sense of fear at the time of trauma occurrence, with characteristic reexperiencing, avoidance, and hyperarousal symptoms in the months and years following the trauma. PTSD has a prevalence of approximately 6%, but can occur in 25-35% of subjectrs who have experienced severe psychological trauma, such as combat veterans, refugees, and assault victims. The incidence and symptoms of PTSD all point toward major sex differences. However, the molecular mechanisms underlying the sexual dimorphism remain largely unknown. Here, combining differential expression and gene coexpression analysis, we provide comprehensive characterization of male and female transcriptional profiles associated with PTSD across 5 cortical brain regions: the subgenual prefrontal cortex (area 25), medial orbital frontal cortex (area 11), dorsal anterior cingulate (area 24), dorsolateral prefrontal cortex (area 9), and motor cortex (area 4). Our results show a major rearrangement of transcriptional patterns between healthy controls compared to PTSD subjects or MDD subjects (non-PTSD psychiatric controls). We identify key regulators of sex-specific gene networks and hub genes underlying PTSD in female SgPFC that differ from those in male subjects, which have their own unique networks and hub in the dACC. We also show differential contributions of cell types to gene expression patterns in males (neurons) and females (astrocytes and microglia). Together, our findings demonstrate PFC subregions as key sites of transcriptional regulation in PTSD brain and highlight sex-specific and cell-type specific gene expression across these cortical regions.

Title: Intranasal oxytocin increases dopamine signaling in the dorsal striatum of anesthetized rats

Authors: *D. E. GINDER, C. RAMELOW, M. P. GAINER, D. P. DABERKOW;
Eastern Washington Univ., Cheney, WA

Abstract: BACKGROUND: The neuropeptide oxytocin (OXT), commonly considered the "love hormone", has been suggested to be involved in many aspects of brain function, such as learning and memory. Current research suggests that OXT treatment is therapeutic for individuals suffering from post-traumatic stress disorder (PTSD), possibly due to OXT's modulatory effects on the brain circuitry involved with learning and memory. Defining the neural mechanisms of OXT is important in order to understand how OXT could be beneficial for individuals with PTSD, and possibly other psychological disorders. The neurotransmitter dopamine (DA) is highly implicated in learning and memory. DA neurons express OXT receptors and therefore could be a site of OXT action. We hypothesize that OXT increases DA neurotransmission in the dorsal striatum, a brain region highly innervated by DA neurons. METHODS: Using fast-scan cyclic voltammetry (FSCV) we monitored electrically evoked DA signals before and after intranasal OXT administration. Male Sprague-Dawley rats (n = 6) were anesthetized and underwent DA electrode placement surgery. DA microelectrodes were placed in the dorsal striatum (coordinates AP= +1.0; ML= +2.0; DV= -4.5) and a bipolar stimulating electrode was incrementally lowered above the medial forebrain bundle (coordinates AP=-4.6; ML=+1.4; DV=-7.0), a brain region containing DA neurons that project to the dorsal striatum. Once stable DA signals were recorded, intranasal OXT at 0.5 µg/kg (or an equivalent volume of saline in controls) was administered. RESULTS: Intranasal OXT treatment increased electrically evoked DA signals (peak amplitude), compared to saline-treated controls. CONCLUSION: OXT increases DA neurotransmission and therefore could have a modulatory effect on learning and memory. Title: Effects of intranasal oxytocin pre- and post-treatment in a rat model of PTSD

Authors: *D. P. D. DABERKOW, S. M. HILFIKER, R. A. WESTERMAN, S. R. STORACI, D. H. OWNBEY, T. M. MOORHEAD, C. F. GUZMAN, R. BARIDO, C. W. JASPER; Eastern Washington Univ., Cheney, WA

Abstract: Oxytocin (OXT) treatment reduces signs of emotional stress after exposure to trauma. The objective of this study was to investigate the time dependent effects of intranasal oxytocin (i.e. before and after fear conditioning) on behavioral (i.e. freezing) and physiological (i.e. corticosterone levels) signs of fear. METHODS: Male Sprague-Dawley rats (8-10 weeks old) were separated into 4 groups (n = 6, per group): *Control* (no shock, no OXT), *Shock* (shocked, no OXT), *pre-OXT* (shocked, 1.0µg/kg intranasal OXT 1h before shock treatment), and *post-OXT* (shocked, 1.0µg/kg intranasal OXT 24h after shock treatment). Rats were handled for 2 weeks prior to fear conditioning. On the day of fear conditioning, rats were enclosed in a sound attenuating box with a shock grid floor (Coulbourn Instruments). After a 120s adaptation period, CS (tone) was presented for 20s, the US (shock) was presented in the last 2s of the CS. Rats were exposed to 5 presentations of the CS/US at 60s intervals. At both 24h and 7d after fear conditioning, rats were re-exposed to the fear conditioning box and CS. After a 30s adaptation period, the CS was presented for 20s (no US). During the re-exposure sessions, each rat had 5 presentations of the CS at 60s intervals. After each re-exposure session, feces were collected for analysis of corticosterone levels (ELISA kit, Cayman Chemical). Re-exposure sessions were video recorded and freezing behavior was analyzed (Actimetrics FreezeFrame). RESULTS: OXT-treated rats demonstrated less freezing behavior and had lower corticosterone levels than saline-treated controls. CONCLUSION: The results of this study suggest that intranasal OXT attenuates behavioral and physiological signs of fear.

Title: Impact of prophylactic intranasal oxytocin on signs of fear in a mouse model of PTSD

Authors: *C. W. JASPER, K. A. WHITWORTH, M. A. CHAMPION, C. A. ALVIS, E. M. KOEHLER, M. L. MCNEILL, R. L. BARIDO, D. P. DABERKOW;
Eastern Washington Univ., Cheney, WA

Abstract: Oxytocin (OXT) is a hormone that has a wide range of central and peripheral effects. OXT is involved in reproduction and has also been seen to attenuate the effects of stress and anxiety. The purpose of this study was to investigate the anxiolytic effects of intranasal OXT pretreatment on the behavioral and physiological signs of fear in mice. METHODS: Three groups (n=10, per group) of adult male mice (4-6 month old) were used. One hour before exposure, OXT was administered intranasally at a dosage of 1.0 µg/kg. OXT (VetOne®) was dissolved in saline (0.9% NaCl) and ~1.3 µl was gently injected, via micropipette, into each nostril of the Shock+OXT group. The Control group (no shock, no OXT) and Shock+saline group (shocked and no OXT) were given an equivalent administration volume of saline. The mice were then placed in a fear conditioning box (Coulbourn Instruments) and allotted a 120s acclimation period followed by 20s of the conditioned stimulus (CS), tone exposure at 2.8kHz delivered by external speaker. A 15s trace interval was used following the CS, followed by the unconditioned stimulus (US), a 0.7 mA scrambled current foot shock for 2s. The mice were exposed to 5 CS-US presentations with an interstimulus period of 10s. One week post fear conditioning, mice were re-exposed to the context and tone. Results: Intranasal OXT pretreatment decreased freezing behavior in mice when re-exposed to the context, relative to saline treated controls. Mice pretreated with intranasal OXT demonstrated slightly more activity in the open field, relative to saline-treated controls (although not significant). The results of this study suggest that intranasal OXT pretreatment ameliorates signs of fear in mice. FUNDING: Eastern Washington University Department of Biology.

Title: Cannabidiol and sertraline-mediated regulation of behavioral and neurochemical disturbances induced by a new long-lasting animal model of pot-traumatic stress disorder

Authors: *J. MANZANARES, F. NAVARRETE, A. GASPARYAN;
INSTITUTO DE NEUROCIENCIAS, UNIVERSIDAD MIGUEL HERNANDEZ-CSIC, SAN JUAN DE ALICANTE, Spain

Abstract: The main goals of this study were to validate and characterize a new chronic animal model of post-traumatic stress disorder (PTSD), and to evaluate the effects of cannabidiol (CBD) and/or sertraline (SERT) on PTSD-like behavioral and neurochemical alterations. To induce the animal model of PTSD, C57BL/6J mice were exposed to stressful stimuli for 5 weeks, alternating 3 weeks of exposure with 2 weeks of resting. PTSD-induced basal (weeks 6-7) and long-lasting (weeks 11-14) behavioral alterations were evaluated by fear conditioning (FC), novelty suppressed feeding test (NSFT), light-dark box (LDB) and elevated plus maze (EPM) paradigms. Effects of CBD (20 mg/kg, i.p.) and/or SERT (10 mg/kg, p.o.) administration on PTSD-induced disturbances were analyzed between weeks 11 to 14. In addition, relative gene expression analysis of corticotropin release factor (CRF) in the paraventricular nucleus, proopiomelanocortin (POMC) in the arcuate nucleus, glucocorticoid receptor (GCr) in the hippocampus, cannabinoid receptors 1 (CB1r) and 2 (CB2r) in the amygdala, and serotonin transporter (5HTT) in the dorsal raphe were carried out by real time PCR. C57BL/6J mice exposed to the PTSD animal model showed significantly increased fear-related memories (FC) and anxiety-like behavior (NSFT, LDB, EPM) under basal (weeks 6-7) and long-term (weeks 11-14) conditions (t-test, $p<0.001$). The pharmacological treatment with CBD or SERT significantly improved PTSD-related emotional alterations, achieving remarkable additive effects with the CBD plus SERT combination (Two-way ANOVA, $p<0.001$). Real time PCR experiments showed higher CRF (+138%) and POMC (+29%) but lower GCr (-16%) gene expression levels in mice exposed to the PTSD model at week 5 (t-test; $p<0.001$). Although increased CRF (+27%) gene expression was maintained until week 14, a significant reduction of POMC (-21%) and increase of GCr (+16%) were observed (t-test; $p<0.001$). Additionally, stressed animals had higher CB1r (+11%) and CB2r (+63%) while lower 5HTT (-42%) gene expression levels at week 14 (t-test; $p<0.05$). Interestingly, the pharmacological treatment with CBD and/or SERT significantly normalized all these neurochemical alterations (Two-way ANOVA, $p<0.05$). In summary, our results show that this new animal model of PTSD induces long-lasting behavioral and neurochemical alterations allowing us to investigate new pharmacological approaches for PTSD. Indeed, this study demonstrates for the first time that CBD actions are comparable to SERT and their combination produces an enhancing effect. Further studies are necessary to explore the therapeutic potential of CBD plus SERT in PTSD patients.

Title: A predator-based psychosocial stress model of post-traumatic stress disorder in females: Influence of estrous phase and ovarian hormones

Authors: *C. S. GOODMAN[1], P. A. D'ALESSIO[1], S. L. SEELEY[2], C. D. KASLER[1], K. E. MUCHER[1], A. S. ALLISON[1], I. F. SMITH[1], J. L. DODSON[1], T. S. STOOPS[2], K. M. ELMOUHAWESSE[1], B. R. RORABAUGH[2], P. R. ZOLADZ[1];
[1]Psychology, Sociology, & Criminal Justice, [2]Pharmaceut. & Biomed. Sci., Ohio Northern Univ., Ada, OH

Abstract: For reasons that are still not entirely clear, traumatized females are significantly more likely than traumatized males to develop post-traumatic stress disorder (PTSD). Still, the inclusion of females in animal models of PTSD has largely been avoided, likely due to the highly variable hormone profile of female rodents. Because a valid animal model of PTSD that incorporates females is still needed, we examined the influence of estrous stage and ovarian hormones on the female rat response to a predator-based psychosocial stress model of PTSD. Female Sprague-Dawley rats were exposed to psychosocial stress or control conditions for 31 days. Stressed rats were given two separate cat exposures and daily social instability; control rats were handled daily. Beginning on Day 32, rats underwent physiological or behavioral testing. In Experiment 1, vaginal smears were collected on days of the first and second cat exposures and each day of behavioral testing to determine estrous stage. In Experiments 2 and 3, ovariectomized or sham control rats were exposed to stress or control conditions. Then, they were given behavioral testing (Exp 2), or their hearts were isolated and subjected to 20-min ischemia / 2-hr reperfusion on a Langendorff isolated heart system (Exp 3). The results indicated that chronic stress increased anxiety-like behavior, irrespective of estrous stage or ovariectomy condition. Ovariectomized females displayed greater startle responses and anxiety-like behavior than sham controls. Stress had no impact on myocardial sensitivity to ischemic injury; however, ovariectomized females exhibited greater ischemia-induced infarction than sham controls. These findings suggest that ovarian hormones may prevent anxiety-like behavior and be cardioprotective in non-stressed controls, but they do not interact with chronic stress to influence the development of PTSD-like sequelae in female rats.

Abstract: In post-traumatic stress disorder (PTSD), trauma causes long-lasting anxiety and hyper-reactivity. While PTSD often results from combat, it is widespread in the civilian population, with a majority of cases in females. This is a difficult subject to study, since, both in humans and animal models, only 30 - 50% might develop PTSD after extreme stress. We introduce a rat model resulting in relatively robust PTSD-like effects. The subjects were 37 female Lewis rats (an emotionally reactive strain). In the stressed group, the rats were conditioned on day 1 and throughout by single housing (particularly stressful to female rats). On days 21 and 31, the rats were exposed for 90 minutes to predator odor threat by reconstituted wildcat urine. For an hour of this, the rats were kept in a tubular restrainer (restraint stress). The rats were also exposed to an intermittent 70 decibel (dB) auditory stimulus (replayed during some later tests). A non-stressed control group was group-housed for 34 days. On days 21 and 31, they were exposed to water in place of predator urine and the same intermittent auditory stimulus. The restrainer was present, but the rats were not restrained in it.On days 41 and 42 all rats were tested under "blind" conditions for acoustic startle response at 100 and 110 dB, anxiety measurement in the elevated plus-maze and anxiety-related alterations of open field behavior. One hour before testing on each day, the non-stressed controls were injected s.c. with saline alone. The stressed rats were injected s.c. with either saline alone or 1.0 mg/kg of the 5HT2A serotonin receptor inverse agonist pimavanserin. Following one-way ANOVAs, post-hoc statistical tests revealed that, compared with the non-stressed/saline controls, the stressed/saline group had stronger startle responses, p=.013; spent less time in the open arm of the plus-maze, p=.011, had less distance traveled in the exposed inner zone of the open field, p=.059; less rearing, p=.002; more freezing, p=.001. Compared with the stressed/saline controls, the

stressed/pimavanserin group had significantly lower acoustic startle scores, p=.012; significantly more time in the open arms of the plus-maze, p=.002; significantly more distance traveled in the exposed inner zone of the open field, p=.022, significantly more rearing, p=.002 and significantly less freezing, p=.001. There were no significant differences between the stressed/pimavanserin, group and the non-stressed/saline group. The results indicate that pimavanserin reversed the long-lasting anxiogenic and hyper-reactive effects of the combined stressors, suggesting a major role for the 5HT2A serotonin receptor in PTSD-like behaviors.

Title: Anterior amygdalohippocampal area was reduced by severe stress event in adult male rats - Longitudinal structural MRI study

Authors: *R. RYOKE, M. HIROBE, H. NONAKA, R. KAWASHIMA;
Dept. Functional Brain Imaging, Tohoku Univ., Sendai, Japan

Abstract: Introduction: Posttraumatic Stress Disorder (PTSD) is an anxiety disorder that may develop following to an exposure to a highly traumatic event. It has been needed to study the neurobiological mechanisms underlying PTSD using animal models. Most of these models have been derived from Pavlovian fear conditioning, and it is known that prior exposure to traumatic stress enhances conditional fear responding to subsequent mild stress. We previously reported that the multiple stress consisted of foot shocks and forced swimming had long-lasting effects on subsequent fear conditioning, even the multiple stress was administrated a day. In this study, we examined the longitudinal study that combined the multiple stress and in vivo magnetic resonance imaging (MRI) to reveal the effects of the traumatic single experience on adult male

rat's brain.
Methods: Two different shock chambers, Context A chamber and Context B chamber, were used for delivering the multiple stress and conducting the fear conditioning, respectively. Male Wistar rats (8 weeks old -)were exposed to the multiple stress consisted of 4 spaced foot shocks (1 mA, 1 s) for 25 min in the Context A chamber and forced swimming for 20 min in a plastic bucket. Non-stressed rats were placed in the chamber and a plastic cage for the same amount of time as the multiple stress animals without foot shocks and swimming, respectively. The T2W MRI images were acquired by 7T MRI (Bruker). MRI was conducted before the multiple stress and after the third retention test of fear conditioning. We used voxel-based morphometry (VBM) that can map changes in regional gray matter volume over the time across the entire rat brain. Contextual fear conditioning was conducted 14 days after the multiple stress for testing the effect of the multiple stress. All animals were exposed 2 mild foot shocks (0.1 mA, 2 s) in the Context B chamber. Conditioned fear response (freezing) in the Context B chamber was assessed in three retention tests, which were conducted on the next, 7 and 14 days after the conditioning.
Results: Rats exposed the multiple stress showed the enhancement of fear conditioning on all retention tests even they experienced MRI before the multiple stress. The results of longitudinal VBM analysis revealed that the gray matter volumes in anterior amygdalohippocampal area was less than non-stressed rats. There were the association between the magnitude of fear conditioning and the regional gray matter volumes which statistically differed between two groups.
Conclusion: It's suggested that amygdalohippocampal area could be related to express enhanced fear response after encountering severe stress.

Title: Examinations of environmental enrichment and morphine for the symptoms of post-traumatic stress disorder in mice

Authors: F. WU[1], A. C.-W. HUANG[2];
[1]Dept. of Psychology, Fo Guang Univ., Yilan, Taiwan; [2]Psychology, Fo Guang Univ., Yilan County, Taiwan

Abstract: Fear and its comorbid depression and anxiety are the essential symptoms of post-traumatic stress disorder (PTSD). However, there was a little research to examine the neural substrates of PTSD. This present study concerned this issue of whether c-Fos activations

involved in the medial prefrontal cortex (mPFC) and amygdala for fear symptom of post-traumatic stress disorder (PTSD). In the study, all mice were tested fear behavior of the PTSD symptoms in behavioral level. Moreover, c-Fos expressions were also measured using immunohistochemical staining (IHC) in the mPFC and amygdala after encountering footshock traumatic events. During the footshock treatment, all mice were divided into two groups. The control group is no footshock treatment. The footshock group was given a severe footshock (3mA, 10s) once a day. Later, all of mice were given a situational reminder treatment once a day for 3 days. During the period of time, mice were put in the footshock box for 2 min and measured the freezing behavior. On the last day of the situational reminder phase, all mice were tested behaviors and then c-Fos expressions were tested. The present results indicated that c-Fos was higher expressions in the mPFC but amygdala was lower expressions for fear behavior testing when the combination of environmental enrichment and morphine injection. In conclusion, our data suggest that the mPFC and amygdala play important roles in PTSD. The present findings might offer some implications for PTSD.

Title: Genetic selection for blunted glucocorticoid responsiveness leads to impaired fear extinction and sleep abnormalities in rats

Authors: *S. MONARI, S. E. WALKER, J. GROSSE, I. GUILLOT DE SUDUIRAUT, S. ASTORI, C. SANDI;
Brain Mind Institute, EPFL, Lausanne, Switzerland

Abstract: Humans show inter-individual differences in vulnerability to develop post-traumatic stress disorder (PTSD) following exposure to traumatic events. Although initial observations linked low cortisol levels to PTSD pathophysiology, whether inter-individual differences in glucocorticoid responsiveness are implicated in the development of PTSD is not yet clear. To address this question, our lab has generated lines of Wistar rats genetically-selected for their differential habituation of the glucocorticoid response to repeated stressor exposure at puberty.

Here, we assessed physiological and behavioral phenotypes of subjects drawn from these lines. Strikingly, when compared to rats with 'normative' glucocorticoid responses, rats with blunted corticosterone responses to stress exhibit strong fear extinction deficits. Importantly, similar to PTSD patients, these rats show smaller hippocampi than controls. We tested whether supplementing with corticosterone would revert the extinction defects. Indeed, post-extinction corticosterone treatment in the low-line rats largely prevented immediate deficits in extinction memory and fear relapse. Given that glucocorticoids are known to modulate memory consolidation during sleep, and sleep disturbances are commonly observed in PTSD patients, we examined sleep/wake cycle and sleep rhythms through polysomnographic (EEG/EMG) recordings. Low responder rats displayed an altered sleep architecture, with shorter bouts of NREM sleep and markedly longer bouts of REM sleep, reminiscent of the excessive REM sleep described in PTSD patients. Our findings strongly support a causal involvement of blunted glucocorticoid responsiveness in physiological and behavioral traits indicative of higher vulnerability to PTSD, consistent with the evidence linking low cortisol levels to PTSD pathophysiology in humans.

Title: Interleukin 1 receptor (IL-1R) within the subfornical organ is a novel neuroimmune regulator of panic-PTSD

Authors: *K. M. MCMURRAY[1,2], R. SAH[1,2];
[1]Pharmacol. and Systems Physiol., Univ. of Cincinnati, Cincinnati, OH; [2]DVA, Cincinnati, OH

Abstract: Panic Disorder (PD) and Post-Traumatic Stress Disorder (PTSD) are prevalent, co-morbid psychiatric conditions with high disability and treatment resistance. Currently, mechanisms underlying PD-PTSD vulnerability are unclear. Accumulating evidence supports a potential role of neuroimmune modulators in PD-PTSD physiology. Recent studies have shown elevated pro-inflammatory cytokines in panic and PTSD patients and importantly, polymorphisms in the interleukin 1 beta (IL-1b) gene in PTSD suggesting a potential role of IL-1b and IL-1R signaling in development of these conditions. The association of IL-1b signaling in

the regulation of panic-PTSD relevant behaviors is currently unclear. We previously reported a role of neuroimmune mechanisms within a BBB-devoid area, subfornical organ (SFO) in fear evoked by carbon dioxide (CO_2), a panic challenge. The SFO has been recognized as an interoceptive locus and projects to panic and fear regulatory regions. Recently, we developed a conjunct panic- and PTSD relevant paradigm using CO_2 inhalation and fear conditioning in mice wherein PTSD-relevant behaviors (fear conditioning extinction deficits, heightened acoustic startle) are observed 1 week after CO_2 inhalation. Our previous data show central IL-1b/IL-1R signaling regulates CO_2-evoked fear. Here, we tested the hypothesis that inhibiting IL-1R signaling specifically within SFO during CO_2 inhalation reduces both immediate (CO_2-evoked fear) and long-term fear outcomes (fear conditioning, acoustic startle 1 week later). IL-1R antagonist (IL-1ra) or vehicle was infused via cannulas targeted to the SFO 30m prior to 5% CO_2 inhalation. One week later, mice underwent acoustic startle, followed by contextual fear conditioning the next day. Sustained region-specific neural activity was quantified by IHC (FosB) in tissue collected 24h after final behavioral testing. Consistent with our hypothesis, a single infusion of IL-1ra attenuated freezing (fear) during CO_2-inhalation and prevented the delayed expression of potentiated startle and contextual fear extinction deficits. Ongoing studies are investigating neuronal activation in SFO-target areas and fear regulatory regions such as the mPFC, BNST, hippocampus and amygdala to delineate associated circuits. Collectively, our data provide the first evidence for an important role of neuroimmune mediators within specialized blood brain barrier devoid loci in regulating fear behavior and highlight SFO IL-1R as a novel target in panic and PTSD physiology.

Title: Tests of freezing and anxiety behaviors in the animal model of post traumatic stress disorder

Authors: *H.-L. CHENG, A. C. W. HUANG;
Fo Guang Univ., Yilan, Taiwan

Abstract: This purpose of the present study imitates the symptoms of PTSD. In the initial period of time, all rats received habituation procedure for 7 days in colony room. Then, rats were given the footshock treatment to induce a traumatic event. On the footshock treatment, all of rats were

divided into two groups: nonfootshock and footshock groups. The control group is given a nonfootshock treatment. The footshock group was conducted a severe footshock (3mA, 10s) once a day. These animals received a situational reminder treatment once a day for 3 days. The rats were placed in the footshock box for 2 min and measured rats' freezing behavior. After the last session of the situational reminder, rats were given an anxiety test in the zero-maze task for 10 min. The spent time were measured in the open arm served as the anxiety index. The results indicated that a 2 x 3 mixed two-way ANOVA showed that the group [$F(1, 17) = 83.62$, $p < 0.05$] and session [$F(2, 34) = 4.04$, $p < 0.05$] were significant differences. However, a nonsignificant difference occurred at the interaction of group and sessions [$F(2, 34) = 0.55$, $p > 0.05$]. For the zero-maze test, a significant difference occurred for nonfootshock and footshock groups [$F(1, 17) = 8.38$, $p < 0.05$].
In conclusion, footshock treatments induced freezing behavior. Moreover, footshock induced anxiety behavior in the zero-maze task. The present data can offer a novel PTSD animal model. The findings should be discussed further.

Title: The blockade of NK1 receptors in the dorsal periaqueductal gray facilitated extinction memory and reduced anxiety-like behavior

Authors: *M. C. CARVALHO[1], C. R. LEITE-PANISSI[3], N. C. COIMBRA[2];
[2]Pharmacol., [1]Univ. of São Paulo/ FMRP, Ribeirão Preto, Brazil; [3]Psychology, Univ. of São Paulo/ FFCLRP, Ribeirão Preto, Brazil

Abstract: Extinction is defined as the learned inhibition of retrieval. It is the mainstay of exposure therapy to treat fear disorders such as post-traumatic stress disorder (PTSD). It is known that extinction requires retrieval involving memory destabilization and relevant protein synthesis-dependent processes in hippocampus and amygdaloid complex, but no attention has been given to the role of mesencephalic structures in this process. The periaqueductal gray matter (dPAG) is involved in coordinating aspects of the fear-related responses. We showed that aversive stimulus-induced reactions related to dPAG activity send information toward higher brain structures (hippocampus and amygdala) that are responsible for the storage of memories of intense threatening stimuli within a given time window (Carvalho et al., 2018). It led us to think

that the dPAG could contribute to the extinction of aversive memories. The behavioral sensitization induced by dPAG electrical stimulation was long-lasting counteracted by NK1 receptor antagonism in the ventral hippocampus and central nucleus of the amygdala of rats submitted to the elevated plus maze (EPM). Then, we evaluated the effects of spantide (SPA), a NK1 antagonist, infused into the dPAG, on extinction memory in rats incapable of showing contextual fear condition (CFC) extinction because of weak training. Male Wistar rats with guide cannulae implanted in the dPAG were submitted to a weak extinction protocol in a CFC apparatus. Rats that received intra-dPAG infusion of SPA (100 pmol/0.2 μL) 5 min before the training expressed less freezing behavior than PBS-treated rats during both extinction training and retention, 1 and 7 days later. These rats showed anxiolytic-like effects in the EPM 8 days after the extinction training. These results suggest that NK1 inhibition in the dPAG is able to induce the consolidation of extinction memory and to reduce anxiety-like behaviors consequent to the trauma. In addition, these findings suggest that the dPAG is an important structure involved in the modulation of extinction memory, a function not addressed in previous works. This ancient structure seems to be part of neural circuitry responsible for modulating long-term memories of intense threatening conditions, similar to what occurs in PTSD.

Title: Pharmacological inactivation of the nucleus reuniens during predator odor exposure and context re-exposure

Authors: *L. C. ORNELAS[1], J. BESHEER[2];
[1]Bowles Ctr. for Alcohol Studies, The Univ. of North Carolina Sch. of Med., Chapel Hill, NC;
[2]Psychiatry; Bowles Ctr. for Alcohol Studies, Univ. of North Carolina - Chapel Hill, Chapel Hill, NC

Abstract: Post-traumatic stress disorder (PTSD) is highly comorbid with alcohol use disorder. Defining models of traumatic stress and alcohol consumption may lead to a better understanding of the neurobiological mechanisms that underlie this comorbidity. The nucleus reuniens (RE), a midline thalamic nucleus, is an emerging area of the brain underlying symptom profiles of PTSD, such as stress and depression. Here we examined pharmacological inactivation (by a baclofen/muscimol cocktail) of the RE prior to traumatic stress to better understand the neural

circuitry involved in regulating response to traumatic stress.
Female (n=32) Long Evans rats were implanted with a unilateral cannula into the RE. One week after surgery, rats received baclofen (1.0 mM) + muscimol (0.1 mM; BM) or aCSF microinjections. 10 min post infusion, rats in the stress group underwent predator odor (PO) exposure using trimethylthiazoline (TMT; synthetically derived fox feces component), for 20 min in a distinct context. 48-72 hr later rats underwent testing for general locomotor activity (open field test; OFT), anxiety-like behavior (light/dark test), and hyperarousal (acoustic startle response, ASR). To measure reactivity to the PO-paired context, 4 weeks following the initial PO exposure, rats were re-exposed to the PO-paired context in the absence of TMT.
During PO exposure, rats administered aCSF showed a significant decrease in total distance traveled and midline crossings, increase time freezing and avoidance of the side of the chamber near the TMT compared to control counterparts. In addition, during PO exposure rats administered BM avoided the side of the chamber near the TMT compared to control counterparts. There were no changes in locomotor behavior in the OFT, Light/Dark test, or ASR. During PO context re-exposure, the PO-exposed groups did not show reactivity to the paired context, which could be due to the 4 week delay between exposure and re-exposure. As a follow up study, in a new cohort of animals, we tested motor activity in the open field after BM administration. There were no changes in distance travel in BM group vs. controls indicating this BM dose does not produces changes in locomotor behavior.
The results indicate that PO exposure produces stress-induced effects as indicated by decreased in total distance traveled and midline crossings, increased time freezing and avoidance of the side of the chamber near the TMT. In addition, pharmacological inactivation of the RE produces no changes in behavioral responses during PO or behavioral reactivity to PO-paired context. Together, these results indicate that inactivation of the RE does not impair fear expression during PO exposure.

Title: Estrogen receptor activation and susceptibility to traumatic stress in an animal model of PTSD

Authors: *M. BIDDLE, D. K. KNOX;
Psychological and Brain Sci., Univ. of Delaware, Newark, DE

Abstract: Post-Traumatic Stress Disorder (PTSD) is an anxiety disorder which occurs following exposure to traumatic stress and results in the inability to properly modulate expression of fear memory. Women are twice as likely to suffer from PTSD as men, but this enhanced susceptibility has been difficult to replicate in rodent-based models of PTSD. One reason for this is female rats are resilient to the effects traumatic stress has on persistent fear memory. A possible cause of this is differences in the natural variation of the ovarian hormone estrogen in female humans vs. female rats. In humans, the menstrual cycle typically lasts between 21 and 45 days, with a period of 5-7 days of notably lower levels of estrogen. This can lead to periods where estrogen receptor activation is low in fear circuits, which in turn could represent a window of stress susceptibility in women. In support of this interpretation a number of studies have shown that low estrogen receptor activation leads to either enhanced susceptibility to PTSD or deficits in extinction memory. In rodents, the estrous cycle is typically only 4-5 days, and the period of lower estrogen levels is comparably shorter as well. Thus, there may not be naturally low levels of estrogen receptor activation in female rats. One way to circumvent this potential issue is to pharmacologically antagonize estrogen receptors prior to traumatic stress. By doing this the effects of low estrogen receptor activation on traumatic stress effects in females and males can be examined. To accomplish this goal we used the single prolonged stress (SPS) model of PTSD. SPS consists of serial exposure to restraint forced swim and ether, and approximates core behavioral and neurobiological PTSD symptoms. Prior to conducting SPS or control stress in rats, the estrogen receptor antagonist (ICI182,780; 0.05mg/kg and 0.005mg/kg) was administered subcutaneously to lower estrogen receptor activation prior to SPS. Rats were then fear conditioned, then subjected to extinction training and testing. Rats were then euthanized and key nodes of the fear circuit examined to identify sex differences in sensitivity to SPS when SPS is conducted under low estrogen receptor activation. While the study is ongoing, preliminary findings suggest an overall decrease in fear conditioning in female SPS rats that received a high dose (i.e. 0.05mg/kg) of the estrogen receptor antagonist prior to SPS. The overall results of the study will help determine if low estrogen receptor activation prior to traumatic stress can lead to stress susceptibility and identify key nodes in the fear circuit through which this susceptibility may manifest.

Title: The effect of ethanol consumption on cue-dependent fear memory in mice

Authors: *K. WININGER[1], A. HO[2], S. PAEK[1], D.-S. CHOI[3];
[1]Neurosci., Mayo Clin. Grad. Sch. of Biomed. Sci., Rochester, MN; [2]Mayo Clin., Rochester, MN; [3]Mol. Pharmacol. and Exptl. Therapeut., Mayo Clin. Col. of Med., Rochester, MN

Abstract: Significant comorbidity is known between posttraumatic stress disorder (PTSD) and alcohol use disorder (AUD). Traumatic events are a common denominator for stress disorders including PTSD, which is highly associated with increased alcohol drinking. Acute alcohol use mitigates and short term relieves PTSD symptomology. However, chronic alcohol use alters circuitry and signaling in the brain and alcohol withdrawal exacerbates PTSD symptoms.This study aims to investigate the effects of chronic pre-exposure to alcohol on cue-dependent fear memory. For this study, three cohorts of C57BL/6J mice underwent fear conditioning training, followed by cue-dependent fear memory testing, extinction training and testing. The first cohort (*n*=32) is ethanol-naïve, while the second (*n*=24) and third (*n*=24) cohorts were pre-exposed to a 2-bottle choice ethanol drinking paradigm (escalating progressively from 3% to 15%) prior to fear conditioning training, and only the third cohort continued with the drinking paradigm (15% ethanol) throughout the study. Cue-dependent fear memory was measured by freezing response during the presentation of cue. Ethanol consumption and preference were recorded every two days. Ethanol pre-exposure significantly reduced freezing response during fear conditioning training, however continued ethanol exposure had no effect on cue-dependent fear memory or fear extinction. Baseline ethanol consumption was correlated with freezing to cue upon re-exposure with no correlation in fear conditioning training or extinction. Ethanol consumption and preference significantly decreased after fear conditioning testing regardless of fear conditioning training. Our findings demonstrate that ethanol consumption prior to fear conditioning reduces fear response during initial fear conditioning however is correlated with the severity of cue-dependent fear response upon re-exposure.

Title: Sex differences in intravenous ketamine infusion on stress and fear in rats

Authors: K. D. RADFORD[1], M. ZHANG[2], R. Y. BERMAN[1], T.-Y. J. WU[1], ***K. CHOI**[2];
[2]Psychiatry, [1]Uniformed Services Univ., Bethesda, MD

Abstract: The U.S. Department of Defense has recently opened combat roles to women that were previously restricted to men. As a result of this policy change, military health care providers can anticipate an increased frequency of combat-related injuries in female service members in the future. Ketamine, an NMDA receptor antagonist, is a preferred battlefield analgesic due to its hemodynamic stability and a lack of respiratory suppression in wounded service members. However, ketamine administration in the peri-trauma period may produce dissociation and hallucination which may worsen traumatic memory consolidation. We previously reported that subanesthetic intravenous (IV) ketamine infusion dose-dependently increased stress hormone corticosterone (CORT) levels and fear memory in male rats. Here, we investigated the effects of IV ketamine infusion on CORT and fear memory in female rats. Adult female Sprague-Dawley rats received a 2-hour IV ketamine infusion (0 and 10 mg/kg) after auditory fear conditioning (3 times of tone and footshock pairing). Spontaneous locomotor activity was monitored during the infusion and plasma CORT levels were measured after the infusion. Fear memory retrieval, fear extinction, and fear recall were tested between 2 and 4 days after the fear conditioning/ketamine infusion. The IV ketamine infusion suppressed locomotor activity and elevated plasma CORT levels in female rats. The IV ketamine infusion following fear conditioning enhanced fear memory retrieval and delayed fear extinction in rats. These results indicate that subanesthetic dose of IV ketamine infusion stimulates stress hormone pathway and enhances fear memory in intact female rats.

Title: Glutamatergic mechanisms enduring vulnerability to maladaptive coping strategies and transient synaptic plasticity following and acute stressor

Authors: C. GARCIA-KELLER, A. M. KEARNS, J. S. CARTER, J. JOPKINS, T. PENALOZA, P. W. KALIVAS, ***C. M. REICHEL**;
Med. Univ. of South Carolina, Charleston, SC

Abstract: Exposure to acute life-threatening stress, such as occurs in combat or a sexual assault, increases the incidence of post-traumatic stress disorder (PTSD), and a diagnosis of PTSD substantially increases a diagnosis of substance use disorder (SUD) relative to the general population. In fact, 30-50% of people seeking treatment for SUDs have a comorbid diagnosis for PTSD. The severity of stress exposure correlates with greater substance use and this relationship supports a self-medication hypothesis, which posits that drug use is a means to cope with anxiety and reduce PTSD symptoms. Using animal models, we showed a remarkable overlap between the enduring neuroadaptations produced in nucleus accumbens core (NAcore) excitatory transmission after acute stress and drug use. Specifically, we discovered that 3 weeks after a single acute stress (2 hr restraint) glutamatergic synapses on NAcore medium spine neurons (MSNs) show increased AMPA/NMDA ratio and dendritic spine density, and a marked reduction in glial glutamate transporter (GLT-1) expression and function. How these neuroadaptations relate to PTSD symptomology and behavior have not been determined. We paired the stressful event with a novel odor, stress conditioned cue (CS), in male and female rats. Using a defensive burying task with the CS, we found stressed rats spent more time burying the CS and immobile during the session relative to control animals. This increased reactivity to the CS is consistent with maladaptive coping strategy reminiscent of PTSD. We hypothesize that exposure to the CS elicits transient-Synaptic Plasticity (t-SP: evokes transient increased in A/N, dh, matrix metalloprotease (MMPs) activity and adaptations in astroglial processes) similar to that seen following 15 min exposure to drug associated cues. We also found stressed female rats have greater preference for sweet solutions relative to their same sex and male counterparts and, in further work, will determine if this preference is related to stress induced changes in motivation. These experiments have the potential to reveal novel behavioral and neurobiological mechanisms of PTSD that induce the increased vulnerability to SUDs. Understanding this link will enhance our ability for rational drug design to treat comorbid PTSD and SUDs.

Title: Changes in the gut-associated microbiome as a result of exposure to a predator-based psychosocial stress model of PTSD

Authors: *I. F. SMITH[1], C. D. KASLER[1], K. L. KRYNAK[2], P. R. ZOLADZ[1];
[1]Psychology, Sociology, & Criminal Justice, [2]Biol. and Allied Hlth. Sci., Ohio Northern Univ., Ada, OH

Abstract: Recent work has established a relationship between physiological responses to stress and the gut-associated microbiome. Research has also shown that changes in the makeup of the gut microbiome can lead to anxiety-like behaviors. However, work concerning how specific anxiety-related illnesses influence the microbiome is limited. The purpose of the present study was to observe changes in the gut-associated microbiome of Sprague-Dawley rats that had been exposed to a predator-based psychosocial stress model of post-traumatic stress disorder (PTSD). We hypothesized that exposure to this model would lead to significant changes in the composition of the gut-associated bacterial microbiome. Ten male rats underwent a well-validated 31-day PTSD model consisting of two exposures to a cat (each exposure separated by 10 days) and daily social instability, which began on the day of the first cat exposure. Ten additional rats served as controls and were handled daily. Before and after the 31-day paradigm, all rats underwent behavioral testing to assess anxiety-like behavior and symptoms of hyperarousal. Fecal samples were collected weekly from both the stressed and control rats in order to assess gut-bacterial composition. DNA was extracted from these fecal samples, polymerase chain reaction (PCR) was used to amplify the 16S rRNA gene region of bacterial DNA, and terminal fragment length polymorphism (TRFLP) analysis was used to assess differences in gut-associated bacterial composition across treatments. Behavioral analyses revealed that stress significantly increased rats' anxiety-like behavior on the elevated plus maze (EPM) and in the open field and significantly increased rats' startle responses. PERMANOVA results revealed significant main and interactive effects of stress and fecal sample collection time point on gut-microbiota composition. However, bacterial community similarities shown by a non-metric multidimensional scaling ordination did not support our prediction that stress would result in a significant shift in gut-bacterial composition relative to controls. Future work is needed to further elucidate the mechanisms by which gut-associated bacteria interact with stress.

Title: Mir-598-3p mediates susceptibility to stress-enhanced remote fear memory

Authors: *M. E. JONES[1], S. E. SILLIVAN[1], S. JAMIESON[1], G. RUMBAUGH[2], C. A. MILLER[3];
[2]Neurosci., [3]Mol. Med. and Neurosci., [1]The Scripps Res. Inst., Jupiter, FL

Abstract: Post-traumatic stress disorder (PTSD) is a debilitating psychiatric disorder that is exacerbated by persistent, maladaptive traumatic memories. We developed a stress-enhanced fear learning (SEFL) paradigm to examine susceptibility and/or resilience to the development of enhanced fear memories in C57Bl/6J mice. In SEFL, mice exposed to 2 hours of restraint stress seven days prior to cued fear conditioning display an enhanced, extinction-resistant memory relative to non-stressed controls. Further, male SEFL mice display greater variability in memory strength than non-stressed controls, such that two distinct subgroups emerge; stress susceptible (SS; enhanced memory) and stress resilient (SR; memory comparable to controls). Interestingly, stressed females do not cluster into distinct susceptible and resilient subgroups, but rather display a more uniform SS-like phenotype. Enhanced fear memory strength observed in SS males is associated with neurobiological changes known to be associated with PTSD, including enhanced immediate early gene expression (IEG) in the basolateral amygdala (BLA), decreased IEG expression in the prelimbic cortex, and enhanced BLA expression of genes associated with PTSD (i.e. PACAP, BDNF, TH, DRD1/2). Identifying mechanisms governing stress-enhanced fear memory in susceptible mice may identify novel therapeutic targets for the selective disruption of pathogenic memories that contribute to PTSD. To this end, we examined the role of microRNAs (miRNAs) in remote fear memory, which have emerged as potent regulators of learning, recent memory and extinction. We first performed small-RNA sequencing on BLA tissue one month after fear conditioning, without retrieval. mir-598-3p, a highly conserved miRNA, was downregulated by fear conditioning, but elevated in SS males. While further decreasing BLA mir-598-3p levels did not alter the expression or extinction of the remote fear memory in non-stressed mice, intra-BLA inhibition of mir-598-3p interfered with expression and extinction of the remote stress-enhanced fear memory in SS males. This effect could not be attributed to an anxiolytic effect of inhibiting this miRNA in the BLA. Further, BLA mir-598-3p was not differentially expressed in females by SEFL. Consistent with this, intra-BLA inhibition did not alter stress-enhanced fear memory expression in females. Finally, bioinformatic analysis following quantitative proteomics on BLA tissue collected 30 days post-SEFL training identified putative mir-598-3p targets and related pathways mediating the differential susceptibility, with evidence for regulation of the actin cytoskeleton.

Sci., Univ. of California Riverside Sch. of Medic, Riverside, CA

Abstract: Childhood obesity hastens the onset of cognitive and psychiatry morbidity. Emerging evidence from our laboratory indicates that the consumption of diets rich in saturated fatty acids and sugars during adolescence reduces the volume of the hippocampus while heightening emotional reactivity to traumatic stress. However, the mechanisms underlying these structural and functional vulnerabilities are poorly understood. Neuregulin-1 (NRG1) and ErbB receptors play critical roles in hippocampal neurogenesis, maturation, and resilience. Furthermore, genetic studies have demonstrated a link between ErbB4 and metabolic disorders, including obesity. In this study, we aimed to determine whether deficits in NRG1-ErbB4 signaling might be present in the hippocampus of adolescent rats exposed to an obesogenic Western diet (WD). We examined whether chronic NRG1 administration during adolescence increases hippocampal volume, cued learning, and ErbB4 phosphorylation. Lewis rats were randomly divided into four groups (12 rats/group): 1) control diet (CD) + vehicle; 2) CD + NRG1; 3) WD + vehicle; 4) WD + NRG1 (NRG1 intraperitoneal injections: 5 μg/kg/day for 21 days between P21-P41). Behavioral tests and magnetic resonance imaging were performed, and several organs and brain regions were harvested to determine NRG1 effects on ErbB activation and signaling. We found that the rats that consumed the WD exhibited reduced hippocampal volumes (8% reduction relative to CD rats). WD rats exhibited deficits in trace cued fear conditioning (fear-potentiated startle, FPS). Chronic NRG1 administration reduced hippocampal volume (9% reduction relative to vehicle), altered working memory and exploratory behavior (Y-maze), and attenuated FPS responses in CD rats (55% reduction relative to vehicle). Interestingly, NRG1 administration had no effects on hippocampal volume and behaviors in WD rats. Consistent with this observation, the rats that

consumed the WD exhibited a reduction in peripheral NRG1 levels in the liver (33% relative to controls). Further, we found that the mRNA levels of the ErbB4 isoforms JMa (18%) and Cyt1 (32%) were elevated in the hippocampus of WD rats. These data suggest a novel interaction between exposure to obesogenic diets and NRG1-ErbB4 signaling in the maturing hippocampus. In conclusion, our results indicate that NRG1-ErbB4 may contribute to the abnormal hippocampal structure and cognitive vulnerabilities observed in obese individuals.

Title: Activity dependent dissection of lateral septal circuits that control stress susceptibility

Authors: D. ALLEN[1], M. HASHIMOTO[1], D. J. ANDERSON[2], ***T. E. ANTHONY**[1]; [1]Neurobio., Boston Children's Hosp., Boston, MA; [2]Caltech, Pasadena, CA

Abstract: A single traumatic experience is sufficient to induce an acute stress reaction that in susceptible individuals can progress to chronic mental illness lasting months to years. The neural and molecular pathways that control the induction, maintenance, and termination of stress-induced states, and how their dysfunction may lead to persistent affective disorders, have not been clearly defined. Functional mapping and optogenetic manipulations indicate that the pattern and intensity of activity in the lateral septum (LS) during stressor exposure determines the nature and severity of the ensuing behavioral responses. However, the mechanisms by which distinct subsets of stress-activated LS neurons promote susceptibility or resilience are largely unknown. To fill this gap in knowledge, we developed a novel approach for genetic tagging of activated neurons which we call tetracycline-regulated activity-dependent cell marking (TRACM). TRACM combines an immediate early gene promoter-driven doxycycline (DOX)-suppressible transcriptional activator (tTA) with a constitutively expressed DOX-activated transcriptional repressor (rtTS), and yields robust and highly specific genetic marking of acute stress-activated

LS neurons with negligible background in naive home cage controls. Notably, the required genetic elements can be delivered entirely via adeno-associated viral vectors (AAVs), thus enabling activity-dependent neuronal tagging in nontransgenic animals. Optogenetic circuit mapping and *in vivo* fiber photometry calcium imaging indicates that acute stress-activated neurons in anterolateral LS influence behavioral responses to salient environmental stimuli via local intraseptal inhibitory connections as well as through long range projections to medial hypothalamus. To determine whether these stress-activated anterolateral LS neurons promote active or passive coping responses to threat, TRACM-mediated chemogenetic and optogenetic functional studies are ongoing and will be presented.

Title: NR2B mRNA expression decreased in ventral hippocampus after exposure to single prolonged stress trauma, a rodent model of PTSD

Authors: *C. V. CHEN[1], N. RAJARAM[2], I. LIBERZON[1];
[1]Texas A&M Univ., Bryan, TX; [2]Ann Arbor VA Healthcare Syst., Ann Arbor, MI

Abstract: Post-traumatic stress disorder (PTSD) is a chronic, debilitating disorder that can emerge following exposure to a traumatic event. It is the 4th most common psychiatric disorder, with lifetime prevalence in the US at 6.8%. PTSD is characterized by a wide range of symptoms including the impaired extinction of traumatic memory. Although this deficit is a hallmark of PTSD, the underlying mechanisms of impaired extinction is not well understood and existing treatment is not equally effective in all cases. Here we investigated the involvement of NMDA receptors in this deficit. For this, we used the animal model of PTSD, Single Prolonged Stress (SPS). Adult male Sprague Dawley rats were exposed to SPS trauma or not (control) and, after a 7-day quiescent period necessary for the development of symptomatology, rats were euthanized and their brains collected for molecular assays. Rats exposed to SPS trauma showed a decrease in NR2B mRNA expression in the ventral hippocampus, which has been implicated in contextual memory and memory consolidation. Further studies will determine the neuron type that express NR2B and the target of their efferent projections to determine function.

Title: Time-dependent effects of single-prolonged stress on amino acid neurotransmitter levels in rat prelimbic and infralimbic cortices: A magnetic resonance spectroscopy study

Authors: *F. GHODDOUSSI[1], A. HARUTYUNYAN[2,3], S. A. PERRINE[2,3];
[1]Anesthesiol. & Pre-Clinical Magnetic Resonance facility, Wayne State University, Sch. of Med., Detroit, MI; [2]Psychiatry & Behavioral Neurosciences, Wayne State University-School of Med., Detroit, MI; [3]Res. Services, John D Dingell VA Med. Ctr., Detroit, MI

Abstract: **Introduction**: Post-traumatic stress disorder (PTSD) is a costly psychiatric disorder characterized by anxiety, avoidance behavior, and hyper-reactivity to trauma-associated stimuli that affects nearly 25 million people in United States. However, the biological mechanisms underlying this disease are still largely unknown or poorly understood. Considerable evidence indicates that PTSD results from dysfunction in highly-conserved brain systems involved in stress, anxiety, fear, and reward. Single-prolonged stress (SPS) is a pre-clinical rodent model that displays behavioral, molecular, and physiological alterations that recapitulate many characteristics observed in PTSD. Our previous research using proton-magnetic resonance spectroscopy (^{1}H-MRS) has shown that glutamate (Glu) and glutamine (Gln) levels are decreased in the medial prefrontal cortex (mPFC), which is believed to be involved in dysregulation of fear learning and extinction. In this study, we measured levels of GABA, glutamate, and glutamine in sub-regions of the medial PFC, including the pre-limbic (PL) and infra-limbic (IL) cortices, following SPS to determine the time-dependent and sub-regional effects within the mPFC. **Methods:** Levels of GABA, Glu, and Gln were determined using, magic-angle spinning 1H-MRS at 11.7T in PL and IL sub-regions of the mPFC in controls rats and animals subjected to SPS and euthanized 1, 7 or 14 days later. **Results:** Glu level was significantly decreased after 1 day and GABA level was significantly increased 7 days after SPS in PL, with no effect on GLN levels at any of the 3 time points. On the other hand, Glu levels were significantly decreased 1 day after SPS in IL and Gln levels were significantly decreased at 7 & 14 days . GABA levels were unaffected in IL at any of the 3 time points.. **Discussion:** Our data indicate that SPS differentially affects sub-regions of the mPCF, with increased inhibitor

control in the PL and decreased excitatory control in the IL. We speculate that this differential sub-regional effect is critical in top-down control of mPFC to amygdala and striatum and inherently involved in the dysregulated fear and reward behaviors observed in PTSD.

Title: Differential brain activity in response to trauma in a predator scent stress rat PTSD model

Authors: *D. DOPFEL[1], C. MESSNER[1], N. ZHANG[2];
[1]Pennsylvania State Univ., University Park, PA; [2]The Pennsylvania State Univ., University Park, PA

Abstract: Post-traumatic stress disorder (PTSD) is caused by an initial traumatic experience. However, only a subset of those who experience trauma will go on to develop PTSD. Individual variability in the perception of that trauma is known to play a role in the likelihood of future PTSD development. Work in our lab suggests this is also true in the predator scent stress rodent model of PTSD, supporting that there is individual variability of functional responses to traumatic experiences. Therefore, understanding the response to trauma is important in the study of PTSD susceptibility. Here, we characterize brain regions that are critical in stress perception and response by exploring brain activity, through BOLD fMRI, during the trauma itself.
We exposed awake Long Evans rats to fox urine during fMRI scans with a total fox urine exposure time of 10 minutes, consistent with our previous study, alternating between scented and unscented airflow. Elevated plus maze was then performed 7 days post-exposure to assess PTSD-like symptomology, which showed a general decrease in open arm exploration in the fox urine exposed animals.
The fMRI data supports that the activity of several brain regions, e.g. the pituitary and retrosplenial cortex, are differentially influenced by fox urine airflow, compared to lemon and unscented airflow. Further work will assess the variations in this response given baseline resting state functional connectivity and long-term PTSD-like symptom assessment. This will determine brain regions that are crucial in stress perception, the stress response and in PTSD susceptibility.

Title: CBD effects on measures of anxiety and depression in a preclinical model of post traumatic stress disorder

Authors: C. N. MULTON, D. C. COOPER, *T. E. KOELTZOW;
Bradley Univ., Peoria, IL

Abstract: The cannabis industry in the US has experienced tremendous growth in recent years, in part due to a more permissive regulatory environment. The availability of cannabidiol (CBD) in a variety of commercial products has fueled consumer experimentation as a dietary supplement for a variety of ailments. There is growing interest in the potential for CBD to provide therapeutic efficacy across numerous pathologies related to inflammation, metabolism and mental health, like anxiety and Post-Traumatic Stress Disorder (PTSD). The first objective of the study evaluated the therapeutic potential of CBD on measures of anxiety and depression. We administered CBD doses (0-5 mg/kg, i.p.) and measured open field activity, elevated plus maze, forced swim and nocturnal locomotor activity in adult, male rats (Sprague-Dawley, 200-225 g, n=8 per condition). CBD increased exploration of the open arms of the elevated plus maze without evidence of deleterious effects across the dose range. The second objective assessed the effects of CBD in male, adolescent rats (Sprague-Dawley, Post-natal day 30-34) to a modification of the single prolonged stress (SPS) model (Liberzon et al., 1999) of PTSD. Rats were randomly assigned to the SPS (two hours restraint stress, 20 minutes forced swim, CO2-induced loss of consciousness, n=16) or sham control (n=22). Antecedent results indicate that SPS decreases the number of open arm entries ($F(1,37) = 5.32$, $p = 0.013$, $d = 0.63$) when tested two weeks later. In contrast, SPS increased spontaneous locomotor activity ($F(1,37) = 10.01$, $p = 0.002$, $d = 1.89$). The final phase of the experiment delivered CBD immediately following SPS induction to assess its ability to ameliorate PTSD-related symptoms. Findings suggest a role for CBD in the treatment of anxiety and depressive symptoms related to PTSD.

Title: Individual resilience or vulnerability to traumatic-stress exposure based on behavioral profile and subsequent ethanol drinking predicted by machine learning

Authors: *R. R. DENNY[1], E. M. UNTERWALD[2];
[1]Temple Univ. Lewis Katz Sch. of Med., Philadelphia, PA; [2]Dept Pharmacol & Ctr. Sub Abuse Res., Temple Univ. Sch. of Med., Philadelphia, PA

Abstract: Post-traumatic stress disorder (PTSD) begins by traumatic-stress exposure and develops into several symptoms including persistent memories and increased sympathetic nervous system arousal. PTSD is also highly co-morbid with alcoholism. The present study investigated individual differences to traumatic-stress and subsequent ethanol consumption. A rat model of traumatic stress, single prolonged stress (SPS), was used in young adult female rats. This modified SPS model included restraint stress, forced swim, and isoflurane exposure followed by 7 days of isolation. After traumatic-stress exposure, rats were behaviorally characterized with elevated plus maze, open field, and cue-reactivity. It was hypothesized vulnerable rats would exhibit both enhanced anxiety-like behaviors and ethanol consumption compared to resilient and control rats. Open field time in center and elevated plus maze number of open arm entries after traumatic-stress were the most predictive of subsequent ethanol consumption. Using a machine learning, individual rats were identified as vulnerable, resilient, or neither based on their open field time in center and elevated plus maze number of open arm entries with 75% accuracy ($P < .00001$). Vulnerable rats had increased anxiety-like behaviors on open field time in center ($P < .0001$), elevated plus maze number of open arm entries ($P < .0001$), and consumed significantly more ethanol compared to resilient rats ($P = .0018$). Overall, these data indicate behavior after traumatic-stress exposure predicts subsequent ethanol consumption. Future studies will use behavioral scores predicting ethanol consumption to investigate neurochemical alterations leading to enhanced ethanol consumption. Title: The adult consequences of trauma exposure are dependent upon developmental period and sex

Authors: *G. I. ELMER[1], C. L. MAYO[1], D. B. BELL[1], J. D. TAPOCIK[2], P. D. SHEPARD[1]; [1]Maryland Psychiatric Res. Ctr., Univ. of Maryland, Baltimore, Baltimore, MD; [2]NIAAA, NIH, Bethesda, DC

Abstract: Childhood trauma dramatically increases the risk of adult psychiatric illness and significantly alters symptom complexity and treatment outcome - it is a pervasive theme in mental illness. Stress can differentially impact CNS function depending upon the type of stressor (psychic, physical, physiological), its relevance to the rodent and controllability. In addition, differences in the neurodevelopmental timing and sex likely impacts the neurobiological and behavioral outcomes. The purpose of this study was to explore the consequences of live-predator trauma during different neurodevelopmental periods in male and female rats.

We have developed a live predator paradigm (snake) with the proposition that a highly salient, ethologically-relevant trauma will engage the nervous system in a manner relevant to studies of psychiatric disorders. The paradigm directly exposes the subject in close contact with the snake yet prevents physical harm. Male and female Wistar rats were exposed to a snake (rat, corn, small python; all 60-100cm long) for 10 min by placing rats in a perforated restrainer tube within a larger arena that holds the live snake. Rats were exposed to live predator (or left in home cage as control) in one of four conditions: A) post-natal days (PND) 31, 45 and 61, B) PND 31, 33, and 36, C) PND 45 and 61, D) PND 61. Since we have no *a priori* reason to suspect specific behavioral consequences for each constellation of trauma exposures we characterized a range of behavioral endpoints in a standardized test battery. The tests include exploratory behavior, sucrose preference, elevated plus maze, t-maze reaction, novelty suppressed feeding, cold pain and learned helplessness (n = 6-12 per condition and sex). Subjects were run at PND 75 in order to assess enduring effects.

The consequences of live-predator exposure were dependent upon the timing during the neurodevelopmental period and sex of the subject. In general, early trauma, conditions A and B versus C and D, had a greater impact as characterized by the number of behavioral endpoints affected (e.g. exploratory behavior, novelty suppressed feeding, learned helplessness). For some behavioral endpoints, a sex X trauma (control vs snake) interaction was observed wherein

opposite effects of the predator exposure were seen. Further investigation is required to identify differences in the neurobiological consequences of trauma exposure at different time frames, the influence of the subject's sex on these variables and the differences between resilient and susceptible subjects. Understanding these differences will help to identify causal factors and potential biomarkers for psychiatric illness.

Abstract: Aims: To test if cannabidiol (CBD), a non-psychotomimetic component of *Cannabis sativa with anxiolytic properties,* could prevent the changes in fear processing induced by severe stress. We also investigated possible mechanisms of this effect. Methods: Male Wistar rats were exposed to single prolonged stress (SPS), a model of PTSD. Fear sensitization and impaired extinction of conditioned fear were evaluated one week later. Starting 2-h after SPS, the animals were treated daily with vehicle, paroxetine (5-20mg/kg) or CBD (2.5-10mg/kg) for 7 days. In a second experiment, a 5-HT_{1A} (WAY100635, 0.3 mg/kg) or CB_1 (AM281, 0.5mg/kg)-receptor antagonist was administered 30 minutes before CBD (5 mg/kg). Twenty-four-h after the last drug injection, the rats were submitted to the contextual conditioned fear procedure (three random electric footshocks, 0.35mA/2s). Fear sensitization and extinction were assessed in two distinct sessions in the next 48 h. The brain levels of phosphorylated neuronal NO synthase enzyme

(pnNOS) were measured at different time points after stress. Results: SPS induced fear sensitization (increased freezing in the first context re-exposure) and impaired fear extinction ($p<0.05$). Paroxetine (10mg/kg) and CBD (5 and 10mg/kg) attenuated these effects. CBD effects were abolished by pre-treatment with WAY100635 or AM281. Increased pnNOS expression in the ventral hippocampus was observed 1h after SPS ($p<0.05$), but not later. Conclusions: CBD attenuates stress-induced impairment in fear processing by facilitating 5-HT_{1A} and CB_1-mediated neurotransmission. Moreover, the stress-induced changes in behavioral responses were associated with early modifications in the nitrergic system. Financial support: FAPESP, CNPq

Title: Post-traumatic stress disorder (PTSD)-like phenotype in female rats

Authors: K. ALEXANDER[1], R. NALLOOR[2], K. BUNTING[2], *A. I. V. VAZDARJANOVA[3,1]; [1]Pharm&Tox, [2]Augusta Univ., Augusta, GA; [3]Charlie Norwood VA Med. Ctr., Augusta, GA

Abstract: Post-Traumatic Stress Disorder (PTSD) is associated with cognitive deficits in humans as well as in rodent models of PTSD using emotional trauma. Our lab has developed a predictive model of PTSD, the Revealing Individual Susceptibility to PTSD-like Phenotype (RISP) model, in which rats are classified as Susceptible, Resilient or Intermediate based on their pre-trauma startle and anxiety-like behavior. We have shown that impairments in learning and memory exist in Susceptible rats prior to trauma and are associated with developing a PTSD-like phenotype after exposure to trauma. However, this model was developed in male rats and the same parameters are not predictive of PTSD-like phenotype in female rats as they do not consistently show the same fear responses as male rats, i.e. freezing. While the literature reports many differences in males and females in terms of fear and stress response, there is no PTSD-phenotype that can be used to study PTSD pre-clinically. Thus, we explored other measures of fear behavior in female rats and found that avoidance, instead of freezing, is a reliable measure of fear behavior and along with increased acoustic startle response and increased anxiety-like behavior can be characterized as a PTSD-like phenotype in female rats.

Title: Sex differences in fear conditioned-induced alternative splicing events in mouse hippocampus

Authors: *S. I. LOMBROSO, S.-J. XU, E. A. HELLER;
Dept. of Systems Pharmacol. and Translational Therapeut., Univ. of Pennsylvania, Philadelphia, PA

Abstract: Posttraumatic stress disorder (PTSD) is characterized by persistent disturbing thoughts and symptoms related to a traumatic experience (APA, 2018). It is estimated that one in 11 adults will be diagnosed with PTSD in their lifetime (DSM-5, 2013). While many people experience traumatic events, only a small subpopulation develop PTSD (Puhan et al., 2017). This, along with twin studies, has supported the hypothesis that there are heritable components of PTSD (Taylor et al., 2010). Furthermore, it has recently been shown that females present with PTSD nearly twice as often as males (Tolin & Foa, 2006). Yet, little is known about mechanisms underlying sex-differences of prevalence and presentation of PTSD. Fear conditioning is frequently used as a model of inducible PTSD (Puhan et al., 2017a). While this paradigm does not recapitulate all aspects of PTSD, it does model aberrant fear-memory behavior (Lubin, Roth, & Sweatt, 2008; Peixoto et al., 2015) and . can be used to measure sex-specific behavioral and transcriptional effects of fear-memory (Sase et al., 2019). In this study we examine the effect of fear conditioning on alternative splicing in both male and female hippocampus. We hypothesize that sex-differences in alternative splicing may underlie differences in fear-memory. First, we analyzed global transcriptome data (Poplawski et al., 2016) from hippocampus of 8-week old, male C57BL/6J mice following fear conditioning using Modeling Alternative Junction Inclusion Quantification (MAJIQ). We identified 770 alternatively spliced junction sites in fear conditioned animals relative to their home cage controls. Using PCR, we validated a subset of these loci in an independent cohort including splice sites within Il1rap, clk1, and cpsf4. We quantified the isoform inclusion ratio at these genes and found that the splice profiles were significantly different across sex after fear conditioning. These data suggest that splice isoform ratio modulates freezing behavior in a sex-specific manner.

Title: Suvorexant reverses stress induced psychosis-like behavior in a rodent model of PTSD

Authors: *H. ELAM, J. DONEGAN, A. BOLEY, D. LODGE;
Pharmacol., UT Hlth. San Antonio, San Antonio, TX

Abstract: Post-traumatic stress disorder (PTSD) is a prevalent condition within the United States veteran population. Not only are approximately 20% of veterans affected by this debilitating condition but 80% of these individuals have comorbid psychiatric illness, including psychosis. A large body of literature has demonstrated a positive correlation between symptoms of psychosis and increases in dopamine neuron activity. Previous data from our lab has demonstrated potential circuits that regulate dopamine neuron activity and mediate psychosis, including projections from the paraventricular nucleus of the thalamus (PVT). Specifically, we have shown that inactivating the PVT leads to a reversal in aberrant dopamine system function. The PVT receives strong innervations from orexin/hypocretin containing neurons, making these neurons a novel target for pharmacological interventions in the treatment of PTSD and comorbid psychosis. Antagonizing these neurons may be a novel approach to reduce PVT activity and subsequently reduce dopamine neuron activity. Using the FDA-approved, orexin receptor antagonist, Suvorexant, we examine changes in psychosis-like behavior in a rodent model of PTSD. In this study, we model PTSD in male rats, using a two-day, inescapable foot shock procedure, to induce psychosis-like behavior. Following inescapable shock, administration of Suvorexant was found to reverse deficits in multiple behavioral correlates of psychosis, including pre-pulse inhibition of startle (PPI), latent inhibition (LI), and MK-801 induced locomotor response. These results suggest that Suvorexant may be a novel pharmacological intervention in the treatment of PTSD and comorbid psychosis.

Title: Modeling gender difference in PTSD with female rats

Authors: *Q. LI, D. DOPFEL, N. ZHANG;
Penn State Univ., State College, PA

Abstract: PTSD (Posttraumatic stress disorder) is a psychiatric disorder which affects about 3.5% of all adults in U.S. Evidence shows women are twice as likely as men suffering this disease. Thus, one of the risk factors of PTSD is gender. Nowadays, most animal models of PTSD are based on males while studies on females are underexplored. Here we studied the predator scent model of PTSD in female rats and examine the sex difference in the model. Fox urine exposure is used to induce PTSD in female rats. Behavior tests, including elevated zero maze (EZM), black-white box, startle response, novel social and novel physical tests, were conducted before and 7 days after fox urine exposure. The fear conditioning and fear extinction paradigms were also used. The results showed an opposite effect of fox urine exposure on anxiety between female and male rats. Future work will focus on imaging functional connectivity between stress related brain regions using fMRI.

Title: Delivery of vaporized nicotine: Effects of gender, dose, and weekly nicotine exposures on behavioral and physiological measures

Authors: *C. MARSTON[1], S. C. HONEYCUTT[2], P. I. GARRETT[2], T. M. HILLHOUSE[2]; [1]Psychology & Neurosci., Weber State Universtiy, Ogden, UT; [2]Psychology & Neurosci., Weber State Univ., Ogden, UT

Abstract: Over the last decade, usage of electronic nicotine delivery systems (ENDS), has seen a substantial increase with approximately 15.4% of the American adults had tried ENDS products and that 3.8% of adults (5.5 million people) were regular users. Moreover, approximately 20.8% of all teenagers (middle school and high school) reported regular ENDS use. Unlike combustible cigarettes, ENDS provides a discretionary amount of nicotine to the user that has made establishing a clear relationship between the amount of vaporized nicotine ingested and behavioral changes difficult to measure. The present study sought to understand how vaporized nicotine dose and number of nicotine exposures per week would differentially impact behavioral and physiological changes between male and female mice. An e-Vape^{TM} system was used to administer vaporized nicotine in which a three second puff was delivered every two mins for 10 mins (6 puffs total). Body temperature was measured before and after administration of vaporized nicotine. Immediately after nicotine administration mice were placed in a standard open field arena and locomotor activity was measured for 20 mins. Overall, we found effects of gender and nicotine exposure. Specifically, male mice with once a week exposure to nicotine had significantly less distance traveled at all doses and significantly less time spent in the center of the open field at 3.0 and 10 mg/ml vaporized nicotine as compared male mice with twice a week exposure. Additionally, once a week exposure significant increased body temperature in male mice at 1.0, 3.0, and 30.0 mg/ml nicotine doses. There was not a significant effect in distance traveled for female mice; however, female mice with once a week exposure to nicotine had significantly more time spent in the center of the open field at 30 mg/ml of vaporized nicotine. Overall, vaporized nicotine dose-dependently increase body temperature in female mice. These results indicated dissociable behavioral and physiological effects following administration of vaporized nicotine in mice that vary based on gender, nicotine exposure per week, and nicotine dose.

Title: Repeated vaporized nicotine administration induces behavioral sensitization in C57BL/6 mice

Authors: *S. C. HONEYCUTT, P. I. GARRETT, A. G. BARRAZA, A. N. MALOY, T. M. HILLHOUSE;
Psychology & Neurosci., Weber State Univ., Ogden, UT

Abstract: Nicotine administration via tobacco products (e.g. cigarettes, chew tobacco, etc.) has been well established as a drug of abuse. Preclinical experiments have used various methods of administration to evaluate the abuse-related and behavioral effects of nicotine (e.g. intravenous, injection, smoke-inhalation); however, there are limited data on the abuse-related effects of vaporized nicotine in rodents. The present study sought to evaluate the abuse-related effects of vaporized nicotine in male and female mice using a behavioral model of nicotine sensitization. Mice were habituated to locomotor activity chambers for three days. Following habituation, mice were administered with nicotine (0.5 mg/kg, i.p.) or vaporized nicotine (0-10.0 mg/ml) for five consecutive days and locomotor activity was measures for 30 mins each day immediately after nicotine administration. An e-Vape^{TM} system was used to administer vaporized nicotine in which a three second puff was delivered every two mins for 10 mins (6 puffs total). A nicotine challenge test was conducted following a seven day withdrawal period. Additionally, body temperature was assessed each day. The positive control 0.5 mg/kg nicotine (i.p.) produced sensitization by significantly increase locomotor activity on days 3-5. Vaporized nicotine produced a dose-dependent (0-3.0 mg/ml) sensitization effect with the most significant sensitization found at 3.0 mg/ml. Treatment with 3.0 mg/ml vaporized nicotine decreased body temperatures on days 2 and 4 for male mice, but has no significant effect on female mice. Treatment with 1.0 mg/ml vaporized nicotine produced sensitization and significantly lower average body temperatures on day 1 for both genders. Treatment with 10.0 mg/ml vaporized nicotine and vehicle vapor (0.0 mg/mL nicotine) had no effect of sensitization or body temperature changes. No significant gender effects were found on behavioral sensitization for injected or vaporized nicotine. Treatment with 0.5 mg/kg (i.p.) and 3.0 mg/ml vaporize nicotine produce a significant increase in locomotor activity on the nicotine challenge day, while the other doses failed to alter locomotor activity on the challenge day. These results suggest that vaporized nicotine produces abuse-related effects in an inverted U-shaped curve for male and female mice that is similar to other routes of nicotine administration. Additionally, the nicotine doses and administration regimen use in the present study provides a foundation for future studies to evaluate the abuse-related, behavioral, and health risk effects of vaporized nicotine.

Title: Effects of nicotine enhanced incentive stimuli on dopamine release in the nucleus accumbens shell and cocaine demand in rats

Authors: *C. T. MAJORS[1], D. HARRYMAN[2], C. E. PONDER-CEPEDA[3], C. A. BRADLEY[5], A. L. SMITH[4], G. A. DEEHAN, JR[2], M. I. PALMATIER[1];
[2]Psychology, [3]Exptl. Psychology, [1]East Tennessee State Univ., Johnson City, TN; [4]Biol., East Tennessee State Univ., Elizabethton, TN; [5]Psychology, Bridgewater Col., Bridgewater, VA

Abstract: Nicotine is one of the most widely used drugs, and experimentation with nicotine typically precedes other drugs of abuse. We have previously shown that nicotine increases responding for primary reinforcers and produces long-lasting changes in the salience of environmental cues that predict reward (incentives). We have hypothesized that these incentive amplifying effects of nicotine increase the release of mesolimbic dopamine (DA) evoked by incentives. The goal of the present studies was to test the hypothesis that nicotine increases incentive-evoked DA release in the nucleus accumbens (NAc) and that nicotine-enhanced incentives promote behaviors that depend on mesolimbic DA release (cocaine self-administration). To investigate these hypotheses, rats were randomly assigned to one of two groups NIC (0.4 mg/kg base) or SAL (placebo), n=15/group. Each group received a subcutaneous injection of their assigned solutions 15 min before Pavlovian conditioned approach (PCA) testing. In each 1-hour PCA session rats received pairings between a conditioned stimulus (CS; lever extension and cue light illumination) and presentation of an unconditioned stimulus (US; 0.1 ml of 20% sucrose). Following 19 PCA acquisition sessions, rats were separated into two experiments. In Experiment 1, rats were instrumented for IV cocaine self-administration and, after learning to respond at the PCA lever for cocaine infusions (0.16 mg/infusion) were subjected to a within-session economic demand manipulation in which cocaine price was increased by systematically reducing infusion duration and thereby cocaine dose. In Experiment 2, rats were instrumented with an intracranial canula targeting the NAc shell for DA microdialysis and were subsequently tested with 3 exposures to the CS after nicotine or placebo injection. Rats pretreated with nicotine during the PCA sessions exhibited greater sign tracking behavior (approach to the CS) relative to saline pretreated rats which exhibited a bias toward approaching the US location (goal tracking). In Experiment 1, there was increased demand for cocaine when it was self-administered with a NIC-enhanced incentive (NIC group), relative to a non-NIC-enhanced incentive (e.g., SAL group). Dopamine samples are being analyzed from Experiment 2; however, preliminary evidence suggests that nicotine pretreated rats will have elevated levels compared to controls. These results indicate that nicotine has potent and long-lasting effects on incentive stimuli and increases mesolimbic DA release evoked by these stimuli in the NAc. The long-lasting nature of this effect may have implications for nicotine as a gateway drug.

Title: Concurrent infusion of lithium chloride reduces nicotine self-administration in rats

Authors: D. C. HARRYMAN[1], C. E. PONDER-CEPEDA[1], C. T. MAJORS[1], A. L. SMITH[2], *M. I. P. PALMATIER[1];
[1]East Tennessee State Univ., Johnson City, TN; [2]Biol., East Tennessee State Univ., Elizabethton, TN

Abstract: Nicotine is considered the most addictive drug in the world and the negative health consequences of self-administering nicotine in tobacco contribute to almost 500,000 deaths annually. While smoking cessation aides remain an important avenue for improving public health, currently there are few cessation aides that are effective at promoting abstinence rates above 20% beyond 12 months after quitting. However, an alternative cessation strategy may be 'counterconditioning' in which the chemosensory stimuli associated with smoking are given negative visceral meaning via aversion conditioning. Activation of the chemoreceptor trigger zone (CTZ) has been shown to reduce responding for gustatory cues (conditioned taste aversion) and rewarding stimuli (sucrose). Activating this system in conjunction with nicotine self-administration may reduce responding for nicotine and promote 'disgust' reactions to tobacco flavors and additives. In order to test this hypothesis 13 Sprague-Dawley rats were instrumented for both intravenous nicotine and subcutaneous lithium chloride (LiCl) self-administration. Following recovery, rats were allowed to self-administer nicotine in one of two ways. For the gustatory group (GUST, n=10) two sipper tubes connected to lickometers and solenoid valves were available. Meeting the schedule of reinforcement on the active sipper tube resulted in delivery of blueberry flavored solution (0.25% v/v) orally and intravenous (IV) nicotine (15 ug/kg/infusion). After stable responding for nicotine was observed, rats began the counterconditioning phase in which LiCl (0.3 mEq/kg) were infused subcutaneously (sc) with each IV nicotine infusion and blueberry flavor presentation. After responding stabilized, sc LiCl was replaced with sc saline (0.9% w/v). For the lever group (LEV, n=3) similar procedures were used but no oral/flavor reinforcer was presented and nicotine was self-administered for meeting the schedule of reinforcement at a lever rather than sipper tube. For both groups, nicotine was self-administered at comparable rates by the end of acquisition. Both LEV and GUST groups earned similar numbers of nicotine infusions on each test session. Infusions of LiCl with nicotine robustly reduced responses and reinforcers earned in both LEV and GUST groups. Further, replacing LiCl with saline resulted in re-acquisition of nicotine self-administration. Reacquisition rates did not differ between the LEV and GUST groups. Activation of the CTZ robustly and

reliably reduced nicotine self-administration. Our findings do not suggest that this approach produces a long-term effect on gustatory cues associated with nicotine.

Title: Concurrent self-administration of nicotine and alcohol in an operant lick model

Authors: M. I. PALMATIER, **M. M. KOSKY**, D. HARRYMAN, C. T. MAJORS, C. A. BRADLEY, *G. A. DEEHAN, JR;
Psychology, East Tennessee State Univ., Johnson City, TN

Abstract: Nicotine (NIC) and alcohol (ETOH) are widely co-used and people with alcohol use disorders (AUDs) smoke tobacco at higher rates than in the general population. In preclinical studies, NIC injections enhance ETOH drinking and increase responding for non-drug rewards (e.g., sucrose). However, in preclinical models of co-use, concurrent access to self-administered NIC and ETOH moderately reduces operant responding for each reinforcer, compared to groups responding for one or the other. This finding is at odds with human co-use, but fits the prediction of operant concurrent choice models (e.g., matching law). Previous studies have not modeled changes in demand that may drive increases in responding over time. We predicted that the reinforcement enhancing effects of NIC represent an increase in reinforcer demand and would promote ETOH consumption as the price of ETOH increased. Alcohol preferring (P) rats were instrumented for IV self-administration and assigned to one of three groups (NIC, ETOH, or NIC+ETOH). During testing, each rat had access to two sipper tubes attached to a lickometer and fluid delivery solenoid. For ETOH and NIC+ETOH rats, meeting the schedule of reinforcement at the ETOH sipper tube resulted in delivery of 0.1 ml of ETOH (15%, v/v) into the sipper tube; for NIC rats meeting the schedule of reinforcement at this sipper tube resulted in delivery of tap water. For NIC and NIC+ETOH rats, meeting the schedule of reinforcement on the alternative sipper tube resulted in delivery of an intravenous (IV) NIC infusion (7.5 ug/kg/infusion) and 0.1 ml of a neutral flavored solution (e.g., 0.25% blueberry extract) delivered orally into the sipper tube. For ETOH rats, meeting the schedule of reinforcement on this sipper tube resulted in oral tap water. After stable responding was observed, the price of NIC was increased from a fixed ratio of 2 (FR2) to FR15, with at least 3 days of testing at each price. In a subsequent experiment, a higher dose of NIC was used (15 ug/kg/infusion) and the price of ETOH was increased from FR2 to FR15. Non-linear regression was used to estimate economic

demand parameters (essential value and elasticity) of NIC or ETOH as the price of each reinforcer increased. Preliminary evidence suggests that concurrent access to NIC significantly increases demand for oral ETOH, relative to rats responding for ETOH alone. Surprisingly, concurrent access to ETOH also significantly increased demand for NIC relative to rats responding for NIC alone. Neither ETOH nor NIC changed the essential value of the alternative. Thus, the effects of ETOH and NIC appear to mutually enhance demand for one-another when both are concurrently available.

Title: Metabolic changes in mice nucleus accumbens following acute IP injection of menthol

Authors: *O. DEHKORDI[1], P. WANG[2], S. LIN[2], R. M. MILLIS[4], M. I. DÁVILA-GARCÍA[3]; [1]Neurol., [2]Radiology, [3]Pharmacol., Howard Univ., Washington, DC; [4]Med., American Univ. of Antigua, Coolidge, Antigua and Barbuda

Abstract: Menthol, a commonly used flavoring additive in cigarettes, has been found to facilitate smoke initiation and nicotine addiction. Much work has been carried out to study how menthol affects gene expression and functional changes of nicotinic acetylcholine receptors (nAChRs) in the reward-addiction pathways. However biochemical and metabolomics consequences of menthol interaction with nAChRs and other receptors in the immediate milieu of ventral tegmental area and nucleus accumbens (NAcc) is not known. In the present study, we applied in-vivo ^{1}H NMR spectroscopy-based metabonomic approach to investigate the changes of cerebral metabolites in the NAcc of mice subjected to acute IP injection of menthol (100mg/kg). The data were obtained using a 9.4T Bruker AVANCE 89mm bore NMR machine and the localized ^{1}H spectra were obtained and processed by LCModel software. The region of interest (ROI) size for NAcc was 3.0×1.0×1.0 mm^3 and extended from 0.85 mm to 1.93 mm relative to bregma. The concentrations of neurometabolites were analyzed with respect to the summed concentration of creatine and phosphocreatine (Cr+PCr) and the results with a standard deviation (Cramér-Rao lower bound) of < 20% were considered acceptable for inclusion in the

statistical analysis. Multiple neurotransmitters and/or their metabolites were detected in NAcc including glutamate (Glu), glutamine (Gln) inositol, taurine, choline, Cr, PCr, and N-acetyl aspartate. Our results showed that menthol induced a significant decrease in the Glu/Cr+PCr and the Glu+Gln/Cr+PCr ratio in the NAcc compared to control ($p < 0.05$). Glutamatergic signals in NAcc are known to play an important role in addiction-related behaviors. It remains to be determined if menthol-induced disturbances in glutamatergic transmission contributes to enhanced nicotine addiction in mentholated cigarettes.

Title: Inverse agonists of the 5-HT2a receptor reduce nicotine withdrawal signs in rats

Authors: *D. H. MALIN[1], M. HENCEROTH[2], S. GADAM[3], J. R. CAMPBELL[4], J.-N. MA[5], P.-H. TSAI[2], J. C. KISHBAUGH[2], E. S. BURSTEIN[6];

Abstract: Previous research has shown that chronic nicotine administration causes adaptive changes in 5-HT2A receptor expression. Based on this relationship, it was hypothesized that inactivating 5-HT2A receptors with the inverse agonists pimavanserin and volinanserin (MDL100907), would reduce the behavioral signs of nicotine withdrawal syndrome. Sprague-Dawley rats were rendered nicotine-dependent by subcutaneous infusion of nicotine bitartrate, 9 mg/kg/day for seven days. The infusions were then terminated, and 22 hours later, rats were observed under “blind” conditions for somatically expressed behavioral nicotine withdrawal signs. One hour before observations, the morphine dependent rats were injected i.p. with saline alone, or either 0.3 or 1.0 mg/kg pimavanserin in saline. Total withdrawal signs were reduced in a dose-dependent manner. A one-way ANOVA (total withdrawal signs as a function of dose) was highly significant, as was the descending linear trend of withdrawal signs as a function of dose. The 1.0 mg/kg dose reduced withdrawal signs nearly to the level exhibited by a comparison group of non-dependent rats injected with saline. A second experiment was conducted in a similar manner, which showed that that volinanserin at 1.0 mg/kg but not 0.25

mg/kg also reduced nicotine withdrawal signs to nearly the level of non-dependent rats. *In vitro* experiments demonstrated that both pimavanserin and volinanserin potently antagonize 5-HT2A receptors, with approximately 25-fold, and 300-fold selectivity over 5-HT2C receptors, respectively. The results suggest that 5-HT2A receptor activity contributes to nicotine withdrawal syndrome, and thus represents a promising target for interventions to aid smoking cessation.

Abstract: Nicotinic agonists play important role in studying addiction, withdrawal, neuroprotection, cognitive behavior, and neural pharmacology. Previous work with nicotine showed that, in addition to undoubted actions on the plasma membrane such as receptor activation and desensitization, pharmacological chaperoning by nicotine, and probably by other agonists, begins intracellularly in organelles such as the endoplasmic reticulum (ER). Previous work also showed that nicotine and varenicline enter the ER. We now report genetically encoded fluorescent biosensors for related nicotinic agonists cytisine, dianicline, and 5-Iodo-A-85380,

which allow comparisons among subcellular pharmacokinetics of nicotinic drugs.
Our sensors utilize OpuBC, a monomeric bacterial periplasmic binding protein (PBP), which contains (a) a binding site for amines including a cation-π box, and (b) ligand-induced "Venus flytrap" conformational change invoked by binding of target ligand. We inserted circularly permuted "superfolder" GFP (cpGFP), flanked by several-residue linkers, within inter-domain hinge regions and applied directed evolution, including X-ray crystallography, to optimize sensing for each drug of interest.
Our iDrugSnFRs ("**i**ntensity-based **Drug**-**S**e**n**sing **F**luorescent **R**eporters") can detect their drug partner with responses of $\Delta F/F0 > 1$ at 1 μM. Using targeting and retention sequences we direct the constructs to the ER or to the PM of clonal mammalian lines and cultured neurons. Live-cell video imaging shows that the kinetics of ER entry/exit differ amongst these nicotinic drugs by > 10-fold.
These differences provide additional insights into aspects of nicotinic agonists, pharmacokinetics, organellar sequestration of drugs by acid trapping, protein trafficking and upregulation—all crucial facets in the expanded understanding of "inside-out" neuropharmacology of neural drugs.

Title: Role of trace-amine-associated receptor 1 in nicotine withdrawal

Authors: *R. WU, J. LIU, B. N. JOHNSON, J.-X. LI;
SUNY At Buffalo, Buffalo, NY

Abstract: Smoking tobacco is a public health burden globally. Nicotine is one of the most addictive components in tobacco. However, it remains a major challenge to develop more efficacious therapies for nicotine addiction. Trace-amine-associated receptor 1 (TAAR1) has emerged as a target for the modulation of dopaminergic activity. We recently found that TAAR1 activation decreased nicotine-induced dopamine release in NAc and attenuated nicotine self-

administration and reinstatement of nicotine-seeking. Nicotine withdrawal-associated negative reinforcement also contributes to development of nicotine addiction. In the present study, we aimed to study the role of TAAR1 in nicotine's withdrawal effects. Rats were divided into three groups: saline, short-access nicotine (ShA, 1h/d) and long-access (LA, 21h/d) nicotine (0.03mg/kg/infusion). After one week acquisition of nicotine self-administration, the training session of LA group was increased to 21 hours per day, while the ShA group maintained with 1 hour per day. We assessed nicotine withdrawal-induced withdrawal signs, anxiety-like behaviors and hyperalgesia. We showed that the LA group of rats developed significant mecamylamine-precipitated withdrawal signs, spent less time in open arms of the elevated plus maze, and hyperalgesia in the Von Frey test. We found that selective TAAR1 agonist RO5263397 attenuated mecamylamine-precipitated withdrawal signs, anxiety-like behavior, and hyperalgesia in nicotine withdrawal rats. Taken together, our results indicated that activation of TAAR1 attenuates nicotine withdrawal, suggesting that TAAR1 is a promising target for the treatment of nicotine addiction.

Title: Nicotinic acetylcholine receptors in the interpeduncular nucleus regulate nicotine consumption

Authors: *S. MONDOLONI[1], C. NGUYEN[1], R. DURAND DE-CUTTOLI[1], N. TORQUET[1], F. MARTI[1], S. TOLU[1], S. PONS[2], U. MASKOS[2], P. FAURE[1], A. MOUROT[1];

Abstract: Nicotine, the main addictive component of tobacco, targets brain nicotinic acetylcholine receptors (nAChRs), which are pentameric ligand-gated cation channels. In the brain, nAChR subunits of the α (α2-10) and β (β2-4) subtypes co-assemble to form a high combinatorial diversity of receptors with distinct properties, localizations and functions [1]. Chronic nicotine consumption modifies the activity and expression levels of nAChRs and consequently the activity of various neuronal networks. The habenulo-interpeduncular (mHb-IPN) axis has recently emerged as a central pathway involved in nicotine addiction, and most

notably in nicotine consumption, withdrawal, and aversion [2, 3]. This pathway contains the highest density and diversity of nAChRs in the brain, including rare subunits such as α3 and β4. It is formed by glutamatergic and cholinergic neurons of the mHb that exclusively project to the IPN, a GABAergic nucleus. However, the long-term molecular and cellular adaptations triggered by nicotine in the Hb-IPN axis are unknown, making it difficult to interpret the role of this pathway in nicotine addiction. Here we used a combination of *ex*-and *in-vivo* electrophysiology, genetic tools and behavioral analysis to investigate the role of nAChRs of the IPN in the regulation of nicotine consumption. In a two bottle-choice paradigm, WT mice showed a decrease in nicotine consumption at high doses of nicotine (200 μg/kg), resulting in a titration at around 10 mg/kg/day. In contrast, $\beta4^{-/-}$ mice did not reduce their consumption at high doses, and therefore did not titer. Using patch-clamp recordings, we have shown that both passive (osmotic minipump) and active (two-bottle choice) nicotine treatment decreased the amplitude of nicotinic currents in neurons of the IPN of WT, but not of $\beta4^{-/-}$ mice. We aim to study the effect of nicotine on the spontaneous activity of IPN neurons *in vivo* using juxtacellular recordings. Altogether, our results suggest that β4-nAChRs of the IPN are key players in the regulation of nicotine consumption. To causally link nicotine consumption with β4-nAChRs, we now aim at manipulating nicotine consumption using house-developed, light-controllable nAChRs [4]. Title: Repeated nicotine exposure in mice alters spontaneous behavioral activity and synaptic function in the central nucleus of the amygdala

Authors: Q. LI[1], R. C. KLEIN[1], L. WANG[1], ***S. D. MOORE**[1,2];
[1]Duke Univ., Durham, NC; [2]Durham VA Med. Ctr., Durham, NC

Abstract: Repeated exposure to nicotine (NIC) causes persistent changes in both behavior and neuronal circuitry in the brain. The central nucleus of the amygdala (CeA) is involved in nicotine addiction and withdrawal in human and animals but underlying mechanisms are poorly

understood. In this study, we repeatedly exposed male C57bl/6j mice to NIC vapor (24mg/ml dissolved in propylene glycol (PG)) or PG-only vapor for 10 consecutive days. In one cohort of mice (n=16) we used the automated IntelliCage system to measure spontaneous activity including corner visits, nose-pokes and licks before, during, and after NIC exposure (10 days each phase). NIC exposure resulted in a significant increase in lick number and duration compared to pre-NIC exposure. In addition, repeated NIC exposure reduced the number of visits and nose-pokes. In a separate cohort of mice, whole-cell current or voltage clamp recordings from CeA neurons in brain slices were performed 3 days after last exposure to either NIC or PG-only. NIC exposure resulted in a slightly reduced mean input resistance measured during sag and steady-state hyperpolarizations (NIC: IR_{SAG} 139.74 ± 13.25 MΩ, IR_{SS} 125.73 ± 11.21 MΩ (n=16), $ratio_{SAG/SS}$ = 1.11 ± 0.03; PG: IR_{SAG} 160.41 ± 24.23MΩ, IR_{SS} 143.31 ± 17.58 MΩ (n=9) $ratio_{SAG/SS}$ = 1.09 ± 0.03). There was also a significant increase in the mean time constant in NIC mice (NIC: 24.11 ± 3.11ms (n=15); PG: 9.35 ± 1.28ms (n=10), $p<0.05$) as well as a significantly lower firing frequency than PG mice (n=9). In addition, spontaneous $GABA_A$ receptor-mediated fast inhibitory postsynaptic current (sIPSC) frequency was significantly higher in NIC mice than PG mice (NIC: 11.7±1.89Hz (n=12);PG: 6.01 ± 1.49Hz (n=19, $p<0.05$)) while there was no effect on the mean IPSC amplitude. To confirm NIC inhalation, the NIC metabolite cotinine was measured in urine 5 days after last exposure. Cotinine from NIC mice was significantly higher than PG-only mice (NIC: 30.112 ± 4.96ng/ml (n=23 mice) vs PG only 0.383±0.08ng/ml (n=16 mice), $p<0.0000001$). Finally, somatic signs of NIC withdrawal (genital licks, scratches, paw tremor, body tremor and teeth chattering) were manifested by mecamylamine (1mg/kg, i.p) administration 20 hours after the final NIC exposure but absent with saline administration (n=6), suggesting that NIC mice entered a robust withdrawal phase after the cessation of NIC. Taken together, these results indicate that repeated NIC vapor exposure alters spontaneous exploratory and drinking behavior, neuroexcitability and inhibitory synaptic function in the CeA in mice.

