Title: Ketamine reduces depression-like behavior of mice resulting from single housing during adolescence and alters the proportion of postsynaptic spines in layer 1 of prefrontal cortex with drebrin immunoreactivity

Authors: *E. MAKOWICZ[1], C. J. AOKI[2];
[1]City Univ. of New York At Hunter Col., New York, NY; [2]Ctr. Neural Sci., New York Univ., New York, NY

Abstract: Ketamine, an NMDA receptor (NMDAR) antagonist, has been shown to alleviate depression symptoms more rapidly and for longer than the traditional anti-depressants targeting the monoamine systems. Ketamine's longer-lasting effect may be due, in part, to increasing BDNF levels and

synaptogenesis in cortex. The current study aimed to elucidate further the mechanism by which ketamine could reduce depressive-like behavior, elicited by single-housing (SH) of male mice during adolescence. We hypothesized that ketamine alleviates depression through synaptogenesis involving drebrin, an F-acting binding protein enriched in spines and previously shown to aid the activity-dependent trafficking of NMDARs into spines and to localize them over postsynaptic densities (PSDs). Depressive-like behavior was quantified based on immobility during two forced swim test[c1] s (FST) administered one week apart, with the 2nd FST preceded 1-3 days by an IP injection with ketamine (10 mg/kg BW) versus saline. Since the[c2] effects of ketamine are reported to result in neuroanatomical changes in layer 1 of the prefrontal cortex, (PFC), we quantified the proportion of postsynaptic spines with and without drebrin-immunoreactivity here by electron microscopic immunocytochemistry (EM-ICC). FST revealed individual differences in immobility prior to ketamine injection: not all of the SH animals exhibited decreased immobility, relative to group-housed mice (9 out of 16). A significant ketamine effect, measurable as reduced immobility, was detected upon SH animals (SH-K, N=16), relative to saline-injected SH littermates (SH-S, N=15) ($p=0.02$). EM-ICC data showed reduced proportion of spines exhibiting intense levels of drebrin in the cytoplasm of the SH-K group, relative to the SH-S group, indicating that ketamine reduced drebrin-mediated trafficking of synaptic proteins between spines and dendritic shafts. Conversely, a more discrete drebrin immunoreactivity over PSDs was observed among spines in the SH-K group, relative to the SH-S group. We have shown previously that this is indicative of increased anchoring of NR2B-containing NMDARs at the synaptic cleft. These findings support the idea that ketamine promotes anti-depressive behavior by altering the drebrin-mediated spine-shaft trafficking of synaptic proteins in layer 1 of PFC.

Title: Behavioral sensitivity to acute and chronic opioid exposure in neuroligin-3 knockout mice

Authors: *D. BRANDNER[1], C. RETZLAFF[1], P. G. MERMELSTEIN[1], P. E. ROTHWELL[2];
[2]Neurosci., [1]Univ. of Minnesota, Minneapolis, MN

Abstract: The neuroligins are a family of postsynaptic cell-adhesion molecules that interact with presynaptic partners, the neurexins, to orchestrate the formation and functional properties of central synapses. Polymorphisms in these synaptic adhesion molecules have been shown to increase impulsivity and addiction-associated behaviors in humans. The mesolimbic pathway is a key neural substrate of addiction, encompassing dopaminergic projections from the ventral tegmental area (VTA) to the nucleus accumbens (NAc). Chronic exposure to drugs of abuse produces alterations in synapse structure and function in this pathway, accentuating the behavioral effects of these drugs. Neuroligin-3 (NL3) is an X-

linked neuroligin family member that has been shown to modify synaptic function in specific cell types within the VTA and the NAc, suggesting a possible role for this cell-adhesion molecule in mediating drug-induced plasticity. However, the mechanism by which NL3 modulates synaptic function remains incompletely understood, and a possible role for NL3 in mediating addiction-related behaviors by controlling synaptic adaptation in the mesolimbic dopamine pathway has not been explored. To characterize the effects of NL3 deletion on mesolimbic circuitry, we began by examining the psychomotor activating effects of morphine in constitutive NL3 KO animals. Owing to X-linkage of NL3, our analyses focused on male animals. Following acute morphine administration, these animals exhibited an increase in locomotor activity similar in magnitude to wild-type littermates. However, psychomotor sensitization was significantly reduced in NL3 KO animals following one week of morphine administered at 20 mg/kg daily. We conducted conditional knockout of neuroligin-3 in key neuronal populations throughout the mesolimbic dopamine pathway, including D1- and D2-dopamine receptor-expressing medium spiny neurons in the NAc as well as VTA dopamine neurons. Our findings show that knockout of NL3 from VTA dopamine neurons phenocopies the attenuated morphine sensitization seen in constitutive NL3 knockout animals. We are currently investigating the possibility that this altered behavioral response to morphine is related to opioid-induced synaptic adaptations that require neuroligin-3 for complete expression. We are also