Title: Modulation of neurotransmission in rodent dorsolateral striatum after acute nicotine exposure *in vitro*

Authors: *O. LAGSTRÖM[1], A. ANDRÉN[1,2], M. E. JOHANSSON[3], B. SÖDERPALM[1,2], M. ERICSON[1], L. ADERMARK[1];
[1]Addiction Biol. Unit, Dept. of Psychiatry and Neurochemistry, Univ. of Gothenburg, Gothenburg, Sweden; [2]Beroendekliniken, Sahlgrenska Univ. Hosp., Gothenburg, Sweden; [3]Dept. of Physiol., Inst. of Neurosci. and Physiol., University of Gothenburg, Sweden

Abstract: Nicotine is a highly addictive substance and smoking is a leading risk factor for cardiovascular and lung disease, as well as cancer. Nicotine use disorder is acknowledged as a chronic brain disease with a high risk of relapse after cessation, and the available interventions are limited. We have previously shown that nicotine produces long-lasting effects on neurotransmission in rodent dorsolateral striatum (DLS), a key brain region for both motor- and reward systems. DLS is highly involved in several reward-related behaviors and has been linked to the transition from recreational to compulsive/habitual drug use (addiction). How nicotine induces changes in DLS neurotransmission is only partly understood. In this study, we aimed to characterize acute nicotine-induced cellular mechanisms in DLS, that are suggested to drive escalated nicotine intake and compulsive drug-taking behavior. The main method for studying the acute effects of nicotine on neurotransmission was *in vitro* electrophysiological field potential recordings performed on Wistar rats and in-house bred mice with a genetic deletion of the α7 subunit of the nicotinic acetylcholine receptor (nAChR). Our results suggest that nicotine reduces excitatory inputs onto dorsal striatal neurons via a combined action at α7 and α4β2 containing nAChR in Wistar rat. Further supporting this finding, we found that the depressant effect of nicotine remained in α7 knock-out mice, and that the combined inhibition of α7 and α4β2 nAChRs was required to fully block the effect. Selective inhibition of astrocytes using the DREADDs (Designer Receptors Exclusively Activated by Designer Drugs) technology combined with electrophysiology indicated no involvement of astrocytes in mediating the effect by nicotine on DLS neurotransmission. However, ablation of cholinergic interneurons using immunotoxin (anti-ChAT-saporine) partially blocked the depressant effect by nicotine. Moreover, modulation of the muscarinic acetylcholine receptors (mAChR) with either an agonist or an antagonist appeared to inhibit the effect of nicotine. We suggest that activation of nAChRs on cholinergic interneurons increases the release of acetylcholine, which indirectly suppresses glutamate release, thereby decreasing excitatory inputs onto dorsal striatal neurons.

Title: Distinct temporal structure of nicotinic ACh receptor activation determines responses of VTA neurons to endogenous ACh and nicotine

Authors: E. MOROZOVA[1], B. S. GUTKIN[2], C. LAPISH[3], P. FAURE[4], ***A. S. KUZNETSOV**[3];
[1]Brandeis Univ., Waltham, MA; [2]Group For Neural Theory, LNC INSERM U960, Ecole Normale Superieure, Paris, France; [3]IUPUI, Indianapolis, IN; [4]Neurosci. Paris Seine, CNRS UMR8246, INSERM U1130, Paris, France

Abstract: The addictive component of tobacco, nicotine, acts through nicotinic acetylcholine receptors (nAChRs). The β2 subunit-containing nAChRs (β2-nAChRs) play a crucial role in the rewarding properties of nicotine and are particularly densely expressed in the mesolimbic dopamine (DA) system. Specifically, nAChRs directly and indirectly affect DA neurons in the ventral tegmental area (VTA). Understanding of ACh and nicotinic regulation of DA neuron activity is incomplete. We explain and provide mechanisms for several apparently contradictory experimental results. First, systemic knock out of β2-containing nAChRs drastically reduces DA neurons bursting even though the major glutamatergic (Glu) afferents that have been shown to evoke this bursting stay intact. Second, the most intuitive way to rescue this bursting - by re-expressing the nAChRs on VTA DA neurons - fails. Third, nAChR re-expression on VTA GABA neurons rescues bursting in DA neurons and increases their firing rate under the influence of ACh input, whereas nicotinic application results in the opposite changes in firing. Our model shows that, first, without ACh receptors Glu excitation of VTA DA and GABA neurons remain balanced and cancel each other. Second, re-expression of ACh receptors on DA neurons provides an input that impedes membrane repolarization and is ineffective in restoring firing of DA neurons. Third, the distinct responses to ACh and nicotine are due to distinct temporal patterns of these inputs: pulsatile vs. continuous. Altogether this study highlights how β2-nAChRs influence co-activation of VTA DA and GABA neurons required for motivation and saliency signals carried by DA neuron activity.

Title: Positron emission tomography measurements of 2-[^{18}F]FA-85380 binding to nicotinic receptors in female and male mice

Authors: S. MITCHELL[1], H. J. ZHANG[1], M. P. BHUIYAN[1], H.-M. TSAI[1], L. LEONI[1], R. FREIFELDER[1], B. ROMAN[1], C.-M. KAO[1], X. ZHUANG[2], *W. N. GREEN[2], J. MUKHERJEE[3], C.-T. CHEN[1];
[1]Radiology, [2]Neurobio., Univ. of Chicago, Chicago, IL; [3]UC Irvine, Irvine, CA

Abstract: Nicotine upregulation is an increase in high-affinity nicotine binding sites in the brain and corresponds with nicotine addiction. High-affinity nicotine binding sites in the brain are largely located on α4β2-type nicotinic acetylcholine receptors (α4β2Rs). We have established a mouse model to study the α4β2R binding kinetics using 2-[^{18}F]-A85380 by PET imaging and discovered gender differences in α4β2R binding kinetics. Among all brain regions, the highest binding kinetics was observed in thalamus and midbrain and the lowest binding in the cerebellum. This is consistent in both genders and ages. This regional difference was eliminated in KO mice, demonstrating the binding specificity of 2-[^{18}F]-A85380 to α4β2 subtype of nAChRs. The α4β2R binding peaks at between 50-60 minutes after the tracer injection in all brain regions regardless gender and age, while maximum binding capacity and dissociation rate showed clear differences between female and male mice. The global brain maximum binding capacity is higher in females than males. Specifically, the averaged maximum binding in females reaches 3.06±0.38% injected dose (ID)/cm^3 tissue compared to 1.85±0.1%ID/cm^3 in the males. The averaged maximum binding was only 1.34%ID/cm^3 in the KO mice. The elevated α4β2 binding remains consistently throughout the entire scan duration with uptake of 2.26±0.13%ID/cm^3 for females, 1.06±0.1%ID/cm^3 for males, and 0.53%ID/cm^3 for KO mice at the end of 3-hour imaging. No significant age differences were observed. The specific α4β2 binding of 2-[^{18}F]-A85380 in a mouse model exhibits significant gender differences, with females showing significantly higher levels of binding. The differences observed between males and females may provide insight into the gender differences of nicotine addiction and help to design gender specific cessation regiments. The gender differences in distribution of the brain α4β2 subtype nicotine receptor in mice is consistent with publications for humans using α4β2 PET radiotracer [^{18}F]Nifene and may therefore be suitable for translational nicotine addiction studies and address gender differences. The elevated binding of 2-[^{18}F]-A85380 also seen in human suggests a higher density of α4β2 subtype receptor in the female brain than the male brain.

Title: The role of endogenous PACAP in nicotine dependence

Authors: *K. LUTFY, S. NEGA, P. MARQUEZ, A. HAMID;
Dept of Pharm Sci, Col. of Pharm., Western Univ. of Hlth. Sci., Pomona, CA

Abstract: Nicotine dependence is a major public health and socioeconomic issue. However, there is a handful of pharmacotherapies to treat nicotine dependence. This is because the underlying mechanism of nicotine dependence is not fully characterized. In the present study, we determined the role of endogenous pituitary adenylyl cyclase activating polypeptide (PACAP) in nicotine reward and dependence. To this end, we assessed if nicotine-induced conditioned place preference (CPP) would be changed in mice lacking PACAP compared to their wild-type controls. We also examined if mecamylamine-precipitated withdrawal would be altered in the absence of PACAP. To assess the role of PACAP in nicotine reward, male and female mice were tested for baseline preference in the place conditioning paradigm on day 1, then received conditioning with saline/nicotine (1 mg/kg) or nicotine/saline (once a day for 6 days) and then tested for postconditioning place preference. On each test day, mice were placed in the central neutral chamber of the CPP apparatus and allowed to explore the three chambers for 15 min. The amount of time that mice spent in each conditioning chamber was recorded. To determine the role of PACAP in nicotine dependence, mice received 2 more conditioning with each treatment and were then tested for affective signs of nicotine precipitated withdrawal 4 days after the last conditioning. On the test day, mice were injected with mecamylamine (3 mg/kg) and tested for anxiety-like behaviors in the elevated plus maze (EPM) paradigm. The amount of time that mice spent on the open arm was recorded. Mice were then, 2 h later, forced to swim for 15 min and tested for depression-like behaviors 24 h later. The amount of time that mice remained immobile in the forced swim test (FST) was recorded for 6 minutes but the last four minutes data were used for analysis. Our results revealed that female wild-type mice spent a significantly greater amount of time in the nicotine-paired chamber compared to the saline-paired chamber ($P<0.05$). However, this response was absent in female mice lacking PACAP. In contrast, male mice lacking PACAP showed a robust CPP. Interestingly, male but not female PACAP-deficient mice exhibited reduced anxiety- and depression-like behaviors compared to their wild-type controls, suggesting that endogenous PACAP protects against the affective signs of nicotine withdrawal.

Taken together, these results suggest that endogenous PACAP is involved in nicotine reward and dependence but there is a sex-related difference in this regard.

Title: Oppositional sex-dependent regulation of α6 and β3 nicotinic receptors by protein kinase Cε: Implications for alcohol and nicotine reward mechanisms

Authors: *J. K. MOEN[1], M. C. DEBAKER[1], J. E. MYJAK[2], K. D. WICKMAN[3], A. M. LEE[3]; [1]Grad. Program in Neurosci., [3]Pharmacol., [2]Univ. of Minnesota, Minneapolis, MN

Abstract: Alcohol and nicotine are the most commonly abused substances worldwide. Emerging evidence from both rodent models and human studies show an effect of sex in drug consumption and reward, but the underlying mechanisms of these sex differences are not well understood. Nicotinic acetylcholine receptors (nAChRs) in neural reward circuitry are critical mediators of both alcohol and nicotine reward, and this receptor system is dynamically regulated at the cell level by a variety of signaling molecules. The CHRNA6-CHRNB3 gene cluster encodes transcripts for α6 and β3 nAChR subunits, which have been implicated in both alcohol and nicotine reward circuits. Previous studies by our group and others have found that protein kinase C epsilon (PKCε) regulates transcription of the CHRNA6-CHRNB3 gene cluster in male mice, such that male PKCε$^{-/-}$ mice show decreased expression of *Chrna6* and *Chrnb3* transcripts in the ventral midbrain and striatum. Additionally, male PKCε$^{-/-}$ mice show reduced alcohol and nicotine consumption, and small molecular inhibitors of PKCε can reduce alcohol consumption in male wild-type (WT) mice. In contrast, we found that female PKCε$^{-/-}$ mice show enhanced expression of *Chrna6* and *Chrnb3* transcripts in the ventral midbrain (*n*=11-15/group). This upregulation functionally impacts nAChR-dependent behaviors, as female PKCε$^{-/-}$ mice exhibit enhanced locomotor activity in response to a dose of nicotine that is subthreshold in WT animals (0.25 mg/kg; *n*=9-12/group). Indeed, we found that female PKCε$^{-/-}$ mice show distinct drug consumption patterns: female knockout mice exhibit reduced alcohol consumption only at a high concentration (20% v/v; *n*=30-35/group) and show higher nicotine consumption during the first

week of a chronic 2-bottle choice assay (*n*=15/group). Additionally, male PKCε$^{-/-}$ mice show increased sensitivity to the sedative properties of alcohol as measured by the loss of righting reflex, an expected result based on data from α6 knockout mice. This effect was absent in female PKCε$^{-/-}$ mice (*n*=6-12/group), indicating that uregulation of α6 nAChRs may be protective against deficits observed in alcohol sedation. Finally, female PKCε$^{-/-}$ mice also show reduced depression-like behavior in response to the nAChR partial agonist varenicline as measured by the tail suspension test (*n*=12-15/group). Overall, these data indicate that ablation of PKCε in female mice results in functional upregulation of α6 and β3 nicotinic receptors and reward behaviors, revealing a bidirectional effect of sex in the regulation of the CHRNA6-CHRNB3 gene cluster by PKCε.

Title: Functional network architectures in schizophrenia, are distorted during memory formation and consolidation: Graph theoretic analyses

Authors: *E. D. MERAM[1], S. J. BAAJOUR[1], A. Z. CHOWDURY[2], J. A. STANLEY[3], V. A. DIWADKAR[4];
[1]Wayne State Univ., Detroit, MI; [2]Dept. of Psychiatry, Wayne State Univ. Sch. of Med., Detroit, MI; [3]Psych & Behav Neurosci, Wayne State Univ. Sch. Med., Detroit, MI; [4]Psychiatry & Behavioral Neurosci., Wayne State Univ. SOM, Detroit, MI

Abstract: Background: Schizophrenia is characterized by impairments in associative memory (Diwadkar et al., 2008). Disordered network interactions distort patients' ability to integrate information, leading to the "dysconnection syndrome" (Friston et al., 2016). Graph theoretic measures (e.g., betweenness centrality, BC) have been used in resting state fMRI, but rarely during learning tasks. We investigated differences in the functional organization of networks induced during periods of associative memory formation, and covert consolidation. Graph theoretic analyses (applied to measures of undirected functional connectivity) were used to summarize network profiles (van Den Heuvel, 2010).
Methods: fMRI data were collected from 59 subjects (32 SCZ, 18<Age<50, 3T Siemens Verio) during an object-location associative memory task. During Memory formation, objects were presented in associated locations for naming. During a subsequent instruction-free period of memory consolidation, participants fixated on a marker (covertly rehearsing memoranda)

(Ravishankar et al., 2019). Eight epochs were used allowing participants to reach asymptomatic performance. Data were processed in SPM12 with standard methods. From processed data, average time series were extracted from 90 regions in the cerebrum (Tzourio-Mazoyer et al., 2002). Each subject's resultant symmetric 90x90 adjacency matrix of correlation coefficients (Pearson's r) was normalized (Fischer's-Z). Average matrices ($HC_{Formation}$, $SCZ_{Formation}$, $HC_{Consolidation}$, $SCZ_{Consolidation}$) were forwarded for calculating BC.
Results: Formation: 1a) HC: Highest BC values were observed in cingulo-frontal (mid cingulate, middle frontal gyrus) and the inferior temporal cortex. 1b) SCZ: By comparison, BC was shifted to the lingual gyrus, superior temporal pole and middle frontal gyrus. BC in SCZ was also higher in visual cortex regions, but lower in the heschl's gyrus and posterior cingulate cortex. Consolidation: 2a) HC: Highest BC were observed in temporal-frontal (middle frontal, inferior temporal, superior medial frontal). 2b) SCZ: By comparison, BC was shifted to the lingual gyrus, calcarine sulcus, and middle frontal gyrus.
Discussion: This is the first study to demonstrate global disorganization of networks in schizophrenia induced during periods of memory formation and consolidation. Our findings are consistent with complementary methods for network analyses during learning and memory in SCZ (Woodcock et al., 2016) but provide a network-wide representation of effects. SCZ is a dysconnection syndrome, and graph theoretic methods can evocatively accentuate how the dysconnection is expressed.

Title: The role of B2- and B3-containing GABAARs in memory and learning

Authors: *A. ABDULZAHIR[1], A. FIGUEROA[1], C. LOR[1], M. G. PERKINS[1], G. E. HOMANICS[2], M. S. FANSELOW[3], R. A. PEARCE[1];
[1]Anesthesiol., Univ. of Wisconsin Madison, Madison, WI; [2]Anesthesiol., Univ. Pittsburgh, Pittsburgh, PA; [3]Dept Psychol, UCLA, Los Angeles, CA

Abstract: Background: The general anesthetic etomidate (ETOM) causes sedation by modulating GABAA receptors that incorporate B2 subunits (B2-$GABA_A$Rs) and surgical immobility by modulating B3-$GABA_A$Rs. Its targets for suppressing learning and memory

remain undefined. Here, we examined the roles of these two receptor subtypes by testing contextual memory in mice carrying a mutation (N265M) in either the B2 or B3 subunit.
Methods: Heterozygous mice carrying the B2- or B3-N265M mutation were created in a mixed C57BL/6J x 129X1/SvJ background, and their homozygous mutant (MUT) or wild type (WT) offspring littermates were used for behavioral studies. Prior to behavioral testing, mice were habituated to the experimental room 30 min per day for one week. Contextual memory was assessed using the Context Pre-exposure Enhancement of Fear Learning (CPEFL) paradigm. On D1, the mice were administered ETOM (9 mg/kg IP) 30 min prior to placement into a conditioning chamber for 10 minutes. On D2, the mice were placed back into the same chamber and shocked 15 sec later for 2 sec at 1 mA, where they remained for 30 sec. On D3, the mice were placed back into the same chamber and allowed to explore freely for 3 min. The amount of time spent freezing was used as a surrogate for memory.
Results: Even in the absence of ETOM, both B2-MUT and B3-MUT mice had reduced freezing scores (B2-WT 34±7% vs. B2-MUT 12±3%, p=0.01; B3-WT 41±9% vs. B3-MUT 12±4%, p=0.001). Other behavioral experiments, including Elevated Plus Maze (EPM), Hot Plate (HP), and Open Field Test (OFT) yielded no differences between the two genotypes. ETOM caused sedation in WT and B3-MUT mice, but not B2-MUT mice. Surprisingly, even the sedated mice displayed learning that was not different than saline controls.
Conclusions: The memory impairment caused by the B2 or B3 mutation alone demonstrates that normal functioning of both receptor subtypes is essential for normal learning and memory. The resistance to sedation in the B2-MUT mice replicates prior findings. The lack of effect of a sedative dose of ETOM on learning suggests that impairment of contextual memory is not the most sensitive endpoint for this drug.

Title: Towards a neural circuit basis of neurodevelopmental disease: The role of a frontal-entorhinal projection in spatial and nonspatial forms of memory

Authors: *E. HISEY, S. H. SODERLING;
Duke Univ., Durham, NC

Abstract: Multiple mutations associated with human brain disorders such as schizophrenia (SZ), intellectual disability (ID), and autism involve genes which encode regulators of the synaptic cytoskeleton. Cognitive deficits, such as working memory impairments, are co-morbid across SZ, ID, and ASD, and currently little is known regarding the neural circuit perturbations that lead to cognitive disruptions. Conditional deletion of an actin cytoskeletal regulator (ArpC3) in mice leads to a dramatic alteration of spine synapse morphology and number as well as cognitive impairments. Though preliminary evidence suggests that rescue of ArpC3 expression in frontal cortex (FC) can restore both episodic and working memory, the specific neural circuit in the FC that underlies these forms of memory is unknown. We chose to examine the functional role of FC cells projecting to the lateral entorhinal cortex (LEC), a brain region known to be involved in complex forms of object recognition and associative learning, in learning and memory. We used a combination of intersectional genetic silencing, circuit-specific conditional knockdown of ArpC3 and *in vivo* imaging in behaving mice to determine the activity signature of FC-LEC cells during spatial working memory as well as the necessity of these cells for a number of cognitive behaviors. Interestingly, we found that FC-LEC cells play a critical role in working memory, possibly encoding decision-making points in time. We also found that proper FC-LEC function is needed for more complex forms of associative learning in a naturalistic digging paradigm. These initial results suggest the pathway from FC to LEC is critical for a number of cognitive behaviors and may be adversely affected in cognitive disorders.

Title: Effect of perineuronal net inhibitor on memory retention in mice

Authors: *J. VALLOVÁ[1,2], J. C. KWOK[3], N. MARTÍNEZ-VAREA[1,2], S. YANG[4], Š. KUBINOVÁ[1], J. W. FAWCETT[5];
[1]Inst. of Exptl. Med. CAS, Prague, Czech Republic; [2]2nd Med. Fac., Prague, Czech Republic; [3]Univ. of Leeds, Leeds, United Kingdom; [4]John van Geest Ctr. for Brain Repair, Univ. of Cambridge, Cambridge, United Kingdom; [5]Cambridge Univ., Cambridge, United Kingdom

Abstract: Perineuronal nets (PNNs) are lattice-like extracellular matrix structures composed of hyaluronan, chondroitin sulfate proteoglycans, tenascin and link proteins, which surround the

surface of the soma and dendrites. The PNNs are responsible for synaptic stabilization in the adult brain, and disruption of PNNs may reactivate neural plasticity. In this study, we investigated the possibility of memory prolongation by reduction of PNNs formation using a PNN inhibitor (PNNi). C57BL/6 adult mice (n=16) were fed by chow containing PNNi for 6 months, in a dose 200mg/mouse/day and compared with the control group without PNNi treatment (n=8). The memory retention was tested using novel object recognition test (NOR) and spontaneous alternation test (SA). NOR test was performed after 2, 3, 6 and 7 months with intervals between the NOR sessions of 3h and 24h. A significant improvement in NOR score after both 3h and 24h was found in animals treated with PNNi during the all treatment period compared with control group. However, 1 month after the end of the treatment, the effect of PNNi did not persist. SA test was performed after 2 and 6 months. Spatial memory and activity have been determined, but no significant differences between PNNi treated group and control groups were observed. To determine if PNNi affects motor coordination, we used two types of tests including grip and rotarod tests. After 6 months of PNNi treatment, we did not observe any significant differences in motor skills between the treated (n=8) and control animals (n=4). The quantitative analysis of PNNs immunofluorescent staining for WFA in hippocampus revealed significant decrease in WFA intensity ($p<0.001$) in the treated group. Real-time qPCR showed that PNNi treatment decreased gene expression for *Has2, Hyal3* and *Ncan* and increased expression of *Acan* and *Lyve1*. The toxicity of high dose of PNNi after 6 months treatment was examined in liver, kidney and spleen. Pathological changes, such as liver steatosis and multifocal liver necrosis, extramedullary hematopoiesis in spleen and tubules vacuolization in kidney were detected in the treated group. Our results suggest that manipulation of PNNs by oral administration of PNNi may increase plasticity and might offer a novel therapeutic approach to the treatment of memory loss in neurodegenerative disorders, however the dose of PNNi must be optimized with respect to the organ toxicity.

Title: Progesterone pretreatment decrease acute stress effect on cognition and Sgk1 expression in Sprague-Dawley rats

Authors: ***E. S. JOHNSON**[1], J. C. GANT[1], J. R. THIBAULT[1], S. D. KRANER[2], K. HARGIS-STAGGS[1], E. M. BLALOCK[1];

[1]Pharmacol. and Nutritional Sci., Univ. of Kentucky, Lexington, KY; [2]Sanders Brown Ctr. on Aging, Lexington, KY

Abstract: Stress is highly prevalent, has negative health consequence, and causes deficits in cognitive function. The impact on cognition is thought to be exerted, at least in part, through stress-induced glucocorticoid action in the brain. Serum and glucocorticoid kinase 1 (Sgk1) is a key downstream effector of glucocorticoid's actions, and has reported influences on both microglial and oligodendrocytic cells. Further, progesterone antagonizes glucocorticoid signaling at transcriptional and allosteric modulating levels, as well as via the benzodiazepine- like action of its metabolite, allopregnanolone. Here, we investigated if progesterone pretreatment alleviates the cognitive deficits and molecular effects associated with acute restraint. Sprague-Dawley rats (21 males/ 10 females) trained in the Morris water maze were placed into one of four groups: unstressed + vehicle (n=9); unstressed + progesterone (n=7); stressed + vehicle (n=7); stressed + progesterone (n=8). Subjects underwent Morris water maze training for 3 days. At the end of each training day, animals were orally dosed with peanut oil (vehicle) or progesterone (10 mg/ kg). On day 4, a 3 hour restraint was applied immediately prior to the water maze probe trial. Progesterone had no effect on any outcome in unrestrained animals. Restraint stress resulted in a significant deficit in probe trial performance that was ameliorated by progesterone pretreatment. Hippocampal Sgk1 protein expression was elevated with stress and reduced by progesterone pretreatment. mRNA expression levels for the Sgk1 and Sgk1.1 splice variants were quantified by RT-PCR, and Sgk1, Iba1, and Mbp were also assessed. These data support the hypothesis that progesterone reduces stress- associated outcomes.

Title: The role of mesolimbic D2 receptors in learning from positive and negative feedback in a reversal learning task

Authors: J. SALA-BAYO[1], J. ALSIO[1], M. SELIN[1], A. MAREK[1], *J. R. NICHOLSON[2], J. W. DALLEY[1], T. W. ROBBINS[1];

Abstract: Impaired cognitive flexibility in touchscreen-based reversal learning tasks has been linked to schizophrenia, obsessive-compulsive disorder, drug addiction and Parkinson's disease. Such cognitive inflexibility is often treatment-resistant or even worsens with pharmacotherapy. Reversal learning tasks, in which subjects learn a simple discrimination problem (approach A+; avoid B-) and then need to adapt to a change in contingencies (avoid A-; approach B+), represent one of the most robust and frequently studied forms of cognitive flexibility. Dopamine (DA) is critical for efficient reversal learning and previous studies have shown that infusions of a D2/3R agonist in the nucleus accumbens (NAc) or lesions of the core and shell sub-regions (NAcC; NAcS) impair reversal learning. However, other studies have reported no effect of NAc interventions on this type of cognitive flexibility. Furthermore, it is unclear whether these effects depend differentially on animals learning to avoid the CS- or approach the CS+. Therefore, we developed a new touchscreen-based reversal learning task for rats that assesses whether animals learn from positive or negative feedback, a task with high translational value and similarity with the human CANTAB-based reversal learning task. Rats were trained to discriminate between two stimuli (A+; B-) on a touchscreen to receive a sucrose reward. Contingencies alternated (A-; B+) until they reached a stable performance. Subsequently, a third stimulus was added to investigate learned non-reward and stimulus-perseveration: standard trials were combined with trials in which A- or B+ (or A+ or B-) was interleaved with a third neutral stimulus (C50/50) that was rewarded in 50% of the trials. We investigated the effects of local microinfusions of D2/3R agonist quinpirole into the NAcC and NAcS. In both cases, we observed a significant improvement in performance. However, whereas infusions in the NAcS improved performance mainly from effects on learning from negative feedback, in the NAcC the improvement was due to a combination of effects on learning from positive and negative feedback. These results indicate that mesolimbic DA inputs to the NAcC and NAcS contribute differentially to reversal learning.

Title: Missing you? Dopaminergic error mechanisms in rat ventral tegmental area are reset by the early appearance of the same reward but not by the early appearance of a similarly-valued but differently-flavored reward

Authors: *Y. K. TAKAHASHI[1], T. A. STALNAKER[1], L. MUELLER[1,2], G. SCHOENBAUM[1,3,4];
[1]NIDA/NIH, Baltimore, MD; [2]Dept. of Pharmacol. and Toxicology, Univ. at Buffalo, Buffalo, NY; [3]Departments of Anat. and Neurobio. and Psychiatry, Univ. of Maryland Sch. of Med., Baltimore, MD; [4]Dept. of Neurosci., The Johns Hopkins Univ., Baltimore, MD

Abstract: Dopamine neurons respond to errors in predicting the value of an event. Thus, they increase firing when a reward appears unexpectedly and suppress firing when an expected reward is omitted. Interestingly, however the omission signal is not generally observed if the expected reward is delivered early; that is, there is an increase in firing when the now-early reward is presented, but there is no suppression at the later time when it was expected. This observation necessitated the introduction of a mechanism whereby an unexpectedly valuable early event resets the temporal difference error signaling mechanism driving dopamine neuron firing (Courville, Daw, and Touretzky, TICS, 2006). Here we attempted to replicate this finding and ask further whether a similar value is sufficient for this resetting. We recorded VTA dopamine neurons in rats performing a choice task in which odor cues signaled reward at one of two fluid wells. Reward consisted of a drop of chocolate or vanilla milk, delivered at either 0.5 or 3s in different blocks of trials. The design created two transitions (1 per well) in which the 3s reward appeared at 0.5s but remained the same, and two (1 per well) in which the 3s reward appeared at 0.5s and also changed flavor (choc->van or vice versa). A single drop of water was delivered at 5s in both wells on all trials to ensure that the rats remained in the well through both prior reward periods. As expected, the dopamine neurons exhibited robust error signals, suppressing firing when the 0.5s reward was delayed to 3s and increasing firing when the 3s reward appeared unexpectedly at 0.5s. In addition, there was no suppression of firing at 3s when the same reward appeared at 0.5s. However, contrary to models in which dopamine neurons know only about value, this apparent resetting only occurred when the earlier reward was the same flavor as the one missing at 3s. In blocks where the reward moved from 3s to 0.5s and also changed flavor, there was an increase in firing at 0.5s and also a weak suppression at 3s. This result is consistent with prior data, however it also shows that so-called resetting does not occur simply as a result of the unexpected value of the early event or for any non-specific reasons. Instead it reflects the cognitive judgement - made on the fly - that the event has moved in time. If the identity of that event is changed such that this is not the logical inference, then the error signaling mechanism is not reset. These data join a variety of other recent results showing that even single midbrain dopamine neurons use of a much richer variety of information to calculate errors than is typically considered in the simple reinforcement learning models applied to understand their firing.

Title: Learning induced transformation of spiking pattern through nonlinear dendritic processing *in vivo*

Authors: *M. WANG, X. CHEN;
Third Military Med. Univ., Chongqing, China

Abstract: Cortical circuits modify their response patterns through learning to meet animal's behavioral needs. However, the specific changes on the level of single neurons remain poorly understood. Here, using two-photon Ca^{2+} imaging combined with whole-cell recordings in mouse auditory cortex *in vivo*, we demonstrate the *de novo* induction of complex spike bursts in a subpopulation of neurons by an associative learning task. Such bursts are promoted by N-methyl-D-aspartate (NMDA) receptor-mediated 'depolarizing waves'. These depolarizing waves are invariably associated with large-amplitude Ca^{2+} transients present throughout the dendrites, revealing the existence of global dendritic NMDA spikes. Thus, we demonstrate that the auditory associative learning is associated with a reliable transformation of neurons from a regular spiking to a bursting mode through mechanisms involving nonlinear dendritic signal processing.

Title: Latent learning with multiple categorical stimuli

Authors: *Y. ZHANG[1,2], A. GORELIK[1], K. GUPTA[1], E. D. BOORMAN[2];
[1]Univ. of California Davis, Davis, CA; [2]Ctr. for Mind and Brain, Davis, CA

Abstract: To successfully navigate our complex environments, we need to learn and infer the changing statistical structures between different stimuli and reward outcomes. But how does the human brain form and update these types of probabilistic associations? Previous research points to the significance of the lOFC and the mPFC in establishing causal relationships. Little is known, however, about the nature of the neural code for causal attributions when outcomes are received. In this study, we test the hypothesis 1 that reactivation of the causal choice at feedback alternates among subregions of the occipito-temporal cortex depending on which visual category (face, scene, body parts and tool) was selected and also the category of an associated item governed by the same cause. Conversely, hypothesis 2 posits that different visual stimuli that share the same causal association will produce a more similar neural code in lOFC and mPFC despite having distinct perceptual qualities. Hungry subjects (N=21, 9 Female, Median age = 21) participated in a food-learning task in which they tracked two systems of independent stimulus-reward probabilistic associations for specific food types. Each system is composed of 2 stimuli from different visual categories but have the same reward outcome probabilities. Subjects thus learned to interrelate the 2 stimuli of a system and update the statistics of one stimulus from information of the other stimulus. A hierarchical Bayesian computational model and multiple logistic regression analyses demonstrate that subjects learned efficiently from both the direct association and also the other inferred association within the same system. We plan to use functional localizers of category-selective cortex to test hypothesis 1. Specifically, we will test whether both the selected stimulus category and the associated stimulus will show reactivation at the time of the outcome. We will use multivariate pattern analyses to test hypothesis 2 by decoding the identity of the other stimulus within a system from the pattern elicited by the chosen stimulus, at the time of reward. We will also test if the determinant for the lOFC choice representation is indeed based on causal probabilities but not visual representations. These findings would provide insights for mechanisms of credit assignment during latent learning.

Title: Evaluation of cognititive function in adult rhesus monkeys using finger maze test

Authors: *K. KEONWOO;
KRIBB Natl. Primates Res. Ctr., Chenogju-si, Korea, Republic of

Abstract: In cognitive function research, the use of experimental animals is essential in revealing human cognitive processes and mechanisms. Furthermore, research on cognitive function using non-human primates is necessary for understanding higher cognitive function. In this study, we assessed cognitive function in 12 adult rhesus monkeys using the finger maze test, which was developed to assess cognitive function in non-human primates, and which we modified to suit our testing environment. The monkeys were trained on how to move a reward in the correct direction to obtain it. If the reward was moved in an incorrect direction, then the monkeys could not obtain it. After the training, the monkeys first completed a learning trial and then completed a memory trial 2 months later. Although the time required for training varied among the monkeys, 11 of them completed the training and achieved a high success rate in the learning trial. They also achieved a high success rate in the memory trial conducted 2 months later. The finger maze test, which is considered a useful test of cognitive function in non-human primates, allowed us to assess learning, memory, and cognitive function in several monkeys simultaneously

Title: Prefrontal subnetworks underlying cognitive flexibility

Authors: *T. SPELLMAN, M. SVEI, C. M. LISTON;
Brain and Mind Res. Inst., Weill Cornell Med. Col., New York, NY

Abstract: The capacity for volitional control of attention is a critical tool for the effective performance of self-directed behaviors, and deficits in this ability underlie core symptoms of multiple psychiatric illnesses, including schizophrenia, annorexia/bullimia nervosa, and ADHD. Despite the prevalence of these disorders and the side effects associated with standard treatments, such as phenethylamine psychostimulants, the circuit mechanisms that underlie the

control of attention within the mammalian brain remain unclear. Elucidating these mechanisms, therefore, is critical to the development of more targeted treatments for this disorder. Attentional set-shifting is a switching behavior commonly used to model the context-specific control of attention in both human and translational rodent models. In a set-shifting task, a subject must inferentially learn to ignore a previously relevant stimulus feature and instead attend to a newly relevant feature. Successful execution of this behavior, which is impaired in patients with ADHD, has been linked to the activity of the dorsolateral prefrontal cortex in humans and its rodent functional analogue, the prelimbic cortex.Theoretical circuit models have been proposed to explain how network architecture and plasticity in prefrontal circuits can give rise to the switching of cue processing across contexts. However, these models have not yet been tested against data from population-level physiology, due in part to technical obstacles to recording the activity of large populations of neurons in ways that capture their laminar and long-range connectivity profiles. To more clearly define the circuit mechanisms by which attentional set-shifting is accomplished in the mammalian cortex, we used *in vivo* calcium imaging and optogenetic manipulations to examine context-related activity in prefrontal cortico-thalamic and cortico-striatal neurons. While broadly-defined task-responsiveness was similar across the two populations, subtle differences were seen in the degree to which each represented task-relevant information, and in the stability of these representations over multiple shifts in task rules. These findings describe a joint contribution by two major prefrontal projection populations to attentional set-shifting behavior and elucidate potential circuit-level targets for future therapeutic interventions in diseases characterized by deficits in set-shifting.

Title: Functional gradient across primate frontopolar, mid-lateral, and posterior-lateral prefrontal cortices revealed by a test battery for assessing higher cognitive functions

Authors: *K. WATANABE[1], M. HIRATA[2], T. SUZUKI[3];
[1]Grad. Sch. of Frontier Biosci., Osaka Univ., Suita, Japan; [2]Dept. of Neurolog. Diagnosis and

Restoration, Osaka Univ. Grad. Sch. of Med., Suita, Japan; [3]Natl. Inst. of Information and Communications Technol., Osaka, Japan

Abstract: The lateral prefrontal cortex (LPFC) plays essential roles in cognition. In macaque, LPFC occupies large cortical areas anterior to the arcuate sulcus, and dorsal and ventral to the principal sulcus (PS). Despite many decades of research, functional differentiation within LPFC remains largely unknown. In monkeys, few attempts have been made to characterize neural activities in the anterior part of LPFC including frontopolar PFC (FP-PFC). In humans, a popular hypothesis postulated that there is a functional gradient along the anterior-posterior axis in LPFC, based on the level of action control or the abstractness of task-relevant rules. This hypothesis argues that the more anterior regions process more abstract and complex information, while more posterior regions process more concrete action information. At the apex of this hierarchy, FP-PFC participates in the parallel processing of multiple goals (cognitive branching). Nevertheless, this claim has recently been challenged by opposing evidence. In this study, we examined functional differentiation in macaque LPFC throughout its anterior-posterior extent. We recorded many neurons in areas 10, 46 and 8 in three monkeys while they performed 8 different tasks: (1) visual flash observation; (2) reward consumption; (3) visually-guided saccade task; (4) oculomotor delayed-response task; (5) visuospatial attention task; (6) cognitive branching task comprised of tasks 3 and 4; (7) visual object discrimination (rapid learning) task, and (8) cognitive branching task comprised of tasks 4 and 7.The result showed that task-relevant activity was almost exclusively observed in the posterior LPFC, while anterior region (FP-PFC and anterior area 46) showed much weaker responses to the task events. Notably, few neurons in FP-PFC showed task-related activity even in cognitive branching tasks (tasks 6 and 8) and rapid-learning task (task 7) that were believed to selectively activate this area. Our data show that FP-PFC exhibited notable activity only in feedback time, and this was consistent across different tasks: FP-PFC neurons retrospectively encoded the conjunction of what the subject did and whether or not that behavior was preferable in the trial just finished. Thus, our data suggest that there is distinct functional subdivision along the anterior-posterior axis of LPFC in monkey, but in a different way from that proposed by the original functional gradient hypotheses in humans.

Abstract: In advanced age, rats are slower to acquire the object-in-place rule on a bi-conditional association task (Hernandez et al., 2015) and to learn to discriminate between objects that share features (Johnson et al., 2017). On these tasks, poor performance is associated with response-driven behavior in which an animal is biased to select an object on a particular side (left versus right) regardless of the feature information of test stimuli. While it has been reported that this response-driven behavior is facilitated by the dorsal striatum (Packard and McGaugh, 1992; Gold, 2004), the neurobiological mechanisms underpinning these cognitive impairments are not completely understood. We recently showed that response-driven behavior correlated with elevated resting state functional connectivity between the anterior cingulate cortex and dorsal striatum (Colon-Perez et al., 2018), but it is unknown if this relates to neural activity during task performance. The current study tested rats on the working memory/bi-conditional association task (WM/BAT), which measures an animal's ability to select an object in a pair-wise discrimination problem based on the location on the maze while simultaneously performing a continuous alternation task. Five young (4 months old) and 4 aged (24 months) Fischer 344 x Brown Norway F1 hybrid rats were trained for 14 days on the WM/BAT. While young rats learned the object-in-place rule within that time frame, the aged rats failed to reach criterion performance and showed a significantly higher response bias compared to the young animals. On the final day of testing, rats completed the WM/BAT and a control alternation task and then sacrificed by rapid decapitation to label brain tissue for expression of the activity-dependent immediate-early gene *Arc* (Guzowski et al., 2001). When *Arc* expression in the dorsal striatum and anterior cingulate cortex was analyzed to identify neurons active during the WM/BAT and alternation task, it was observed that the proportion of active cells within the anterior cingulate cortex during both tasks was similar between young and aged rats. In contrast, in the dorsal striatum more cells were active during WM/BAT in aged compared to young rats. This pattern of elevated *Arc* expression was not observed during the alternation task. Together these data suggest that elevated activity in the dorsal striatum is associated with an increase in the use of a suboptimal response-based strategy in aged rats, which could contribute to enhanced functional connectivity between the striatum and other cortical regions.

Abstract: The basis of learning processes contributing to adequate behavioral selection and flexible switching are mediated via the dorsal striatum, which is a key component of the basal ganglia circuit. To understand the mechanism for the information processing and its regulation through this circuit, we recently established a new vector for neuron-specific retrograde gene transfer (NeuRet) with pseudotyping of fusion glycoprotein type E with mutated P440E (FuG-E (P440E)), which consists of the N-terminal region (440 amino acids) of the extracellular domain of rabies virus glycoprotein (RVG, CVS strain) and the membrane-proximal region (15 amino acids) a short C-terminal portion of the extracellular domain and the transmembrane/cytoplasmic domains of vesicular stomatitis virus glycoprotein (VSVG) (Kato et al., 2019). This vector provides us a powerful tool for the study of neural circuit mechanisms of neural networks underlying a variety of brain functions. In our previous report, the functional elimination of the parafascicular nucleus of thalamus (PF)-derived thalamostraital pathway was involved in cognitive function in the visual discrimination task (Kato et al., 2011). In the present study, we investigated the central lateral nucleus of thalamus (CL)-derived thalamostriatal circuitry function. As a result, CL-derived thalamostriatal pathway possesses distinct roles in the control of behavioral selection and flexibility against PF-derived thalamostriatal pathway. Our results suggest that the main contribution of the CL thalamostriatal neurons might be functional control of the basal ganglia circuit linked to the prefrontal cortex.

Title: Influence of normal aging on tau isoforms and post-translational modifications in transentorhinal cortex

Authors: *J. A. MCQUAIL[1], S. A. JOHNSON[1], M. N. LITENSKI[1], S. GHAY[1], B. HELLBUSCH[1], G. PEGUERO[1], S. L. ROSSI[2], P. CHAKRABARTY[1], B. I. GIASSON[1], P. R. RAPP[2], S. N. BURKE[1], J. L. BIZON[1];

Abstract: Intracellular inclusions comprised of hyperphosphorylated tau are among the earliest neuropathological features of Alzheimer's disease (AD). Abnormal tau phosphorylation is posited to promote self-aggregation of tau associated with altered protein conformation and solubility that culminates in the formation of neurofibrillary tangles. Mouse models developed from rare disease-associated mutations are useful to study the progression of tau pathology, but few studies have characterized the contribution of normal aging, the most common risk factor for AD, on expression of naturally occurring tau isoforms and associated post-translational modifications. Critically, the transentorhinal cortex is highly sensitive to the effects of normal aging and the first cortical region to exhibit AD tau pathology. Therefore, the overarching goal of the current study was to investigate interactions between normal aging and tau biochemistry in order to identify factors that render transentorhinal neurons susceptible to tau pathology. In Experiment 1, expression of tau isoforms was measured in area 35 of the perirhinal cortex and lateral entorhinal cortex (the rat homolog of human transentorhinal cortex) of young adult (6 months) and aged (24 months) Fischer 344 × Brown Norway F1 rats. Young and aged rats expressed three distinct tau isoforms ranging from ~55-67 kDa and these same isoforms were observed in TBS-, triton-, and SDS/urea-soluble fractions. However, aging did not change the

relative expression of these tau isoforms or differentially influence tau solubility. In Experiment 2, young and aged rats received stereotaxic delivery of rAAV1 containing constructs to drive expression of human wild type 0N4R tau-eGFP (AAV-hWTtau) or eGFP alone (AAV-CON). Two months after surgery, brains were harvested for biochemical analysis. Compared to un-injected and AAV-CON-injected rats, young and aged rats injected with AAV-hWTtau expressed an additional, high-molecular weight tau isoform that contained the human-specific CP27 epitope. Rat and human tau isoforms were phosphorylated as demonstrated using the phospho-specific 7F2 antibody generated to the AT8 epitope. Ongoing studies will determine if this AAV-mediated increase in total and phosphorylated tau is associated with conformational changes (i.e. Alz50 or PHF1) and whether aging exacerbates the propagation of abnormally phosphorylated tau to interconnected brain regions such as the CA1 subregion of hippocampus.

Title: Neural correlates of ordinal knowledge during serial-order tasks in pigeons

Authors: *M. JOHNSTON, B. S. PORTER, M. COLOMBO;
Psychology, Univ. of Otago, Dunedin, New Zealand

Abstract: Many tasks require multiple behaviours or actions to be executed in a sequential order to obtain a desired outcome. Such behaviour is known as “serial-order” behaviour, and is considered crucial for complex cognition requiring ordinal knowledge including language, learning, and memory. Most serial-order tasks can be thought of as either externally-ordered (EO) or internally-ordered (IO). An EO serial-order task has a predetermined sequence in order to obtain the reward. Conversely, in an IO serial-order task the order is chosen by the subject with the only requirement that a previously chosen item cannot be chosen again. In the current study, we trained pigeons to complete either EO or IO tasks. Half of the pigeons were trained on two three-item EO lists, with the first list consisting of colours (red→blue→green) and the second list consisting of patterns (Pattern1→Pattern2→Pattern3). The remaining pigeons were trained on a three-item IO list consisting of one colour (red). For both tasks, each stimulus response was separated by a delay period. We recorded single neurons from the nidopallium caudolaterale (NCL), the avian “prefrontal cortex” during both the stimulus response and delay periods to determine the role of the NCL in ordinal knowledge. Behaviourally, pigeons on both

the EO and IO tasks performed well above chance. Neuronally, for the EO task we found 45.66% and 43.35% of neurons fired significantly different from baseline during at least one of the stimulus or delay periods respectively. For the IO task, 66.36% and 44.55% of neurons fired significantly different from baseline during at least one of the stimulus or delay periods respectively. Many of the neurons demonstrated coding of ordinal knowledge, such that neurons showed a rank preference for the first, second, or third item or delay in each list. Across both tasks, the stimulus response neurons favoured was the first item, whereas the delay neurons tended to prefer the third delay period. One possibility is that the stimulus response neurons are involved in planning of upcoming stimulus responses, whereas the delay neurons reflect reward anticipation. Taken together, it appears the avian NCL is important for coding ordinal knowledge.

Title: Tbx1, a 22q11.2 cnv-encoded gene, in neonatal progenitor cells determines the postnatal development of affiliative social behaviors

Authors: *T. HIRAMOTO[1], S. BOKU[2], G. KANG[1], S. ABE[3], M. NAGASHIMA[4], R. GORDAN[6], P. O'BROIN[7], K. YE[5], T. V. MICHURIN[8], G. N. ENIKOLOPOV[9,10,11], N. Abstract: Copy number variants (CNVs) at 22q11.2, ranging from 1.5Mb to 3.0 Mb, are associated with high rates of schizophrenia and autism spectrum disorder (ASD). However, how individual 22q11.2-encoded genes contribute to dimensional aspects of diverse psychiatric

disorders is still poorly understood. We have identified the transcription factor Tbx1 as one of 22q11.2 genes that functionally contribute to social interaction deficits, a dimension relevant to schizophrenia and ASD. We have further tested the cellular and molecular substrates through which Tbx1 deficiency causes social interaction deficits. Male nestinCreERT;$Tbx1^{flox/+}$ mice were treated with Tamoxifen at postnatal days 1 to 5 (P1-5) or postnatal days 21 to 25 (P21-25) and tested for affiliative reciprocal social interaction and other behaviors 1 month later (n=9-22 mice/group). Hippocampal progenitor cells derived from P0 neonatal C57BL/6J pups were passaged and cultured to evaluate expression of Tbx1 during cell cycle (n=4-6 culture dishes/group) and the role of Tbx1 in the proliferation of progenitor cells (n=4-5 culture dishes/group). The target genes of Tbx1 were validated by ChIP, Tbx1 knockdown and deletion and mutation of the promoter region of a target gene (n=6-27 culture dishes/group). Tbx1 binding to a small promoter region was examined by NoShift assays (n=6-8 per group; duplicates of n=3-4). Conditional *Tbx1* heterozygosity in neural progenitor cells reduced reciprocal social interaction more effectively when it was initiated at P1-5 than at P21-25 ($P<0.05$). Tbx1 expression peaked shortly before cell proliferation in vitro ($P<0.05$). Knockdown of Tbx1 reduced the rate of proliferation of neural progenitor cells in vitro ($P<0.05$). ChIP identified Tbx1 binding peaks in the promoter region of Pten. Tbx1 was found to be expressed in Pten-positive cells in the hippocampal progenitor cells granule cell layer in vivo. Knockdown of Tbx1 by siRNA reduced the transcription and expression of Pten in vitro ($P<0.05$). Segmental deletions and point mutations of the Pten promoter identified a 35bp region to be a Tbx1-binding site that is functionally critical for *Pten* transcription ($P<0.05$). Moreover, NoShift assays showed that this 35bp region contained Tbx1 binding ($P<0.05$). Tbx1 deficiency in progenitor cells during the neonatal period impairs their proliferation and social interaction later. Pten was identified as one of the downstream genes of Tbx1. ASD associated with 22q11.2 CNV and Pten mutation share a molecular cascade for social interaction deficits.

Title: Bortezomib levels in the brain and cerebral spinal fluid and the effects on cognition

Authors: *P. HUEHNCHEN[1], W. BOEHMERLE[1], A. SPRINGER[4], S. KOHLER[1], T. ALEXANDER[2], F. HIEPE[2], A. MEISEL[3], M. ENDRES[3];
[1]Exptl. Neurol., [2]Rheumatology, [3]Neurol., Charite Universitaetsmedizin Berlin, Berlin, Germany; [4]Inst. of Chem. and Biochem., Freie Univ. Berlin, Berlin, Germany

Abstract: Bortezomib (BTZ) is a 26S proteasome inhibitor frequently used to treat multiple myeloma. In recent years, increasing data has emerged proving bortezomib's effectiveness in the treatment of antibody-mediated autoimmune disorders such as anti-NMDA receptor encephalitis or thrombotic thrombocytopenic purpura in patients refractory to conventional therapy. However, one of bortezomib's major limiting side effects is its toxicity towards the (peripheral) nervous system with the development of a sensory axonal polyneuropathy. We have previously gathered preclinical evidence in mice that BTZ might also lead to cognitive deficits. To further extend the safety data, we have measured pharmacokinetic profiles of BTZ in the mouse brain and human cerebral spinal fluid (CSF). Furthermore, we investigated whether BTZ also affects cognitive functions in patients treated for myasthenia gravis (MG) or systemic lupus erythematodes (SLE). Male eight-week old C57Bl/6 mice were injected with 0.4mg/kg BTZ intraperitoneally and sacrificed after 5, 10, 15, 30, 60, 120, 240, 720 and 1440 minutes and BTZ levels measured in the serum, cortex and hippocampus with liquid chromatography-tandem mass spectrometry (UPLC-MS/MS). BTZ concentrations in the brain reached only 5% of serum concentrations and did not exceed 1,5nM with only slightly higher concentrations measured in the hippocampus than the cortex. CSF was collected from a patient with anti-CASPR2 antibody encephalitis at 30, 60, 90, 120, 240, 360 and 720 minutes after subcutaneous application of 1.3mg/m^{2}BTZ. BTZ levels in the CSF again reached only about 7% of serum concentrations but were considerably lower compared to BTZ concentrations measured in mice with a maximum of 0.14 nM. Patients enrolled in a clinical trial to examine the effects of BTZ therapy on MG and SLE (TAVAB trial, NCT02102594) received two cycles of BTZ resulting in a total of eight subcutaneous injections of 1.3mg/m^{2}BTZ each. Six patients underwent neuropsychological testing for verbal memory, working memory, visuo-spatial memory, executive functions and semantic fluidity using standardized tests. With the exception of a slight learning effect in executive functions, overall performance in the other cognitive domains did not change after BTZ application compared to pre-treatment values.In summary, subjects with an intact blood-brain-barrier show low BTZ concentrations in the brain and CSF after systemic application and cognitive functions remain unchanged after recurrent treatment with BTZ up to two cycles. Overall, our data demonstrate that BTZ is a safe medication with regards to central nervous system toxicity.

Title: Vagus nerve stimulation enhances prefrontal-cortical mediated cognitive flexibility

Authors: *L. K. P. ALTIDOR[1], M. M. BRUNER[1], J. F. DESLAURIERS[1], T. S. GARMAN[1], S. RAMIREZ[1], D. G. LAMB[2,5], A. M. FINNER[1], E. W. DIRR[3], K. P. OLCZAK[3], A. P. MAURER[1,3], K. J. OTTO[3], S. N. BURKE[1], B. SETLOW[1,2], J. L. BIZON[1,4];
[1]Neurosci., [2]Psychiatry, [3]Biomed. Engin., Univ. of Florida, Gainesville, FL; [4]Psychiatry, Univ. of Florida, Gainesvillle, FL; [5]Brain Rehabil. Res. Center,, VAMC, Gainesville, FL

Abstract: Cognitive flexibilityis a core prefrontal cortical-dependent neurocognitive process that enables modification of one's behavioral strategy in response to a change in environmental contingencies. Reversal learning is a form of cognitive flexibility in which the learned reinforcement contingencies associated with a two choice discrimination are reversed (e.g., A+/B- becomes A-/B+). Therapies to enhance cognitive flexibility may have broad functional benefit to individuals engaged in some forms of learning (e.g., acquiring a new language) and may attenuate maladaptive perseverative behavior in conditions in which cognition is compromised (e.g., aging and psychiatric disorders). Electrical stimulation of the vagus nerve (VNS) is approved for treatment of epilepsy and several other neuropsychiatric disorders, and preclinical evidence suggests that VNS can also enhance cognition. The current study evaluated whether VNS enhances cognitive flexibility in a reversal learning task.Adult male Brown Norway rats were trained in a reversal learning task performed using operant chambers in which visual stimuli are projected on a touch-sensitive video screen. In this task, rats initially received training sessions consisting of intermixed presentations of two pairwise visual discrimination problems (e.g., W+/X- and Y+/Z-). For these problems, touching the correct stimulus in each pair (W+ and Y+) earned a food pellet reward. Once rats learned to perform accurately on both problems (>80% correct on each), the contingencies were reversed for the stimuli in one of the problems, whereas they remained consistent for the other (W-/X+ and Y+/Z). In naïve rats, initial performance accuracy was markedly lower on the reversed problem in comparison to the consistent problem, but improved over the course of subsequent testing. To evaluate the effects of VNS on reversal learning accuracy, a within-subjects design was used to compare VNS (120 µs pulse width, 700 µA, 0.8 s train duration) to no-stimulation conditions. When paired with presentation of the reversed problem, VNS at 30 Hz (but not at 10 Hz or 50 Hz) significantly enhanced reversal learning performance. In contrast, 30 Hz VNS paired with presentation of the

consistent (non-reversed) problem had no effect on performance, demonstrating the temporal specificity of the enhancing effect of 30 Hz VNS on reversal learning. Importantly, the enhancing effect of VNS was not accompanied by changes in response latency or number of trials completed. Considered together, these results show that acute VNS can enhance cognitive flexibility, and that the timing of VNS delivery is critical for these effects.

Abstract: Electrical stimulation of the vagus nerve (VNS) is approved for treatment of epilepsy and several other neuropsychiatric disorders. Moreover, substantial prior work has demonstrated that sustained VNS can attenuate inflammation in chronic conditions. The goal of this study was to determine peripheral and central effects of a relatively short VNS regimen that has been shown to acutely enhance cognitive performance. Adult male Brown Norway rats underwent surgery to implant a cuff electrode around the left vagus nerve. After 2 weeks of recovery, rats received daily 1 h sessions for eight days during which they were tethered to a constant current stimulator. In each session, rat received either 100 VNS trains (30 Hz, 120 µs pulse width, 700 µA, 0.8 s train duration) distributed over 1 h or no stimulation (control group). Rats were sacrificed 48 hours after the final VNS session. Peripheral tissues and blood were collected, and the hippocampus and prefrontal cortex were dissected for multiplex ELISA and western blot

analysis. Locomotor activity during stimulation sessions did not differ between groups; however, rats receiving VNS tended to gain less weight across the experiment in comparison to control rats. No differences between VNS and control rats were observed in a post-mortem analysis of body fat composition and adrenal weight. VNS did, however, reliably attenuate expression of the pro-inflammatory cytokines TNF-α and interferon-γ measured in plasma. In addition, tissue inhibitors of metalloproteinases TIMP-1 and TIMP-2, which have been implicated in neuroprotection, were upregulated in the hippocampus of VNS compared to control rats. VNS also reduced RANTES, Prolactin and T-cell immunoglobin and muscin family-1 (TIM-1) in prefrontal cortex. Finally, western blot analysis indicated that VNS altered expression of glutamic acid decarboxylase and receptors for GABA in the prefrontal cortex. Together, these findings suggest that even relatively brief VNS regimens can attenuate peripheral inflammation, promote neuroprotection and shift expression of excitatory/inhibitory signaling proteins in brain regions important for cognitive function.

Title: The effects of early and late onset oral contraceptive use on emotional working memory in women

Authors: *R. SHARMA[1], N. BOUKINA[1], B. TAYLOR[2], A. SMITH[1], N. ISMAIL[1];
[1]Univ. of Ottawa, Sch. of Psychology, Ottawa, ON, Canada; [2]Cardiff Univ., Wales, United Kingdom

Abstract: Millions of women worldwide use oral contraceptives (OCs), often starting at a pubertal age when their brains are in a crucial developmental stage. For girls, puberty marks the transition to womanhood whereby the surge of ovarian steroid hormones confers reproductive competence and initiates brain reorganization that gives rise to the social, emotional, and cognitive development across adolescence. The influx and fluctuations of these hormones in women contribute to sex differences in mood disorders, as women are disproportionately affected. Given that OCs suppress endogenous production and that, the age of first OC onset is decreasing towards early- to mid-puberty due to their marketability as “regulators”, examining the influence of hormonal OCs on women’s brain structure, function, and mood is warranted.

Therefore, the objective of the current study was to examine the effects of early- and late-onset OC use and the natural menstrual cycle on brain activity during an emotional working memory task. We hypothesized that OC use would alter regional brain activity compared to naturally cycling (NC) women. We also hypothesized there would be differences between pubertal- and adult-onset users, as age of onset/duration of OC use has not been accounted for in the existing literature. To test these hypotheses, undergraduate women (N=74) underwent functional magnetic resonance imaging while being exposed to a working memory task comprised of emotionally arousing images. Preliminary results show that all OC users display greater frontal and insular activity during working memory for negatively arousing images and negative emotional processing compared to NC women. OC users show a positive association between salivary progesterone levels and brain activity for negative working memory. NC women, on the other hand, show a positive correlation between salivary progesterone levels and working memory for positively arousing images. The findings of the current study advance our understanding of how OCs impact the brain, especially during pubertal onset, and are relevant to women's health at both individual and societal levels.

Abstract: Schizophrenia (SCZ) and Bipolar Disorder (BD) are highly heterogeneous psychiatric disorders consisting of multiple cognitive and behavioral impairments. While they are considered to be distinct disorders, both are marked by impaired functioning of the prefrontal cortex (PFC) leading to behavioral deficits associated with executive functioning, such as cognitive flexibility. Many protein-coding genes have been associated with SCZ and BD, specifically those expressed

at the post-synaptic density (PSD), which are associated with synaptic transmission and plasticity. Homer protein homolog 1 (HOMER1), is a PSD-expressed, psychiatric disease-associated, scaffolding protein known for its interaction with group 1 metabotropic glutamate receptors and its role in regulating synaptic transmission. Recently, circular RNAs (circRNAs) have been found to be produced from *Homer1* and to be highly expressed in cortical brain regions. circRNAs, in particular *circHomer1*, have been postulated to regulate their linear counterparts as well as impact expression of multiple other targets either through direct or indirect mechanisms. We have previously shown that *circHomer1*, one circRNA derived from *HOMER1*, is reduced in postmortem orbitofrontal cortex (OFC) samples from patients with SCZ and BD. Additionally, *in vivo circHomer1* knockdown in male C57BL/6J mouse OFC alters the expression and synaptic localization of multiple targets and impairs visual reversal learning, a measure of cognitive flexibility dependent on OFC function. To examine changes in excitatory neuronal activity that may underlie OFC dysfunction, the current work uses *in vivo* electrophysiological recordings during visual discrimination and reversal learning. We analyze changes in OFC spike activity during impaired reversal stages and inter-trial phase consistency, which is a measure of coordinated regional activity important for functional inter-regional signaling. Further, we correlate mRNA expression changes with neuronal activity to uncover possible mechanisms associated with impaired firing. From this work, we are able to elucidate the impact of a circRNA on the electrophysiological properties underlying a behavioral flexibility impairment associated with SCZ and BD.

Title: Response signals in dorsal medial striatum and behavior are dependent on medial prefrontal cortex

Authors: *A. T. BROCKETT, S. S. TENNYSON, C. A. DEBETTENCOURT, M. A. KALLMYER, M. R. ROESCH;
Univ. of Maryland, College Park, MD

Abstract: Cognitive control is the ability to flexibly adapt behavior in accordance with internally maintained goals, while simultaneously suppressing more automatic responses. This ability is an essential component of cognition and is often diminished in patients with schizophrenia and depression (Shenhav et al., 2016). Previous work has implicated the anterior cingulate cortex (ACC) and medial prefrontal cortex (mPFC) in facilitating switching between behavioral strategies that have been shown to be represented, at least in part, in areas such as the dorsal medial striatum (DMS) (Bryden et al., 2012). However, the respective roles of ACC and mPFC in facilitating cognitive control have yet to be fully distinguished. Some work suggests that ACC is important for managing conflict and changing behavior accordingly (Shenhav et al., 2016), whereas mPFC is tasked with monitoring task performance and automating behavior (Gourley and Taylor, 2017). Despite these theoretical accounts, few studies have attempted to dissociate the roles of these two brain regions in subjects performing a conflict task. In this study, we utilized a directional stop-change task, in which on 80% of trials (GO trials) a light directs rats to make an operant response in order to obtain reward (Bryden et al., 2012, 2016). On the remaining 20% of trials (STOP trials) rats must inhibit their initial response to the first light when presented with a second light instructing the rat to redirect its behavior in the opposite direction. Using this task, previous research has demonstrated that the firing of neurons in DMS appears conflicted on STOP trials, but how DMS mitigates this conflict is unclear (Bryden et al., 2012). Neurons in mPFC have been shown to signal response direction and monitor conflict, firing more strongly on STOP trials than on GO trials. However, firing does not peak until after the response epoch (Bryden et al., 2016). Here we performed unilateral lesions of rat mPFC (n = 8) while simultaneously recording downstream from DMS. We show that mPFC lesions disrupt responding to the first cue, but the ability of rats to detect/ mitigate conflict is left intact, suggesting that the primary role of mPFC is to control the automated process of rapidly responding to the first cue light.

Title: Anticipatory contrast in instrumental behavior of rats

Authors: *K. KAWASAKI, M. TAGA;
Psychology, Hoshi Univ., Tokyo, Japan

Abstract: Anticipatory contrast (AC) refers to the phenomenon of inhibition of access behavior to the prior reward which is followed by more desirable reward. AC has been interpreted as resulting from anticipation of the impending preferred reward and its comparison with the currently available first reward. And we proposed the amygdala basolateral nucleus as one of the brain region candidates responsible for comparing the two rewards underlying this phenomenon. Recently, we reported that the amygdala basolateral nucleus is involved in AC (Kawasaki et al., 2017). However, as is the case with our previous studies, most studies showing AC in rats have been conducted on consummatory behavior. Therefore, care must be taken when generalizing these results. Williams (1990) reported that pigeons trained on multiple schedules showed AC, while rats trained on the same schedule did not show AC. However, the method of Williams (1990) is not only targeted for instrumental behavior, but it differs from the experimental schedule targeting consummatory behavior because it uses a multiple lever schedule of two levers. Therefore, we conducted 3 experiments with the objective of ascertaining whether AC occurs in instrumental behaviors of rats by the method that is as close as possible to the schedule used in consummatory behavior. In the 1st experiment 45 male Wistar-Imamichi rats were trained in FR1 schedule of nose poking on both of 1st (3 min.) and 2nd (3 min.) component of daily session for 10 days. Both 1st and 2nd components were separated by a 30 second break. The reward was one 20mg food pellet on 1st component and 1, 2, or 4 of pellet(s) on 2nd. Mean numbers of nose poking on 1st component in last 5 days were suppressed in function of number of reward pellets on 2nd component. But there was no statistical significance. In 2nd experiment 24 rats were trained in FR2 schedule of nose poking on 1st component and in FR1 or FR2 on 2nd component of daily session for 14 days. The reward was one 20mg food pellet on both 1st and 2nd component. Mean numbers of nose poking on 1st component in last 4 blocks of 2 days were slightly suppressed in the rats given FR1 schedule on 2nd component. But it was not significant. In 3rd experiment 24 rats were trained in FR3 schedule of nose poking on 1st and in FR1 or FR3 schedule on 2nd component of daily session for 10 days. While one 20mg pellet was given for all the subject on 1st component and FR3 rats on 2nd component, 3 pellets for FR1 rats in 2nd component. Mean numbers of nose poking on 1st component in last 2 blocks of 2 days were significantly suppressed in the rats given FR1 schedule on 2nd component. That is, in this experiment, AC in instrumental behavior was observed for the first time.

Title: Increased impulsivity like behaviors in mice lacking Gpr88

Authors: *S. BEN HAMIDA, M. MCNICHOLAS, E. MORONCINI, E. CLARKE, E. DARCQ, B. L. KIEFFER;
Douglas Mental Hlth. Inst., Montreal, QC, Canada

Abstract: The neural orphan G protein coupled receptor GPR88 is most enriched in the striatum of both rodent and human brains, and also in central amygdala and cortex although with lower density. Total deletion of *Gpr88* gene in mice leads to a range of phenotypes consistent with the strong striatal Gpr88 expression. In brief, these include altered dopamine signaling and enhanced medium spiny neuron excitability, increased basal activity and locomotor responses to psychostimulants, increased stereotypies, motor coordination deficits, low anxiety, as well as altered cue-based and procedural learning[1-3]. In addition, sensorimotor gating[1] and sensory processing[4] deficits are also observed in Gpr88 knockout mice, possibly related to cortical Gpr88 expression and concordant with disrupted functional connectivity at the level of several cortical areas in these mutant mice[5]. Finally, we found enhanced motivation to seek and consume alcohol in Gpr88 knockout animals, and this phenotype correlated with reduced functional connectivity between the Pre-frontal cortex (PFC) and the Nucleus Accumbens (NAC)[6], both involved in high-order cognitive controls. Here, we hypothesized that the combined hyperactive and high-drinking phenotypes of Gpr88 knockout mice, together with their altered brain connectivity patterns in both cortical and striatal networks could also reveal/reflect an impulsive endophenotype in these animals. Our results indicate that both in an operant Go/No-Go task and a 5-choice serial reaction time (5-CSRT) task, Gpr88 knockout animals showed reduced inhibitory control, as demonstrated by increased premature responses and higher commission errors compared to control animals. We also detected an altered attentional performance in Gpr88 mutant mice as indicated by reduced choice accuracy in the 5-CSRT procedure. These findings suggest that GPR88 receptor function may contribute to cognitive control disorders, a trait implicated in the pathogenesis of addiction.

Title: Impulsivity in a global cerebral ischemia rodent model: Optimization of a delay discounting task

Authors: *A. MORIN[1], H. PLAMONDON[2];
[1]Psychology, Univ. of Ottawa, Ottawa, ON, Canada; [2]Dept Psychol, Univ. Ottawa, Ottawa, ON, Canada

Abstract: Delay discounting (DD) tasks have been used to quantify impulsive behaviors in healthy animals and following various pathologies. To our knowledge, this task has not served to assess impulsive behavior in rat models of global cerebral ischemia. In this pilot study, rats were trained and tested on their ability to delay reward from the juvenile period to adulthood. Briefly, male Long Evans rats (n=8), maintained at 85% of normal body weight, were trained to lever-press using an autoshaping (AS) task. AS training was considered successful when the rat pressed a minimum of 60 times on both levers combined for three consecutive sessions. Each lever press triggered the delivery of one sucrose pellet. Following shaping, rats performed 30 daily sessions of DD, each consisting of 5 blocks of 12 trials lasting 100 seconds each. Rats could choose between pressing a smaller-sooner (SS) lever that provided an immediate small reward (1 pellet) or a larger-later (LL) lever that provided a bigger reward (4 pellets) at an increasing delay between blocks (0, 5, 10, 20, and 45 seconds). Performances over time were measured by comparing choice ratio (CR - the ratio of LL lever presses to total lever presses) between blocks and 3-day clusters. Based on two essential criteria, our results support the validity of the DD paradigm. First, no significant differences in CR were observed between clusters, indicating that performance achieved stability over time. Second, CR was elevated in the initial blocks (involving shorter delays) compared to later ones, allowing to determine changes in impulsivity between animals. Notably, as the delay increased to obtain a maximal reward, the number of omissions also increased. Thus, while this DD task is properly acquired by healthy rats, subsequent testing involving sham and ischemic animals will consider the motivation factor in selecting proper delays to assess changes in impulsivity level and overall performance.

Title: Effects of lesions of orbital frontal cortex and medial prefrontal cortex on the acquisition and extinction of DRL operant behavior in the rat

Authors: *R.-M. LIAO[1,2], S.-F. CHEN[2], Y.-H. YANG[2], Y.-J. YANG[1], C.-Y. CHUANG[2]; [1]Dept. Psychology, [2]Instit. Neurosci., Natl. Cheng-Chi Univ., Taipei, Taiwan

Abstract: Prefrontal cortex (PFC) is known to be critically involved in the execution of high-level cognitive functions including behavioral inhibition and timing process. These two are thought to be required for the operant response on differential reinforcement of low-rate response (DRL) schedules, and yet the role of PFC in DRL schedule-controlled behavior remains poorly understood. With the hypothesis of functional heterogeneity of PFC, the present study investigated the lesion effects of orbital frontal cortex (OFC) and medial prefrontal cortex (mPFC) on a DRL behavioral task in the rat. The lesion was made by using ibotenic acid before behavioral experiments. The rat received a basic training of lever press to obtain a water reinforcer before being subjected to a DRL 10 sec (DRL 10-s) for 18 days and then a DRL 15-s for 10 days in terms of acquisition. Subsequently, a 4-day extinction protocol was conducted and followed by a recovery test, where the reinforcer contingency resumed, on DRL 15-s task given four times intermittently over 12 days. The efficiency ratio, the number of reinforced responses divided by the number of total responses, was used in measuring behavioral response. The results showed the rats with OFC or mPFC lesion did not differ to those of sham controls in acquiring basic lever-pressing, neither for DRL 10-s response. When shifting to DRL 15-s task, a significant lesion effect of OFC was detected, but no such effect observed for that of the mPFC. During the extinction, the sham control rats significantly decreased responses across 4 test days. There was a significant lesion effect of mPFC, but no such effect for the OFC manipulation. For the recovery test, the results show that the lesion of OFC, but not mPFC, differed significantly from its sham control. Together, these data indicate that both the OFC and mPFC may contribute to the acquisition and extinction of DRL behavior in rats, but in different profiles. Specifically, OFC lesion yielded behavioral changes in DRL task with interval upward shifting and the recovery test, whereas the mPFC lesion affected responding in the extinction phase.

Title: A high-throughput mouse stop signal task (SST)

Authors: *A. CAGLAYAN, K. STUMPENHORST, Y. WINTER;
Humboldt Univ. - Inst. Biologie, Berlin, Germany

Abstract: Behavioural inhibition is broadly defined as inhibiting a pre-potent response allowing animals to behave adaptively. It has multiple facets, one of which - namely action cancellation - consists of ceasing an ongoing motor response. The stop signal task (SST) has commonly been used to measure action cancellation (Logan, Cowan, & Davis, 1984; Eagle & Robbins, 2003; Humby, et al., 2013). Here we describe how a sorting system based on ID chips (ID sorter, PhenoSys) enabled the development of a quick and less labor intensive stop signal task for mice. In a stop signal task, subjects are first trained to quickly respond to the presentation of a go signal (go response). Once the go response is established, a stop signal is introduced to a proportion of trials. This stop signal is presented after the go signal but before the estimated time of completion of the go response (individual subject´s mean reaction time). The shorter the time interval that remains from presenting the stop signal to the completion of the go response, the more difficult it is for a subject to successfully stop the go response. Longer delays between the go signal and the stop signal thus decrease the percentage trials with successful action cancellation (stopping). Thus, by giving various stop signal delays (SSD), the subjects` ability for action cancellation is estimated. Several neurobiological disorders such as attention-deficit/hyperactivity disorder (ADHD), schizophrenia, and obsessive-compulsive disorder are associated with decreased action cancelation abilities. To better understand the nature of action cancelation and to develop potential treatment options requires analysing action cancelation in different rodent models. However, existing tasks for mice and rats require long training periods (~40 days before introducing SSDs) and are labour intensive. In this study we used a sorting system based on an ID chip gating system to allow group housed mice to individually enter the operant chamber in a self-determined manner. Female C57BL/6 mice were gradually trained to perform a quick go response upon initiating trials by themselves through an initiation response. After the go response was established, a stop signal (4.5 kHz, 65 dB tone) was introduced to 20% of the trials. Initially the stop signal coincided with trial initiation and mice learned to stop upon hearing the stop signal. Afterwards, delays (SSDs) were introduced between trial initiation and stop signal. It was observed that with increasing delay, stopping success decreased. The results

suggest that our current automated task delivers hallmarks of SST while greatly decreasing experimenter labour and the time required for training.

Title: Behavioral disinhibition as a cognitive endophenotype for early detection of Alzheimer's disease

Authors: T. PETERSON[1], Z. STEINBERG[1], M. R. DUGGAN[1], I. ASCI[1], *V. V. PARIKH[2]; [1]Psychology and Neurosci. Program, [2]Temple Univ., Philadelphia, PA

Abstract: Alzheimer's Disease (AD) is a neurodegenerative disorder effecting predominately older populations, and there is currently no means to accurately diagnose the disease before its progression has become severe. The existence of an effective behavioral biomarker for early detection of AD would improve diagnosis and encourage the implementation of a mechanism-based intervention for the initial stages of disease progression. Here, we utilized triple transgenic (3xTg) mice that harbors three mutations (APP Swedish, MAPT P301L, and PSEN1 M146V) associated with AD to delineate behavioral endophenotype at an early stage when neuropathological features are not visible. Wild type (WT) and 3xTg AD mice of both sexes were trained and tested in an automated operant go/no-go visual discrimination task that was designed to assess attention as well as behavioral inhibition under conditions of response conflict in mice. In the longitudinal study, animals started training at 2-3 months of age and were tested for behavioral performance until 9 months. Although 3xTg AD mice did not display decision-making deficits under 50%go/50%no-go condition at any age, higher false alarms were observed when the proportion of go trials was unpredictably reduced to 20%. These behavioral changes were visible in 3xTg-AD mice as early as 3 months of age. In general, AD mutants exhibited faster response times vs. WTs, which may indicate alterations in behavioral inhibition and their utilization of a more impulsive decision-making strategy under conflicting conditions. In the crossectional study, we compared the performance of young (3 months) and aged (9-10 months) old WT and AD mice. No differences in performance were noted in the 80%go/20%no-go condition. However, when the proportion of no-go trials was increased to 80%, older 3xTg-AD

mice exhibited reduced response latencies for both go-trials and false alarms, indicating strategy differences in response inhibition. Thus, regardless of the study design, behavioral disinhibition emerged as a possible cognitive endophenotype that was visible in the 3xTg-AD mutants before the onset of neuropathology. Provided that the integrity of the prefrontal cortex is critical for a wide range of executive processes, including behavioral inhibition, it is possible that early alterations in prefrontal networks may predict AD pathology, and that these networks may be targeted for early intervention.

Title: Pharmacological and behavioral modulation of impulsivity in the touchscreen-based mouse 5-choice serial reaction time test

Authors: *A. RAHBARNIA[1], A. R. ABELA[2], P. J. FLETCHER[3];
[1]Univ. of Toronto, Toronto, ON, Canada; [3]Section of Biopsychology, [2]Ctr. For Addiction and Mental Hlth., Toronto, ON, Canada

Abstract: In humans, impulsive behavior is a common feature of several neuropsychiatric disorders. Animal models have proven to be critical in understanding the neurobiology of impulsivity. An established test of impulsivity is premature responding in the rat five-choice serial reaction time test (5CSRTT). Recently, a touchscreen version of the 5CSRTT has been developed for mice. While premature responding in the 5CSRTT is well established as a test of impulsivity in rats, its transferability to mice and touchscreens is less documented. We evaluated whether task parameter and pharmacological manipulations that influence premature responding in the rat 5CSRTT exert similar influences in the touchscreen mouse 5CSRTT. Mice were trained to detect and respond to the presentation of a visual stimulus in one of five spatial locations for milkshake reward. Responses made prior to stimulus presentation were scored as premature and used as an index of impulsive responding. Impulsivity was then evaluated in three conditions. First, we investigated whether increasing the inter-trial interval (ITI) from 5s to 9s would enhance premature responding. Secondly, we assessed whether premature responding could be enhanced by drugs known to increase impulsivity in rats. Mice were tested with cocaine (7.5, 15 mg/kg i.p.), the selective 5-HT_{2C} receptor antagonist SB242,084 (0.125, 0.25 mg/kg

i.p.), and the alpha-2 adrenoreceptor antagonist yohimbine (0.313, 0.625 mg/kg i.p.). Thirdly, we assessed whether premature responding could be reduced by drugs known to decrease impulsivity in rats. Mice were tested on the 9s ITI version of the 5CSRTT following treatment with the 5-HT_{2C} receptor agonist lorcaserin (0.05, 0.1, 0.2 mg/kg s.c.), the selective norepinephrine reuptake inhibitor atomoxetine (0.5, 1 mg/kg i.p.), and the selective serotonin reuptake inhibitor citalopram (5, 10 mg/kg i.p.). Increasing the ITI to 9s reliably enhanced premature responding, an effect that was maintained over repeated tests. Cocaine, and to a lesser extent, SB242,084 increased premature responding. Yohimbine had no effect. Lastly, lorcaserin, atomoxetine, and citalopram significantly decreased premature responding. These results indicate that the touchscreen version of the 5CSRTT can reliably be used to measure impulsive action, and that there is some correspondence between the effects of pharmacological and behavioural manipulations on the 5CSRTT in rats and mice.

Title: Serotonin impairs social avoidance

Authors: *H. B. WEINBERG-WOLF, N. A. FAGAN, S. W. CHANG;
Yale Univ., New Haven, CT

Abstract: Many primates, including humans and rhesus macaques, must gather information about the social intention of conspecifics and select appropriate social behaviors in response. In macaques, threatening expressions and directed eye contact generally communicate dominance and an intent to aggress. On the other hand, lipsmacks generally communicate affiliation, subordinancy, and intention to submit. By monitoring these, and other facial expressions, individuals are able to learn and maintain their dominance status.
Recently, we have shown that i.m. injections of the serotonin precursor l-5-hydroxytryptophan (5-HTP) effectively increases central concentrations of serotonin in CSF and modulates looking duration to social images in rhesus macaques (Weinberg-Wolf et. al 2018), suggesting a role of the serotonergic system in social monitoring. However, successful social monitoring also requires balancing the needs to approach appetitive stimuli and avoid threatening stimuli (Weinberg-Wolf and Chang, 2019). Here, we tested whether the serotonergic system is also implicated in approaching or avoiding affiliative and threatening social stimuli. Monkeys were cued to look to (approach), or look away from (avoid), faces of unfamiliar conspecifics displaying threatening expressions, affiliative expressions, or luminance-matched scrambled

versions of these images. In this task, we examined how 5-HTP, compared to saline baseline, impacts approach and avoid behaviors using a repeated, within-subject, study design.
At baseline, monkeys approached the to-be-approached stimuli nearly perfectly. However, individuals varied in their avoidance behaviors and erroneously approached to-be-avoided stimuli frequently, indicating an overall prepotency for approaching stimuli. While enhancing central serotonin with 5-HTP generally shifted performance downward in the task, it especially impaired monkey's ability to avoid social stimuli depicting either threatening or affiliative expression. Our results suggest that approach and avoidance behaviors are regulated by the serotonergic system, especially when these stimuli contain social information about the intention of conspecifics. These findings are consistent with the view that the serotonergic system is implicated in adaptive regulation of social approach and avoidance, ultimately contributing to adaptive social monitoring.

Title: Midbrain dopamine neuron activity predicts impulsive actions in mice

Authors: *T. P. PINKHASOV[1,2], S. STAROSTA[1], A. KEPECS[1];
[1]Cold Spring Harbor Lab., Cold Spring Harbor, NY; [2]Neurobio. and Behavior, Stony Brook Univ., Stony Brook, NY

Abstract: Impulsivity, or acting without forethought or self-control despite negative consequences, increases the risk of suicidality, substance abuse, and violence. Dopamine (DA), the neuromodulator that is central to reward processing, has long been implicated in this behavior. While there is overwhelming evidence that DA drives conditioned behavior, pharmacological manipulations of DA have been found to both increase and decrease the ability to suppress conditioned responses that are maladaptive. Here, we study this issue and investigate how ventral tegmental area (VTA) DA activity reflects the ability to withhold prepotent responses during reward expectation. We developed a novel cued-reward lick-withholding task in which head-fixed, water deprived mice must suppress anticipatory licking during reward predicting cues. The task accomplishes the following: 1. It places Pavlovian cue responses in conflict with self-restraint, enabling us to study the neural substrates of action impulsivity. 2. It manipulates the degree of impulsivity by randomly interleaving three different auditory cues that

predict three different reward sizes. 3. It provides a quantitative, trial-by-trial measure of action impulsivity that can be precisely related to neural activity in real-time. The neural recordings were obtained using fiber photometry. Our behavioral results show that mice can discriminate between the three trial types and learn to exhibit self-restraint. In addition, mice behave more impulsively in anticipation of the larger reward, despite it resulting in a reduced rate of reward receipt. Neural recordings show that DA dynamically encodes for the failure to suppress conditioned responses. First, cue-induced phasic DA activity is predictive of impulsivity level, independent of reward expectancy. Second, changes in phasic DA cue responding may explain trial-to-trial variability in impulsivity. Third, DA ramping predicts the onset of impulsive actions. Lastly, impulsive actions lead to greater DA reward responses, suggesting a mechanism for the persistence of this maladaptive behavior. These data imply that phasic cue-induced DA activity drives action impulsivity.

Title: Effects of dorsal and ventral STN stimulation on stopping performance

Authors: N. C. VAN WOUWE[1], S. A. WYLIE[2], P. M. KASKAN[3], E. B. BRADLEY[5], A. M. GIFFORD[2], S. SELVAM[2], S. HUGHES[5], A. LOPEZ[5], J. D. SCHALL[6], F. T. PHIBBS[5], B. M. DAWANT[7], J. S. NEIMAT[4];

Abstract: Objective: Patients with frontal-basal ganglia dysfunction, like Parkinson's disease (PD), often experience problems with controlling their actions, for example, they have difficulty stopping a voluntary action. The PD motor symptoms can be effectively treated with deep brain stimulation (DBS) of the Subthalamic nucleus (STN). However, the precise role of the STN in cognitive functions like stopping control is unclear. The STN consists of functional sub-territories linked to dissociable cortical networks although the boundaries of the subregions is still under debate. The corticostriatal circuitry linking preSMA and right IFC with central STN has recently been associated to stopping control. We investigated whether stimulating subregions of the STN, and stimulation of left versus right STN would show dissociable effects on the

ability to stop. Methods: In experiment 1, we studied 11 PD patients with STN DBS. Patients with two adjacent contacts positioned within the bounds of the dorsal and ventral STN completed two testing sessions (off medication) with low amplitude stimulation (0.4mA) of either the dorsal or ventral contact. Patients performed a stop task with both stimulation settings. The second experiment (prelim data) included two groups of PD patients, receiving stimulation at either dorsal (n=7) or ventral STN (n=5) contacts with 4 different DBS settings: OFF stimulation, right lead DBS only, left DBS only, both left and right DBS. Both groups performed the stop task with each of the 4 DBS settings. Results: In the first experiment, ventral but not dorsal DBS improved stopping latencies ($p<.01$). Go reaction times were similar between dorsal and ventral DBS STN. Preliminary results from experiment 2 indicate that stopping tended to be faster with right ventral DBS STN, whereas stopping was slower with right dorsal STN DBS in comparison to OFF stimulation ($p=.09$). Neither bilateral nor left side stimulation settings modulated stopping and going speed in dorsal and ventral STN subregions. Conclusions: DBS in ventral (but not dorsal) subregion of the STN improved stopping speed. In contrast, previous work by our lab had shown improved conflict control with dorsal stimulation. Current study confirms the involvement of the STN in stopping control and provides support for STN functional subregions. More specifically, ameliorated stopping with right ventral DBS suggest a right lateralized network of inhibition of voluntary action.

Title: Individual differences in impulsivity correlate with weight-gain following DBS for the treatment of Parkinson's disease

Authors: *P. M. KASKAN[1], N. VAN WOUWE[1], W. BURKE[1], J. CHON[2], R. ALI[4], F. PHIBBS[3], P. KONRAD[2], J. NEIMAT[1];
[1]Neurolog. Surgery, Univ. of Louisville Sch. of Med., Louisville, KY; [2]Neurolog. Surgery, [3]Neurol., Vanderbilt Univ. Med. Ctr., Nashville, TN; [4]Restorative and Functional Neurosurg., Michigan State Univ., Grand Rapids, MI

Abstract: Deep brain stimulation (DSB) of the subthalamic nucleus (STN) is intended to treat the motor symptoms of Parkinson's disease (PD) yet can produce a number of non-motor related side-effects. STN stimulation can elicit impulsive or frequent and erroneous responding, increase autonomic responses to affective stimuli, and alter subjective value. Side-effects like weight-gain, common following DBS for the treatment of PD, may be due to altered inhibitory control. We retrospectively reviewed a database which included body mass (BMI), neuropsychological measures, and cognitive data before and after surgery in a population of patients undergoing DBS for the treatment of PD at the Vanderbilt Movement Disorders Clinic (2012-2017). Pre- and post-surgical changes in BMI were calculated, and pre-surgical impulsivity was measured by the Questionnaire for Impulsive Compulsive Disorders Rating Scale (QUIP-RS). Pre-surgical performance on the Simon conflict task provided an additional objective measure of impulsivity. Post-surgical coordinates of active electrode contacts in STN and globus pallidus internus (GPi) were included. Seventy-nine patients were included (STN = 51, GPi = 28). The mean age at surgery was 61.7 years with male:female ratio of 2.5:1. There was a significant increase in weight following DBS (BMI-Pre = 27.4, BMI-Post = 28.8, p <0.001). Performance on the Simon task (STN = 30, GPi = 14) indicated that fast impulsive errors on Simon conflict trials (r = -0.381, p = 0.038), and faster reaction times with those errors (r = -0.368, p = 0.045) correlated with weight-gain in patients with STN targets (but not GPi). Of patients that gained weight (n = 66), patients with STN implants gained more weight than those with GPi implants (weight-gain x DBS target, p = 0.043), especially in patients with impulse control disorder (ICD) (weight-gain x impulse control disorder x DBS target, p = 0.028), corroborating findings on the Simon task. Our current study suggests patients with STN implants could experience a greater increase in BMI compared to patients with GPi implants, particularly when diagnosed with ICD pre-operatively. Future work will investigate the role of active contact location in STN (i.e. limbic, motor, and associative sub-regions), subjective reward sensitivity, response inhibition, and changes in activity in relation to post-surgery weight changes.

Title: Decision-making, impulsivity, and attentional performance in heterozygous dopamine transporter knockout mice

Authors: Y. H. SABER[1,3], O. CHAKER[2], ***F. S. HALL**[2];
[1]Pharmacol. and Exptl. Therapeut., [2]Univ. of Toledo Col. of Pharm. and Pharmaceut. Sci., Toledo, OH; [3]Ninevah Col. of Med., Mosul, Iraq

Abstract: Introduction: Dopamine is a neurotransmitter that has major roles in attention, working memory, reward, motivation, and motor activity. Dopamine signaling perturbations have been implicated in several developmental psychological disorders including attention deficit hyperactivity disorder (ADHD), schizophrenia, and obsessive-compulsive disorder. The dopamine transporter (DAT) has a critical role in regulating dopamine release dynamics. Consequently, during development dopamine activity influences prefrontal cortex maturation, with potential consequences on response inhibition, attention and decision making. DAT +/- mice have reduced DAT expression compared with DAT +/+ mice that produces behavioral and anatomical alterations that have been suggested to model aspects of ADHD. To further evaluate this model, decision-making and attentions were assessed in the 5-choice continuous performance test (5CCPT) and a mouse version of the Iowa gambling task (IGT). Methods: Separate groups of adult male DAT +/+ and DAT +/- mice were tested in the 5CCPT and the IGT. All mice were socially housed throughout testing and mildly food-deprived. The effects of amphetamine (0, 0.3, 0.66, 1.5 mg/kg) were also examined in the 5CCPT. Training in the 5CCPT was modified to accelerate training and testing so that the procedure could be completed in 10 days, to allow testing during the adolescent period in a separate group of mice. Results: In adolescence, DAT +/- mice had a lower sensitivity index (SI), but this was not observed in adult DAT +/- mice. This lower SI resulted primarily from poor response inhibition during no-go trials. Adult DAT +/- mice had more premature errors and incorrect response, and these impairments were reduced by amphetamine. Amphetamine also increased the SI in DAT +/+ mice. In the IGT, adult DAT +/- mice had an impaired ability to switch away from the disadvantageous choices to the advantageous ones. Conclusion: In the present study, adolescent DAT +/- mice showed deficits in response inhibition that impaired performance in the 5CCPT. In adulthood performance was again impaired on other measures, and these deficits could be ameliorated by amphetamine. Adult mice also showed impairments in decision making in the IGT, having difficulty switching from less advantageous choices to more advantageous choices. These cognitive impairments, deficits in decision making and impulsivity are all symptoms of ADHD, and further support the suggestion that DAT KO mice model aspects of ADHD. Moreover, these data suggest that heterozygous DAT deletion, that has more validity for human variation in DAT function, also models cognitive changes that underlie ADHD.

Title: Vagus nerve stimulation attenuates impulsivity in a 5-choice serial reaction time task

Authors: *J. F. DESLAURIERS[1], M. M. BRUNER[6], L. ALTIDOR[2], T. S. GARMAN[1], S. RAMIREZ[1], E. W. DIRR[1], K. OLCZAK[7], A. P. MAURER[3], K. J. OTTO[1], S. N. BURKE[2], D. G. LAMB[4], B. SETLOW[5], J. L. BIZON[8];

Abstract: Impulsivity is a neurobehavioral phenotype that associates with a number of psychiatric disorders, including attention-deficit hyperactivity disorder and substance use disorder. Impulsivity can be assessed in rodent models using a 5-choice serial reaction time task in which rats must wait for presentation of a brief visual cue, the location of which indicates where a response will earn a food reward. Drugs modulating norepinephrine can attenuate premature responses in this task but these drugs also can also have off-target effects. Electrical stimulation of the vagus nerve (VNS) is approved for treatment of epilepsy and several other neuropsychiatric disorders and many of these beneficial effects are attributed to modulation of noradrenergic neurons in locus coeruleus. The current study evaluated whether VNS can inhibit premature responses on the 5-choice task. Adult male Brown Norway rats were trained in operant chambers, in which stimuli are projected on a touch-sensitive video screen. Under baseline conditions, individual differences in performance were observed such that some rats reliably made a high number of premature responses per session (i.e,10-50, “high impulsive”) and others made very few (<5, “low impulsive”). “High impulsive” rats showed worse attentional accuracy and a trend toward fewer omissions compared to “low impulsive” rats. Rats were then tested using a randomized, within-subjects design in which VNS (50 Hz, 60 µs pulse width, 500 µA, 0.8 s train duration) was delivered upon correct responses. These VNS parameters decreased premature responses in high impulsive rats, in the absence of effects on either attentional accuracy or trial omissions. Several additional VNS parameters (30 Hz, 120 µs pulse width, 700 µA, 0.8 s train duration, or 12.5 Hz, 100 µs pulse width, 400 µA, 1.25 s train duration) had no effects on performance. For comparison, a separate group of rats was tested in the 5-choice task following acute administration of the noradrenergic reuptake inhibitor atomoxetine (0, 0.3, 1.0, 3.0 mg/kg), using a randomized, within-subjects design. As has been previously reported, atomoxetine reduced premature responses, but also impaired attentional accuracy and increased trial omissions. Considered together, the data show that VNS is efficacious for reducing motor impulsivity, in the absence of off-target effects evident in pharmacological approaches. The findings suggest that VNS might be useful in conditions characterized by elevated impulsivity.

Title: Symptoms of post traumatic stress disorder in police officers are related to ERP measures of cognitive control in a Go/NoGo task

Authors: *J. L. SHUCARD[1], X. WANG[1], M. EVANS[1], T. J. COVEY[1], J. M. VIOLANTI[2], D. W. SHUCARD[1];

Abstract: Police officers are frequently exposed to traumatic events and are at high risk for the development of Posttraumatic Stress Disorder (PTSD). This study examined the effects of PTSD symptoms on the ability of active duty police officers to make rapid and critical decisions. Dense electrode (256 channels) electroencephalography (EEG) was used to extract event-related brain potentials (ERPs) from the scalp-recorded EEG obtained while trauma-exposed police officers and non-trauma exposed civilians performed two visual A-X CPT Go/NoGo tasks (each approximately 10 minutes in length). Participants had to respond (Go) with a button press to an "X" when it followed an "A", and inhibit their response (NoGo) when a letter other than "X" followed the "A." The first task had normal letter stimuli and the second had visually degraded stimuli, which increased the difficulty of stimulus discrimination. The tasks provide behavioral and neural measures of target detection (Go), response inhibition (NoGo), and ability to screen irrelevant stimuli. ERPs are uniquely able to measure the timing (in msec) of neuronal decision-making events that require cognitive control mechanisms necessary to respond or inhibit a response. The N2 and P3 components are thought to reflect different aspects of cognitive/response control, with the NoGo N2 being related to conflict monitoring and the NoGo P3 to inhibition of a response. We hypothesized that conflict monitoring, as measured by N2, and inhibitory control, as measured by the NoGo P3, would be affected by the level of PTSD symptoms in police. Degraded stimuli were hypothesized to increase conflict and demand on inhibitory processes, thereby enhancing the ability to detect deficits in cognitive control. Preliminary examination of ERPs components for high PTSD symptom police, low symptom police, and controls (32 officers and 14 controls) from an ongoing large-scale study showed that all three groups had the expected Go/NoGo effects for N2 and P3, with greater fronto-central amplitude NoGo compared to Go for the regular stimuli. However, differences were present in the waveforms, particularly for the degraded stimuli, that were dependent on the degree of PTSD

symptoms. For example, the high PTSD symptom police group had the greatest fronto-central P3 amplitude to NoGo stimuli, and an attenuated fronto-central N2 for the NoGo degraded stimuli. These findings may reflect reduced cognitive control and increased activation of response inhibition in high symptom police relative to the other two groups.

Title: Rats play hide & seek, an elaborate role-play game

Authors: *A. S. REINHOLD, J. I. SANGUINETTI SCHECK, K. HARTMANN, M. BRECHT;
Bernstein Ctr. for Computat. Neurosci., Humboldt Univ. of Berlin, Berlin, Germany

Abstract: Evolutionary, cognitive and neural underpinnings of mammalian play are not yet fully elucidated. We played 'Hide & Seek' – an elaborate role-play-game – with rats. We did not offer food-rewards, but engaged in playful interactions with rats after finding or being found. All rats quickly acquired the game and learnt to switch roles. During 'Seek', rats systematically searched a large $30m^2$-room and guided searches by visual cues and memories of past hiding locations. Hiding strategies included preferences for non-transparent over transparent hiding enclosures and frequent changing of hiding locations.
Rats emitted complex ultrasonic vocalizations during 'Hide & Seek' that varied with game-events and trial types. Vocalization rates peaked at the beginning of the game, when finding the experimenter, during playful interactions and when being returned. Rats called very little when searching, when hiding and when being found. Hence, ultrasonic calls might coordinate rat role-play. The game of 'Hide & Seek' affords rules. Rats played by these rules and showed highly distinct behavior between 'Hide' and 'Seek' trials.
'Hide & Seek' has found little attention in science, but our findings confirm pet-owner-reports that animals enjoy playing 'Hide & Seek'. Fast acquisition, strategic behavior and game-adequate vocalization patterns – traits, which emerged without specific conditioning – point to an innate preparedness for role-play and elaborate cognitive and neural capacities for 'Hide & Seek' in rats. We suggest that role-play in general and 'Hide & Seek' in particular might be very old.

The paradigm established here offers a playful approach to the mammalian mind and the comparative study of social role-play behavior.

Title: Neural correlates of 'hide and seek' in medial prefrontal cortex

Authors: *J. I. SANGUINETTI-SCHECK[1], M. CONCHA-MIRANDA[2], A. S. REINHOLD[1], K. HARTMANN[1], M. BRECHT[1];
[1]Humboldt Univ. of Berlin/ BCCN Berlin, Berlin, Germany; [2]Lab. de Neurosistemas, Fac. of Medicine, Univ. of Chile, Santiago, Chile

Abstract: Rats have elaborate cognitive capacities for playing 'Hide & Seek' (accompanying poster Reinhold et al, 2019). Rats are able to switch roles, they use strategies for successful play and develop differential game-related vocal patterns. The brain is rarely studied during such rich unrestricted behavior. We investigated the neural correlates of 'Hide & Seek' by performing tetrode recordings of single neurons (n=177) in rat medial prefrontal cortex, a brain area previously associated to decision making, social proximity and task rules. A data logger system allowed us to record from untethered freely playing animals in a 30 m^2 room. We assessed if medial prefrontal cortex neurons are engaged with 'Hide & Seek'. Our recordings revealed intense prefrontal cortex activity that varied with game-events (initiation, finding, being-found, interaction, etc.) and trial-types ('Hide' vs. 'Seek') and might thus coordinate role-play behavior. Our results indicated that medial prefrontal cortex follows closely the narrative of the game. We then also asked, what happens in rat medial prefrontal cortex, when the animal observes others playing vs when the animal plays 'Hide & Seek' itself? We again found prefrontal cortex activity (n=110) that was sharply locked to game-events, when the animal played itself. Observing play, however, did not lead to a comparable activation of rat medial prefrontal cortex. Average firing rates during observing play were lower than during real play and neural responses during observing game-events did not mirror event responses during play. We conclude that even though rat medial prefrontal cortex is highly engaged during 'Hide and Seek', it's activity does not mirror play-events under our experimental conditions. We wonder if the lack of prefrontal

activity while observing play points to the necessity of a ‘play brain state’ for engaging prefrontal cortex.

Title: Basolateral amygdala and recognition memory for social odors

Authors: *Z. SONG[1], S. SWARNA[2], J. MANNS[1];
[2]Dept. of Neurosci. and Behavioral Biol., [1]Emory Univ., Atlanta, GA

Abstract: The amygdala, a key component of the neural circuitry that supports adaptive affective behavior, is implicated in a variety of behavioral disorders including autism, PTSD, and psychopathy. It is essential for learning and leveraging the affective salience of stimuli, including not only associating tones with fear responses, but also including processing stimuli with particular relevance to social interactions. The present project examined the extent to which the basolateral complex of the amygdala (BLA) in female rats was involved in processing social cues and more specifically the recognition memory of social odors. Urine odors of female and male rats were used as stimuli, as conspecific urine is a potent social cue that conveys a range of socially-relevant information such as health, sex, social status, and reproductive status. Household aromatherapy scents were used as nonsocial control stimuli and were presumed to not bear any biological significance. All the social odors and aromatherapy scents were novel to the rats prior to each experiment. Recognition memory was tested using a spontaneous preference for novel odors paradigm, and one question was whether differences in baseline preference for social versus nonsocial odors might impact the results. In general, female rats showed preference for male urine as compared to female urine and nonsocial odors. In addition, inactivation of the BLA via infusion of muscimol, as compared to infusion of saline, appeared to impact both baseline preference and recognition memory of male urine more than for female urine. The results suggested that the role of the BLA in spontaneous preference for novel social odors might differ for same-sex versus opposite-sex urine, perhaps indicating a role for the BLA in modulating both preference and memory.

Title: New model to assess prosocial behaviours in juvenile rats: An operant box sharing task

Authors: *V. CHARRON, J. TALBOT, H. PLAMONDON;
Sch. of Psychology, Dept. of Neurosci., Univ. of Ottawa, Ottawa, ON, Canada

Abstract: Altruism is characterized by a behaviour associated with a cost to the animal while granting a beneficial outcome for others. Prosocial behaviours have been studied in primates and other animals, including rodents. The majority of models used is pain or fear related, but positive prosocial behaviours are not as much studied in rodent models. Existing literature supports that rodents can exhibit prosocial behaviours, although research on altruistic behaviours is sparse and limited. This pilot study aims to establish a novel method measuring prosocial behaviours in rats. Long-Evans adolescent male rats (PND 28- *n*=8) were housed in pairs. During the test, one rat was assigned an observer's role while its cagemate could engage in prosocial behavior. A modified operant box unit with two levers was used. The box was divided by a plexiglass wall were rats could see, smell and hear each other. The task was designed so that the actor could choose to press an easy lever (35 g of pressure needed), which dispenses one single pellet to the actor, or push a harder lever (75 g of pressure needed), dispensing one pellet to the actor and one pellet to the observer. Our findings showed that the actors pressed more frequently the hard lever compared to the easy one. This method could help assess different social behaviours, including altruism, cooperation and prosocial choices, helping to understand prosociality in rodents. It could also help determine bio/behavioural responses underlying mental health disorders, including autism, depressive and anxiety-like behaviours.

Title: Prior relationship as a mediator in prosocial behaviours in rats: A stranger rat operant box task model

Authors: *J. TALBOT, V. CHARRON, H. PLAMONDON;
Sch. of Psychology, Dept. of Neurosci., Univ. of Ottawa, Ottawa, ON, Canada

Abstract: Previous research investigated animals' ability to display prosocial behaviour under aversive conditions or constraints. As a result, current literature is sparse and limited when it comes to altruistic behaviour testing using a stranger rat scenario. This study aims to compare a prosocial behaviour in a sharing scenario where the rat is either a stranger versus a cagemate. Based on findings from previous research on the same theme, we speculate that faced with a concrete reward in form of pellets, actors will be more prone to display a prosocial behaviour towards cagemates versus stranger rats (i.e., making a greater effort in order to give a reward to the other rat). Male Long-Evans late adolescent through early adulthood rats (PND 28- *n*=8) were used. The task consisted of an actor and an observer, where the observer was either a cagemate or a stranger rat. The actor has a choice of two levers, one of which dispenses one sucrose pellet only to himself (defined as the easy lever, 35 g of pressure needed), while the hard lever (75 g of pressure needed) dispenses one pellet to both rats. Preliminary results show that the actors tend to prefer pressing the harder prosocial behaviour lever over the more selfish approach, when facing their cagemate. At present, the second phase using a stranger rat is still ongoing. Once acquired, the data will help create a solid anchor and could help direct future studies in prosocial behaviour observation in rodent models.

Title: VIP neurons support CA2 input-timing dependent plasticity and social memory

Authors: *F. LEROY, C. A. DESOLIS, A. ASOK, S. A. SIEGELBAUM;
Neurosci., Columbia Univ., New York, NY

Abstract: CA2 pyramidal neurons receive strong excitatory input from entorhinal cortex (EC) that is capable of triggering CA2 spike output. CA3 pyramidal neurons also receive excitatory input from the CA3 Schaffer collaterals (SC). However, the SC input to CA2 is dominated by strong feedforward inhibition mediated by PV^+ interneurons (INs). In contrast to the well-known ability of SC inputs to CA1 to support long-term synaptic potentiation, the SC inputs to CA2 are highly resistant to LTP induction. As CA2 neurons are important for social memory, one important goal is to identify the cellular and molecular mechanisms that may contribute to CA2 memory storage. In previous work we found that CA2 pyramidal neurons undergo input timing-dependent plasticity (ITDP), a heterosynaptic, circuit-based form of plasticity in feedforward inhibition first described in CA1. Pairing of the direct entorhinal cortical (EC) inputs to CA2 with the CA2 SC inputs at a 20 ms delay interval (EC before SC) produced a δ-opioid receptor-dependent long-term depression of PV^+ IN feedforward inhibition. Social interactions with a novel mouse reduced the magnitude of ITDP, suggesting that social memory storage may recruit CA2 ITDP. Finally, we found that infusion of the δ-opioid receptor (DOR) antagonist naltrindole through a cannula into CA2 impaired social memory, suggesting that ITDP may provide CA2 with a mnemonic plasticity mechanism. To further explore the mechanism of CA2 ITDP and its link to social memory, we searched for the source of enkephalin (ENK), the principal DOR agonist, released during CA2 ITDP. Consistent with previous studies, we found that ENK and VIP expression overlap extensively in CA2/CA3. Using a VIP-cre mouse line to selectively identify or target VIP^+ INs, we activated or silenced these cells using optogenetic tools in acute dorsal hippocampal slices. We found that VIP^+ INs in the CA2 region received excitatory input from both EC and CA3, suggesting that they could integrate these distinct inputs during paired stimulation. Importantly, optogenetic stimulation or inhibition of the VIP^+ INs, respectively, triggered or blocked CA2 ITDP. Moreover, activation of VIP^+ INs failed to elicit ITDP when naltrindole was present in the bath to block DORs. Finally, using viral injections to express the inhibitory DREADD (iDREADD) in VIP^+ INs in CA2 and neighboring hippocampal regions, we found that silencing hippocampal VIP^+ INs *in vivo* with systemic injection of the DREADD ligand CNO was sufficient to impair social memory. Overall, our results support the hypothesis that enkephalin release from VIP^+ INs during social interactions triggers CA2 ITDP and allows the formation of social memory.

Title: Regulation of social behavior along the dorsoventral axis of the hippocampal subregion CA2

Authors: *L. M. BOYLE[1], F. LEROY[1], R. B. SAHAI[1], S. IRFAN[2], S. A. SIEGELBAUM[3]; [1]Columbia Univ., New York, NY; [2]Barnard Col., New York, NY; [3]Dept of Neurosci., Columbia Univ. Coll P & S, New York, NY

Abstract: Altered social behavior is a prominent feature of psychiatric and neurological disorders including autism spectrum disorder (ASD), depression, and schizophrenia. The neuropeptide vasopressin has emerged as one essential signaling molecule for social cognition and behavior. Polymorphisms in the AVPR1b vasopressin receptor subtype are associated with ASD, and knockout of this receptor in mice results in decreased sociability, social recognition memory (SRM), and social aggression. In the hippocampus, AVPR1b is exclusively expressed in the CA2 region. Recently, activation of vasopressin inputs from the paraventricular nucleus (PVN) to the CA2 region in dorsal hippocampus was shown to enhance SRM in mice, while inhibition of dorsal CA2 (dCA2), and in particular the projections of dCA2 to ventral hippocampus, results in an impairment in the encoding, consolidation and recall of SRM. Multiple studies demonstrate that while the dorsal hippocampus primarily regulates contextual memory and spatial navigation, ventral hippocampus plays an important role in anxiety, emotional processing and social memory. Here, we explore the hypothesis that, whereas dorsal CA2 may influence SRM, ventral CA2 may influence other aspects of social behavior. As the dorsal-ventral extent of CA2 remains relatively unexplored, we first examined the expression of several molecular markers that are characteristic of dorsal CA2. We find that whereas the expression of some CA2 markers is restricted to more dorsal regions of hippocampus, a population of AVPR1b-expressing cells, defined using an AVPR1b-Cre line, extends along the entire extent of the dorsoventral axis of CA2. Moreover, the ventral CA2 region receives dense vasopressin inputs from the PVN. Anterograde tracing reveals that dorsal and ventral CA2 project topographically to output regions, providing a potential mechanism for a differential functional role. We are therefore using a pharmacogenetic approach to compare how selective manipulations of dorsal versus ventral CA2 affect different aspects of social behavior.

Title: The role of hippocampal area CA2 in the pilocarpine mouse model of mesial temporal lobe epilepsy

Authors: *A. C. WHITEBIRCH, K. VADDURI, B. SANTORO, S. SIEGELBAUM; Neurosci., Columbia Univ., New York, NY

Abstract: Mesial temporal lobe epilepsy (MTLE) is a drug-resistant form of epilepsy associated with a pattern of pathology termed mesial temporal sclerosis, in which there is extensive cell loss in the hippocampal CA1 and CA3 areas while the dentate gyrus and CA2 remain relatively intact. The fact that the hippocampus is a major site of seizure activity in MTLE, despite the degeneration in CA1 and CA3, suggests that epileptiform activity may be generated in or conveyed through surviving CA2 circuitry. Accumulating evidence also suggests that CA2 may have a key role controlling hippocampal network excitability in the healthy brain. However, relatively little is known about CA2 circuitry under either physiological or pathological conditions. To explore whether changes to CA2 excitability or functional synaptic connectivity may contribute to seizure activity in MTLE we utilized the pilocarpine mouse model of temporal lobe epilepsy, in which a single dose of pilocarpine (PILO) induces acute *status epilepticus* and ultimately causes recurring spontaneous seizures. We used optogenetic and chemogenetic excitation and inhibition to selectively manipulate CA2 using Cre-dependent viral expression in the *Amigo2-Cre* mouse line and obtained electrophysiological recordings from CA2 pyramidal neurons (PNs) in acute hippocampal slices from control and PILO-treated mice. We found that in normal brain tissue, CA2, like CA3, forms an auto-associative excitatory network. Thus, CA2 PNs send longitudinal projections that excite other CA2 neurons. However, normally this recurrent excitation is small and dominated by feedforward inhibition. Similarly powerful feedforward inhibition is also recruited by CA3 Schaffer collateral input to CA2 and by CA2 PN back-projections to CA3. Preliminary recordings in slices from PILO mice revealed a significant reduction in feedforward inhibition recruited by excitatory inputs to CA2 PNs, including the CA3 Schaffer collateral inputs and CA2 recurrent collateral inputs. Notably, fast inhibition mediated by $GABA_A$ receptors shows a greater reduction than slow $GABA_B$-mediated inhibition. In addition we found an increase in the intrinsic excitability of CA2 PNs, largely as a result of

increased input resistance. Taken together, these data suggest a shift in the inhibitory-excitatory balance of the CA2 network and provide support for the hypothesis that CA2 may contribute to the generation of epileptiform activity in the hippocampus.

Title: Ca2 ripples regulate social memory

Authors: *A. OLIVA[1], S. A. SIEGELBAUM[2];
[1]Columbia Univ., New York, NY; [2]Dept of Neurosci., Columbia Univ. Coll P & S, New York, NY

Abstract: Sharp-wave ripples (SWRs) represent a synchronous pattern of population activity in the hippocampus during slow wave sleep that are necessary for spatial memory consolidation. This mnemonic function likely results from the sequential reactivation of place cells that replay spatial trajectories recently experienced by the animal. Although the role of SWRs in spatial memory is well established, it is not known if they are also involved in other types of hippocampal-dependent memory. Here we explore the role of SWRs in social memory, the ability of an animal to recognize and remember a conspecific. Recent evidence suggests that social memory encoding, consolidation and recall require the participation of the hippocampal CA2 region *and* that CA2 acts as a local source of SWR generation. These separate findings led us to investigate the role of SWRs and CA2 in social memory. We found that CA2 and CA1 ensembles that were more active during social exploration of a novel animal were reactivated during SWRs during sleep. Moreover, specific optogenetic silencing of CA2 pyramidal cells during social exploration impaired memory performance and SWR reactivation during sleep. In addition, closed-loop interference with spontaneous SWRs, using strong brief pulses of optogenetic stimulation of CA2 pyramidal neurons, suppressed the formation of social memory. Furthermore, promoting SWR firing during consolidation using weak shaped light pulse activation of CA2 pyramidal cells enhanced social memory duration. We are currently investigating the computational capabilities by which the hippocampus represents such social

episodes. Social memory deficits associated with mental disorders, such as schizophrenia, are recapitulated in a genetic mouse model (Df(16)A+/-) of the human 22q11.2 deletion syndrome that has intrinsic and synaptic alterations in CA2. Most SWRs in these mice had abnormally high frequency components, with a minority of physiological SWRs showing normal physiological parameters. By combining optogenetic closed-loop SWR disruption and generation we were able to interfere with aberrant SWRs and promote normal SWRs using appropriate light pulses during consolidation. Remarkably, this manipulation was sufficient to rescue social memory deficits to a level comparable to wild-type animals. Our results demonstrate that SWRs and CA2 reactivation are both necessary for the consolidation of social memory, a non-spatial, complex form of information storage, and sufficient to enhance social memory performance in wild-type mice and restore social memory in a neuropsychiatric disease model.

Title: Population dynamics during olfactory discrimination of hippocampal area CA2 in mice

Authors: *S. HASSAN[1], S. A. SIEGELBAUM[2];
[1]Neurosci., Columbia Univ., New York, NY; [2]Dept of Neurosci., Columbia Univ. Coll P & S, New York, NY

Abstract: Social cognition is one of the key features that underlie an animal's sense of a stable community and allows formation of lasting social relationships. It refers to the psychological and neural processes that are involved in the perception, encoding, storage, retrieval and regulation of information about conspecifics in relation to an individual, including the process of social memory, the ability to recognize and remember an individual conspecific. Despite a growing body of research aimed at resolving the underlying mechanisms of social cognitive processes, a detailed understanding about the brain regions involved and especially their specific population activity dynamics in the context of social behavior is still lacking.
Recent work in our lab identified a crucial role of the CA2 subregion of the hippocampus in social recognition memory in rodents. Silencing of excitatory output from CA2 resulted in the loss of the encoding, consolidation and recall of social recognition memory and also suppressed social aggression between a resident male and an intruder. An important next step is the characterization of the underlying dynamics and processing of sensory cues that take place

during social recognition in CA2, ideally employing a high resolution approach that allows the identification of population dynamics during social recognition and memory recruitment. Olfactory stimuli, and in particular olfactory social stimuli such as urine, are one candidate salient cue that may enable mice to recognize conspecifics. We are using an olfactory discrimination task involving both social and non-social odors in awake, head-fixed mice while using 2-photon imaging of CA2 neuron activity based on GCaMP6s fluorescence signals. Our preliminary results indicate that mice are able to discriminate social odors from distinct male conspecifics and that these odors trigger robust CA2 activation. Experiments in progress explore whether CA2 activity can distinguish social from non-social odor cues.

Title: Humans and monkeys playing an interactive chicken game with an option to cooperate

Authors: *W. S. ONG, M. L. PLATT;
Univ. of Pennsylvania, Philadelphia, PA

Abstract: Competitive opponents today might be cooperative allies tomorrow. Navigating social environments requires understanding the strategies of others, and how their actions may change across different situations. The neurobiological mechanisms that mediate dynamic social interactions remain poorly understood. To address this gap, we devised a variant of the “chicken” game that alternates between competitive and cooperative scenarios that can be played iteratively, by pairs of players, either monkey or human, thus opening up the possibility of studying the underlying neurobiology at multiple levels.
Two individuals (S1&S2) faced each other across screen(s) showing 2 colored annuli and 4 response targets. On some trials, the larger reward (denoted by visual tokens) was opposite S1 behind S2’s annulus and smaller rewards were on the left (see figure). S1 is tempted to choose straight, but if S2 also chooses straight the annuli collide and neither player receives reward. On some trials, a “cooperation bar” allows both players to unlock larger rewards if and only if they both choose to swerve; if only one swerves he receives a smaller reward and the other player

receives the larger reward for going straight.
To understand the underlying process, we created a model in which S1 uses his beliefs about S2's strategy to predict his behavior on each trial. S1's beliefs about S2's strategy are represented as a logistic regression relating the potential payoffs on a trial to the probability of S2 swerving or going straight. S1 learns S2's strategy by updating his beliefs using a strategic prediction error, computed as the mismatch between his expectation of S2's choice and what S2 actually did.
Most human players (181 pairs) preferentially played cooperative strategies irrespective of the payoffs on the current trial, consistent with the simplest model. By contrast, monkeys (4 pairs) were much more attentive to payoffs for self and other, consistent with the belief updating model. We also collected eye-tracking data (n=75) and EEGs (n=20) on a subset of pairs of human players. Humans rarely looked at their opponents, unlike monkeys, although both species preferentially looked at their opponents after they made selfish choices.

Abstract: The ability to guess other's mental states, such as beliefs or desires driving their behavior, is fundamental to social interactions among individuals. Acquisition of this function, called "theory of mind (ToM)", is critically evaluated by testing whether one predicts others' actions according to their beliefs, even when those beliefs are different from reality. Human neuroimaging studies using various false-belief (FB) attribution tasks have revealed the relationship between ToM and brain networks including the medial prefrontal cortex (mPFC). However, whether the mPFC plays a causal role in ToM remains unsettled due to the lack of interventional studies to manipulate neuronal activity using appropriate animal models of FB attribution. In the present study, we initially used an anticipatory looking FB paradigm in eight macaque monkeys and found spontaneous gaze bias of the monkeys implicitly anticipating others' FB-driven actions. We next examined whether there is causation between the neuronal activity of the mPFC and the animals' spontaneous gaze bias to the FB targets. A lentiviral vector incorporating hM4Di, an inhibitory DREADD (designer receptor exclusively activated by designer drugs) was injected into the mPFC in five monkeys. Six weeks following viral injection, we chemogenetically inactivated the mPFC by intramuscular injection of clozapine N-oxide (CNO), a specific ligand to hM4Di. Within 60 to 80 minutes after CNO injection, neuronal activity in the mPFC was significantly inhibited. We found that chemogenetic deactivation of the mPFC by CNO injection in hM4Di-expressing monkeys specifically altered the gaze bias to the FB target. If CNO was injected into animals without hM4Di expression, or saline was injected into hM4Di-expressing animals, the gaze bias remained significant. Thus, hM4Di induction or CNO application alone did not alter, but their combination did alter FB comprehension in macaques. Therefore, FB attribution-like behaviors underpinned by shared neural circuits with humans are demonstrated in non-human animals, suggesting that the mPFC would have evolved as a crucial hub of the brain network causally linked to mental attribution in the primate lineage.

Title: Effect of anterior cingulate cortex damage on live social interactions in rhesus monkeys

Authors: *B. M. BASILE, J. SCHAFROTH, C. KARASKIEWICZ, E. A. MURRAY;
Lab. of Neuropsychology, Natl. Inst. of Mental Health, NIH, Bethesda, MD

Abstract: The anterior cingulate cortex (ACC) has been implicated in social cognition. Previous work from our lab has shown that rhesus monkeys with selective ACC damage do not acquire the species-typical preference for giving juice to a familiar conspecific over giving juice to nobody. This suggests a deficit in social valuation. However, it is less clear the degree to which ACC lesions affect more natural social relationships. To fill this gap, we assessed the dominance relationships of monkeys before and after selective, bilateral, ibotenic acid lesions of the ACC. We tested nine monkey dyads in total. First, individuals sat opposite each other in chairs while we video recorded them. To assess dominance, we coded the time gazing at the other monkey, the number of looks at the other monkeys, affiliative lipsmacks, aggressive yawns, and stress yawns. Next, we tested each dyad on a food competition task in which individual grapes were sequentially placed between the two monkeys. Finally, we solicited subjective ratings of which individual seemed most dominant from the monkeys' primary handler and a monkey expert who viewed the videotapes but did not know these monkeys. Three individuals, representing six of the nine dyads, were then given bilateral ACC lesions, the remaining three dyads were left intact as controls, and we re-ran our tests. Preliminary results suggest one dominance reversal and subtle changes in viewing pattern of monkeys with ACC damage, but no robust social dysregulation. These data help characterize the role of the ACC in live social interactions.

Title: Agent related activity in area 10 of macaque monkeys during a social interactive task

Authors: *L. FERRUCCI[1], S. NOUGARET[1], V. FASCIANELLI[1], R. C. SAUNDERS[2], A. GENOVESIO[1];
[1]Dept. of Physiol. and Pharmacol., Univ. of Rome Sapienza, Rome, Italy; [2]Lab. Neuropsychol, NIMH, Bethesda, MD

Abstract: The most anterior part of the frontal cortex in primates is represented by the Frontal Pole (FP), also known as Broadmann's area 10, and contributes in many aspects of cognition.

Human imaging studies suggest that the FP mainly contributes to complex reasoning and problem-solving and that its position among the neighboring prefrontal regions enables a flexible control of decision-making. To date, the only electrophysiological study available highlights the importance of the FP in the encoding of monkey's decision at feedback time. The present work aims to study the contribution of the FP in the monitoring and the evaluation of goals achieved through self-generated decisions and other agent's decisions. With this purpose, we recorded the activity from three 96-channels arrays implanted on the FP of two monkeys while they performed two different variants of a Non-Match-To-Goal task. The task's rule required the monkeys to discard the stimulus selected in the previous trial and to select the other one. Following the same Non-Match-To-Goal rule, the monkeys performed the task in two different conditions, interacting in a subset of trials with a human or a computer agent, alternating their roles as actor or observer. Both monkeys showed high performance in both conditions. They were able to keep in mind not only their own previous choice but also the human's or the computer's choice to select the stimulus accordingly in their following trial. We recorded the single-unit activity of 319 cells to investigate whether and how FP neurons encoded the agent identity. As reported before, the greatest modulation was found around feedback time. Of 319 cells, 109 (34%) cells were modulated at feedback time depending on who performed the trial, either the monkey or the human partner. In the same way but to a less extent, 62/319 cells (19%) showed a significant difference in their activity at feedback time between monkey and computer trials. This finding indicates that the FP distinguishes agents, monitoring differently self-generated and others agent's behaviors. The higher number of cells encoding the agent in the human interaction condition compared to the computer interaction condition (34% vs 19%, $p < .001$) indicates that the FP also differentiates real physical agent from computer and plays a key role in social cognition.

Title: Superior temporal sulcus (STS) neurons integrate social cognition with economic value in monkeys trading in a simulated stock market

Authors: *A. W. HUTTUNEN[1], M. L. PLATT[1,2,3];
[1]Wharton Marketing, [2]Dept. of Med., [3]Dept. of Psychology, Univ. of Pennsylvania, Philadelphia, PA

Abstract: In social environments, information gleaned from others' movements, facial expressions, or gaze often serves as an important factor in our own decision-making calculations. Evolutionarily, the ability to make inferences about the intent behind others' behavior (i.e. Theory of Mind, ToM) leads to improved chances of foraging success and escape from predation. However, individuals in stochastic financial markets often maladaptively employ ToM when forecasting others' value estimations, leading to 'bubble' markets and market crashes. Prior research supports the hypothesis that connections between brain areas associated with value judgements (e.g. ventromedial prefrontal cortex; vmPFC) and those associated with ToM (e.g. temporal parietal junction; TPJ) underlie suboptimal decision making due to artificial inflation of stock values (De Martino et al., 2013). Current work in our lab demonstrates that macaque middle superior temporal sulcus (mSTS), the putative homolog of human TPJ, is engaged during strategic social decision making, highlighting a potential role for mSTS in social biasing of decisions in financial markets. In order to further explore the evolutionary roots and neural circuit mechanisms underlying these behaviors, we developed a rudimentary 'stock market' task for rhesus macaques (Macaca mulatta; N=2), which was also validated in humans (N=350). Multichannel electrodes recorded electrophysiological activity from mSTS while monkeys made investment decisions on a touchscreen computer for juice reward in 4 conditions: 1) computer opponent, 2) replay opponent, 3) decoy opponent, and 4) live opponent. We speculated that willingness-to-pay would be biased by other monkeys' choices in the social condition, but not by the computer's choices in the non-social condition. We then intranasally delivered the social neuropeptide oxytocin (or saline) prior to performing the task to determine its effect on behavior and neural activity. Our behavioral results indicate that both humans and macaques are willing to pay more per share when playing with a conspecific compared to a computer. In monkeys, mSTS differentially signals the value of M1 actions in social and non-social contexts, and firing rates are modulated by M2 choices in the social condition only. We also observed an overall increase in engagement of mSTS as well as increased 'herding' behavior under oxytocin conditions compared to saline controls. This research suggests that mSTS encodes a social information signal that is likely integrated into downstream valuation computations (e.g. in vmPFC), which biases choices toward suboptimal decisions in bubble markets.

Title: Effects of the CB1 receptor antagonism on social interaction in capuchin monkeys

Authors: *R. S. MAIOR, N. GONCZAROWSKA, F. V. CAIXETA, C. TOMAZ;
Univ. of Brasilia, Brasilia, Brazil

Abstract: University of Brasilia, Brazil. The Endocannabinoid System (ES) is an important modulator of different neural functions, including memory and emotions. Changes in the ES's activity is known to play a role in several neurological disorders, such as autism spectrum disorders (ASD). In the present study, we evaluated the ES's role in social interaction in *Sapajus* spp. by blocking the CB1 receptor with the antagonist AM251. Social and non-social behaviors of five adult males were observed after administration of AM251 at the doses of 0.3, 1.0 and 3.0 mg/kg, i.m. All behavioral sessions were carried out in the animals' home cage. AM251 administration increased self-directed behaviors while it decreased social behaviors at the highest dose. No changes were observed in vigilance and locomotion. These preliminary results corroborate findings of studies with rodents, implicating an important role for CB1 receptor in social interaction. Taken together, the results indicate that the CB1 receptor may be involved in social deficits observed in (ASD). Supported by CNPq (455532/2014-1) from Brazil.

Title: Decoding others' intention to interact in the human parietal lobule

Authors: *M. HAN[1], Q. LIANG[1], S. KUAI[1,2];
[1]Sch. of Psychology and Cognitive Sci., East China Normal Univ., Shanghai, China; [2]NYU-ECNU Inst. of Brain and Cognitive Sci., New York Univ. Shanghai, Shanghai, China

Abstract: It is essential for human beings to understand others' intention to interact with him/her in a social environment. Previous studies have indicated other people's heading direction and distance are critical cues for judging their social interaction. However, there has been little quantitative analysis of these cues. In this study, we asked participants to report whether a virtual avatar was intended to interact with him/her while their brain activation was recorded in an MRI scanner. In an event-related run, a virtual avatar was presented at a distance of 1m, 2m, 4m, or 6m. The heading of avatars varied from -75° and 75° at a step of 15°. Our behavioral results showed that the probability of interaction significantly decreased as a shift of heading direction and an increase of distance. We used a psychophysical model to fit the probability of interaction and defined 50% as the threshold. The thresholds were 28.83°, 22.79°, 16.60° and 13.03° at the distance of 1m, 2m, 4m, and 6m respectively. In the fMRI data analysis, we selected the occipital area, superior parietal lobule (SPL) and the precuneus as the region of interest (ROI). In each ROI, we trained support vector machine classifiers to predict whether the avatar intended to interact with participants in each stimulus trial. We found that thresholds of the occipital area (mean threshold = 46.24°) were significantly higher than that of behavioral data (mean threshold = 20.31°). The mean threshold decreased to 33.29° in SPL and 27.85° in the precuneus, which was comparative with that of behavioral threshold. The results indicate that the human brain analyzes the heading direction and distance of others in the occipital regions, and then interprets the others' intention to interact with him/her in the high-level parietal area, such as precuneus.

Abstract: Recognitions of others may occur at different levels: social hierarchical status, health (e.g., parasitic load), emotions (e.g., stress-empathy), genetic relatedness (kin recognition) familiarity (have I met you before?) and individual identity (yes, you are Alma). To maintain successful complex social behaviors, the neural network must allow dynamic acquisition, representation and retrieval of the social cues. The involvement of the CA2 subfield of the hippocampus in social memory have been well established[(1-4)]. Still, the way these memories are encoded by it remains, for the most part, unknown. We created a transgenic mouse line expressing Cre driven by the vasopressin 1b receptor (Avpr1b) promoter that allows us to target the viral delivery of a Cre-dependent calcium sensor (GCaMP6s) into the pyramidal neurons of CA2 hippocampal subfield. We found a unique scheme of neural encoding in the dCA2 for social memories that is different from that for inanimate object memory encoding. These results provide insight into the neural correlates of social memory and will promote more studies of its architecture.References: 1. Young, W. S., J. Li, S. R. Wersinger, and M. Palkovits. Title: Cross brain neural signatures of strategic pairwise interaction in humans and monkeys

Authors: *Y. JIANG, M. L. PLATT;
Neurosci., Univ. of Pennsylvania, Philadelphia, PA

Abstract: Animals and humans alike compete with conspecifics for various resources. Even though social competition involves at least two agents with opposing goals dynamically interacting and continuously updating their expectations about each other, so far most studies have only focused on examining the behavior and underlying neurobiology of a single agent making reiterated two alternative forced choices. Here pairs of humans and rhesus macaques played a zero-sum competitive soccer game, in which one player (the kicker) tried to continuously circumnavigate the other player (the goalie) to win a point. Simultaneously, neural recordings were obtained using EEG in humans and single unit electrophysiology in monkeys. Behavioral analyses and computational modeling with Gaussian Processes revealed that the interactions between human and monkey players were similarly complex. Both species utilized comparable strategies and were equally sensitive to their opponents'. In monkeys, we found that firing rates of neurons in mid-superior temporal sulcus (mSTS), a potential homologue to human temporo-parietal junction (TPJ), encoded various aspects of the game including strategy, behavioral context, and game outcome. Most importantly, there were two distinctive populations of mSTS neurons and they retained different types of information regarding local trial history. Silencing these neurons with the GABA agonist muscimol critically impaired performance, demonstrating these neurons contribute functionally to strategic gameplay. On a single trial, behavioral strategies and accompanying neural activity from two players interlinked and co-evolved; ultimately it was the joint firing rate patterns across two brains that determined game outcome. Over much longer periods of time, local field potentials in monkeys and EEG recordings in humans indicated that slower changes in brain states predicted game performance.

These findings confirm that our computerized soccer game captures the essence of real life competition cross species. The observation that mSTS in monkeys functionally contributes to strategic gameplay endorses the hypothesis this area is the homologue of human TPJ. Finally, examining TPJ activity across different time scales offers us great insight as to how interacting agents effectively and flexibly select strategies in an ever changing environment.

Title: Mechanical differences in social deficit process are revealed between two mouse models of autism, BTBR T+tf/J and BALB/cJ

Authors: *H. ARAKAWA;
Anat. and Neurobio., Univ. of Maryland Baltimore, Baltimore, MD

Abstract: Autism is a complex spectrum of disorders characterized by core behavioral deficits in social communicative behavior. Social behaviors are governed by multiple processes including motivated approach to social signals for assessment and appropriate expression of specific responses to would-be social partners, which are essential for exhaustive analysis of preclinical mouse models. Two inbred strains, BTBR T+tf/J (BTBR) and BALB/cJ (BALB), both of which have been used as an animal model of core behavioral deficit in autism, were compared to standard strain C57BL/6J (B6) in a variety of social factors and situations. All three strains (all female subjects) were capable of recognizing differences in inanimate objects and social features (strain, sex, and familiarity) of the opponents. However, BTBR and BALB mice poorly expressed approach to stimulus mice, while BTBR mice exhibited avoidance to BTBR stimuli, in the 3-chamber test situation, in which mice mainly express approach, but not contact, behavior to assess the social (olfactory) cues. When allowed direct contact, all three strains displayed similar patterns of social approach/contact to either strain of stimulus mouse, although they exhibited the highest amount of approach/contact to BALB and the lowest to BTBR stimulus mice. In addition, BALB mice displayed more facial investigation (approach) compared to other strains. The brain serotonin plays a role in facilitating social behavior. An injection of buspirone, serotonin 1A partial agonist, enhanced social approach in the 3-chamber test and increased social contacts during direct social interaction in B6 and BTBR mice, but not in BALB mice. A sequential analysis of social interaction revealed that buspirone injected into the subject mice

substantially facilitated social approach in the stimulus mice that were not given the injection. The stimulus dependency was confirmed by the 3-chamber test, in which B6 mice increased approach to buspirone-injected stimulus mice (but not in BALB stimulus mice). Social deficits shown in BTBR mice likely stem from odorant communication, while those in BALB mice would be associated with a defect of serotonergic system.

Title: Physiological and molecular differences in specific medial prefrontal cortex subpopulations mediate social hierarchy

Authors: *T.-Y. CHOI[1], B. KANG[2], Y. JEONG[1], J. KIM[1,3], H. JEON[4], S. JEONG[1], M. CHOI[4], J. KOO[1,3];

Abstract: Social hierarchy is a universal phenomenon observed in many animal species including mice and humans and it is essential for individuals' life and survival. Although it was recently revealed that the medial prefrontal cortex (mPFC) is a hub brain region of social hierarchy, we still do not know about the relevant neural circuits and molecular mechanisms in detail. To address this question, we compared physiological and molecular differences in mPFC subpopulation neurons that project to other brain regions that has been implicated in social behaviors - nucleus accumbens (NAc), ventral tegmental area (VTA), and amygdala (AMY) - from social dominant and subordinate mice, which were determined by tube dominance test. Neuronal excitability of social dominants was increased in mPFC-NAc, but decreased in mPFC-VTA, compared to social subordinates. However, neuronal excitability in mPFC-AMY was not different between social dominants and subordinates. We next measured in vivo neural activity of mPFC-NAc and mPFC-VTA using fiber photometry during tube dominance test. We finally conducted single-cell RNA sequencing (scRNA-seq) of mPFC regions from social dominant and

subordinate mice to compare molecular differences of social hierarchy in mPFC subpopulation neurons. Collectively, these results suggest that specific physiological and molecular changes in mPFC subpopulations mediate social hierarchy.

Title: Behavioral evaluation of the impact of different types of bedding in laboratory rat

Authors: *L. D. PANTALEON[1], J. Z. MAGALHÃES[3], J. R. CAMUSSO[2], A. ARNOLD[2], M. O. RIBEIRO[2], E. L. RICCI[4];

Abstract: Recently there is a crescent concern for the welfare of laboratory animals, to increase their comfort and to ensure reliable experimental results. Despite this concern, there is still few studies that address this issue. Scientific literature describe the influence of the microenvironment in animals behavior and physiology. The type of bedding used in animals cages is an important factor that can influence their behavior. This study aimed to evaluate the impact of three types of bedding material in rats behavior. Twenty seven male Wistar rats were separated into groups and habituated for two weeks in different types of bedding materials: group A - *Pinus sp* wood ships; group B - *Pinus sp* wood flakes; group C - corn cob (n=9 animals/group). After this period the behavioral evaluation were performed as follow: 1st day - open field; 2nd day - elevated plus maze; 3rd-5th days - social interaction; 6th day - preference test. For the open field test it was evaluated the frequencies of locomotion, rearing and grooming, and time of immobility. In the elevated plus maze it was measure the frequencies of entry in the open and close arms, head-dipping and risk assessment, and total time in the open and close arms. The parameters evaluated in the social interaction were the frequencies of sniff, chase and pass over the othe animal. In the preference test it was evaluated the time spend in each zone of the test during the three periods of the day (morning, afternoon and night) and the total time spend in each zone. The analysis of the behavior of male rats in the open field, elevated plus mazes and social interaction did not showed alterations in any parameter evaluated, indicating that all animals behave accordingly, regardless of the bedding material they were in. Regarding the preference test, the analysis showed that 1) the animals from the wood chips cages stayed

longer in the corn cob zone compared to the wood flakes in the total time ($p<0,01$); 2) the rats from the corn cob cages stayed longer in the wood chips zone compared to the corn cob zone and the wood flakes zone in the total time ($p<0,0001$); 3) the animals from the wood flakes cages stayed longer in the wood chips zone compared to the wood flakes zone at night and stayed longer in the wood chips zone compared to the corn cob ($p<0,001$) and the wood flakes ($p<0,0001$) zones in the total time. This results indicate, althought all rats presented the expected behavior for the species, there is a clear preference for the bedding material, suggesting that this material could reflect in other kinds of alterations in this animals. Therefore, future studies needs to be done in order to elucidate the influence of these materials on physiological and biochemical parameters.

Title: NMDA receptor dysfunction in the medial prefrontal cortex of NL3 R451C knock-in mice

Authors: *W. CAO, Q. XIA, J. XU, J. LUO;
Zhejiang Univ., Hangzhou, China

Abstract: Neuroligins (NLs) are critical for synapse formation and function. NL3 R451C is an autism-associated mutation. NL3 R451C knock-in (KI) mice exhibit autistic behavioral abnormalities, including social novelty deficits. Our previous paper reported that gamma oscillation dysfunction in the medial prefrontal cortex (mPFC) led to social deficits in KI mice, and manipulating mPFC parvalbumin (PV) interneurons could reverse the deficits. However, the underlying mechanism is not clearly understood. Glutamate N-methyl-D-aspartate receptors (NMDARs) dysfunction exists in some ASD mouse models. NMDARs disruption in specific brain regions or on PV-containing interneurons lead to autism-like phenotypes. Thus, we focused on the NMDARs function in both pyramidal neurons and interneurons in the mPFC, which may play a vital role in social defects. We found decreased NMDAR function in both pyramidal neurons and fast-spiking (FS) interneurons in the KI mice. We also found that GluN2A and GluN2B density decreased in cultured cortical neurons of KI mice. A partial agonist of NMDARs, D-cycloserine (DCS), restored the NMDAR function,FS interneuron excitability and

social novelty deficits in the KI mice. Together, our findings suggest that declined NMDARs function may contribute to the development of ASD-like phenotypes in the KI mice.

Title: Effects of oxytocin administration on social behaviors in felids

Authors: *J. C. BURKHART[1], N. D. BORREGO[1], S. R. HEILBRONNER[2], E. R. DE KOCK[4], C. PACKER[3];
[1]Ecology, Evolution, Behavior, Univ. of Minnesota, St. Paul, MN; [2]Neurosci., Univ. of Minnesota, New Brighton, MN; [3]Univ. of Minnesota, St. Paul, MN; [4]Kevin Richardson Wildlife Sanctuary, Pretoria, South Africa

Abstract: Felids of the genus Panthera form a monophyletic clade, yet exhibit a divergence of social structures. The African lion is highly social, forming life long bonds, while the leopard is completely solitary. Male cheetahs are semi-social, whereas female cheetahs are considered solitary. It is uncommon to find a system so closely related with such divergent social organization, making Panthera a good model for neurological comparisons. In other such systems, such as voles, sociality is mediated by the neuropeptide oxytocin, although this has largely been studied in the context of reproductive social behavior. We hypothesized that behavioral responses to oxytocin in felids would be different according to whether the behaviors are social or non-social in nature, and according to the social organization of the species. Using a DeVilbiss Atomizer, 10 IUs of oxytocin were administered to semi-free-ranging African lions, leopards, and cheetahs during a variety of social and non-social tasks. A significant increase in affiliative behaviors, as well as a decrease in vigilance, was observed in African lions post oxytocin administration as compared to baseline and saline trials. These results indicate that administration of oxytocin modulates social behavior in African lions. Responses of leopards and cheetahs will be analyzed and compared. We anticipate that oxytocin's ability to modulate social behavior in these less social animals will be decreased. These results have important implications for our understanding of the evolution of social circuitry, as well as for conservation (reintroduction) efforts.

Title: Learning vicariously - Role of anterior cingulate cortex in social cognition

Authors: ***K. N. SCHNEIDER**[1], X. SCIARILLO[2], J. NUDELMAN[2], J. F. CHEER[3], M. R. ROESCH[4];
[1]Psychology, [2]Univ. of Maryland Col. Park, College Park, MD; [3]Anat. and Neurobio., Univ. of Maryland Sch. of Med., Baltimore, MD; [4]Univ. of Maryland at Col. Park, College Park, MD

Abstract: Socially-derived cues help us navigate social interactions and continuously provide information about the environment, allowing us to learn without risking an adverse personal experience. In psychiatric disorders such as autism or psychopathy our ability to perceive these social cues is impaired, resulting in maladaptive behavior. However, the circuits underlying social cognition and how they influence learning remain unclear. Previous research has shown that the anterior cingulate cortex (ACC), a region of interest for social cognition, may engage deeply with the reward system. In order to examine how social cues modulate learning, and investigate the role of ACC in these processes, we recorded single-unit activity from observer (‘self’) rats undergoing a novel Pavlovian Social Outcome Task with a conspecific (‘other’). In the task, both rats were separated in a chamber by a see-through grate while four blocks of trials were used, alternated between two sequences, during which three cues were either appetitive (sugar pellets), aversive (foot-shock) or neutral (no outcome). Based on the block type, rats underwent conditioning or extinction, together or separately, leading to congruent or contrasting learning contexts. As a social control, training included sessions where 'self' rats were alone in the chamber, while 'other' outcomes were delivered to an empty side. Preliminary results showed that the relative conditioning context of other rats modulated appetitive and aversive performance of self rats undergoing extinction, suggesting social cues influence this form of learning. Moreover, neural recordings revealed differences in the firing rate of ACC neurons between learning contexts (e.g., simultaneous extinction vs incongruent extinction) in response to outcomes to both the 'self' and the 'other.' Our preliminary findings suggest that rats utilize social cues to update their predictions about the environment, influencing both their appetitive and aversive strategies. Further, the profile of ACC activation observed, during either appetitive or aversive outcomes delivered to both the 'self' and the 'other,' would suggest that the ACC

plays a broader role in processing social cues that is regardless of valence, and relevant to outcome prediction errors. We continue to examine ACC responses to the different transitioning social contexts in the task, as well as its influences on classical associative learning paradigms, in comparison to social controls (alone).

Title: Dissecting the role of VIP interneurons within the anterior cingulate cortex in a social cognitive task

Authors: *W. W. YEN[1], R. LIU[2], A. O. THOMAS[3], C. JOHNSON[4], L. N. KRETSGE[5,6], D. P. LEMAN[4], F. S. HAUSMANN[4], M. MINNIG[9], E. FUCHS[4], T. P. H. NGUYEN[7], A. CRUZ-MARTIN[1,6,8];

Abstract: As converging evidence implicates the anterior cingulate cortex (ACC) as a critical area for social cognition and emotional responses, there is an increasing need for a better understanding of the underlying circuitry and regulation of this area. Vasoactive intestinal polypeptide-expressing (VIP) interneurons are a subtype of cortical interneurons that drive strong cortical disinhibition, placing them in a key position to regulate the overall activity of the ACC. Here, we investigate the role of VIP interneurons located within the ACC of mice during a cognitive task that assess social memory and novelty. Using miniaturized, head-mounted fluorescence microscopes (“miniscopes”) in combination with genetically encoded calcium indicators (GECIs), we were able to study the activity patterns of this sub-population within ACC in freely moving, behaving mice. The use of miniscopes in lieu of other head-fixed techniques, such as 2-photon microscopy, allow our experiments to occur in a more naturalistic setting as the mice are free to explore their environments with little to no physical impedance. We first injected viral vectors containing flex-GCaMP6f, a GECI, into the ACC of VIP-IRES-

Cre mice in order to selectively target VIP interneurons in this area. This was then followed by a surgical implantation of a gradient-index (GRIN) lens to allow for optical imaging via miniscopes. The miniscopes used in these experiments were a custom-designed variant of the open-source FinchScope that were modified to allow for the removal of the miniscope in between experiments. This allowed us to co-house all experimental animals. Finally, in order to characterize the response of VIP interneurons to social versus non-social environments, mice were put through a battery of social and analogous object recognition tasks that occurred within a large acrylic chamber. Our data suggests that VIP interneurons in the ACC preferentially activate to social stimuli relative to objects.

Title: Post-natal immune activation in a mouse model of tuberous sclerosis results in sexual dimorphic microglia dependent deficits underlying social memory impairments

Authors: *M. F. LOPEZ-ARANDA[1], I. CHATTOPADHYAY[2], T. SILVA[1], C. THADANI[1], S. TALOMA[1], E. LUGO[1], A. RZHETSKY[3], A. SILVA[1];

Abstract: There is evidence for differences between females and males in the prevalence of certain neuropsychiatric disorders, such as autism spectrum disorder (ASD). Additionally, there is growing evidence that environmental factors, such as immune activation, contribute to the severity and range of cognitive phenotypes in neuropsychiatric disorders. We found that early post-natal immune activation triggers long lasting social memory deficits in male but not female mice with a mutation in the tuberous sclerosis 2 gene ($Tsc2^{+/-}$). Approximately half of the patients with tuberous sclerosis are diagnosed with ASD. We have multiple lines of evidence that immune activation during a critical phase of early post-natal development triggers an mTOR-

dependent, self-perpetuating cycle of increased interferon (IFN) production in microglia that is responsible for social memory deficits in $Tsc2^{+/-}$ male mice. Previous results implicated microglia in behavioral phenotypes associated with animal models of autism. Our studies showed that deletion followed by repopulation of this cell type in the adult brain reversed the social memory deficits of $Tsc2^{+/-}$ male mice with early post-natal immune activation. Importantly, this procedure opened a window of susceptibility in adult $Tsc2^{+/-}$ female mice, such that immune activation during microglia repopulation triggered lasting social memory deficits in these female mice. Importantly, our human epidemiological studies show a strong correlation between the prevalence of infections during early childhood in male (but not in females), and a future diagnose of neuropsychiatric disorders, suggesting that our results in mice are mirrored by human findings. These results open new therapeutical opportunities for neuropsychiatric disorders, and demonstrate the critical importance of microglia development for cognitive phenotypes associated with neuropsychiatric conditions.

Title: Axons, dendritic spines, glia, and perineuronal nets are atypical in the CA2 and CA3 regions of the hippocampus in a mouse strain with deficient social and object memory

Authors: *E. C. COPE, A. D. ZYCH, N. J. KATCHUR, B. J. LAHAM, C. Y. PARK, C. G. DIAS, R. C. WATERS, K. A. PAGLIAI, M. J. LOTITO, E. GOULD;
Princeton Univ., Princeton, NJ

Abstract: Several studies suggest that the CA2 and dorsal CA3 (dCA3) regions of the hippocampus are important for social memory as well as for spatial and contextual processing (Hitti and Siegelbaum, 2014; Stevenson and Caldwell, 2014; Chiang et al., 2018). Recent work suggests that synaptic function involves presynaptic and postsynaptic neurons, along with glial cells and the extracellular matrix (ECM), which together comprise the tetrapartite synapse (Dityatev and Rusakov, 2011; Cope and Gould, 2019). We examined these synaptic components in the CA2 and dCA3 of a mouse strain with deficient social and contextual processing, the BTBR mouse. First, we verified that BTBR mice have deficits in social recognition and object

location memory compared to control C57BL/6J mice. Then, we explored a neuronal population known to innervate both the CA2 and dCA3 regions, the granule cells of the dentate gyrus. We specifically examined adult-generated granule cells and their mossy fiber axons in these target regions, using the immature neuron marker 3R-tau, and found reduced numbers of new neurons, and diminished mossy fiber projections, in BTBR compared to control mice. Examination of postsynaptic sites revealed that BTBR mice have reduced numbers of dendritic spines, sites of excitatory synapses, on DiI labeled pyramidal neurons of the CA2 and dCA3. We next examined whether there were changes in glial cell numbers in areas of synapse loss. Compared to controls, BTBR mice had robust decreases in iba1-labeled microglia in the CA2 and dCA3, as well as decreases in GFAP-labeled astrocytes in the CA2. We also found perineuronal nets (PNNs), specialized ECM structures that surround certain types of neurons and limit brain plasticity, to be increased in volume and intensity in the CA2 as well as increased in PNN+ cell number in the dCA3. Ongoing studies will determine the potential role these differences in CA2 and dCA3 play in mediating social recognition and object location deficits in BTBR mice.

Title: Neuronal dynamics of social representation in the hippocampus

Authors: *K.-H. LEE[1], Y.-B. LEE[1], J. DO[1,2], E. KONG[1,2], J. KIM[1,2], D. LEE[1];
[1]Inst. for Basic Sci., Taejon-City, Korea, Republic of; [2]Korea Advanced Inst. of Sci. and Technol., Taejon-City, Korea, Republic of

Abstract: Animals engage in various forms of social interactions in daily life such as aggression, avoidance, cooperation, mating as well as forming a hierarchy. It has been challenging to understand neural underpinnings of such social behaviors due to their inherent complexity. One of the most critical cognitive elements shared by different social behaviors is an ability to recognize the social counterpart and retrieve associated information in order to exhibit appropriate behavioral responses during social interactions. We developed a novel social discrimination paradigm that requires a subject mouse to distinguish between two familiar mice presented in random order and associate each with either a reward or a punishment. This

paradigm utilizes head-restrained mice repetitively engaged in simplified and stereotyped social interactions and thus allows us to quantitatively measure behavioral performance and to precisely correlate behaviors with neuronal activities. Most mice could perform the task with a higher than 80% accuracy within 2 weeks of training. The performance was dropped to a chance level when dorsal hippocampus was inactivated by injecting muscimol. Behavioral results showed that the subject mice can recognize a conspecific within a second and the established social memory lasted for at least more than a week even in single housing conditions. *In vivo* two-photon calcium imaging revealed that dorsal CA1 neurons show various responses to different task variables. By imaging the same neuronal population over multiple days up to three months while repeatedly reversing the reward contingency, we could identify neurons whose activities selectively code for different social identities. Our results suggest that activities of the dorsal CA1 neurons are critical for associative social memory formation.

Abstract: The hippocampus is essential for spatial navigation and memory and harbors place cells, coding an animal's location in space. The hippocampus has also been suggested to code "social" information, such as about the spatial position of conspecifics. "Social place cells" have been reported for tasks where an observer mimics the behavior of a demonstrator. We examined whether hippocampal neurons may encode the behavior of a minirobot, however without requiring the animal to mimic it. Rather than finding "social place cells" we observed that place

cells were modulated by the robot's behavioral patterns. During task performance, the rat's own positions correlated with robot movements. Hippocampal ensemble activity coded information about robot movement patterns, even when correcting for changes in rat position. Interneurons were more informative on robot movements than principal cells. In conclusion, when the animal's own behavior is conditional on external agents, the hippocampus multiplexes information about self and others.

Title: Neural correlates of competitive social interaction in the anterior cingulate cortex

Authors: *I. M. MARCELO[1,2], R. M. COSTA[3,1], S. A. KUSHNER[2];
[1]Champalimaud Ctr. for the Unknown, Lisbon, Portugal; [2]Erasmus MC, Rotterdam, Netherlands; [3]Neurosci., Columbia Univ., New York, NY

Abstract: Social behavior and cognition are ubiquitous in the animal kingdom, crucial for both individual fitness and species survival. Behavioral repertoires like pair bonding, parental care, prosocial or aggressive displays, are especially important for group fitness and cohesion. Fundamental to all is the animal's dynamic capabilities of perceiving and deploying correct action to important aspects of its surrounding, in particular cues arising from conspecifics that make up its social environment.
Previous results from our laboratory, using an automated version of the Lindzey Tube Test, have shown that groups of mice are able to establish and maintain stable long-term social hierarchies, based on dyadic interactions in which hierarchy is operationally defined by advancing or retreating against defined conspecific opponents.
Given that recent literature has suggested a crucial role for the Anterior Cingulate Cortex (ACC) in social cognition, with particular relevance in building models of perseverance and others' intentions, we have investigated the function of the ACC in the context of competitive social interactions in the Lindzey Tube. For this purpose, we adapted the classical version of the task to permit simultaneous GCaMP6f-enabled *in vivo* 1-photon calcium imaging of all pairwise matches among 3 groups of 4 interacting male conspecifics. Mice were imaged during individual tube crossings, pairwise matches and pseudo-matches with a dummy mouse. Our results suggest the importance of ACC neural activity during social interactions, notably in a pairwise competitive setting. In particular, we find that ACC neurons robustly predict impending conflict and outcome resolution of socially competitive interactions.

Title: Sex difference in the way dorsal hippocampal D2-type dopamine receptors interact with gonadal sex hormones to mediate social learning in mice

Authors: *N. BASS[1], S. CRASTO[1], C. CRAWFORD[1], E. CHOLERIS[2];
[2]Psychology, [1]Univ. of Guelph, Guelph, ON, Canada

Abstract: Social learning, the process by which learning occurs via the interaction with, or the observation of, a conspecific (Galef, 1988) is poorly understood, and in animals may be tested using a social transmission of food preference (STFP) paradigm. During the STFP, the preference for a novel flavored food diet is acquired during social interaction with a recently fed conspecific. The catecholamine dopamine (DA) modulates many forms of cognition including feeding, reward and social behavior. By antagonizing D2-type DA receptors in the dorsal HPC, the STFP was blocked in female but not male mice suggesting an interaction between these receptors and sex hormones (Matta et al., 2017). Both estrogens and androgens modulate DA action. Indeed, estrogens have been directly implicated in social learning whereas the role of androgens has not been investigated. Collectively, these findings suggest that D2-type DA receptors interplay with sex hormones to modulate social learning. Here, we bilaterally infused D2-type DA receptor antagonist raclopride (18 μg/μL, 20 μg/μL, or saline) into the dorsal HPC (0.5 μL per hemisphere) of gonadally intact and gonadectomized 2-3-month old CD1 male and female "observer" mice 10 minutes prior to a 30-minute social interaction with a recently fed same-sex familiar "demonstrator". Immediately following the social interaction, the "observer" mice began an 8-hour flavored food choice test between 2 novel flavored food diets, one of which their respective "demonstrator" mice had consumed earlier. Food intakes were taken at 2, 4, 6, and 8 hours. Findings revealed that raclopride shortened the duration of a socially acquired food preference in gonadally intact females whereas it prolonged the food preference in ovariectomized mice. Notably, ovariectomy alone significantly reduced the duration of a socially acquired food preference. Lastly, raclopride prolonged the duration of a socially acquired food preference in gonadally intact males whereas castration prevented the prolonging effects of raclopride. These results suggest that gonadal female sex hormones interact with D2-type DA receptors in the dorsal HPC during the STFP in female mice, and that gonadal male sex hormones modulate social learning in male mice. Thus, there appears to be a sex difference in the way that D2-type DA receptors in the dorsal HPC interact with gonadal sex hormones to mediate social learning.

Title: Neuropathological examination of fetal rat brain in valproic acid induced cognitive deficits autistic rats: A protective effect of granulocyte colony stimulating factor (GCSF)

Authors: *A. MISHRA[1], R. SINGLA[1], R. RAJPOOT[1], P. SARMA[1], B. MEDHI[2];
[1]Pharmacol., Post Grad. Inst. of Med. Educ. & Res., Chandigarh, India; [2]Pharmacol., Post Grad. Inst. of Med. Educ. & Res. (PGIMER0, Chandigarh, India

Abstract: Introduction
Autism is a group of complex neurodevelopmental disorder of unknown etiology which manifests with problems like social interaction, language, communication and behaviour deficits like stereotypic and repetitive behaviour. Granulocyte-Colony Stimulating Factor (GCSF) is a glycoprotein that stimulates the bone marrow to produce granulocyte and release them into the blood stream. It has well known neuro-protectant, anti-inflammatory, anti-apoptotic, neurogenesis and excitoprotective properties in both human and rodent models of CNS disorders. The present study is designed to the evaluate the neuroprotective effect of GCSF in VPA induced autistic rats.
Method
Animals were divided into six groups. Group 1 (Control, received only Normal saline 0.9%), Group 2 (VPA 600mg/kg on PND 12.5), Group 3 (Pups, Risperidone 2.5 mg/kg, PND 23 to 43) and group 4-6(GCSF 10, 35,70 µg/kgPND 23 to 43).All the groups were subjected to different behaviour (Three chamber sociability test,Morris water maze) and histopathological examination using 0.1% Cresylviolet(for Nisslstaining).
Result
Treatment group showed significant improvement in the behavioural parameters.The histopathological evaluation implied extensive neuronal loss in the CA1 region of the hippocampus in the VPA treated groups. Decrease in the neuronal score was seen with GCSF treatment. Maximum effect was seen with GCSF dose of 70 µg/kg.

Title: Neuroprotective effect of homotaurine in modulation of GABAergic signaling in VPA-treated rat model of autism: Role of GAD67

Authors: *R. SINGLA[1], A. MISHRA[2], R. RAJPUT[2], B. MEDHI[2];
[1]Pharmacol., [2]Post Grad. Inst. of Med. Educ. & Res., Chandigarh, India

Abstract: Introduction
Autism is a heterogeneous neurodevelopmental and neurobehavioral disorder of unknown etiology which manifests difficulties in social interaction, communication and usually behavior deficit like stereotype and repetitive behavior. Homotaurine is demonstrated to have a neuroprotective effect and also has a GABAergic activity. Based on previous literature glutamate and GABA -related abnormalities are found in the autistic brain.The present study is designed to investigate the role homotaurine in VPA induced autistic rat via GABAergic signalling.
Method
Animals were divided into six groups. Group 1 (Control, received only Normal saline 0.9%), Group 2 (VPA 600mg/kg on PND 12.5), Group 3 (Pups, Risperidone 2.5 mg/kg, PND 23 to 43) and group 4-6(Homotaurine 10,25,50 mg/kg PND 23 to 43). All the groups were subjected to different behaviour (Three chamber sociability test,Morris water maze) and expression of GAD 67 protein by immunohistochemistry (IHC) in different brain region (Prefrontal cortex , Hippocampus , Cerebellum).
Result
Significant improvement in the behavioral parameters were seen at 50 mg/kg dose of homotaurine. IHC staining of brain sections indicated the homotaurine treated rats exhibited significantly higher expression of GAD 67 in prefrontal cortex and hippocampus. However, no differences were observed in GAD67 expression in the cerebellum.

Title: Automatic tracking and classification of mouse social behavior by 3D videography

Authors: *C. L. EBBESEN[1], R. C. FROEMKE[2];
[2]Otolaryngology, [1]New York Univ., New York, NY

Abstract: Measuring mouse social behavior is difficult. Mice are small, their movements are fast, and mice move in 3 dimensions (during mounting, for example). Currently, most studies of social behavior rely on labor-intensive methods, such as manual annotation of individual video frames. These methods are susceptible to experimenter bias and have a very limited throughput. We present an experimental setup and a robust calibration and tracking method that allows us to measure the behavior of multiple freely moving mice in 3 dimensions with high spatial and temporal precision (90 frames/s). In addition to this 3D data, we collect accelerometer data and record ultrasonic vocalizations (which are classified into call types using unsupervised clustering methods). These data allow us to construct a matrix representation of the 3D postures and movements (within and between mice) and patterns of ongoing ultrasound vocalizations - a kind of "social state space". This representation gives us a fine-grained read-out of social behaviors and how they change with circuit manipulations. Because our system uses the third dimension, the method is robust and tracks the identity of individual mice, even in unmarked animals that overlap in individual images.

Title: Social learning and social behavior of the triple-transgenic mouse model of Alzheimer's disease

Authors: B. A. SULKOWSKI[1], H. R. LEBLANC[2], A. C. WILLIAMSON[3], B. V. ROHR[4], B. G. GENTRY[3], ***C. C. WRENN**[1];

Abstract: The pathology of Alzheimer's disease (AD) results in behavioral problems which include memory deficits and impaired social behavior. The present study assessed social learning

and social behavior in a transgenic mouse model of AD (3xTg-AD). In the first study, WT (B6/129 hybrids) and 3xTg mice were compared in their performance in the social transmission of food preference (STFP) task, an olfactory memory test that depends on social behavior. The effect of daily ingestion of the soy phytoestrogen genistein on STFP performance in both WT and 3xTG mice was also assessed. In the second study, sociability and social recognition was assessed in WT and 3xTg mice using the three-chamber social interaction task. In this task, sociability was measured by the subject's preference for investigating a conspecific over a novel object. Social recognition was measured by the subject's preference for a novel conspecific over a familiar conspecific. Further, we tested the utility of the three-chamber task as a test of social memory persistence by varying the delay (0, 20, 120, and 240 min) between initial exposure to the familiar conspecific and the exposure to the familiar versus novel conspecific. In the STFP experiment we found that both WT and 3xTg mice had unimpaired olfactory, social-dependent memory, and social behavior in the task did not differ between the genotypes. Daily ingested genistein impaired olfactory memory in the STFP, and this impairment occurred in both genotypes. In the three-chamber task, we found that both WT and 3xTG mice had a preference for a conspecific over a novel object. In the social recognition test, WT mice preferred the novel conspecific, but 3xTg showed no preference indicating an impairment in social recognition. Neither genotype preferred the novel conspecific when the delay was increased to 20, 120, or 240 minutes showing that even in WT mice, social memory is disrupted by a short delay. These studies show that compared to WT mice, the 3xTg mouse has similar baseline sociability, similar socially-dependent olfactory memory, and similar memory sensitivity to genistein. Social recognition was impaired in the 3xTg mice. Current studies are testing whether this impaired recognition phenotype is specific to differences in the social domain, generalizable to other stimuli, or due to an anxiety-like response to novel stimuli.

Title: Large scale recording of population activity during social cognition in freely moving non-human primate

Authors: *M. FRANCH[1], A. WRIGHT[1], B. AAZHANG[2], V. DRAGOI[1];
[1]Neurobio. & Anat., UTHealth - McGovern Med. Sch., Houston, TX; [2]ECE, Rice Univ., Houston, TX

Abstract: Social interactions, a ubiquitous aspect of our everyday life, are critical to the health and survival of the species, but little is known about their underlying neural computations. The major limitation preventing our understanding of the neural underpinnings of social cognition is the lack of a suitable framework to allow us to study how it emerges in real time from interactions among brain networks. Indeed, examining the neural bases of complex social interactions has been traditionally performed by studying the brain of nonhuman primates (NHP) in a laboratory environment in which the head and body are restrained. However, it has become increasingly understood that studying the brain in spatially confined, artificial laboratory rigs poses severe limits on our capacity to understand the function of brain circuits. To overcome these limitations, we propose a novel approach using high-yield (up to 200 channels) wireless electrical recordings and eye tracking to study the cortical dynamics of social interactions in visual and prefrontal cortex while animals learn to simultaneously push and hold buttons to cooperate for food reward. Over time, animals developed a cooperative strategy, with one animal's actions leading cooperation. Furthermore, we found that reward value influences social behavior, and animals learn to cooperate faster for low reward across sessions. Neural activity in prefrontal and visual cortex is modulated by reward anticipation and the animals' choices. Population activity in prefrontal cortex is sensitive to reward value, and the motivation to cooperate increases on trials with larger reward. This new approach will enable us to uncover the dynamics of neuronal network activity that drives social interactions in an ethologically relevant behavioral task that involves sensory integration, memory, and complex decision-making. Furthermore, our proposed research has the potential to constitute a paradigm shift by moving social neuroscience from simply observing animal behavior and recording the responses of single cells to a quantitative understanding of the distributed neuronal network encoding during social behavior in freely moving NHPs performing naturalistic tasks.

Title: Prenatal stress results in molecular and behavioral deficits associated with abnormal function of the hippocampus

Authors: *B. E. POWERS, M. SODHI;
Loyola Univ. Chicago, Maywood, IL

Abstract: A post-transcriptional process known as RNA editing regulates the trafficking and function of α-amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid glutamate receptors (AMPARs), which are critical for synaptic plasticity, learning and memory. RNA editing of AMPARs has been associated with stress, anxiety, schizophrenia, mood disorders and suicide. Prenatal stress results in abnormal brain development and is a risk factor for several psychiatric disorders. We have tested the hypothesis that the long term effects of prenatal stress are mediated by altered RNA editing. We analyzed prenatal restraint stress (PRS)-induced effects on behavior and RNA editing in the hippocampus of C57BL/6J mice. Pregnant dams were subjected to PRS from gestation day 7 until birth. In adulthood, offspring were assessed for social interaction behavior, locomotor activity, and spatial learning and memory. The hippocampus of each mouse was analyzed for the expression of the RNA editing enzymes (ADARs 1-3) in addition to analysis of the RNA editing levels of the AMPAR subunits. PRS reduced social interaction behavior and reduced hippocampal RNA editing of the AMPAR subunits GluA2, GluA3 and GluA4. Social interaction deficits and alterations of GluA2 RNA editing were normalized by treatment with the antipsychotic drug clozapine. Additional experiments using a reduced intensity of PRS failed to produce behavioral deficits. Our data show that PRS produces long-term changes in behavior that may be due to abnormal development of the hippocampus. Therefore the long-term behavioral deficits resulting from severe PRS may be mediated through a molecular pathway involving AMPAR RNA editing.

Title: Brain-wide mapping of neural activity during observational learning

Authors: *K. M. SEAGRAVES[1], T. J. PISANO[1,2,3], Z. DHANERAWALA[1], S. S.-H. WANG[1,2];
[1]Princeton Neurosci. Inst., [2]Dept. of Mol. Biol., Princeton Univ., Princeton, NJ; [3]Robert Wood Johnson Med. Sch., Rutgers Univ., New Brunswick, NJ

Abstract: During observational learning animals acquire new information by observing a social partner's response to a stimulus. This form of social learning is thought to be a primary way humans learn social norms, and also serves as an adaptive mechanism for avoiding potentially harmful situations. Despite the clear importance of observational learning in the development of mental models of the world, the long-range neural circuits that control this social learning phenomenon remain poorly understood. To address this, we used whole-brain clearing, antibody labeling, and light-sheet microscopy to image brain-wide c-Fos protein expression following a fear-based observational learning paradigm. In this paradigm an observer animal witnesses the fear of a social partner (the demonstrator) while that animal undergoes classical delay fear conditioning. The imaged brain volumes were registered to the Allen Brain Atlas, and c-Fos+ cells were identified using a custom algorithm. The c-Fos pattern of observers was compared to that of demonstrators, and to control animals that experienced the same paradigm without the fear-inducing stimulus. As expected from previous work, brain areas typically associated with direct fear conditioning, such as various amygdalar nuclei, show elevated c-Fos levels compared with controls. Furthermore, observers show elevated c-Fos in the anterior cingulate cortex, a region known to be involved in observational learning, compared with demonstrators. Surprisingly, the parabrachial nucleus, which is strongly activated in demonstrator animals, did not show elevated c-Fos expression during observational learning, despite previous work showing that it responds to other types of perceived threats. This suggests differential involvement of the parabrachial nucleus in the acquisition of socially-learned fear. Overall, this study has generated a comprehensive activation map of the brain areas that may be coordinating both direct and indirect fear learning, and provides insight into the areas that are specifically involved in the social aspect of observational learning.

Title: Chemogenetic inhibition of Purkinje cells in the anterior cerebellum disrupts motor coordination, social recognition and interaction

Authors: *O. Y.-H. CHAO, Y.-M. YANG;
Biomed. Sci., Univ. of Minnesota Med. Sch., Duluth, MN

Abstract: The posterior cerebellum has been implicated in social cognition, while the involvement of the anterior cerebellum, evidenced for sensorimotor processes, remains enigmatic in social behaviors. To address this issue, we applied NMDA lesions, and chemogenetic inhibition of Purkinje cells with AAV-L7-hM4Di-mCherry or a control AAV-hSyn-EGFP, into the cerebellar lobules IV/V of male C57BL/6 mice. Three weeks after the surgery, clozapine-*N*-oxide (1 mg/kg, i.p.) was injected to activate chemogenetic receptors 30-40 minutes before each behavioral test. In the open field, the lesioned and hM4Di groups travelled longer distance than the control group, and their performance on a rotarod was impaired. The control and hM4Di groups showed intact object recognition memory, while the lesioned group showed low amount of object exploration. In the social recognition test, the control group, but not the lesioned and hM4Di groups, sniffed the novel stranger more than the familiar one. In the free social interaction test, the lesioned and hM4Di groups exhibited less interaction than the control group. Subsequent *c-fos* imaging indicated that the functional connectivity required for free social interaction was disorganized in the lesioned and hM4Di groups. Collectively, chemogenetic inhibition of Purkinje cells of the cerebellar lobules IV/V or lesions of the region impaired motor coordination, along with social recognition and interaction. These findings suggest that the anterior cerebellum is critically involved in social behaviors although being masked by its sensorimotor role.

Title: Observational learning in a working memory, food-reward task in rats

Authors: *R. TROHA[1], T. SHAO[1], N. HERNANDEZ[1], A. BUZZANCA[2], J. WANG[1], E. J. MARKUS[3];
[1]Univ. of Connecticut, Storrs, CT; [2]Univ. of Connecticut, Storrs, IN; [3]Univ. of Connecticut, Storrs Manfld, CT

Abstract: Observational learning allows an animal to indirectly learn the outcome of an action by watching a conspecific. Seminal work by Bandura (1961) illustrated how children imitate the behavior of adults. Although this behavior can be seen in humans, animal models have only recently been developed to study the neural circuitry involved in this behavior. The bulk of these experiments rely on social fear conditioning and fewer experiments examine observational learning of a reward-based behavior. Such a task would allow comparison of the brain areas involved in these two contrasting scenarios. We have shown that rats can learn the location of a

food reward on a T-maze by watching another rat. However, this task is limited by a limited number of daily trials, proximity of the two rats, and that only the first trial per session requires observation. The current task includes two attached operant chambers with the observer and demonstrator at close proximity. The demonstrator responds randomly at one of two nose-poke locations in order to receive a food reward. The observer must continuously monitor the behavior of the demonstrator to correctly respond in its own chamber. The issue of local enhancement is addressed by using a light cue to indicate whether the correct choice is either the same or opposite the performer. This within-animal design provides a way to test the same animal using many different manipulations and provides a powerful method for studying observational learning in a reward-based task. This could lead to a better understanding of disorders in which social learning deficits are seen, such as Autism Spectrum Disorder and Schizophrenia.

Title: Neural correlates of gaze direction in basolateral amygdala

Authors: *B. MAHMOUDIAN[1], B. W. CORRIGAN[2], J. LAU[3], W. W. PETTINE[4], J. MARTINEZ-TRUJILLO[5];
[1]Univ. of Western, London, ON, Canada; [2]Neurosci., [3]Univ. of Western Ontario, London, ON, Canada; [4]Ctr. for Neural Sci., New York Univ., New York, NY; [5]Western Univ., London, ON, Canada

Abstract: Social communication in primates relies heavily on visual cues. Head and eye orientation can signal one's gaze direction and provide cues for directing attention (Ghazanfar & Santos, 2004). the amygdala, a subcortical structure in the anterior temporal lobe, has been shown to respond to elements of a face such as eyes (Mosher et al. 2015). One possibility is that the amygdala contains circuits that encode gaze direction. However, evidence in favor of this hypothesis is scarce. Amygdala lesions impair performance of individuals in spatial cueing tasks utilizing social cues (eye) but not in case of arrow (non-social) cues (Akiyama 2007). Although fMRI studies provide evidence for differences in basolateral amygdala nuclei (BLA) activation in viewing static images of direct vs averted gaze (Hoffman 2007, Mormann 2015, Tazumi

2010), there exists little evidence of how the local amygdala circuitry might encode gaze direction. To address this gap we have designed a spatial cueing task in which the animal must utilize gaze direction cues to locate the rewarded target while single unit activity of BLA is monitored.Hypothesis: We hypothesize that different populations of neurons in primate BLA are tuned for gaze cues of head and eye orientation. Two Rhesus Macaques will be placed in front of a computer screen and head fixed while their eye positions on the screen are recorded during experiment. In a four-alternative choice task, the animal must utilize the presented direction of social or non-social cue to attend the location of the rewarded target. Social conditions include avatar monkey models cueing the target location using different combinations of head and eye rotations. Non-social conditions will employ a variety of non-biological cues (e.g. an arrow) to indicate the position of the target. Recordings from single neurons in the BLA amygdala will be conducted using 64 microwire electrode. Eye movements will be recorded to determine the animal's gaze position. We have recorded behaviorally data from two animals. In the social (avatar) condition the animals quickly learned to make gaze saccades towards the cued location (in the direction of the avatar's gaze). They also follow the avatars gaze when it deviates from the usual target locations suggesting that the animals indeed interpret gaze cues. Preliminary recordings show that neurons in the amygdala are responsive to gaze cues.

Title: Neuronal encoding of prosocial helping behavior in the mouse prefrontal cortex

Authors: *P. B. GABRIELI, S. W. LI, J. L. DEMAREE, J. CAI, Z. WILLIAMS; Massachusetts Gen. Hosp., Boston, MA

Abstract: Prosocial behaviors, typically defined as voluntary actions that benefit others, are a cornerstone of both human and animal societies. Unlike other sensorimotor processes, however, the act of helping others is also complex, requiring individuals to not only perceive the need of others but also select behaviors that can provide specific help. Further, abnormal prosocial

behavior is a major characteristic of several psychosocial conditions, including autism spectrum disorders (ASD), schizophrenia, and antisocial personality disorder. Here, we discover neurons in the mouse dorsomedial prefrontal cortex (dmPFC) that encoded the aversive experiences of others as well as a distinct group of neurons that reflected specific selection of helping behavior. To investigate prosocial behavior in an animal model, we developed a novel prosocial assay based on a modified real-time place preference (RTPP) task, in which the position of a subject mouse controlled the aversive experience of a nearby conspecific partner. Interestingly, we find that wild-type C57BL/6J males demonstrated helping behavior that reduced their partner's aversive experience when their partner was familiar but not when they were unfamiliar. Male mice with ASD-related *Shank3*$^{+/-}$ mutation, by contrast, did not demonstrate helping behavior under any condition. By further recording from the dmPFC, we identified specific subsets of neurons that encoded the demonstrator's aversive experiences, changing their activity when their partner received a brief shock. Other neurons, by comparison, encoded the act of helping the other, displaying changes in their activity prior to selecting the area that did not shock their familiar partner. Taken together, these findings suggest a neuronal mechanism in the mouse dmPFC for enacting helping behavior and an early cellular substrate for pro-sociability.

Title: Dorsomedial prefrontal cortex encodes collective behavioral states in groups of mice

Authors: *S. W. LI, Z. WILLIAMS;
Massachusetts Gen. Hosp., Boston, MA

Abstract: Social interactions among individuals within a group are remarkably complex, often involving the simultaneous actions of numerous individuals. Unlike many other forms of behavior, intragroup interactions are highly multi-dimensional, meaning that they require group members to consider factors such as their partners' identities, behavioral strategies, past decisions and the dynamic relation between them. Although prior behavioral observations have provided important insight into how individuals within groups interact or how they may

represent the behavior of others, the basic cellular mechanisms that underlie group behavior are largely unknown. In this study, we aimed to examine whether and how group behavioral states and the interaction between animals may be encoded by individual neurons in freely behaving groups of mice. Nests of three or six familiar mice were allowed to freely interact in a large open arena while we telemetrically recorded single neuronal activity from the dorsomedial prefrontal cortex (dmPFC) in one individual from the group. Using dimensionality reduction and unsupervised clustering algorithms, we characterized collective group behavioral states and their evolution over time. We further classified and ordered specific group level measurements (e.g. group velocity, group polarization, group spread) that are most relevant for determining these behavioral states by using a regression tree analysis. Lastly, we identified subsets of dmPFC neurons that differentially encoded group level measurements, collective behavioral states of the group, and dynamical relationships between self and group. Interestingly, we found that dmPFC neurons exhibited temporally modulated and divergent roles specific to self-group versus others-group interactions, and that these neurons were modulated by the behavioral state of the group. Taken together, data from this study reveals a remarkably rich neuronal process in the mouse prefrontal cortex for representing the collective behavior of social groups and the complex interactions within them.

Title: Single-neuronal differences in social encoding between males and females during social competition

Authors: *L. STRAHS, S. W. LI, Z. WILLIAMS;
Massachusetts Gen. Hosp., Boston, MA

Abstract: Males and females perceive and respond to social information differently, a property that plays a powerful role in the behavior of both animals and humans. Whether or how social information is encoded differently in males and females at the single-cell level, however, is largely unknown. A common example of sexual dimorphism manifests in the way individuals

interact within groups or how they compete for resources. Significantly, these processes are dysfunctional in psychosocial disorders such as Autism Spectrum Disorders (ASD), which also presents differently in males and females. Here, we investigated the single-neuronal encoding mechanisms by which males and females may differ by using a mouse model of group competition. Behaviorally, we show that males display a highly positive correlation between competitive success and hierarchical rank when competing for resources within groups. Females, by contrast, demonstrate little relation between social rank and competitive success. We also demonstrate that males and female utilize differing social strategies to obtain a limited resource in a competitive environment. Building on these behavioral findings, we next performed single-neuronal recordings in the animal's dorsomedial prefrontal cortex (dmPFC), an area thought to be involved in social behavior. We find that dmPFC neurons are able to track not only the hierarchical standing of particular individuals within a group, but also their competitive success by predicting competitive outcomes based on information about competitors. Preliminary data further suggests that information encoded in the dmPFC about hierarchical standing, success and competitors are encoded differently between males and females. Taken together, this study provides a functional framework to decode the neuronal mechanisms governing sexually dimorphic behaviors between males and females.

Title: Theta state related septal cholinergic neurons disrupt hippocampal sharp wave-ripples via muscarinic receptors

Authors: X. MA[1], Y. ZHANG[1], L. WANG[1], N. LI[1], E. BARKAI[2], X. ZHANG[3], ***J. XU**[1], L. LIN[1];
[1]Key Lab. of Brain Functional Genomics, Shanghai, China; [2]Sagol Dept. of Neurobio., Haifa, Israel; [3]State Key Lab. of Cognitive Neurosci. & Learning, Beijing, China

Abstract: The septo-hippocampal cholinergic system is critical for hippocampal function. However, a quantitative description of the *in vivo* firing patterns and physiological function of

medial septal (MS) cholinergic neurons are yet to be shown. Combining optogenetics with multi-channel *in vivo* recording, we were able to continuously record MS cholinergic neurons' firings in freely behaving mice for 5.5 - 72 hours and found that their firings were highly correlated with hippocampal theta states. MS cholinergic neurons were highly active during theta-dominant epochs, such as active exploration and rapid eye movement sleep, and almost inactive during non-theta epochs, such as slow wave sleep (SWS). Interestingly, optogenetically activating these MS cholinergic neurons during SWS suppressed CA1 sharp wave-ripples. This suppression could be rescued by muscarinic M2 or M4 receptor antagonists. These results suggest an important physiological function of MS cholinergic neurons: maintaining high hippocampal acetylcholine level by persistent firing during theta epochs, consequently suppressing ripples and allowing theta oscillations to dominate.

Title: A sexually dimorphic role of dentate gyrus oxytocin receptor expressing neurons in social and memory related behaviors

Authors: *M. MEYER[1], K. NISHIMORI[2], J. M. RADULOVIC[3];
[1]Northwestern Univ. - Chicago, Chicago, IL; [2]Grad Sch. of Agric Sci, Tohoku Univ., Sendai-Shi, Japan; [3]Psychiatry & Behavioral Sci., Northwestern Univ., Chicago, IL

Abstract: The neuropeptide oxytocin and its receptor have a well-established role in modulating social behaviors, including parental behavior, pair bonding, and social memory. Due to the body of literature supporting the role of the oxytocin system in social behavior, oxytocin has been proposed as a therapeutic target for psychiatric disorders involving social behavior, such as autism spectrum disorder. Importantly, the oxytocin system often regulates sex-specific social behaviors, which may be due to known sex differences in synthesis and receptor expression. Therefore, clinical strategies should consider that oxytocin may have differential treatment effects in males and females. Given the well-established role of the hippocampus in social behavior and memory, we set out to investigate the role of hilar oxytocin neurons in social and

non-social memory-related behaviors in mice of both sexes. We first performed a detailed cellular characterization of oxytocin receptor-expressing neurons and their connectivity, followed by chemogenetic and circuit inactivation approaches to test the functional role of these neurons. Our findings demonstrated that hilar oxytocin receptor-expressing neurons affect behavior in a sexually-dimorphic manner, with a predominant role in social behavior in males, and a predominant role in memory-related behavior in females. These studies begin to elucidate a cellular population of oxytocin neurons that differentially regulate behaviors between sexes. Identifying sexual dimorphisms in oxytocin system function is important for developing practical treatment strategies for patients, of both sexes, who suffer from psychiatric disorders involving social behavior.

Abstract: The role of cortical efferents to the hippocampus in the formation of episodic-like memory is well established, however, less is known about the contribution of subcortical memory circuits to memory. In the present study, we studied the roles of several subcortical inputs into the dorsal hippocampus in mouse models of contextual fear conditioning, extinction, and reinstatement. Fear conditioning was induced by a single exposure of mice to a context followed by foot shock. Subsequently, mice were exposed to daily extinction trials. After significant reduction of freezing, indicating successful extinction, mice were exposed to a brief reminder shock and re-tested in the conditioning context. Circuit manipulations were performed

by chemogenetic silencing with the inhibitory designer receptor exclusively activated by designer drugs (DREADD) hM4(Gi) or targeted cholinergic depletion induced by 192 IgG-saporin, at different stages of fear conditioning, extinction, and reinstatement. We identified projection- and neurotransmitter-specific roles of discrete circuits, indicating complex regulation of fear-inducing memories by subcortical afferents.

Title: Effects of arsenic trioxide-induced oxidative stress on basal forebrain of mice

Authors: *B. KAUR, K. MEHTA, K. K. PANDEY, P. DHAR;
Anat., All India Inst. of Med. Sciences, New Delhi, New Delhi, India

Abstract: Background: Arsenic trioxide (As_2O_3) has been considered for therapeutic purposes over a long period and presently is in use as chemotherapeutic agent for treatment of acute promyelocytic leukemia (APL). As_2O_3-induced oxidative stress is considered as the major mechanism for its chemotherapeutic action as well as for associated toxic effects on various organ systems including cholinergic system in central nervous system which is responsible for cognitive functioning. Basal forebrain (BF) region of brain houses the majority of cholinergic neuronal population projecting to different regions of brain such as hippocampus and prefrontal cortex. Any insult to BF area or to its projection fibres may result in cognitive deficits. Thus, the present study was undertaken to investigate the effect of arsenic trioxide induced-oxidative stress on the cognitive functions and neuronal population of basal forebrain.
Material & methods: Adult male mice were divided into control group (I) and experimental group (II). The experimental group received increasing dosage of As_2O_3 (2, 4 & 8 mg/kg) via oral route for a period of 45 days. Open field test (OFT) and Morris Water Maze (MWM) test were carried out during the experimental period. On day 46, perfusion fixed and freshly obtained brain tissue from animals was processed for immunohistochemical localization of various proteins and estimation of oxidative stress markers and western blot analysis respectively.
Results: The animals receiving higher dose of As_2O_3 spent significantly less time in central zone of open field as compared to control group. In MWM, during acquisition phase As_2O_3 treated mice showed prolonged escape latency and travelled longer distance to find the platform whereas

in probe trial, these animals showed less number of platform crossing. Decreased levels of glutathione and antioxidant enzymes (superoxide dismutase and catalase) were recorded in BF of As_2O_3 treated groups. Immunoexpression of ChAT and AChE was significantly downregulated while that of SCGN was upregulated in As_2O_3 alone treated animals as compared to controls. **Conclusion:** These preliminary observations do suggest increase in oxidative stress markers and alterations in behavioral parameters alongwith changes in neuronal population of BF in mice exposed to increasing concentration of As_2O_3.

Title: Electrophysiological recording on basolateral amygdala and ventral hippocampus during memory tasks induced by high fat diet during adolescence

Authors: *C. I. PEREZ[1,3], A. I. HERNANDEZ-COSS[2], M. G. MORENO[1], G. FERREIRA[4], G. PACHECO-LOPEZ[3], F. BERMUDEZ-RATTONI[5], R. GUTIERREZ[1];

Autónoma Metropolitana (UAM), Campus Lerma, Mexico; [4]Nutrineuro, INRA-Bordeaux Univ., Bordeaux, France; [5]Inst. de Fisiologia Celular, UNAM, Ciudad de Mexico, Mexico

Abstract: The prevalence of obesity in adolescents has become a major challenge for public health. This is particularly worrisome since this period is crucial for the maturation of some brain structures like amygdala and hippocampus, areas that are involved in learning and memory process. Previous studies demonstrated that high-fat diets (HFD) impair hippocampal-dependent memory and hippocampal glutamatergic neurotransmission, also enhances emotion-induced neuronal activation of the basolateral complex amygdala. However, the link between obesity during adolescence and cognitive dysfunction in rodents remains poorly characterized, and more studies at the neural level are important to identify the functional circuits involved in emotional and spatial memory. To address this issue, we characterized the influence of HFD given to juvenile rat upon memory performance. Wistar rats have *ad libitum* access to either regular diet

(2.9 Kcal/g; A04, Safe) or HFD (4.7 Kcal/g; D12451, Research Diet) starting at weaning until 12 weeks old (adulthood). After this period, rats were implanted with an electrode that consisted of 8 filaments of tungsten wires targeting the basolateral amygdala and 8 more the ventral hippocampus. Neuronal activity was recorded in both structures simultaneously during the acquisition and test of object recognition memory (ORM) and then, during a conditioned odor aversion (COA). Our results confirm that rats that started to consume HFD during the adolescence were less efficient than their control Chow feeds counterparts in performing spatial ORM task and enhances long-term emotional memories as assessed by odor-malaise association (COA). The analysis of neuronal recordings will be presented at the conference. Nevertheless, we hypothesize that juvenile obese rats will show enhanced neuronal activity in the amygdala, while hippocampus has the opposite effect on the retrieval during object recognition memory and odor memory. This study has the goal of revealing the participation of both ventral hippocampus and basolateral amygdala on memory impairment induced by consumption of HFD during adolescence.

Title: Signals in hippocampus (CA1) and dorsomedial striatum (DMS) predict response in a visuomotor conditional association task

Authors: *K. GURLEY[1], T. G. WEYAND[2];
[1]Cell Biol. and Anat., LSU Hlth. Sci. Ctr., New Orleans, LA; [2]Louisiana State Univ. Med. Ctr., New Orleans, LA

Abstract: The hippocampus and striatum are associated with two broad types of learning thought to drive competing behavioral strategies. The hippocampus is central to context learning, in which behavior is driven by associations between contiguous cues in the environment, and the striatum is central to habit learning, in which behavior is driven by subconscious recall of a cued motor response. While many studies have focused on dissociating the functions of these structures, here we focus on potential cooperativity. Rats performed an operant visuomotor conditional association task, in which they must nose-poke a left or right port based on one of two visual stimuli. A correct nose-poke was reinforced with a drop of 25% sucrose solution.

Naive Bayesian decoding of multiunit spike activity show decision-related signals in both regions emerging ~75 msec prior to the nose-poke, with decoding accuracy increasing to significant levels in the hippocampus prior to the striatum. Furthermore, gamma coherence of the local field potentials in CA1 and DMS increase prior to nose-poke, suggesting the potential for synchronized communication between the regions. Collectively these data support the idea that both CA1 and DMS simultaneously facilitate context-dependent decision-making.

Abstract: The obesity epidemic is increasing at an alarming rate. According to the World Health Organization, the global prevalence of obesity has almost tripled between 1975 and 2016. The prevalence of overweight and obesity is also increasing dramatically in children and adolescents. Mexico and USA are today the countries amongst most childhood/youth obesity in the world. In addition to being associated with diseases such as hypertension, cancer and diabetes, obesity affects neurocognitive features including learning and memory. Adolescence is a crucial period for maturation of limbic brain structures like hippocampus and amygdala. Recent studies have shown a particular vulnerability of juvenile individuals to the effects of the early onset of obesity in memory function. To assess the effects of obesity in adolescence on hippocampal and amygdala function, we use a model of diet induced obesity in male Wistar rats. Rats were exposed to a regular diet (control group, 2.9Kcal/g) or a high-fat diet (HFD group,4.7Kcal/g) after weaning for 3 months thus covering adolescence. After exposure to the diet, rats were trained in the hippocampal dependent Morris water maze (WM) or amygdala-dependent

conditioned odor aversion (COA). We also measure metabolic parameters. The individuals who received HFD showed an increase in body weight with respect to control diet animals. The HFD group also exhibited an increase in basal glucose blood levels, diminished glucose tolerance and insulin sensitivity. The cognitive tasks showed that HFD rats have an impaired performance in WM´s long term memory. This is consistent with previous findings indicating a functional deterioration of the hippocampus due to a high fat and/or high sugar induced obesity. Regarding amygdala-dependent long-term memory performance, we found that the consumption of HFD increases the aversive response in COA. This could be due to catecholaminergic deregulation since tyrosine hydroxylase (TH) levels in the amygdala were affected in the HFD group, while in the hippocampus TH levels remained equal within the groups The specificity of changes in the amygdala could explain the increase in the aversive response while interrupting spatial memory.

Title: Auditory context-modulation of taste recognition memory relies on the accumbens hippocampus dopaminergic circuit

Authors: *A. B. GRAU-PERALES[1], E. R. LEVY[2], A. A. FENTON[2], M. GALLO[1]; [1]Dept. of Psychobiology. Inst. of Neurosciences, Univ. of Granada, Granada, Spain; [2]Ctr. for Neural Sci., New York Univ., New York, NY

Abstract: Rodents exhibit neophobia to novel tastes which attenuates across days if consumption is not followed by visceral negative consequences, indicating safe taste recognition memory. This attenuation of taste neophobia (AN) is context-dependent because the attenuation is disrupted when contextual cues change. A dopaminergic circuit involving the dorsal hippocampus (HC) has proven to be involved in spatial context-dependent AN. Whether non-spatial auditory contexts might also modulate AN and whether the hippocampus has a role has been largely unexplored. We confirmed that a change in the auditory context disrupted AN in adult male mice. This effect was lost following NMDA excitotoxic lesions targeted to dorsal

CA1 hippocampus. A similar disruption of the context-dependent AN was induced by intracerebral administration of 6-OHDA targeted to ventral CA1 hippocampus in rats. Moreover, systemic administration of the D1 dopamine receptor (D1DR) antagonist SCH-23390 resulted in a delayed AN in mice whether or not the auditory context changed, even if the drug was given a day after the context change. Finally, we used DREADD chemogenetics by combining intracerebral injection of two viral vectors to identify the crucial dopaminergic-hippocampal circuit. The retrograde Cre-recombinase expressing CAV-Cre was targeted to ventral CA1, and the DREADD pAAV-hSyn-DIO-hM4D(Gi)-mCherry was targeted to the nucleus accumbens shell. Intraperitoneal injection of clozapine-N-Oxide hydrochloride (CNO: 2mg/kg of body weight) 2 hours before the taste session interrupted AN similar to the previously observed D1DR antagonist, causing delayed AN when the context remained constant. Administering CNO a day after changing the auditory context also altered context-dependent AN. We conclude that the ability of changes in the auditory context to modulate taste recognition memory requires the activity of a dopaminergic nucleus accumbens shell-hippocampal circuit involving D1DRs that might be crucial for acquiring the taste-context association which is relevant for taste learning and memory. Title: Intracellular dynamics of midline thalamic neurons during ripple-slow wave coupling in anesthetized mice

Authors: *D. BASHA[1,2], I. TIMOFEEV[3,1];
[1]CERVO Brain Res. Ctr., Quebec, QC, Canada; [3]CRIUSMQ, [2]Univ. Laval, Quebec, QC, Canada

Abstract: **Background:** Increased cortico-hippocampal synchrony during slow wave sleep is closely linked to sleep-mediated consolidation of memory. Specifically, the coupling of hippocampal high frequency oscillations **(*ripples; 100-300 Hz*)** to the phase of the neocortical slow oscillation ***(< 1 Hz)*** results in a selective increase in the recall and consolidation of spatial

memory. **However, the pathways that coordinate *ripple-SW coupling* in the sleeping brain remain unknown.** The midline thalamus has major reciprocal connections with the cortex and hippocampal structures, constituting a central node in cortico-hippocampal communication. Yet, little is known about the intracellular activity of the midline thalamus during cortico-hippocampal synchrony. **Methods:** Using sharp glass micropipettes and tungsten microelectrodes, we obtained intracellular recordings of 13 identified neurons of the midline thalamus together with local field potential recordings of the hippocampus and EEG in mice anesthetized with ketamine-xylazine. **Results:** All recorded midline thalamic neurons revealed membrane potential depolarization during the active phase of the EEG slow oscillation. Phase analysis revealed a propensity for hippocampal ripples to occur during thalamic silent states with a significant decrease in ripple incidence during the active state. This pattern was also observed in first order neurons of the ventromedial nucleus although the active state in these cells corresponded to a marked hyperpolarization. **Conclusions:** Given the anatomical connections of the midline thalamus with hippocampal and parahippocampal structures, the results suggests a role for the activate state of the thalamic slow oscillation in biasing the timing of hippocampal ripples. The cortical drive to the midline thalamus is likely the main source of cortico-hippocampal feedback during slow oscillatory activity.

Title: Investigating the spatial coding properties of lateral septum GABAergic neurons in freely behaving mice using miniaturized microscopy

Authors: *S. VAN DER VELDT, G. ETTER, F. SOSA, B. RIVARD, S. WILLIAMS; McGil University, Douglas Inst., Montreal, QC, Canada

Abstract: There is little evidence on how the hippocampal spatial map is processed in downstream regions such as the lateral septum (LS) for spatial navigation. The GABAergic cells of the lateral septum receive dense, converging projections from the pyramidal neurons of CA3, CA1 and subiculum. The inputs from the anatomical subregions of the hippocampus to the lateral septum appear to be highly anatomically organized, with more caudal regions receiving

inputs from CA3, rostral areas receiving stronger projections from the CA1 area. Spatially tuned cells have been previously reported in the LS (Tingley & Buszaki, 2018; Zhou et al., 1999; Leutgeb and Mizumori, 2002; Takamura et al., 2006), yet how their firing characteristics relate to hippocampal inputs remains unknown. Using calcium imaging with miniaturized fluorescence microscopy in behaving animals, we characterized the spatial firing properties of cells in the LS based upon their anatomical connections and hypothesized functional relationship with the hippocampal formation. For this, we have identified that approximately 15% of LS GABAergic cells are spatially modulated. We observed a decrease in place field stability along the dorsal-ventral axis of the LS, but not along the anterior-posterior axis. We compared LS place cell stability, mutual information and in-field firing rate with hippocampal place cell firing in open field and linear track paradigms, finding that the LS carries a highly similar, yet degraded firing rate code for position. The LS has emerged as an important structure in context recognition, as suggested by its role in context induced cocaine reinstatement (McGlinchey & Aston-Jones, 2018) and contextual fear condition (Vetere et al., 2017). Using the unique advantage of the miniscope to reliably follow the activity of the same cells over the course of multiple days, we followed these LS GABAergic assemblies activity pattern over the course of multiple days in same and different open fields, to assess the stability and remapping properties of the LS spatial code as compared to its hippocampal inputs. In addition, we have characterized the LS firing dynamics and distribution of place field centroids in response to objects or reward zones to determine whether the LS firing rate carries a purely spatial code, or anchor to salient cues in the environment.

Title: Role of the nucleus reuniens in object memory consolidation in mice

Authors: *M. R. SCHWABE, L. R. TAXIER, K. M. FRICK;
Dept. of Psychology, Univ. of Wisconsin-Milwaukee, Milwaukee, WI

Abstract: Coordinated activity between the hippocampus and medial prefrontal cortex (mPFC) is required for memory encoding and retrieval. Recently, (Tuscher et al., 2018) our laboratory

demonstrated that simultaneous subthreshold chemogenetic inactivation of the dorsal hippocampus (DH) and medial prefrontal cortex (mPFC) impairs the consolidation of object recognition (OR) and object placement (OP) memories in female mice, suggesting that these two brain regions work in concert to promote memory consolidation. However, direct anatomical connections between the DH and mPFC are relatively sparse, so the mechanisms through which these brain regions interact to promote memory consolidation remains poorly understood. A small cluster of cells in the midline thalamus known as the nucleus reuniens (RE) facilitates communication between the hippocampus and mPFC through bidirectional excitatory projections. Furthermore, recent work indicates that the RE is necessary for spatial working memory and fear extinction learning. Collectively, these data suggest that the RE may be a key element of a memory circuit including the DH and mPFC, in which the RE mediates interactions between these regions. However, much is unknown about the RE's contribution to memory, including its role in memory consolidation. The goal of this study was to determine whether activity in the RE is necessary for object recognition and object placement memory. Kappa-opioid receptor DREADD (KORD) virus activated by Salvinorin B was used to inactivate excitatory neurons in the RE. Mice infused with GFP virus or saline were used as controls. KORD virus, GFP virus, or saline was infused into the RE of 9-week old ovariectomized female mice and 3 weeks were given for recovery and optimal expression before training. During training, mice were allowed to explore 2 identical objects placed near the corners of a large white box, and then received a 10 mg/kg injection of Salvinorin B immediately afterwards to target effects to the consolidation phase of memory formation. During testing, a training object was moved (OP) or replaced with a novel object (OR). OP and OR testing was conducted 4 h or 24 h after training, respectively, timepoints at which control animals remember the identity and location of the training objects. Preliminary data indicate that, unlike controls, KORD-treated mice did not exhibit intact OP memory consolidation, supporting a key role for the RE in spatial memory consolidation. Ongoing studies are investigating the necessity for RE activity for OR memory consolidation and potential mechanisms for interaction with the mPFC and DH.

Abstract: The process of determining the allocation of information to particular neurons and synapses within a neural network is known as the theory of `Memory allocation`. These particular set of neurons are termed engram cells, in which activating these engram cells either by physiological or artificial input can drive the recall of that specific event. However, how memory is allocated to these specific subpopulations of neurons is still poorly understood. Here we show that spontaneously evoked “pre-configured” ensembles formed during pre-learning sleeping periods are highly correlated with those formed during novel experience only in engram cells. A compatible imaging system was established to observe the neuronal activity of CA1 neurons and the labelled engram cells; through a photoconvertible fluorescent protein Kikume Green Red (KikGR). The neuronal activity of hippocampal CA1 neurons was observed, through Ca^{2+} influx with G-CaMP7 in freely-moving animals by miniature head-mount fluorescent microscopy. Our advanced imaging system of engram cells and non-engram cells provides deeper insights into the dynamics of the neural activity across several memory processing stages. Using Non-negative Matrix Factorization (NMF) analysis, engram cells showed that sub-ensembles detected during learning were highly correlated with sub-ensembles found during pre- and post-learning sleep sessions as well as retrieval sessions, however these correlations were abolished upon exposure to a different context. In contrast, these features were not observed in the non-engram cells. These findings suggest that the hippocampal network is pre-configured into cellular sub-ensembles that could rapidly be used to encode the near future novel experience.

Title: Pcdhs modulate synchronous activity in the hippocampus

Authors: *H. ASAI[1,2], N. OHKAWA[1,2,3], K. GHANDOUR[1,2,3], Y. SAITOH[1,2,3], M. MATSUO[1], H. NISHIZONO[1], T. HIRAYAMA[4,5], R. KANEKO[6], S.-I. MURAMATSU[7,8], T. YAGI[4], K. INOKUCHI[1,2];

Abstract: Clustered protocadherins (Pcdhs), a large subgroup of adhesion molecules, are important for neural morphology, such as axonal projection and dendrite spread. Pcdhs have two unique characteristics: diversity based on the complex combinations of expressing isoforms in each cells and highly specific interaction with each other. Therefore, Pcdhs are thought to have crucial roles in forming diverse neural circuits. However, little is known whether Pcdhs affect neural activity. Observation of neuronal activities with two methods, in vivo Ca^{2+} imaging and immunostaining with neural activity marker cFos in Pcdhs-mutant mice, demonstrates that Pcdhs modulate neuronal activities in cellular ensemble and hippocampal circuit levels. Ca^{2+} imaging showed that Pcdhβs-deletion remarkably reduced repetitive activity during novel context exploration, which was revealed by correlation matrix analysis, and that Pcdhβs-deletion increased the number of large ensembles, which were extracted with non-negative matrix factorization analysis based on synchronous activity. Majority of the large ensembles showed low frequent activity. In immunostaining, the expression of cFos, induced by novel context exploration, was slightly reduced in the hippocampus of Pcdhβs-deletion mice. Pcdhβs-deletion mice showed significant correlation in the number of cFos-positive cells between hippocampal subregions, suggesting that Pcdhβs modulate neural activities in the hippocampal circuit level. Together Pcdhβs play an important role in controlling neuronal activity in the hippocampus.

Title: Sub second dynamics of theta gamma coupling in hippocampal CA1

Authors: *L. ZHANG[1], J. LEE[1], C. ROZELL[1], A. C. SINGER[2];
[2]Coulter Dept. of Biomed. Engin., [1]Georgia Inst. of Technol., Atlanta, GA

Abstract: Oscillatory brain activity reflects different internal brain states including neurons' excitatory state and synchrony among neurons. However, characterizing these states is complicated by the fact that different oscillations are often coupled, such as gamma oscillations (30-120 Hz) nested in theta (6-12 Hz) in the hippocampus, and changes in cross-frequency coupling are thought to reflect distinct states. In CA1, at least three gamma oscillators have been described with distinct gamma frequencies and theta-phase coupling: high gamma (>100 Hz) thought to be generated within CA1; median gamma (60-120 Hz) and low gamma (30-80 Hz), thought to originate from CA3 and entorhinal cortex (EC) respectively. Previous characterization of these different gammas and their cross-frequency coupling was mainly based on methods that quantify signals over long time scales and therefore cannot detect short-timescale variations in gamma or theta-gamma coupling. Thus, how theta-gamma coupling varies in both frequency and theta-phase and how theta-gamma coupling changes over short timescales remains unclear. Here, we describe a new method to separate single oscillatory cycles into distinct states based on frequency and phase coupling. Using this method, we identified four theta-gamma coupling states in rat hippocampal CA1. These states differed in abundance across behaviors, phase synchrony with other hippocampal subregions, and neural coding properties suggesting that these states are functionally distinct. We captured cycle-to-cycle changes in oscillatory coupling states and found frequent switching between different theta-gamma states showing that the hippocampus rapidly shifts between different functional states. This method identify cross-frequency coupling states within single oscillatory cycles and track cycle-to-cycle changes in these states provides a new approach to investigate oscillatory brain dynamics broadly.

Title: Inhibitory connections are disrupted during spatial navigation in the 5XFAD mouse model of Alzheimer's disease

Authors: *S. M. PRINCE[1], A. L. PAULSON[2], N. JEONG[1], S. M. AMIGUES[2], A. C. SINGER[2];

Abstract: Alzheimer’s disease (AD) is the most common form of dementia and is associated with protein accumulation and neurodegeneration, resulting in neural dysfunction from the level of synapses to networks. One of the best correlates of cognitive impairment in AD is synaptic loss, which suggests that synaptic dysfunction is important to the pathogenesis of AD. While synaptic dysfunction in AD has been well characterized *in vitro*, synaptic changes in awake, behaving animals have not been examined because it is technically very challenging to record such alterations in mice, the primary animal model of AD. Here, we use a virtual-reality behavioral task and an *in vivo* measurement of synaptic efficacy in order to overcome the challenges of recording and measuring synaptic dysfunction in behaving animals. We show *in vivo* deficits in the inhibitory connection strength of interneurons onto pyramidal cells in the 5XFAD mouse model of AD, a well-established AD model that expresses five familial AD mutations. Inhibitory activity in hippocampus is critical for sharp wave ripple activity, high frequency network oscillations that are important for memory consolidation and retrieval. Thus, these synaptic deficits could be related to previously reported lower sharp wave ripple rates in 5XFAD mice. Indeed, we found that these 5XFAD mice had not only fewer but also shorter sharp wave ripples and decreased place cell activation during sharp wave ripples. These results show that *in vivo* synaptic dysfunction occurs in the 5XFAD mouse model of AD during spatial navigation behavior, revealing a potential mechanism of the deficits in network oscillations observed in humans and animal models of AD. This work has broad implications for how neural

circuits for memory are disrupted in AD, and in bridging the gap between synapses, neural activity, and cognitive deficits.

Title: Impaired CA2 place cell remapping in response to social olfactory stimuli in a rat model of fragile X syndrome

Authors: *E. ROBSON[1,2], A. J. MABLY[1,2], L. T. HEWITT[1,2], J. B. TRIMPER[1,2], L. L. COLGIN[1,2,3];

Abstract: The CA2 region of the hippocampus has been implicated in social memory. A recent study showed that CA2 place cell firing patterns change ("remap") during social interactions, a response that is not apparent in CA1 place cells (Alexander et al., *Nature Communications* 2016). Our preliminary results show that CA2 place cells remap after a rat interacts with a familiar rat's empty homecage that contains only the rat's odors. On the contrary, CA2 place cells do not remap in response to interactions with an identical cage containing the rat, but with clean bedding and no familiar rat odors (Mably et al., SfN Abstracts, 2018). These results suggest that CA2 place cells remap in response to the olfactory content of social experiences. Interestingly, preliminary data using a rat model of Fragile X Syndrome (FMR1 knockout rats or "FXS rats") suggest that CA2 place cell remapping does not occur in FXS rats in response to olfactory social stimuli. Necessary control experiments (e.g., to assess whether CA2 place cells respond to non-social odors in control and FXS rats) will also be discussed.

Title: Selective modification of hippocampal representations of a goal location after learning

Authors: *E. HWAUN[1], C. ZHENG[2], L. L. COLGIN[3];
[1]UT Austin, Austin, TX; [2]Acad. of Med. Engin. and Translational Med., Tianjin Univ., Tianjin, China; [3]Ctr. for Learning and Memory, Univ. of Texas At Austin, Austin, TX

Abstract: Solving a goal-directed navigation task requires estimation of current position and a goal location. While many studies have shown that neurons in the hippocampus provide information about current position, the question of how goal information is processed in the hippocampus has received less experimental attention. To address this question, we recorded spiking activity of place cells in hippocampal subregion CA1 while rats learned a new goal location in a delayed match-to-sample task. We found that ensembles of place cells developed an over-representation of a goal location by recruiting new place cells to fire at the goal location. To balance excess activity near a goal location after learning, there was suppression of place cell activity that had already been present around a goal location before learning. In addition to changes in spatial representations upon learning of a new goal location, we also found that those place cells that emerged at a goal location after learning increased their firing rates during sharp wave–ripples more than other place cells. Moreover, replay trajectories decoded from ensemble activity of place cells during sharp wave-ripples developed biases to start or end near a goal location. Together, these results add to our understanding of how goal representations in the hippocampus are modified and reactivated following learning.

Title: Estimating probabilities of potential synaptic connections by axonal-dendritic overlap in local hippocampal circuits

Authors: *C. TECUATL[1], D. W. WHEELER[2], G. A. ASCOLI[3];
[1]Ctr. for Neural Informatics and Bioengineering Dept., [2]Volgenau Sch. of Engin., [3]George Mason Univ., Fairfax, VA

Abstract: A quantitative description of the synaptic architecture in the hippocampal formation (dentate gyrus, CA3, CA2, CA1, subiculum, and entorhinal cortex) is essential for understanding the neural correlates of memory. Yet, the existing knowledge of connectivity statistics between different neuron types in the rodent hippocampus only captures a mere 5% of this circuitry. To supplement these scarce data, we present a systematic pipeline to produce first approximation estimates for the majority of the missing information. Leveraging Hippocampome.org, we derive the local connection probabilities between distinct pairs of morphologically identified neuron types from their axonal-dendritic overlap calculated from published illustrations in the peer-reviewed literature. Specifically, we start with 202 representative 2D reconstructions of characterized neuron types. Next, we adapt pixel-counting algorithms from modern image analysis technology to determine the axonal and dendritic lengths in each layer for every neuron type. We then compute the probabilities of axonal-dendritic connection using relevant anatomical volumes from the adult mouse brain Allen Reference Atlas and ultrastructurally-established interaction distances. Finally, we validate the results with the available subset of experimentally-quantified connections. With this approach, we estimate probabilities of connection for over 1800 neuron type pairs, increasing the available quantitative assessments more than 13-fold. Connectivity statistics thus remain unknown for only a minority of potential synapses in the hippocampal formation, including those involving long-range (23%) or perisomatic (4%) connections and neuron types with no available morphological tracings (9%). The described approach also yields approximate measurements of synaptic distances to/from the soma along the dendritic and axonal paths, which may affect signal attenuation and delay. In conclusion, this dataset fills a substantial gap in quantitatively describing the hippocampal synaptic circuits and provides useful model specifications for biologically realistic neural network simulations until direct experimental data become available.

Title: Towards hippocampome.org 2.0: A simulation-ready knowledge base of rodent hippocampal neuron types

Authors: *D. W. WHEELER[1], C. M. WHITE[1], A. O. KOMENDANTOV[1], D. J. HAMILTON[1], S. VENKADESH[2], K. MORADI[2], S. M. ATTILI[2], C. TECUATL[1], J. D. KOPSICK[2], G. A. ASCOLI[1];
[1]Volgenau Sch. of Engin., [2]Neurosci. Program, George Mason Univ., Fairfax, VA

Abstract: Hippocampome.org is an open-access knowledge base of the rodent hippocampus, which uses peer-reviewed literature to define over 120 neuron types by their main neurotransmitter and the patterns of their axonal and dendritic presence across the parcels of the rodent hippocampal formation: dentate gyrus, CA3, CA2, CA1, subiculum, and entorhinal cortex. For each neuron type, the knowledge base also encompasses information on molecular markers, which includes both direct and inferential evidence; known and potential connectivity; intrinsic electrophysiological parameters and corresponding experimental conditions; quantitative firing-pattern classification; and parametrically identified single- and multi-compartmental Izhikevich models. Additional accumulating information includes estimated counts of each of the neuron types, which are derived from multiple constraints including the cellular distributions in Nissl images from the Allen Brain Atlas; the quantification of the presence of the axons and dendrites across a given parcel, which enables the statistical estimation of the probability of potential connectivity between neuron types; data on the amplitude, kinetics and short-term plasticity of synapses; and information concerning the phase locking of neuronal firing to theta and gamma rhythms in the hippocampus. All data are linked to extracted publication excerpts and illustrations, which facilitate users' abilities to confirm all data interpretations. We are continuing to endeavor toward using the collated data in a computational simulation of the complete hippocampal formation. As we grow, we also expand the underlying foundations of Hippocampome.org by continually data mining the literature for new neuron types and neuronal properties while cross-linking and integrating new and prior data.

Title: Contextual fear conditioning increases intrinsic excitability in activated neuronal ensembles in CA1 pyramidal neurons

Authors: *E. V. BARRAGAN[1], J. H. WILMOT[2], B. J. WILTGEN[1,2], J. A. GRAY[1,3];
[1]Ctr. for Neurosci., [2]Psychology, [3]Neurol., Univ. of California Davis, Davis, CA

Abstract: Learning induces long-lasting changes in synaptic strength that are required for memory formation. It also produces transient changes in intrinsic excitability, the function of which are not yet understood. In the hippocampus, learning increases the excitability of CA1 neurons for several days, a change that is thought to enhance replay and promote memory consolidation. If this is the case, then increases in intrinsic excitability should only be observed in neurons that were strongly activated during learning (e.g. memory cells). However, until recently, it was not possible to identify these neurons and perform *in vitro* whole-cell recordings after learning. To accomplish this, we used activity-dependent reporter mice (TetTag) to label active neurons in CA1 for several days. In these animals, activation of the c-Fos promoter leads to expression of the long-lasting protein H2B-GFP. To determine if intrinsic excitability changes occur specifically in neurons activated by learning, we trained these mice on a contextual fear conditioning task and prepared acute hippocampal slices 48 hours later. Consistent with our hypothesis, we found that tagged CA1 neurons (GFP+) exhibited increased firing rates compared to neighboring cells that were not labeled during learning (GFP-). This increase in excitability persisted for at least two days. In contrast to previous studies using trace eyeblink conditioning in rabbits, we found that changes in the medium afterhyperpolarization (mAHP) could not explain the different excitability observed in GFP+ neurons compared to GFP- cells. Therefore, a distinct mechanism may underlie the increases in CA1 excitability following context fear conditioning.

Title: Functional integration of adult-generated granule cells in the avian hippocampus

Authors: *D. F. MARRONE, C. C. DAMPHOUSSE;
Wilfrid Laurier Univ., Waterloo, ON, Canada

Abstract: Adult neurogenesis of granule cells (GCs) is a key mechanism of structural plasticity in the hippocampus, as these cells are thought to be for proper memory function in the face of high similarity between items of information to be remembered. Although it is known that birds also generate new GCs throughout life, this process is modulated by experience, and ablating these cells causes memory deficits, our knowledge could be furthered by tracking the activity of newly-born GCs during behavior. As a critical intermediate point towards this goal, here we establish the timecourse by which GCs integrate and become active (i.e., express activity-dependent *Egr1*, a reliable reporter of activity in individual neurons) during spatial behavior. Groups of Japanese quail were injected with 100mg/kg BrdU for a period of 1, 2, 3, 4, 5, or 6 weeks. Following each delay, birds explored a novel environment to engage GCs, and were then sacrificed and the tissue was analyzed using immunohistochemistry for NeuN, BrdU, and Egr1. These data will map the progression of neurogenesis in the avian hippocampus and reveal the optimal timing for examining the activity of these cells in further experiments.

Title: Response in the avian hippocampal formation to incremental changes in context

Authors: *C. C. DAMPHOUSSE, N. Y. MILLER, D. F. MARRONE;
Wilfrid Laurier Univ., Waterloo, ON, Canada

Abstract: Multiple avian species exhibit behaviours consistent with having cognitive maps. Recent data also show that many birds exhibit “place-cell-like” patterns of neuronal activity. In mammals, we know that many different types of information can shift place cell mediated representations but information regarding what kinds of cues most powerfully drive spatial representation in the avian hippocampal formation (HF) is lacking. In the current experiment, quail were placed into an arena in which multiple cues were manipulated over two separate epochs (geometric properties of the arena itself, the objects within the arena, or both). Analysis via catFISH techniques allowed us to determine which condition caused the greatest proportion of remapping within the avian HF. These findings contribute to the potential discovery of an avian hierarchy of spatial information processing in which certain cues within the environment may be more salient and utilized more heavily during encoding of spatial environments.

Title: Representation of visual landmark configurations in mouse retrosplenial cortex

Authors: *J. VOIGTS[1], E. H. TOLOZA[2], J. P. NEWMAN[1], I. R. FIETE[1], M. A. WILSON[1], M. T. HARNETT[1];
[1]MIT, Cambridge, MA; [2]Harvard/MIT, Cambridge, MA

Abstract: Navigating an environment using sensory cues requires the context-dependent integration of a multitude of signals over time. For example, visual cues can be used as landmarks for navigation if their position in the environment is known a-priori. Crucially, the

integration of sensory information into an estimate of position occurs while an agent moves through an environment over a period of time. At any given point, an agent might have a hypothesis of its position in space, and this hypothesis is revised based on sensory data. Retrosplenial cortex (RSC) has been proposed to serve a central role in performing such computations by translating between egocentric visual information and allocentric representations of an agent's position. Neurons in RSC are known to integrate multiple navigational variables, including visual information and position relative to landmarks, allocentric location within an environment, and heading. However, the circuit computations in RSC that assign meaning to visual landmarks are not well understood. Here, we examine the role of RSC in forming hypotheses about an agent's position in space by employing a novel miniaturized 3D-tracking system, integrated with the next-generation Open Ephys headstages, in freely behaving mice that perform a landmark-based navigation task. By examining the encoding of visual information and allocentric position while mice localize themselves in an environment, we find that RSC encodes a multitude of egocentric and allocentric navigational variables that are anchored to visual landmarks. Our results indicate that RSC translates between representations of visual information and location in space, based on the animal's prior knowledge of the environment, providing a substrate for memory-guided visual navigation.

Title: Spatial learning impairments in mutant mice without a dentate gyrus

Authors: *C. JOU[1,2], S. HU[1], A. RATTNER[3], J. NATHANS[3], A. FENTON[1,4,5];
[1]Ctr. for Neural Sci., New York Univ., New York, NY; [2]City Univ. of New York, New York, NY; [3]Johns Hopkins Univ. Sch. of Med., Baltimore, MD; [4]Neurosci. Inst. at the NYU Langone Med. Ctr., New York, NY; [5]Physiol. and Pharmacology, Robert F. Furchgott Ctr. for Neural and Behavioral Sci., State Univ. of New York, Downstate Med. Ctr., Brooklyn, NY

Abstract: The dentate gyrus (DG) is crucial for discriminating between similar spatial memories, perhaps because it performs pattern separation computations to distinguish between representations of experiences in similar conditions that are also different in important ways. For example, optogenetic silencing of either mature or immature adult-born dentate granule cells or

ablation of the latter, does not impair learning or memory in an active place avoidance task that requires a mouse on a slowly rotating arena to avoid the location of a stationary shock zone. However, the DG manipulations impair conflict learning in a task variant that requires memory discrimination when the shock zone is relocated in the otherwise unchanged environment. Here we examine spatial learning in a mutant mouse that does not develop a DG. We studied mutant mice (MT, n=14) with Wls deleted in GFAP-expressing cells (mainly astrocytes), the result of crossing GFAP-Cre and floxed-Wls mice. Genotype-blind comparisons were made with littermate control mice (CT, n=15), using both sexes. We observed no differences between the sexes. Nor did we observe alterations in locomotion, motor control, or sensorimotor integration in a battery of neurological tests. In contrast, active place avoidance learning was impaired in the mutant mice according to multiple measures of the conditioned avoidance (number of entrances to the shock zone, latency to first entry, and maximum time avoided). Conflict learning was assessed by relocating the shock zone 180 deg. This learning was also slower in the mutant mice. The genotypes did not differ in extinguishing the avoidance when shock was turned off. Impaired active place avoidance learning in a new environment was again observed in the mutant mice; this also indicated they had not learned to learn during the initial experiences. The learning impairment was then tested using a T-maze left-right discrimination task, requiring mice to successfully remember and choose which one of the two arms was safe and which one was associated with a footshock. The contingencies switched every 10 trials, after a 10-min rest between the 4 sessions. The two groups differed only in the last session, when memory-related interference was maximal. These results are the first behavioral characterization of a mouse model of genetic DG deletion, showing that developmental elimination of DG results in a more general learning deficit than DG lesion in adulthood. This may be due to other consequences of the developmental manipulation.

Title: Learning to learn persistently modifies a neocortical-hippocampal inhibitory microcircuit

Authors: *A. CHUNG, A. A. FENTON;
Ctr. for Neural Sci., New York Univ., New York, NY

Abstract: The brain can learn to learn. Although cognitive behavior therapy (CBT) takes advantage of cognitive control training to improve cognitive abilities, the critical neurobiological evidence of 1) CBT-induced 2) long-lasting, and 3) memory-independent changes in synaptic circuit function is lacking. Here, we test predictions of "the neuroplasticity hypothesis" by investigating ifthe entorhinal cortex (EC) to dentate gyrus (DG) perforant path circuit changes after cognitive control training (CCT). Adult mice received either CCT in the active place avoidance task, or place learning (PL) to avoid the same location in a task variant with lower cognitive control demand, or unconditioned spatial exploration (SE) in the same environment with no cognitive demand. Upon subsequent testing to learn a new CCT task in a novel environment, only the CCT-trained mice showed learning to learn. Some mice had been implanted with stimulating electrodes in the perforant path and 32-site recording electrodes spanning the somatodendritic axis of dorsal hippocampus. DG evoked potential responses were measured in response to test stimulation before and 2h after each training session. Initial training in CCT mice but not PL or SE mice, reduced the fEPSP slope localized to the inner molecular layer of the supra-pyramidal blade of DG (supDG); changes were minimal in the population spike and at the infra-pyramidal blade (infDG). This circuit change persisted 60 days without further training. Subsequent learning in a novel environment did not cause further changes. Optogenetic manipulations with evoked potential recording in urethane-anesthetized Gad2-Cre-ChR2-eYFP mice, showed that DG interneuron activation mimics the CCT-induced changes without training, and CCT training occludes the changes, indicating that CCT modifies inhibitory interneuron circuit function. Paired pulse ratio results showed that CCT causes faster activity dependent release from inhibition. Optogenetic manipulations of DG interneurons in *ex vivo* hippocampus slice showed that CCT increases feedforward disinhibition in supDG. Immunofluorescence for PKMzeta, which is necessary and sufficient for maintaining LTP, confirmed that CCT persistently increases PKMzeta expression, specifically in somatostatin expressing GABAergic interneurons in DG hilus. These findings confirm predictions of the neuroplasticity hypothesis, demonstrating that cognitive training causes persistent changes to an entorhinal-hippocampus disinhibitory microcircuit independent of the sparse excitatory-excitatory synaptic changes that are assumed to encode specific memories.

Title: Cognitive inflexibility in the Fmr1-null mouse model of autism is associated with excessive dentate spikes

Authors: *A. A. FENTON[1], D. DVORAK[2];
[2]Ctr. for Neural Sci., [1]New York Univ., New York, NY

Abstract: Dentate spikes (DS) are large amplitude, short duration field potentials which are localized to the hilar region of dentate gyrus (DG). While the exact role of DS is still unknown, several theories proposed a role in learning, memory consolidation and hippocampal circuit stabilization through anti-excitation.
To understand the role of DS in hippocampal function, we recorded local field potentials (LFP) using 32-channel linear electrode arrays spanning the somato-dendritic axis of dorsal hippocampus in wild-type (WT) and Fmr1-null mice that mimic the genetic cause of Fragile X Syndrome (FXS). Fmr1-null mice express cognitive inflexibility in tasks that require switching between relevant and irrelevant information in memory.
In task-naïve mice, we identified two types of DS based on their current source density profiles. DS type I (DS1) has sinks at the outer molecular layers of DG, corresponding to the lateral entorhinal cortex layer 2 (LECII) terminal, while DS type II (DS2) has middle molecular layer sinks, corresponding to the medial EC terminals (MECII). The DS morphologies, including amplitude and width did not differ between the genotypes. During stillness, DS1 rates were also not different, but DS2 rates were exaggerated in Fmr1-null mice. DS2 often followed DS1 but the opposite was rare.
Effects of DS on oscillatory activity at CA1, were studied using independent component analysis (ICA) to identify input-specific currents. The stratum radiatum IC (srIC) identified slow gamma (25-45 Hz) oscillations associated with the CA3-CA1 pathway. The lacunosum moleculare IC (lmIC) identified mid-frequecy gamma (50-90 Hz) oscillations associated with the MECIII-CA1 pathway. The srIC was strongly increased during DS2 and slightly decreased during DS1. In contrast, lmIC was increased during DS1 and decreased during DS2. DS exhibited strong modulation by CA1 stratum pyramidale theta oscillations. Specifically, DS1 occurred predominantly on the early descending phase of theta, similar to lmIC, while DS2 occurred predominantly around the trough of theta, similar to srIC. Sharp-wave ripples were reduced after DS1 and increased after DS2 with no genotypic differences.
Excessive DS2 rates in Fmr1-null mice suggest a role of DS in the cognitive inflexibility of previously learned hippocampal representations, that manifest as an overexpression of CA3-associated memory recollection events.

Title: The effect of high fat diet and sleep deprivation during adolescence on adult behavior and memory

Authors: *K. GLUSHCHAK, J. DAVIS, T. ZEUTHEN, T. J. SCHOENFELD;
Belmont Univ., Nashville, TN

Abstract: The adolescent period is critical for normal brain development. Abnormalities that may occur during the adolescent period can have a profound effect on brain structure and behavior into adulthood. Diet and sleep are two central aspects of life and their compounded impact has not been investigated in rodent models, especially their long-term effects on behavior and brain structure. Therefore, we investigated the effects of high-fat diet (HFD) and sleep alterations (through chronic light deprivation) during adolescence on stress-affected memory in young adult rats. Adolescent Long-Evans rats were given either a HFD, HFD plus light deprivation, or control diet for 4 weeks (4-8 weeks old). After the manipulations, the rats recovered for six weeks, all maintained on control diet and normal light cycles. Adult rats (14 weeks old) were tested using two memory tests: novel object recognition (perirhinal cortex-dependent) and object location (hippocampal-dependent). For both tests, objects were learned and tested 24-hours later by altering either the type of object or location of object in the test phase. Directly after object learning, all rats were physically restrained for 30 minutes to induce stress effects on memory consolidation. Rats given HFD and light deprivation during adolescence were the only group to show significant object recognition learning; all other groups showed no evidence of novel object recognition. However, the object location test revealed that all three groups displayed object location memory equally well. Following the object location test, brains were extracted to measure hippocampal volume and c-fos activation to understand the role of HFD and light deprivation on brain structure and activation changes. This study examined the long-term effects of HFD and light deprivation during adolescence on memory and brain activation in adulthood.

Title: Exercise prevents frustration-induced anxiety-like behavior in rats

Authors: *T. J. SCHOENFELD, J. TAYLOR, B. FICZERE;
Belmont Univ., Nashville, TN

Abstract: Running consistently decreases anxiety-like behavior in experimental rodents, both at baseline and following stressful events. Frustration is an emotional event arising from a decrease in expected reward following motivated behavior and has been associated with stress and anxiety in humans, albeit rarely studied in rodents. Rodent studies do show that anxiety-like behavior is a side effect of inducing frustration in operant conditioning scenarios, although the mechanisms and potential preventative actions for frustration are wholly unknown. Thus, we modeled frustration in both control and running rats and predicted that running would buffer anxiogenic effects of frustration. Long-Evans rats (N = 16) were evenly split into home cage environments with or without access to a running wheel. All rats were trained on a progressive variable ratio (VR) lever pressing schedule up to VR20. After reaching criterion, rats went through a frustration trial, during which no reward was given following lever pressing behavior. After both the first VR20 and frustration trial, corticosterone was measured in tail blood and anxiety-like behavior was analyzed in an open field. Lastly, hippocampal tissue was analyzed for dendritic spine density. Control rats had increased anxiety-like behavior and corticosterone levels following induced-frustration, however running rats were prevented from these increases and had higher spine density throughout the hippocampus. The present findings demonstrate running as a robust stress coper that prevents the maladaptive effects of frustration on physiology and ongoing behavior.

Title: Effect of neurogenesis on microglial activation

Authors: *A. SMITH[1], K. M. WILLIAMS[1], T. J. SCHOENFELD[2];
[2]Psychological Sci., [1]Belmont Univ., Nashville, TN

Abstract: The geriatric population of America has grown exponentially in the past century. Health degradations and expensive medical care and attention are characteristic of this population with many of these costs due to age-related cognitive decline. It is essential to completely understand the mechanisms of normal and abnormal aging in the search for treatments for cognitive decline. A reduction of neurogenesis is a common factor in aging, but this reduction is even more drastic in individuals experiencing cognitive decline. It is unclear what effect the reduced neurogenesis has on the extracellular environment, including glial cells. In particular, changes in microglial activation could be related to cognitive decline, and it is possible that reduced neurogenesis could influence microglial activation. To determine the functional effect of prolonged ablation of neurogenesis on microglial activation, a pharmacogenetic rat model (GFAP-TK) was used. Wild type (WT) rats had normal neurogenesis throughout the experiment, while transgenic (TK) rats given valganciclovir (VGCV) had neurogenesis inhibited starting at eight weeks old. Microglial activation and hippocampal volume were measured for three different age groups (VGCV treatment for 4, 9, and 14 weeks) in both WT and TK rats to determine effects of prolonged neurogenesis-ablation on markers related to aging. Despite no rats being old adults in our study, the expected finding is that microglial activation will increase and hippocampal volume will decrease along with aging in TK rats, with little effects in WTs; indicating that reducing neurogenesis speeds up the aging process in the hippocampus of rats.

Title: Hippocampal extracellular potassium levels and spatial memory effects in response to retrodialysis insulin administration

Authors: *S. DOUGLASS, G. M. SHAMES, C. M. LEVINE, E. C. MCNAY;
Behavioral Neurosci., State Univ. of New York at Albany, Albany, NY

Abstract: Insulin is the most common treatment for hyperglycemia, such as that caused by type 1 or type 2 diabetes mellitus. Insulin causes cellular uptake and storage of glucose to restore homeostasis. Importantly, insulin also regulates other systems such that administration of exogenous insulin may cause an imbalance: an important example is regulation of potassium transport. In the periphery, insulin administration has been shown to increase the cellular uptake of potassium via Na^+/K^+ ATPase, leading to hypokalemia. Research in our lab and others has shown that insulin is a key regulator of cognitive function and local metabolism within the hippocampus. To date, however, no studies have examined whether insulin acts to regulate potassium levels within the brain, nor whether such regulation might correlate with cognitive effects caused by administration of exogenous insulin.
The current study sought to extend our previous work on the impact of exogenous insulin delivery to the hippocampus: specifically, we measured the impact of intrahippocampal insulin administration on local extracellular potassium levels, both at baseline and during a cognitive task. Rats were tested using a spontaneous alternation task in a four-arm maze with concurrent microdialysis and retrodialysis of insulin for the period corresponding to the behavioral task. Insulin was added to the perfusate at 6.67 mU/mL in an artificial extracellular fluid vehicle. Samples were collected throughout acclimation, baseline, testing, and recovery periods, then analyzed for potassium and glucose. Hippocampi and prefrontal cortices were collected and analyzed for Na^+/K^+ ATPase protein concentrations. We hypothesized that insulin administration would lower extracellular potassium levels, and Na^+/K^+ ATPase will be upregulated in relation to controls. A key next step will be parsing the cognitive impact of insulin's multiple cellular actions.

Title: A novel substrate-competitive inhibitor of glycogen synthase kinase-3 augments glucose uptake in primary hippocampal cells

Authors: *G. M. OSTRANDER[1], M. ZIAMANDANIS[1], L. P. MALLON[1], E. C. MCNAY[2]; [1]State Univ. of New York At Albany, Albany, NY; [2]Behavioural Neurosci., Univ. At Albany, Albany, NY

Abstract: Inadequate brain and hippocampal utilization of glucose, often linked to dysregulated central insulin signaling, is known to cause cognitive impairment and is a key correlate of Alzheimer's disease (AD). Inhibition of glycogen synthase kinase-3 (GSK3) has recently received attention as a potential treatment for both dysregulated insulin signaling and AD. GSK3 is directly modulated by insulin, and insulin signaling may be simultaneously modulated by GSK3. In the periphery, inhibition of GSK3 facilitates insulin signaling and enhances glucose utilization; however, less is known about these relationships in the brain.
Several studies in this area have used GSK3 modulators that are ATP-competitive. ATP-competitive inhibitors have shown promising results in basic research but failed to achieve success in clinical trials. Many of these inhibitors cause off-target side effects that may be harmful, likely due to evolutionarily-conserved residue sequences of alternative proteins targeted by ATP-competitive small-molecule inhibitors of GSK-3. The current study employed an alternative, substrate-competitive peptide inhibitor of GSK3 (L807-mts), to investigate how an alternative route of GSK3 modulation may facilitate glucose uptake within primary hippocampal neurons. We treated neuronal cultures with several dosages of L807-mts concomitantly with 2NBDG [2-(N-(7-Nitrobenz-2-oxa-1,3-diazol-4-yl)Amino)-2-Deoxyglucose], in order to measure glucose uptake via quantitative immunofluorescent analyses. We found a strong and positive dose-dependent effect of GSK3 inhibition on glucose uptake. Across multiple biological replicates, L807-mts treatment facilitated uptake of glucose in the presence, but not in the absence, of insulin: this is consistent with prior work in the periphery.
Our data suggest a promising, novel alternative for treatment of insulin resistance within the central nervous system. We propose that this pharmacological intervention could potentially mitigate dysregulation of downstream molecular effectors that may contribute to the comorbidity between insulin resistance and AD.

Title: Phase coding as a possible mechanism of sleep dependent memory consolidation

Authors: *Q. SKILLING[1], B. C. CLAWSON[1], J. P. ROACH[4], N. OGNJANOVSKI[5], S. J. ATON[2], M. R. ZOCHOWSKI[3];
[2]Molecular, Cellular, and Developmental Biol., [3]Physics, [1]Univ. of Michigan, Ann Arbor, MI; [4]Cold Spring Harbor Lab., Cold Spring Harbor, NY; [5]Molecular, Cellular, and Developmental Biol., Univ. of Michigan Aton Lab., Ann Arbor, MI

Abstract: It has been shown that sleep is critical for consolidation of contextual fear memory and that hippocampus plays central role in that process. However neuronal mechanisms underlying this consolidation are not well understood. In this study, we develop a computational model that closely (a) recapitulates network-level phenomena analyzed from *in vivo* recordings of fear-conditioned mice and (b) provides insights on network-level mechanisms underlying fear-memory consolidation during during sleep. The proposed mechanisms center around cholinergic modulation of network level dynamical behaviors associated with changes in muscarinic membrane currents. Acetylcholine levels are known to be high during wakefulness and rapid eye-movement (REM) sleep but low during non-REM sleep (slow-wave sleep; SWS), resulting in a change in membrane excitability from Type 1 to Type 2, respectively. Previous work has shown that neurons (and networks) exhibiting Type 2 excitability are amenable to sub-threshold resonance and synchronization through simple spike-timing relationships. Here, we expand on this data to show that neuronal networks composed of Type 2 neurons exhibit network-level resonance, whereby fast-spiking neurons recruit slower-spiking neurons to participate in slow oscillatory events in the 4-12 Hz range in a phase-dependent manner, a mechanism we refer to as phase-coding. In contrast, networks composed of Type 1 neurons are amenable to PING-like oscillations, where neuronal firing rates cause network-level bursts of activity, a process referred to as rate-coding. We show that rate-coding and phase-coding result in different functional network properties and conclude that it is phase-coding during non-REM sleep that accounts for fear memory consolidation in mice.

Neurosciences, [4]John van Geest Ctr. for Brain Repair, Univ. of Cambridge, Cambridge, United Kingdom; [5]Univ. of Leeds, Leeds, United Kingdom

Abstract: Perineuronal nets (PNN) play a crucial role in the maturation and plasticity of neurons and synapses. PNNs have been shown to have effects on memory formation, retention and extinction in a variety of animal models. It has been proposed that the cavities in PNNs containing synapses can act as a memory store, which is stable after events that cause synaptic withdrawal such as anoxia and hibernation. We are examining this idea by monitoring positional memory before and after synaptic withdrawal caused by acute hibernation. This is carried out in normal animals and in animals lacking PNNs due to chondroitinase ABC treatment or knockout of CNS aggrecan.
In our study, we used mice model of induced hypothermia via intraperithoneal injection of 5´adenosine monophosphate (5‘AMP) which leads to a torpid (hibernation-like) state (HLS) with a significant retraction of synapses observed in the CA1 region of the hippocampus (Peretti et al.,2015). In this model we tested the effect of enzymatic digestion of PNN structure ((chondroitinase ABC/ saline control))±HLS, n≥10/group, male) or Cre inducible CNS aggrecan knockout ((Cre $AGG^{-/-}$ / littermate non CRE control)±HLS, n≥10/group, male) on learned behaviour in the Morris water maze task (MWM). The number of synapses retracted by deep cooling and altered by changes in the PNNs, was measured by FIB-SEM electron microscopy. A 3D analysis was performed in the CA1 dendritic area. Western blot analysis (pTau, PSD95, GAD65/67, NMDR1,etc.) and immunohistochemical stainings (WFA, Agg, PVA) confirmed the enzymatic efficacy and impact of the hibernation like state. All treatments i.e. HLS, chondroitinase injection/AGG knockout or their combination, showed a significant effect on the already learned behaviour, affecting both; established memory and learning in MWM task, which was supported by the changes observed in FIB-SEM, IHC and Western blot analyses.

Title: Subthreshold coherence of multiple CA1 pyramidal cells during *in vivo* theta oscillations

Authors: *A. NOGUCHI, N. MATSUMOTO, Y. IKEGAYA;
Pharmaceut. Sci., Lab. Chem Pharmacol, Grad Sch. Pharmaceut Sci, Univ. Tokyo, Tokyo, Japan

Abstract: Theta (θ) oscillations (3-10 Hz) in the hippocampal LFPs (θ_{LFP}) are associated with active exploration and attention. Previous reports suggest the role of θ_{LFP} in cognitive function, such as memory encoding and spatial representation; however, how θ_{LFP} originates from collective activity of individual neurons is not fully understood. One of the major contributors of LFP signal is thought to be synaptic transmembrane currents (Buzsáki et al., 2012), which is also the main component of subthreshold membrane potentials (*V*m) of each neuron. We thus focused on how collective dynamics of subthreshold *V*m are reflected in θ_{LFP}. In the present study, we conducted simultaneous recordings of hippocampal CA1 LFPs and subthreshold *V*m of up to four CA1 pyramidal neurons in urethane-anesthetized mice. We found intermittent θ oscillations in subthreshold *V*m (θ_{Vm}), often during θ_{LFP}. In about 50% CA1 pyramidal cells, the time changes in θ_{Vm} powers were positively correlated with those in θ_{LFP} power. In about 70% cell pairs, the time changes in their θ_{Vm} powers were positively correlated between them. The simultaneously occurring θ_{LFP} and θ_{Vm} and the simultaneously occurring θ_{Vm} of CA1 neuron pairs had similar frequencies, although the frequencies of θ_{LFP} and θ_{Vm} per se fluctuated between 3 and 10 Hz over time. We also focused on the relationships between θ_{LFP} and θ_{Vm} of multiple CA1 pyramidal cells. The θ_{LFP} powers became larger when more CA1 pyramidal neurons simultaneously emitted θ_{Vm}. When multiple CA1 pyramidal neurons exhibited θ_{Vm} with more similar frequencies, θ_{LFP} power became greater, and its frequency became more similar to the mean frequencies of the θ_{Vm}s of those neurons. These results suggest that hippocampal CA1 θ_{LFP} is predictable from an ensemble of θ_{Vm} of a few CA1 pyramidal cells.

Abstract: The hippocampus is a key structure for processing spatial information including the discrimination of the location of inaccessible objects in space. How this critical ability is represented at the level of hippocampal neuronal ensembles has not yet been clearly described. We combined single-unit electrophysiological recordings in rats with the operant behavior task using virtual reality. This provided us with the possibility to study the discrimination of positions of visual objects located in a part of an environment that is not accessible to the animal. We trained rats to press a lever for food reward when an object displayed on a distant computer screen was at a particular position and not to press it when the object was at other positions. Once a rat reached asymptotic performance, an array of tetrodes was implanted and the activity of hippocampal CA1 neuronal ensembles was recorded during the task. We studied how the activity of neuronal ensembles represents the information about the displayed object's position. We binarized a given experimental session into bins of 2 seconds and obtained spike-counts vector per bin reflecting the number of spikes fired by every cell in the ensemble at that particular moment, and then estimated Kendall's correlation coefficient between all bins and stimuli. Our data suggest that individual positions of an inaccessible object are represented differentially by neural ensembles in the hippocampus.

Title: Neuronal ensembles dynamics during spatial learning in CA1 mouse hippocampus

Authors: M. ALTAMIRA[1], *R. OLIVARES-MORENO[1], M. LOPEZ-HIDALGO[2], G. ROJAS-PILONI[1];
[1]Dept. de Neurobiología del Desarrollo y Neurofisiología, Inst. de Neurobiología, Univesidad Nacional Autónoma de México, Queretaro, Mexico; [2]Escuela Nacional de Estudios Superiores, Unidad Juriquilla, Univ. Nacional Autónoma de México, Queretaro, Mexico

Abstract: In recent years, properties of hebbian neural ensembles have been studied in vivo, including overlapping, sparse coding, dynamic persistence and dynamic completion. However, the dynamic construction and reconstruction has been poorly studied due to technical limitations to follow simultaneously groups of neurons along the time. Here, we analyzed the neural activity, in hippocampal CA1 region, during spatial learning in free moving C57BL transgenic mice expressing fluorescent calcium indicator GCaMP6f under Thy1 promoter, using miniaturized microscope to record calcium activity. The animals were trained in a 'Y' maze under two conditions A and B. In condition A, a tone was presented to drive the animals to the maze right side (tone-right). In condition B, a luminic stimulus was presented to drive the animals to the maze left side (light-left). In a second experimental phase, when the animals reached a performance success of 80%, we carry out a re-learning process switching the conditions (tone- left, light- right). In this way, we evaluated behavioral performance and neuronal ensemble composition. Our data show, that during trainning the number of active neurons decreased gradually reaching a stable state, giving rise to two ensembles that represent conditons A and B. Moreover, during re-learning process, we identified modifications in the number of neurons and their activity in both neuronal groups, suggesting a dynamic construction and reconstruction of ensembles. We conclude that is possible to follow the activity of a neuron population over weeks, and thus, analyze the ensemble construction and reconstruction process that underlies a spatial learning.

Title: Encoding of spatial information by calcium dynamics of hippocampal astrocytes

Authors: *S. CURRELI[1], J. BONATO[2], S. PANZERI[2], T. FELLIN[1];
[1]Inst. Italiano di Tecnologia, Genova, Italy; [2]Inst. Italiano Di Tecnologia, Rovereto, Italy

Abstract: Neural place cells in the hippocampal formation are known to encode navigational information through the modulation of their firing rate as a function of the animal's spatial location, providing a cellular substrate for spatial cognition. Growing evidence suggests that glial cells are involved in the processing of sensory information, but whether navigational information is encoded in glial networks or rather exclusively encoded in neuronal circuits is unknown. Here we tested the hypothesis that astrocytes, the major class of non-neural cells in the brain, encode navigational information in their intracellular calcium dynamics. To this aim, we trained mice to navigate in a virtual environment and we combined astrocyte-specific expression of genetically encoded calcium indicators with two-photon functional imaging to capture subcellular calcium dynamics of hippocampal CA1 astrocytes during spatial navigation in head fixed animals. We found that astrocytic calcium signaling was significantly modulated by the spatial position of the animal in the virtual track. Calcium events accumulated at preferred spatial locations and this phenomenon occurred in topologically restricted regions of the astrocyte, including the cell body and the proximal processes. Importantly, using a support vector machine decoder we found that spatial information in astrocytic calcium dynamics could be reliably decoded and these calcium signals could be used to infer the animal's spatial location. Altogether, these findings indicate for the first time that information-encoding cellular dynamics during high-level cognitive functions such as spatial cognition extend beyond neural circuits to astroglial networks.

Title: Hippocampal neuronal responses in rats during avoidance behaviour relative to a moving robot

Authors: *N. AHUJA[1,2], V. LOBELLOVA[1], D. RADOSTOVA[1], A. STUCHLIK[1], E. KELEMEN[3];
[1]Dept. of Neurophysiol. of Memory, Inst. of Physiol., Prague, Czech Republic; [2]Dept. of Physiol., Charles Univ., Prague, Czech Republic; [3]Dept. of Exptl. Neurobio., Natl. Inst. of Mental Hlth., Klecany, Czech Republic

Abstract: Navigation relative to other moving animals (conspecifics, potential prey or predators) or objects is a cognitive ability that is important for animals in many ethologically relevant situations. Our aim is to study neuronal substrates of navigation relative to a salient moving object.
We have developed a behavioural paradigm to study the rat's ability to assess not only distance from, but its position relative to a moving object. Rats were trained to avoid a circular shock zone (39cm in diameter) around a robot moving on a circular arena (130cm in diameter). Shock zone was defined by spatial relationship relative to the robot, it was in front or either side of the robot.
Trained rats made significantly fewer entrances to the shock zone compared to the equidistant safe areas around robot ($p's < 0.05$). Action potential discharges were recorded from neuronal ensembles in the hippocampus of rats interacting with the moving robot without reinforcement. In the CA1 and CA3 hippocampal areas we observed neurons with spatially-tuned responses relative to the room as well as neurons with responses reflecting the relative position of the rat and the robot. We are now in a position to study the dynamics of interacting representations of mutual positions of the rat, robot and the environment.
This work provides new insights into neuronal dynamics underlying the ethologically important ability to navigate with respect to significant moving objects in an environment.

Abstract: Navigation is one of the fundamental cognitive skill found in many animals across all of the animal kingdom and it is important for finding food, shelter and mates in order to survive. A critical component of the ability to navigate is a sense of direction and a sense of speed. However, almost nothing is known about the neural representation of direction and speed in the brain of vertebrates outside the mammalian class. The goldfish, which is a bony fish, the largest vertebrate family, have the cognitive ability to navigate using allocentric and egocentric cues. In addition, the lateral pallium in the goldfish brain is a possible homolog of the mammalian hippocampal formation and associated with allocentric navigation. Using a novel wireless recording system, we measured the activity of single cells in the lateral pallium of a freely swimming goldfish and found speed cells and conjunction head-direction and speed cells, i.e. velocity encoding cells. Those cells types are similar to cell which are found in the mammalian hippocampal formation and believed to be the building blocks of path integration. Our study sheds light on how kinematic information is encoded in the fish brain and whether the mechanisms encoding the kinematic variables are shared across evolution.

Abstract: Objects and landmarks present in an environment are essential for successful navigation through it. Experiments in navigation saw the emergence of various types of spatial cells in the hippocampal-entorhinal complex. However, they were conducted in the absence of any landmark cues (objects) within the enclosure. Recent studies by Hoydal et al. confirmed the presence of cells that exclusively fired in response to the objects placed in an environment namely, the Object cell that fired when the animal was at the location of the object and another type of cell called the Object Vector Cell (OVC) that fired when the animal was at a certain distance and direction from the object (Høydal et al., 2019). The latter was extensively studied by Høydal et al and will thus be the focus of our work as well. We employ a hierarchical oscillatory network model to study the emergence of OVCs in the absence of an explicit visual input. The model constitutes a Head Direction (HD) layer comprising of cells, each coding for a particular direction. The responses of this layer along with the speed information is given to an oscillatory Path Integration (PI) Layer. This is followed by two layers of Lateral Anti- Hebbian Network (LAHN1 and LAHN2) trained by unsupervised learning for optimal feature extraction from the inputs. A virtual agent forages in a circular environment of 2 units radius with a circular object of radius 0.2 units and the representations of neurons in LAHN2 are observed. Neurons that fired at a particular distance and direction from the object are chosen (fig. 1). It is observed that these neurons maintained the distance-direction relationship irrespective of the position of the object within the environment and did not fire in the absence of an object, as observed in the experimental study by Hoydal et al. We also postulate that although visual input might confer stability to OVC firing, the emergence of these cells do not explicitly depend on a visual input and that there is sufficient information in the trajectory dynamics encoded by the path integration to account for this class of spatial cells.

Title: Homologous gene expression patterns within the mouse and human subiculum

Authors: *M. S. BIENKOWSKI, N. KHANJANI, H. DONG;
USC Stevens Neuroimaging and Informatics Inst., Keck Sch. of Med. of USC, Los Angeles, CA

Abstract: The hippocampus is widely believed to be structurally and functionally homologous across species. The major output region of the hippocampal formation, the subiculum (SUB), is considered to be organized as distinct columnar subregions along the longitudinal axis (dorsal vs. ventral in rodents; posterior vs. anterior in humans). However, our previous study analyzing gene expression patterns to create the mouse Hippocampus Gene Expression Atlas (HGEA) revealed that the SUB pyramidal layer contained a hidden sublaminar organization that was also highly related to connectivity. Based on the distribution and representation of four SUB gene expression lamina, the mouse HGEA defines five distinct SUB subregions, including a novel caudal ventral extension of the dorsal SUB. Although the HGEA provides a detailed description of the mouse SUB, it is currently unknown if this organization is also present in the human SUB. Using *in situ* hybridization data from the online Allen Human Brain Atlas project, we provide evidence that the same laminar organization of gene expression observed in the mouse is also present within the human SUB. In the posterior human SUB, neurotensin (*Nts)* is strongly expressed within SUB pyramidal neurons closest to the molecular layer, but not in deep pyramidal neurons adjacent to the alveus white matter tract. In contrast, *Chrm2* (muscarinic cholinergic receptor 2) expression reveals the reciprocal distribution pattern. Together, *Nts* and *Chrm2* expression patterns delineate distinct gene expression lamina in the human posterior SUB that is highly similar to the mouse dorsal SUB. Overall, this study provides evidence that the genetic organization of SUB neuronal cell types is conserved across mammals and provides a foundation for creating a translational human HGEA for understanding hippocampal cell types and how they are affected by Alzheimer's disease.

Title: A computational model combining dorsal and ventral hippocampal place field maps: An analysis of multiple-scale contributions

Authors: P. SCLEIDOROVICH[1], J.-M. FELLOUS[2], ***A. WEITZENFELD**[1];
[1]Computer Sci. and Engin., Univ. of South Florida, Tampa, FL; [2]Psychology, Univ. of Arizona, Tucson, AZ

Abstract: We present in this work a model for spatial cognition based on the multi-scale organization of the dorsal-ventral axis of the hippocampus. Existing studies in rodents conducted in simple and small environments show that dorsal place cells are primarily involved in spatial navigation, containing cells with small place fields, while ventral place cells are primarily involved in context and emotional encoding, containing cells with large place fields. Recent findings suggest however that ventral place cells are involved in spatial navigation in complex environments. In this work we examine the effect of combining fields from dorsal and ventral place cells during spatial navigation. For this purpose, we developed a multi-scale computational model where a rat can map an environment by activating partially overlapping place fields from dorsal and ventral place cells. The model shows that combining dorsal and ventral place field maps may improve task learning performance, in terms of either path optimality or learning time, depending on the particular combination of place field sizes. The task consists of a rat learning to find a goal by starting from different locations in both a fully open environment and an environment containing an internal wall that can only be traversed through a corridor. The computational model is based on an actor-critic reinforcement learning architecture with and without eligibility traces. Results were obtained from simulations in a virtual environment. Corresponding statistical results are presented. This computational study suggests that the combination of dorsal and ventral hippocampal information may be advantageous for spatial learning and memory tasks.

Title: Dynamical analyses of hippocampal local field potential activities across maturation of spatial navigation in the juvenile rat

Authors: *D. G. MCHAIL[1], J. R. CRESSMAN[1], T. BERRY[1], R. OGOE[1], T. C. DUMAS[2]; [2]Psychology, [1]George Mason Univ., Fairfax, VA

Abstract: Hippocampal networks undergo continued refinement during the third postnatal week in rats, around the same time that spatial navigation ability first emerges. This delayed maturation presents an opportunity to identify what characteristics of hippocampal networks are necessary to enable spatial cognition in mature animals. Hippocampal local field potential (LFP) oscillations have been well studied in adult rodents and related to specific aspects of network activity (i.e. coordinating discharge of place cell ensembles) and spatial learning and memory (i.e. route planning and on-line navigation). However, relatively little is known about the development of hippocampal networks in rodents. Prior research has focused on maturation of the theta rhythm in juveniles, and recent investigations have found that gamma rhythms undergo changes during this time period as well. Cross-frequency interactions (such as coupling between theta and gamma wavebands) have not been examined in juveniles. Furthermore, no prior studies have examined changes in local field potential activity relative to performance in spatial tasks in juveniles. Techniques typically applied to analyses of LFP activity and behavior are correlational and cannot identify causation. Tools from nonlinear dynamical analysis may help identify changes in local field potential dynamics that are involved in the maturation of spatial cognition. In particular, diffusion-mapped delay coordinates (DMDC) can help identify and discriminate between attractors in the local field potential during maze performance. In addition, a reservoir computer can be used to model and predict local field potential activity relative to maze behaviors. As such, we recorded from dorsal hippocampal area CA1 as juvenile rats performed spatial tasks (Y-maze, Barnes maze). Using DMDC, we identified changes in hippocampal LFP dynamics specific to age, movement speed, and waveband content. Ongoing analyses will also assess whether LFP dynamics during separate aspects of goal-directed behaviors in the Barnes maze can be discriminated by DMDC. In addition, we will leverage the predictive capability of machine learning (reservoir computing) to determine upcoming LFP states based on prior LFP data.

Title: Selective loss of septohippocampal cholinergic projections is associated with more circuitous homeward progressions

Authors: ***J. R. OSTERLUND**[1], A. A. BLACKWELL[1], M. LIPTON[1], V. CASTILLO[1], G. L. KARTJE[2], S.-Y. TSAI[3], D. G. WALLACE[1];

Abstract: Rodents rely on self-movement cues as a source of information to maintain spatial orientation during exploration. The vestibular system provides a source of self-movement cues that are processed by the septohippocampal cholinergic system, and when damaged, disruptions in movement organization are observed. The current study examined the effects of medial septum infusion of 192 IgG-saporin on movement organization during a single exploratory session that limited rats to using only self-movement cues. Rats organize their exploratory behavior into stops and progression. Although stops occur throughout the environment, they tend to cluster within a restricted area indicative of home base establishment. In the current study, movement organization characteristics and home base stability were similar between the lesion and sham groups. However, the lesion group exhibited greater path circuity during progressions returning to the home base. Increases in path circuity have been implicated in spatial disorientation, indicating a role for medial septum cholinergic projections in processing self-movement cues to maintain spatial orientation. These results provide a foundation for future work to investigate the efficacy of interventions that enhance neuroplasticity within the septohippocampal cholinergic system.

Title: Restoration of network dynamics and improved cognitive outcome after implantation of inhibitory interneuron progenitor cells in a rodent model of temporal lobe epilepsy

Authors: *W. CURRY[1], A. HERNAN[1], G. RICHARD[1], M. WESTON[1], R. SCOTT[1,2];
[1]Larner Col. of Med., Univ. of Vermont, Burlington, VT; [2]Inst. of Child Hlth., Univ. Col. London, London, United Kingdom

Abstract: The past decade of epilepsy research has revealed both scant evidence for major contributions from seizures to the cognitive deficits associated with epileptic syndromes and urgent need for alternative treatments to combat these cognitive deficits. One possibly fruitful paradigm currently being explored is the implantation of inhibitory interneuron progenitor cells obtained from a developmental structure known as the medial ganglionic eminence (MGE), which is responsible for upwards of 90% of interneurons in the neocortex and hippocampal structures. Previous studies have found that, when implanted into adult mice, progenitors have the ability to mature, migrate, and integrate into neocortical and hippocampal circuits, and do so in several pathological models, including: Parkinson's disease, temporal lobe epilepsy (TLE), and Alzheimer's disease. In an epilepsy framework, integration manifests as increases in inhibitory drive, reductions in the duration and frequency of seizures, and, in at least one study, improvement on a task of spatial working memory. This latter finding, while compelling, has been insufficiently explained. Using *in vivo* electrophysiology, this current work seeks to establish systems-level causality for observed improvements following progenitor implantation. We used the lithium-pilocarpine model of status epilepticus, which reliably induces many human symptoms of TLE. After observing frank seizures, adult epileptic Sprague-Dawley rats were bilaterally implanted with MGE progenitor cells in the dorsal hippocampus. 30 days post-transplantation, sham, SE, and MGE cohorts performed in the Morris Water Maze (MWM), a standard task of spatial working memory. MGE progenitor recipients' performance more closely resembled that of sham animals when compared to SE animals. Single-unit recordings in CA1 of the hippocampus during an open-arena foraging task revealed a partial restoration of excitatory neuron parameters, namely, mean firing rate and spike width, in MGE animals. Postmortem histological analysis confirmed survival and maturation of implanted cells, and their expression of markers of interneuron subtypes such as parvalbumin and somatostatin. Together, these

findings implicate progenitor cells' ability to normalize network parameters as an explanation for the behavioral improvements observed.

Title: Spiking network models of sharp-wave/ripple attractor sequences

Authors: *J. D. MONACO[1], G. M. HWANG[3], K. ZHANG[2];
[1]Biomedial Engin., [2]Dept Biomed Engin., Johns Hopkins Univ., Baltimore, MD; [3]Johns Hopkins Univ. Applied Physics Lab., Laurel, MD

Abstract: The spatial representations of active place cells in a particular environment collectively form a spatial map, the function of which has remained unclear. Sequential place-cell activation organized by theta oscillations during active movement or by sharp wave/ripple complexes (SWRs) during pauses in navigation may serve a critical role in subsequent spatial decision-making and behavior. In particular, SWR sequences have been shown to represent spatial trajectories that follow unexplored paths through space with reward-dependent biases toward goal locations. Pfeifer & Foster (2015) reported compelling evidence that decoded SWR trajectories dwell at discrete locations before discontinuously jumping, potentially reflecting metastable expression of recently experienced attractor states. While that report suggested the attractor expression was phase-locked to slow gamma (ca. 30 Hz) oscillations, a subsequent laminar recording study by Oliva et al. (2018) revealed that relationship as a possible artifact of CA1 ripple-power (150-200 Hz) envelopes. This dispute regarding the existence of neuronal gamma-locking during SWRs raises critical questions about the dynamical basis of SWR trajectories. Here, we propose a theoretical framework for flexible, internal sequence generation for online route planning during spatial navigation. We embedded realistically Poisson-distributed place-field maps into the synaptic weights of a CA3 network model to quantify sharp waves as a stochastic sampling process of spatial attractors. We projected CA3 output to a CA1 network model with recurrent inhibition producing transient ripple currents. The excitatory (pyramidal cell) and inhibitory (interneuron) connectivity of our CA3/CA1 models were subsequently tuned to generate theta oscillations driven by high levels of cortical/subcortical input and to stochastically produce SWRs during an irregular state driven by reduced input

levels. Modulating gamma power via inhibitory coupling revealed minimal gamma-dependence of CA1 ripple-filtered outputs. Alternatively, factors including noise, synaptic depression, sporadic ascending inputs, and reduced subcortical inhibition supported online dynamics that explain physiological and computational features of SWR trajectories. Thus, SWR trajectory sequences may rapidly collapse the slowly varying cognitive map into transitory metastable states that probabilistically sample possible routes through an animal's immediate surroundings.

Title: The role of objects during complex spatial navigation in the rat

Authors: *M. P. SOUDER[1], M. ROGERS[1], Y. QIN[2], P. SCLEIDOROVICH[3], A. WEITZENFELD[3], J.-M. FELLOUS[1];
[1]Dept. of Psychology, [2]Undergraduate Biol. Res. Program, Univ. of Arizona, Tucson, AZ; [3]Dept. of Computer Sci. and Engin., Univ. of South Florida, Tampa, FL

Abstract: The neural substrate of rodent spatial navigation involves a large variety of cells selective to place, reward, head direction, object location and borders. This complex system is usually studied in small and simple mazes. However, both humans and rats need to navigate in complex environments, and accordingly need to use dedicated neural systems for complex spatial navigation. Spatial navigation utilizes both path integration and landmark navigation, and it has been shown that the hippocampus and its place cells are involved in both. Previous studies (The Traveling Salesrat: Insights into the Dynamics of Efficient Spatial Navigation in the Rodent. Watkins L., Gereke B. G. M. Martin, JM Fellous. J Neural Engineering, 8(6), 2011) have used the Traveling Salesperson Problem (TSP) as a model to study spatial navigation optimization in rats. This model is a spatial problem in which the shortest path between a number of rewarded ‘cities’ must be found over multiple trials. Previous versions of this task utilized small environments with cities represented by identical copies of rewarded cups. In the current

study, we used a much larger environment and different objects, each paired with a reward. The objects were used in a configuration designed to study optimization and the effect of object manipulation on navigation. After the rats optimized their navigation through 6 rewarded locations, we switched two of the objects with each other and hypothesized that if the rats were using the objects as landmarks for finding the optimal path, the object switch would affect their navigation. These configurations were compared with the identical reward cups configurations for both male and female rats. Single cell and network activity were recorded from the dorsal CA1 area of hippocampus while rats performed the task. Preliminary results show differences in sharp wave activity between cup and object configurations. The results also show that the presence of objects decreases the number of trials to task completion. Current work focuses on the analysis of place cells during the task.

Abstract: The effect of Metabolic Syndrome (MetS) on spatial learning and memory and the temporal effect of the induction of this experimental model has not been thoroughly reported. In our laboratory, use the injection of amyloid-$\beta_{25\text{-}35}$ peptide ($A\beta_{25\text{-}35}$) to investigate some neurotoxic mechanisms and memory impairment in rats, in association with Alzheimer's disease. The aim of this work was evaluate if MetS at 2 and 6 months of induction produce a differential effect on spatial learning and memory in hippocampal lesioned rats with the $A\beta_{25\text{-}35}$. We used *Wistar* male rats (250-280 g) randomly assigned in MetS and Control (C) group. MetS model was obtained by consumption of 20% sucrose solution meanwhile C received drinking water, *ad libitum* for two (2mo) and six (6mo) months in separate cohort of rats. At the end of each period, the MetS model was evaluated. After, all rats were yield to stereotaxic surgery to the injection of

vehicle or $A\beta_{25-35}$ [100µM] into CA1 subfield of Hippocampus, (coordinates; AP: -4.0, L: ±2.3, P: -2.6). The experimental groups were C+Vehicle, MetS+ Vehicle, C+$A\beta_{25-35}$ and MetS+$A\beta_{25-35}$ 2mo and 6mo for each cohort of rats. At 15th day post-surgery, experimental groups were tested for spatial learning in Morris Water Maze (MWM) and 5 days later, were memory tested. Our finding indicates that MetS+Vehicle 2mo does not impair learning and memory in MWM. Regarding to MetS+$A\beta_{25-35}$ 6mo, showed an increase in the scape latency on 15, 16 and 17 days post surgery compared to MetS+$A\beta_{25-35}$ 2mo. The MetS+Vehicle 6mo exhibited memory impairment with an increase in latency to the first crossing at platform zone (40%) and decrease de crossing number (41%) at this site. We conclude that the induction time on MetS is determining to cause damage in spatial learning and exacerbate the memory impairment evaluated in MWM probably by a disturbance of neuronal function associated with oxidative stress, neuroinflammation and loss of neurochemical communication, therefore it is necessary to evaluated proteins involved in modulation of spatial learning and memory.

Title: Robust emergence of sharply tuned place cell responses in hippocampal neurons with structural and biophysical heterogeneities

Authors: *R. BASAK, R. NARAYANAN;
Indian Inst. of Sci., Bangalore, India

Abstract: Place cells in the hippocampal CA1 region are endowed with complex dendritic arborization, exhibiting heterogeneity in structural features such as length, diameter and branching patterns. These neurons are electrotonically non-compact structures effectuating immense bidirectional attenuation to signal propagation, and are capable of sustaining the generation and active propagation of dendritic spikes. We recently showed that synapses that are randomly dispersed across the dendritic arbor of such neurons endowed with disparate ion channel distributions yield sharply tuned place cell responses through dendritic spike initiation

[1]. Although our analyses had demonstrated that sharp place-cell tuning could emerge in the presence of expansive heterogeneities in synaptic and channel profiles, the impact of morphological heterogeneities on place-cell tuning has remained unexplored. In this study, we asked if sharply tuned place-cell responses mediated by dendritic spikes would emerge in different CA1 pyramidal neuron morphologies, each expressing heterogeneities in channel expression and synaptic localization as well. To do this, we performed independent stochastic searches of a 21-parameter space (covering passive and active properties involving 6 somato-dendritic channels) in 5 distinct morphologies, each endowed with randomly dispersed synapses (100 synapses carrying place-field information), and found models that manifested sharp place-field tuning. Next, we validated this subset of sharply-tuned models against 12 electrophysiological measurements (input resistance, resonance frequency, total inductive phase and backpropagating action potential amplitude at 3 locations each) from CA1 pyramidal neurons. This two-step validation process from stochastic searches spanning thousands of parametric combinations yielded several models that were both sharply tuned and intrinsically valid, independently for each of the five morphologies, with disparate profiles of synaptic localization and parametric combinations. Mechanistically, employing virtual knockouts of NMDA receptors or dendritic sodium channels, we found the initiation of dendritic spikes to be a critical contributor to sharpness of place-cell responses in all morphologies. From the functional standpoint of achieving sharply-tuned feature encoding and concomitantly maintaining homeostasis of intrinsic excitability, our results point to ion channel degeneracy and suggest neuronal morphology to be a “sloppy” parameter even in electrotonically non-compact structures.

Title: Representation of 3D space in the hippocampus of freely moving marmosets

Authors: *D. BUITRAGO-PIZA[1], B. W. CORRIGAN[4], B. MAHMOUDIAN[2], R. A. GULLI[3], W. J. ASSIS[1], L. E. MULLER[5], J. C. MARTINEZ-TRUJILLO[6];

Jolla, CA; [6]Dept. of Physiol. and Pharmacol. and Psychiatry, Brain and Mind Institute, Univ. of Western ON, London, ON, Canada

Abstract: The role of the hippocampus in representing space is widely supported. Neurons that increase their firing rate when an animal occupies a certain region, 'Place Cells', have been thoroughly identified and studied in multiple species. This unique population of neurons has been thought to support a cognitive-map like representation of space in the brain; however, little is known about how these representations are formed in the common marmoset during free navigation in a 3D environment. Moreover, whether these representations are modulated by the position of conspecifics or the presence of reward has yet to be determined. In this work, we sought to identify the firing properties of neurons in the CA fields of the hippocampus while we register spatial and view information of freely navigating marmosets as they engage in a variety of foraging and social behaviours in 3D space. For this purpose, we habituated the experimental subjects in pairs, to freely move inside a plexiglass recording chamber with four vertical levels while wearing affixed infrared reflective markers on top of skull implants that allowed for 6 degrees of freedom position and head direction camera tracking (Optitrack, Natural Point Inc, USA). Using MRI guided neuro-navigation techniques we chronically implanted a 34-microwires array in the left hippocampus region CA1 (Microprobes Inc., USA) of common marmosets. We recorded the responses of neurons using a wireless recording system during the aforementioned behaviors. Data from 2 animals was analyzed, subjects were able to successfully forage in 4 different locations in 2 different levels of the chamber, animals also explored most of the space within the chamber and they engaged in socially relevant behavior (mutual gaze contact and grooming). Single units were found to respond significantly as a function of spatial position, reward location and head orientation.

Title: A ventral hippocampus CA1-lateral septum pathway regulates spatial memory for food location

Authors: *E. A. DAVIS[1], C. M. LIU[2], A. N. SUAREZ[1], E. E. NOBLE[1], S. E. KANOSKI[1,2]; [1]Human and Evolutionary Biol., [2]Neurosci. Grad. Program, USC, Los Angeles, CA

Abstract: Research on rodent hippocampal involvement in visuospatial memory has predominantly focused on the "dorsal" (septal) hippocampus, and has utilized memory tasks that involve escaping aversive conditions (e.g., swimming, bright lights). Comparatively much less is known about the functional role of the "ventral" (temporal) hippocampus (vHPC) in spatial memory, and more specifically, the role of the vHPC in spatial memory related to food location. Given recent findings revealing that the vHPC is critical in regulating food intake and conditioned aspects of feeding behavior, we hypothesized that vHPC neurons play a role in memory for the spatial location of food. Our results reveal that vHPC excitotoxic lesions in rats impair memory retention for food location using a novel spatial food seeking procedure developed in our lab. To further elucidate the precise neural pathways that mediate these effects, we next investigated whether the lateral septum (LS) is a downstream target mediating vHPC-dependent food-related spatial memory. To examine this hypothesis, we used conditional dual viral approaches to either reversibly (via cre-dependent pathway-specific inhibitory chemogenetics) or permanently (via cre-dependent pathway-specific caspase-induced lesions) disconnect the ventral CA1 (vCA1) to LS monosynaptic pathway. Results show that both acute and chronic disruption of vCA1 to LS signaling impairs memory retention in the spatial food seeking task. Collectively, these data indicate that vHPC communication to the LS plays an important role in memory retention for food-related environmental spatial cues, thereby identifying a novel neural pathway of relevance to foraging behavior.

Title: Correction for single-event path integration errors in the hippocampal place code using visual cues

Authors: *E. R. REDINGTON[1], S. SOLTANIAN-ZADEH[1], A. SILBERSTEIN[1], E. QIAN[1], R. ZHANG[1], S. FARSIU[1], Y. GONG[2];

Abstract: Hippocampal place cells become active when an animal visits specific spatial locations. The spatially tuned activity of place cells arises from a combination of internal,

movement-related cues and external, sensory-related cues. Multiple models of hippocampal activity suggest that the internal cues generate a continuous representation of self-location via path integration while the external cues correct the errors that accumulate in path integration. We wish to determine how information from external visual cues corrects sudden errors in the place code's representation of self-location. We hypothesize that the place code combines visual sensory information with path-integration information on different timescales. We tested this hypothesis by using virtual reality (VR) to decouple movement from sensation; we rapidly shifted the position of mice along a VR track while optically recording the activity of hippocampal pyramidal neurons. We found that unexpected changes in visual scenery created a mismatch between the place code's representation of position and the animal's VR position but did not completely change the representation of the environment. From this evidence, we reached two conclusions: (1) visual information is sufficient to overwhelm movement-related input and drive large shifts in the place code following an error in the place code's representation of self-location; and (2) the correction in place code lags behind visual sensory inputs.

Title: Correlated fluctuations in hippocampal neural ensemble activity patterns limit the accuracy of spatial representations

Authors: *O. HAZON[1], D. P. TOMÀS[2], V. H. MINCES[3], S. GANGULI[1], M. J. SCHNITZER[1], P. E. JERCOG[4];
[1]Stanford Univ., Stanford, CA; [2]IDIBAPS, Barcelona, Spain; [3]UCSD, San Diego, CA; [4]IDIBAPS & Cellex Inst., Barcelona, Spain

Abstract: A substantial body of theoretical and experimental research has shown that correlated noise fluctuations in the dynamics of multiple neurons can affect the ability of a neural ensemble to encode and transmit high-fidelity information. In essence, correlated fluctuations can limit the extent to which downstream brain areas are able to improve signals by pooling the outputs of multiple cells. Theoretical work suggests that this phenomenon is likely to be especially important when considering large neural ensembles. However, experimental studies of correlated

fluctuations have usually examined cell pairs, and the published literature is inconclusive as to whether correlated noise fluctuations truly limit information-encoding by neural populations. To study activity correlations at the level of neural ensembles, we used a miniature, head-mounted fluorescence microscope to image the somatic calcium dynamics of hundreds of CA1 hippocampal pyramidal neurons in freely behaving mice trained to run back and forth on a linear track. We monitored hundreds of neurons in each mouse across hundreds of running laps, allowing accurate characterizations of both the average neural ensemble activity patterns as well as fluctuations about the mean values. We constructed computational decoders that estimated the mouse's running trajectory based on the set of neural activity traces. Correlated fluctuations in the neural ensemble activity patterns limited the accuracy with which these decoders could estimate the mouse's position. Notably, decoders that accounted for the statistical structure of these correlated fluctuations achieved higher accuracy than decoders that were insensitive to such fluctuations. Overall, these findings reveal information-limiting noise correlations in hippocampal neural ensembles and demonstrate the importance of accounting for these correlations to achieve optimal decoding of animal behavior.

Title: Naturalistic encoding of spatial working memory in the primate lateral prefrontal cortex in a virtual environment

Authors: *M. KHAKI[1], M. ROUSSY[1], N. MORTAZAVI[1], R. LUNA[1], A. J. SACHS[2], J. C. MARTINEZ-TRUJILLO[3,1];
[1]Dept. of Physiol. and Pharmacol. and Psychiatry, Univ. of Western Ontario, London, ON, Canada; [2]Brain and Mind Res. Inst., Univ. of Ottawa, Ottawa, ON, Canada; [3]Brain and Mind Inst., London, ON, Canada

Abstract: Since Fuster and Alexander (1971) provided the first electrophysiological evidence of persistent neural activity during the delay in the prefrontal cortex, spatial working memory

(WM) has been studied using highly controlled tasks that utilize simple visual stimuli and constrain eye movement. Using these tasks, a myriad of studies has shown that neurons in the primate lateral prefrontal cortex (LPFC) encode WM representations in the absence of external stimuli. One caveat of this highly controlled approach is that it departs from natural behaviour. One issue that remains unclear is whether neurons in the LPFC encode spatial WM during natural behaviour, that is, in the presence of distracting information and eye movements.
To address this issue, we created a naturalistic spatial WM task that takes place in a virtual environment that incorporates complex 3D visual stimuli and does not constrain eye movement. During a trial, a cue is presented to the subject in a virtual arena in one of nine possible locations. This cue disappears during a delay period and must be remembered in order for the subject to navigate towards the target's location using a joystick in the response period. Position in the virtual environment and eye position were recorded during all trials. Neural recordings were conducted in two male rhesus macaques during this task using two 10×10 microelectrode arrays located in the LPFC (areas 8Ad/v).
Both animals successfully performed this task and demonstrated neural tuning during cue and delay periods at the level of individual neurons and neuronal population. A classifier was able to decode target location on a single trial basis during cue and delay periods with accuracies >80% (chance = xx). These findings were not explained by neural activity influenced by target location-specific patterns of eye movement. Moreover, we found that only a small subpopulation of neurons was required (>20) to decode correct target location robustly. We were also able to distinguish between correct and incorrect trials using this method. These findings show that primate LPFC neurons encode both perceptual and WM representations of space in conditions resembling natural environments

Title: Vestibular updating of the head direction cell signal during movement between vertical planes: Inside corners

Authors: *P. OZEL, P. A. LACHANCE, J. L. MARCROFT, J. S. TAUBE;
Dartmouth Col., Hanover, NH

Abstract: Head direction (HD) cells encode an animal's directional heading in the azimuth plane of an environment. How do the compass-like properties of HD cells apply to navigation in three-dimensional (3D) space? Two models, the rotational plane hypothesis and the dual-axis model, offer different accounts for how HD cells shift their preferred firing directions (PFD) during 3D movement across horizontal and vertical 2D planes. The rotational plane hypothesis (Taube et al., 2013) postulates that the cell's PFD shifts to align with any plane that the animal is moving in—except if the animal is inverted—and treats the new plane as an extension of the horizontal plane. The dual-axis model (Page et al., 2018) predicts a 90º PFD shift when crossing vertical boundaries—clockwise for rightward travel and counterclockwise for leftward travel across 'outside' vertical corners. In contrast, the model postulates that the PFD should shift in the opposite direction when crossing 'inside' vertical corners. Previous work has only tested this hypothesis in animals that travel around outside vertical corners. Here, we tested these hypotheses by recording anterodorsal thalamic HD cells from 4 rats as they traversed an inside vertical corner. Cells were monitored as the rat moved from the floor onto an elevated horizontal surface after traversing a route that comprised both outside and inside vertical corners. Results revealed PFD shifts consistent with the dual-axis model for both outside and inside corners. The mean shift when going around an outside corner towards the left was 88.9 ± 7.2º (range: 48 to 144°; n = 22). For traversing a leftward inside vertical corner, the PFD shifted -87.8 ± 7.2º (range: -156 to -24°; n = 22). Similar firing patterns occurred when animals completed the task in the dark in the absence of visual information; left outside corner: 75.4 ± 7.3°; left inside corner: 70.3 ± 8.5° (n = 15 sessions). The peak firing rate (PFR) remained stable across all planes, with a small rate decrease on the top horizontal plane. Across all cells the mean PFR decreased -24.1 ± 0.04% (n = 24) from the initial floor session to the top horizontal plane under light conditions and -24.4 ± 0.1% for dark sessions (n = 6). Compared to the floor session, the mean PFR change was +5.3 ± 0.1% for the first wall (-9.4 ± 0.1% dark), +0.6 ± 0.1% for the wall following an inside corner (-9.4 ± 0.1% dark), and -2.7 ± 0.1% for the wall after an outside corner (-22.2 ± 0.1% dark). Our results suggest that the vestibular system, both the semicircular canals and the otoliths, plays a key role in updating the HD cell's PFD when the animal moves between horizontal and vertical planes, even in the absence of visual information.

Title: Criteria for three dimensional tuning in head direction cells

Authors: *J. S. TAUBE;
Psychological & Brain Sci., Dartmouth Col., Hanover, NH

Abstract: Head direction (HD) cells fire as a function of the rat's head direction in the horizontal plane, independent of the animal's location and on-going behavior. They have been identified in a number of species and different brain areas. HD cells are now considered to be classified into two broad categories of 'classic' cells and HD-modulated cells - the latter having low peak firing rates and modulated by secondary spatial parameters. Many so-called HD cells in bats and monkeys appear to be tuned to orientations outside the horizontal plane in allocentric (world-centered) coordinates. However, it is has been questionable whether HD cells in rodents can also be optimally tuned to orientations outside the horizontal plane. Here we describe the criteria that should be satisfied in order to establish that a HD cell is tuned in 3D space. By definition, for a cell to be considered tuned to an orientation outside the horizontal plane, cell firing should be related to the allocentric reference frame and have a 1) substantial, 2) consistent, and 3) meaningful firing rate that is elevated over that observed when the animal is in the horizontal plane. Previous studies have shown that HD cell peak firing rates are similar when an animal locomotes on the floor and along a vertical wall (Stackman et al., 2000; Calton and Taube, 2005; Taube et al., 2013). This finding makes it problematic for arguing that HD cells are tuned to 3D volumetric space in allocentric coordinates because there is more than one direction in allocentric space in which the cell is tuned. Alternatively, the cell's reference frame could be defined in both egocentric and allocentric coordinates, whereby the cell's reference frame shifts with the animal's plane of locomotion as it moves between different planar surfaces, which is consistent with the dual-axis model. Another criteria is that the cell's firing rate should be greater than that in the horizontal plane - keeping in mind that a cell's peak firing rate varies between different sessions. For example, when rats were passively rotated in different tilt and roll planes, HD cell peak firing rates varied across sessions even when the rat was in the same upright orientation. The mean percent increase or decrease between sessions was 32.1 ± 5.8% (range: 0.70 - 100.4%, n=23) or -20.3 ± 3.3% (range: -0.80 to -60.7%, n=21), respectively. Due to this variability, a cell should change its peak firing rate consistently by more than these amounts when the animal is in a different tilt or roll plane, in order to consider a cell 3D-tuned. Finally, cells should show a 'meaningful' change in their firing rate, such that it would have a significant impact on downstream networks.

Title: Reasons why Alzheimer's disease is “diabetes of the brain”

Authors: *A. S. SHINGO[1], S. KITO[2];
[1]Section of Neurosci., Okinaka Mem. Inst. For Med. Res., Tokyo, Japan; [2]Shonan Hosp., Kanagawa, Japan

Abstract: The object of this study is showing evidence that the intraventricularly streptozotocin injected rat (brain diabetes rat) is a definite Alzheimer disease model. Behavioural, immunohistochemical studies were performed together with dendritic spine analysis of the hippocampal granular cells. As methods, 1) Spatial cognitive function tests were performed on intraventricularly streptozotocin injected “brain diabetes” rats by the Morris water maze (n=7). Controls were injected with PBS (n=10). 2) Quantitative immunohistochemicalexaminations of amyloid β protein, insulin-degrading enzyme, somatostatin, AKT, p-CREB were performed using the rat hippocampal tissue (brain diabetes: n=7, control: n=10). 3) Dendrites of granular cells of the hippocampal dentate gyrus were quantitatively evaluated. 4) A single injection of detemir, a long-acting insulin analogue, into the third ventricle of the rat was done (brain diabetes: N=3, n=1, control: N=3, n=15). The results were summarised as follows. The spatial cognitive function of rats with “brain diabetes” has been impaired. Immunohistochemistry of the hippocampus revealed an increase in amyloid β protein and decreases in all other tested values. Spine densities of the granular cells were significantly decreased. By intraventricular single injection of the insulin analogue, all the tested values approached to those of control rats. From the results above, we concludedthat the “brain diabetes” rat is a definite model of Alzheimer disease.

Title: Contextual remapping of medial entorhinal cortex inputs to CA1 in head-fixed mice exposed to a virtual environment

Authors: *T. CHOLVIN, T. HAINMUELLER, M. BARTOS;
Univ. of Freiburg - Inst. For Physiol. I, Freiburg Im Breisgau, Germany

Abstract: The medial entorhinal cortex (MEC) harbors numerous different spatially tuned cells including grid cells, border cells, head-direction cells, and cells with conjunctive responses, i.e. combining several of those spatial patterns of activity. Overrepresented within the superficial layers of the MEC, those excitatory neurons are either pyramidal cells or stellate cells. Fibers originating from those cells distribute extensively over the hippocampal area: pyramidal cells of the MEC project to CA1, while stellate cells are innervating the dentate gyrus (DG) and CA3. MEC inputs provide the major spatial contextual information to the hippocampus. A fraction of hippocampal place cells typically display environment-specific spatial activity patterns called place fields. While hippocampal place cells encode particular locations in a given environment, MEC spatially modulated cells are known to mainly retain their basic firing characteristics between environments, providing a metric to the neuronal representation of space. How spatial information from the MEC is translated to hippocampal place cells remains so far unclear. Previous investigations suggested that grid cells are the primary determinant of hippocampal place cell firing. However, while hippocampal neurons can retain context-specific spatial firing in the absence of MEC inputs, the inhibition of those inputs reduces the stability of CA1 place cells, indicating their importance for place cell activity and stability. Thus, knowing the relationship between MEC inputs and CA1 place cell activity would shed new light on this central problem. It has recently became possible to use Two-Photon (2P) Ca^{2+} imaging to record axons *in vivo* during behavioral tasks in head-fixed mice. Here we established and used 2P functional imaging to assess in CA1 the activity of GCAMP6s-loaded axon terminals originating in the MEC while animals are running through virtual environments. Our preliminary data indicate that MEC inputs are spatially tuned and undergo remapping once mice are exposed to different virtual environments.

Title: Manipulating temporal event structure via top-down script activation

Authors: *A. REBLANDO[1], T. KELISHADI[1], C. BALDASSANO[2];
[1]Columbia Univ., New York City, NY; [2]Psychology, Columbia Univ., New York, NY

Abstract: The brain “chunks” the continual stream of sensory information into discrete events of increasing timescales along the cortical hierarchy. Event segmentation is not driven solely by the

external features of the current stimuli, but is also influenced in a top-down manner by activated internal representations of the current situation. These internal "event scripts," constructed by abstracting consistent schematic structure from prior experiences, can mold online perception and memory for the current stimulus. An unexplored question is the extent to which an activated script affects the segmentation of a naturalistic narrative into events. We designed an experiment with a novel set of stories, in which each story features a combination of two different scripts. For example, a story about two people conducting a business deal while eating at a restaurant contains two overlapping stereotyped sequences of events: eating at a restaurant (entering, being seated, ordering, and getting food), and conducting a business deal (greeting, making the initial offer, making a rebuttal, concluding the deal). This is consistent with realistic experiences in which multiple sequences of events often occur simultaneously, requiring top-down attentional guidance to choose an appropriate temporal representational structure. In this experiment, the most relevant event segmentation of the story is manipulated across subjects, e.g. by placing subjects into the role of a restaurant critic or a business reporter. Our hypothesis is that changing the script that subjects are deploying will lead to changes in both the timing of neural pattern shifts and the information content of these patterns themselves. In preliminary behavioral experiments, subjects were asked to provide a subjective segmentation of the stories into discrete, coherent events. Participants primed with the same script had significantly more correlated judgements of when new events in the story began, compared with participants primed with the alternative script ($p = .045$), supporting our hypothesis that activation of a top-down event script influences perceived the temporal structure of a narrative.

Title: A naturalistic navigation task reveals rich distributed representations of information across the human cerebral cortex

Authors: *T. ZHANG[1], J. L. GALLANT[1,2];
[1]Joint Grad. Group in Bioengineering, [2]Dept. of Psychology and Helen Wills Neurosci. Inst., Univ. of California, Berkeley, Berkeley, CA

Abstract: Navigation in the natural world is a challenging problem that requires the interaction of multiple cognitive systems, including those for evaluating and integrating cognitive maps, attention, motor control, and planning (Spiers & Maguire 2006). However, most fMRI navigation studies use highly simplified environments and tasks that are unlikely to engage a broad range of cognitive processes. Thus, they do not provide information sufficient to create detailed functional cortical maps of the many different types of information that are likely relevant for natural navigation.
To recover detailed functional cortical maps of navigation-related information, we used fMRI to record brain activity while subjects performed a taxi driver task in virtual reality. The pilot environment used a 1×1 km town without other agents. The main environment used a 1×2 mile map that includes traffic, traffic rules, pedestrians, and various neighborhoods and off-road areas. Subjects drove using an MR-compatible steering wheel and pedal set constructed in our lab. Whole-brain activity was recorded from two subjects using a 3 T Siemens Tim Trio scanner. One subject participated in the pilot for 130 minutes and the main environment for 260 minutes. A second subject participated in the pilot for 90 minutes.
We applied the voxelwise modeling framework developed in our lab (Kay et al. 2008, Naselaris et al. 2009, Nishimoto et al, 2013) to the data. We extracted stimulus and task features from the experiment, and used regularized banded ridge regression to find an optimal set of weights for each feature for every voxel in each subject. We evaluated 6 feature spaces: route progression, semantic segmentation, navigational affordances, planned path, spatial position, and visual motion-energy. We then used a separate data set to test statistical significance, prediction accuracy, and generalization of each model in each subject.
The recovered functional cortical maps from each of the two subjects show the parahippocampal place area (PPA), retrosplenial cortex (RSC), and occipital place area (OPA) represent information about roads, buildings, and boundaries. RSC and OPA also represent navigational affordances. RSC and precuneus tracks route progression. Visual motion-energy is represented across much of visual cortex, including the posterior parts of RSC, OPA, and PPA. The fusiform face area and extrastriate body area represent information about pedestrians and other vehicles. Our data replicate many results reported previously in the human and rodent literature, and they reveal how navigation networks interact with other cognitive systems during naturalistic navigation.

Title: Discriminating functional connectivity patterns during visual and kinesthetic motor imagery, and motor execution

Authors: *E. KIM[1], W. LEE[2], H. SEO[1], B.-M. OH[1], M. BANG[1];
[1]Seoul Natl. Univ. Hosp., SEOUL, Korea, Republic of; [2]Seoul Natl. Univ. Col. of Med., Seoul, Korea, Republic of

Abstract: How motor-related functional connectivity patterns are distributed during visual motor imagery (VI), kinesthetic motor imagery (KI), and motor execution (ME) is interest of this study, which may determine effectiveness of motor imagery training for rehabilitation. Block-designed 3T fMRI experimental paradigm was given to 18 participants (30.3+-4.3 years). During 5 experimental sessions, each condition was presented 7 times as a block, consisting of 5 trials of grasping/releasing of right hand (or motor imagery) in every 4 seconds. The data was preprocessed (slice-timing correction, realignment, coregistration, normalize, and smoothing). To find out the most fundamental motor-related functional connectivity patterns, region of interest (i.e., the left primary motor area; M1) was determined by examining contrast of ME and perceptual control condition in a group level analysis. Temporal correlations between the seed region and other whole brain voxels were computed in each block, and converted to z scores. Maximally 21 seed-based functional connectivity were constructed in each individual. We generated data matrix consisting *individuals*-by-*conditions*-by-*voxels*, and segmented it based on the Automated Anatomical Labeling template. Multi-voxel pattern analysis was applied to the data to find brain regions where functional connectivity patterns during the conditions were significantly different (Fig1). As a result, functional connectivity patterns during VI, KI and ME were all classified above chance level within 6 ROIs. Among them, the seed-based functional connectivity patterns within the right cerebellum VI, vermis VIII, and left lingual areas were classified significantly above chance level ($P<0.05$), The null hypothesis was that sum of the correctly predicted label across all three conditions is obtained by random chance. Taken together, this study provided evidence that patterns of functional connectivity with the left primary motor cortex within the cerebellum and visual area is important to discriminate the two types of motor imagery and motor execution.

Title: Temporal dynamics of memory recall for familiar people and places

Authors: A. KIDDER[1], ***A. L. CORRIVEAU**[1], S. G. WARDLE[1], E. H. SILSON[2], C. I. BAKER[1];
[1]Natl. Inst. of Mental Hlth., [2]NIH, Bethesda, MD

Abstract: Recall of familiar people or places elicits activation in distinct sets of cortical regions, including ventral temporal cortex, medial parietal cortex, and posterior parietal cortex. To investigate the temporal dynamics of recall, we collected magnetoencephalography (MEG) data while participants visualized highly familiar people or places. Prior work looking at the temporal dynamics of memory and imagery have often focused on the visualization of recently seen novel images. In contrast, participants in our study were asked to recall highly familiar people or places in the absence of any prior visual presentation, relying on retrieval of long term internal representations. Conditions were personalized to each participant and they each provided the names of six personally familiar people (e.g. Aunt Shirley, Dr. Silson) and places (e.g. office desk, Metro Center). In a retrocue paradigm, two names were presented sequentially on the screen (800 ms each with a 200 ms gap) followed by a blank screen (400 ms) and then the presentation of a retrocue (500 ms). This retrocue was either the number 1 or 2, indicating that the participant should recall and visualize either the first or the second item named. Participants then visualized the cued item as vividly as possible for 4000 ms. Each condition was presented 32 times and cued 16 times over the course of 192 trials. Trials were broken into 8 runs in which each name was seen 4 times and cued for recall twice. Data was sampled across 272 channels at 600 Hz with whole-brain coverage, then downsampled to 200 Hz. Principal component analysis was implemented to retain the components explaining 99% of the variance. We applied multivariate pattern analysis to the responses measured across sensors using a pair-wise linear discriminant analysis classifier. We primarily focused on the ability to decode whether the participant was recalling a person or a place. Decoding showed a transient peak immediately after the presentation of the retrocue (~ 300 ms after onset), before declining and then strengthening again into the recall period, persisting until the end of the trial. These results reveal the evolution of the temporal representation of memory recall over time.

Title: Performing actions in lucid and nonlucid dreams

Authors: *K. KONKOLY[1], R. MALLETT[2], M. CARR[3], C. MAZUREK[1], K. A. PALLER[1]; [1]Dept. of Psychology, Northwestern Univ., Evanston, IL; [2]Psychology, The Univ. of Texas at Austin, Austin, TX; [3]Swansea Univ., Swansea, United Kingdom

Abstract: The scope of behavioral output that is possible during human sleep may not be as limited as commonly assumed. Here we evaluated this speculation in the context of lucid dreaming--being aware that one is dreaming while asleep. Furthermore, we combined lucid dreaming with a methodology for altering dream content, which can open up new opportunities for insights into downstream effects of dreaming and into the contrast between dream versus wake experiences. We recently developed a method of "hypertraining," whereby existing methods of cognitive training for inducing lucid dreams are accelerated in a 20-minute pre-sleep session linked with visual and auditory cues. The same cues are then presented during Rapid Eye Movement sleep (REM). This method can be considered a variant of targeted memory reactivation (TMR), by which memories are reactivated during sleep via stimuli previously associated with learning. In our prior study, this method induced lucid dreams in 50% of laboratory participants in a morning nap. However, it is unknown whether lucid dreams induced by this method would enable enough volitional control to complete complex tasks. Here, we expand hypertraining by investigating whether participants can perform a predetermined sequence of eye-movement and fist-clench actions in their dreams. One group received hypertraining in which cues were associated with lucidity, and participants were asked to, once lucid, complete the sequence of actions (lucid group). A second group of participants completed modified hypertraining in which cues were associated with mental rehearsal of the sequence of actions, but not lucidity (task group). Thus far, 9 participants in the lucid group were cued during REM; 5 completed varying steps of the task, evidenced by EOG and EMG activity (electro-oculography and electromyography) and accompanying dream reports. Four participants in the task group were cued during REM; all 4 completed parts of the task. Results showed that lucidity

can be induced via hypertraining, and that lucid participants had varying levels of success in completing tasks within the dream environment. We conclude that electrophysiologically verified actions within a dream can be elicited following the hypertraining procedures, and that we can systematically manipulate dream content to engender eye-movement and fist-clench actions during both lucid and nonlucid dreams.

Title: Behavioral and electrophysiological effects of transcranial direct current stimulation (tDCS) in the Müller-Lyer illusion

Authors: *F. V. CAIXETA, W. MEDEIROS, G. S. P. DAL PONT, E. M. BORIGATO, Í. B. RIOS, J. BRASIL-NETO, C. H. TAVARES, R. S. MAIOR;
Univ. of Brasilia, Brasilia, Brazil

Abstract: Recent evidence suggests that the neural substrate responsible for the Müller-Lyer illusion is located in the extrastriate visual cortex, most likely in the lateral occipital cortex, where the ventral visual processing pathway starts. The use of tDCS, a non-invasive method capable of altering cortical excitability may yield insights into the local contribution of cortical areas to cognitive processes. In this study, we recorded the pattern of neural activation of healthy subjects under the Müller-Lyer illusion and tested the effect of tDCS on the perception of this illusion. Healthy participants were divided into three groups, all of which were exposed to the Müller-Lyer illusion: electroencephalography (EEG) only, tDCS only, and tDCS with simultaneous EEG recording. The stimuli were presented on a computer screen. We assessed whether tDCS over various regions involved with visual processing altered either the participant's point of subjective equality or the temporal latency of the responses but found no statistically significant differences between the control group and the stimulated group. We also characterized EEG activity and the evoked potential in occipital and temporal electrodes. In the group with simultaneous EEG and tDCS the behavioral data generated again showed no significant difference in the perception of the Müller-Lyer illusion, but there was a marginal difference in the electrical activity between P280 and P450 on the O2 and T6 electrodes. In the present study, the perception of the Müller-Lyer illusion was not modified by tDCS stimulation

of the lateral occipital cortex. More studies will be conducted to test whether tDCS stimulation in different sites can alter perception and neural activity during the Müller-Lyer illusion.

Title: Knowledge about the action goal modulates posterior parietal activity during action observation

Authors: *L. GROSSE, A. ZABICKI, J. MUNZERT, B. KRUEGER;
Justus Liebig Univ., Giessen, Germany

Abstract: It has been proposed that the frontoparietal action observation network (AON) plays a central role in understanding observed actions. Within this network, the posterior parietal cortex (PPC) has been discussed as a key node for detecting the intentions of the observed act, being linked to action prediction and simulation. However, there has been an ongoing debate regarding the contribution of higher-order knowledge about the actor's intention prior to the action observed. While some theories favor a bottom-up explanation of intention decoding, others suggest a top-down modulation of the AON. Using fMRI and Representational Similarity Analysis, we sought to compare the activation patterns elicited in PPC and visual area 5 (V5) during observation of actions both with and without prior knowledge about the intention. 16 right-handed adults (eight females) observed videos of an arm performing reaching movements along four straight paths sharing a common origin. In each video, the movement was performed either from the origin to an end point (forward) or vice versa (back). Participants either knew (for the back conditions) or did not know (for the forward conditions) what the intended movement path and goal were going to be, before observing the movement. Participants completed twelve fMRI runs, each containing two trials of every video. Region of interest maps (ROIs) for PPC (i.e. SPL, IPL, IPS) and visual area 5 (V5) were computed for each subject. Noise-normalized beta maps corresponding to the activation during the observation of the movement were compared to each other. The resulting representational dissimilarity matrices were then compared to three different models. Model 1 predicted structured activation (low dissimilarity) within both the back and forward conditions, model 2 only during the forward conditions (no knowledge about intention) and model 3 only during the back conditions (knowledge about intention). While in V5, model 1 performed significantly better than the other models, this was

not the case for SPL. Here, model 2 showed significantly higher correlations to subject's RDMs. These results indicate that during action observation, PPC activity is indeed modulated top-down by prior knowledge about the intended movement goal, especially within the SPL.

Title: Content-specific neural patterns in sensory cortices during auditory imagery

Authors: *M. REGEV[1], A. R. HALPERN[2], A. M. OWEN[3], A. D. PATEL[4], R. J. ZATORRE[1]; [1]Montreal Neurolog. Inst., Montreal, QC, Canada; [2]Psychology, Bucknell Univ., Lewisburg, PA; [3]Western Univ., Brain and Mind Inst., London, ON, Canada; [4]Psychology, Tufts Univ., Medford, MA

Abstract: As part of their mental world, humans are able to internally represent ongoing auditory information without a direct external stimulus. Auditory imagery, the internal representation of sounds, has been mostly studied by looking for spatially overlapping neural responses while listening versus internally recalling sounds. However, that approach does not allow a distinction between general mechanisms of imagery as opposed to representation of specific imagined content. In the present work, we venture beyond basic spatial localization of averaged signals by comparing the unique temporal response profile of heard and imagined complex and continuous sounds. Twenty-five subjects memorized six distinct minute-long melodies to a high standard of accuracy in musical content and timing. Next, using whole-brain 3T fMRI, we recorded neural responses in three conditions: 1) silently imagining each melody to the rhythm of a visual metronome ("imagery"), while either tapping a finger to the beat of the melody or keeping motionless; 2) passively listening to the original melodies ("listening"); and 3) watching the visual metronome without imagining the melody ("control"). We directly compared the response time-courses in the imagery and control conditions to the listening condition within different brain regions, using inter- and intra-subject correlation. During imagery, melody-specific response patterns were reinstated in the superior and medial temporal gyri (lateralized to the right), the visual cortex, and the supplementary motor area. In addition, the melody-specific patterns in the temporal cortex were more strongly reinstated when imagery was accompanied by rhythmic tapping, compared to motionless imagery. These results indicate

that areas in sensory cortices are not only involved in recreating a complex internal experience of music, but that they can also encode melody-specific information similarly, both when it is externally perceived or internally recalled. Furthermore, rhythmic motion can enhance the reinstatement of neural patterns associated with the experience of complex musical content, in keeping with models of motor to sensory influences in auditory temporal processing.

Title: The relationship between motor system activation during movement imagery and motor system adaptation following movement imagery training

Authors: *E. YOXON, T. N. WELSH;
Fac. of Kinesiology and Physical Educ., Univ. of Toronto, Toronto, ON, Canada

Abstract: Movement imagery (MI) is a cognitive-motor process that shares neural networks with movement execution and observation. As such, MI may play an important role in motor learning and rehabilitation. Previous research has demonstrated that both physical and action observation training can elicit rapid neuro-plastic changes in the cortical representation of movement (e.g. Stefan et al., 2005). In these studies, a series of TMS pulses was used to generate thumb movements and the dominant direction of these thumb movement as used as the index of the neural representation of thumb movements. This dominant direction of TMS-evoked movements changed after training by physically executing or observing thumb movements in the opposite direction. We have recently demonstrated this same effect with MI training (Yoxon & Welsh, submitted). In action observation, the magnitude of these training effects is related to the magnitude of corticospinal system activation during individual instances of action observation (i.e. the change in amplitude of TMS induced motor evoked potentials [MEPs]; Ray et al. 2013). To further understand the mechanisms of MI training, the relationship between neuro-plastic MI training effects and the amplitude of MEPs during MI was examined. In Experiment 1, the dominant direction (i.e. flexion or extension) of TMS-evoked thumb movements was assessed before and after MI training. During training, participants imagined moving their thumbs in the direction opposite to the pre-determined dominant direction. Prior to training, TMS was also used to determine the change in corticospinal excitability during MI (amplitude of MEPs during

MI of thumb movements in both the flexion and extension directions). There was no significant relationship between MEP amplitude during MI and the pre-post changes in the direction of TMS-evoked thumb movements in Experiment 1. However, pre-post changes in the direction of these thumb movements were modest. The MI intervention in Experiment 2 was modified to enhance the potential of training effects. The preliminary results of Experiment 2 suggest that there may be a relationship between corticospinal activation during MI and neuro-plastic changes in the representation of movement following MI training.

Title: Changes in the global state of consciousness affect brain activity related to conscious and non-conscious visual perception differently

Authors: *A. FONTAN[1], L. LINDGREN[2], T. PEDALE[1], F. BERGSTRÖM[3], C. BRORSSON[4], J. ERIKSSON[1];
[1]Dept. of Integrative Med. Biol., Umeå Ctr. For Functional Brain Imaging, Umeå, Sweden; [2]Dept. of Nursing, Umea Univ., Umea, Sweden; [3]Coimbra Univ., Fac. of Psychology and Educ. Sci., Coimbra, Portugal; [4]Dept. of Anaesthesia and Intensive Care, Inst. of Surgery and Perioperative Sci., Umeå, Sweden

Abstract: Until now, investigations of consciousness have used two basic experimental paradigms: one evaluating differences related to the content of consciousness (*i.e.* what is it like to experience something) and the other evaluating differences related to the global state of consciousness (*e.g.* sedated *vs.* non-sedated). There is currently a debate regarding how to conceptualize the relation between these two aspects of consciousness. Therefore, in this fMRI study, both aspects of consciousness were manipulated for the first time within a single experimental setting, which enabled us to formally investigate the relation between these two fundamental aspects of consciousness. We used continuous flash suppression to present visual stimuli consciously or non-consciously while participants performed a simple perceptual detection task during fMRI scanning and simultaneously, the state of consciousness was manipulated by injecting a sedative (Propofol). Participants could perform the task at all times under two different levels of sedation (*i.e.* low and moderate). Reaction time increased with the level of sedation, confirming the experimental manipulation of the state of consciousness.

Irrespective of sedation level, task accuracy was near perfect for conscious trials, but at chance level for non-conscious trials. Crucially, multivariate pattern analyses of BOLD signal in the occipital cortex revealed that sedation levels affected both conscious and non-conscious perceptual processes (significant classification of low *vs.* moderate sedation levels). In addition, low *vs.* moderate levels of sedation was significantly better classified for non-conscious processes than for conscious processes, showing that non-conscious processes were affected more than conscious processes by the sedation. Thus, contrary to intuition, a reduction of the global state of consciousness does not primarily affect neural activity related to conscious experiences.

Title: Effects of the hollow mask illusion on children

Authors: *A. KATES;
Albright Col., Reading, PA

Abstract: The Hollow Mask Illusion depicts a concave mask (pointing away from the viewer) that is painted in a manner that creates an illusion of convexity (pointing towards the viewer. The illusion itself has been used before in various areas of research, including infant perceptual development and areas regarding perception in individuals with schizophrenia. The current study aimed to examine potential differences in children's (4-6-years old) perception of this illusion in comparison to adults. We hypothesized that the illusion would be stronger in adults than in children. Additionally, a new mask was created from a popular character (Elmo), to investigate if there are other faces that may be more palatable to children for use in this experiment, as the human mask has the potential to appear less friendly to children. Data analyses found that children see a stronger illusion than adults ($F(1,27) = 4.402$, $p < .05$) suggesting the contribution of top-down processes in perceiving faces is stronger in children, who may be primed to see faces as convex even when context is deceitful.

Title: Bold activity in the posterior superior temporal gyrus and sulcus predicts comprehension of noisy audiovisual speech

Authors: *J. RENNIG, M. S. BEAUCHAMP;
Neurosurg., Baylor Col. of Med., Houston, TX

Abstract: Regions of the human posterior superior temporal gyrus and sulcus (pSTS) respond both to the visual mouth movements that comprise visual speech and the auditory vocalizations that comprise auditory speech (Zhu & Beauchamp, 2017; Rennig & Beauchamp, 2018). We hypothesized that these multisensory responses in pSTS underlie the observation that comprehension of noisy auditory speech is improved when it is accompanied by visual speech (*e.g.* Sumby & Pollack 1954). To test this idea, we presented audiovisual sentences that contained either a clear auditory component or a noisy auditory component while measuring brain activity using BOLD fMRI. Participants (N = 22) reported the intelligibility of the speech on each trial with a button press. *Post hoc* trial sorting was used to examine brain activations during sentences that were more or less intelligible. Our analysis focused on regions of the pSTS identified with a visual speech localizer, consisting of the contrast between viewing faces making silent mouth movements and faces making silent eye movements (Fig. 1A). For noisy audiovisual sentences (AnV) that were rated as intelligible (AnVintel), the amplitude of the BOLD signal in the pSTS did not differ from the response to clear audiovisual (AV) sentences (0.75% *vs.* 0.74%, $p = 0.959$; Fig. 1B). In contrast, for noisy sentences that were rated as unintelligible (AnVunintel) the pSTS response was significantly less than the response to clear sentences (0.75% *vs.* 0.62%, $p = 0.011$) and the response to intelligible noisy sentences (0.74% *vs.* 0.62%, $p = 0.019$). To better understand the fine-grained structure of these differences, we conducted a multivariate representational similarity analysis. The neuronal representation of intelligible noisy speech was more similar to clear audiovisual speech than the representation of unintelligible noisy speech was (average $r = 0.93$ for AV*AnVintel *vs.* average $r = 0.65$ for AV*AnVunintel, $p = 0.008$, Fig. 1C). These results suggest that visual speech regions of pSTS are related to the perceptual benefit of visual speech during perception of noisy auditory speech.

Title: Insight into objects' function biases perception

Authors: *D. DUBBELDE[1], S. S. SHOMSTEIN[2];
[2]Psychology and Inst. for Neurosci., [1]George Washington Univ., Washington, DC

Abstract: Perception is largely a result of visual processing in two streams: ventral, underlying object identity recognition, and dorsal, underlying physical interaction with objects (Kravitz et al., 2013). Segregation of processing into two streams is supported by differing proportions of parvocellular (p) and magnocellular (m) input (Livingstone & Hubel, 1988). The p-pathway has

higher spatial resolution and projects primarily to the ventral stream, while the m-pathway has higher temporal resolution and projects primarily to the dorsal stream. Furthermore, recognition of objects associated to action (tools) evokes more dorsal stream processing than objects without such associations (non-tools) (Smith & Goodale, 2015). We hypothesize that differing processing of tools and non-tools across the two streams should lead to perceptual differences concurrent with the resolution of each stream - non-tool recognition should yield higher sensitivity to spatial detail and tool recognition should yield higher sensitivity in temporal changes. To test the hypothesis predicting behavioral differences between perception of tools and non-tools, participants were presented with either tool or non-tool objects (10 tools and 10 non-tools) with one of two target types each exploiting the streams' resolution: detecting object flicker for the temporal resolution of the dorsal stream and detecting a small gap in object outline, for the spatial resolution of the ventral stream. Non-tools induced higher sensitivity for detecting spatial gaps as compared to tools, suggesting that the differences in dorsal stream recruitment between tools and non-tools directly predicts behavioral benefits. A follow-up experiment controlled for possible low-level differences between tool and non-tool objects by inverting objects (preserving low-level characteristics while reducing object-recognition). Inversion abolished differences between tools and non-tools, suggesting that the perceptual difference between the object groups is driven by semantic content. The final experiment tested the influence of the m-pathway by manipulating background color as red or green. The m-pathway is suppressed by red light due to the inhibitive, red-selective receptive field surrounds of many m-cells (Wiesel & Hubel, 1966), which predicts reduction in difference between object groups with red light. As predicted, the perceptual advantage for non-tools in the spatial task was observed only under green light. Together, these experiments show there are perceptual differences between tool and non-tool recognition which arise from differential recruitment of the two visual processing streams.

Title: Mental rotation task and brain structural changes in early onset Parkinson's disease

Authors: *C. DOUGHERTY[1], B. MULLEN[1], M. P. SUBRAMANIAN[1], S. RAVI[1], K. VENKITESWARAN[1], D. WAGNER[1], P. ESLINGER[1], J. WANG[2], T. SUBRAMANIAN[1]; [1]Neurol., [2]Radiology, Penn State Col. of Med., Hershey, PA

Abstract: Early onset Parkinson's disease (EOPD) is characterized by onset of symptoms between the ages of >40 <60 without any known genetic cause. Previous research indicates that decreased performance on mental rotation task (MRT) (Mullen 2018 SfN) in individuals with EOPD. To date, no studies have compared brain structure between left and right sided onset PD. In this study we examined brain structure in cognitively intact EOPD patients and its relationship to MRT performance. Structural MRIs and MRT data from 32 EOPD subjects were analyzed. All subjects were right handed and had to be in H&Y stage I PD to enroll. The sample consisted of 20 males of which 9 were left sided onset (L) and 11 right sided onset (R) PD and 12 females of which 5 were L onset and 7 R onset PD. Of the above, 10 males (6L and 4R) and 11 females (4L and 7R) had MRT data. Data from visit 1 of this long-term natural history study is presented here. Freesurfer V6.0 was utilized to obtain volumetric data for five parietal lobe regions. Two sample T-test was performed between L and R onset PD brain volumes for males and females. Significantly different regions were then correlated with MRT data using Pearson's R. We found that left ($p < .012$) and right ($p < .0017$) Inferior parietal lobe volume was significantly different between L and R onset male PD patients and left ($p < .049$) inferior parietal lobe was significantly different between L and R onset females. MRT performance was significantly positively correlated with left inferior parietal volume in left onset males ($r = .87$, $p < .02$) and left and right inferior parietal volume in left onset females ($r = .96$, $p< .04$ and $r = .96$, $p < .04$). Right onset male or female groups' MRT scores did not correlate significantly with inferior parietal volumes. Our findings show that inferior parietal lobe may be related to MRT performance in EOPD. The inferior parietal lobe closely corresponds with the angular gyrus which has been shown to be involved in manipulation of internal mental representations. This study is the first to report structural differences between left and right sided onset EOPD patients and their relationship to MRT performance. Our findings further define the neural substrates which mediate MRT performance in EOPD and may represent a new biomarker for disease progression.

Title: The neural basis of mental calendars

Authors: *V. RAMACHANDRAN, Z. MARCUS;
UCSD, San Diego, CA

Abstract: We explored the manner in which we construct an internal mental calendar, involving mapping time-sequence onto spatial maps.
When asked to visualize an annual calendar, the majority of people (over 98%) report seeing a vague, indistinct, rectangular shape hovering in front of a face. But about 2 % of the population almost literally "see "the calendar as a hoola-hoop, U, L or V shape with actual letters and words (e.g., January 22) being clearly visible. We now use a novel reverse reading task to establish that these calendars act more like real objects activating sensory pathways rather than purely abstract symbolic descriptions that need bear no geometric resemblance to an actual calendar. For example, when projected on real tilted lines or curves the calendar gets tilted or deformed as in geometric illusions. If the background of straight or curved lines are alternated at 3hz, the calendar deforms in opposite directions in the two frames - generating vivid apparent motion (a case of illusory motion produced from internally generated - non-existent - lines). Furthermore, if the subject looked to the right, the memories from months on the left became blurred and hard to retrieve. And when questioned about events pertaining to specific months her eyes spontaneously moved toward appropriate spatial location. In Subject RN the calendar was a U-shaped, coronal ribbon - the top of the right limb twisted (as in a mobius strip). Remarkably, when switching to an allocentric point of view, the words that were mirror reversed-on the subject's right became legible, and those on what was originally the left became reversed and less legible.
We propose the calendar is enshrined in a circuitry involving the hippocampal place cells and entorhinal grid cells. These are connected to the dominant angular gyrus via the inferior longitudinal fasciculus. Our research has shown that this gyrus embodies a sequence module; we have found that patients with angular gyrus lesions have pronounced difficulty with cognitive tasks involving sequence. This may explain their deficits with reading, writing, left-right confusion, arithmetic (and - we suspect - calendars). Similar lesions in children produces similar deficits, as well as a new one that we dubbed 'calendar agnosia'(difficulty with temporal sequencing of memories whose content is, nonetheless, preserved). Sequence agnosia may - in turn - explain our observation that the rules of transitivity (e.g., A>B, B>C, therefore A>C) are compromised in dyslexics. It is a sobering thought - that the dominant angular gyrus - originally evolved for grasping branches, enables us to reach for the stars.

Title: Breathing load effect on perception and emotion during exercise

Authors: C. MABE, ***S. ADAMS**;
Pfeiffer Univ., Misenheimer, NC

Abstract: Anxiety amplifies afferent sensory components of breathing which can alter the perception of need for air and breathing load. It is unknown if baseline anxiety will alter a collegiate athletes interoception to a respiratory load during a submaximal treadmill test. PURPOSE: Determine if a breathing load (restricted snorkel) affects a collegiate athletes' perception of need for air, perception of exertion, urge to stop, and emotion. METHODS: Collegiate athletes were separated into low anxiety (n=8) and moderate anxiety (n=5) based on State Trait Anxiety Index (STAI) pre-testing. Baseline testing included a VO_{2max} test, one week later a 40-60% $VO_{2submax}$ restricted breathing (10%) for 1.6 miles. During the restricted breathing protocol, Urge-To-Stop (UTS), Rating of Perceived Exertion (RPE), Perceived Breathing Effort (RBE), Need for More Air (NFA), and post-test Self Assessment Manikin (SAM) outcomes were measured. RESULTS: RPE was 18% higher with moderate anxiety (11.96±1.6 SD, p=0.03) compared to low anxiety (9.8±1.67 SD). RBE was 22% higher in moderate anxiety (11.72±1.39 SD, p=0.01) compared to low anxiety (9.1±1.72 SD). NFA was 33% higher in moderate anxiety (1.5±0.0 SD, p=0.02) compared to low anxiety (1.0±0.5). Sense of Happiness (SOH) was 17% lower in moderate anxiety (3.8±0.75 SD, p=0.05) compared to low anxiety (4.6±0.07 SD). Sense of Control (SOC) was 17% lower in moderate anxiety (3.8±0.75 SD, p=0.03) compared to low anxiety (4.8±0.43 SD). CONCLUSION: A restricted breathing load appears to elicit a heightened afferent sensation evidenced by higher body-state scores in collegiate athletes with moderate levels of anxiety.

Title: The comparison of the ability of stereoscopical spatial vision of children with special needs, their age-matched mainstream peers, and the members of the year 2018 U16 European Champion Hungarian women's adolescent national handball team based on a new functional stereo test

Authors: *J. PALI[1], I. STUBER[2], S. MOLNAR[4], Z. ELEK[4], P. WALSH[5], E.-M. BAKO[6], C. KOROM[7], S. TAYLOR[5], L. EICKE VON H[5], J. DODLA-BHEMAH[5], G. FARKAS[3], S. KISS[8], A. PETERVARY[2], I. TAMAS[9];

District Office, Budapest, Hungary

Abstract: On behalf of the Hungarian governmental organization North-Budapest School District Office, we have been developing a special educational methodology utilizing a 3D television screen with polarization glasses and synchronized camera pairs of different viewpoints for children with special needs in three independent locations (Woking (UK), Sepsiszentgyörgy (Romania), and Budapest (Hungary)).
Before having started the proper somatopedagogic programs, children aged 7-17 (n=191; 65 girls, 126 boys; autism: 43, Down's syndrome: 7, ADD and ADHD: 29, severe mental handicap: 17, SLCN and/or learning difficulties: 95) were examined using a sequence of figures comprising 15 stereo picture pairs with special spatial vision-related clues. Each of the 15 pieces of 3D images showed a number of balls (1-5), the friendliest object, of different colours (white, blue, yellow, red). No child rejected to perform the test. Even non-speaking autists (they have not been involved in the current study) could pick and show them from a set of balls in front of them.
The first 5 pictures of the vision test served to examine blindness and eye domination problems (7 children were found). Nevertheless, the repeating of the vision test once or twice as a training (3-5 min) could switch on the weaker eye.
The second five images tested the basic stereoscopical vision abilities. 6 boys from the control group (n=226; 104 girls, 122 boys) and 5 from the mentally impaired group could not execute all of the images properly.
In the last 5 pictures, balls were arranged in a very tricky manner. Children with special needs could successfully accomplish pictures #11-15 in 95.45%, 91.19%, 75.28%, 47.73%, and 45.53% whereas their healthy peers in 99.54%, 100%, 85.05%, 57.42%, and 53.08%, respectively. No significant difference was found comparing the scores of the healthy boys and girls regarding the last 5 pictures (3.85 ± 1.03 vs. 4.06 ± 1.04, respectively; $p>0.05$ (Student t test)). Having compared the groups of mentally impaired boys and girls, there was also no significant difference between their test results (3.49 ± 1.3 vs. 3.66 ± 1.21; $p>0.05$). By contrast, in cases of both girls and boys, children with special needs could obtain slightly but significantly less scores while performing the stereo test than their healthy mates ($p<0.05$). The European Champion Hungarian women's adolescent national handball team members (n=17) performed 3.65 ± 1.22 in average on the test whereas their age-matched (15-16 years old) control peers (n=25) scored 3.71 ± 1.04 ($p>0.05$).

Finally, 0.79% of all tested children in Hungary, 6.35% in the UK, and 10.17% in Romania perceived the yellow balls in test images to be green (9 girls, 9 boys).

Title: Propose the new method for error detection in BCI system using Microstate

Authors: ***S.-K. KIM**, L. KIM;
Korea Inst. of Sci. and Technol., Seoul, Korea, Republic of

Abstract: Brain computer interface used to control robots and to study intuitive interaction between humans and robots. Motor-Imagery is a method of identifying a user's intention that appear when they imagine a certain movement. It has the advantage of being able to perform commands in the most intuitive manner to move a robot. However, its accuracy is low and results are different depending on the performance of users. Thus, we focus on the detection of error for improve MI performance. In many studies, used error-related potentials as error feature for detect. It is characterized by the negative potential over fronto-central regions that appears between 50~100ms and by the positive potential over parietal regions that occurs between 200~500ms after incorrect response. However, they were difficult to clearly detect, so we explored other features as a component of error. Microstate analysis provides a sparse feature of large-scale brain network activity. It also can be used both rest and task state. Using this, we proposed a new feature as appears error component. 10 subjects (6M; aged 26.6±2.91) asked to concentrate on visual cues and followed prompts to complete the corresponding MI. A trial included a preparation state (+, 3s), a concentrate state (auditory cue, 1s), an MI state (L/R hand grasping, 3s), a feedback state (correct/error robot control video, 2s), and a break (1.5s). 60 trials were performed per block, and this was repeated 5 times. We led the subjects into thinking that the feedback stimulus was presented in real time. In practice, 30% of all trials were configured to randomly generate error responses. We used data in feedback state to analyses. Using average epoch about correct or error, Top 5 microstates were calculated to best represent the correct/error epoch. In this result, rank 1 to 4 microstate are same between correct and error, however, 5th microstate (green in figure 1) is different between correct and error. In addition to, the microstate

occurs between 200~500ms and active in parietal region. Thus, we conclude the 5th microstate is component of error response.

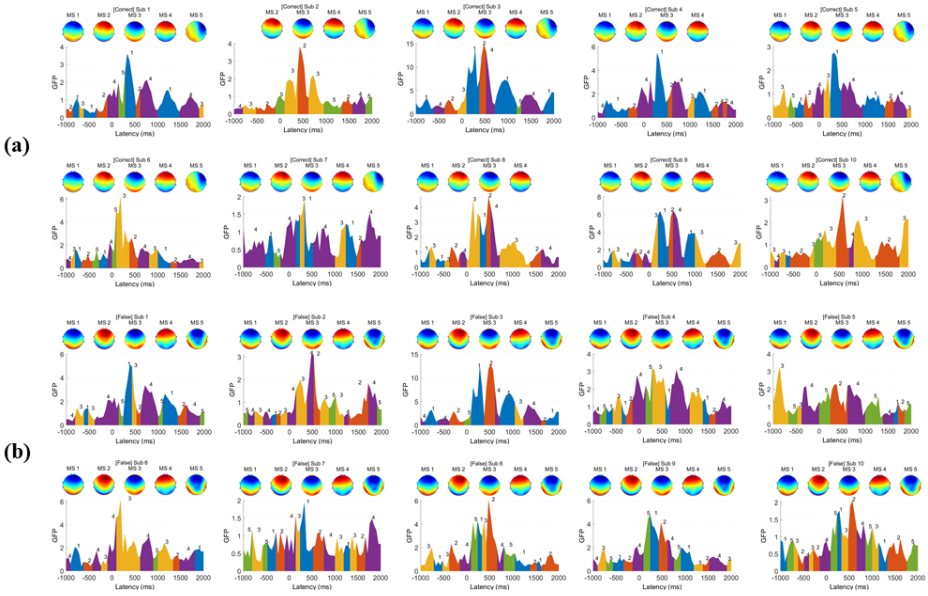

Figure1. The back-fitting graph using 5 microstates (a) Correct response about 10 subjects; (b) Error response about 10 subjects; GFP is Global field power

Title: Orientation anisotropies compared in human psychophysics and two-photon imaging of macaque V1

Authors: ***S. GUAN**, X. ZHAO, S. TANG, C. YU;
Peking Univ., Beijing, China

Abstract: Humans are more sensitive to cardinal orientations than to oblique orientations. Whether V1 is responsible for this oblique effect remains controversial. Another form of orientation anisotropy is the superior processing of radial orientation compared to tangential orientation. To gain more insights into these orientation anisotropies, we measured

psychophysical orientation discrimination at these orientations, and reanalyzed two-photon imaging data from an earlier study (SfN2017), to compare the effects in human performance and macaque V1 responses. All the data were collected in parafovea (human: 3º; macaque: 2-4º), and two-photon imaging data were obtained from V1 superficial layers of four macaques.Psychophysics:Human orientation discrimination thresholds were lower at the cardinal orientations than oblique orientations for a Gabor presented on the right horizontal meridian or the lower vertical meridian, confirming the oblique effects. When the Gabor was centered at the lower-right or -left visual quadrant, superior orientation discrimination at radial orientations (lower-left 45º or lower-right 135º) was not observed when compared to performance at tangential orientations, failing to replicate the previous results. Two-photon imaging: Responses to a drifting Gabor at 6 SFs and 12 orientations were measured in six 850x850 μm^2 imaging windows, each at 150 and 300 μm depths, to produce 12 data sets. A total of 8798 cells' orientation tuning functions at the best SF were obtained. There were no more neurons tuned to cardinal orientations (0/90º ± 10º) than to oblique orientations (45/135º ± 10º) (19.5±0.9% vs. 22.0±1.3%, p = 0.31). The orientation tuning bandwidths between these two groups of neurons were not significantly different either (18.6±2.1 vs. 17.1±1.5 º , p = 0.19). However, there were significantly more neurons tuned to radial orientations than to tangential orientations (14.0±1.4 % vs. 8.0±1.0 %, p=0.01), but there were no significant differences in orientation tuning bandwidths (15.8±1.5 vs. 16.2±1.5 º, p=0.73) and response strengths (0.40±0.02 vs. 0.40±0.03, p =0.82). The population orientation tuning functions showed similar tuning bandwidths but less variations at radial orientations than at tangential orientations (19.9±1.2 vs. 21.1±1.4 º).Our two-photon imaging results from ~9000 neurons confirm that the oblique effect may not be represented in V1, at least not in parafovea. A radial-tangential anisotropy does show in V1 sub-neuronal population sizes and variations of population tuning. It is unknown why a radial-tangential anisotropy is absent in our psychophysical observations.

Title: Physiological activities in response to different airflows in an air-conditioned test room

Authors: *K. TAMURA[1], S. MATSUMOTO[1], Y. TSENG[2], T. KOBAYASHI[3], J. MIWA[4], T. HIRAO[5], T. OKAMOTO[1,2];
[1]Fac. of Arts and Sci., [2]Grad. Sch. of Systems Life Sci., Kyushu Univ., Fukuoka, Japan;

[3]Mitsubishi Heavy Industries, LTD., Tokyo, Japan; [4]Mitsubishi Heavy industries, LTD., Tokyo, Japan; [5]Mitsubishi Heavy Industries Thermal Systems LTD., Tokyo, Japan

Abstract: Feelings of indoor thermal comfort can be influenced by airflow sensation. However, to our knowledge, few studies have investigated the physiological responses related to velocity and/or direction of airflow generated from an air-conditioning system. Hence, this study compared the physiological responses to different airflow conditions, directly or indirectly to the face, under similar temperature and humidity in an air-conditioned test room. Cooling and heating experiments were performed in seven healthy volunteers (4 females; age, 21–27 years). Participants performed cognitive tasks under two different airflow conditions: direct (DIRECT) or indirect (INDIRECT). Indoor thermal environments were controlled by draft control flaps (Mitsubishi Heavy Industries Thermal Systems LTD., Tokyo, Japan), which can prevent exposure to a constant airstream. Each task consisted of five sessions: resting, subjective evaluation of thermal sensation and affective states, time counting following time signals, time counting without any signals, and mental calculation. These five sessions were repeated thrice per condition. During the experiments, we recorded electroencephalography (EEG), electrocardiography (ECG), and additional physiological data. The experiments were approved by the local ethics committee of Kyushu University. All methods were performed in accordance with the approved guidelines.
The EEG theta band amplitudes in the frontal areas were higher in the heating-INDIRECT than in the heating-DIRECT condition. From this result, we can suggest that the participants could sustain higher attention in the heating-INDIRECT condition. For heart rate variability analysis, we calculated the ratio of the low frequency and high frequency (LF/HF) component as indices of autonomic nervous activity. The statistical testing of LF/HF showed a significant main effect of session in the heating-DIRECT but not in the heating-INDIRECT condition. Hence, autonomic nervous activity was normal in the heating-INDIRECT than in the heating-DIRECT condition. In conclusion, avoiding direct blowing in a heating environment helps maintain a stable mental state. This study is expected to contribute to understand the neuronal mechanism of airflow sensation and development of comfortable air-conditioning system.

Title: Maintenance strategy and task difficulty modulate delay activity and subsequent memory

Authors: *C. REICHERT PLASKA[1,2], A. ARANGO[2], K. NG[3], T. M. ELLMORE[2,1]; [1]Psychology, The City Univ. of New York, New York, NY; [2]Psychology, The City Col. of New York, New York, NY; [3]Neurosci., The CUNY Advanced Sci. Res. Ctr., New York, NY

Abstract: Working memory (WM) and subsequent long-term memory (LTM) may be facilitated by articulatory rehearsal (AR). There is a rich behavioral literature on AR for verbal stimuli, but few studies have examined the benefits of AR for complex novel visual stimuli. Neural delay period studies have largely failed to control for the use of AR, which makes activity patterns during maintenance difficult to interpret. Two studies examined changes in delay activity while participants maintained complex novel scenes and perceptually similar scrambled scenes. Forty-four participants completed a modified Sternberg Task. 64-channel scalp EEG was recorded during WM and long-term recognition. Participants either saw novel scenes (NS) that contained visual semantic information or phase-scrambled scenes (SS) that contained the same colors and spatial frequencies but lacked semantic information. Participants were instructed to generate a descriptive label (i.e. beach) and covertly rehearse the label (CR) or suppress rehearsal (AS, i.e. repeat "the") during the delay period. WM and LTM (10-mins later) performance were measured as proportion of correct trials. Artifact-corrected delay activity (temporal-spectral amplitude) was compared as a function of maintenance strategy (CR vs AS) and stimulus type (NS vs. SS) and was also correlated with performance on the WM and LTM tasks. Performance on the WM task for NS revealed that there was no significant difference in performance between CR and AS suggesting that CR did not provide a short-term behavioral advantage. There was also no long-term behavioral advantage on the delayed recognition task for CR. When task difficulty increased with SS, there was both a significant short-term advantage of CR over AS (85% vs 78% correct, $p<.001$) as well as a long-term advantage for images from the CR condition (71% vs 62% correct, $p<.001$). Comparison of sensor-level delay activity during the maintenance phase for NS and SS revealed two distinct patterns of neural activity. During rehearsal with NS, there was greater amplitude in the beta range in the right parietal and centromedial regions but it was not correlated with performance. For SS, greater amplitude was observed in the upper alpha and beta ranges across all sensors during CR and was significantly correlated with WM performance. Memory for difficult to remember phase-scrambled scenes benefited from rehearsal, whereas easy to remember intact scenes did not. Delay activity increased and correlated with subsequent memory in the former but not the latter suggesting that neural modulation during the delay period depends on both task difficulty and maintenance strategy.

Title: A simultaneous EEG/fMRI study of scene working memory

Authors: *A. M. ARANGO[1], C. REICHERT PLASKA[1,2], J. ORTEGA[1], B. GOMES[2], G. SILVA[1], F. ANTARA[1], K. NG[3], A. SHEREEN[3], T. M. ELLMORE[1,2];
[1]Psychology, The City Col. of New York, New York, NY; [2]Psychology, The City Univ. of New York, New York, NY; [3]Neurosci., Advanced Sci. Res. Ctr., New York, NY

Abstract: Past studies show scene processing is supported by specialized neural circuitry and that scene memory is both high capacity and long-lasting. Less is known about the neural mechanisms supporting the encoding and maintenance of scenes in working memory (WM). 32-channel EEG was acquired simultaneously with BOLD-fMRI in 24 participants to map spatiotemporal activity patterns during a variant of the Sternberg WM paradigm. Participants viewed novel outdoor scenes during an encoding period followed by Fourier phase-scrambled stimuli with similar color and spatial frequency during a delay period. Scrambled scenes provided a perceptual baseline while participants maintained the scenes presented at encoding. Each participant completed 50 low- and 50 high-load trials presented in separate runs with order randomized and counterbalanced. Performance was above chance but did not differ between loads (low 87.37(26.15)%, high 77.54(28.07)%, paired t(23)=1.43, p=0.17).
Group paired t-test difference maps between encoding (ENC) and delay (DEL) were computed from BOLD fMRI data in AFNI. A posterior occipitotemporal network (consisting of right and left hippocampus and parahippocampal gyrus, right middle occipital gyrus) showed significantly greater activity (FDR=0.01) during ENC vs. DEL. A more anterior frontal-parietal network (consisting of left pre- and post-central gyrus, right angular gyrus, right and left inferior frontal gyrus, left and right middle frontal gyrus, left and right thalamus, left cerebellum, and right calcarine gyrus) showed greater activity during DEL vs. ENC.
Topographic voltage amplitude distribution maps were created from the simultaneously acquired EEG data using BESA and paired-t difference maps (ENC vs. DEL) were computed in BESA Statistics.
The low-load condition showed broad overlap with fMRI, with significant posterior ERP differences (ENC > DEL) over bilateral occipital and right centroparietal sensor locations

occurring as early as 106 ms and anterior ERP differences (DEL > ENC) at left frontocentral and temporal sensors occurring as early 134 ms.
The high-load condition showed overlap with fMRI, with significant posterior ERP differences (ENC > DEL) over centroparietal and centrooccipital sensors occurring as early as 76 ms and anterior ERP differences (DEL > ENC) over right frontocentral and temporal sensors occurring as early 210 ms.
The results show a posterior network is rapidly activated during scene encoding, with differences in a more anterior network appearing slightly later during maintenance. These findings add to our understanding of the neural dynamics for how scenes are encoded and maintained in WM.

Title: Tracking spatial working memory representations during distraction

Authors: *G. HALLENBECK[1], T. C. SPRAGUE[2], M. RAHMATI[1], K. K. SREENIVASAN[3], C. E. CURTIS[4];
[1]New York Univ., New York, NY; [2]Psychological and Brain Sci., Univ. of California, Santa Barbara, Santa Barbara, CA; [3]New York Univ. Abu Dhabi, Abu Dhabi, United Arab Emirates; [4]Psych & CNS, NYU, New York, NY

Abstract: A robust working memory (WM) system requires the maintenance of past but relevant information in memory against a continuous flow of newly incoming but irrelevant information. Recent reports conflict on how WM representations encoded in visual and parietal cortex are susceptible to interference (e.g., Bettencourt & Xu, 2016; van Moorselaar et al., 2017; Lorenc et al., 2018; Rademaker et al., pp2018). Here, we test how WM representations are affected by an intervening task by leveraging the robust ability to decode spatial WM representations from retinotopically organized visual field maps in human cortex. We measured brain activity with high-speed fMRI (1.33 Hz) while participants performed a memory-guided saccade task. On 30% of trials the delay was blank. The remaining 70% were dual-task trials where participants performed a challenging motion discrimination task within a small aperture appearing at

counterbalanced locations with respect to the WM target while remaining fixated. We used an inverted encoding model (Sprague & Serences, 2013) to reconstruct spatial WM representations across the delay interval in visual field maps defined in occipital, parietal, and frontal cortex. Performing the intervening task slightly reduced memory-guided saccade precision, indicating that the task was effective. In all visual field maps and with high fidelity, we could reconstruct the remembered location on trials with blank delays and in the epoch prior to the intervening stimulus on dual-task trials. However, the intervening task caused a temporary reduction in, but not loss of, reconstruction fidelity in all maps, accompanied by the ability to temporarily reconstruct the location of the intervening aperture. Before the end of the delay period, after distractor disappearance, reconstruction of the working memory representation recovered in visual, parietal cortex, and frontal cortex. Therefore, WM may be distractor-resistant because it is supported by a widely-distributed network of brain areas.

Title: Neural representations and temporal dynamics of rejection template in visual search

Authors: *W. WEN[1], Z. HUANG[1], S. LI[1,2];
[1]Sch. of Psychological and Cognitive Sci., Peking Univ., Beijing, China; [2]PKU-IDG/McGovern Inst. for Brain Res., Beijing, China

Abstract: To perform challenging visual search tasks, attention should be selectively allocated to task-relevant items through target promotion or distractor inhibition. Previous studies have suggested that the benefits of rejection template exist only if the to-be-ignored features remain unchanged (i.e., fixed-cueing condition) rather than change in a trial-by-trial basis (i.e., varied-cueing condition). To resolve the contradictory behavioural findings in fixed and varied distractor-cueing contexts, researchers have proposed that stable rejection template is essential in distractor inhibition and is created only under the fixed-cueing condition, whereas the varied-cueing context obstructed its formation. So far, there was little direct neural evidence shedding lights on the existence of rejection template or the underlying dynamics of its formation. By recording electroencephalography (EEG) of human participants, the current study investigated the neural representation of rejection template along with its temporal dynamics in both fixed-cueing and varied-cueing conditions in a typical visual search task. Participants were asked to locate the target and perform an orientation discrimination task. Before the search array onset,

they were informed of the color of the shapes where the target never appeared. In the matched distractor trials (75%), the cued color reappeared in the search array as the distractor color, while a randomly selected new color would be the distractor color in neutral trials (25%). Robust and persistent reconstruction of the to-be-ignored color from EEG signals in the fixed-cueing condition indicated the successful creation of rejection template. These neural representations could explain the overall significant behavioural suppression benefit. By contrast, there was a strong attention-related signal to the to-be-ignored color in the varied-cueing condition, as reflected by occipital lateral alpha oscillation and transient above-chance reconstruction after cue onset. Meanwhile, stronger frontal theta oscillation was found in the varied-cueing condition, suggesting the goal-directed disengagement from the to-be-ignored color as well as the rejection template transformation process. Finally, during the rejection template execution period, frontal-midline theta oscillation after search array onset positively correlated with individual behavioural suppression benefits in the varied-cueing condition. Overall, the current study demonstrated the neural signature of the rejection template as well as the distinctive neural dynamics underlying its formation and execution in visual search.

Title: Spatial working memory “precision” related to bump drift: Evidence from distraction

Authors: *J. F. O'RAWE, H.-C. LEUNG;
Stony Brook Univ., Stony Brook, NY

Abstract: Fitting measurement models to continuous recall measures as an estimate for working memory precision has been fruitful in discriminating different computational models. However, under a simplified Gaussian drift model of working memory, the behavioral readout at the end of the retention interval combines not only variance from the precision of the actual memory representation, but also the variance due to drift in that representation across the time of the delay. We show that distraction, much like cueing, reduces spread in responses in the bump attractor model, as predicted by the simplified Gaussian drift model. This makes a unique prediction that in conditions of distraction, the location of the output (centered on the target, therefore bias) should be negatively correlated with the spread of the output. We collected data from 59 human subjects in a spatial working memory task which included manipulations of distraction. We presented a target dot stimulus along a circular array, followed by a distractor in ¾ of the trials (of varying distances from the target: 18 degrees, 36 degrees, 54 degrees) after a

variable delay (manipulation unrelated). Then after another variable delay the participants were probed with a free response to rotate a probe dot around a circle until it matched the remembered dot location. We found an increased location recall bias with increasing distance of distractors from the target. Importantly, we found that in 7/9 conditions of distraction, the location parameter was significantly negatively correlated with the spread parameter, while in 0/3 conditions without distraction showed this negative correlation. This provides another line of evidence demonstrating the importance of representational drift in the precision of working memory readout.

Title: Prefrontal cortical aperiodic activity tracks the number of items held in short-term memory

Authors: *T. TRAN[1], B. VOYTEK[2,3,1,4];
[1]Neurosciences Grad. Program, [2]Cognitive Sci., [3]Halıcıoğlu Data Sci. Inst., [4]Kavli Inst. for Brain and Mind, UCSD, La Jolla, CA

Abstract: Successful memory encoding is linked to decreased power in low-frequency neural activity and concomitant increased power in high-frequency activity across a wide network of temporal and frontal cortical regions. These changes have often been seen in the examination of individual memory items successfully maintained in short-term memory. However, it is not known to what extent similar changes in on-going, non-stimulus-evoked aperiodic activity might also track, over time, the contents of short-term memory as more and more items are maintained. To investigate this, we analyzed previously collected electrocorticographic (ECoG) recordings from 28 patients undergoing treatment for drug-resistant epilepsy. These patients performed a delayed free recall task in which multiple lists of serially presented words were provided, and after each list, patients were asked to recall as many words from the previous list as possible. From these recordings, we measured lateral temporal (LTL) and lateral prefrontal cortical (LPFC) aperiodic (1/f-like) slope using neural activity immediately preceding each word presentation. We hypothesized that the “flattening” of aperiodic slope over time would track the number of words currently being maintained in short-term memory. To test this, we calculated, for each patient, the difference in aperiodic slope between last- and first-available words per list.

Next, we examined the per-patient relationship between aperiodic slope difference values and recall percentages across lists. We found that aperiodic slope difference values from LPFC, but not from LTL, were positively correlated with list recall percentages consistently across patients. Specifically, increases in aperiodic slope values over time were indicative of more words memorized and subsequently recalled. These results demonstrate that the number of items maintained in short-term memory can be tracked using characteristics of on-going baseline aperiodic activity in the LPFC, and they also suggest that the degree to which prefrontal cortical neural populations can shift towards more asynchronous activity states has a direct effect on memory maintenance and capacity.

Title: New computer based training improves working memory and cognitive functions

Authors: *S. ICHIHARA-TAKEDA[1], K. TAKEDA[2], S. FUNAHASHI[3];
[1]Fac. of Hlth. Sci., Kyorin Univ., Tokyo, Japan; [2]Dept. of Psychiatry, Natl. Ctr. of Neurol. and Psychiatry, Kodaira, Tokyo, Japan; [3]Beijing Inst. of Technol. & Kyoto Univ., Kyoto, Japan

Abstract: How to maintain and improve cognitive functions in elder people is an important subject in cognitive psychology and mental health. Although a variety of training methods have been introduced, most of these could improve specific capacity only to achieve these tasks and do not improve overall cognitive capacity. We developed a new method to measure and improve working memory capacity and cognitive functions for elders. In this method, subjects need to solve problems that they frequently encounter in their real life (e.g., preparing food, planning a travel, or shopping). The problems that subjects want to solve can be selected by themselves depending on their interest and the parameters of problems (e.g., difficulty, time to solve the problem) can be changed easily by the experimenter and flexibly adapted to each subject's ability. In the present study, we examined effectiveness of this method by comparing the performance of this method with the performance of seven neuropsychological tests using Pearson's correlation coefficient. A stepwise multiple regression (SMR) analysis was also used to examine whether potential predictors were independently associated with the behavioral components of this method. Healthy elders performed this method and seven generally used neuropsychological tests. Correct performance rates of this method were significantly correlated

with those of mini-mental state examination (MMSE), category fluency test, digit span backward task, and trail making test. SMR analyses showed that neuropsychological capacities for trail making test B, MMSE, and category fluency test are closely related to the performance of this method. These results indicate that performance of our method requires working memory capacity, attentional control, and cognitive flexibility, and suggest that This method can be help to maintain and improve cognitive functions for elders.

Title: Exploring working memory in the DLPFC through direct stimulation

Authors: *P. S. ROLLO[1], O. WOOLNOUGH[1], K. J. FORSETH[1], N. TANDON[2];
[1]UTHSC at Houston, Houston, TX; [2]Vivian L. Smith Dept. of Neurosurg., Houston, TX

Abstract: Introduction: Cortical stimulation mapping (CSM) is a powerful research tool that allows researchers and clinicians to causally assign function to cortex in a way that eludes other collection modalities by allowing temporary disruption of local brain networks. Working memory is a crucial function as the short-term storage and manipulation of information involved enable so much of everyday human behavior. It has been extensively investigated using nonhuman primates as well as lesion and imaging studies in humans but the literature can benefit from stimulation work. Here we used CSM to localize regions of the brain that contribute to the process of working memory.
Methods: We collected data in 20 patients undergoing intra-operative language mapping using direct cortical stimulation (5-10mA, 50Hz, 2s). Working memory was evaluated with a battery of tasks including sentence repetition and digit manipulation. Digit manipulation was assessed by giving patients a list of three numbers, which patients were expected to repeat in reverse order. Stimulation sites were mapped onto a cortical model generated from the patient's MRI. The spatial extent of stimulation-induced depolarization modeled on the pial surface with a current spread model to generate subject-specific maps of memory disruption that were then projected onto a standard group atlas to produce a population-level representation.
Results: The stimulation yielded regions of sentence repetition disruption and regions of digit manipulation disruption. Sites of digit manipulation disruption were mostly confined to DLPFC, in agreement with the literature. However, these sites were distinct from the regions in which repetition was disrupted.
Conclusion: We have demonstrated DLPFC is essential to working memory providing evidence

of a new human population, separate from lesion and imaging studies. Additionally, we have shown the distinction between anatomically distinct regions for the storage and manipulation of information. These data serve to further validate the prevailing understanding of a divided system of working memory, separating storage and manipulation of information, while also providing causal evidence for where parts of those individual networks exist in the brain.

Title: Electroencephalographic features of middle aged women with high and low performance in a working memory test

Authors: *M. SOLIS-ORTIZ, E. GONZÁLEZ-PÉREZ;
Inst. Invest Med, Univ. Guanajuato, Leon, Mexico

Abstract: Working memory is an executive function which is key for effective cognitive performance. This memory has shown deficits in middle aged women, although the results are inconclusive. An electroencephalographic (EEG) approach during the application of a working memory test and a discriminant analysis may aid in understanding these cognitive deficits, particularly in women who show high and low performance. The aim was to explore EEG features of middle-aged women through the execution of a test demanding working memory and to determine the predictor variables that best classify cases into the two groups. EEG activity was recorded through the execution of the Wisconsin Card Sorting Test in twenty-four middle-aged healthy women. The women were divided into a low execution group (n=10) and a high execution group (n=14), according to the number of completed categories of the test. Two completed categories were indicative of low performance. A stepwise discriminant analysis was performed to determine if participating women could be discriminated based on the following variables: delta, theta, alpha1, alpha2, beta1, beta2 absolute power, the number of completed categories, correct responses (trials), perseverative errors and test errors. The discriminant analysis showed that Wilks' lambda, as a test of discriminant function, was significant (lambda=0.101; X^2=36.71, p=0.001) and selected the four following variables as predictors of high and low performance: completed categories (F=54.27, p=.001), delta (F=48.57, p=.001), theta (F=40.41, p=.001) and alpha1(F=33.45, p=.001) power. These findings indicate that the calculated discriminant function based on the four predictor variables was useful for distinguish

membership to the high and low execution group during performance test, highlighting slow EEG activity.

Title: Preservation of working memory capacity after orbitofrontal damage

Authors: *A. LLORENS[1,2,3], I. FUNDERUD[3], A. O. BLENKMANN[3], J. LUBELL[3], M. D. FOLDAL[3], S. LESKE[3], R. J. HUSTER[3], T. R. MELING[2,3,4], R. T. KNIGHT[1], A.-K. SOLBAKK[2,3,5], T. ENDESTAD[3,5];

Abstract: Orbitofrontal cortex (OFC) is implicated in multiple cognitive processes including inhibitory control, context memory, recency-judgment, and choice behavior. Despite an emerging understanding of the role of OFC in memory and executive control, its necessity for core working memory (WM) operations remains understudied. Therefore, we assessed the impact of OFC damage during a Recent Probes task (RPT) where subjects are asked to memorize a set of five letters and to indicate whether a probe letter was presented in set. Four conditions were created according to the response (yes / no) and the recency of the probe (presented in the previous trial set / in the current one). We compared behavioral and EEG responses between healthy subjects and patients with focal bilateral OFC damage (n=14). Even though OFC patients had prolonged reaction times to probes compared to controls across all conditions, the two groups showed the same core RPT recency pattern of slower response latency when the probe was presented in the previous trial. The within-group electrophysiological results showed no condition difference during letters encoding and maintenance. Indeed, the cluster-based permutation F-test made over the visual ERPs elicited by the visual presentation of the letters and over the four second of retention did not show significant cluster. In contrast, the same

analysis made over the ERPs observed after probe presentation showed distinct condition by group effects. Condition differences for controls occurred within the same time window (300-500 ms after probe presentation) and were observed in two distinct spatial clusters including right centro-posterior and left frontal electrodes, respectively. Both clusters showed ERPs difference elicited by the response effect and one cluster was also sensitive to the recency manipulation. Condition differences for the OFC group involved two other clusters, both encompassing only left hemisphere electrodes and occurring during two consecutive time windows (345-463 ms and 565-710 ms). Both clusters were sensitive to the response effect, but no recency effect was found despite the behavioral recency effect. Although the groups had different electrophysiological response, the maintenance of letters in WM, the evaluation of the context of the probe, and the decision to accept or reject a probed letter were preserved in our patient cohort. The results suggest that neural re-organization may contribute to intact response and recency judgment after OFC damage.

Title: Local DLPFC network causal measures predict working memory load

Authors: *D. P. DARROW[1], C. SAIOTE[1], A. HERMAN[1], Z. SHA[1], T. HENRY[1], M. C. PARK[2];
[2]Neurosurg., [1]Univ. of Minnesota, Minneapolis, MN

Abstract: Introduction: Working memory has been studied as a paradigm using EEG and fMRI. Frontal and parietal cortices have been identified as playing the most significant role underlying the neural basis for working memory centered on the prefrontal cortex. No intracranial studies in humans have reported on the spatial or temporal features associated with the N-back, a common working memory task. We evaluated the electrocortical event-related potentials and spectral activity during the N-back task during invasive recordings.
Methods: Four patients with pharmacoresistant epilepsy undergoing surgery for seizure localization completed N-back tasks with randomized degrees of load (0-, 1-, 2-, and 3-back) during a ten day stay in the epilepsy monitoring unit in a randomized order. Evoked-related potentials and spectral analysis were performed on a block-by-block basis.
Results: More than 800 individual time-locked epochs were completed by each patient resulting

in more than 48 blocks of 0-, 1-, 2-, or 3-back in equal proportions. Electrodes provided coverage over the medial and lateral prefrontal cortex, orbitofrontal cortex, hippocampus, and lateral temporal lobe in all patients. ERP analysis (permutation testing, cluster-based multiple comparison correction, $p<0.025$) revealed functionally selective effects of N-back load in the prefrontal cortex corresponding to DLPFC, and large but undifferentiated ERPs in the hippocampus. Spectral analysis revealed specific patterns of increased alpha/beta and gamma activity in prefrontal electrodes near the DLPFC with gradient representation of increasing back. Cross-validated SVM classification accuracies for task vs. baseline and load were found to be significantly above chance ($p < 0.0001$). Conclusion: We report analysis from the first intracranial recordings during the N-back working memory task. We found significant regional specificity for the task in the prefrontal cortex with task-dependent spectral differences most significant in gamma and alpha/beta bands. Event related potentials also demonstrated load specificity within the prefrontal cortex while large evoked-responses in the hippocampus dominated changes when compared to baseline.

Title: Spatial working memory precision across eccentricity and time

Authors: *L. JIANG, A. TSEGAI-MOORE, Y. LIU, H.-C. LEUNG;
Psychology, SUNY Stony Brook, Stony Brook, NY

Abstract: How accurately target locations are represented and maintained in working memory remains unclear. Previous neurophysiology studies found weak or no clear topographic organization of spatial working memory representation in higher order regions, such as dorsolateral prefrontal cortex, while behavioral studies suggested both foveally-directed and quadrant-centered spatial distortions in the reproduction of spatial working memory. As most previous studies examined spatial working memory in one dimension (with targets arranged along a circle), the nature of working memory distortion across two-dimensional (2D) space remains to be determined. Here, we conducted a memory-guided saccade experiment to examine the variation in precision of spatial working memory recall across 2D space by varying target

eccentricity (3 to 13 degrees of visual angle) and delay duration (1.5 to 3 sec). Eye position was monitored and recorded from 6 participants. We calculated both systematic and unsystematic error of endpoint saccade to the to-be-remembered target location across trials for each individual. The figure shows the endpoint saccade distribution from a sample subject, and the systematic and unsystematic errors of individual data and group average. We found increases in both types of recall error with increasing target eccentricity, while only unsystematic error increases with increasing delay. Individual differences in both radial and angular bias of endpoint saccade were evident, though more participants showed memory-guided saccade biased toward the center of the quadrant and toward the fovea. Taken together, these findings indicate a reduced spatial working memory precision with increasing eccentricity and retention interval, suggesting the heterogeneity of working memory representation across space and time.

Title: Parametric modulation of distractor filtering in visuospatial working memory

Authors: *D. BESTUE[1], A. COMPTE[1], T. KLINGBERG[2], R. ALMEIDA[3];
[1]IDIBAPS, Barcelona, Spain; [2]Dept. of Neurosci., Karolinska Inst., Stockholm, Sweden;
[3]Stockholm Univ., Stockholm, Sweden

Abstract: Although distractor filtering is a fundamental component of working memory (WM), there are not many tasks where distractors are parametrically modulated both in the temporal and the similarity domain. Here, 21 subjects participated in a WM task where distractors could be presented prospectively or retrospectively at two different delay times (0.2 and 7s). Moreover, distractors were presented close or far away from the target. As expected, changes in the temporal and the similarity domain induced different distraction behaviours. In the similarity domain, we observed that close-by distractors induced an attractive bias while far distractors induced a repulsive one. Interestingly, this pattern of biases occurred both for prospective and retrospective distractors, suggesting common mechanisms of interference with the relevant target. This result is in line with a previously validated bump-attractor model where diffusing bumps of neural activity attract or repel each other in the delay period (Almeida et al, 2015). In the temporal domain, we found a stronger effect for prospective distractors and short delays (0.2s). As our experiment consisted of consecutive trials, we analyzed the effect of previous targets on current trial responses, or serial effects, showing that previous relevant information biased behaviour in a similar way as distractors did. The storage of irrelevant information reflected in different interference behaviours motivated an fMRI (3T) experiment to explore the storage of relevant (target), previously relevant (serial effects) and irrelevant (distractors) information in 3 candidate ROIs: visual cortex, IPS and PFC. Based on previous studies where sensory areas were not resistant to distractors (Bettencourt and Xu, 2016), we hypothesized that visual cortex would represent all stimuli while associative areas like IPS and PFC would subserve memory function in different ways for the increasingly relevant information. We test this by mapping parametric behavioral outputs to neurophysiological readouts (Ester et al, 2015) for the different distractor conditions and we explore the brain mechanisms storing information with increasing behavioural relevance. Taken together, our study opens the door to an integrative model of WM where different neural mechanisms and multiple brain regions are incorporated.

Title: A non-monotonic relationship between working memory capacity and load-related increases in brain activity

Authors: *C. R. WALSH[1], J.-B. POCHON[2], K. D. ENRIQUEZ[2], H. TRUONG[2], A. LENARTOWICZ[2], S. K. LOO[2], C. A. SUGAR[2], C. E. BEARDEN[1,2], R. M. BILDER[1,2], J. RISSMAN[1,2];
[1]Dept. of Psychology, [2]Dept. of Psychiatry and Biobehavioral Sci., UCLA, Los Angeles, CA

Abstract: One fruitful functional neuroimaging approach for identifying regions involved in working memory (WM) has been to vary the number of to-be-maintained items and examine the degree to which activity increases as storage demands increase. Studies using delayed-match-to-sample paradigms are capable of isolating WM load effects during the encoding, maintenance, and response phases of a working memory trial. Whereas prior fMRI investigations have focused on documenting which brain regions exhibit load-dependent changes in brain activity, few studies have examined the relationship between individual differences in WM capacity and the expression of these WM load effects. In the present study, we collected an extensive battery of behavioral measurements of WM capacity from a large sample (N=170) of adult participants, who also underwent fMRI scanning while performing a delayed face recognition task. Each trial of the fMRI task involved the encoding of one face (low load) or three faces (high load), which needed to be maintained across a 7.5 s delay period followed by a match/nonmatch discrimination. General linear model analysis identified sets of prefrontal and parietal lobe regions exhibiting significant load-related increases during each task phase. We then split our sample into three groups (Low, Medium, and High Capacity) based on a composite measure of WM ability derived across ten behavioral tasks. When examining WM load effects across these subject groups, a striking pattern emerged. During the task phases when stimuli were present (i.e. encoding and probe phase), the magnitude of load effects increased markedly from Low Capacity to Medium Capacity subjects and then plateaued for High Capacity subjects. But during the maintenance phase (i.e. the delay period), we observed an inverted U-shaped relationship, such that Medium Capacity subjects showed greater load effects than either Low Capacity or High Capacity subjects. This pattern was highly consistent across regions, and suggests the search for strictly monotonic relationships between capacity and brain activity may be misguided. Low Capacity subjects may be unable to adequately increase frontoparietal delay period activity when challenged with high load, whereas High Capacity subjects may accomplish high load maintenance without the need for substantially elevated delay period activity. In contrast, the Medium Capacity subjects were the ones who engaged the most sustained activity of frontoparietal regions to succeed. Better understanding the nature of this relationship may support Research Domains Criteria (RDoC) efforts to relate neurocognitive markers of WM capacity to psychopathology.

Title: Neural systems supporting flexible top-down control over the priority of working memory representations

Authors: *J. M. SCIMECA, L. K. ROSS, M. D'ESPOSITO;
UC Berkeley, Berkeley, CA

Abstract: Control processes that can prioritize goal-relevant information in memory are critical to successful WM performance. However, the capacity, costs, and mechanisms of controlling priority within WM remain unclear and contentious. To address these gaps, we used semantic retrospective cues (retrocues) to indicate multiple high-priority items maintained in WM and assessed performance with a novel two-probe paradigm. First, we found converging evidence from behavior and computational modeling experiments that participants (N=136) can use semantic retrocues to prioritize multiple items in memory. We show that prioritization incurs clear costs to non-prioritized items, and that mnemonic prioritization is dissociable from task set preparation and spatial attention. These findings challenge recent theories proposing cost-free prioritization and a focus of internal attention with a one-item capacity, and instead suggest a flexible trade-off in priority between mnemonic representations that is under top-down control. Next, we used fMRI (N=20) to characterize the neural systems that support flexible prioritization within WM and to address ongoing debates regarding the contributions of frontoparietal (FP) and cingulo-opercular (CO) regions to mnemonic control. We first compared retrocue trials to neutral cue trials to identify transient activity at the retrocue versus sustained activity during the subsequent delay period. We found that both FP and CO regions are transiently recruited by retrocues. In contrast, sustained delay-period activity is reduced in CO regions following retrocues relative to neutral cues. There was differential recruitment of FP region when prioritizing items based on spatial versus non-spatial features, which occurred transiently at the retrocue and did not persist throughout the delay. However, there were persistent differences in visual sensory cortices when prioritizing a subset of items. Together, these findings support a model in which both FP and CO networks support an internally-directed attentional control process that can dynamically bias mnemonic representations in sensory cortices in favor of multiple high-priority items, and suggest that this selective bias is initiated by transient top-down control signals from frontoparietal regions.

Title: Alpha-band activity finely tracks remembered locations within a visual hemifield

Authors: *D. W. SUTTERER, G. F. WOODMAN;
Psychology, Vanderbilt Univ., Nashville, TN

Abstract: Recent work (Foster et al., 2016, Sutterer et al., 2018) has shown that the topography of EEG alpha-band activity can be used to track remembered locations of objects. The locations in these demonstrations were presented around central fixation, and a well-known characteristic of alpha-band activity is that alpha power decreases contralateral to remembered stimuli and increases ipsilateral to remembered stimuli. Thus, an open question is whether tracking of remembered locations reflects relatively crude differences in alpha-band power across cerebral hemispheres or if alpha-band activity can more finely track remembered locations within a visual hemifield. To answer this question, we used a lateralized spatial estimation task and presented stimuli in a single hemifield (e.g., the left visual field). Human observers maintained fixation while remembering the location of one or two colored dots (blue or green) presented to the left of fixation. Dots were presented on a circle (radius of 4 degrees of visual angle) that was centered 6 degrees of visual angle to the left of fixation. We reasoned that if the large-scale difference of alpha-band responses across hemispheres enables tracking of remembered locations, we would be unable to track the precise location of each stimulus when stimuli were presented in a single hemifield. Alternatively, if alpha-band activity patterns can more finely track remembered locations, we would be able to track remembered locations even when they were presented in a single hemifield. By applying an inverted encoding model (IEM) to the topography of alpha-band activity on the scalp, we found that we were able to successfully estimate remembered locations for both one and two-item trials. In addition, we found that we could train the IEM on one-item trials and successfully recover the remembered location on two-item trials, suggesting that the format of alpha-band representations is similar when multiple items are maintained.

Together these results provide evidence that alpha-band activity tracks the precise location held in mind.

Title: Competition between similar visual working memory items produces repulsion effects

Authors: *P. S. SCOTTI, Y. HONG, A. B. LEBER, J. D. GOLOMB;
Dept of Psychology, Ohio State Univ., Columbus, OH

Abstract: Competition between items in visual working memory results in poorer memory performance (Ahmad et al., 2017; Lewis-Peacock & Norman, 2014). Here we consider a particular type of memory error where subjects report a memory feature biased away from a reference or nontarget feature (e.g., reporting bluish-purple when presented with a purple target and red distractor). These repulsion effects have been well-established in visual working memory (e.g., Bae & Luck, 2017; Golomb, 2015; Golomb, L'Heureux, & Kanwisher, 2014) but theoretical accounts are debated. In a series of behavioral experiments, we consider an active competition framework where concurrent processing of working memory contents leads to increased reliance on relational information, such that memory items close in feature space become more distinct with increased competition. On each trial, subjects were instructed to simultaneously study two real-world objects for 1 second followed by a brief blank delay, and were then asked to report the color of one of the objects. The blank delay between study and test was 1 or 3 seconds, randomly intermixed. Repulsion effects were stronger for the 3-second compared to the 1-second condition. In a second experiment, we explored why repulsion was stronger at a longer delay. In addition to the 3-second blank delay condition, we tested another condition where, following a 1-second blank delay, a 2-second filler task was presented where subjects made a size judgment on two different objects. Hence, both conditions posed the exact same temporal delay between study and test, with the only difference being that the filler task was expected to disrupt the processing of the memory items and therefore interfere with active competition-based processes. Repulsion was indeed weaker for filler task trials compared to non-filler task trials. These results suggest that repulsion cannot be explained by temporal decay

(Barrouillet, De Paepe, & Langerock, 2012) or memory strength (Chunharas, Rademaker, Brady, & Serences, 2019). We suggest that an active competition framework can explain repulsion, a framework amenable to the neural processes of lateral inhibition (Johnson, Spencer, Luck, & Schöner, 2009) or off-target neuron tuning (Navalpakkam & Itti, 2007).

Title: Decoding stimulus-specific features and task rule from the TMS-evoked response during a visual working memory task in humans

Authors: *M. WIDHALM[1], J. SAMAHA[2], N. ROSE[1];
[1]Univ. of Notre Dame, Notre Dame, IN; [2]Univ. of California - Santa Cruz, Santa Cruz, CA

Abstract: Research has shown evidence for the reactivation of latent representations in working memory (WM) with transcranial magnetic stimulation (TMS) and simultaneously-recorded EEG (Rose et al., 2016, *Science*). The present study extends this work by examining the representational substrates of both stimulus-specific features and task rules in the retention and reactivation of latent WM.
First, we localized the TMS target site by applying single pulse (sp) TMS to left V1/V2 to localize phosphenes in the lower right visual field for each participant. In the ensuing WM task, one oriented grating was presented at the location of that individual's phosphene and another was presented in the opposite (left) hemifield at the same angle and distance from central fixation. These gratings were to be retained with two retro-cues and two recognition probes on each trial, such that one grating would be attended and the other unattended following each retro-cue. During the delay period following each cue, spTMS was applied to the retinotopically-localized site in left V1/V2 at 110% of phosphene threshold to target the sensory representation and assess direct effects on items presented in the right vs. left hemifield.
We used inverted encoding models to reveal if the specific orientation of the latent memory items could be reconstructed from the TMS-evoked response on simultaneously recorded EEG. Reconstruction was conducted using voltage from posterior channels that were contralateral to item presentation (i.e. left posterior channels for items presented on the right). While we found no reconstruction for the item on the left, the item on the right – which was directly targeted by TMS – showed robust reconstruction. This finding was replicated in a second experiment on different subjects. The second experiment also extended our findings by adding a DLPFC stimulation condition to allow comparison of stimulation site. A logistic regression classifier

trained and tested on delay period EEG was able to decode the task rule (attend left vs. right) using spectral power changes evoked before, during, and after both occipital and DLPFC TMS. In sum, not only can task rule be decoded from neural activity during the delay period of a visual working memory task, but TMS of retinotopic visual cortex also allows for reconstruction of stimulus-specific features.

Title: Information dynamics of input gating and output gating in visual working memory

Authors: *E. J. LEVIN, D. BADRE;
Cognitive, Linguistic, and Psychological Sci., Brown Univ., Providence, RI

Abstract: Visual working memory is a capacity-limited system that requires control processes to manage what information enters memory and to select what information guides a response. These control mechanisms are often conceptualized as gates, allowing transfer of information into or out of memory when the gate is open and prohibiting transfer when it is closed. Gating mechanisms are also important because they mediate the balance between the predicted utility of an item and our limited memory capacity (Chatham and Badre, 2013). For example, input gating proactively updates information to memory that is relevant (high priority) and filters information that is irrelevant (low priority). Output gating manages the contents of memory when relevance is known after encoding. The present experiment investigated whether the information content of working memory differs between input gating and output gating, and depending on the priority of items for the task. Participants performed a modified gating task previously developed by our laboratory (Chatham et al., 2014) across two fMRI sessions. In this task, participants had to maintain one or two orientation gratings over one or two delay periods, respectively. Participants were also presented with a higher-order context-cue that indicated which of the two orientations was relevant. This context-cue could either come first, putting task demands on input gating, or last, putting task demands on output gating. We then used an inverted encoding model (IEM) to assess the population-level tuning responses of working memory representations during input gating events and during output gating events in visual cortex (V1 and V2). We were able to reconstruct the orientation during the perceptual event as well as when the orientation was being

maintained over the delay period for both input gating and output gating events. We found that the reconstructions of relevant items in input gating conditions were narrower than the reconstructions for distractor items in input gating conditions, indicating better precision for the item that was higher priority. Further, we observed that items being maintained during output gating trials, in which the relevance was unknown, were reconstructed at a medium level of precision between the levels of high and low priority items. These results suggest that the precision of information held in working memory tracks priority, with higher-priority items maintained with more precision, and lower-priority items maintained with less precision.

Title: Nematode and human brain architecture

Authors: *M. OBAYASHI;
Metacube Co.,Ltd., Tokyo, Japan

Abstract: A constitutive and theoretical model (hypothesis) of the brain, based on data for the nematode *Caenorhabditis elegans* as a model organism, is presented. Analysis of the nerve cell sketch of the hippocampus and cerebral cortex column by Ramón y Cajal is performed in detail, identifying each element of the neuron and glial cell in the core unit. In the memory model of the core circuit, the memory associated with time and space is dispersed and stored in the core circuit of the associative area and the motor/sensory area, spreading to the cerebral cortex. The memory determines whether or not the stimulus from the sensory neuron of the current sensor is similar to that of the past, and, as a whole, a pattern similar to the past memory is reproduced. At this time, the core circuit serves as a multilayered storage device (hierarchical associative memory), and can hold memory that recognizes time. As a result, the mechanism by which the hippocampal function synchronizes the firing patterns of neurons in the brain has been clarified. To date, it has been considered that *C. elegans* does not possess a central nervous system similar to the human brain structure. However, analysis of the *C. elegans* data from the viewpoint of the core circuit model suggests that the neural circuit is the basis of the human neural circuit, and it is presumed that all elements are retained and homologous. The findings strongly suggest that these structures are homologous between nematodes and humans, and are common in biological systems with brain framework.

	Assumed role
L1	Body of hierarchical memory (capture time series firing pattern of input F3) : Identify the firing level of layer.
L7	Body of inter-connective memory between L4t4 circuits
F3	Projection input (sensor neuron) : Associate time series firing patterns.
F1	Interneuron (maintains firing state of input F3 in short term)
F2	Interneuron (become familiar with inhibitory neuron) : Internal sync signal control : Phase adjustment in operation cycle
F4	Projection output (depending on F3, L1, F1, F2)
F5	Input from homogeneous neuron group (thalamus etc.) : As the origin of the indirect pathway. F5 has a role of quantitatively transmitting the firing status of F4 and B4 (of the previous phase) to B2.
F6	Clock input for synchronization
B2	Interneuron (amygdala etc.) : Internal sync signal control : Phase adjustment in operation cycle
B1	Interneuron (output adjustment) : Chemical adjustment for B4, etc.
B3	Clock output for synchronization
B4	Projection output (depending on L1, F5, B2, B1; which affected neighboring firing pattern)

Title: Factors that predict working memory maintenance and decline in older adults

Authors: *S. CANSINO[1], F. TORRES-TREJO[1], C. ESTRADA-MANILLA[1], M. PÉREZ-LOYDA[1], L. RAMÍREZ-BARAJAS[1], M. HERNÁNDEZ-LADRÓN-DEGUEVARA[1], A. NAVA-CHAPARRO[1], S. RUIZ-VELASCO[2];
[1]Lab. NeuroCognition, Nat Autonomous Univ. of Mexico, Mexico City, Mexico; [2]Applied Mathematics and Systems Res. Institute, Nat Autonomous Univ. of Mexico, Mexico City, Mexico

Abstract: The aging process is associated with the gradual decline of several cognitive functions, and working memory is particularly affected. Although the majority of older adults experience a deterioration of their working memory, some individuals maintain their working memory in older age and some suffer an extreme deterioration of their working memory. The purpose of the present study was to identify, among a total of 120 potential predictors, those that significantly contributed to these two extreme outcomes in working memory. A sample of 588 healthy adults was examined with the n-back task in the spatial and verbal domains using a 2-back level of difficulty. Individuals were classified as working memory maintainers or decliners if their discrimination level in the two domains was superior to the 80th percentile or inferior to the 20th percentile, respectively. The study is exploratory because as any cross-sectional experiment, the causal influence of the variables in the model cannot be confirmed. Logistic regression identified eight and six significant predictors of working memory maintenance and decline, respectively. High vocabulary scores and smoking more were significant predictors of working memory maintenance; however, in the opposite direction, these same variables predicted working memory decline. Both logistic models revealed that having a healthy cardiovascular system is an essential condition for preserving cerebrovascular functioning and, consequently, working memory. In the working memory maintenance model, lack of hypertension, lower consumption of cholesterol and moderate alcohol intake support this conclusion, while in the working memory decline model, decline is based on higher consumption of myristic acid. Another relevant consumption habit that predicted working memory decline was a lower consumption of vitamin D, which has a direct influence on brain areas supporting memory functions. Psychological traits and everyday activities were present in both models. We identified specific predictors involved in extreme an uncommon working memory performance in older age.

Abstract: Recent studies have reported that piano practice may improve cognitive function of older adults. However few studies on older adults have investigated the influence of instrumental practicing on neural efficiency during cognitive tasks. In addition, our previous study showed that playing keyboard harmonica might be beneficial to verbal memory of older adults. Therefore, in this study, we conducted a randomized controlled trial to further investigate the effects of musical instrument practice program using keyboard harmonica on cognitive functions and neural efficiency in older adults. Fifty-three musically naive healthy older adults (ages 61-85) were assigned to either the intervention group (n = 27), which received a 4-month keyboard harmonica classes or an untrained control group (n = 26). Cognitive measurements, and the brain activity (measured by functional magnetic resonance imaging) during a visual working memory task were administered before and after the intervention in both groups. Our results showed that intervention group significantly improved performance on the logical memory II test (a measure of delayed recall) as compared to control group. Moreover, after the 4-month intervention, the intervention group showed a reduction in brain activation in the middle frontal gyrus and superior parietal lobule, indicating less effort for the visual working memory task. Such intervention effects, increased neural efficiency together with improved memory performance, were consistent with the previous research on effects of multitask exercise intervention.

Title: Cognitive performance of severely hearing-impaired older adults before and after cochlear implantation

Authors: *V. VAN ROMPAEY, E. ANDRIES, A. GILLES, V. TOPSAKAL, P. VAN DE HEYNING, G. MERTENS;
Antwerp Univ. Hosp., Edegem, Belgium

Abstract: Objective: To evaluate cognitive change in severely hearing-impaired older adults after cochlear implantation.
Study Design: Prospective, longitudinal cohort study with assessments before, and at 6 and 12 months after implantation.
Patients: Twenty older adults (median age: 71.5 yr).
Main Outcome Measures: Change in the Repeatable Battery for the Assessment of Neuropsychological Status for Hearing-impaired individuals (RBANS-H) total score and subdomain scores were used to assess cognitive evolution. In addition, change in best-aided speech audiometry in quiet (monosyllabic words) and in noise (Leuven Intelligibility Sentences Test [LIST]) was examined, as well as patient- reported measures of health-related quality of life (Nijmegen Cochlear Implant Questionnaire [NCIQ]), self-perceived hearing disability (Speech, Spatial, and Qualities of hearing Scale—12 [SSQ12]), sound quality (Hearing Implant Sound Quality Index—19 [HISQUI19]), and states of anxiety and depression (Hospital Anxiety and Depression Scale [HADS]).
Results: The RBANS-H total scores improved significantly after 12 months cochlear implant (CI) usage ($p < 0.001$). At subdomain level, significant improvements were observed in the immediate and delayed memory domain ($p < 0.005$ and $p < 0.002$, respectively), and to a lesser extent also in the attention domain ($p < 0.047$). Furthermore, speech perception in quiet and in noise improved significantly after 6 months and remained stable after 12 months. Similarly, a significant improvement was observed on all patient-reported measures after 6 months of CI usage. These results remained stable after 12 months, except for the HADS.
Conclusions: A significant improvement in overall cognition after 12 months of CI usage was established. However, future research is imperative to further disentangle possible practice effects from the effects of the cochlear implantation. The significant, positive effect of cochlear implantation on speech perception and patient-reported measures was confirmed.

Title: Reconfiguration of frontoparital and default network related to working memory aging

Authors: *C. YANG, J. FAN, C. LIU, J. XIA, Z. ZHANG;
State Key Lab. of Cognitive Neurosci. and Learning, Beijing Normal Univ., Beijing, China

Abstract: The human brain is well organized into a set of functionally specific networks to support higher cognitive operations and daily behaviors. Of these networks, the frontoparietal network (FPN) and the default network (DN) have been found to play crucial roles in working memory (WM), involving regions like dorsolateral prefrontal cortex (DLPFC), middle frontal gyrus (MFG), superior and inferior parietal gyrus (SPL/IPL) and precuneus as well as cingulate cortices (Anticevic et al., 2012; Rottschy et al., 2012). However, little is known about how the FPN and DN, as well as their interactions, are functionally linked to WM in old age. Thus, we have acquired N-Back WM task fMRI data (TR = 2s, TE = 30ms, 3mm voxel) from a community-based cohort of 273 old individuals (aged from 45 to 86, 121 females), and the task-

induced BOLD signals were processed with the approach of background connectivity to remove task-evoked activity (Al-Aidroos et al., 2012; Norman-Haignere et al., 2012), resulting a task state-related WM activity. We then defined FPN and DN based on Power's 264 atlas (Power et al., 2011), and estimated the within- and between-network background functional connectivity (bFC) through Pearson's correlations. The age-related alterations of bFC strength were explored with network-based statistic (NBS) (Zalesky et al., 2010), and their relationships to WM performance were evaluated by connectome-based predictive modeling (CPM) (Shen et al., 2017). Here, we observed widespread age-related decrease of bFC strength within both FPN and DN (FDR corrected $p < 0.05$), and but only bFCs identified within FPN could significantly predict individual WM accuracy rate ($r = 0.1867$, $p = 0.0018$, 5000 permutations). Furthermore, we also found age-related increase of bFC strength between these two networks (FDR corrected $p < 0.05$), mainly connecting brain regions like MFG, IFG, angular gyrus (AG) and medial superior frontal gyrus (mSFG), and when combined with the within-network bFCs in FPN and DN, the between-network bFCs could also predict WM performance ($r = 0.1825$, $p = 0.0023$, 5000 permutations). Taken together, these results implicated the reconfiguration of FPN and DN, with age-related weaken within-network bFCs and enhanced between-network bFCs, and these alterations have been significantly associated with individual WM in old age.

Title: Mean cortical thickness predicts cognitive change in healthy aging

Authors: ***M. HOU**, M. A. DE CHASTELAINE, B. E. DONLEY, M. D. RUGG;
Ctr. for Vital Longevity and the Sch. of Behavioral and Brain Sci., Univ. of Texas at Dallas, Dallas, TX

Abstract: Cortical thickness has been related to cognitive function in healthy older adults in prior research. However, relatively little is known about the relationship between cortical thickness and longitudinal change in cognitive function. In the present study, we investigated the relationship between baseline cortical thickness and cognitive change over 3 years in 50 healthy older adults. Participants (age range: 63 - 76, mean age: 67.9, 25 female) were administered a neuropsychological test battery at Session 1, and were re-tested on the same battery after one month (Session 2) and again after 3 years (Session 3). T1-weighted whole brain images were

acquired at Session 1. Test performance across sessions was reduced to four constructs - labeled Memory, Speed, Fluency and Crystallized IQ - based on a principal component analysis applied to a larger sample tested at Session 1. To control for practice effects, mean performance across sessions 1 and 2 served as the baseline for assessment of change at session 3. Over three years, older adults showed significantly decline in Speed but not in other constructs. Controlling for chronological age, mean cortical thickness was negatively correlated with longitudinal change in Memory and Crystallized IQ. In addition, thickness was positively correlated with baseline scores in Speed and Fluency. Further analysis indicated that the correlations between cortical thickness and longitudinal change, and between thickness and baseline scores, did not significantly differ across the different cognitive constructs. Consequently, cortical thickness was negatively correlated with a composite longitudinal change score, and was positively correlated with a composite baseline score. These results suggest that cortical thickness is not only predictive of cognitive performance in older adults, but is also predictive of short-term cognitive change in this population. Furthermore, mean cortical thickness appears to capture variance shared across different cognitive domains.

Title: Dual task gait speed modifies the association between cardiovascular risk and visuospatial working memory in older adults

Authors: ***S. BUSS**[1], L. APONTE-BECERRA[1], J. TREVINO[1], R. E. MCGLINCHEY[2], C. B. FORTIER[2], V.-A. LIOUTAS[1], P. NOVAK[3], C. MANTZOROS[1], L. NGO[1], V. NOVAK[1]; [1]Beth Israel Deaconess Med., Boston, MA; [2]Geriatric Res, Educ, and Clin. Ctr. & Translational Res. Ctr. for TBI & Stress, VA Boston Healthcare Syst., Boston, MA; [3]Brigham and Women's Hosp., Boston, MA

Abstract: Background: Cardiovascular disease is a major risk factor for cognitive dysfunction and dementia. Some older adults with cardiovascular comorbidities show greater susceptibility to cognitive decline than others. Walking speed predicts 5-year survival and cardiovascular

mortality. Dual task (DT) gait speed, measured while preforming a working memory task, is related to attention and executive function. We hypothesize that subjects with faster DT gait speed are less vulnerable to the effect of cardiovascular risk factors on cognition.
Objective: To test if DT gait speed modifies the relationship between cardiovascular risk factors and cognitive performance.
Methods: 190 older adults (Mean ± SD, age: 65.6 ± 9.0 years, gender: 50% female) participated in the study. Visuospatial working memory was evaluated using the Paired-Associated Learning (PAL; total errors adjusted) test. The Framingham Risk Score (FRS, %) was used to measure 10-year cardiovascular mortality risk. Gait speed was assessed during DT walking (m/s). A general linear model using SAS 9.4 tested the effect of FRS, DT gait speed, and their interaction on PAL. Participants were divided into quartiles based on DT gait speed. Within each quartile, separate linear models were used to test the association between FRS and PAL.
Results: Baseline characteristics were obtained for PAL errors (32.2 ± 21.3), FRS (17.2 ± 9.6; intermediate risk), and DT gait speed (1.1 ± 0.2). Higher PAL error score was associated with higher FRS (β=1.8, $p<0.0001$) and slower DT gait speed (β=-3.4, $p=0.0002$). The slowest DT walking quartile (range: 0.4-0.9) had higher FRS (20.1 ± 9.3) and more PAL errors (41.1 ± 23.0). Higher FRS is associated with more PAL errors in the lowest DT quartile (β=1.02, $p=0.003$), but not in the second, third, or fourth quartiles.
Conclusion: High cardiovascular risk and slow DT gait speed predicted more errors during a task of working memory. Faster walking speed during DT is associated with a smaller impact of cardiovascular risk factors on cognitive performance. DT gait speed has potential as a simple and objective physiologic metric of brain resilience in patients with cardiovascular risk factors.

Title: Theta, alpha, and beta band oscillations related to value-directed strategic processing in cognitively normal younger and older adults

Authors: *L. T. NGUYEN[1], S. A. SHENDE[2], F. MARINI[3], D. A. LLANO[1,4,5], R. A. MUDAR[1,2];

Abstract: Strategic processing allows for value-based preferential encoding of information. It involves an interplay between selective attention to relevant information and inhibition of irrelevant information, both of which are known to decline with age. However, behavioral studies using value-directed recall have found that strategic processing remains relatively stable with age. Examining underlying neurophysiological processes linked to value-directed processing may better clarify the effects of age. The current study examined EEG-derived event-related spectral perturbation (ERSP) power differences between 21 younger adults (13F; mean age: 22.2 ± 1.2 years; mean education: 15.8 ± 1.1 years) and 21 older adults (16F; mean age: 63.2 ± 6.5 years; mean education: 16.8 ± 2.3 years) in theta (4-8 Hz), alpha (8-12 Hz), and beta (12-30 Hz) bands, related to processing of high- and low-value information in a value-directed strategic processing task. The task used five word lists, each with a unique set of high- and low-value words presented one at a time while EEG was recorded. Participants were instructed to recall as many words as possible after each list with the goal of maximizing their score. Behaviorally, younger and older adults recalled significantly more high- than low-value words for the five lists, showing that older adults engaged in strategic processing similar to younger adults. Neurally, parietal alpha and beta bands showed differences between processing of high- and low-value information, with desynchronized alpha power for high-value words, and synchronized alpha and beta power for low-value words. Group differences were observed in the alpha band, with greater synchronized power for low-value words in older compared to younger adults. No significant effects were seen for frontal theta power. These findings suggest that alpha and beta bands index selective attention to high-value words and inhibition of low-value words. Importantly, alpha band differences between groups for low-value information suggests early neural changes in normal cognitive aging are observed in inhibitory processes linked to strategic attention and these alterations are not pronounced enough to show behavioral consequences. Such ERSP measures may be valuable for detecting and characterizing early neural changes in pathological cognitive aging, such as mild cognitive impairment.

Title: Impact of a 12-week aerobic exercise intervention on interhemispheric inhibition and motor control in sedentary older adults

Authors: *J. OMAR[1], J. R. NOCERA[2], M. R. BORICH[2], B. A. CROSSON[3], L. KRISHNAMURTHY[4], V. KRISHNAMURTHY[3], K. MAMMINO[4], K. M. MCGREGOR[3]; [1]Neurosci. and Behavioral Biol., [2]Dept. of Rehabil. Med., [3]Dept. of Neurol., Emory Univ., Atlanta, GA; [4]Atlanta VA Med. Ctr., Atlanta, GA

Abstract: Previous cross-sectional work has shown there to be a general pattern of decreased interhemispheric inhibition and increased bilateral activation during a unimanual motor task in sedentary older adults as compared to aerobically active adults. The current study aimed to examine the impact of a 12-week aerobic exercise intervention on relateralizing motor function to a single hemisphere in sedentary older adults. Twenty-four participants were randomized into an aerobic spin cycling exercise group or a non-aerobic balance training group. Participants completed a pre- and post-intervention battery of motor control tasks and a pre- and post-intervention cardiovascular fitness assessment (estimated VO2max). Magnetic resonance images were acquired prior to and after the intervention and a block-design, right-hand motor task was used to evaluate interhemispheric cortical activation patterns. The aerobic exercise group showed significant improvements in their cardiovascular fitness as compared to the balance group. A significant decrease in bilateral primary motor cortex (M1) activity was not observed between the aerobic exercise group and the balance group. It was observed that those who completed the aerobic exercise intervention showed less left M1 and supplementary motor area (SMA) activity as compared to those who completed the non-aerobic balance intervention. Significant differences in motor performance were not observed between the groups although there was a trend of improved motor performance for those in the aerobic exercise condition as compared to those in the balance condition. In conclusion, the current study provides preliminary evidence indicating that a 12-week aerobic exercise intervention has the potential to alter cortical activation patterns. The present work also provides evidence suggesting that these changes in cortical activation patterns may be associated with clinically relevant improvements in motor functioning. Additional work is needed to precisely characterize the differential changes in cortical activation patterns between the right (ipsilateral) and left (contralateral) primary motor cortices after an acute aerobic exercise intervention and the rehabilitative significance associated with those changes.

Title: Context-dependent memory in cognitively-normal older e4 carriers and non-carriers

Authors: *J. M. PALMER[1,2], A. V. LAWRENCE[1,2], M. D. GRILLI[1,2], M. J. HUENTELMAN[3], J. S. TALBOOM[3], L. RYAN[1,2];

Abstract: The ability to distinguish between highly similar objects requires the use of pattern separation or orthogonalizing information into distinct representations in the brain. Older adults generally perform worse on pattern separation tasks compared to younger adults by incorrectly identifying similar objects as ones seen previously. This suggests that older adults may have a decreased ability to create distinctive representations for objects with many overlapping features compared to younger adults. Context plays an integral role in recognition memory for objects, and the context in which an object is viewed can lead older adults to make even more similarity judgement errors. Older adults are more likely to make pattern separation errors (falsely recognizing similar objects as "old") when these similar objects are embedded in a context that was previously seen. Age-related impairment in pattern separation may therefore be a combination of a lack of utilizing details along with an over-reliance on the familiarity of the context in which an object is placed. Evidence suggests that changes in perirhinal cortex may be the neural mechanism underlying older adults' bias toward context familiarity. In contrast, preliminary data from our laboratory suggest that older adults who carry the APOE e4 allele are *less* likely to be influenced by the scene context during object recognition compared to older noncarriers. The e4 allele may confer a memory benefit that moderates older adults' susceptibility to rely on contextual familiarity, rather than object details. Participants were recruited from an existing pool in our laboratory. Older adults were carefully screened to exclude cognitive impairment. APOE status was determined from saliva by the Translational Genomics Institute in Phoenix, Arizona. Objects were embedded in semantically-related scenes and presented one at a time. Participants indicated whether each presented object was "new", "similar", or "different" compared to objects seen previously. Each object was either embedded in a context that was seen previously, a new context that had not been seen before, or on a white

background. Behavioral performance was compared between e4 carriers and noncarriers. Our results indicate that carriers and noncarriers do not differ on traditional recognition performance. However, consistent with our preliminary data, older e4 carriers were less susceptible to the influence of repeated contexts. The results suggest that the presence of the e4 allele may provide a memory benefit to older adults because carriers may not be biased toward relying on the scene context.

Title: EEG microstates in young and elderly people

Authors: ***T. HAMAMOTO**[1,2], H. IMAMIZU[1,3], T. ASAI[1];
[1]Dept. of Cognitive Neuroscience, Cognitive Mechanism Labs., ATR Intl., Kyoto, Japan; [2]Grad. Sch. of Frontier Biosci., Osaka Univ., Osaka, Japan; [3]Dept. of Psychology, The Univ. of Tokyo, Tokyo, Japan

Abstract: Background: Recently, many experts in electroencephalogram (EEG) have focused on EEG microstates (Lehmann et al., 1987). EEG microstates are known as the four spatial patterns of EEG topographies. Each microstate can be analyzed according to the duration and occurrence. Previous studies, for example, have suggested that the effect of aging on EEG microstates. Many studies have aimed to determine the mechanism underlying the aging-induced deterioration of cognitive function and how this could be improved. However, only a few studies report the relationship between aging and EEG microstates. Therefore, the aim of this study was to compare the features of EEG microstates between young and elderly people, in accordance with the brain functional connectome. Method : We measured the resting-state brain activity of EEG from 25 subjects (Young:10, Elderly:15). The sampling frequency was 500 Hz. The data was further down sampled to 100 Hz and filtered to 2-20 Hz. The microstates were defined as follows.1. When the dispersion of EEG data from each channel peaked, the topography of EEG was saved.2. The topographies were clustered into 4 patterns by k-means method.3. The

topographies of original EEG data were compared with 4 topography patterns, and we chose the one with the most resemblance as labels.4. The labels were analyzed in terms of the occurrence and duration. Results : There were significant differences in occurrence of microstate class labeled C and D between young and elderly subjects. Young subjects had more occurrence of microstate C versus elderly subjects. However, elderly subjects had a greater occurrence of microstate D versus young subjects. In microstate A and B, there was no significant difference between the two groups. Discussion : The significant difference in the occurrence of microstate C and D between young and elderly people is congruent with some previous studies. Additionally, schizophrenic patients have fewer occurrences of microstate D versus healthy people (Hernandez et al., 2015). We may see a shared deterioration of cognitive function between people with aging and schizophrenia. Further studies should investigate the relationship between EEG microstates and cognitive function.

Title: Age related modulation of microsaccade rate in rapid serial visual presentation

Authors: *K. NAGANO[1], T. KOHAMA[1], H. YOSHIDA[2];
[1]Kindai Univ., Kinokawa, Japan; [2]Fac. of Biology-Oriented Sci. and Technol., Kindai Univ., Kinokawa, Wakayama, Japan

Abstract: Development of innovative technologies for the elderly to enable an independent life of high quality has become an urgent need in Japan. Therefore, the effects of aging on vital functions should be evaluated. Many regions in the human brain play functional roles in visual information processing, and the effect of visual dysfunction on the quality of life has shown to be more severe compared to those by dysfunction of other senses (Fischer et al. 2009). This indicates that the effects of aging on visual functions should be clarified. In this study, we analyzed microsaccades, which are small involuntary shifts in visual fixation, in rapid serial visual presentation (RSVP) tasks to examine the association between the subjects' age and the microsaccade characteristics. A total of 100 subjects, aged 20 to 60 years, participated in the study. Subjects were instructed to maintain a stationary gaze on a 10 Hz RSVP of alphabetical characters displayed at the center of a liquid crystal display screen. To control the subjects' focus of attention by changing the contrast of the target characters, we conducted 3 experimental tasks: (1) high contrast task (HC), (2) low contrast task (LC), and (3) no contrast task (NC) as a control. The eye movements were measured using an EyeLink CL system (SR Research, Ontario,

Canada) at a sampling frequency of 2000 Hz. Microsaccades were detected using an order-statistic time-window analysis (Ohtani et al. 2016). The results showed that the proportion of correct target detection in HC or LC significantly correlated with the subjects' age (HC: $r=-0.60$, $p<0.01$; LC: $r=-0.72$, $p<0.01$). The microsaccade rates showed rebound following inhibition in response to the onset of targets in HC and LC, which reflected the state of covert attention (Laubrock et al. 2005). The time taken to attain peak microsaccade rate after target onset was longer in LC compared to that in HC and increased with age (HC: 560 ms in 20-29 years, 663 in 30-39, 746 in 40-49, 745 in 50-59, and 948 in 60-69; LC: 582 in 20-29, 749 in 30-39, 753 in 40-49, 952 in 50-59, and 945 in 60-69). These results suggest that the need of attentional resources to increase in cognition with age, and thereby, delay the inhibition of microsaccades.

Title: Resting state functional connectivity patterns in older adults after the PICMOR intervention program: A preliminary report

Authors: *H. SUGIMOTO[1], T. KAWAGOE[2], M. OTAKE-MATSUURA[1];
[1]RIKEN, Tokyo, Japan; [2]Rikkyo Univ., Saitama, Japan

Abstract: We developed an intervention program, named Photo-Integrated Conversation Moderated by Robots (PICMOR), to improve cognitive functions in older adults. The PICMOR program is characterized by a moderated group conversation with robotic supports, in which participants are encouraged by robots to make a speech using photos they took beforehand, listen to others' talks, ask questions to others, and answer questions from others. The time allocated to each participant is equalized between talking and listening by robots to balance between inputs and outputs of information during the conversation. To examine the effect of PICMOR on cognitive functions in older adults, we conducted a randomized controlled trial (RCT), in which sixty-five healthy community-dwelling older adults were randomly allocated to the intervention group (INT) and the control group (CONT). Thirty-two participants assigned to INT took part in the PICMOR program once a week for 12 weeks, while thirty-three participants assigned to CONT took part in a free conversation program, in which they enjoyed a group conversation

without photos and robotic supports. Before and after the RCT, multiple neuropsychological data were acquired from all participants. In addition, resting state fMRI (rsfMRI) data were collected from 31 participants in INT and 30 participants in CONT only after the RCT due to our technical circumstances. In neuropsychological data, the increase in the score of a phonological verbal fluency task (PVFT) through the RCT was significantly larger in INT than in CONT. Based on the findings from a meta-analytic fMRI study, in which the left inferior frontal gyrus (LIFG) and middle frontal gyrus (LMFG) consistently show significant activation in PVFT, we analyzed the rsfMRI data by comparing the functional connectivity (FC) patterns with these language-related regions between INT and CONT. Results showed that the FC between the LIFG seed and the right temporal pole (RTP) in INT was significantly higher than that in CONT, whose strength was positively correlated with the PVFT score in INT. In contrast, the FC between the LMFG seed and the posterior cingulate cortex and precuneus, which are probably in the default mode network (DMN), was significantly lower in INT than in CONT. These findings may suggest that PICMOR has a beneficial effect on language production, and that the enhancement is related to the enhanced FC between the LIFG and semantic-related RTP and the suppressed FC between the LMFG and DMN. Further investigation will be done to confirm the possible effect of PICMOR on the brain network related to language production through pre-post analysis on rsfMRI data of the future RCT study.

Title: Heterogeneous functional and structural degradation of category-selective regions in the ventral visual cortex during normal aging

Authors: *Z. ZUO, Z. ZUO, N. LIU;
State Key Lab. of Brain & Cognitive Sci., Inst. of Biophysics, Chinese Acad. of Sci., Beijing, China

Abstract: Accumulated evidence has shown that the function and structure of the ventral visual cortex degenerate during normal aging. However, the ventral visual cortex is a heterogeneous collection of functionally specialized cortical regions. For example, functional magnetic resonance imaging (fMRI) studies have revealed several discrete regions in the ventral visual cortex, which respond more strongly to one visual category relative to others, so-called category-selective regions. It is unclear whether age-related changes are uniform across these category-selective regions or not. To address this question, we examined how the functional and structural

properties of category-selective regions are affected by aging. In the present study, 20 young adults (mean age of 24.75 years) and 20 old adults (mean age of 62.45 years) were enrolled. First, we identified regions in each subject that were selective for faces, places, and objects, and calculated the category selectivity in each of these regions. Then, structural properties for these category-selective regions were measured by quantitative MRI. By comparing the category selectivity and structural properties of these regions between the young and old subjects, we found that both the function and structure of category-selective regions degraded during normal aging. Importantly, such aging-related changes exhibited heterogeneous patterns across different kinds of category-selective regions. Specifically, the degradation was most pronounced in place-selective regions and, to a less extent, in face-selective regions, while no significant degradation was found in object regions. Therefore, our results demonstrated that the aging-related changes in both functional and structural domains in the ventral visual cortex are highly heterogeneous, with different category-selective regions showing different degrees of degradation. It implies that the degradation of the ventral visual cortex during normal aging exhibits a complex pattern that may be related to functional segregation of regions.

Title: Healthy aging and stiffness of the brain, hippocampus, and hippocampal subfields

Authors: *P. L. DELGORIO[1], L. V. HISCOX[1], F. SANJANA[1], A. M. DAUGHERTY[2], M. D. J. MCGARRY[3], H. SCHWARB[4], C. R. MARTENS[1], C. L. JOHNSON[1];
[1]Univ. of Delaware, Newark, DE; [2]Wayne State Univ., Detroit, MI; [3]Dartmouth Col., Hanover, NH; [4]Univ. of Illinois at Urbana-Champaign, Urbana, IL

Abstract: Magnetic resonance elastography (MRE) is a noninvasive medical imaging technique that can quantitatively assess brain viscoelastic mechanical properties to provide sensitive measurements of neural tissue health. Previous work has shown that global brain (GB) tissue stiffness decreases with healthy aging due to neurodegeneration, and aging effects on regional stiffness, such as in the hippocampus (HC), may be related to cognitive decline. We aim to

understand how HC stiffness changes with age, and, for the first time, how stiffness of individual HC subfields (HCsf) are differentially affected by age. Twenty-eight healthy subjects (22-74 years) were imaged on a 3T Siemens Prisma MRI scanner with a protocol including: (1) MRE scan at a 1.25 mm isotropic resolution with 50 Hz vibration; (2) T_1-weighted MPRAGE scan at 0.9 mm isotropic resolution; and (3) high-resolution T_2-weighted hippocampus scan at 0.4x0.4x2.0 mm^3 resolution. Whole-brain maps of stiffness were estimated from MRE data using a nonlinear inversion algorithm (NLI). FreeSurfer 6.0 was used to segment the bilateral HC and bilateral HCsf (dentate gyrus/CA4 (DG-CA4), CA1, and subiculum (SUB)) from T_1- and T_2-weighted images. Individual regional volumes were registered to MRE space. GB ($r^2 = 0.815$, $p < 0.001$) and HC ($r^2 = 0.364$, $p = 0.004$) stiffness exhibited quadratic relationships with age. In older adults (>50 y, n=16), GB and HC stiffness exhibited strong, linear decreases with age (GB: $r = -0.841$, $p < 0.001$; HC: $r = -0.674$, $p = 0.004$), while in younger adults (<50 y, n=12), GB and HC stiffness did not significantly correlate with age (GB: $r = -0.075$, $p = 0.818$; HC: $r = 0.299$, $p = 0.345$). Stiffness of each individual HCsf in the older group also displayed significant linear correlations with age (DG-CA4: $r = -0.692$, $p = 0.003$; CA1: $r = -0.588$, $p = 0.017$; SUB: $r = -0.695$, $p = 0.003$). To examine differential trajectories of HCsf stiffness with age, we also normalized each HCsf by whole HC stiffness. Normalized DG-CA4 ($r = -0.630$, $p = 0.009$) and CA1 ($r = 0.521$, $p = 0.038$) significantly correlated with age (though in different directions), while normalized SUB ($r = 0.179$, $p = 0.506$) did not exhibit a significant relationship with age. This suggests that, compared to whole HC stiffness, CA1 stiffness declines slower with age while DG-CA4 stiffness declines faster. Overall, our results confirm previous reports of brain softening with increasing age, especially in older adults. Notably, we also report that the stiffness of individual HCsf exhibit different rates of decline indicating a differential sensitivity of HCsf integrity to aging. Future analyses may use MRE of the HCsf to probe memory performance and impairment in aging.

Title: Mediation of age and hippocampal volume by temporal lobe white matter hyperintensities differ in relation to APOE e4 status in healthy older adults

Authors: *E. J. VAN ETTEN[1,6], P. K. BHARADWAJ[1,6], G. A. HISHAW[2], T. P. TROUARD[3,6], G. E. ALEXANDER[1,4,5,6,7];
[1]Dept. of Psychology, [2]Dept. of Neurol., [3]Dept. of Biomed. Engin., [4]Dept. of Psychiatry, [5]Dept. of Neurosci. & Physiological Sci. Grad. Interdisciplinary Program, Univ. of Arizona, Tucson, AZ; [6]Evelyn F. McKnight Brain Inst., Tucson, AZ; [7]Arizona Alzheimer's Consortium, Phoenix, AZ

Abstract: While white matter hyperintensities (WMH) have been associated with hippocampal atrophy, less is known about how the regional distribution of WMH may differentially affect hippocampal volumes in healthy aging. Apolipoprotein E (APOE) ε4 carriers may be at an increased risk for WMH and greater hippocampal atrophy. The present study sought to investigate whether regional WMH mediate the relationship between age and hippocampal volume and whether this relationship is moderated by APOE ε4 status in healthy aging. A cohort of healthy adults (n=192, 94F/98M, mean±sd age=70.5±10.1, mean±sd Mini-Mental State Exam=29±1.2, APOE ε4 status (yes/no) = 59/133), 50 to 89 years of age were included. T1-weighted 3T volumetric MRIs were obtained and processed using Freesurfer (v5.3) software to obtain hippocampal volumes averaged across hemispheres. WMH in the four cerebral lobes were computed using T1 and T2 FLAIR scans and a lesion segmentation toolbox (Schmidt et al., 2012) with Statistical Parametric Mapping (SPM12). Total intracranial volume was computed for each participant using SPM12 to adjust hippocampal and WMH volumes for differences in head size. Mediation analyses were conducted with PROCESS macro software (Hayes, 2012) on SPSS, using bootstrap resampling with 10,000 iterations to produce bias corrected 95% confidence intervals. Temporal lobe WMH significantly mediated the relationship between age and average hippocampal volume, and this effect was moderated by APOE ε4 status (-.02 (SE=.01), 95% CI, [-.04, -.003]. APOE ε4 carriers, but not non-carriers, showed negative indirect effects of age on hippocampal volume through temporal lobe WMH (APOE ε4 carrier: -.02 (SE=.01), 95% CI, [-.03, -.003]; APOE ε4 non-carrier: .00 (SE=.01), 95% CI, [-.01, .02]). These findings remained significant after additionally adjusting for sex, years of education, and hypertension status. There were no significant mediation effects for frontal, parietal, and occipital lobe WMH, with or without covariates. The results indicate that the effects of aging on hippocampal volume are mediated by WMH regionally localized to the temporal lobes and that this effect depends on APOE ε4 carrier status. Together, these findings suggest that differences in hippocampal volumes observed in the context of healthy aging may be in part related to the influence of APOE ε4 on WMH and associated vascular mechanisms. Further research is needed to evaluate how regional WMH may influence other neuroanatomical effects of brain and cognitive aging.

Abstract: As humans age, their vasculature becomes stiffer and less responsive to vasoactive stimuli. This stiffening, however, is not equal throughout all levels of vasculature. The levels of cerebral vasculature start with pial arteries just outside the parenchyma, from which penetrating arteries descend into brain tissue. These penetrating arteries then multifurcate into smaller arterioles and then into even smaller capillaries. At each level, the vascular structure is distinct, and the biological factors that contribute to aging and age-related vascular pathology impact each level in different ways. We hypothesize that these level-specific effects mediate age-related changes in brain function and cognition. In this study, we sought to ascertain whether differences in vascular reactivity across layers of cortex contribute to processing speed differences between younger and older adults. We used a measure called arteriovenous compliance (AVC), derived from the arterial cerebrovascular reactivity (CVR_a) and venous cerebrovascular reactivity (CVR_v), in different cortical layers to see if the reactivity across layers corresponded to the processing speed changes characteristic of aging. Relationships between AVC and processing speed were stronger in younger adults than in older adults. The results implicate neural-vascular coupling dysfunction in age-related cognitive slowing.

Title: Age-related impairments for maintaining separate memories for highly similar experiences in mice and humans

Authors: *B. S. KOLARIK, A. A. KEISER, S. M. STARK, M. A. WOOD, C. E. STARK; Univ. of California Irvine, Irvine, CA

Abstract: Aging brings about structural and functional changes in the hippocampus, which lead to impairments in the ability to encode and maintain memories for competing stimuli. Failures of pattern separation, a hippocampal computation that allows highly similar inputs to be represented distinctly, with minimal overlap, may underlie this impairment. Here, we hypothesized that age-related memory impairments are, in part, driven by a decrease in the ability to separate and maintain distinct memories for similar experiences. To test this hypothesis, we developed parallel tasks for both mice and humans that evaluate memory for similar experiences. In experiment 1, both young (9 week) and old (18 month) mice learned objects in two locations (A-B). Later, one of the objects was moved to a new location (A-C). At test, mice were presented with objects in 4 locations (A-B-C-D) and exploration time for each items was quantified, with longer exploration times expected for novel object-location pairings. In contrast to younger mice, older mice showed no preference for any of the object-locations, including the novel object (D), suggesting that older mice generalized the object-location pairings without separating the original and updated experiences into distinct events. In contrast, younger mice showed a preference for the novel object-location, indicating that they were able to maintain memories for the experience of both the original (B) and updated (C) locations. In experiment 2, we tested younger (18-24y) and older (60-80y) human participants on their ability to maintain separate memories for two similar experiences, using images of everyday objects in a continuous recognition paradigm. Later, some images were repeated, along with new items and highly similar lures. At test, participants were presented with two similar images simultaneously and responded with which images they had seen previously (original, lure, both or neither). There were no age-related differences in performance for repeated or new items, however on those trials where both images had been previously seen, older adults were significantly less likely to indicate that they had seen both, suggesting that they had a single memory, dominated by the most recent event, where younger participants are able to maintain two distinct memories for

highly similar events. Thus, across two experiments in both mice and humans, we find evidence that aging impairs the ability to separate and maintain memories for two highly similar, overlapping experiences, likely resulting from failed pattern separation and increased pattern completion processes, which leads to a more generalized memory representation.

Title: Interactive effects of sex and BDNF Val66Met polymorphism on cognition in older adults

Authors: *S. MATIJEVIC[1], M. ELIAS[1], M. J. HUENTELMAN[2], L. RYAN[1];
[1]Psychology, Univ. of Arizona, Tucson, AZ; [2]Neurogenomics, The Translational Genomics Res. Inst., Phoenix, AZ

Abstract: Brain-derived neurotrophic factor (BDNF) promotes synaptogenesis and neurogenesis, and may play a critical role in supporting plasticity mechanisms underlying hippocampal-dependent memory. The BDNF gene Val66Met polymorphism contributes to individual variation in BDNF secretion, as carriers of the Met allele have abnormally reduced BDNF levels. Consequently, the Met allele has been shown to negatively influence hippocampal function, and in turn, episodic memory. This has implications for cognitive aging, given the susceptibility of the hippocampus to age-related damage and dysfunction. Indeed, the Met allele has been linked to enhanced memory deficits in older adults. To a lesser degree, BDNF has been implicated in the relationship between age and other cognitive domains, such as executive functioning. Evidence from the animal literature indicates that BDNF protein expression may differ by sex, as estrogen appears to regulate BDNF expression in the brain. Sex may therefore moderate the relationship between the Met allele and cognitive performance. The present study thus aims to characterize how the interactions between age, sex and the BDNF Met allele affect memory and executive function performance in older adults.
Neuropsychological testing and genotyping was carried out for 268 cognitively normal older adults (mean age = 72.27, ages 60-90). Participants with a BDNF Met/Met or Val/Met genotype were classified as Met allele carriers. Memory and executive function composite scores were

calculated from the neuropsychological test data (Glisky & Kong, 2008). Univariate GLMs were run to assess interactions and main effects of age, sex and BDNF Met carrier status on the composite scores.
For the memory composite scores, significant effects were found for Age ($F = 22.73$, $p < 0.001$), Sex ($F = 36.32$, $p < 0.001$), and the three way interaction between Sex, Carrier status, and Age ($F = 5.038$, $p = 0.026$). Females scored higher than males. While this difference increased with age among the Met non-carriers, it lessened among the carriers, as the memory composite scores negatively correlated with age only in the carrier females and non-carrier males. For the executive function scores, the effects of Age ($F = 9.95$, $p = 0.002$) and Sex x Carrier status interaction ($F = 6.61$, $p = 0.011$) were statistically significant. Male carriers performed better than both non-carrier males and carrier females.
BDNF carrier status is shown to interact with sex to influence both memory and executive function performance. These results suggest that the presence of the met allele may be less detrimental for males than for females, and perhaps even beneficial in regards to executive functioning.

Title: Age-related changes in gray and white matter neurite density and diffusion within hippocampal subfields and the medial temporal lobe reflect memory performance

Authors: *H. RADHAKRISHNAN, S. M. STARK, C. E. L. STARK;
Univ. of California, Irvine, Irvine, CA

Abstract: Data from both human and animal models support the hypothesis that age-related alterations in hippocampal connectivity (e.g., fornix and perforant path) contribute to age-related memory decline. Recent advances in diffusion weighted imaging (DWI) have given us the ability to have a far more comprehensive view of these microstructural changes. In particular, Neurite Orientation Dispersion and Density Imaging (NODDI) lets us study diffusion not only in white matter, but in gray matter as well, letting us determine whether microstructural changes in gray matter also correlate with memory decline. We performed diffusion weighted imaging and structural MRI on 25 young (20-39; 12M) and 26 older (60-84; 11M) healthy adults. We used both fixel-based analysis and NODDI analyses to identify age-related changes in the medial

temporal lobe. Using the well-established age-related change in diffusion within the fornix, we first replicated this effect using an analysis of fiber orientation distributions via spherical deconvolution (MRTrix3), demonstrating that the overall fornix fiber density (FD) linearly decreases with age while fiber cross-section (FC) of the fornix linearly increases. We also found that fornix FD and FC were correlated with cognitive performance on the Rey Auditory Verbal Learning Test (RAVLT) and Mnemonic Similarity Task (MST). We then applied the NODDI model to the fornix and found that Free Water Volume Fraction (FISO) significantly increased with aging. Turning to diffusion within gray matter, we observed that the local neurite density index (NDI) increased with age (indicating more hindered gray matter diffusion) in the dentate gyrus (DG), CA1, and subiculum. We also observed that FISO decreased in all grey matter segments of the medial temporal lobe (save the entorhinal cortex) in stark contrast to its relationship with white matter. More importantly, we observed that the FISO (which was modulated by age) was significantly correlated with RAVLT scores in only the DG and the CA1, further supporting the idea that structural modulations in these regions primarily contribute to cognitive deficits in the aged population. These results not only shed more light into system-wide changes in tissue types, but also demonstrate that DWI is evolving into a tool to study more than just white matter changes, and might be in a unique position to resolve structural differences in gray matter more effectively.

Title: Age-related reductions in functional connectivity in social brain systems during an economic trust task

Authors: *N. M. HENNINGER[1], V. KELLY[2], K. HACKETT[2], D. S. FARERI[5], S. KATTA[2], L. J. TEPFER[2], C. REECK[3], T. GIOVANNETTI[2], E. C. BEARD[4], J. DENNISON[2], B. MUZEKARI[2], D. F. DESALME[2], R. KINMARTIN[2], A. LANG[2], J. M. CIPRIASO[2], E. HUNTER[2], C. MORRISON[2], D. V. SMITH[2];

Abstract: Positive social interactions are often built upon trust and reciprocity, signals which facilitate learning about others and maintaining close relationships. We have previously demonstrated that neurocomputational representations of reciprocity vary with respect to our relationship with an interaction partner (De Quervain et al., 2005; Delgado, Frank, & Phelps, 2005; Fareri & Delgado, 2014; Fareri, Chang, & Delgado, 2012; King-Casas et al., 2005). However, given that the nature of our relationships and susceptibility to social influence change across the lifespan, an important outstanding question is how decisions to trust close and unknown others change between young and older adults. To address this issue, we sought to characterize the relationship between decisions to trust familiar and unfamiliar others when sharing money, and whether there is a difference in this process based on age. We recruited 32 participants (20 younger adults, ages 20 - 35; 12 older adults, ages 65 - 80). Participants performed an economic trust game in an fMRI scanner in which they were presented with decisions to share (i.e., invest) money (up to $8 on a given trial) with either a same-sex friend (who also attended the session), a same-sex and age-matched stranger (confederate), or a computer (task based on Fareri, Chang, & Delgado, 2015). Participants received feedback on each trial as to whether the person they were sharing with chose to reciprocate or not. We found that participants shared more money with friends in comparison to computers ($t(31)=4.31$, $p<.001$), and also shared more money with friends than strangers ($t(31)=3.00$, $p<.001$). However, this social network effect did not interact with age ($F(31)=1.48$, $p=.223$). Replicating our prior work, we found that reciprocated trust (relative to unreciprocated trust) evoked activation in the ventral striatum. This study extends our prior work by demonstrating that younger adults (compared to older adults) exhibited enhanced functional connectivity between the fusiform face area and precuneus (cluster-defining threshold of $Z > 3.1$, FWE = 0.05, corrected). Taken together, these results demonstrate that cognitive aging is associated with alterations in functional connectivity within social brain systems. Understanding how social decisions involving trust and social closeness change across the lifespan main help shed light on the mechanisms that increase vulnerability to financial fraud in older adults.

Title: Individual differences in neural differentiation during episodic encoding predict associative retrieval in putatively healthy older adults

Authors: *M. B. HARRISON[1], V. A. CARR[4], N. CORSO[1], G. DEUTSCH[1], C. FREDERICKS[1], S. GUERIN[1], W. GUO[5], M. HUNT[1], M. JAYAKUMAR[6], J. JIANG[2], G. A. KERCHNER[3], A. M. KHAZENZON[1], C. WAGNER[1]; [2]Psychology, [1]Stanford Univ., Stanford, CA; [3]Stanford Univ., San Francisco, CA; [4]Psychology, San Jose State Univ., San Jose, CA; [5]Psychology, Univ. of Oregon, Eugene, OR; [6]Columbia Univ., New York, NY; [7]John Hopkins Univ., Baltimore, MD; [8]Neurol. and Neurolog. Sci., Stanford, Stanford, CA

Abstract: The magnitude of age-related episodic memory decline varies across older adults, raising fundamental questions about the causes of individual differences in memory late in the lifespan. One factor that is hypothesized to contribute to diminished memory in older adults is dedifferentiation — that is, a reduction in the specificity of cortical patterns that represent event features during encoding. To investigate the relationship between dedifferentiation at encoding and subsequent associative retrieval, the Stanford Aging and Memory Study collected high-resolution fMRI data while putatively 'healthy' older adults (N=100; age 60-88; CDR=0) encoded words paired with either a face or a place. Following encoding, participants encountered studied and novel words, and indicated whether they recalled the associate that had been paired with the word (face or place), whether they recognized the word as old in the absence of associative recall, or whether they perceived the word as new. FMRI analyses on data from targeted regions of interest entailed computing neural pattern similarity across encoding events, yielding measures of within-category similarity and between-category similarity. First, we explored whether neural differentiation (within category similarity > between category similarity) varied with age. Analyses revealed that differentiation declined over the later decades of life, with an age-related decrease (a) for faces in angular gyrus (p=0.01) and parahippocampal cortex (PHC) (p=0.001), and (b) for places in ventral temporal cortex (p=0.0001) and PHC (p=0.004). Second, we explored whether individual differences in neural differentiation partially account for differences in memory performance. Analyses revealed that, after controlling for age, neural differentiation in PHC was associated with better associative memory for places (β =3.59, p=0.03). Finally, a meditation analysis revealed that the relationship between age and associative memory was significantly mediated by neural differentiation for places in PHC($F_{(2,97)}$=6.58, p=0.002). These results suggest that cortical neural differentiation during encoding contributes to both age-related and individual differences in episodic memory late in the lifespan.

Title: Cognitive reserve over different life stages in association with cognitive performance in healthy elderly

Authors: *C. GARCÍA-CAMACHO, T. VILLASEÑOR-CABRERA, M. JIMÉNEZ-MALDONADO, F. JÁUREGUI-HUERTA, J. RUÍZ-SANDOVAL;
Univ. De Guadalajara, Guadalajara, Mexico

Abstract: Cognitive reserve refers to factors that generate protection and favors recovery against brain injury or cognitive decline. This reserve arises through the life course and the activities that integrate it could vary such as its frequency.*Objectives:* To investigate if there's a life stage associated with the acquisition of more cognitive reserve and to identify the protective activities associated with a better cognitive performance during elderly.*Methods:* Descriptive, transversal and retrospective study. We included 61 healthy subjects ranging from 60 to 70 years old. People with a history of substance abuse, psychiatric disorders or traumatic brain injury were excluded. Cognitive function was measured with the Montreal Cognitive Assessment (MoCA), Phonological Fluency (PF), Digit Span and Vocabulary subtest (WAIS-IV). Cognitive reserve was obtained with Cognitive Reserve Questionnaire (CRC) and protective activities frequency was investigated with the Escala de Reserva Cognitiva y Envejecimiento (ERC).*Results*: The mean age was 63.9 y.o (SD=3.0), 73.8% were women. The average for education was 12.8 years (SD=5.2). 41% of analyzed subjects were retired, 36% still working and 23% never had formal job. The mean MoCA score was 25.3 points (SD=1.6), Digit Span subtest's average score was 9.3 points (SD= 2.1), Vocabulary subtest's score was 9.8 points (SD= 1.9), and mean Phonological Fluency was 13.6 words per minute (SD=3.4). 3.3% of the subjects evidenced low range cognitive reserve, 11.5% had a middle-low range, 47.5% had a middle-high range and 37.7% had a high range cognitive reserve. The stage of life where more cognitive reserve activities were reported was the late stage (41-60 y.o) (M=58.5, SD=9.1), followed by middle stage (21-40 y.o) (M=57.9, SD=10.4) and finally the early stage (first 20 years of life) (M=46.9, SD=13.7).Some daily activities like economy management, housework and basic technology use are present in all life stages; meanwhile academic activities or advanced technology use are more present on mid and late stages. Regarding hobbies, the most frequent activities during all life

stages are reading, watching television, listening music and exercise. Social interaction with diverse generations was the most frequent social activity in all life stages.*Conclusion*: Our results evidenced a strong association between high cognitive reserve and better cognitive performance in healthy subjects. The activities most frequently reported were those related to day-by-day functioning, knowledge acquisition, hobbies and practice of social skills. No differences were seen between life stages when correlated to generating activities.

Title: Resveratrol, a calorie restriction mimetic for the treatment of Alzheimer's disease: A preclinical investigation

Authors: *V. BENADE[1,2], P. JAYARAJAN[1], N. KRISHNADAS[2], V. KAMUJU[1], S. GANDIPUDI[1], R. NIROGI[1];
[1]Suven Life Sci. Ltd., Hyderabad, India; [2]Pharmaceut. Sci., Manipal Acad. of Higher Educ., Manipal, India

Abstract: The major barrier in understanding Alzheimer's disease (AD) is a lack of knowledge about the etiology and pathogenesis of neuronal degeneration. Research in recent years accrued considerable data indicating the possible involvement of increased oxidative stress and free radicals in the pathogenesis of neuron death in AD. Tissue injury itself can induce reactive oxygen species (ROS) generation. Although, it is not known whether free radical generation is a primary or secondary event to other initiating causes, they are harmful and part of a cascade of events that can lead to neuronal death, suggesting that therapeutic efforts aimed at removal of ROS or prevention of their formation may be beneficial in AD. Resveratrol is a polyphenol found in red wines and in various plants, including grapes, berries and peanuts. Various *in vitro* and *in vivo* studies demonstrated antioxidant properties of resveratrol in addition to its other biological attributes, like anti-inflammatory activities, anti-platelet aggregation effect and anti-atherogenic property. Additionally, studies have provided insights into the effect of this compound on the life span of yeasts and flies, implicating the potential of resveratrol as an anti-aging agent. Due to the antioxidant and anti-aging properties, resveratrol has a potential in the treatment of age-related neurodegenerative disorders and in the current preclinical investigation resveratrol was evaluated as a potential treatment approach for AD. Rats were treated with Aluminium chloride (AlCl3; 10 mg/kg, i.p.) for 20 days for induction of oxidative stress leading

to neurodegeneration. Animals were treated with resveratrol (10, 15 and 30 mg/kg, p.o.) in parallel to AlCl3. Control group of rats received either saline alone or AlCl3 alone. Animals were subjected for evaluation in object recognition task followed by assessments of biomarkers (Malondialdehyde, glutathione, BDNF and SIRT-1 expression). Impaired cognitive abilities were observed in rats treated with AlCl3 alone; however resveratrol produced significant improvement in the cognitive performance at the highest dose tested. Similarly, oxidative stress evaluated through the measurement of malondialdehyde, glutathione was increased in animals treated with AlCl3, and resveratrol produced decrease oxidative stress. SIRT-1 and BDNF expression were found to be increased after the treatment of resveratrol. Results from current studies indicate potential benefits of resveratrol in the pharmacotherapy of AD through improvement of anti-aging properties.

Title: Association between telomere and brain in large population study

Authors: *R. E. KIM[1], C.-H. YUN[3], R. THOMAS[4], I. BAIK[5], C. SHIN[2];
[1]Korea Univ., Ansan, Korea, Republic of; [2]Korea Univ., Seoul, Korea, Republic of; [3]Bundang Seoul Natl. Univ. Hosp., Bundang, Korea, Republic of; [4]Harvard Univ., Boston, MA; [5]Kookmin Univ., Seoul, Korea, Republic of

Abstract: Objective Prior studies have found a possible association of telomere attrition with small brain volumes and decreased cognitive function. This study is to access whether telomere length, as an indicative of a potential modifier of brain aging, interacts with age for brain volume and cognitive performance in mid-to-late adulthood. Prior studies have found a possible association of telomere attrition with small brain volumes and decreased cognitive function. **Methods** The present study investigated 1831 cognitively normal individuals. All subjects and data used in this study were derived from the Ansan Korean Genome Epidemiology Study. In

total, 5 brain sub-regions from magnetic resonance imaging and 15 cognition tests were analyzed with relative telomere length (TL) groups. **Conclusions** Telomere length seems related to both brain volume and cognitive function. In addition, longer TL may indicate relative protection from cognitive decline associated with aging. Our data sets the state for longitudinal analysis of TL effects on brain aging.

Title: Impact of apolipoprotein E and depression symptom on cognitive decline and white matter alteration in healthy aging adults

Authors: *H. AHN[1], R. KIM[1], S. KIM[1], C. SHIN[1,2];
[1]Inst. for Human Genomic Study, Col. of Med., Korea Univ., Seoul, Korea, Republic of; [2]Dept. of Intrnl. Med., Korea Univ. Ansan Hosp., Ansan, Korea, Republic of

Abstract: Introduction: The E4 allele of apoliprotein E (APOE) is the major genetic risk factor for Alzheimer's disease (AD). Previous studies have reported synergetic interaction between depressive symptoms and APOE E4 on risk of developing incident AD and mild cognitive impairment (MCI). Although significant relationships between depression symptoms and incident AD and MCI were observed in E4 carriers, the neurocognitive decline of this relationship in healthy aging adults was not fully reported. The aim of this study was to investigate the cognitive decline and possible cerebral modification of white matter integrity on depression symptom in APOE E4 and E3 carriers using diffusion tensor imaging (DTI).
Methods: A cohort of 2213 cognitively normal elderly adults from Korean Genome Epidemiology Study were evaluated. All participants underwent a brain MRI scanning and a comprehensive neuropsychological test battery that included memory and executive function measures. Participants were also asked to answer questions on the Beck Depression Inventory (BDI) to measure levels of depressive symptoms. Participants were divided in to one of four group base on result from BDI and genomic testing: depressed E4 carrier (n=80), non- depressed E4 carrier (n=386), depressed E3 carrier (n=364), and non-depressed E3 carrier (n=1483). The T1 weighted images were acquired in addition to 16 diffusion weighted images in a 1.5T MR scanner. The imaging data were processed using FSL´s Diffusion Toolbox; Tract Based Spatial Statistics (TBSS).
Results: A linear regression analysis showed that depressed subjects with APOE E4 carriers showed significantly lower Digit Symbol Test score ($p = 0.004$) and Trail Make Test score ($p = 0.013$) compared with non-depressed subjects who were also E3 carriers. Whole-brain WM integrity was analyzed using non-parametric t-tests and permutations. The results showed significant difference between depressed APOE E4 carriers and non-depressed APOE E3 carriers in multiple area such as frontal part of the right Inferior fronto-occipital fasciculus, bilateral superior longitudinal fasciculus, and right corticospinal tract regions ($p < 0.05$).
Conclusions: We found synergetic interaction between APOE genotype and depression symptom on executive function and white matter alteration. These findings provide an evidence for the high risk of developing incident AD and MCI in depressed adults with E4 carriers.

Title: Visuospatial/executive function in mild cognitive impaired patients correlate with performance in the visible-platform stage of a virtual navigation task

Authors: *N. K. ROGERS[1], C. SANMARTIN[2,3], D. P. PONCE[2], J. VALDÉS[2], M. I. BEHRENS[2];
[1]Univ. De Chile, Santiago, Chile; [2]Univ. de Chile, Santiago, Chile; [3]Univ. Mayor, Santiago, Chile

Abstract: Amnestic mild cognitive impairment (aMCI) is recognized as a prodromal stage of Alzheimer's disease (AD). The hippocampus is recognized as an important structure compromised in AD, as observed in early disturbances in memory in aMCI and AD patients. Changes in spatial navigation have also been described in virtual Morris Water Maze (vMWM) navigation tasks. Correlations between vMWM performance and other cognitive functions besides memory, such as visuospatial and executive functions, have only been previously reported in younger population (Korthauer et al., 2017). The role of these functions in vMWM performance of MCI and AD patients has not been previously characterized, in spite of evidence supporting that visuomotor integration is impaired both in cognitively healthy elderly population and early stages of dementia. Our aim was to investigate the correlation between scoring of the visuomotor/executive sub-items of the Montreal Cognitive Assessment (MoCA) and performance in a vMWM-like navigation task. We recruited 38 patients (20 healthy controls and 18 patients with aMCI diagnosis. Montreal Cognitive Assessment (MoCA) and Clinical Dementia Rating were used as tools for diagnosis. There was no significant epidemiological differences between groups in age, sex, comorbidities and educational level. Spatial navigation was tested through a three-staged version of a vMWM of increasing complexity; stage one has a visible platform and stages two and three describe predominantly egocentric and allocentric spatial navigation, respectively. A main component named "Efficiency score (ES)" was extracted with Principal Component Analysis (PCA). aMCI patients had an overall worse vMWM performance when compared with healthy controls (ES = 0.2479434 vs -0.2754926 AU, $p < 0.001$ t-test), observed in the first two stages. Age was an independent variable for overall vMWM performance in controls but not in aMCI patients. aMCI patients performed worse in the visuospatial/executive (VE/E) MoCA-sub-item score (3.5 vs 4.65 points, $p < 0.05$ t-test) (Total

MoCA score was 20.6 in aMCI vs 28.6 points in controls, p <0.0001, t-test). The VE/E score was significantly correlated with the overall performance in the vWMW for all subjects, even when normalized by age (pearson's correlation, r=0.3999 p<0.05). aMCI patients vMWM's performance in stage1 (visible platform test) also significantly correlated with VE/E scoring (pearson's correlation, r=0.5093 p<0.05), while in control patients it did not.

Title: The role of the dopaminergic and noradrenergic system in episodic memory

Authors: ***Y.-J. YI**[1,2], F. LÜSEBRINK[2], D. HÄMMERER[1], O. SPECK[3], E. DÜZEL[1]; [1]German Ctr. for Neurodegenerative Dis., The Inst. For Cognitive Neurol. and Dementia Res., Magdeburg, Germany; [2]Fac. of Med., [3]Fac. of Natural Sci., Otto-von-Guericke-Universität Magdeburg, Magdeburg, Germany

Abstract: A large body of evidence suggests that progressive cell loss in midbrain and brainstem neuromodulatory structures is significantly implicated in age-related decline in memory function, and they are among the first structures affected in dementia. However, it is currently unclear how a functional decline of noradrenergic and dopaminergic brain structures relates to altered memory capacities. To address this question, our project will use memory-encoding paradigms

tailored to assess the involvement of dopaminergic and noradrenergic modulation. Specifically, a reward-and-punishment and oddball paradigms are used to potentially induce cerebral DA and NA release. We hypothesised that the reward-associated stimuli would show a higher hit rate than the others during the delayed recall phase. Twelve subjects performed 4 tasks throughout 2 sessions. In the first session, they performed a reward task where the subject was asked to classify scene pictures into two categories and was given either a reward or punishment depending on the counterbalanced contingency condition. Afterwards, an immediate recall memory test and an oddball task with face stimuli followed. During the first session, 3-Tesla structural and functional magnetic resonance imaging scans (MRI), concurrent pupil dilation, which is a proxy indicator for NA activity, and behavioural indicators such as reaction time, recall accuracy, and recall confidence were collected. After a 2-hour break, participants performed a delayed recall test; only behavioural and pupillometric data were collected. Behavioural data analyses of memory tests show that the hit rate of the punishment-associated stimuli was higher. Moreover, pupil dilation for punishment-associated stimuli during delayed recall was significantly larger. Pupil dilation was larger for the oddball condition than standard condition. More data are required for robust analyses and further conclusions. Based on the final results after further data collection, the main study using 7-Tesla MRI and concurrent MRI-positron emission tomography will be conducted to assess functional correlates of reward-related dopamine release and high resolution structural and functional imaging of the noradrenergic system. The results are expected to contribute to obtaining a more comprehensive view of altered neuromodulatory systems in the context of healthy ageing and shed light on how it manifests in altered episodic memory.

Title: The effects of cardiovascular risks on task switching in healthy older adults: An fMRI study

Authors: *S. QIN[1], C. BASAK[2];
[2]The Ctr. for Vital Longevity, [1]Univ. of Texas at Dallas, Dallas, TX

Abstract: Arterial plasticity and physical fitness, both factors of cardiovascular risk, have been independently associated with older adults' fMRI activations during executive functions. However, no fMRI study has investigated the combined effects of these two factors on executive

functions related brain activations in older adults. In the current fMRI study, we examined not only the separate, but also the combined, effects of these two cardiovascular risk factors on brain activations during task switching in healthy older adults. A hybrid design task switching paradigm (Basak et al., 2018; Nashiro et al., 2018) was used, allowing examination of both sustained (global switch cost, GSC) and transient (local switch cost, LSC) activations. Sixty healthy older adults (M_{age}=70) were recruited for this study, and their data were compared to existing fMRI task-switching data from 28 younger adults (M_{age}=21). Arterial plasticity was measured by pulse pressure (systolic - diastolic blood pressure). Physical fitness was measured by metabolic equivalent (MET) of VO_2Max. Whole-brain group contrasts were conducted in older adults to examine the separate and combined effects of the two risk factors in GSC and LSC. Older adults with low arterial plasticity and low MET showed reduced suppression of default mode regions (e.g. bilateral lingual gyrus), than those with lower cardiovascular risk for GSC. Older adults with low MET showed increased activation for GSC in the left inferior frontal gyrus (IFG) than those with high MET. Furthermore, increased GSC activations in the left IFG was associated with worse task performance in older adults. Older adults with 2 risk factors showed reduced suppression in default mode regions and increased left IFG activation compared to older adults with lesser number of risk factors (0 and 1). Additionally, we examined task-sensitive regions of interest for GSC and LSC, defined from previously published studies (Basak et al., 2018; Nashiro et al., 2018). Older adults with low plasticity showed diminished neural modulation for transient task switching (LSC) in the left post central gyrus, compared to high plasticity old. Across all analyses, older adults with low cardiovascular risk (high plasticity, high fitness, and with 0 risk factor) showed similar activation patterns compared to younger adults. Such results suggested that high cardiovascular risk was associated with both maladaptive overactivation and reduced task-sensitive activation in healthy older adults.

Title: Striatal iron modulates neural signatures of working memory

Authors: *A. SALAMI[1,2], G. KALPOUZOS[2];
[1]Integrative Med. Biol., Umea; Univ., Umea, Sweden; [2]Karolinska Inst., Stockholm, Sweden

Abstract: Intracellular non-hem iron in the brain is involved in numerous biological processes, such as neurotransmitter synthesis, synaptic plasticity, and myelination, which are crucial for early life development. However, elevated iron content in old age has found to be deleterious for brain cells because of triggering oxidative stress. Given previous evidence for the association between iron and cognitive measures, it is plausible that such an association varies across different age groups. Moreover, iron content could directly impact brain activity via astrocytic dysfunction: the astrocytes, cells where iron concentration increases with aging, are involved in the neurovascular coupling on which the blood oxygen level-dependent (BOLD) signal measured with functional MRI (fMRI) relies. Here we investigated age-related differences in brain iron content and their associations with differences in working memory and concomitant alterations in brain activation across the adult lifespan. We found that striatal iron was negatively associated with working memory (but also episodic memory and processing speed) in the older group, whereas positive associations (for episodic memory and processing speed and a trend level for working memory) were found in the younger group. Critically, a significant pattern revealing positive and negative associations of striatal iron to BOLD response during working memory in the striatal-cortical circuit was observed in younger and older adults, respectively. Taken together, striatal iron was related to working memory ability and associated BOLD response in an age-dependent manner, and future research needs to shed light on a mechanism behind the age-varying relationship.

McKnight Brain Inst., Univ. of Arizona, Tucson, AZ

Abstract: Recently, our web-based cognitive study of over 75,000 individuals between the ages of 18-85 (www.mindcrowd.org) revealed that women's paired associates learning (PAL) performance was significantly higher at the fifth decade of life. Coinciding with this timepoint in a woman's life is menopause, marked by a cessation of ovarian hormones. Numerous studies have linked ovarian hormones and their cessation at menopause to cognitive changes in women. To evaluate potential links between menopause and cognition in our cohort, we developed a ten question menopause survey. Survey questions asked women about their contraceptive and hormone therapy use as well as if they had undergone an oophorectomy or hysterectomy. To date, over 7,130 women have completed the survey. We found the number of years that women reported using contraception was significantly associated with lower PAL performance (b=-0.034 word pairs/year of contraception, p=0.017). This effect was found after controlling for age, education, and several other factors related to PAL performance. This finding is in line with prior animal work linking contraception exposure to lower cognitive performance. This study helps further bridge the gap between animal and human studies and highlights the translational impact of contraception on cognition.

Title: Neurophysiological and neurocognitive correlates of obstacle avoidance behavior in older adulthood

Authors: *I. R. FLINT[1], A. R. WAARA[2], K. M. TREWARTHA[1,2];
[1]Dept. of Cognitive and Learning Sci., [2]Dept. of Kinesiology & Integrative Physiol., Michigan Technological Univ., Houghton, MI

Abstract: The objective of this research is to identify the neurophysiological and neurocognitive correlates that contribute to older adults' ability to make rapid evasive actions in response to sensory feedback during an ongoing movement. Rapid motor corrections allow us to make evasive actions, avoid knocking over objects in cluttered workspaces, and navigate around other people in crowded rooms. In the current research, we recorded electroencephalographic (EEG) signals while 18 older adult participants (*M* = 72.4, *SD* = 5.5 years old) and 18 young adult participants (M = 20.4, SD = 1.5 years old) used a robotic manipulandum (Kinarm, BKin Technologies) to correct for unpredictable visual "cursor shifts" while reaching for visual targets and avoiding visible haptic obstacles. Upon contact between the participants' cursor and the obstacles the robot applied a repulsive force to the hand, simulating a collision with a physical obstacle. On each trial the cursor briefly disappeared behind a rectangular occluder positioned in front of the start position, and emerged either unperturbed, or shifted by a small, medium, or large distance to the left or right of a straight line to the target. We focused our analyses on the behavior during the large jump condition, which uniquely required participants to switch hand paths around the outside of the obstacles, instead of between them, to be most efficient. Too assess neurocognitive correlates, we administered a battery of perceptuomotor, processing speed, and executive control tasks. We show that for older adults processing speed and executive control are significant predictors of the frequency of obstacle collisions. Additionally, when successfully navigating around the outside of the obstacles on large jump trials, movement times were predicted by measures of executive functioning in the older adults. To assess EEG correlates, we computed event-related potentials (ERP) associated with responses to the cursor shifts and conducted frequency analyses of the EEG data taken during the obstacle avoidance task. The results of this study add to the growing literature examining the neurophysiological impact of aging on adaptive motor behavior, as well as our understanding of the nature of neurocognitive contributions to rapid feedback control.

Title: Physical fitness as a protective factor against age related declines in executive processes of working memory: A fMRI study on cue predictability, updating and switching

Authors: *C. BASAK[1], P. SKOLASINKA[3], S. QIN[2];
[1]Ctr. for Vital Longevity, [2]Univ. of Texas At Dallas, Dallas, TX; [3]Ctr. for Vital Longevity, Univ. of Texas at Dallas, Dallas, TX

Abstract: Everyday cognition critically depends on working memory, the ability to maintain information and adaptively update it. An important function of working memory is not just to retain the information in a capacity-limited short-term store, but the executive processes that control the information. This study is designed to determine the age-related differences in brain activation during these executive processes, and whether physical fitness could protect against age-related declines in some, if not all, of these processes. Although fitness is associated with changes in brain activations in older adults during executive processes of dual tasking and inhibition, these studies lacked data from younger adults, the functional control, to help interpret the fMRI results. Moreover, they did not investigate fitness effects on brain activations related to the executive processes of working memory.
We investigated fMRI activations using a hybrid blocked and event-related design 2-Match task. Three different types of executive processes were evaluated during working memory: cue-predictability (Predictable vs. Unpredictable), updating, and switching. We recruited 48 adults: Young, Low Fit Old (LF) and High Fit Old (HF); *n=12* in each group. LF and HF older adults differed significantly in physical fitness [measured by Metabolic Equivalent of VO_2Max, MET]. Young adults, compared to old, had higher accuracy. Importantly, higher fitness in old was associated with higher accuracy ($r = .519$, $p = .004$).
Whole-brain fMRI analyses identified distinct brain regions associated with predictable cues, unpredictable cues, and updating. Moreover, results from older adults showed increased activations in R SMG during predictable condition for LF, not HF. This increased activation in LF is maladaptive, because higher activity in R SMG in old was correlated with worse performance in predictable condition ($r=.35$). For updating, however, HF showed increased activations in R frontal cluster (DLPFC, IFG) and the precuneus. Moreover, increased activation in the precuneus during updating was correlated with higher accuracy ($r = .49$, $p = .008$). We conclude that physical fitness might play an important role in preserving executive processes, esp. updating information, and its related brain functions among older adults. Patterns of neural modulation in response to increased updating demands were similar across HF older adults and young. In contrast, increased activity in LF, compared to HF and Young, is deemed maladaptive.

Title: Cingulate function in typical cognitive aging

Authors: R. J. BERTHIAUME[1], S. M. NYABWARI[2], J. T. LEE[3], *J. V. PARDO[4];
[1]Biosci., [2]Continuing Educ., Univ. of Minnesota, Minneapolis, MN; [3]Cognitive Neuroimaging Unit, [4]Dept. Psychiatry, Univ. of Minnesota, Minneapolis Veterans Hlth. Care Syst., Minneapolis, MN

Abstract: The anterior cingulate cortex (ACC) undergoes marked changes in metabolism that correlate with declining executive function during typical cognitive aging. In contrast, although the posterior cingulate cortex (PCC) is among the first regions to undergo hypometabolism and amyloid deposition in early Alzheimer's disease, its metabolism is relatively stable with typical aging. The ACC and PCC are themselves densely interconnected anatomically and functionally. Here, we analyze publicly-available and published data from ADNI (A); Pardo et al. *Neuroimage* 35:1231 (2007) (B); Andrews-Hanna et al. *Neuron* 56: 924 (2007) (C); and Goyal et al. *Cell Metab* 25:353 (2017) (D) to examine cingulate function during aging. All subjects were cognitively intact; some (A-C) had amyloid imaging. The ACC showed a much greater metabolic decline than the PCC during aging. The smaller sample (N = 46) with wider age range (18-91) in B produced highly significant aging-related declines in the ACC but not in the PCC. The larger sample beginning at age 55 years in A showed significant decline in both ACC and PCC metabolism, but the correlation with age for the ACC was significantly greater than for the PCC. The large N (over 200) in A enabled identifying statistically ACC metabolism as a mediator between executive function and aging. The ACC and PCC functional connectivity (C) from BOLD timeseries did not change under age 35 years but declined precipitously after 60 years even when amyloid negative as reported previously in B. Aerobic glycolysis (D) in both ACC and PCC declined markedly from young adulthood to age 50 years without change afterward. This did not occur in control regions such as primary sensory cortices. Static intersubject connectivity (i.e., correlation between ACC and PCC metabolism across subjects within a sliding window for age) was grossly constant in young adulthood but declined with further aging. Thus, the ACC shows marked decline in metabolism and AG in young to middle adulthood, while in later life there appears a dissociation. ACC/PCC functional connectivity remained stable in younger adults but declined in later older adulthood. The results highlight dissociations in ACC and PCC function with aging. The decline in ACC metabolism and AG does not appear related to disconnection between the ACC and PCC.

Title: Frontostriatal white matter connectivity declines with age and predicts cognition and dynamic BOLD modulation

Authors: *C. E. WEBB, D. A. HOAGEY, K. M. RODRIGUE, K. M. KENNEDY;
Ctr. for Vital Longevity, The Univ. of Texas at Dallas, Dallas, TX

Abstract: Frontostriatal circuitry is important for several regulatory activities, with dorsal prefrontal - dorsal striatal pathways specifically involved in aspects of cognitive control. The prefrontal cortex and striatum are among the structures most sensitive to effects of aging, yet the study of the pathways connecting these regions is limited. White matter connections are particularly vulnerable to aging, thus knowledge of frontostriatal pathway aging will be beneficial to understanding age-related and individual differences in cognitive control, as well as the function of these important gray matter regions. Here, we sought to examine age effects on frontostriatal white matter connections, and associations with both executive function performance and dynamic range of blood oxygen level dependent (BOLD) modulation to task difficulty. In a lifespan sample of 169 healthy adults aged 20-94 we used deterministic tractography to isolate a dorsal prefrontal - dorsal striatal white matter pathway. Frontostriatal fractional anisotropy (FA), a measure of the directionality of water diffusion, decreased linearly with age, while diffusivity metrics (mean, axial, and radial diffusivity) increased in a quadratic fashion across the lifespan. Frontostriatal diffusivity (but not FA) was associated with poorer executive function performance and this negative association strengthened with increasing age. Because age-related degradation of white matter likely influences the efficiency of communication between gray matter regions connected by white matter structure, we then examined whether age-related alterations of frontostriatal white matter connectivity were associated with functional modulation of BOLD activity in response to increasing working memory load on a digit n-back task. Whole-brain analysis results indicated an association between frontostriatal mean diffusivity and functional BOLD modulation selectively in the striatum. This association was moderated by age, such that younger and middle-aged individuals showed reduced dynamic range in response to increased difficulty as a function of increasing frontostriatal diffusivity. These findings illustrate that age-related alterations in frontostriatal

white matter negatively impact both executive function and dynamic range of functional modulation to cognitive challenge. Executive function performance showed sensitivity to frontostriatal aging across the age span, whereas frontostriatal effects on the ability to flexibly modulate striatal BOLD activity were apparent earlier in the lifespan, highlighting the importance of capturing brain changes occurring in middle adulthood.

Title: Longitudinal fluctuations in memory and executive function correlate with Alzheimer's disease pathology in non-cognitively impaired elderly

Authors: *M. MALEK-AHMADI[1], S. E. PEREZ[2], E. J. MUFSON[3];
[1]Banner Alzheimer's Inst., Phoenix, AZ; [2]Dept Neurobio., [3]Neurobio., Barrow Neurolog. Inst., Phoenix, AZ

Abstract: Although the use of within-subject measures to characterize changes in cognition is increasingly prevalent, few studies have investigated whether these measures of cognition correlate with hallmark Alzheimer's disease (AD) neuropathology. Previous work by our group found that higher subject-level variability between cognitive domains is associated with increased tau containing neurofibrillary tangles (NFTs), but not with beta-amyloid (Aβ) neuritic plaques (NPs) or diffuse plaques (DPs). Longitudinal studies indicate that higher NP and NFT burdens are associated with an increase in the rates of antemortem cognitive decline, however the degree to which year-to-year fluctuations in cognition are associated with AD neuropathology remains an underinvestigated area. Here we investigated whether antemortem within-subject fluctuations in cognition correlate with post-mortem measures of AD neuropathology. Longitudinal cognitive data from 106 non-cognitively impaired (NCI) subjects from the Rush Religious Orders Study were analyzed. Average age at baseline was 76.38±6.13 years and average age at death was 84.27±5.58 years. The average length of follow-up was 7.62±4.75 years and the average post-mortem interval was 7.12±6.93 hours. Females comprised 48% (n = 51) of the sample. Intrasubject standard deviation (ISD) values derived from episodic memory and executive function composite scores were calculated for each subject. Negative

binomial (NB) regression models were used to assess the association between cognitive ISDs and AD neuropathology (NPs, DPs, and NFTs) while adjusting for age at death, sex, education, and APOE ε4 carrier status. Episodic memory ISDs were not associated with DP (β = 0.60, 95% CI (-1.52, 2.72), p = 0.58) or NP load (β = 0.18, 95% CI (-1.97, 2.33), p = 0.87), but were significantly related to NFT load (β = 1.39, 95% CI (0.30, 2.48), p = 0.01). Executive function ISDs were not associated with DP (β = 1.07, 95% CI (-1.57, 3.71), p = 0.43) or NFT load (β = -0.52, 95% CI (-1.91, 0.47), p = 0.87), but were significantly related to NP load (β = 2.94, 95% CI (0.28, 5.61), p = 0.03). ISDs did not correlate with subject-level slopes for episodic memory and executive function, indicating that higher ISDs were not the result of linear declines in cognition. These results show that year-to-year within-subject cognitive variability is associated with AD pathology severity in NCI older adults.

Title: EEG markers from a novel oddball task predicts subject's mental abilities, data from 443 adults

Authors: *J. DREO[1], D. SAKIC[2], Z. PIRTOSEK[2];
[1]Med. Faculty, Univ. of Ljubljana, Ljubljana, Slovenia; [2]Chair of Neurology, Fac. of Medicine, Univ. of Ljubljana, Ljubljana, Slovenia

Abstract: Due to population ageing, dementia-related expenses will rise in the coming decades. Even in the absence of disease-modifying therapy, developing cost-effective and non-invasive methods of diagnosing Alzheimer’s disease is essential to reduce health-care expenses. As part of a Slovenian research initiative aimed at early dementia detection (ADAM project) we performed 64-channel EEG recordings on 443 healthy elderly subjects in addition to conducting the Montreal Cognitive Assessment (MoCA). We designed an extremely short (3 min) novel oddball-like task that was intended to probe short-term memory recall. The subjects were instructed to pay attention to a series of images of several categories, some of which repeated while others did not. They did not need to perform any other task. EEG data was used to compute ERPs to different image types (repeats and non repeats). The resulting P3 (P300) potentials were compared between different image types and subjects with different cognitive (MoCA) scores. Sizable and significant changes were found in ERP latency, amplitude and, especially topographical distribution. These results indicate that our novel oddball task can offer

valuable objective insight into the cognitive performance of older adults and might point the way towards development of future EEG-based strategies to predict cognitive decline or dementia development.

Title: The continuum from temperament to mental illness

Authors: *W. SULIS;
Psychiatry and Behavioural Neurosci., McMaster Univ., Hamilton, ON, Canada

Abstract: Background: Temperament and mental illness are thought to represent varying dynamical phases within a continuum of neurobehavioral regulation. This regulation primarily involves monoamine and cholinergic systems as well as opiate receptor systems. Trofimova has developed a taxonomy pf temperament (Functional Ensemble of Temperament model "FET") based upon linkaages between ensembles of regulatory systems and specific temperament traits. This model is sensitive to subtle alterations in neurobehavioral regulation and this is expected to show consistent and disease specific effects in the presence of various mental illnesses. This could in turn provide the basis for a new taxonomy of mental illness. Most popular models of temperament, being based heavily on emotionality traits, show very poor ability to discriminate between mental disorders. The main goal of this study was to examine whether the FET, which is based on modern neurophysiology and possesses an extensive set of non-emotionality traits provides better discrimination between Major Depression (MD), Generalized Anxiety (GAD) and Comorbid MD and GAD, in comparison to emotionality-based temperament models. **Methods**: Using the Structure of Temperament Questionnaire, the temperament profiles of 687 individuals (396 clients of private psychiatric and psychological practice, and 291 control subjects) were compared across four adult age groups (18-24, 25-45, 46-65, 66-84). **Results:** MD and GAD appear to be accurately distinguished by the traits of Motor Endurance and Motor Tempo (much lower values in depression), and Neuroticism (much higher value in anxiety). Comorbids can be distinguished based on a significant decrease in the traits of Plasticity, Intellectual Endurance, Sensitivity to Probabilities, and increased Impulsivity. These effects seemed independent of age and gender. **Conclusions**: The results suggest the benefits of including non-emotionality-related traits and the usefulness of a functional approach to both taxonomy of temperament and classification of mental disorders.

Title: Quantitative MCell model shows competition and dynamic equilibrium within PDZ domain of PSD-95 at the postsynaptic density

Authors: *S. SAMENI[1], T. M. BARTOL, Jr[1], M. B. KENNEDY[2], T. J. SEJNOWSKI[1]; [1]Salk Inst. For Biol. Studies, La Jolla, CA; [2]Caltech, Pasadena, CA

Abstract: A major challenge in synaptic plasticity has been to understand how synaptic proteins that govern learning and information storage are regulated and to clarify the molecular mechanisms of plasticity. Although the existence of electron-dense structures known as postsynaptic densities (PSDs), comprising the key proteins that regulate synaptic plasticity and homeostasis have been studied for more than 60 years, it is still unclear how these structures are formed and regulated. We have made a stochastic computer model using MCell to simulate protein interactions in PSDs. We examined the competition among synaptic proteins including synGAP and AMPAR-TARPs for binding sites on PSD-95. SynGAP and PSD-95 are two of the most abundant PSD components. Their mutation has been linked to intellectual disability, autism and seizure. The competition for binding among these molecules leads to the formation of multiple equilibria within the PSD. A reduction of affinity of synGAP for PSD-95 shifts the balance to form a new equilibrium based upon the concentration and affinity of other components. In particular, the reduction of affinity of synGAP for PDZ 1 and 2 shifts the balance to form a new equilibrium with AMPAR-TARPs.

Abstract: Selective serotonin reuptake inhibitors (SSRIs) are the most used class of antidepressants, although they are known to have delayed onsets of clinical effects. Elucidating the distribution of SSRIs throughout the brain may provide insights into their precise mechanism of action. Here, in order to visualize SSRIs directly *in situ* at a high resolution, we combined the bioorthogonal alkyne tag with surface-enhanced Raman spectroscopy (SERS). Raman spectroscopy detects chemical compounds by detecting molecular vibrations of chemical bonds. Notably, the alkynyl group exerts a strong Raman peak in the silent region of the Raman spectrum and is therefore detected specifically. SERS amplifies spontaneous Raman scattering via the adsorption of chemical bonds to the surface of a nanoparticle. Focusing on the SSRI S-citalopram, we incorporated an alkynyl group by replacing the nitrile group at the C-5 position of the 1,3-dihydroisobenzofuran ring and chemically synthesized alkynylated S-citalopram. We

simulated its binding mode to the human serotonin transporter (hSERT) *in silico* and found that alkynylated S-citalopram bound to the hSERT similarly to S-citalopram. We then analyzed the brain transitivity of alkynylated S-citalopram by quantifying alkynylated S-citalopram in brain homogenates using liquid chromatography-tandem mass spectrometry. We found that alkynylated S-citalopram levels in the brain were not significantly different from S-citalopram levels. We also analyzed the serotonin release by alkynylated S-citalopram in the medial prefrontal cortex using brain microdialysis. We found that serotonin levels were not significantly different between alkynylated S-citalopram and S-citalopram administered mice. We then tested whether alkynylated S-citalopram can be detected with SERS *in vitro*. Alkynylated S-citalopram exerted a strong Raman peak in the silent region and was detected with a sensitivity of 400 pM. Finally, we performed SERS imaging on coronal mouse brain sections and successfully visualized alkynylated S-citalopram in the dorsal raphe nucleus. This study shows the combined alkyne tag and SERS imaging approach as a potent method for detecting low molecular drugs targeting the brain, and opens the door for the technique to be developed further to determine drug distribution.

Title: Depigmentation and clearing technique for planaria allowing optically accessible staining and fluorescence imaging of the complete worm

Authors: P. E. B. NICKERON[1,2], A. D. STILLAR[2], *M. J. SAARI[2];
[1]Donald K Johnson Institute, Krembil Res. Institute, Univ. Hlth. Network, Toronto, ON, Canada;
[2]Nipissing Univ., North Bay, ON, Canada

Abstract: Planaria, Dugesia Dorocephala, appear to be behaviourally sensitive to their social environment. In our hands, singly housed planaria show reduced activity and increased environmental “scanning” in comparison to group-housed planaria. Thus, they may serve as a potentially useful model for the examination of environmentally-mediated neural and behavioural plasticity. Previous studies have demonstrated their usefulness in the study of neural regeneration and toxicology studies, including exposure to alcohol during regeneration, among others. Classical histological techniques have offered effective means to characterize the

microscopic anatomy of developing and regenerating planaria. Although informative, cryosectioning and staining of serial sections represent an artifact-rich and labour-intensive methodology when attempting to reconstruct the three-dimensional (3D) microanatomy of whole organisms. Recent advances in whole-specimen clearing techniques have provided us with a platform wherein we can generate a whole-organism preparation that is optically accessible to laser-scanning fluorescence microscopy. We employed depigmentation techniques coupled with modified CUBIC clearing to generate optically accessible planarian worms that can be stained with conventional inorganic (vital) dyes. Worms stained with nuclear (DAPI) and neuronal (Nissl) stains can be mounted and 3D tile imaged, on a confocal microscope, revealing a detailed and comprehensive microanatomical view of the planarian nervous system. Conclusion: This depigmentation and clearing protocol mitigates a processing bottleneck in higher-throughput evaluation that is inherent to classical histological analysis. This protocol will be useful for the examination of neural plasticity of the planarian in numerous experimental models including environmentally mediated behavioural plasticity.

Title: Carbon nanotube optical reporter maps changes in endolysosomal lipids

Authors: *L. E. KOMER[1], T. V. GALASSI[1], P. V. JENA[2], J. SHAH[2], Y. BRAM[1], A. FRANKEL[3], J. PARK[1], J. JESSURUN[1], D. S. ORY[4], A. HAIMOVITZ-FRIEDMAN[2], R. E. SCHWARTZ[1], F. R. MAXFIELD[1], D. A. HELLER[2];

Abstract: When lysosomes accumulate fat due to disposal problems, the accumulation can lead to toxic effects. This is found in a variety of lysosomal storage disorders, such as Niemann-Pick disease, which is an inherited condition of malfunctioning lipid metabolism. It is also implicated in cancer and neurodegenerative diseases. There are limited methods for detection of

accumulation of endolysosomal lipids, and it is particularly difficult to address *in vivo*. Many techniques provide lipid content quantification in organs, but there is limited specificity for individual organelles. Our lab has developed an optical reporter to detect endolysosomal lipid accumulation and fluctuations both *in vitro* and *in vivo*. Our optical reporter is composed of a photoluminescent carbon nanotube that responds to the accumulation of lipids by modulating the nanotube's optical band gap. The nanomaterial is made of short, singlestranded DNA and a single chirality, which allows it to localize exclusively to the endolysosomal organelle lumen. This is done without adverse effects to cell viability, proliferation, morphology, integrity, or function.

Near-infrared (NIR) fluorescence microscope was used to acquire the photoluminescence emission of single-walled carbon nanotubes, based on the intrinsic fluorescence of carbon nanotubes which have unique properties. The nanotubes were then added to Niemann-Pick disease model cells. We show detection of lysosomal lipid accumulation in Niemann-Pick type A/B (NPA/B) and Niemann-Pick type C (NPC) disease models, and primary cells from an NPC patient.

For *in vivo* models, the nanotubes are injected into the mouse via intravenous injections, and monitored noninvasively via NIR excitation/emission. We found hepatic lipid accumulation in the mouse model of NPA/B and NPC. We used the reporter to monitor lipid accumulation in KC endolysosomal organelles, and saw the effects of dietary intervention in non-alcoholic fatty liver disease and nonalcoholic steatohepatitis. This reporter has widespread implications for many disorders, such as monitoring lipid accumulation in neurodegenerative diseases such as Parkinson's and Alzheimer's disease.

Title: Imaging of neurotransmitters using AuNPs with laser desorption ionization mass spectrometry

Authors: *N. K. MCLAUGHLIN[1], K. STUMPO[2];
[1]Biol., [2]Chem., Univ. of Scranton, Scranton, PA

Abstract: Imaging of neuroactive molecules, specifically those with primary amines, are a challenge for mass spectrometry. The small molecular weight coupled with low abundance in biological tissues results in low ionization efficiencies. However, gold nanoparticles (AuNPs) as matrices in Laser-Desorption Ionization Mass Spectrometry (LDI-MS) have been established for ionization of biomolecules due to their flexibility in solvent preparation and salt tolerance. These properties may lend themselves to increased resolution for endogenous small molecular weight metabolites, such as neurotransmitters. Specifically, dopamine (DA), serotonin (5-HT), glutamate (Glu), gamma-Aminobutyric acid (GABA), Octopamine (OT), norepinephrine, (NE), acetylcholine (Ach), epinephrine(EPI) are of interest here. This study aims to advance the application of AuNPs of small neurogenic amines with LDI-TOF MS, including imaging MS techniques. Neurotransmitters were effectively ionized by 2 and 5 nm AuNPs. In addition to ionization of these small molecules, which is traditionally difficult, unique patterns of fragmentation has been observed with different sized AuNPs, with 2 nm AuNPs facilitating greater fragmentation. The mechanism for this phenomenon is still being investigated. NP-to-analyte ratio and laser power both factor into the incidence of fragmentation; complementary experiments are being conducted with attempts to enhance or diminish fragmentation. Because of the difficulty with traditional acid matrices, a comparison with DHB and CHCA will be done. These matrices self-ionize heavily and result in significant chemical noise in the m/z 150-300 range. This is problematic due to the fact that neurotransmitters often have masses in this area; for instance, the masses of DA, 5-HT, and GABA are 153, 176, and 147 Da, respectively. Imaging MS methods have thus far been optimized using AuNPs. Continuing experiments will evaluate limits-of-detection for each neurotransmitter, as well as further experiments using these molecules on biological tissue.

Title: A flow cytometry-based approach to study molecular alterations in synapses

Authors: *F. J. RUBIO[1], E. M. HILAIRE[1], P. V. SELVAM[1], C. A. MEJIAS-APONTE[1], S. ZHANG[1], R. CIMBRO[2], B. T. HOPE[1];
[1]NIDA IRP, Baltimore, MD; [2]Johns Hopkins Sch. of Med., Baltimore, MD

Abstract: Learning plays a central role in cue-induced drug craving. Synapses that are activated during learning are thought to undergo long-lasting alterations to form a long-lasting engram encoding the memory. To identify and characterize these alterations in activated synapses, we first need to isolate them from the surrounding less activated synapses. Synapses can be isolated biochemically as synaptoneurosomes, which contain the presynaptic terminal attached to a resealed post-synaptic spine. Here we validated the use of flow cytometry using an optimized synaptoneurosome preparation to study molecular changes in candidate protein markers of activated synapses induced by drug administration. We first injected virus expressing yellow fluorescent protein (eYFP) into the medial prefrontal cortex (mPFC) to label presynaptic terminals in the striatum. We then administered one injection of 20 mg/kg of cocaine (IP) and harvested synaptoneurosomes from the striatum 0, 5, 10, 30 and 60 min later. After fixation with 0.1% PFA and permeabilization with 0.2% Tween-20, the synaptoneurosomes were stored at -80 °C in 5% DMSO and used later for immunolabeling. Within the gate chosen for synaptoneurosomes (eYFP-positive events), 60 or 80% of them were PSD95- or synaptophysin-positive for post-synaptic and pre-synaptic compartments, respectively. Different antibodies were used for analyzing candidate markers of synaptic activity, including Arc protein, CaMKII, phospho-CaMKII, ribosomal protein S6 and its phosphorylated form. We found time-dependent molecular alterations following cocaine administration, with the biggest alterations (4-fold) at 60 min for phospho-CaMKII and ribosomal protein S6. We will use these 2 protein labels as markers of activated synapses on activated (Fos-expressing) neurons associated with learning and cue reactivation in models of drug relapse. Further immunohistochemical analysis will be used to validate changes in these candidate proteins at the synapses.

Title: A high-loading drug delivery system with pH response based on magnetic nanomaterials modified by hyperbranched phenylboronic acid for glioma cell targeting treatment

Authors: H. SONG[1], Y. WANG[1], J. ZHANG[2], ***Y. LU**[1], R. GAO[2];
[1]Sch. of Basic Med. Sci., Xi'an, China; [2]Sch. of Sci., Xi'an, China

Abstract: Glioma is the one of the most insidious and destructive type of brain tumor. The therapeutic effect is not satisfied by using surgery, radiotherapy and chemotherapy to treat glioma. Especially, the limited functionality of chemotherapy is due to the side effects to the normal glia cells. In this study, we have designed a novel hyperbranched phenylboronic acid (PBA) magnetic drug delivery system (DDS) capable of high drug loading, glioma targeting, and pH-responsive release to overcome the limited drug loading capacity of magnetic nanopharmaceuticals arising from the relatively large mass of the metal core. The preparation conditions, adsorption and desorption capability, and glioma cells targeting ability of the DDS were investigated in detail through chemical and biological experiments. The drug loading amount and thermodynamic fitting results of the DDS demonstrate its high drug loading capacity and multilayered adsorption process. The experimental results in U-87 MG malignant glioma cells confirm the glioma cells targeting and pH-responsive release properties of the DDS compared with primary cultured astrocytes. Moreover, the hemolysis assay shows that the DDS has good histocompatibility, which is a crucial prerequisite for *in vivo* experiments and further clinical application. The developed method could be an alternative solution for designing high-loading DDSs with a high-mass metal core and provides new perspective of thinking for studies on magnetic targeting, magnetic resonance imaging and magnetocaloric effects in glioma therapy.

Title: Iterative direct expansion microscopy

Authors: *D. SARKAR[1], A. WASSIE[1], J. KANG[1], T. TARR[2], A. TANG[2], T. A. BLANPIED[3], E. S. BOYDEN[1];
[1]MIT, Cambridge, MA; [2]Univ. of Maryland, Baltimore, MD; [3]Dept. of Physiol., Univ. of Maryland Sch. of Med., Baltimore, MD

Abstract: While dense biomolecule-rich structures (such as synapses) support diverse biological functionsof importance in brain computation and pathology, visualization tags such as antibodies often cannot access biomolecules of interest in those crowded environments. Thus, visualization and deciphering of the nanoscale organization of such compact structures remains difficult. Here, we report a technology that not only allows nanoscale resolution imaging of intact tissues in ascalable way, but also offers a novel protein de-crowding effect allowing access of tags to individual biomolecules within densely packed structures, otherwise inaccessible.
This technology is the next generation of expansion microscopy, our technique for overcoming the diffraction limit of optical microscopy through physical magnification of biological specimens (Science (2015) 347(6221):543-548). While, in the original expansion microscopy(ExM) process, about 4.5x linear expansion and hence, a resolution of 60 nm (300 (diffractionlimit) / 4.5 (expansion factor)) was achieved, we recently demonstrated that, by iterating the expansion process (iExM), it is possible to obtain higher expansion factors (~20x) and higher resolution (300/20 ~15 nm) (Nature Methods (2017) 14, 593-599). However, in iExM, the biomolecules themselves were not retained during the process, but instead DNA strands were used to encode relative location information, which requires staining before expansion withDNA-conjugated antibodies.
Our new technology, which we call iterative direct expansion microscopy (idExM), not only allows iterative rounds of expansion leading to high expansion factors (up to 100 fold) and thus,excellent super resolution (<10 nm resolution) on ordinary microscopes, it retains the biomolecules throughout the whole process. Thus, the tags can be brought in to label the biomolecules after the expansion, when they are de-crowded from each other and more accessible to tags such as antibodies. We are now using idExM to visualize nanoscale details of highly complex and compact architectures in intact brain circuits.

Title: Enhanced sensitivity and selectivity in the detection of serotonin *in vivo* using N-shaped fast cyclic square wave voltammetry

Authors: H. SHIN[1,4], *Y. OH[1], C. PARK[4], Y. KANG[4], A. RUSHEEN[1], A. S. BARATH[1], K. E. BENNET[2], C. D. BLAHA[1], K. H. LEE[1,3], D. JANG[4];

Abstract: Background: Serotonin is thought to be involved in numerous physiological processes underlying anxiety, impulsivity and compulsivity, mood, social behavior, and stress. *In vivo* microdialysis has been useful in establishing the role of serotonin in these disorders and others, but is constrained in both spatial and temporal measurement resolution. Conventional N-shaped fast scan cyclic voltammetry (N-FSCV) in combination with carbon fiber microelectrodes (CFM) has been shown to be able to detect serotonin *in vivo*, but has relatively low sensitivity and selectivity compared to microdialysis. Thus, there is a need to improve current voltammetric techniques in both sensitivity and selectivity to serotonin. Based on our previous studies using fast cyclic *square wave* voltammetry (FCSWV) for *in vivo* dopamine measurements, we have modified this technique to optimize the detection of serotonin *in vivo*. **Methods**: A series of large amplitude square-shaped potentials was superimposed onto an N-shaped waveform to provide cycling through multiple redox reactions within the N-shaped waveform to increase sensitivity and selectivity to serotonin. We electrically stimulated (0.35 mA amplitude, 60-90 Hz frequency, 2 ms biphasic pulse width for 2-5 sec) the medial forebrain bundle in the urethane (1.5 gm/kg i.p.) anesthetized rat (AP:-2.7, ML:+1.7, DV:-8.0) with a bipolar parallel electrode and recorded stimulation evoked phasic release of serotonin in the substantia nigra reticular (SNr) with a CFM (AP:-4.8, ML:+2.0, DV:-8.5). Pharmacological confirmation of serotonin was performed with escitalopram (ESCIT, 10 mg/kg i.p.), a serotonin selective reuptake inhibitor. **Results**: N-shaped fast cyclic *square wave* voltammetry (N-FCSWV) showed 3 times higher sensitivity to serotonin than conventional N-FSCV. In addition, N-FCSWV could differentiate serotonin from dopamine and 5-hydroxyindoleascetic acid. N-FCSWV was confirmed that the square waveform did not influence local neuronal activity, and it could monitor electrical stimulation evoked phasic release of serotonin in the rat SNr before and

after injection of ESCIT. **Conclusions**: Here, we introduce N-FCSWV as a novel *in vivo* voltammetric technique for serotonin measurement by combining large amplitude CSWV with a background subtraction method based on conventional N-waveform design. Application of a large amplitude square wave potential induced multiple redox chain reactions within a single square wave pulse resulting in increased sensitivity to serotonin.

Title: A high efficacy selection method for transfected cells utilizing recombinant isolectin B4-saporin

Authors: M. A. GALVAN, P. A. SHRAMM, R. BOUAJRAM, D. A. LAPPI, *L. R. ANCHETA;
Cytologistics, LLC, San Diego, CA

Abstract: Transfection protocols often rely on the use of antibiotics for the selection of transfected cells and has become the accepted approach for *in vitro* research and therapeutic applications. Antibiotics have several shortcomings such as cost, continuous use, and harmful effects -- even on the transfected cell population. In addition, selection pressures are often inefficient and fail to provide a population of cells that express the gene of interest (GOI) at high levels. We have used three separate GOI's to select for solely high-expressing transfectants using targeted toxin selection pressure. Normal Rat Kidney Cells (KNRK) were individually transfected to express green fluorescent protein (GFP), melanopsin or the low-affinity nerve growth factor receptor (p75) using an innovative new transfection delivery vector called pGEI. The results from various assays were utilized to visually determine the expression rate and pattern of the targeted toxin selection method. Melanopsin and p75 -- a photopigment and nerve growth factor, respectively -- were of great interest to express in our transfected cells as a means to study their role in the development and function of neurons. The delivery vector, pGEI, removes resident Galalpha(1-3)Gal epitopes from non-human mammalian cell surfaces. This residue is the target of recombinant Isolectin B4 - Saporin (IB4-SAP), a selective targeted toxin. IB4-SAP is extremely potent, with an EC_{50} in the low picomolar range for alpha-D-galactopyranoside expressing cells *in vitro*. The cells with the highest expression of the inserted vector, and therefore the GOI, will have these residues removed. Those that fail to express the

vector or do not express the vector in high enough amounts, will not have all the residues removed, and will be targeted and eliminated via IB4-SAP. This method of selection provides a means of purifying the highest-expressing transfected populations using a more cost-effective and time-saving approach.

Title: Nicotine and THC exposure in rats using JUUL®-related electronic cigarette devices

Authors: *E. L. HARVEY[1,2], J. D. NGUYEN[1,2], Y. GRANT[1,2], T. M. KERR[2], M. COLE[3], M. A. TAFFE[1,2];
[1]Psychiatry, Univ. of California San Diego, La Jolla, CA; [2]Neurosci., The Scripps Res. Inst., La Jolla, CA; [3]La Jolla Alcohol Research, Inc, La Jolla, CA

Abstract: The popularization of electronic nicotine delivery systems (ENDS), including the JUUL® device, in recent years stimulates the need for preclinical models examining this method of drug delivery. The appearance of third-party refillable pods, which can be substituted for the nicotine containing JUUL® pods, , gives rise to the potential for this device to be used for the delivery of other psychoactive substances, most notably Δ9-tetrahydrocannabinol (THC). In the present study, nicotine and THC were administered to rats using a vapor inhalation system modified with an adapter for JUUL® vaporizers, to compare with prior results using a canister style ENDS device. Blood plasma levels of nicotine, cotinine and THC were measured to assess the efficacy of drug delivery. Adult male rats were implanted with intravenous catheters to facilitate blood draws within the inhalation chamber. Subjects were administered vaporized nicotine or THC during 30-minute vapor sessions. Blood samples (~500 µL) were collected from the catheters at sequential time points within session (t = 5, 15, 30 and/or 35 min). Plasma nicotine, cotinine, and THC levels were then quantified via liquid chromatography/mass

spectrometry (LC/MS) using an Agilent 1100 series HPLC system coupled with an Agilent MSD6140 mass spectrometer configured for selected ion monitoring [nicotine (*m*/*z* = 163.1), nicotine-d4 (*m*/*z* = 167.1), cotinine (*m*/*z* = 177.1), cotinine-d3 (*m*/*z* = 180.1), THC (*m*/*z* = 315.2), THC-d3 (*m*/*z* = 318.2)]. Nicotine blood plasma levels showed a time/cumulative dose-dependent increase across the 30-minute session, with a peak of 17.82 ng/mL (±0.92 SEM) at the t = 30 min. time point. Cotinine levels demonstrated a similar rise, increasing to 16.16 ng/mL (±3.62 SEM) at t = 35 min. THC analysis is currently in progress. Plasma drug concentrations observed with the JUUL® device are consistent with results previously observed in our laboratory using refillable canister style ENDS . These data confirm that physiologically relevant doses of psychoactive compounds can be delivered to rats via inhalation using JUUL® devices. Therefore it is possible to use JUUL® ENDS for preclinical studies of the psychoactive effects of nicotine or other drugs when delivered by vapor inhalation.

Title: Sox-based sensors for protein kinases and phosphatases for neuroscience discovery and drug development

Authors: *E. SCHAEFER[1], S. CORNELL-KENNON[1], B. LU[1], J. FISHMAN[2], E. BERG[2], B. IMPERIALI[3];
[1]Assayquant Technologies, Marlborough, MA; [2]Peptide Chem., 21st Century Biochemicals, Marlborough, MA; [3]Chem. & Biol., MIT, Cambridge, MA

Abstract: Introduction: Protein kinases are a diverse group of 535 enzymes whose dysregulation lies at the center of many diseases including brain tumors, neuroinflammation and neurodegeneration. Although 50 drugs are approved, these are predominately ATP-competitive inhibitors. More recently, there is an expanded focus on inhibitors with different modes of action, where new tools are needed to effectively characterize mechanism of action and predict drug potency. Methods: We harnessed chelation-enhanced fluorescence by combining the sulfonamido-oxine (Sox) chromophore with high-throughput solid-phase peptide synthesis to create optimized peptide sensors for quantitative and homogenous detection of kinase and phosphatase activity. The same sensor can be monitored kinetically using fluorescence intensity (Ex/Em 360/485 nm) or in endpoint mode using Europium and time-resolved fluorescence (Ex/Em 360/620 nm). Results: We established a robust process to rapidly identify novel

optimized substrates based on physiological sequences. We identified highly-generic substrates for detection of 80 Tyr kinases and highly-selective substrates for quantitative detection in crude cell or tissue lysates including analysis of Protac-mediated degradation of kinases. The resulting panel of neuroscience-related sensors created for high-profile tyr kinases: EGFR & clinically-relevant mutants, Src, TEC-family (BMX, BTK, ITK, TEC, TXK) & TRKA-C, and, ser/thr kinases: AMPK (+/- AMP), CAMK2a, b, d (+/- Ca/Calmodulin), CDK5, GSK3b, LRRK2, MAP3Ks (DLK, Raf), MAPKs (ERK1/2, JNK1-3, p38a-d), MARK1-4, PKR (+/- RNA)/EIF2AKs, PKA, PKC (+/- Ca/lipid) & PKG (+/- cGMP), illustrates the broad applicability of our approach, including enabling the study of Tau phosphorylation and the role of LRRK2 in Parkinson's disease. In addition, we created CSox-based phosphopeptide sensors to monitor protein phosphatases with specificity for tyr (PTP1B, SHP1/2) or ser/thr (PP2A, PP2B, PP2C, PHLPP1/2). Conclusions: The generation of robust activity-based sensors for a range of neuroscience kinase and phosphatase targets opens new areas for discovery and drug development. The described kinetic assay format is ideal for elucidating drug mechanism of action, potency, and enzyme regulation, while the Red/endpoint format is ideal for HTS, SAR and profiling. Together, these formats can be applied across the entire discovery and drug development workflow, providing a quantum improvement in creating next generation protein kinase and phosphatase inhibitors.

Title: rsCaMPARI: An erasable marker of neuronal activity

Authors: *F. SHA, A. S. ABDELFATTAH, R. PATEL, J. J. MACKLIN, E. R. SCHREITER; Janelia Res. Campus, Howard Hughes Med. Inst., Ashburn, VA

Abstract: Identifying and comparing active neuron ensembles underlying different complex behaviors is a key challenge in neuroscience. Recent tools such as CaMPARI have enabled the optical marking and selection of active neuron populations[1,2]. However, CaMPARI is based on the activity of a photoconvertible fluorescent protein whereby the marking is permanent and irreversible. These properties limit the utility of CaMPARI in samples where multiple snapshots of activity are desirable or where different activity profiles must be compared within the same sample. We sought to overcome these limitations by developing an erasable neuronal activity marker based on a reversibly switchable fluorescent protein. Here we introduce a new tool

named rsCaMPARI, a reversibly switchable calcium marker that enables spatiotemporal precise marking, erasing, and remarking of active neuron populations under widefield illumination. rsCaMPARI photoswitching kinetics are modulated by calcium concentration when illuminating with blue light, and the fluorescence can be recovered with violet light. We demonstrate the utility of rsCaMPARI for repeated marking and erasing of calcium activity in cultured neurons and freely swimming larval zebrafish.

Title: Comparison of occlusion and staining techniques in rodents with induced cva injuries and the use and effectiveness of ischemia contrast stain

Authors: *S. O. AHMAD[1], K. BARILLIER[1], B. KINGSLEY[1], M. KUMNICK[1], J. BAUN[2], T. YORK[2], R. SWITZER, III[2];
[1]Occup. Sci. and Occup. Therapy, St. Louis Univ., St. Louis, MO; [2]NeuroScience Associates, Knoxville, TN

Abstract: The purpose of this methods project is to investigate the efficacy and implications of various methods of occlusion and staining techniques on Sprague-Dawley rats with a Middle Cerebral Artery Occlusion. Through a literature review, ten studies were identified for comparative analysis of factors including: animal information, occlusion method, length of time of occlusion, amount of time post-occlusion at which staining occurred, type of stain used and the outcomes of the study. Fluroro-Jade B, NeuN, Nissel, and Hematoxylin and Eosin were all used in one study respectively, and Cresyl-Violet was used in two of the studies. Our Method: Neurohistology Embedding, Sectioning & Staining Brains or spinal cords received at NeuroScience Associates were examined, then treated overnight with 20% glycerol and 2% dimethylsulfoxide to prevent freeze-artifacts. The specimens were then embedded in a gelatin matrix using MultiBrain®/ MultiCord® Technology (NeuroScience Associates, Knoxville, TN).

The blocks were rapidly frozen, after curing by immersion in 2-Methylbutane chilled with crushed dry ice and mounted on a freezing stage of an AO 860 sliding microtome. All sections were cut through the entire length of the specimen segment and collected sequentially into series of 24 containers. Ischemia Contrast stain - For Ischemia Contrast staining, sections are first mounted onto gelatinized (subbed) slides then stained with a modification of the Weil method for myelin. They are dehydrated through alcohols, then rehydrated and stained in Hematoxylin/ Ferric Ammonium Sulfate staining solution. They are then differentiated first in 2% Ferric Ammonium Sulfate, rinsed in deionized water rinses, and secondly in a Potassium Ferricyanide/ Sodium Borate solution.Unlike myelin staining, the gray matter is left dark in order to highlight ischemic areas. Following deionized water rinses, the slides are dehydrated in a standard alcohol series, cleared in xylene and coverslipped. Following serial ordering of the slides, rostral to caudal for each stain, the slides were numbered by permanent ink in the upper right corner. Results: Comparative analysis was performed using Ischemia Contrast Staining, Nissl and Hematoxylin staining with pixel distance and greyscale. The image and accompanying gray level range data show that the ICS stain is more capable of showing lesion areas (visually and through data acquisition) compared to HE and thionine: ICS data -- Min. gray value = 4.1, Max gray value = 112.4, Range = 108.3 Thionine data -- Min. gray value = 187.1, Max gray value = 241.0, Range = 54 H&E data -- Min. gray value = 142.6, Max gray value = 180.0, Range = 37.4

(ASHBi), Kyoto Univ., Kyoto, Japan

Abstract: An optical clearing method, ScaleS, provides stable tissue preservation and thus can be combined with electron microscopy (EM). However, there is still room for improvement on membrane integrity in the cleared samples. In the present study, we aim to establish a pipeline optimized for multi-scale imaging from macro- to nano-levels based on ScaleS technology. We first modified a ScaleS method, and succeeded in transparentizing 1-mm-thick brain slices of mice and marmosets within 14 hours without any change in tissue size. Even after fixation with glutaraldehyde (GA) of a high concentration (2%), the tissue transmittance was retained. Furthermore, by using EM, we observed that addition of GA contributed to preservation of ultrastructures in cleared brain tissue. The effect of fixation with GA on ultrastructures was investigated not only in mice but also in marmosets. Then, aiming at realizing successive LM/EM imaging, we developed an AAV vector expressing a fusion protein of EGFP and APEX2 (peroxidase enzyme). To deposit biotin molecules in APEX2 expressing cells, we performed tyramide signal amplification (TSA) method with brain slice immediately after fixation, and carried out ABC-DAB reaction after tissue-clearing and fluorescence microscopy. Now, we are trying successive LM/EM imaging by combining ScaleS technology with the AAV vector to achieve multi-scale imaging in large scale 3D structure.

Abstract: Tissue expansion techniques physically magnify gel-embedded samples to enhance effective imaging resolution, but this costs signal dilution, imaging time and photobleaching. We introduce a hydrogel conversion-based expansion method, termed ZOOM, that allows for easy adjustment of the expansion ratio (up to 8-fold in a single expansion process) for individual needs, while simplifying expansion procedure, improving gel uniformity and preserving biomolecules for multi-round labeling. ZOOM can be flexibly applied to nanoscale imaging of subcellular details of cultured cells, brain tissues as well as exoskeletal *C. elegans*.

Title: New advanced tissue clearing method

Authors: *E.-S. LEE, G.-H. KIM, Y.-I. PARK, S.-I. GUM;
Binaree, Inc., Daegu, Korea, Republic of

Abstract: Conventional histology techniques are laborious and require tissue sectioning, which are barriers toward rapid three-dimensional (3D) visualization of organ structures. The recent development of potent tissue-clearing methods enables rapid 3D imaging of a mouse brain when combined with confocal and light-sheet fluorescence microscopy. In the past seven years, many tissue clearing protocols have spawned. However, a previous method requires expensive equipment and complicated processes, resulting in non-reproducible data. In addition, other methods make too toxic or soft cleared tissue to proceed next steps. Here, we introduce novel tissue clearing method named Binaree tissue clearing methods. Binaree method has simple processes, uses non-toxic solution and takes only 3 days to complete 1-mm thick mouse brain tissue clearing. The maintenance of endogenous fluorescence and single cell resolution within tissues using Binaree tissue clearing were much better than that of other tissue clearing method. In addition, Binaree tissue clearing allow immunostaining of more than 1 mm thick brain tissue. Our results support that Binaree tissue clearing method be a first choice, when you are looking for simple, non-toxic and reproducible clearing method.

Abstract: The three dimensional (3D) imaging of intact adult human organs at cellular and molecular level is a high interest of biomedical sciences. However, standard histology for human tissues can routinely be applied only on micrometers thick tissue slices due to lack of scalable methods. Here, we introduce SHANEL, a highly scalable method that renders human organs transparent for cellular mapping. To demonstrate SHANEL's utility, we generated first transparent intact adult human brain and kidney, and performed 3D histology using antibodies and dyes in centimeters thick human tissues. We revealed structural details of sclera, iris and suspensory ligament in the human eye, as well as the vessels and glomeruli in the human kidney. SHANEL technology is also applicable on other large mammals including pigs. We mapped complex structures of EGFP expressing beta cells in > 10 cm size pancreas of transgenic pigs. Overall, SHANEL is a robust and unbiased technology to map the cellular and molecular architecture of intact human organs.

Abstract: Reliable detection of disseminated tumor cells and of the biodistribution of tumor-targeting therapeutic antibodies within the entire body including into the brain has long been needed to better understand and treat cancer metastasis. Here, we developed an integrated pipeline for automated quantification of cancer metastases and therapeutic antibody targeting in the whole-body including the CNS, named DeepMACT. First, we enhanced the fluorescent signal of tumor cells more than 100-fold by applying the vDISCO method (Cai et al., 2019, Pan et al.,2016) to image single cancer cells in intact transparent mice. Second, we developed deep learning algorithms for automated quantification of metastases with an accuracy matching human expert manual annotation. Deep learning-based quantifications in a model of spontaneous metastasis using human breast cancer cells allowed us to systematically analyze clinically relevant features such as size, shape, spatial distribution, and the degree to which metastases are targeted by a therapeutic monoclonal antibody in whole mice. DeepMACT can thus considerably improve the discovery of effective therapeutic strategies for metastatic cancer (Pan et al., 2019).

Title: Establishing an experimental protocol for making transparent brain for neurodegenerative disease research

Authors: *K. LEE[1], H. LAI[2], R. C. CHANG[1,3];
[1]Lab. of Neurodegenerative Diseases, LKS Fac. of Medicine, Univ. of Hong Kong, Hong Kong, China; [2]Sch. of Biomed. Sciences, LKS Fac. of Medicine, Univ. of Hong Kong, Hong Kong, China; [3]State Key Lab. of Brain and Cognitive Sciences, The Univ. of Hong Kong, Hong Kong, China

Abstract: Until recently, different techniques have been developed to clear tissues to become transparent. However, to speed up the process, most of the methods involve many steps of chemical treatments or extreme temperature. This leads to several issues including fluorescent quenching, protein degradation, and distortion to tissue architecture due to swelling/shrinkage. While some techniques protect tissues by cross-linking them with acrylamide and epoxy monomers, these treatments are usually irreversible. Until now, there is no technique that can preserve tissues from exposing to many steps of chemicals or extreme temperature. Therefore, we have established a delipidation-based technique to preserves tissue structure without the use of any external monomer network.

In this study, we performed partial delipidation by adding OPTIClear, a refractive index (RI) matching solution, into SDS solution. We found that tissue clearing with SDS-OPTIClear not only reduced the required clearing time than usual SDS solution, but also showed less protein loss and no intense swelling/shrinkage.

We further demonstrated that tissues cleared with SDS-OPTIClear would have better antigen preservation, thus allowing better quality in immunohistochemical staining. Previously, it has been reported the failure of immunofluorescence staining with Iba-1, a marker of microglia, after SDS-treatment. Here, we demonstrated Iba-1 immunoreactivity in the hippocampus treated with SDS-OPTIClear and SDS solution. Under the same condition, tissues cleared with SDS-OPTIClear showed better morphology and deeper penetration depth compared to the one cleared with SDS. Immunohistochemical staining of other antigens such as ChAT and TOMM-20 showed that they had stronger signal and deeper penetration depth in tissues treated with SDS-OPTIClear.

Finally, we performed TO-PRO-3 staining on tissues and visualized under confocal microscopy before and after clearing such that the degree of distortion after clearing can be examined and quantified. While tissues cleared with SDS showed dramatic size change upon clearing and RI matching, SDS-OPTIClear did not trigger swelling effect. Tissue morphology was preserved throughout clearing and RI matching.

Taken together, we demonstrated that SDS-OPTIClear preserved better tissue morphology and architecture without the requirement of tissue embedding. This is a simple and cost-effective methodology. This allows us to investigate neurodegeneration with high resolution in a three-dimensional manner without intense swelling/shrinkage.

Title: Effects of omega-3 fatty acids in modulating the role of glia cells in synaptic plasticity in dementia

Authors: *D. SARAJ[1], S. ARYAL[2], T. EID[4], S. DAVANGER[3];
[1]Dept. of Mol. Med., [3]Anat., [2]Univ. of Oslo - Inst. of Basic Med. Sci., Oslo, Norway; [4]Dept Lab. Med., Yale Univ., New Haven, CT

Abstract: The effects of omega-3 fatty acids on brain function and ageing is currently of public interest, likewise the use of diet-based interventions to counteract age-related disorders. High intake of DHA and other omega-3 polyunsaturated fatty acids (n-3 PUFAs) have been described as protective against age-related cognitive decline, dementia and Alzheimer's disease. These molecules may act as endogenous anti-inflammatory mediators and are produced during the resolution phase of inflammation. Our aim is to investigate the possible role of omega 3 fatty acids in the prevention of Alzheimer's disease, through glial cell/synapse interactions. We will use omega-3 fatty acids as anti-neuroinflammatory agents to intervene with glial cell phagocytosis of synapses in the hippocampus and related regions of the cerebral cortex of young mice. We have initially fed young mice with a diet with or without the omega-3 fatty acids docosahexaenoic acid (DHA) and eicosapentaenoic acid (EPA) for 5 months after weaning. This dietary intervention led to a 65 % increase in the concentration of DHA in whole brain synaptosomal phospholipids compared to the negative controls, while the corresponding increase in EPA was even higher (457 %). We observed increased concentrations of glutamate receptor subunits, including GluA1, GluA2, and NR2B, and synaptic vesicle proteins synaptophysin and synaptotagmin 1 in hippocampal synaptosomes of omega-3 fatty acid-fed mice as compared to the deficient group. In contrast, a decreased concentration of neuronal inositol 1,4,5-trisphosphate-receptor 1 (IP3-R1) was observed in the omega-3 fatty acid enriched group. Furthermore, omega-3 fatty acid enrichment increased the long-term potentiation (LTP) in stratum oriens of the hippocampal CA1 area, but not in stratum radiatum. The mice will also be investigated for cognitive/behavioural changes, astrocyte and microglial inflammatory activation patterns, and dendritic spine density. We will use the same intervention in a mouse model of Alzheimer's disease (5xFAD) with manifest Amyloid plaques.

Title: Ethanolic extract of garcinia kola (heckel) affects the histology of organs of the hypothalamic-pituitary-gonadal axis in adult Wistar rats

Authors: *A. U. OBI[1], P. U. NWOHA[2];
[1]Dept. of Anat. and Neurobio., Imo State Univ., Owerri, Nigeria; [2]Anat. and Cell Biol., Obafemi Awolowo Univ., Ile Ife, Nigeria

Abstract: This study was designed to evaluate whether or not the extract of *Garcinia kola* affects organs in the neuro-endocrine-reproductive axis in adult male Wistar rats. Four groups A, B, C and D (6 rats per group) of adult Wistar rats were used for this study. Group D, served as the control, had normal saline, while groups A, B and C formed the experimental groups and receivrd 500mg, 1000mg and 1500mg respectively of the ethanolic extract of *Garcinia kola* per kilogram body weight for four weeks. All groups were fed normal rat chow, and free access to tap water *ad libitum.* At the end of the second and the fourth week, three rats from each group were sacrificed; the hypothalamus, pituitary and the testis were harvested, fixed in formal saline, processed and stained with haematoxylin and eosin stains. Results of the study showed significant histological alteration in the organs of study of the 1500mg/kg group. These alterations presents more evident in the testis than in the hypothalamus. There was degeneration of the leydig cells, and the luminal spermatozoa. The present study suggests that exposure or consumption of *Garcinia kola* could alter the histology of organs in the hypothalamo-pituitary-gonadal axis in adult male Wista*r* rats.

Title: Multimodal measurement of neuron morphology, molecular identity, and connectivity using novel clearing and expansion technology

Authors: *F. Y. SHEN[1], H. CHENG[3], L. WALKER[1], K. FINOS[1], M. HARRINGTON[1], X. LI[4], D. CAI[2];
[2]Cell and Developmental Biol., [1]Univ. of Michigan, Ann Arbor, MI; [3]Cell and Developmental Biol., Univ. Of Michigan, Ann Arbor, MI; [4]Cell && Developmental Biol., Ann Arbor, MI

Abstract: A tremendous goal in neuroscience is to catalog all the different neuronal cell types in the brain. The difficulty is that neurons can be defined by many different criteria, including anatomical, molecular, and functional properties. Moving forward, it'll be fundamentally important to perform multimodal measurements of neuron properties to ameliorate conflicting definitions of cell types. To address this correspondence problem, we have developed a multi-round antigen preserving expansion (mapEx) protocol that can be combined with multicolor genetic labeling strategies (Brainbow) to simultaneously interrogate morphology, molecular identity, and connectivity in thick brain sections. The capacity for 3-4x linear expansion of the tissue specimen gives us the ability to perform "super-resolution" imaging to untangle densely labeled neurons and trace their neurites using nTracer, a custom ImageJ software. By optimizing the preservation of antigens in a hydrogel, we are able to carry out multiple rounds of immunostaining for Brainbow fluorophores and cell type markers. As a proof of concept, we demonstrate that mapEx can be applied to Brainbow labeled inhibitory neurons in the basolateral amygdala to correlate inhibitory neuron cell types with their morphologies and local anatomy network. Furthermore we show that Brainbow immunostaining can be combined with pre- and post-synaptic markers to measure synaptic connectivity between neurons. We envision mapEx combined with Brainbow to be a powerful tool researchers can use to perform multimodal analysis of neuronal structure, molecular identity, and connectivity.

Title: Tissue clearing of both hard and soft tissue organs with the PEGASOS method

Authors: D. JING[1], ***H. ZHAO**[2];
[1]Texas A&M Univ. Col. of Dent., Dallas, TX; [2]Texas A&M University, Col. of Dent., Dallas, TX

Abstract: Tissue clearing technique enables visualization of opaque organ and tissue in 3-dimension by turning tissue transparent. Current tissue clearing methods are restricted by limited types of tissue that can be cleared with each individual protocol, which inevitably led to the presence of blind-spots within whole body or body parts imaging. Hard tissues including bones and teeth are still the most difficult organs to be cleared. In addition, endogenous fluorescence loss remains to be a major concern for solvent based clearing methods. Here, we developed a polyethylene glycol (PEG) Associated Solvent System (PEGASOS), which rendered nearly all types of tissue transparent and preserved endogenous fluorescence. Bones and teeth could be turned to nearly invisible after clearing. The PEGASOS method turned the whole adult mouse body transparent and we were able to image an adult mouse head composed of bones, teeth, brain, muscles and other tissues with no blind areas. Hard tissue transparency enabled us to reconstruct intact mandible, teeth, femur or knee joint in 3-D. We were able to image intact mouse brain at sub-cellular resolution and to trace individual neurons and axons over a long distance. We were able to visualize dorsal root ganglions directly through vertebrae. Finally, we revealed the neural network distribution pattern in 3-dimension within the long bone marrow space. These results suggest that the PEGASOS method is a useful tool for general biomedical research.

Title: The second generation PEGASOS method: A new solution for high-resolution connectome mapping in large organs

Authors: *Y. YI[1], H. ZHAO[2];
[2]Dept. of Restorative Sci., [1]Texas A&M University, Col. of Dent., Dallas, TX

Abstract: Contradictions between resolution, working distance and optical aberration in deep region are major challenges for current tissue clearing methods during connectome mapping. To solve these problems, based on our previous PEGASOS tissue clearing method, we developed the second generation PEGASOS method (PEGASOS 2). PEGASOS 2 technique is a combination of block surface imaging and tissue clearing. The clearing process is composed of fixation, decalcification (for hard tissues), decolorization, delipidation, dehydration and clearing. Finally, the clearing medium could be conveniently converted into transparent gel embedding the sample from inside to outside. The gel formation embedding process improves the tissue strength by over 150 folds. Embedded tissues remain highly transparent and GFP fluorescence remains unchanged after gel formation. Images were acquired only for the superficial regions of the sample ranging from 200 micrometers to several millimeters depending on the objective working distance and resolution requirement. The embedded samples were sectioned to remove the superficial regions and exposed deeper regions were then imaged. Strong mechanical properties of the solvent gel prevent distortion from the cutting process. All stacks were stitched together with no noticeable discontinuity or distortion. The PEGASOS 2 method is applicable for all types of tissue including brain, bones, spinal cord of any size. It is also compatible with any objective disregarding their working distance. We used 40X 1.3NA confocal objective with 240 micrometer working distance to image brain (figure), vertebrae, bone and body trunk of over several millimeters thickness with nearly identical resolution throughout the entire sample. Projections of neural axons were clearly identified. In summary, PEGASOS 2 method provides a powerful tool for high-resolution connectome mapping of large organs composed of complex tissue types.

Title: Chronic mouse imaging: From optical systems to functional ultrasound

Authors: *K. KILIÇ, J. TANG, E. ERDENER, S. SUNIL, J. T. GIBLIN, B. S. LEE, D. D. POSTNOV, A. I. CHEN, D. A. BOAS;
Biomed. Engin., Boston Univ., Boston, MA

Abstract: Functional ultrasonography (fUSG) of the brain is a recently introduced imaging technique in the neuroscience field. Power Doppler-based fUSG has shown promising results for imaging cerebral hemodynamics of the entire mouse brain with ~100 μm resolution. Microbubble tracking-based ultrasound localization microscopy (ULM) has the ability to map the microvasculature of the entire brain with ~10 μm resolution. The whole rodent brain imaging capabilitymakes fUSG a great tool for obtaining macro scale information complementary to most commonly used optical imaging techniques.The inclusion of macro-scale information can be critical in the study of functional changes due to aging, stroke, and neurodegenerative diseases. Chronic preparations make longitudinal studies possible and allow awake imaging that removes the confounds of anesthesia for functional imaging. Owing to variability in behavior among animals, performing multimodal and repeated measurements within the same subject is highly desirable and can lead to higher scientific rigor. Here we propose a chronic preparation method using polymethylpentene sealed cranial windows suitable for imaging with fUSG and optical methods such as optical coherence tomography, 2-photon microscopy, intrinsic optical signal imaging and laser speckle contrast imaging for a span of three to six months.

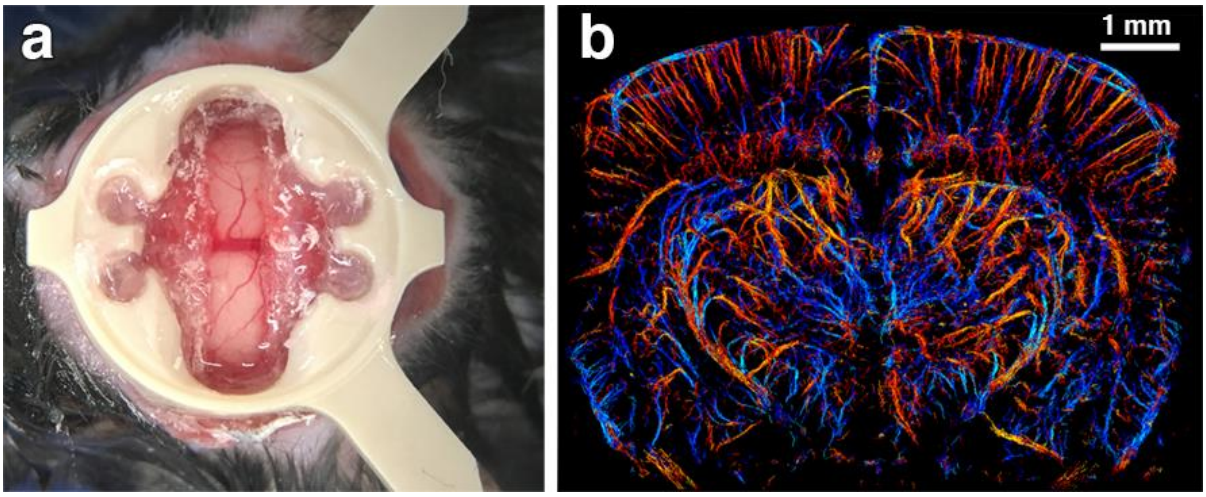

Figure: a) Example of an imaging window. B) Example of an ULM imaging.

Abstract: Three dimensional (3D) imaging of large volume tissues at high resolution has become increasingly important in biomedical research. In recent years, tissue optical clearing technique has been proposed for imaging deeper inside tissues. Among various methods, aqueous-based clearing methods are known for good fluorescence preservation and scalable size maintenance. However, most of these methods suffer from either long incubation time or poor clearing performance. To address these issues, we developed a novel aqueous clearing method with reasonable incubation time, good clearing performance and robust compatibility, termed MACS. MACS can render intact organs and rodent bodies highly transparent in a relatively short time and possesses ideal compatibility with multiple fluorescent probes. Using MACS, we performed 3D imaging and reconstruction of the neural structures of transgenic whole adult brains and immunostained mouse embryos, as well as the neural projections throughout the whole brain labelled by viruses. We also visualized the vascular structures of various organs, including mouse brain, spinal cord, heart, spleen, small intestine, and generated 3D pathology of glomeruli tufts in healthy and diabetic kidneys by MACS and light-sheet microscope. We believe MACS can provide a powerful tool for 3D imaging and reconstruction of intact organs and is expected to facilitate the biomedical studies.

Abstract: Three-dimensional (3D) imaging of intact tissues at high resolution is becoming essential in life science researches. The conventional histological tissue analysis based on individual sections is rather valuable but often labor-intensive and prone to registration errors. The recently developed automated serial sectioning and imaging techniques, such as STP or fMOST, enabled high-throughput data acquisition but inevitably lead to sample destruction. Tissue optical clearing technique has been proposed as a distinct method for 3D imaging of large-volume tissues combined with multiple optical imaging techniques. In the past decade, kinds of optical clearing methods have been developed and contributed as powerful tools for deep biological imaging of various intact tissues. Organic solvent-based clearing methods, such as 3DISCO, present the advantages of high clearing efficiency and size reduction for imaging of large samples such as whole organs, and even whole bodies. However, 3DISCO results in a rapid quenching of endogenous fluorescence, which has impeded its application in many studies. Here, we propose an optimized method named FDISCO to overcome this limitation. FDISCO can effectively preserve the fluorescence of various fluorescent probes, including GFP, YFP and tdTomato, and it can also slow the quenching of multiple chemical fluorescent probes. It can

achieve a long storage time up to 1 year while retaining potent clearing capability. We applied FDISCO to clear various tissues, including mouse brain, spinal cord, kidney, skeletal muscle, and so on. Combined with light sheet microscope, we obtained high-resolution imaging and reconstruction of neuronal and vascular networks in different organs. Moreover, FDISCO is compatible with labelling by multiple viruses (RV, PRV, AAV) and enables fine visualization of neurons with weak fluorescence labelling in the whole brain. These results show that FDISCO is an effective alternative to the 3D mapping of whole organs and can be extensively used in biomedical studies.

Title: Exploring the potential of sodium magnetic resonance velocity imaging for determining white matter fiber directionality

Authors: *Y.-A. CHEN, W.-Y. I. TSENG;
Inst. of Med. Device and Imaging, Natl. Taiwan University, Col. of Med., Taipei, Taiwan

Abstract: Efficient information transfer in the brain is supported by white matter tracts. Although diffusion weighted imaging allows the estimation of white matter fiber orientation, there is currently no non-invasive method of estimating the direction of fiber projection. Information on fiber directionality is indispensable for understanding brain connectivity because signal propagation is directional. Previous studies suggested correlation between the direction of current flow along the axon and the direction of axon projection. Because current is composed of moving electrolytes, some of which possessing NMR properties, we conducted simulations to explore the possibility of estimating fiber directionality using sodium magnetic resonance (MR) velocity imaging. To investigate the magnitude and direction of sodium drift under the influence of electric field, we built an axon model based on Hodgkin-Huxley equations and cable equation. Three types of ion channels are used to simulate action potential generation: Fast sodium channels, non-inactivating potassium channels, and fast-transient potassium channels. Since previous measurement results are obtained on peripheral nerves, we adjusted the parameters according to previous experimental results obtained on rat sciatic nerves. The half-width of an action potential generated by the axon model is 0.78 ms, and the conduction velocity is 80.075 m/s. Applying a 0.5-nA current stimulus induces saltatory conduction with a spatiotemporal voltage distribution similar to those observed using voltage-sensitive dye imaging.

Spatiotemporal distribution of electric field derived from the voltage distribution was used to compute the net electric drift of 80 sodium ions equally spaced along an 800-μm myelinated internode. The simulation results showed that, on average, an intracellular sodium ion moves 6.58×10^{-6} μm toward the axonal terminal during the passage of an action potential. Varying internodal length from 100 μm to 800 μm changes the drift pattern but not the order of magnitude of the drift distance. It was also found that the drift distance accumulates over multiple action potentials during T1 relaxation time. However, the order of magnitude of accumulated drift distance did not exceed 10^{-4} μm. The simulated drift velocities are far lower than the theoretical resolution limit of MR velocity imaging. In conclusion, the simulation results indicate that sodium MR velocity imaging is not feasible for estimating the direction of fiber projection.

Title: Recombinant miniaturized antibodies for studying brain structure and function

Authors: *J. S. TRIMMER[1], J.-X. DONG[2], L. PALAO, III[2], C. DUMITRAS[2], B. GONG[2], K. D. MURRAY[3], S. BRIAND-SCHUMACHER[4], B. DREIER[4], A. PLÜCKTHUN[4], J.-C. MONTANARO-PUNZENGRUBER[5], R. SHIGEMOTO[5], R. SANDO[6], T. C. SUDHOF[6]; [1]Physiol. and Membrane Biol., [2]Neurobiology, Physiol. and Behavior, [3]Psychiatry & Behavioral Sci. and Ctr. for Neurosci., Univ. of California, Davis, Davis, CA; [4]Biochem., Univ. of Zurich, Zurich, Switzerland; [5]IST Austria, Klosterneuburg, Austria; [6]Mol. and Cell. Physiology/HHMI, Stanford Univ., Stanford, CA

Abstract: Antibodies (Abs) and related affinity reagents are widely research reagents used to label, isolate and manipulate the function of specific target molecules in complex experimental preparations including in vivo. We have pursued a multi-pronged approach to develop renewable recombinant Abs and related affinity reagents that exhibit specific binding to neuronal target proteins distinctly expressed in specific subcellular structures, cell types, circuits and/or activity states within the brain for use in diverse neuroscience research applications. We have converted a substantial portion of an existing library of mouse monoclonal antibodies (mAbs) into

recombinant form, allowing for their archiving in and dissemination from plasmid banks, and their reliable expression as defined recombinants. This also allows for their engineering into alternate forms more amenable to multiplex labeling applications, and their miniaturization into single chain variable fragments (ScFvs), which are ≈25 kD or 1/6 the mass of the intact parent mAb. We have also generated novel llama nanobodies (nAbs) against neuronal targets. nAbs are nanoscale antibodies derived from atypical heavy-chain only antibodies and represent one of the smallest (≈15 kD) autonomous antigen binding domains known. We have also isolated from highly diverse combinatorial libraries Designed Ankyrin Repeat Proteins or DARPins against neuronal targets. DARPins are small (≈14-18 kD) designer proteins of high affinity and specificity. While each of these binder classes has distinct and somewhat complementary properties, in general the small size, solubility and stability of ScFvs, nAbs and DARPins facilitates their functional expression in mammalian cells, allowing for their use as intracellular antibodies or intrabodies. Their small size also enhances the resolution of imaging obtained when they are used as immunolabels, and enhances their penetration into tissue, cells and subcellular compartments. We have developed ScFvs, nAbs and DARPins that function as intrabodies to deliver cargo to specific neuronal subcellular compartments to report on and/or manipulate neuronal function in vivo. We have also developed these as miniaturized nanoscale immunolabeling reagents to allow for higher resolution imaging of the molecular anatomy of neurons at the ultrastructural (immunogold-EM) and super-resolution scales, and to allow for enhanced penetration into brain tissue for correlative microscopy and whole brain imaging approaches.

Title: A new application of fluorescent organosilica nanoparticles as an imaging tool

Authors: *N. YUASA, Y. FUJIKI, K. HASHINO;
Tokyo Chem. Industry Co., Ltd., Tokyo, Japan

Abstract: The novel type of organic silica nanoparticles, organosilica nanoparticles, has been developed by Nakamura and colleagues. These nanoparticles can be prepared in a single-step reaction and have good size control and dispersibility[1,2]. Organosilica nanoparticles are different

from common silica nanoparticles structurally and functionally. Organosilica nanoparticles have SH groups on the surface and inside, and it is possible to incorporate a fluorescent dye as internal functionalization. Because organosilica nanoparticles contain SH groups as surface functionalization, it is easy to modify their surface with antibodies and other protein molecules. We synthesized 100 nm fluorescent organosilica nanoparticles that are internally functionalized by fluorescein isothiocyanate (FITC) and then conjugated an anti-mouse IgG antibody, protein A, and streptavidin to these nanoparticles. The antibody, protein A, and streptavidin can be chemically modified while retaining their binding ability. It is possible to obtain high-resolution fluorescent images because these probes (i.e., fluorescent nanoparticle conjugates) have photoresistance; therefore, we applied these probes to immunofluorescence staining of mouse brain tissue sections and cultured neurons. We also discuss other biological applications, including *in vivo* imaging, and a whole mouse brain that is treated by a tissue-clearing technique.

Title: Cellular composition of the harbor porpoise (Phocoena phocoena) cortex

Authors: J. KASAI, T. MATSUSHIMA, ***N. PATZKE**;
Biol. Sci., Hokkaido Univ., Sapporo, Japan

Abstract: Toothed whales are commonly accepted to be the world's second most intelligent animals, with only humans displaying greater brainpower. Recently it has been proposed that this cognitive advantage of primates/humans is a direct result of higher neuronal density, and hence total number of neurons in the cerebral cortex in comparison to non-primate mammalian species with similar brain size. Moreover, it was demonstrated that the relationship between mass of cerebral cortex and the number of neurons has been shared between non-primate mammals,

following the same neuronal scaling rule, but differs from that in primates. Primates are characterized by an evolutionarily derived scaling relationship that results in more cortical neurons building a given cortical volume compared to non-primates. Thus, the question arises, if the presumable higher cognitive ability of toothed whales is also accompanied by higher cortical neuronal number as seen in primates or if the cortical neuronal number is as projected from the non-primate scaling rule. To test our hypothesis, we analyze the number of neurons in the cerebral cortex of the harbor porpoise (*Phocoena phocoena*), a small toothed whale (brain mass ca. 560g) using the isotropic fractionator technique. Our results demonstrate that while cortex of the harbor porpoise conforms to the universal non-neuronal scaling rule that applies to all mammals, including primates, it has a higher cortical neuronal number than one would predict from the non-primate cortical scaling rule. These results indicate that brain evolution of toothed whales might have been driven by increased information-processing demand imposed by complex social systems, which lead them deviate from other non-primate mammalian species.

Title: Development of an antibody-free staining method for the visualization of oxytocin receptors in tissue: Histochemical detection of a biotinylated ligand

Authors: *S. M. FREEMAN[1,2], M. C. PALUMBO[2], M. MUTTENTHALER[3], K. L. BALES[2]; [1]Dept. of Biol., Utah State Univ., Logan, UT; [2]California Natl. Primate Res. Ctr., Univ. of California, Davis, Davis, CA; [3]Inst. for Mol. Biosci., Univ. of Queensland, Brisbane, Australia

Abstract: Oxytocin (OT) can act as a potent neuromodulator in a variety of species to influence complex social behaviors, including social bonding, affiliation, and social reward. As a result, the OT system has been highly implicated in the biology and treatment of several psychiatric conditions that are characterized by deficits in sociality, including autism spectrum disorder. Because of this high translational potential for OT to benefit human health, it is crucial that research efforts focus on the fundamental neuroanatomy and physiology of the OT system in the brains of both animals and humans. Thanks to the suite of transgenic tools available, research in mice has contributed considerably to our understanding of the function of OT in the regulation of social behavior. However, non-mouse models are increasingly being used, including monogamous rodents as well as nonhuman primates. To complement the elegant behavioral

pharmacology being done in these species, rigorous neuroanatomical work is required to characterize the underlying neural circuits. Currently, the most reliable and widely available technique for the visualization of OT receptors (OXTR) in brain tissue is receptor autoradiography, but this method only resolves receptors at the gross anatomical level. The most common technique to visualize receptors on the cellular level is immunohistochemistry (IHC) but there are no reliable, commercially-available primary antibodies for OXTR. We have been working to advance the field of OT research by developing a novel method for the cellular staining of OXTR in brain tissue. This technique relies on the histochemical detection of biotin, which has been covalently bound to a selective OXTR ligand. Our biotinylated ligand is deamino-lysine vasotocin (dLVT), which is an analog of OT that binds selectively to OXTR. Here we report our progress in prairie vole brain tissue to develop this staining technique, which we call "autohistochemistry" because it combines the receptor-binding steps at the start of autoradiography with the deposition of a chromogenic stain at the end of immunohistochemistry. We have assessed the effects of the following variables in our optimization experiments thus far: tissue freezing methods, sectioning thickness, fixation strength/duration, the type and duration of blocking steps, signal specificity, and washing procedures. Our future work will combine our autohistochemistry method with IHC for tyrosine hydroxylase in the same tissue sections to demonstrate our ability to use a a double-labeling approach to detect OT-sensitive dopaminergic neurons, which will advance the study of OT neural circuitry in non-mouse organisms.

Title: A novel radioligand for *in vitro* and *in vivo* alpha-synuclein imaging

Authors: *B. JANSSEN[1], Z. LENGYEL[1], C.-J. HSIEH[1], J. J. FERRIE[2], A. RIAD[1], K. XU[1], C. HOU[1], C.-C. WENG[1], W. E. KLUNK[3], C. A. MATHIS[4], E. J. PETERSSON[2], R. H. MACH[1]; [1]Radiology, [2]Chem., Univ. of Pennsylvania, Philadelphia, PA; [3]Psychiatry, Neurol., [4]Radiology, Univ. of Pittsburgh, Pittsburgh, PA

Abstract: The major pathological hallmark in synucleinopathies is α-synuclein (α-syn) fibril formation. Cellular localization and distribution patterns of α-syn aggregates differ between diseases, and therefore α-syn could be a useful marker for diagnosis and disease progression

(Kotzbauer *et al. Clin. Transl. Imaging* 2017). However, a successful ligand for α-syn imaging has yet to be developed. Recently, various antibodies have been shown to bind to α-syn differently in post-mortem brain tissue of Parkinson's disease (PD) patients (α-syn in Lewy bodies) versus that of multiple system atrophy patients (glial inclusions of α-syn; Peng *et al. Nature* 2018). This is in agreement with the identification of multiple binding sites (e.g. sites 2 and 9) in α-syn fibrils (Hsieh *et al*. *ACS Chem. Neurosci.* 2018), and highlights the importance of α-syn specific ligands, that may even be disease-specific. Aim of this study was to validate a hit-to-lead approach from molecular modeling to *in vitro* binding studies to identify new radioligands with high affinity for α-syn.
Based on *in silico* modeling data, **BJ-1-094** was synthesized and K_i values for two binding sites in α-syn fibrils were determined via competitive inhibition with [^{3}H]**tg-1-90b** (site 2) and [^{3}H]**BF-2846** (site 9). Radioiodination was performed to yield [^{125}I]**BJ-1-094**, which was then used to obtain K_d values in both α-syn and Aβ42 fibrils, and for *in vitro* autoradiography on brain sections of an 18-month old transgenic A53T mouse. In addition, binding studies on brain tissue homogenates of PD and Alzheimer's disease (AD) patients and control brain were executed, as well as an *ex vivo* biodistribution in normal balb/c mice.
K_i values for **BJ-1-094** for site 2 and site 9 were 5.2 nM (95% CI 3.2-8.6 nM) and 3.6 nM (95% CI 1.5-8.6 nM), respectively. K_d values of 0.48 ± 0.08 nM for α-syn fibrils and 2.47 ± 1.30 nM for Aβ42 fibrils were obtained using [^{125}I]**BJ-1-094**. Increased binding of [^{125}I]**BJ-1-094** was observed in regions with high α-syn antibody staining in A53T mouse brain. Binding of [^{125}I]**BJ-1-094** to PD tissue was elevated compared with control brain and showed 2-fold selectivity over AD tissue. [^{125}I]**BJ-1-094** entered mouse brain (6 ± 1 %ID/g at 2 min p.i.), and since **BJ-1-094** also bears a methyl group amenable to carbon-11 labeling, further *in vivo* studies with this ligand are ongoing.

Title: Individually tailored segmentation method for distorted hypothalamus in craniopharyngioma patient

Authors: *M. LEE[1], A. HONG[4], J. LEE[2], J. KIM[3], Y. KIM[2], H. CHOI[1];
[1]Dept. of Anat., [2]Dept. of Neurosurg., [3]Dept. of Intrnl. Med., Seoul Natl. Univ. Col. of Med.,

Abstract: Introduction:
Segmentation of specific brain region contour is an essential process for neuroimaging study. Auto-segmentation and semi-auto-segmentation methods are developed for some brain regions. However, certain brain regions, such as hypothalamus, are difficult for segmentation due to low signal contrast. Another problem related to brain region segmentation is a distortion due to surgery or tumor. Therefore, segmentation of low signal contrast structure in distorted brain is a challenging process. The present study aimed to investigate the optimal methods for hypothalamus segmentation of craniopharyngioma patients who have underwent surgical removal.
Methods:
Seventy seven (43 male and 34 female) adult craniopharyngioma patients who underwent tumor removal surgery in Seoul National University Hospital between 2012 and 2017 were analyzed. Manual segmentation of hypothalamus in 3 tesla MRI images was carried out by two independent raters, well trained neuroimaging analyst and expert neurosurgeon. Segmentation was carried out in T1-weighted and T2-weighted MR images of 3mm thickness acquired at 3 Tesla, Sixty one patients' data was analyzed for method 1 and 77 patients analyzed in methods 2. Method 1: segmentation on T1-weighted images in order to established boundaries of hypothalamus. Method 2: segmentation was carried out based on T2-weighted images. Lateral borderline was individually tailored in order to adjust for their distortion level. And thalamus area was excluded.
Results:
Median of age and post-operative duration were 46 years (range: 18-76 years) and 37 months (range: 3-95 months). Pre-operative tumor size was 8142mm3, sd=11804. Hypothalamic volume of 61 segmented by method 1(m=631.73mm3, sd= 227.36) is larger than those by method 2(m= 507 mm3, sd=112.31), t=4.730, p<.001, but positively correlated, r=.412, p=.001. In method 2, hypothalamic volumes in 77 patients were 496.mm3, sd=114.83 in first rater, 497mm3, sd= 128 in second rater. Inter-rater correlation was excellent, r=.852, p<.001. Association between post-operative hypothalamus volume and clinical parameters, such as metabolic phenotype and surgical complications, are analyzed.
Conclusions:
In patients with severe damage, hypothalamic volume could be biased by outwardly displaced location of optic nerve. We have attempted to find an optimized method for hypothalamic volume segmentation by performing quantitative analysis on a large number of cohorts of various degrees of damage. We suggest that an individually tailored assessment is required depending on the degree of hypothalamic damage.

Title: Age-related shrinkage of medial temporal lobe subfields is differentially exacerbated by arterial hypertension: A six-year longitudinal study of healthy adults

Authors: *A. M. DAUGHERTY[1], Q. YU[1], A. R. BENDER[2], L. TANG[1], C. L. DAHLE[1], N. OFEN[1], N. RAZ[1];
[1]Wayne State Univ., Detroit, MI; [2]Dept. of Epidemiology & Biostatistics, Michigan State Univ., East Lansing, MI

Abstract: Hippocampal subfield volumes may change differently across the lifespan and are differentially vulnerable to cardiovascular risk factors. Yet, prior reliance upon cross-sectional designs precludes valid estimates of change trajectories and their moderators. Healthy adults (at baseline: N = 261, age 18-82 years; M = 48.18, SD = 17.96) were assessed three times over six years, with attrition of about 50% at each assessment occasion. Volumes of medial temporal lobe (MTL) subfields - subiculum, combined Cornu ammonis (CA) sectors 1 and 2, combined CA3-dentate gyrus, and entorhinal cortex - were segmented in the length of the hippocampal body on high-resolution MR images ($0.4 \times 0.4 \times 2$ mm^3) using a custom atlas based on highly-reliable manual tracing. Latent change score models estimated sequential change in regional volumes of each subfield across assessments, and hypertension diagnosis was tested as a moderator of the mean changes and age-related differences therein (all effects $p<0.01$, corrected for multiple comparisons). In the total sample, entorhinal cortex volume declined linearly from the baseline to assessment 2 ($change_{12}$ = -12.96) and to assessment 3 ($change_{23}$ = -15.04). Subiculum ($change_{12}$ = -10.25; $change_{23}$ = -11.82), CA1-2 ($change_{12}$ = -11.02; $change_{23}$ = -12.96), and CA3-dentate gyrus ($change_{12}$ = -9.20; $change_{23}$ = -10.72) also demonstrated significant linear decline that was comparable among regions. However, significant individual differences in change were noted. Participants with uncomplicated arterial hypertension (n = 42; mean age = 63.74, SD = 9.98) were older than their normotensive counterparts: t (259) = -6.61. Normotensive adults exhibited a decelerated trajectory of age-related shrinkage in the subiculum (b_{23} = 0.19) and CA3-dentate gyrus (b_{23} = 1.73). In contrast, hypertensive participants evidenced accelerated decline in older age in the CA3-dentate gyrus (b_{23} = -2.08; group difference = 3.82). Differential sensitivity of the medial temporal lobe subfields supports the role of cardiovascular risk as a

negative modifier of aging. Because cardiovascular risk can be modified by behavioral and pharmaceutical means, it can be targeted to promote neural and cognitive function into senium.

Title: White matter microstructure moderates effects of hippocampal volume on memory in older adults

Authors: *A. R. BENDER[1,2], A. BRANDMAIER[1,3], S. DÜZEL[1], A. KERESZTES[1,4,5], O. PASTERNAK[6], S. KÜHN[1], U. LINDENBERGER[1,3];

Ctr. for Natural Sci., Hungarian Acad. of Sci., Budapest, Hungary; [5]Fac. of Educ. and Psychology, Eotvos Lorand Univ., Budapest, Hungary; [6]Psychiatry and Radiology, Brigham and Women's Hospital, Harvard Med. Sch., Boston, MA

Abstract: Age-related memory deficits have been linked to differences in medial temporal lobe (MTL) structure, including limbic white matter (WM) microstructure and hippocampal (HC) volume. However, despite their functional and anatomical interdependence, the combined influences of WM microstructure and HC volume on learning and memory among older adults are rarely investigated. Moreover, in light of mixed extant findings linking HC volume with learning and memory we sought to determine whether this association varies as a function of WM microstructure. In a subsample of 337 older adults (M_{age}=69.66, SD_{age}=3.92 years) originating from the Berlin Aging Study II (BASE-II) who were eligible for MR imaging, we modeled the joint contributions of limbic WM microstructure and HC subfield volumes on the rate of verbal learning. Participants completed a standardized auditory verbal learning task of serially recalling the same 15-item word list over five successive trials. Participants also underwent magnetic resonance imaging (MRI), including structural and diffusion scans. From the latter, we sampled mean fractional anisotropy (FA) from four bilateral limbic WM tracts,

corrected for free water contamination. We segmented three HC subregions from high-resolution structural MRI data, using an established semi-automated method. We used a structural equation modeling (SEM) approach for data analyses. First, we modeled differences in learning rate by fitting a negatively accelerating exponential growth function to the scores from the five learning trials. Second, volumes of each left and right HC subfields as well as the FA of each WM tracts served as indicators to model individual latent factors. Next, we estimated individual latent factors for each of the three HC subfields and each of the four WM tracts. These served as indictors for second-order factors for HC and WM to test their overall associations with the learning slope. Last, we used a latent moderated SEM (LMS) approach to test a hypothesized interaction between HC volume and WM microstructure in explaining variance in verbal learning. LMS results showed differences in learning rate that were explained by limbic WM FA and by the interaction of HC volume and WM FA - but not by HC volume alone. Subsequent analyses showed HC volume is only associated with learning rate in individuals with WM FA values in the upper half of the distribution. We conclude that WM microstructure consistently contributes to verbal learning in older adults, but the association of HC volume depends on WM microstructure. Our results suggest that future studies relating HC volume to learning and memory in older adults should account for differences in WM.

Title: Simultaneous recording of multi-channel electrophysiology and whole-brain-level resting state fMRI on rats

Authors: *Y. MA[1], W. TU[2], T. NEURBERGER[1], N. ZHANG[1];
[1]Biomed. Engin., [2]the Huck Inst. of the Life Sci., Penn State Univ., University Park, PA

Abstract: Multi-channel electrophysiology and resting state fMRI (rsfMRI) have been widely applied in animal studies to investigate neural activity/connectivity at whole brain level. Combining those methods provides a powerful tool to understand neural mechanisms underlying resting-state functional connectivity. During the simultaneous recording, fMRI imaging pulse

sequence induces strong electromagnetic interference on the electrophysiological recording, making it difficult to extract useful electrophysiological signal. Recent studies used a small number of imaging slices to provide a relatively long 'quiet' time for electrophysiological recording without MRI interference, which prevent the acquisition of continuous electrophysiology signals. In addition, this method is difficult to be applied to experimental setup that requires multiple slices of fMRI coverage. In this study, we developed a new animal setup for concurrent acquisition of rsfMRI with electrophysiology at multiple brain sites, and a new denoising method. Data were measured in rats under anesthesia. Results showed that our denoising method successfully removed MRI-induced artifacts, achieving sufficiently high SNR for analyzing local field potential. We also observed that the time course of gamma band (20-100Hz) power was tightly correlated to blood oxygenation level dependent (BOLD) signals in the cortex.

Title: Relationship between electroencephalographic complexity and cortical cholinergic tone during subanesthetic ketamine: A high-density electroencephalogram study in rats

Authors: *M. A. BRITO, D. LI, J. DEAN, C. I. RYBICKI-KLER, T. LIU, A. FRYZEL, G. A. MASHOUR, D. PAL;
Dept. of Anesthesiol., Univ. of Michigan, Ann Arbor, MI

Abstract: Electroencephalographic (EEG) complexity, as quantified through information-theoretic measures such as Lempel-Ziv complexity (LZC), has been used as a surrogate for the brain's repertoire of causal states and the level of consciousness. Recent studies have reported increased EEG complexity as a common feature of the psychedelic state induced by hallucinogenic drugs, including subanesthetic doses of ketamine. Ketamine is known to increase high gamma oscillations and cortical acetylcholine (ACh) levels in rodent models. Increased cortical cholinergic tone is a feature of states associated with phenomenological experience, such as wakefulness or rapid eye movement sleep, and is thought to track with the level of consciousness. However, the scope of studies aimed at investigating EEG complexity in humans during psychedelic states has been limited by lower frequency bandwidths (55Hz or lower) and a

lack of data on cortical cholinergic tone, while studies in rodent models have been limited by the use of sparse EEG channel-density. To overcome these limitations, we optimized a methodology to record high-density (30 channels) EEG data along with multi-site microdialysis of cortical ACh in a rat model. We then investigated the effect of subanesthetic ketamine on simultaneous changes in cortical complexity and cholinergic tone. After establishing baseline data during wakefulness, male Sprague-Dawley rats (n=3) were administered subanesthetic ketamine during the recording of 30-channel EEG while ACh levels in prefrontal and parietal cortices were quantified by high performance liquid chromatography. Ketamine was delivered as a bolus (5mg/kg) over 2.5 minutes followed by continuous low dose infusion (30 mg/kg/hr) for 60 minutes. Changes in EEG complexity were quantified using LZC in 5-minute epochs representing wake state, subanesthetic ketamine, and post-ketamine recovery. As compared to the wake state, subanesthetic ketamine increased cortical complexity [6.5% increase in temporal LZC (Cohen's D=3.01) and a 0.89% increase in spatial LZC (Cohen's D=0.19)] and caused an approximate 2-fold increase in ACh levels across prefrontal (226%) and parietal (146%) cortices. To our knowledge, this is the first study in rat to employ simultaneous measurement of cortical complexity using high-density EEG recordings and changes in ACh levels at multiple cortical sites using microdialysis. These results suggest a correlation between cortical cholinergic tone and EEG complexity during the dissociative state induced by subanesthetic ketamine.

Title: Subcortical-cortical evoked potential for electrophysiology-guided deep brain stimulation targeting for Tourette syndrome

Authors: *J. CAGLE[1], R. S. EISINGER[2], E. OPRI[1], K. D. FOOTE[3], M. S. OKUN[4], A. GUNDUZ[1];
[1]Biomed. Engin., [2]Neurosci., [3]Dept. of Neurosurg., [4]Dept. of Neurol., Univ. of Florida, Gainesville, FL

Abstract: Tourette syndrome (TS) is a lifelong condition that is highly prevalent and socially embarrassing. Deep brain stimulation (DBS) has emerged as a promising treatment option for

addressing tics in appropriately screened cases. In our patient cohort, two 4-contact macroelectrodes are placed during DBS surgery in the centromedian-parafascicular thalamic (CM-Pf) nuclei bilaterally, which is known to suppress tic activity in TS patients, and two subdural strips are placed over the primary motor (M1) cortex. Previously we have shown a significant difference of treatment outcome when the macroelectrode is misplaced in the ventral intermedius (VIM) nucleus of thalamus instead of CM-Pf nuclei, and we had developed a cognitive task utilizing attention and visual evoked potential to differentiate Vim and CM-Pf nuclei of thalamus. In addition to such cognitive tasks, we also explored connectivity markers such as stimulation evoked potentials by examining the stimulation effect in different nuclei of thalamus. To date, the stimulation evoked potentials were collected from three TS patients with chronic DBS implantation. Each patient underwent 3 minutes of stimulation while sitting still, and neurophysiological recordings from DBS electrodes and subdural strips were recorded using sensing-capable implanted neural stimulation, Medtronic Activa PC+S. The stimulation was delivered at 2Hz frequency with 300μs pulse width at 4V amplitude at each bipolar stimulation contacts. This process was repeated with inverted stimulation polarity hoping to remove stimulation artifacts after averaging. The results showed a stimulation evoked potential in M1 cortex 50ms after stimulation when stimulating the VIM nucleus but not when stimulating the CM-Pf nuclei. The result coincides with the attention based visual evoked potential tasks and further support our hypothesis on electrophysiology-guided DBS targeting in TS for improved outcomes.

Title: Functional electroencephalographic connectivity in resting state of premenopause and early postmenopause

Authors: *E. G. GONZALEZ-PEREZ[1], M. S. SOLIS-ORTIZ[2], M. F. MÜLLER-BENDER[3]; [1]Univ. De Guanajuato, Leon, Guanajuato, Mexico; [2]Univ. de Guanajuato, Leon, Guanajuato, Mexico; [3]Univ. Autónoma del Estado de Morelos, Cuernavaca, Morelos, Mexico

Abstract: Postmenopause is the stage in a woman´s life in which her hormone levels decrease causing changes in her entire body, specifically her brain. Estrogens have shown to be one of the most significant hormones to influence these changes. Women were studied in postmenopause compared to women in premenopause in their ovulatory period specifically, because during this

phase their estrogen levels are at their highest peak. The electrical activity in their brains was recorded using electroencephalograms, each group measured held 13 women between the ages of 40 and 60 years old and every EEG was done with eyes closed condition. The frequency bands considered during this analisis were: Delta, Theta, Alpha1, Alpha2, Beta1 y Beta2. Graph theory was used to evaluate brain connectivity. Postmenopausic women showed an increased power of Theta, Alpha2 and Beta 1 bands in frontal, central and temporal brain regions. In brain connectivity, postmenopausic groups showed a more global and local efficiency, and clustering coeficient for Alpha 1, Alpha 2, Beta 1 and Beta 2 bands. These analisis explain that postmenopausic women compared to premenopausic women have better functional connectivity in fast frequency bands, which is explained as a compensatory mecanism towards a posible brain disconnection.

Title: Presence of Targets and Nontargets in ERP-based Complex Trial Protocol (CTP) Significantly Increases P300 Effect as an Index of Stimuli Recognition in Evaluation of Memory Deficit and Malingering

Authors: *E. DAVYDOVA[1], E. LABKOVSKY[2], J. P. ROSENFELD[3];
[1]B. Khmelnytsky Cherkassy State Univ., Cherkassy, Ukraine; [2]Psychology Dept., [3]Northwestern Univ., Evanston, IL

Abstract: Our previous studies demonstrated effectiveness of the Complex Trial Protocol (CTP) to detect concealed information and malingering. The CTP hit rates range from 84 to 100%. The current study investigates how presence or absence of Target and Nontarget stimuli in CTP-like, ERP-based malingering assessment affects outcome.Method: The original CTP utilizes one "Probe" (a relevant/familiar to the subject item), a few (usually 4 or 6) "Irrelevants" (which are irrelevant to the subject items), one "Target" (stimulus with an assigned significance, usually "11111"), and four "Nontargets (random, non-related to the subject stimuli, usually strings of numbers, like "22222", "33333", "444444", and "55555."In the current experiment we tested two types of stimulus (2 blocks): 1) "semantic" (with subject's birthday as probe) and 2)"episodic" (with experimenter's name as probe). There were two conditions: 1) "TARGET" condition, where Targets and NonTargets were presented (in the second part of each trial) along with Probes and Irrelevants (in the first part of each trial) and 2) "NOTARGET" condition,

where Targets and NonTargets were absent. Thus, we had four block/condition combinations or groups: 1) with a subject's birthdate as a Probe and Target/Nontargets included in the protocol (TBD), N=20; 2) with the experimenter's name as a probe and Target/Nontargets included (TNM) N=20, ; 3) with a subject's birthdate as a Probe but without Target/Nontargets (NTBD), N=17; 2) with the experimenter's name as a probe but without Target/Nontargets (NTNM), N=17.Results: A 3-way ANOVA on P300 amplitudes revealed:1) significant group difference, $F(1,29)=8.894$, $p=.006$; T>NT;2) significant block ("semantic" vs "episodic") effect $F(1,29)=16.587$,$p<.0001$, Semantic > Episodic, and nonsignificant condition ("TARGET" vs "NOTARGET") by group interaction $F(1,29)=0.486$, $p=.491$; 3) significant stimulus type ("probe" vs "irrelevant") effect $F(1,29)=68.825$,$p<.0001$, and significant condition ("TARGET" vs "NOTARGET") by group interaction $F(1,29)=4,719$, $p=.038$; and4) significant block ("semantic" vs "episodic") by stimulus type ("probe" vs "irrelevant") interaction $F(1,29)=7.441$, $p<.011$, but NO triple interaction $F(1,29)=.926$, $p=344$. Conclusions: The original CTP protocol with Target and Nontarget stimuli included in the protocol proves to be superior for detection of deception and malingering compared to an ERP protocol lacking Targets and Nontargets.Further research is required to investigate how introduction of countermeasures might affect the accuracy of ac CTP-like protocol without Target/Nontarget stimuli.

Title: Burst suppression latency predicts anesthesia depth

Authors: *D. WANG[1], Q. GUO[1], D. LIU[1], G. ZHANG[1], X. KONG[1], Z. XU[1], A. MANNAN[1], Q. ZHANG[1], S. XIA[1], J. YANG[1], H. ZHANG[1,2], H. DING[1,2], J.-L. CAO[1,2,3];

Abstract: Background: General anesthesia produces various patterns on the electroencephalogram (EEG). Burst suppression is a characteristic phenomenon of deep anesthesia, which could be harmful to patients. The previous reports showed that burst suppression ratio (BSR) had a negative correlation with BIS when the BSR was more than 40. Unfortunately, present clinical monitoring technique is not good enough to predict the depth of anesthesia. The present study was designed to investigate how to predict the subsequent anesthetic depth by testing correlation between burst suppression latency (BSL) and BSR.
Methods: Adult C57BL/6 mice were adopted in the study. The mice were divided into 5 groups, 2 groups were anesthetized by 1.0% and 1.5% isoflurane respectively; the other 3 groups were pretreated with intraperitoneal injection of ketamine (25 mg/kg), dexmedetomidine (15ug/kg) or midazolam (0.5 mg/kg) 5 minutes before 1.0% isoflurane anesthesia. Simultaneously, EEG of all groups was recorded in frontal, parietal and occipital lobe for 2 hours.
Results: There was a negative correlation between BSL and BSR of the EEG (frontal: *P*=0.0876, r=-0.600; parietal: *P*=0.0125, r=-0.7833; occipital: *P*=0.0310, r=-0.7132, n=9) in adult mice under 1.0% isoflurane. When the isoflurane concentration was 1.5%, only occipital EEG displayed negative correlation between BSL and BSR (*P*=0.0149, r=-0.8096, n=9). In the adult mice, the pretreatment of ketamine and midazolam rather than dexmedetomidine not only decreased the BSL, but also increased the BSR during 1.0% isoflurane anesthesia. And the EEG had the consistent correlation between BSL and BSR in occipital lobe compared to isoflurane-only (ketamine: r=-0.8291, *P*=0.0057; midazolam: r=-0.7584, *P*=0.0178; dexmedetomidine: r=-0.8189, *P*=0.0069, n = 9, respectively).
Conclusions: Our study indicated that BSL could predict the subsequent anesthesia depth in subjects received both isoflurane inhalation only and combination of isoflurane inhalation with intraperitoneal injection of ketamine, dexmedetomidine or midazolam. Furthermore, ketamine and midazolam pretreatment could decrease BSL and increase BSR during isoflurane inhalation. In the clinical, anesthesiologist can adjust anesthetics in time according to BSL and chose combination rationality to avoid the occurrence of deep
anesthesia. As anesthesia deepening, the occipital lobe may be the best position to predict or detect subsequent anesthetic depth.

Title: Cortico-cortical evoked potential amplitude is predicted by diffusion imaging-based tractography

Authors: *B. H. SILVERSTEIN[1], E. ASANO[2], A. SUGIURA[2], M. SONODA[2], M.-H. LEE[2], J.-W. JEONG[2];
[1]Translational Neurosci. Program, [2]Pediatrics, Wayne State Univ., Detroit, MI

Abstract: Cortico-cortical evoked potentials (CCEPs) can be utilized to identify effective networks in the human brain. Following electrical stimulation of cortical electrodes, evoked responses are recorded from distant cortical areas. A negative deflection (N1) which occurs 10 - 50 ms poststimulus is considered to be a marker for direct cortico-cortical connectivity. However, with CCEPs alone it is not possible to observe the pathways that conduct the signal or predict N1 amplitude given a stimulation site. Here we used diffusion weighted imaging (DWI)-based tractography to predict N1 amplitude. We hypothesized that CCEP voltage is proportionate to the between-electrode resistance, which we modeled according to V=IR. Assuming constant I, we defined R as the ratio of streamline length to streamline count, reflecting the length and thickness of the "wire."
Eighteen neurosurgical patients underwent both CCEPs during extraoperative recordings and DWI scans. Subdural grids of 3 mm diameter electrodes were used for stimulation and recording, with 98-128 useable electrodes per patient. CCEPs were elicited by trains of 1 Hz stimuli with an intensity of 5 mA and recorded at sample rate of 1 kHz. N1 peaks and latency were defined as the maximum of a negative deflection within 10-50 ms post-stimulus with a z-score > 5 relative to baseline. Electrodes were coregistered to DWI for tractography.
(Figure 1)

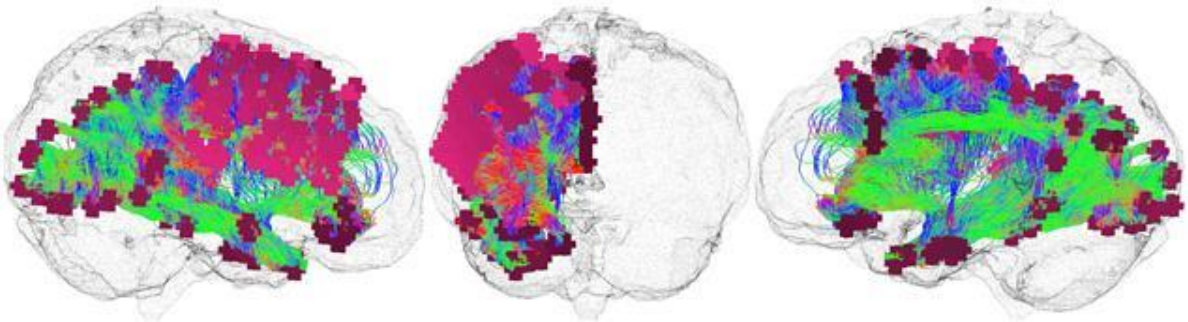

Figure 1: Representative electrode tractography from one patient. Whole-brain probabalistic tractography was estimated from 3T DWI scans (55 directions, b=1000 s/mm2, 2x2x3 mm voxels) in the MRtrix framework. Electrodes were coregistered with the DWI to identify inter-electrode streamlines. Mean streamline length and streamline count were computed to estimate R. Electrodes within 10 mm of the stimulation site were excluded from analysis.

All subjects and electrodes were pooled in a mixed model framework. We observed that voltage was best predicted by log(R): [β = -13.0, SE = 1.19, CE: -15.3, -10.7]. Thus, as R decreases, N1

peak amplitude increases exponentially. However, R did not predict N1 latency [β = 6.1e-4]. Age, recording hemisphere, and number of antiepileptic drugs were used as covariates, but no significant effects were noted.
We have demonstrated that CCEP N1 amplitude is dependent on properties of the underlying white matter network, not volume conduction. The nonlinear relationship between N1 and R suggests that there are unobserved factors which influence N1 amplitude, such as myelination, neurotransmitters, or N1 morphology.

Title: Electrodiagnostic characteristics of upper lumbar stenosis: Discrepancy between neurological and structural levels

Authors: *K. KIM[1], J. PARK[2];
[1]Seoul Natl. Univ. Hosp., Seoul, Korea, Republic of; [2]Hanyang Univ. Guri Hosp., Gyeonggi-do, Korea, Republic of

Abstract: Lumbar spinal stenosis is a common degenerative disease frequently accompanying lumbosacral radiculopathies. Conventional knowledge of lumbar spine suggests that n/n+1 level lesion will result in n+1 radiculopathy. However, the principle seems not applicable to spinal stenosis of upper lumbar levels, of relatively low incidence. This study aimed to investigate electrodiagnostic manifestation of upper lumbar stenosis. Consecutive patients were recruited from a tertiary university hospital. Inclusion criteria were 1) spinal canal stenosis at upper lumbar level (L1/2, L2/3, or L3/4) confirmed in magnetic resonance image (MRI), 2) abnormal electromyography (EMG) including active denervation potentials, and 3) MRI and EMG conducted within 3 months interval. Exclusion criteria were 1) concomitant peripheral polyneuropathy of clinical significance, 2) structural lesions at L4/5 or L5/S1 levels in MRI to explain EMG abnormalities. 24 patients sufficed inclusion criteria and 10 patients were excluded; 14 patients were enrolled in the study. All the patients showed denervation potentials in the distal lower extremity muscles innervated by L5 and S1 roots although the structural lesions were above. L2, L3, or L4 myotomes were rarely affected; only one case exhibited chronic reinnervation in the vastus medialis. Active denervation in the proximal L5 or S1 innervated muscles were observed in 8 patients. Any neuropathic findings were observed bilaterally in 10 patients versus unilaterally in 4 patients. Accordingly, all the EMG findings

could be categorized into 4 types based on symmetry, length-dependency, and myotomal distributions of electrophysiologic abnormalities: ‘motor dominant peripheral polyneuropathy’-like (symmetric, length-dependent; 5 patients), ‘bilateral polyradiculopathy’ (bilateral, asymmetric, non-length-dependent; 5 patients), unilateral polyradiculopathy (unilateral, non-length-dependent; 2 patients), and mono-radiculopathy (2 patients). In conclusion, general belief that n/n+1 level lesion results in n+1 radiculopathy did not apply to upper lumbar stenosis. Without the knowledge of electrodiagnostic characteristic of upper lumbar stenosis, it might be confused as a peripheral polyneuropathy or polyradiculitis without corresponding structural lesion.

Abstract: EEG/MEG are currently the only methods to non-invasively record human neural dynamics with millisecond temporal resolution. These signals are correlated with nearly all healthy and pathological brain functions. However, it is still difficult to infer the underlying cellular- and circuit-level origins without simultaneous invasive recordings. This limits the translation of EEG/MEG signals into novel principles of information processing, or into new treatment modalities for pathologies. To address this limitation, with funding from the NIH BRAIN Initiative we have built the Human Neocortical Neurosolver (HNN): an open-source software tool to help researchers and clinicians without formal computational modeling or coding experience interpret the neural origin of their human EEG/MEG data. HNN provides an intuitive graphical user interface (GUI) to an anatomically and biophysically detailed model of a neocortical brain circuit, with layer-specific thalamocortical and cortico-cortical drives. Unique to HNN is an underlying neural model that accounts for the biophysics generating the primary electric currents underlying EEG/MEG signals from cortical pyramidal neuron dendrites. This construction enables direct visual and statistical comparison between model output and source localized data in equal units (nAm). Users can change model parameters in the GUI for testing hypotheses on signal differences under varied experimental conditions or in patient populations. Users can visualize both macroscale current dipole and microscale circuit activity, including layer-specific responses, cell spiking activity, and membrane voltages. The first freely-available version of HNN was released in 2018 online at http://hnn.brown.edu. Here, we give an overview of HNN and describe new developments and applications, including updated online resources for installing HNN on all major platforms or running online via Neuroscience Gateway Portal or Amazon Web Services. We describe recent expansions including, (i) updated tutorials on simulating event-related potentials (ERPs) and low-frequency oscillations, (ii) conversion of the model to the NetPyNE (http://netpyne.org) specification to enable flexible network development, (iii) development of a new web-based GUI in collaboration with MetaCell (http://metacell.us), (iv) simulation of local field potential and current source density facilitating direct comparison to animal data, and (v) inclusion of model parameter optimization tools. In total, HNN is an unprecedented tool for the EEG/MEG community to translate their human signals to underlying cellular and network-level dynamics.

Title: Temporal pharmacodynamics of intranasal oxytocin: A human EEG study

Authors: *M. ZELENINA[1], K. BRODMANN[2], A. AVILA[2], J. DA CRUZ[3], P. FIGUEIREDO[3], D. PRATA[1];
[1]Inst. De Biofísica E Engenharia Biomédica, Lisbon, Portugal; [2]Inst. de Medicina Mol., Lisbon, Portugal; [3]Inst. Superior Tecnico, Lisbon, Portugal

Abstract: Human neuroscience research has extensively used intranasal oxytocin (OT) to modulate social behavior and its neural correlates. Therefore, it is crucial to know for how long intranasal OT has a measurable effect in human brain activity. Previous studies inferred availability of intranasal OT in the brain indirectly, from OT levels in saliva[1,2] or blood[3,4]. Existing analyses of the cerebrospinal fluid[4] and the regional cerebral blood flow[5] show heterogeneous results. Moreover, the studies stopped recording the data at around 75 min, focused on very specific brain areas, and used research-unconventional doses (40 international units (IU). In this pharmaco-EEG study, we aimed to answer: "For how long does intranasal OT, in the most commonly used research dose of 24 IU, affect the whole brain activity as measured by EEG microstates (MS) and frequency bands?". We collected EEG data from 19 healthy male participants in a double-blinded, placebo-controlled, within-subjects design with intranasal administration of 24 IU of OT/placebo, up to 102 mins post administration, split into three time points: early, middle, late. We preprocessed the data and extracted the following features: duration, occurrence and contribution of four conventional MS, transition probabilities (TP) between each unique pair of MS, and relative amplitudes of frequency bands α, β, θ, δ, differentiated between scalp locations and sides. For MS features, we performed statistical analysis with two-way repeated-measures MANOVAs, and post-hoc analysis with one-way ANOVAs and t-tests. For frequency features, we performed a preliminary exploratory analysis with a non-parametric Wilcoxon test. Our MS results showed significant differences in TP from MS 4 to MS 1 and 2, and from MS 3 to MS 4 in the late time point, and a trend in TP from MS 3 to MS 4 in the early time point. Preliminary results from frequency analysis showed significant results across the whole observation period, varying between bands and scalp locations. We conclude that OT influenced electrical brain activity up to 102 mins post-administration and agree with saliva studies that OT may stay in the system longer than previously thought. As the MS are associated with resting-state brain networks, our results may indicate that OT influences salience and attention re-orientation at 15-45 and 75-102 mins post-administration. However, need for care remains when attempting to cross-correlate or interpret OT availability between saliva, blood, CSF and brain.

Title: Electrophysiological changes in the human brain associated with intake of commercial sweeteners

Authors: S. LOPEZ-MEZA[1], G. A. OTERO.OJEDA[2], J. A. ESTRADA[4], F. J. ESQUIVEL.HERNANDEZ[5], G. GONZALEZ-GONZALEZ[3], *I. CONTRERAS[4];

Autonoma del Estado De México, Toluca, Mexico; [5]Interdisciplinary Res. Unit in Hlth. Sci. and Educ., Univ. Nacional Autonoma de Mexico, CIudad de Mexico, Mexico

Abstract: Introduction Studies performed in both animals and humans have shown a link between non-nutritive sweetener intake and changes in systemic energy metabolism; however, their effects in the brain have not been studied in detail. **Objective** The objective of this study was to compare the effect of short-term consumption of commercially available nutritive and non-nutritive sweeteners on brain cortical electrical activity, using quantitative electroencephalography. **Methods** The sample consisted of 26 clinically healthy people with a normal body mass index. The participants underwent a washout period with restricted intake of food and beverages with added sweeteners. Subsequently, quantitative electroencephalographic (qEEG) records were obtained for all participants. After the first recording, participants were randomly divided into two experimental groups; each group consumed either sucrose (40g) or commercial sucralose (4g) daily, for a period of six weeks. After supplementation, a final qEEG record was obtained from all participants, under the same conditions used in the first session. **Results** The results show significant alterations in cortical activity in the sweetener-supplemented groups. Sucrose intake had significant effects on the left temporal-occipital region, with an increase in absolute power in theta activity and a decrease in the absolute power of delta waves in the left frontal lobe. The sucralose group had an increase in absolute power in theta waves in the occipital lobe and the ventral midline. **Conclusions** Our results show that short-term, frequent intake of nutritive and non-nutritive sweeteners promotes changes in the cortical

activity of the brain, which can have significant effects on the cognitive processes of the people who consume them regularly.

Title: Brain network motifs are markers of loss and recovery of consciousness

Authors: *C. DUCLOS, Y. MAHDID, D. NADIN, S. BLAIN-MORAES;
McGill Univ., Montreal, QC, Canada

Abstract: Functional motifs are patterns of inter-connections between nodes of a complex network. As the basic building blocks of directed networks, motifs could contribute to the understanding of the neural building blocks of consciousness. This study explored the re-organization of 3-node network motifs during loss and recovery of anesthetic-induced unconsciousness. Nine healthy subjects (5 men; 24.4 ±1.0 yo) underwent a controlled anesthetic protocol with propofol (15-min induction) and isoflurane (3h maintenance), while brain activity was recorded through 128-channel electroencephalography (EEG). Five-minute segments of EEG were extracted for the following time points: 1) baseline; 2) induction; 3) unconsciousness; 4) 30-min prior to recovery of consciousness (ROC); 5) 10-min prior to ROC; 6) 5-min prior to ROC; 7) 30-min post ROC; and 8) 180-min post-ROC. EEG data were bandpass filtered between 0.1 and 50 Hz, visually inspected, and segmented into theta (4-8 Hz) and alpha (8-13 Hz) frequency bands. A binarized weighted and directed phase lag index matrix was used to calculate the frequency of occurrence of a motif against 100 random networks. To quantify inter- and intra-subject similarity of motif topological configurations across eight time points, we measured the cosine similarity between network motif configurations across time points. Repeated measures ANOVAs were carried out over all time points for motif frequency and cosine similarity. P-values were corrected using a Greenhouse-Geisser correction. Of the five possible 3-node motifs, three were significant across all time points, when compared to random networks (motifs 1, 2, 7). Repeated measures ANOVAs across all time points showed a significant change in the frequency of theta motif 7 only ($F(11,88) = 3.35$, $p < 0.05$), while cosine similarity

showed a significant change for all motifs, for both alpha and theta (F-values(11,88) > 3.5, p-values < 0.05). A post hoc Dunn-Sidak test revealed that cosine similarity differed significantly during unconsciousness for alpha motifs 2 and 7, and for all three theta motifs (p-values < 0.05). Our results confirm that anesthetic-induced unconsciousness does not suspend motifs, but rather causes a topological re-organization in network motifs. Overall, motifs reveal granular shifts in networks across states of consciousness, and could reveal the neural building blocks of consciousness.

Title: Multi-scale neural resampling to map and monitor neural circuits in non-human primates

Authors: *A. L. ORSBORN[1,2,3,4], J. CHOI[5], C. WANG[6], C. CHIANG[6], J. VIVENTI[6,7,8], B. PESARAN[4];
[1]Electrical & Computer Engin., [2]Bioengineering, [3]Washington Natl. Primate Res. Ctr., Univ. of Washington, Seattle, WA; [4]Ctr. for Neural Sci., [5]New York Univ., New York, NY; [6]Biomed. Engin., [7]Neurobio., [8]Neurosurg., Duke Univ., Durham, NC

Abstract: Neural computations governing behavior are performed across many spatial scales, from individual neurons to distributed populations of neurons. Measuring neural activity relevant to behavior requires both large coverage and high spatial resolution. For a fixed number of recording contacts, there are inherent trade-offs between the total brain area studied and sampling density. Devices such as micro-wire arrays (e.g. Utah array) and linear probes (e.g. Neuropixels) provide dense sampling of spatiallylocalized signals but cover small areas of cortex (~20mm^2) or a single cortical column. No existing recording technology provides highly-resolved dense sampling of large areas. To overcome these limitations, we propose a repeated resampling strategy to effectively build super-resolution composite datasets. We designed a modular neural implant for non-human primates that permits resampling. The implant accommodates a range of hardware to make spatially co-registered repeated measurements. A novel artificial dura (AD) provides chronic subdural access. The AD is divided into a

chronically-implanted cover over dural edges and a removable mating piece over the brain surface (AD hat). We embed a μECoG array into the AD hat, which provides repeatable array positioning within the chamber in 4 orientations. We also align a microdrive containing an array of penetrating electrodes with the AD hat to enable simultaneous spike-field-ECoG recordings. We implanted this system in two male rhesus macaques, over sensorimotor cortices exposing a 254mm^2 area of cortex for study. A μECoG array (244 200 μm diameter contacts, spaced 0.75 mm) was repeatedly implanted in different orientations over months. Recordings were made as animals observed visual stimuli and performed reaching tasks. We find that μECoG responses mapped across the cortex are highly consistent over days for a given μECoG array placement. Moreover, we find that μECoG maps measured across different placements can be converted into a common chamber-based coordinate system to yield similar maps. Fitting spatial maps with spline models allowed us to estimate the spatial alignment of maps and spatial resolution of our measurements. This modular subdural implant allows repeated neural resampling with many measurements, which could overcome coverage- density tradeoffs. Resampling strategies could also create composite longitudinal datasets to overcome longevity limitations of chronic implants, which will be critical for learning studies. Multi-scale composite datasets will be essential for studying large portions of the brain at high resolution to link neural circuit activity to behavior.

Title: Contrasting amplitude and phase-based measured of functional connectivity across states of consciousness

Authors: *Y. MAHDID, C. DUCLOS, J. DA SILVA CASTANHEIRA, S. BLAIN-MORAES; McGill, Montreal, QC, Canada

Abstract: Functional connectivity and graph theory measures, which are based on either envelope- or phase-based coupling modes, may provide powerful insight into the neural

correlates of consciousness. However, these coupling modes have generally been used mutually exclusively in the literature, and a lack of consensus persists around which coupling mode is best suited for identifying the neural correlates of consciousness. This study aims to assess the prediction accuracy of envelope- and phase-based functional connectivity in the prediction of states of consciousness.
Nine healthy subjects (5 men; 24.4 ± 1.0 yo) underwent a controlled anesthetic protocol (propofol induction and isoflurane maintenance), while brain activity was recorded through 128-channel electroencephalography (EEG). EEG was bandpass filtered between 0.1 and 50 Hz, visually inspected, and segmented into the alpha α (8–13 Hz) frequency band, which shows most changes under anesthetic-induced unconsciousness. Data was divided into 10-sec windows across 5 consciousness states (Baseline, Induction, Unconsciousness, Pre-Recovery of Consciousness and Recovery). Mean source activity of the 82 cortical regions of interest (ROI), defined by the Automated Anatomical Labeling Atlas, was extracted to generate a single time series for each ROI, across all subjects and consciousness states. For each 10-sec window and each consciousness state, amplitude envelopes were generated via a Hilbert transform and Phase-lag Index (PLI) was calculated for all ROI pairs. Each subject's whole-brain amplitude envelope correlation (AEC) and PLI functional connectivity matrix was averaged to produce group-level matrices for both AEC and PLI, across states of consciousness. Each 10-sec window was then used to train a linear Support Vector Machine (SVM) classifier to detect each consciousness state, with a mixed subject design. Each window value for each subject's consciousness state was normalized between 0 and 1, and was then separated in a testing and a training set with a 30%-70% split (765 windows for training, 1770 windows for testing). A 5-fold cross validation scheme was used to select the best penalty parameter C for the Linear SVM and the reported generalization accuracy was obtained by training the best classifier on the 30% training split before testing on the remaining 70%.
AEC and PLI both showed state-dependent changes across states of consciousness. In predicting state of consciousness, PLI and AEC showed 54% and 97% accuracy, respectively, suggesting that AEC has stronger prediction accuracy in a mixed subject setting than PLI.

Title: A mobile system for concurrent high density EEG, EMG and closed-loop tCS

Authors: N. YASAR, R. APPARIES, T. POULSON, A. M. WILDER, S. HIATT;
Ripple Neuro, Salt Lake City, UT

Abstract: Electroencephalography (EEG) has long been a leading tool for non-invasive measurement of cortical activity in humans for both clinical and research purposes. Similarly, electromyography (EMG) is a useful non-invasive tool for studying and treating movement disorders or as an indicator of performance in cognitive and other studies. More recently, the use of Transcranial Stimulation (tCS) to non-invasively modulate cortical activity has seen increasing popularity for a number of applications. Although several systems exist for each application, few systems offer concurrent EEG and EMG recording and tCS stimulation in a mobile system. The ability to record and stimulate in a freely moving subject is both useful for research involving movement and natural behavior, as well as long-term clinical interventions. We have developed a low-cost system capable of concurrent high-density EEG and EMG with simultaneous tCS, selectable on any of the EEG recording channels. The system features on-board processing to allow for triggering or modulation of tCS based on the electrophysiological response, and offers up to 512 channels of recording at a resolution of 24 bits and a sampling rate of up to 7.5 ksps. It is capable of several commonly used modalities of tCS, including Direct Current Stimulation (tDCS), Alternating Current (tACS), monopolar or bipolar Pulsed Current (tPCS), and Random Noise (tRNS). The simulation output can also be programed with arbitrary waveforms to take advantage of future modalities as they are developed. The stimulation parameters can be actively configured (manually or preprogrammed), with a compliance voltage of ± 9-30V, and current limit of 100µA - 15mA. Limits on these adjustable settings can be preset to ensure safe boundaries for different stimulation modalities. The system is easily portable as it is small (measuring 183 x 95 x 36mm), light-weight (700g), and features WiFi connectivity for wireless streaming of data. Data can also be stored on the 512GB internal memory for stand-alone operation. An internal battery allows for up to 2 hours of recording, while a hot-swappable battery allows for endless wireless recording (4-6 hours of use per battery between charge).

Title: Visual blindness oscillating in phase with the EEG alpha rhythm

Authors: *K. E. ALEXANDER[1], J. R. ESTEPP[1,3], S. M. ELBASIOUNY[2,1];
[1]Biomedical, Industrial, & Human Factors Engin., [2]Neuroscience, Cell Biology, and Physiol., Wright State Univ., Dayton, OH; [3]711th Human Performance Wing, U.S. Air Force Res. Lab., Wpafb, OH

Abstract: The neural mechanisms underlying the posterior alpha (8-12 Hz) rhythm measured in the electroencephalogram (EEG) are still largely unknown. However, a prominent theory is that alpha oscillations are the result of repeated T-type Ca^{+} channel burst firing in the thalamo-cortical visual relay cells. Each burst results in large, excitatory postsynaptic potentials in their target cells in the primary visual cortex, which appear as alpha peaks in the EEG. After each burst, the cells enter a refractory period that appear as alpha troughs in the EEG. Therefore, we hypothesized that thalamo-cortical visual relay cells do not relay low intensity visual afferentations from the optic nerve to the primary visual cortex during these refractory periods. To test this hypothesis, visual stimuli of threshold intensity will be presented to participants during times of high amplitude alpha oscillations. The visual stimuli will be Gabor patches during an eyes-open condition and light flashes in an eyes-closed condition. In the eyes-open condition, the stimuli will be presented separately to each visual hemifield to control for phase asymmetry between the hemispheres. And, the alpha phase relative to stimulus onset will be measured over the contralateral visual cortex. In the eyes-closed condition, visual hemifields cannot be isolated, so a centered light flash will be used and trials in which left and right occipital alpha oscillations are out of phase will be rejected. In both conditions, alpha phase relative to stimulus onset will be measured after an interval accounting for the neuronal conduction delay since it is theorized that the phase of the measured alpha wave reflects the past state of thalamo-cortical neurons. We expect that stimuli presented with a corresponding trough of the alpha oscillation will not be responded to by the participant. In this way we will provide further evidence of thalamo-cortical burst firing as the underlying generator of alpha oscillations.

Title: The effects of mental workload on P300 amplitude for use in cognitive probing

Authors: *C. L. WINTERMUTE[1], J. R. ESTEPP[1,3], K. E. ALEXANDER[1], A. M. PIASECKI[4], S. M. ELBASIOUNY[2,1];
[1]Dept. of Biomedical, Industrial, and Human Factors Engin., [2]Neuroscience, Cell Biology, and Physiol., Wright State Univ., Dayton, OH; [3]711th Human Performance Wing, Air Force Res. Lab., Wright-Patterson AFB, OH; [4]Ball Aerospace, Fairborn, OH

Abstract: Passive brain-computer interfaces (pBCI) provide support to a human-machine system by sending implicit inputs from neurological signals of the human to his or her machine teammate without generating an explicit output the user intends or even perceives. These neurological signals can be in reaction to cognitive probes the pBCI deploys in order to establish the user's cognitive state. It can be beneficial to adapt a user's experience in a system with a pBCI, such as preventing task-irrelevant stimuli from distracting the user during high workload, thus conserving cognitive resources needed for the primary task. Further, the multiple resource theory predicts a relationship between responses to cognitive probes and task load. The goal of this project was to confirm the presence of this relationship when probing different sensory channels independent of a visual primary task. To achieve that, we used electroencephalography (EEG) to monitor cortical activity in participants while they completed a series of continuous performance paradigms, specifically an n-back working memory task and a tracking task, at varying task difficulty levels. A task-irrelevant, oddball stimulus design was simultaneously deployed as a cognitive probe in a secondary task to elicit a P300 event-related potential (ERP). The oddball used auditory and tactile stimuli to avoid interfering with the visual sensory channel required of the primary task. The hypothesis was that the oddball P300 could be used to index the relative mental workload the participant was undergoing in both continuous tasks, and for both oddball sensory modalities, with some generalizability between primary task conditions. We expected to measure a decrease in P300 amplitude relative to increased mental workload experienced by the participant; further, we expected this attenuation of P300 amplitude to be observable in both primary tasks. The significance of this research will be the observation of how cognitive probes can be utilized effectively in ancillary sensory channels without competing against chiefly visual primary tasks, the flexibility in selecting those ancillary sensory channels, and initial findings about how generalization of the cognitive probe between primary tasks may be achieved.

Title: Evaluation and quantification of the electrical activity of different isolated preparations, with the application of melatonin

Authors: *E.-B. NARANJO-RODRIGUEZ[1], O. ESPEJO-GONZÁLEZ[1], I.-G. CASTRO-TORRES[2], A.-. S. LIRA-ROCHA[1];
[1]Pharm., [2]South-CCH, Natl. Autonomous Univ. of Mexico, Mexico City, Mexico

Abstract: Melatonin [(MT) (N-acetyl-5-methoxytryptamine)] participates in various physiological processes, which allow different species to have a specific behavior. MT, indole derived from tryptophan, is a hormone synthesized and secreted, with a circadian pattern by the pineal gland and peripheral vertebrate tissues. In this work, with conventional rat tissue isolated, the spontaneous electrical activity of duodenum, ileum, colon and uterus was recorded. Aorta (stimulated with carbachol [10^{-8}, 10^{-7}, 10^{-6} M]) and vas deferens (stimulated with electrical activity; F = 0.1 Hz, V = max, D = 1 msec), all were treated with MT [10, 20, 40, 80, 160 and 320 μg/mL]) and the electrophysiological response in brain slices (extracellular records of the hippocampus); with low frequency stimulation trains (1Hz), with MT [15, 30, 45 and 90 μM] the values of the spike were quantified, and compared with the positive control. The analysis of data, considered: Amplitude (AMP), Frequency (FREC) and Area under the curve (ABC). For the analysis of the data, these were captured, stored and analyzed with statistics, by coupling the registration system to a computer. We conclude that the electrical activity of duodenum, ileum, colon and uterus decreased with the application of MT. The similar effect in aorta and the vas deferens. In brain slices, the MT produced specific modulation of plasticity in pyramidal neurons of the hippocampus. The responses obtained were dependent on the concentration, an effect that is produced by the presence of MT receptors in them, allowing us to study the mechanism of action of MT. **Support Proyect: PAL. Title: Electrical brain activity in left and right handed while performing a mental rotation task

Authors: *A. ALCÁNTARA QUINTERO, I. G. GALÁN, Y. DEL RÍO-PORTILLA;
UNAM, Mexico City, Mexico

Abstract: Laterality or handedness is measure by manual preference o manual development (Mcmanus et. al., 2013). Manual preference has been classified as left or right, depending on the hand people uses to write; nevertheless, it also includes the hand preference use to perform different actions (Annett, 1970). The left hemisphere is known for being involved in language processing and the right hemisphere for visuospatial processing; although, this has just been studied in right handed people, in left-handers there is no clear pattern of functional brain organization. Several studies have shown brain activity differences, associated to manual preference (Shimoda, Takeda, Imai, Kaneko, & Kato, 2008). These studies show how EEG is an optimal way to find out differences in networking development. The purpose of this study was to understand the performance of brain functional organization in left and right handed, while answering a mental rotation task. The sample included 20 left handed and 20 right handed participants. Participants were evaluated with different tests of visuospatial skills and were EEG recorded; baseline and during a mental rotation task: two simultanously portrayed 3D rotated shapes were to be compared and asked if both shapes were the same o different is spite of the rotation. The main results showed a significant behavioral perfomance in left handers, whom obtained more correct answers ($p<0.05$). Regarding to electrical brain activity, results showed that right-handers had a higher absolute power in the Theta1 band (F4) and in Gamma band (F7, C4) during the mental rotation task. A pattern of increased interhemispheric temporal coupling for Delta, Theta and Gamma bands in the posterior temporal regions during the task, was found in right-handers. Related to Intrahemispheric temporal coupling, right-handers presented an increased in temporal coupling on both hemispheres, mostly of fronto-temporal and medial regions for Theta1 (F2-T6, T6-P4), Theta2 (F4-FZ), Beta1 (F1-C3, F8-P4, F8-O2, CZ-PZ), Beta2 (F1-P3, F1-T5, F1-CZ, F1-PZ, T3-CZ, F2-O2, F8-O2) and Gamma (F1-C3, T5-FZ,T5-CZ, P3-CZ). Unilateral control could present advantages such as quickness, due to less conductivity between hemispheres and would avoid duplication, which is beneficial in complex functions (Ringo, 1994 and Corballis, 2009). Although, these data showed that eventhough right-handers have more intrahemispheric activity than interhemispheric, these is too much compared to left-handers, whom in conclusion have less temporal coupling making their visuospatial rotation processing more efficient, providing a better development in this type of tasks.

Title: Investigating the impact of landmarks on spatial learning during active navigation

Authors: J. LU[1], A. WUNDERLICH[2], *A. K. SINGH[1], T.-T. N. DO[1], K. GRAMANN[2,1], C.-T. LIN[1];

Abstract: It is well accepted that landmarks play a significant role in spatial navigation but their effects on spatial learning and the accompanying brain dynamics in actively moving participants have not been explored yet. This study proposes a systematic approach to compare the brain dynamics during active physical navigation addressing spatial knowledge acquisition based on allocentric and egocentric reference frames using local and global landmarks. To this end, different spatial navigation tasks will be utilized using high-density EEG synchronized to head-mounted virtual reality. In a pilot experiment we investigated participants' behavior during active exploration of a medium scale VR environment called "Sydney park" (see Figure 1). The environment consists of local landmarks (e.g. bench, lake, table etc.) and global landmarks (lighthouse, Sydney Opera House, Sydney Tower Eye) combined with roads, junctions, bushes, trees etc. similar to the environment of Sydney Royal Botanical Gardens. In this experiment scenario, participants were asked to explore the "Sydney Park" following auditory navigation instructions. The route was defined in a way that balanced participants' exposure to local and global landmarks. At the end of a navigation phase, we asked participants to perform a map drawing task followed by combined wayfinding and pointing tasks to test their spatial knowledge about the navigated environment. The collected data was analyzed using the Gardony Map Drawing Analyzer and customized Matlab scripts.
The results from behavioral data suggest that the participants were able to explore the "Sydney Park" effectively as shown by the quality of their map-drawings. It can thus be concluded that participants were able to develop a mental representation of the "Sydney Park" and that the scenario is acceptable for a full study with EEG. In a next step, we plan to perform the actual experiment with EEG and other physiological measures to investigate the impact of landmarks on spatial learning and its neural correlates.

Title: Mitigating the effects of electrode biofouling for improved long-term measurement of dopaminergic signaling

Authors: B. T. SEATON[1], D. F. HILL[2], S. L. COWEN[3], ***M. L. HEIEN**[1];
[1]Chem. and Biochem., [2]Dept. of Physiol., [3]Dept. of Psychology, Univ. of Arizona, Tucson, AZ

Abstract: Dopamine is an important neurotransmitter that governs many physiological and behavioral systems. Disruption of dopaminergic signaling is involved in chronic pain, Parkinson's disease, and mental disorders. Fast-scan cyclic voltammetry (FSCV) is an electrochemical technique that allows dopaminergic release to be studied in real time. FSCV measurement requires the subtraction of nonfaradaic background current, necessitating a stable background signal over the course of the study for reliable detection of dopamine. Long-term (days to months) FSCV studies thus present a challenge, as the implantation of electrodes in the brain elicits a cascade of immune responses that target the electrodes and degrade voltammetric performance, an effect generally referred to as "biofouling". In FSCV, biofouling manifests as a shift in the nonfaradaic background signal that begins days after implantation and worsens over the course of weeks, confounding dopamine detection. This shift appears to be the result of two biofouling-induced events: a cathodic shift in the Ag/AgCl reference electrode potential due to dechlorination and an increase in reference electrode impedance due to glial encapsulation. These two factors were investigated using scanning electron microscopy/energy-dispersive X-ray spectroscopy (SEM/EDS) and electrochemical impedance spectroscopy (EIS), respectively. A three-electrode headstage that utilizes a platinum counter electrode was designed to compensate for the increased impedance. This headstage significantly reduced ($n = 4$, two-tailed t-test, $p < 0.05$) the FSCV background signal shift in comparison to a conventional two-electrode headstage *in vivo* using Sprague-Dawley rats. However, a shift was still apparent due to the change in reference electrode potential, which declined progressively for 2 to 3 weeks after implantation until settling at ca. 200 mV cathodic to the original potential ($n = 4$). Thus, a reference electrode that keeps its original potential after implantation is vital in obtaining a stable FSCV signal in long-term studies. The potential stabilities of alternate reference electrode materials subjected to *in vitro* biofouling environments are being investigated. In conjunction with the 3-electrode headstage, a stable reference electrode will provide a permanently stable FSCV signal that will allow for reliable dopamine detection over the course of weeks to months, improving the validity of long-term dopaminergic signaling research (e.g. chronic pain and Parkinson's disease).

Title: Synchronous recording of dopamine neurochemical and striatal electrical activity in non-human primates

Authors: *H. N. SCHWERDT[1,2], K.-I. AMEMORI[1], D. J. GIBSON[1], L. STANWICKS[1], T. YOSHIDA[1], S. AMEMORI[1], R. LANGER[3,2], M. J. CIMA[4,2], A. M. GRAYBIEL[1];
[1]Brain and Cognitive Sciences, McGovern Inst. for Brain Res., [2]Koch Inst. for Integrative Cancer Res., [3]Dept. of Chem. Engin., [4]Dept. of Materials Sci., MIT, Cambridge, MA

Abstract: Impaired dopamine neurotransmission is implicated in mood disorders and Parkinson's disease. These disorders also involve abnormal changes in the neuronal activity in the striatum, a major recipient of dopamine. We developed systems to monitor concurrently dopamine and neural electrical activity in non-human primates to examine the multiple modes of striatal signaling involved in key mood and motor behaviors that are compromised in many disorders. Multiple sensors were implanted into the striatum of two rhesus macaques to selectively measure sub-second dopamine concentration changes and oscillatory local field potentials (LFPs) by employing simultaneously fast-scan cyclic voltammetry and electrophysiology. Physiological parameters including pupil diameter, licking and pulse oximetry were also recorded in a monkey to identify cryptic behavioral states. These multi-modal measurements were made as the monkeys performed a reward-biased visual saccade task in which eye movements to targets appearing on the left or right were rewarded with a small or large amount of liquid food. Dopamine concentration changes were greater for large reward trials than for small reward trials in the ventral striatum of the first monkey. These results concord with the well-established role of ventral striatal dopamine signaling reward value. Most measurements in both monkeys were taken from the dorsal striatum where dopamine changes and LFPs displayed diverse site-dependent patterns related to different aspects of motivation. Early analysis suggests changes in dopamine concentration are significantly modulated following

initial trial start cue, peripheral target cue, and reward events as a function of reward condition and target position (left or right) as well as striatal site. Behaviorally contingent dopamine changes were further reflected in the LFPs measured at neighboring sites. These neural signals were also related to measures of autonomic response (heart rate variability and pupil diameter) and vigor (licking), but the dynamics of such relationships are under investigation. The early work described here suggests heterogeneous functions of dopamine that are closely tied to LFP activity in mediating various aspects of motivation. These findings strengthen the rationale for targeted strategies for a number of disorders to help alleviate symptoms originating from dysfunction at specific brain sites. Further investigations are needed to understand the site-specific functions of dopamine and striatal activity in motor and mood behaviors, which could help identify new therapeutic targets.

Title: Kainate induces oscillations in *ex vivo* hippocampal sections on perforated micro electrode arrays

Authors: *J. C. RODRIGUEZ DIAZ[1], K. S. JONES[2];
[1]Neurosci. Grad. Program, [2]Pharmacol., Univ. of Michigan, Ann Arbor, MI

Abstract: Coordinated and synchronized activity in the brain can result in oscillatory activity. Oscillations play crucial roles in many cognitive processes such as memory formation and attention. GABAergic interneurons are crucial for synchronizing neuronal activity leading to gamma oscillations (30-60 Hz).Abnormal oscillatory activity in the hippocampus has been implicated in the pathology of some mental disorders including schizophrenia, however, the neurobiological mechanism underlying these abnormal oscillations are not yet fully understood. We set out to develop an assay that would allow for the study of gamma oscillations in hippocampal sections using microelectrode arrays. Extracellular electrophysiological recordings were performed using 60- channel perforated microelectrode arrays (pMEAs). Oscillatory activity in the gamma band was induced pharmacologically with kainate application. Established

oscillations were inhibited by bath application of the GABAA receptor antagonist bicuculline. Bath application of kainate-induced and maintained oscillatory activity in the gamma band in both CA1 and CA3 regions of the hippocampus. CA1 oscillations had a narrow band with a peak at around 30 Hz while in CA3 the oscillations were broader. Kainate-induced oscillations in CA1 and CA3 were abolished by application of the GABAA receptor antagonist bicuculline. These studies suggest that kainate-induced oscillatory activity can serve as a model of *in vivo* GABA-dependent gamma oscillations in the hippocampus. Furthermore, pMEAs provide a tool to study oscillations in nearby regions during chemically induced oscillations. Future studies will focus on determining the oscillations sensitivity to glutamate receptor antagonists and comparing these with oscillations induced in an animal model of schizophrenia.

Title: Role of human induced pluripotent stem cell-derived spinal cord astrocytes in the functional maturation of motor neurons in a multielectrode array system

Authors: *A. TAGA[1], R. DASTGHEYB[1], C. W. HABELA[1], J. A. JOSEPH[1], J.-P. RICHARD[1], S. GROSS[1], G. LAURIA[2], G. LEE[1], N. HAUGHEY[1], N. J. MARAGAKIS[1];
[1]Johns Hopkins Univ., Baltimore, MD; [2]Fondazione I.R.C.C.S, Inst. Neurologico Carlo Besta, Milan, Italy

Abstract: Objective and rationale: The ability to generate human induced pluripotent stem cell (hiPSC)-derived neural cells displaying region-specific phenotypes is of particular interest for modeling central nervous system (CNS) biology *in vitro*. With the increasing number of differentiation techniques, the electrophysiological characterization of hiPSC-derived neurons has become crucial to provide accurate measures of their function. We describe a unique method by which spinal cord hiPSC-derived astrocytes (hiPSC-A) are cultured with spinal cord hiPSC-derived motor neurons (hiPSC-MN) in a multielectrode array (MEA) system to record electrophysiological activity over time.
Methods: Through the critical steps of caudalization and ventralization, we generated spinal cord hiPSC-A and -MN. We then optimized the co-culture paradigm for MEA recording and

investigated astrocyte variables that influenced MN maturation. Immunocytochemistry and quantitative PCR were used to analyze astrocyte and neuronal populations. MEA recordings were performed weekly over a four-week period, to obtain electrophysiological parameters including spike and burst rate and the percentage of spiking and bursting electrodes. Finally, we used MEA recording to test the electrophysiological effects of drugs targeting hiPSC-MN receptors (i.e. AMPA/Kainate receptor and GABA receptor) and hiPSC-A transporters (i.e. EAAT2 and Cx43).
Results: We show that hiPSC-A enhance hiPSC-MN electrophysiological maturation in a time-dependent fashion. The sequence of plating, density, and age in which hiPSC-A are co-cultured with MN, but not their respective hiPSC line origin, are factors that influence neuronal electrophysiology. When compared to co-culture with mouse primary spinal cord astrocytes, we observe an earlier and more robust electrophysiological maturation in the fully human co-cultures. These findings are supported by immunocytochemistry and real time PCR studies in parallel cultures demonstrating human astrocyte mediated changes in the structural maturation and protein expression profiles of the neurons. Interestingly, this relationship is reciprocal and co-culture with neurons influences astrocyte maturation as well. Pharmacological assays confirmed increased expression over time of hiPSC-MN receptors and hiPSC-A transporters in co-cultures.
Conclusions: This fully human *in vitro* platform for the electrophysiological evaluation of spinal cord astrocyte/MN interactions has the potential to more accurately model human diseases with spinal cord pathology, including spinal muscular atrophy (SMA) and amyotrophic lateral sclerosis (ALS).

Title: Monitoring activity of *Drosophila* larvae with impedance measures

Authors: *N. S. F. DE CASTRO[1], R. L. COOPER[2];
[1]Biol., Univ., Lexington, KY; [2]Dept Biol, Univ. of Kentucky Dept. of Biol., Lexington, KY

Abstract: Monitoring *Drosophila* larval movement with electrical detection allows one to record movements without the use of lights and cameras. This may be a more suitable technique in some experimental paradigms such as those using light sensitive proteins in optogenetic techniques. In determining when an larva starts to move or continue to moves after a light induced activation of Channel Rhodopsins, expressed either in body wall muscles or neurons, is of interest as one can determine that the recovery period or if the light stimulus is inducing a cessation of movement. We have developed a technique using an impedance measure of the media the larvae are in as a index of larvae movement. As a proof of concept, we record with IR camera the larval movement simultaneous with impedance measures. The two techniques parallel each other in their ability to index larval movements. The disadvantages of impedance measures is the environmental disturbances such as air movement over the preparation or drying out of the media; however, these environmental conditions need to be controlled when performing behavioral assays using a camera or an impedance measure. Bright LED light used in optogenetic experiments tend to saturate cameras unless filters are used and different filters maybe necessary depending on the LED spectrum and sensitivity of the camera. Impedance measure are independent of the type of LED or brightness.

Abstract: Bioelectronic medicine (BM) uses implantable neural interfaces to treat chronic diseases through the modulation of selected neural circuits regulating specific organ and system functions. Given the numerous afferent and efferent vagal fibers innervating multiple organs,

vagus stimulation is one of the most promising applications in BM. At the same time, being the vagus the most complex visceral nerve, its precise modulation is possible only using closed-loop control approaches. Several steps are required to achieve this goal since the design of optimal neural interfaces is limited by the inadequate knowledge of the way vagal neural activity regulates specific physiological processes.
In this study, we recorded vagus nerve activity with different types of neural interfaces during alterations of physiological parameters. In 9 anesthetized farm pigs, left (n=4) and right (n=5), cervical vagus nerves were surgically implanted with a tripolar cuff electrode and a self-opening neural interface (SELINE) to record electroneurograms. Physiological variables such as respiratory volume/rate, arterial blood pressure, heart rate, and glycemia were altered, respectively, by mechanical ventilation and intravenous infusions of angiotensin II or sodium nitroprusside or 20% glucose solution or insulin. Spectral analysis of the neural recordings revealed that changes in vagal activity in response to those alterations are reflected by variations of low-frequency (< 40 Hz) and high-frequency components. Interestingly, we were able to find specific spectral modulations associated with each manipulation of physiological variables. This paves the way to algorithms decoding online vagus activity for closed-loop applications. Results strongly varied with electrode type: while recordings acquired from cuff electrodes had poor spatial resolution and selectivity (with high redundancy among channels), SELINE displayed higher selectivity by detecting, through its multiple active sites, spatially distinct and stimulus-specific changes in low and high-frequency neural activities. Subsequent histological examination of the nerve with the SELINE probe left in place allowed the identification of fiber fascicles adjacent to specific recording sites. These novel findings support the possibility to map the topographical heterogeneity of vagal electrical activity within the nerve as a preliminary step towards the development of highly selective BM interventions.

Title: Noise reduction in MEG measurement during transcranial alternating current stimulation

Authors: *S. SHIBUSAWA[1,2], A. OTSUKA[2], K. AMANO[2,1];
[1]Osaka Univ., Osaka, Japan; [2]Natl. Inst. of Information and Communications Technology, Ctr. for Information and Neural Networks, Osaka, Japan

Abstract: Transcranial alternating current stimulation (tACS) is a promising tool to non-invasively manipulate neural oscillations, and is known to be effective for affecting several brain functions such as motor (Brignani et al., PLoS One, 2013), memory (Reinhart & Nguyen, Nat Neurosci, 2019) and perception (Minami et al., Curr Biol, 2017). However, the direct effects of tACS on brain oscillations have remained unclear because broadband noise and the peaked noise at the stimulation frequency make MEG measurements difficult.
In a typical tACS setting, the cables extending to the anode and cathode electrodes runs parallelly and causes an antenna effect, which amplifies the noises originating from the stimulation current. From the aspect of MEG measurements during tACS, it is better to make the antenna effect as small as possible by maximally twisting the cables. This will, however, limit the degree of freedom in electrode arrangement. Here we used simNIBS to simulate the difference in current density distribution between a conventional electrode arrangement and the arrangement where the electrodes are rotated by 90 deg from the conventional arrangement and the cable side of the electrodes are facing closely with each other so that the cables are maximally twisted.
The simulation was performed for the stimulation protocol of our previous study where the peak alpha frequency was manipulated by the current stimulation applied to the parieto-occipital area (Minami et al., Curr Biol, 2017). As a result, it was found that the stimulated brain areas did not change depending on the orientation of the electrodes. The current density in the brain was rather increased with the twisted electrode arrangement so that the current intensity can be reduced. This is better for noise reduction and helps to prevent trapping and flipping of the MEG sensor, which means loss of brain activity information near the stimulation brain areas. When MEG was measured during tACS in both arrangements, the arrangement with maximally twisted cables significantly reduced the broadband noise and the harmonics of the stimulation frequency. Simulation of the current density distribution generated by tACS revealed that the arrangement with the rotated electrodes enables us to reduce current intensity to obtain the current density distribution comparable to a conventional configuration. Reduction of both current intensity and antenna effect with this setting leads to noise reduction of the MEG sensor and prevents trapping and flipping, enabling high signal-to-noise ratio measurements. Our results contribute to the simplification of noise modeling in the separation of noise generated by tACS and brain activity.

Title: Improving an open-source commercial system to reliably perform activity-dependent stimulation

Authors: *S. BUCCELLI[1,2], M. D. MURPHY[3], Y. BORNAT[4], D. T. BUNDY[3], R. J. NUDO[3], D. J. GUGGENMOS[3], M. CHIAPPALONE[1];

Abstract: Activity-dependent stimulation (ADS) protocols are designed to manipulate and strengthen in vivo neural connections and offers a promising tool for promoting neurophysiological reorganization following a brain injury. The effectiveness of these protocols relies on the accurate detection of events from the extracellular field of one area and the timing of the delivery of stimulation pulses at fixed, short-duration latencies to a separate region. Typically, this pairing is done by using single- or multi-unit as the trigger event, which may limit the functional application of this protocol. In order to expand the potential scope of this therapy we are developing ADS protocols in which low frequency signals (i.e. < 300Hz) can be used as the trigger event by utilizing a particular phase and a power above threshold within specific frequency bands of the local field potential signal. A challenge of ADS regardless of signal type is that trigger detection can suffer in awake and behaving animals due to biological signal sources such as movement and chewing, necessitating the use of methods that can robustly distinguish between neural unit activity and biological noise, which may negative impact the ability to strengthen the targeted connections. Here, we improved a low-cost commercial system to reliably perform both spike detection and local field potential filtering in awake rats. We implemented a spike detection state machine on a commercial field-programmable gate array (FPGA) based on multiple user-programmable thresholds. A series of offline and online analyses showed that our implementation was able to appropriately trigger stimulation during epochs of biological noise such as chewing with an overall accuracy higher than 97%. Notably, this implementation improves upon the capabilities of a commercial, low-cost neurophysiological acquisition system (Intan Technologies) with minimal disruption to existing workflows designed to use it. Our improvements have been made open-source and are freely available to all scientists working on closed-loop neuroprosthetic devices.

Title: Biological sex differences in response to vagus nerve stimulation: Investigation into cardiovascular and immune system effects

Authors: F. YAGHOUBY, K. JANG, U. HOANG, ***S. VASUDEVAN**;
U.S. Food and Drug Admin., Silver Spring, MD

Abstract: Vagus nerve stimulation (VNS) has been approved for the treatment of epilepsy, depression and cluster headache. While VNS has been reported to be an effective treatment for other conditions such as rheumatoid arthritis and tinnitus, the importance of biological sex differences for off-target effects has been overlooked, despite the existence of anatomical and physiological differences between men and women. Our objective is to study the biological sex differences associated with VNS on the cardiovascular and immune systems. This is being studied using chronic rodent models implanted with wireless Electrocardiogram (ECG) devices and custom VNS cuff implants. Under approval by the Institutional Animal Care and Use Committee (IACUC) at the FDA, male and female Lewis rats (n = 16) were first implanted with a wireless physiological monitoring device for continuous ECG recording. After three weeks, each animal was implanted with a custom cuff electrode around the left cervical vagus nerve. Upon complete recovery from surgeries, a daily stimulation protocol was triggered and continued for 8 weeks using a wireless programmable pulse generator. To characterize the immune system effects, blood samples were collected on a weekly basis and the expression of inflammatory cytokines was examined. Cardiovascular variables from ECG and cytokine concentration levels were compared between male and female animals at different time points of the experiment to evaluate VNS effects. Two groups of rats including treatment (n=8) and sham (n=8) were used in this study with an equal number of male and female animals (n=4) in each group. Comprehensive analysis of ECG signals was performed to quantify cardiovascular effects. ECG features and cytokine levels were averaged for each week and compared between groups at different time points of the experiment. Sex-specific cardiovascular responses were observed for selected ECG variables. Additionally, immune system effects reflected by cytokine concentrations showed a notable increase after surgeries with slight differences between male and female rats. Biological sex differences in safety assessment of Vagus nerve stimulation (VNS) have been primarily neglected, despite sex-specific anatomical and physiological differences. In this animal study, we investigated the off-target effects of VNS on cardiovascular

and immune systems and the role of sex differences in safety assessments. In a cohort of male and female rats, significant differences were observed for heart rate variability analyses. However, inflammatory biomarker assessment did not reveal significant effects between the two groups.

Title: A multi-channel asynchronous neurostimulator with artifact suppression for neural code-based stimulations

Authors: *S. ELYAHOODAYAN, W. JIANG, H. XU, D. SONG;
Biomed. Engin., USC, Los Angeles, CA

Abstract: A novel 32-channel neurostimulator for generating neural code-based, precise, asynchronous electrical stimulation pulses is designed, fabricated and characterized. This system can deliver charge-balanced, constant current biphasic pulses, with arbitrary pulse patterns in multiple electrodes using a multiplexer to save power and area. The design also features a stimulus artifact suppression technique that can be integrated with commercial amplifiers. Using an array of CMOS switches, electrodes are disconnected from recording amplifiers during stimulation, while the input of the recording system is shorted to ground through another CMOS switch to suppress ringing in the recording system. The timing of the switches used to block and suppress the stimulus artifact are crucial and are determined by the electrochemical properties of the electrode. This system allows stimulation and recording from the same electrodes to monitor local field potentials with short latencies from the region of stimulation for achieving feedback control of neural stimulation. In this way, timing between each pulse is controlled by inputs from an external source and stimulus magnitude is controlled by feed-back from neural response from the region of stimulation. The system was implemented with low-power and compact packaged microchips to constitute an effective, cost-efficient and miniaturized neurostimulator. The device has been first evaluated in phantom preparations and then tested in hippocampi of behaving rats. Benchtop results demonstrate the capability of the stimulator to generate arbitrary spatio-temporal pattern of stimulation pulses dictated by random number generators to control magnitude and timing between each individual biphasic pulse. In vivo results show that evoked potentials elicited by the neurostimulator can be recorded ~2ms after the termination of stimulus

pulses from the same electrodes where stimulation pulses are delivered, whereas commercial amplifiers without such an artifact suppression typically result in >60ms recovery period. This neurostimulator design is desirable in a variety of neural interface applications, particularly cortical prostheses aiming to restore cognitive functions by reinstating neural code transmissions in the brain.

Title: Evoked haptic sensations in the foot through high-density transcutaneous nerve stimulation

Authors: L. PAN, L. VARGAS, X. HU, H. HUANG;
UNC/NC State Joint Dept. of Biomed. Engin., North Carolina State Univ. and Univ. of North Carolina-Chapel Hill, Raleigh, NC

Abstract: Evoking haptic sensation on upper limb amputees via peripheral nerve stimulation have been investigated intensively in the past decade, but the related study on lower limb amputees is limited. This study aimed to evaluate the feasibility of using non-invasive transcutaneous nerve stimulation to evoke haptic sensation of amputated foot in transtibial amputees. A high-density electrode grid (4x4) was placed over the skin surface above the intersection of the sciatic, tibial, and common peroneal nerves. We hypothesized that electrical stimulation delivered to distinct electrode pairs created unique electric fields, which can activate selective sets of sensory axons innervating different skin regions of the foot. Five transtibial amputee subjects (three unilateral and two bilateral) were tested by scanning all possible electrode pairs. All subjects reported various haptic percepts at distinct regions of the foot corresponding to specific electrode pairs. Compared with the evoked sensation in the upper limb through transcutaneous nerve stimulation, the evoked haptic sensations of the foot had lower spatial resolution. Although sensation was perceived at different regions of subjects' phantom foot, sensation at the heel was rare in a majority of the subjects. These results demonstrated the capability of our non-invasive nerve stimulation method to evoke haptic sensations in the foot of transtibial amputees. The outcomes can help us understand the neurophysiological mechanism of missing limb sensation in lower-limb amputees, and can also facilitate future development of strategies to manage phantom pain and enhance embodiment of prosthetic legs.

Title: Parametric characterization of implanted and non-invasive vagus nerve stimulation strategies in rat

Authors: *J. E. BUCKSOT[1], K. MORALES CASTELAN[2], S. K. SKIPTON[2], S. A. HAYS[1]; [1]Bioengineering, Univ. of Texas At Dallas, Richardson, TX; [2]Behavioral and Brain Sci., Univ. of Texas at Dallas, Richardson, TX

Abstract: Vagus nerve stimulation (VNS) has rapidly gained interest as a treatment for a variety of disorders. A number of methods have been employed to stimulate the vagus nerve, but the most common is through a cuff electrode implanted on the cervical vagus nerve. Recently, two non-invasive methods have gained traction: transcutaneous cervical VNS (tcVNS) and transcutaneous auricular VNS (taVNS). Despite promising clinical results, there has been little direct comparison of these methods to the traditional implant. In this study, we compared both non-invasive strategies to stimulation with an implanted cuff in rats using activation of the Hering-Breuer reflex, a well-established biomarker of VNS. We found that the threshold to activate the vagus using an implant was 0.582 ± 0.053 mA, and there was no detectable muscle twitching in the neck at intensities below 2.5 mA. The threshold to activate the vagus using tcVNS was 28.36 ± 2.25 mA. The threshold to cause twitching of the neck muscles with tcVNS was 2.18 ± 0.18 mA, indicating substantially stronger stimulation intensities are needed to elicit activation of the vagus nerve. With taVNS, we found no activation of the Hering-Breuer reflex at any parameter. These results demonstrate that tcVNS can activate the cervical branch of the vagus nerve, however, the required stimulation intensities are well above the tolerable intensities used clinically. These results provide greater insight into activation of the vagus nerve with each strategy and provide a framework for selecting stimulation parameters and implementations for future studies.

Title: Electrical stimulation waveform modulates spatial and temporal activation of cortical neurons *in vivo*

Authors: *K. C. STIEGER[1,2], J. R. ELES[1], K. A. LUDWIG[5,6], T. D. Y. KOZAI[1,2,3,4,7];
[1]Bioengineering, [2]Ctr. for The Neural Basis of Cognition, [3]Ctr. for Neurosci., [4]McGowan Inst. for Regenerative Med., Univ. of Pittsburgh, Pittsburgh, PA; [5]Biomed. Engin., Univ. of Wisconsin Madison, Madison, WI; [6]Neurolog. Surgery, Univ. of Wisconsin, Madison, WI; [7]Neurotech Ctr., Univ. of Pittsburgh Brain Inst., Pittsburgh, PA

Abstract: Although electrical stimulation has been used for over a century to investigate the functional role of neural circuits, the direct neurobiological response to stimulation is highly variable and remains poorly characterized within the vast parameter space. Stimulation of spatially localized neuronal populations could increase the reliability of activation and limit damage during long stimulation trains. Current hypotheses suggest that electrical stimulation activates proximal axons resulting in poor spatial localization and rapid accommodation at higher frequencies (> 90 Hz). Asymmetric waveforms have the potential to selectively activate specific neuronal compartments by taking advantage of the nonlinear properties of voltage-gated sodium channels. Utilizing male C57BL/6J-Tg(Thy-1-GCaMP6s) mice we used in-vivo two-photon microscopy to image neuronal calcium activity in layer 2/3 neurons and widefield mesoscale imaging to image larger population activity during 30s stimulation trains while varying polarity and waveform asymmetry. Our preliminary data suggest distinct spatial and temporal differences based on stimulation waveform. Specifically, in mesoscale imaging we observed decreases in the peak and average area of activation during the 30s stimulation train in the first stimulation paradigm. However, compared to a second stimulation paradigm, we observed increases in peak and average area of activation. Using two photon imaging we observe decreases in the number of neurons activated, the neuronal activation time, and mean and maximum normalized changes in fluorescence, and a slight increase in the percentage of activated neurons within 100μm of the electrode in the first paradigm compared to the second. These findings suggest that stimulus waveform and polarity may play a major role in the spread of activation and entrainment of neurons during electrical stimulation, which may be critical for research in neural circuits in addition to clinical therapeutic use.

Title: Selective DRG neuromodulation by flexible parylene based electrode array

Authors: *T. GUO, L. CHEN, S. ILHAM, N. NOLTA, M. HAN, B. FENG;
Univ. of Connecticut, Storrs, CT

Abstract: *Background*: The dorsal root ganglions (DRG) consisting of clustered afferent somata in the spinal cord foramina have emerged as novel neuromodulatory targets for alleviating symptoms like chronic pain. Compared with other neuromodulatory targets, DRG offer more selectivity not only than the spinal cord due to the distinct dermatomes innervated by different DRG, but also than the peripheral nerves due to the larger spatial distribution of the afferent somata in contrast to the tightly wrapped axons in fascicles. Indeed, our recent GCaMP6f recordings indicate that high-threshold colorectal afferents that are putative visceral nociceptors have neural somata concentrated in the caudal region of mouse L6 DRG. In this preliminary study, we developed a flexible stimulating electrode array, the first of this kind that could potentially allow selective targeting of the caudal region of the DRG to alleviate visceral pain. *Methods*: The multichannel electrode array was micro-fabricated on a flexible material (paryleneC) to conform to the surface curvature of the DRG. In each channel, we enhanced the spatial selectivity of electrical stimulation by surrounding the stimulating electrode with a concentric returning electrode. The preliminary electrode array consisted of four channels for stimulating the anterior, posterior, medial, and lateral region of one DRG. We deposited gold as the electrode material via E-beam evaporation and covered the gold wires with another layer of paryleneC. The electrode surfaces were exposed by reactive ion etching and modified with iridium oxide films by cyclic reduction/oxidation reactions. *Results*: Fabricated electrode array showed low impedance (<10 kΩ) as measured by electrochemical impedance spectroscopy, suitable for safe delivery of 100 μA currents under the voltage limit of 1V. GCaMP6f fluorescent recordings from L6 DRG in transgenic mice confirmed local activation of the caudal DRG by the novel flexible electrode array. *Conclusion*: The current study reported an innovative flexible electrode array that allowed selective activation of a sub-region of DRG somata to limit the off-target side effects. One potential application of this electrode array is to target the caudal region of the DRG to relieve nociceptive visceral pain.

Sci., Tehran, Iran, Islamic Republic of

Abstract: Pseudo random binary codes such m-sequences are usually used in code modulated brain computer interfaces to evoke code modulated visual evoked potentials (c-VEPs). These codes are favorable because of their broadband spectrum and correlation properties and provide high speed with low cross interference of target stimuli in BCIs. However, these codes cause high visual fatigue. In this study, we generated broadband chaotic code to evoke c-VEPs and examining whether they could be used in designing more comfortable code modulated BCIs or not. Four lagged versions of m-sequence and chaotic code with 31-bit length were used visual stimuli and presented to evoke c-VEP (code modulated VEPs) in normal subjects (n=44, 21 females), then the EEG responses to corresponding codes were recorded. We used Canonical correlation analysis (CCA) and spatiotemporal beamforming (STB) methods for analysis of EEG signals. Additionally, we evaluated the subjective visual fatigue using self-reported VAS scores for both types of codes. The results of analysis indicate that chaotic codes decoded from their evoked responses successfully as well as m-sequence codes. The total average accuracies of all subjects were 93.6 ± 11.9 % and 94 ± 14.4 % for chaotic and m-sequence codes respectively. The statistical analysis of obtained accuracy did not show significant difference in accuracy rates However, there was significant visual fatigue reduction by using of chaotic codes compared to m-sequence (paired t-test (t (43) =4.054, p=0.0005)). The newly introduced chaotic codes for evoking c-VEPs evaluated successfully by CCA and STB methods. The chaotic codes cause low fatigue rates compared to m-sequences because of their inherent properties of chaos theory

which is more compatible with visual neural system. Therefore, we suggest use of binary chaotic codes in order to design comfortable and ergonomic code modulated BCIs.

Title: Real-time application of machine learning algorithms to electroencephalography for predicting brain states

Authors: *M. OGANESYAN, I. TARASENKO, N. VYSOKOV;
Brainpatch, London, United Kingdom

Abstract: Commercial electroencephalography (EEG) devices are becoming cheaper and are rapidly entering the consumer market, but with the high inter-trial variability and low signal-to-noise ratio (SNR) the performance of data analysis remains a challenge. At the same time, modern machine learning techniques are used to discriminate between brain states or responses. However, most of the published research has at least one of two key limitations: need for some degree of human involvement at the preprocessing stage for complex problems, or simplistic binary classification with disregard for intermediate brain states.
In this work, we report a pipeline capable of processing an 8 channel EEG signal from consumer-grade equipment (OpenBCI) and predicting the state of a subject's brain in real time, with no human involvement. We have used relaxation/concentration as a positive control, and to compare performance of existing approaches with our system. The training dataset was collected by recording relaxed (eyes closed), idle and concentrated states, with subjects performing a range of standard working memory or mental performance tests. At real-time inference stage, the state (binary or multiclass classification) was determined by first dynamically pre-processing the data, generating a robust feature space, and finally classifying using a random forest. We achieved a high degree of accuracy (>80%), F1 score (>0.8), and reproducibility of our pipeline for determining the brain states in real time.
Thus, our approach is capable of effectively distinguishing between both the extreme forms of relaxation and concentration, as well as the idle states in between. The low computational requirements of a random forest compared to popular deep learning techniques allow for portability to embedded low-cost consumer grade devices, while high confidence predictions

across ‘unseen’ subjects allow for commercialization of this technology in an industrial and office setting. Furthermore, of particular scientific interest is the capability of the random forest to track EEG features that yield the greatest prediction power out of a wide range of autogenerated interaction features (unlike the black box behavior of deep learning architectures), thereby potentially unmasking inner workings of a particular brain state.

Title: Evoked movements and muscle activations through transcutaneous stimulation near the spinal cord

Authors: Y. ZHENG[1], ***X. HU**[2];
[2]BME, [1]Univ. of North Carolina at Chapel Hill, Chapel Hill, NC

Abstract: Functional electrical stimulation (FES) can help individuals with neurological disorders to restore the motor function of upper extremities. However, the application of conventional FES is limited because stimulation at the muscle belly activates muscles in a non-physiological way (i.e., inaccessible to deep muscles, highly synchronized activation of muscle fibers, and non-physiological recruitment order of motor units), which can lead to fast fatigue and limited motions. To address these issues, we sought to elicit arm and hand motions by transcutaneously stimulating near the spinal cord (C5 to T1) with an electrode array. Joint kinematics were captured using a motion capture system, and electromyography (EMG) signals were recorded to quantify the muscle activation patterns. Our results showed that the near spinal cord stimulation was able to elicit various independent or coordinated motions, which included flexion/extension of the elbow, wrist, and fingers, and forearm pronation/supination, by adjusting the stimulation location and intensity (5-10 mA). Both H-reflex and highly asynchronized muscle activities with a long latency (50 ms) after stimulation onsets were observed, which demonstrated the activation of sensory axons or/and dorsal roots and the involvement of spinal-

supra circuitry. Compared with the conventional FES, our approach has two advantages. First, various upper arm and hand motions can be elicited through an electrode array with a low current intensity. Second, our approach can recruit motor units in a more physiological way through the recruitment of central pathways, which can lead to more fatigue-resistant motions and also faciliate neuroplasticity of the central nervous system. Our approach can potentially address different issues of conventional FES, and improve the application of electrical stimulation for rehabilitation/assistance of individuals with impaired motor function.

Title: Therapeutic potential of deep brain stimulation for the treatment of spinocerebellar ataxia

Authors: *P. ASTHANA[1], G. KUMAR[1], C. TIN[2], C. H. E. MA[1];

Abstract: Spinocerebellar ataxia (SCA) is a genetically inherited progressive neurodegenerative disorder characterized by poor coordination of gait, hands, speech, and eye movements. Neuronal degeneration occurs in cerebellum, which is related to motor control. Until now, there is lack of medication and surgical intervention for treating SCA. Deep brain stimulator (DBS) has been used extensively in patients with essential tremor, Parkinson's disease, primary dystonia and obsessive-compulsive disorder. We therefore test the therapeutic potential of DBS in treating SCA. In present study, conditional knockout mice ablating a transcription factor expression specifically in mature Purkinje’s cells (PCs) was generated without showing any loss of PCs and exhibited ataxia phenotype. We delineated abnormal movements of SCA and monitor disease progression by synchronising high-speed video kinematics with multi-channel electromyography (EMG) recording, rotarod test, pole climb test and walking track analysis. Mice were implanted with multichannel electrodes in cerebellum and gastrocnemius muscle for DBS and EMG recording, respectively. After DBS, SCA mice exhibited improved motor coordination by showing increased retention time in rotarod test, increased stances length in footprint walking test, decreased variation in stance and swing phase duration in video kinematics test, increased spontaneous walking speed, and increased root mean square)

amplitude of gastrocnemius muscle as compared with baseline. In conclusion, our pilot study demonstrated improved motor coordination in SCA mice after DBS in cerebellum.

Title: Epicranial cortical stimulation: A novel minimally invasive neuromodulation method

Authors: A. KHATOUN, B. ASAMOAH, ***M. MC LAUGHLIN**;
KU Leuven, Leuven, Belgium

Abstract: Rationale Electrical brain stimulation methods can treat a range of medically refractory neurological and psychiatric disorders. These methods fall into two categories: invasive brain stimulation, such as deep brain stimulation and invasive cortical stimulation (ICS); and non-invasive methods such as transcranial electric stimulation (TES). ICS can successfully treat neuropathic pain and has been investigated as a treatment for movement disorders. However, significant risks and cost are associated with the surgical implantation. TES on the other hand is noninvasive with significantly lower risks and cost. However, TES effects are often weak and stimulate a large area. Epicranial cortical stimulation (ECS) has been proposed as a novel, minimally invasive brain stimulation method where electrodes are implanted on the skull. By overcoming some limitations of TES and ICS, ECS may fit a specific niche and could offer beneficial therapy to certain patient groups. **Objective** Use rat experiments and human head computational models to investigate the feasibility of using concentric-ring electrodes with ECS to achieve focused and strong electric fields in the cortex. **Methods** Wistar rats (n=6) were implanted with a concentric-ring ECS electrode to target the motor cortex. Limb movements were quantified using an accelerometer. We then investigated the feasibility of concentric-ring ECS in humans by using a human head computational model. We modeled the electric field generated by concentric-ring ECS and compared it to ICS and TES. **Results** Using the concentric-ring electrodes we focused stimulation to selectively target one specific limb. Thus demonstrating that concentric-ring ECS can target small brain areas in rodents. The computational model results helped bridge the gap between rodent and human. The human head model showed that for a 1 mA current, the electric field in the brain is stronger with ECS (~4

V/m) than with TES (~0.3 V/m) but ECS generates a weaker electric field than ICS (~40 V/m). An insulating back layer on the ECS electrodes allows increasing stimulus amplitude up to 10 mA without stimulating the skin. ECS at 10 mA generated an electric field strength approximately equivalent to that of ICS at 1 mA. Concentric-ring ECS electric field was also relatively focused, as predicted from the high selectivity observed in the rat experiments. **Conclusions** Concentric-ring ECS can generate comparatively strong and focused electric fields in the brain. Specific patient groups may benefit from chronic, minimally invasive, focused neuromodulation. Further studies using chronic ECS in larger animals are needed to explore safety and long-term feasibility.

Title: Modulated electrocortical current density dynamics in major depression following mindfulness-based cognitive therapy

Authors: P. L. A. SCHOENBERG[1], J. M. HENRY[1], *D. R. VAGO[1], A. E. M. SPECKENS[2]; [1]Vanderbilt Univ. Med. Ctr., Nashville, TN; [2]Radboud Univ. Med. Ctr., Nijmegen, Netherlands

Abstract: Mindfulness-Based Interventions (MBIs) are steadily infiltrating mainstream healthcare as non-pharmacological alternatives with evidence-based efficacy for depression and anxiety, common co-morbid symptoms among chronic conditions. Mindfulness-Based Cognitive Therapy (MBCT) shows high clinical utility for mood disorders, whilst mechanistic specificity has not been fully disentangled. **Aim:** Extant research has focused largely on psychological clinical scale outcomes. Here, we examined neurophysiological mechanisms related to clinical outcomes for treating depression with MBCT. Specifically, the following regions of interest and connectivity across multiple frequency spectra were examined: (1) the prefrontal and anterior cortical hubs (such as FPC and ACC) involved in executive functioning; (2) the insula and Posterior Cingulate Cortex (PCC) related to self-referential processing, including visceral interoceptive awareness and 'default-mode' function; and (3) fronto-parietal connectivity associated with regions specialized in inhibitory control. **Method:** we conducted a Randomized Clinical Trial (RCT) in 43 patients with Major Depressive Disorder (MDD), without significant other co-morbidity, exposed to either MBCT vs. wait-list control (WL). We recorded patients' electroencephalographic (EEG) data before and after the 8-week treatment interval (or 8-weeks

waitlist). LORETA based current density vector magnitude localization and connectivity dynamics were examined concomitant to an affective Go/NoGo paradigm pre-to-post treatment for patients in both groups. **Results:** Confirming our hypotheses, significant modulation was apparent in the ACC, part of the inhibitory and executive network that would be required to mediate affective bias towards negative stimuli. Findings highlighted decreases in current density magnitude within the insular cortex and PCC, specific to theta, beta, and gamma-2 spatial frequency bands. **Significance:** This first examination of complex neurophysiological parameters in MBCT contributes greater insight into the multi-dimensional functional and connectivity network dynamics underlying its clinical efficacy and action.

Title: Two-photon calcium imaging in mice shows neural effects of transcranial current stimulation

Authors: *J. DUIJNHOUWER, P.-O. POLACK, B. KREKELBERG;
Rutgers University-Newark, Newark, NJ

Abstract: Transcranial current stimulation (tCS) is a non-invasive technique that has shown therapeutic potential in human behavioral studies. Yet, little is known about its mechanisms of action. To help fill this void, we used two-photon imaging in awake, behaving mice expressing GCaMP6f to study the effects of tCS at the neuronal level. As the mice also expressed tdTomato in GAD2 positive neurons, we were able to distinguish GABAergic interneurons from pyramidal neurons. We measured the responses to drifting gratings of layer 2/3 neurons in primary visual cortex during transcranial alternating current stimulation (tACS; 10 Hz) with current strengths of 50, 100, 200 μA, or no current. We found that, for the neurons that were significantly tuned to the orientation and/or the motion-direction of the gratings, the overall response increased with current strength, showing a slight increase over the 0-100 μA range and a marked jump at 200 μA. Inspection of the tuning parameters using a sensitive Bayesian analysis revealed that for some neurons this response increase resulted mostly from an increase of the response to the preferred orientation, while for others it was orientation non-specific (offset). Tuning width and preferred-orientation/direction were not affected by the electrical stimulation. These findings did not differ qualitatively between the sub-populations of pyramidal neurons and interneurons.

Title: Acquisition of sensory neural signals from stretchable penetrating multi-shank neural interface of peripheral nerve in rat

Authors: W. CHOI[1], H. PARK[1], J. KIM[1], S. OH[1], ***J. KIM**[2];
[1]Korea Inst. of Sci. and Technol., Seoul, Korea, Republic of; [2]Ctr. for Bionics, KIST Korea Inst. of Sci. & Tech., Seoul, Korea, Republic of

Abstract: Recently, a variety of approaches to the development of the peripheral neural interface has been taken. The flexible penetrating microelectrodes which can directly contact the nerve fibers within the fascicles have a better spatial selectivity and were able to minimize mechanical mismatch between neural interface and nerve fiber.
Here, the suggested neural interface which was developed by applying the advantage of the transversally penetrating microelectrode can also reduce the stress caused by surrounding body tissues pulling on both the nerve and the implanted electrodes. Also, this neural interface can increase the chances of a selective neural signal acquisition due to its regular spacing between the four shanks.
The neural interface with four shanks is fabricated based on photosensitive polyimide material as structural substrate. In each shank of the neural interface are located eight channels, which allows the interface to have the total 32 channels. The structure between each shank of the neural interface has the meander structure designed for reduction of the stretching force from the sciatic nerve. Each fabricated sensing electrode has the impedance of 300 kOhm, which is confirmed to be appropriate for acquisition of the neuro sensory signal.
12-week-old male SD rats were anesthetized, and 4 shanks of the electrode were inserted into the right sciatic nerve. Shanks are implanted in a row with regular intervals in the nerve. Ground and reference electrode are connected subcutaneously. The neural interface was connected to the recording device (Intan technologies, US) and the laptop for the neural signal acquisition. Nonconductive object was used to physically stimulate the right paw of the rat. With each of the paw stimulation, the sensory signal was acquired from a few of the 32 channel electrodes. The experiment for recording and decoding of the neural signals with varying kinds of stimulation is under progress. Also, further experiment on chronic implantation and neural sensory signal

acquisition, and the evaluation of long-term stress on the sciatic nerve is planned to be carried out.

Title: Metalized printed microstructures (MPMs): A novel approach for high-density, geometrically-customizable neural interfaces

Authors: J. GLEICK, T. GARDNER, *T. M. OTCHY;
Boston Univ., Boston, MA

Abstract: Implantable neural interfaces are engineered devices designed to study and treat the nervous system: cochlear implants restore hearing, deep brain stimulation alleviates Parkinsonian symptoms, and vagal neuromodulation attenuates inflammatory responses for a range of chronic diseases. The enormous potential of these systems - both for therapeutic and basic research applications - has spurred the development of new electrode arrays to interface with targets throughout the nervous system. To enable targeting of more discrete ensembles of neurons - and thus achieve greater specificity - the trend in neural interfacing is toward arrays of ever larger numbers of densely-placed electrodes. However, current electrode fabrication approaches are limited in both the geometry and density that can be achieved.
We aim to overcome this hurdle, increasing the planar reach and spatial densities of electrode sites, while maintaining an electrochemical profile suitable for *in vivo* studies, using our rapid, high-resolution resonant direct laser writing system (rDLW; see Pearre et al. 2018; arXiv:1803.07135). We print geometrically complex acrylic microstructures directly onto the electrode pads of traditionally-fabricated thin-film electrode arrays. These polymer microstructures are subsequently metalized via gold vapor deposition (i.e., sputtering), producing a highly-conductive surface for *in vivo* electrical interfacing. This approach extends the electrochemically active surface out of the two-dimensional plane, potentially allowing for more intimate and efficacious contact with targeted neural structures. In addition, we anticipate that this rDLW-based fabrication process will enable the realization of electrode arrays with geometries, densities, and minimum feature sizes that have not been achievable with current fabrication methods. In addition, our fabrication method supports the rapid production of

different designs using basic CAD software, enabling the on-demand, study-specific prototyping of new electrode configurations within hours. Here, we demonstrate the potential of this fabrication approach with bench-top mechanical testing, *in vitro* electromechanical testing, and acute *in vivo* recordings.

Abstract: Flexible neural probes have been established as tools for neuroscience research. While many studies report on short-term implantation, the question remains whether thin-film metallization as electrode material embedded in a flexible polymer is applicable for translational research in chronic settings. We have established micromachining process technology of polyimide with embedded platinum tracks and electrode sites with a total thickness of 10 µm. Electrode sites were coated with iridium oxide to reduce the noise floor in recordings and increase the maximum reversible charge injection rate in stimulation applications. Designs range from flexible shaft electrode with 30 µm width to epicortical arrays with close to 500 recording electrodes in the central nervous system in different animal models (rat, ferret, non-human primate). Electrode site diameters vary from 15 to 1 mm depending on the neuroscientific specification as well as the arrays size. In the peripheral nervous system, transversal intrafascicular multielectrode arrays (TIME) have been developed with 14 electrode sites of 80 µm diameter and probe width of 220 µm for stimulation of peripheral nerves. Human clinical

trials in 7 subjects after limb amputation were conducted. Manufacturing of probes in a cleanroom is of utmost importance to prevent entrapment of dust particles that eventually burns during processing and leave pinholes that reduce insulation in recording applications and might lead to electrolysis of water and destruction of the insulation layer during electrical stimulation. Integration of adhesion layers provided compound stability of the thin-film metallization with the polyimide that serves as substrate and insulation layer at the same time. Reliable assembling of the electrode arrays to cables and connectors is key to ensure longevity. First failures might already occur due to (wrong) handling during implantation within the surgical intervention procedure. (Mis-) use of implantation shuttles, additional glues and surgical tweezers cause disintegration of connectors from the arrays, clotting of electrode sites and destruction of insulation layers or interconnecting lines on the probes since these probes are different in handling than tungsten wires. We were able to conduct chronic experiments with functional recordings in different laboratories and animal species for more than a year in the CNS. Human clinical trials went up to six months with stable stimulation thresholds. Therefore, we conclude that flexible micromachined electrode arrays are suitable for chronic implantation in translational research when proper manufacturing and handling is considered.

Title: Electrical stimulation of the vagus nerve modulates intrinsic reward value during decision-making

Authors: A. Z. RAJALA[1], E. M. MUELLER[1], M. E. MALONE[1], J. P. NESS[2], W. ZENG[3], W. B. LAKE[4], R. L. JENISON[1], A. J. SUMINSKI[5], ***L. C. POPULIN**[1];
[1]Neurosci., [2]Biomed. Engin., [3]Surgery, [4]Neurolog. Surgery, [5]Dept. of Neurolog. Surgery, Univ. of Wisconsin, Madison, WI

Abstract: Electrical stimulation of the vagus nerve (VN) is an effective method to modulate and change the function of the nervous system in a controlled and timely manner due to its direct access to neuromodulatory centers and arousal mechanisms via its projections to the nucleus

tractus solitarius. Pairing stimulation of the VN with behavior is known to increase cortical plasticity during auditory discrimination and motor tasks and drive functional rehabilitation after injury. Importantly, vagus nerve stimulation (VNS) has also been implicated in the improvement of cognitive performance in patients. While the timing of stimulation with respect to behavior appears to be important in sensorimotor tasks, it remains unclear if similar modulation is induced by VNS during different epochs of higher order cognitive tasks. Here we test the hypothesis that applying VNS at different epochs in a temporal discounting task changes the subjective value of the upcoming reward. Two male rhesus monkeys (Macaca mulatta) were chronically implanted with cuff electrodes(2mm ID, 7mm inter-electrode spacing, LivaNova Inc) on the cervical VN using sterile technique. Following recovery, they were tested in a temporal discounting task that required them to choose between an immediate small reward (SS) or a large reward given after a long delay (LL). Eight fractal images represented each of the 4 SS and LL conditions. The SS delay was constant at 0 sec with 4 reward magnitudes (0.2, 0.3, 0.4, and 0.5 mL) while the LL reward magnitude was constant at 0.59 mL with 4 delay times (2, 4, 8, and 16 sec). The task required fixating a red dot straight ahead, after which two images appear to the right and left of the fixation representing the SS and LL. When the fixation dot was turned off, the subject made an eye movement towards one of the images indicating his reward choice. A set of 16 blocks of 10 trials each contained all possible combinations of SS and LL and were presented in either ascending or descending order. VNS was performed using trains of 8 biphasic (cathode leading) pulses 100-250mA or 450-600mA, 200us per phase, 30Hz and was delivered at image presentation on every trial. Behavioral data were modeled using a hyperbolic discounting function and a probability choice model to estimate the rate of temporal discounting and the randomness of choice. VNS at the time of image presentation reduced the rate of temporal discounting but increased the randomness of choice as a function of increasing stimulation amplitude in the ascending condition. The data suggest that VNS modulates cognitive function in the context of the temporal discounting task. Future work will examine the neural mechanisms underlying these changes.

Title: Patterned cortical microstimulation by wireless ensembles of chronically implanted microelectronic chiplets in freely moving rat model

Authors: J. LEE[1], F. L. LAIWALLA[1], ***A.-H. LEE**[2], E. MOK[1], V. LEUNG[4], S. SHELLHAMMER[5], L. LYNCH[1], Y.-K. SONG[3], L. LARSON[1], A. V. NURMIKKO[1]; [1]Sch. of Engin., Brown Univ., Providence, RI; [2]Grad. Sch. of Convergence Sci. and Technol., Seoul Natl. Univ., Seoul, Korea, Republic of; [3]Seoul Natl. Univ., Suwon/Gyeonggi-do, Korea, Republic of; [4]Electrical engineering, Univ. of California San Diego, La Jolla, CA; [5]Qualcomm, San Diego, CA

Abstract: To achieve high-density and multi-areal cortical interfaces, we have proposed an approach where microscale, autonomous, wireless devices offer an alternative to e.g. current monolithic microelectrode array. Other groups have proposed related and free-floating microstimulator (Muller et al., 2019 and Etienne-Cummings et al., 2018). At present, demonstrating scalability is a critical bottleneck as published works are so far limited to only a few stimulation channels which will be not enough for a cortical prosthesis application. Here, we describe and demonstrate an independent 56 channels microscale (~500 µm size) ensemble as a wireless networked system of "Neurograins" for time-programmable patterned cortical electrical microstimulation. In our system, each neurograin harvests energy transcutaneously near 1 GHz radio frequency (RF) for power and communicates bi-directionally through a custom inductive wireless system. Along with the RF circuits, the chiplets house digital logic and a programmable current source, enabling up to 25 uA bipolar current injection Individual chips have a unique laser-written address as an additional customized feature. The chiplets were post-processed to integrate PEDOT: PSS planar electrodes for epicortical use or equipped with intracortical penetrating microwires. Radio-frequency power and telecommunications management are handled by software defined radio which serves a wearable external "Epidermal Skinpatch" unit for mobile use. The Skinpatch transmits commands for the full ensemble of neurograins by time-domain multiplexing setting stimulation parameters for each chip. Network protocol and the hardware is capable of control more than 1000s of neurograins, though only 56 chiplets were in this work due to the anatomical constraints of the rat animal model. Selective patterned stimulation by the neurograin array was first validated in ex-vivo mouse brain slice experiment with a single chip evoking significant local field potential changes in the target cortical area. To characterize the chronic performance of the system, we have implanted 56 chips with intracortical microwires to multiple cortical areas of rats. Bilateral craniotomy was performed to maximize the neurograin interarea coverage across the motor, the somatosensory and the visual cortices. The freely moving animals performed a standard detection task to learn to associate cortical microstimulation with a reward at report ports in a chamber. The results of ex-vivo and in-vivo experiments validate the capability of ensembles of our microdevices system to selectively modulate neural activity through patterned electrical stimulation.

Title: Effect of estrous cycle on stimulation thresholds of the dorsal nerve of the clitoris to reflexively activate the external urethral sphincter in rats

Authors: *R. JUAREZ, Sr[1], Y. CRUZ[2];
[1]Ctr. de Investigaciones Cerebrales, Univ. Veracruzana, Veracruz, Mexico; [2]Univ. Autónoma de Tlaxcala, Centro Tlaxcala de Biología de la Conducta, Mexico

Abstract: Pelvic functions are under control of the nervous system. Innervation of pelvic organs can be damaged during pelvic surgeries or during natural reproductive processes, such as childbirth. This is supported by previous observations in an animal models of vaginal distension in rats. The application of electric current to nerves can be used as a treatment for nerve regeneration due to the fact that this treatment induces the release of neurotrophins in rats. The external urethral sphincter (EUS) neural circuit can be activated reflexively through mechanical stimulation of the clitoris, suggesting that the EUS neuromuscular circuit may be reflexively modulated by transcutaneous electrical stimulation (TES) of the dorsal nerve of the clitoris (NDC). In addition, it has been shown that the receptive field of the pudendal nerve changes across the estrous cycle. Thus, the objective of the present study was to determine the electrical current threshold for TES of the DNC that triggers the activity of EUS in female rats, and to compare the differences between two phases of the estrous cycle; diestrus and estrus. Adult female Wistar rats were used 4 in diestrus and 4 in estrus. The animals were anesthetized with urethane. The electromyograms (EMG) of the EUS were recorded, the electrical stimuli were applied to clitoral skin using a stimulator, and the current was kept constant. The TES of the clitoris sheath was applied by bipolar electrodes. Current stimuli of 10 µA to 14 mA were applied until the EUS response was observed. The results show that the EUS EMG activity was triggered by TES and that the stimulation thresholds are affected by the estrous cycle conditions of the rat, estrus rats require less current (2.6±2.5mA) to trigger the reflex than animals in diestrous (8.8±1.5 mA). Is concluded that different electrical stimulation parameters should be used depending on the estrous cycle and the area of interest to be stimulated. FUNDING: CONACYT RJM 623059; SEP-DEGESO.

Abstract: Miniature electrical neural stimulators enable less invasive surgical implantation and the ability to target tiny nerves or brain areas. However, as these neural stimulators become smaller, we must engineer new ways to deliver power. Conventional power deliver relies on long wires to deliver power from an implanted battery or subcutaneous antenna. These leads can limit device placement and cause device failure due to lead breakage or infection. To address this critical need, several wireless neural stimulation technologies have been demonstrated; however most of these technologies cannot generate effective stimulation amplitudes at therapeutic frequencies when placed more than a few millimeters away from the power transmitter. Approaches that can generate sufficient power have limited channel count or stimulation frequency.
Here we show that magnetoelectric devices can harness enough power from an externally applied magnetic field to deliver effective therapeutic stimulation at frequencies approaching 100 Hz. These materials show excellent power densities even as the devices are made small allowing them to be fully implanted and wirelessly powered. We demonstrate that these mm-sized wireless devices can be used to power different types of conventional stimulation electrodes when implanted in rabbits, pigs, and freely moving rats. Furthermore, these miniature electrical stimulators can be adapted to power many individually addressable stimulation channels while still maintaining a small overall device footprint.

Title: Effects of transcutaneous electric nerve stimulation on proprioceptive discrimination

Authors: A. LEVITSKY, J. KLEIN, P. ARTEMIADIS, *C. A. BUNEO;
Arizona State Univ., Tempe, AZ

Abstract: Proprioceptive loss is a common sequelae of several neurological conditions. However, the clinical evaluation and treatment of proprioceptive loss remains largely inadequate. Recent studies employing robots have greatly improved our understanding of limb proprioception in both neurologically intact subjects as well as patients, but the extent to which proprioception is modifiable by interventions such as exogenous neuromodulation is unclear. To investigate this, we used a proprioceptive discrimination task and signal detection analysis to characterize upper limb proprioceptive function following the application of transcutaneous electric nerve stimulation (TENS) delivered to the cervical spine. The right arms of human subjects were coupled to a trough that was held by a 7 degree-of-freedom robot arm. Sensitivity to imposed displacements of the endpoint of the arm was evaluated using a “same/different” task, where on each trial, subjects’ hands were moved from a reference position, along a distracter loop, to a judgment position located 1-4 cm away. At the end of each displacement, subjects were required to respond ‘same’ if the judgment position was the same as the reference position or ‘different’ if it was not. These responses were used to compute sensitivity and bias. Four groups of 20 subjects were tested. All groups had electrodes applied to the cervical spine at the C3/C4 level. One group served as a sham and received no stimulation. The remaining groups received TENS at one of 3 frequencies (30 Hz, 300 Hz, and 3 kHz) for 10 minutes prior to performing the task. No stimulation was provided during task performance. Sensitivity and bias were analyzed statistically using 2-factor mixed ANOVAs, with distance as a within-subjects factor and frequency as a between-subjects factor. A significance level of $\alpha = 0.05$ was used for all tests. As expected, sensitivity increased monotonically with displacement distance, an effect that was statistically significant. Although no main effect of frequency on sensitivity was found ($p=.162$), there was a significant interaction between frequency and distance. Bias also varied with distance, tending to be greatest at 1-2 cm but decreasing precipitously for larger distances. Although the effect of distance was statistically significant, there was no statistically significant effect of frequency ($p=.158$) and no significant interaction effect ($p=.902$). In summary,

transcutaneous electrical stimulation of cervical spinal nerve afferents appears to have beneficial effects on proprioceptive discrimination, but these benefits depend on both stimulation frequency and discrimination distance.

Title: Kinetic augmentation of deep brain stimulation programming optimization across multiple motor symptoms in essential tremor

Authors: *H. S. BAWEJA[1], F. B. NAHAB[2], D. J. GOBLE[3];

Abstract: Successful programming of Deep Brain Stimulation systems in the treatment of movement disorders is influenced by two factors: (i) electrode placement, and (ii) post-surgical optimization of the setting of stimulation parameters (contacts, polarity, amplitude, pulse width, frequency). Currently, optimization involves a clinician manually sweeping through a multitude of stimulus parameters to identify the most beneficial setting for the patient and often relies on trial and error. Furthermore, improvements in symptoms in response to changes in these settings are based on clinical judgment, and less than ideal. In this study, we developed a computationally efficient, symptom-based, kinetic assessment to augment DBS programming. We tested the notion that stimulation programming that utilized an objective assessment of motor symptoms would allow for selection of parameters based on quantitative measures rather than being solely reliant on clinical judgment. We evaluated the feasibility of a kinetic assessment alongside standard programming methods as a means of objective optimization and verification of successful DBS programming. The subject was a 69-year-old male with a 22-year history of essential tremor (ET) prior to undergoing DBS surgery. Six months post-surgery, and multiple programming sessions later, he presented with worsening tremor and gait ataxia, which may occur in ET. At this time, balance testing using a force plate was undertaken both pre- and post-programming. Balance testing consisted of ten, 20-second trials, half with eyes open and half with eyes closed. Balance score was calculated as the average COP excursion across the trials respectively. Furthermore, the postural sway signal was divided into 4 frequency bins following a continuous wavelet transform to glean out contributions of postural (0-4 Hz) and ET (4-10 Hz) oscillations pre- and post-programming. Our findings demonstrate a significant improvement in multi-directional postural sway, fall-risk, and a reduction in tremor (sway oscillations >4 Hz)

under both testing conditions post-programming. In this first of a kind feasibility study, we demonstrated the use of an objective balance measurement tool for augmenting and validating current DBS programming standard of care. DBS has been shown to be effective in the significant suppression of tremor. Our findings extend this to balance and fall risk. This kinetic assessment provides both time- and cost-effective method to help optimize programming of DBS systems.

Title: Histological evaluation of anatomical differences of cervical vagus nerve in pig to inform vagal nerve stimulation

Authors: *M. L. SETTELL[1], A. L. MCCONICO[1], E. N. NICOLAI[1], B. E. KNUDSEN[1], A. SHOFFSTALL[3], K. GUSTAFSON[3], S. CHEN[1], S. TANG[1], C. HUANG[1], E. K. ROSS[4], N. A. PELOT[5], W. M. GRILL[5], A. J. JOHNSON[2], K. A. LUDWIG[6];

Abstract: Cervical vagal nerve stimulation (VNS) is an FDA approved treatment for epilepsy and depression and is currently being evaluated for treatment of numerous other disorders including pain, anxiety, cognition and memory, as well as inflammatory disorders. VNS also received European market approval for heart failure, bronchoconstriction and diabetes; however approval for these indications was based on studies in animals such as dogs and rats, whose vagal nerve size may not have been representative of humans. When subjected to double-blinded, randomized, sham controlled studies for subsequent U.S. approval, many of these CE-marked VNS indications failed to meet their primary efficacy endpoints. More than 100,000 patients have undergone VNS, but despite the efficacy of vagal nerve stimulation in a subset of

patients, many fail to reach stimulation levels that result in alleviation of symptoms without triggering unwanted side effects.
Post-hoc studies of the patient population have suggested that VNS may not engage the intended fiber pathways in humans, despite engagement in preclinical studies in mouse, rat, or dog. Stimulation parameters were limited in these studies as they first activated unintended fibers that cause side effects such as cough, voice alteration, and dyspnea. Discrepancies between stimulation amplitude needed for intended effect versus unwanted side effect could be directly related to the relative size of the vagus nerve in across animal models, variations in fascicle organization, or variations in branching patterns. To address translating improvements in VNS from the lab to the clinic, neuroanatomical evaluation of the cervical vagus and surrounding nerves with respect to placement of the epineural cuff is critically important.
We evaluated the utility of the porcine model in approximating the clinical environment, due to the similar size and fascicular organization of porcine and human vagus nerves. Using Masson's trichrome stain, microdissection, ultrasound and MicroCT we determined the organization and distribution of fascicles throughout the cervical vagus trunk, as well as their relationship to cervical branches that may be involved in side-effects, including the superior and recurrent laryngeal branches. Leveraging this anatomical mapping, we seek to inform vagal nerve stimulation in terms of cuff placement for target engagement, without causing unwanted side effects through activation of muscles innervated by the vagus.

Title: Cortical changes induced by neuromodulation during a working memory task

Authors: *M. SEMPRINI[1], F. BARBAN[1], G. BONASSI[2], E. PELOSIN[3], D. MANTINI[4], M. CHIAPPALONE[1], L. AVANZINO[2];

Abstract: Transcranial alternate current stimulation (tACS) is emerging as an effective and versatile clinical tool to prime brain activity prior to or during neurorehabilitation and can be applied to foster plasticity induction [1]. However, neurophysiological changes induced by tACS are only partially understood [2].
High-density electroencephalography (hdEEG) is now an effective methodology for brain research, because it allows to perform accurate source localization from its signals [4]. hdEEG is especially useful in this context, given its application in a wider variety of experimental framework with respect to traditional brain imaging techniques.
We developed a platform based on source localization from hdEEG aiming at investigating the cortical changes induced by a rehabilitation protocol, involving a cognitive (or motor) task, with/without tACS. Here we present the results related to testing our system with a protocol involving a working memory (WM) task [5] with the goal of: (i) investigating which brain regions and in which frequency bands are modulated during a working memory task, and (ii) correlate behavioral effects of tACS neuromodulation during task with change in brain signals.
Neural activity via hdEEG was assessed focusing on changes of activity across the cognitive network. We first reconstructed neural oscillations in the cortex [3] and we then applied event related synchronization and desynchronization analysis on the reconstructed signals, and investigated how WM load and tACS modulate brain plasticity.
Preliminary results of data without stimulation indicated a frequency and location specific modulation of brain signals. Moreover, we found an increase in task performance following the stimulation.
Further, we will extend the study to neurological patients with cognitive impairments (e.g. Huntington disease). This will shed light on the neural machineries underlining the beneficial effects of a NIBS-based rehabilitation protocol and will exploit usability of our platform for investigation of rehabilitation of neurological disease.
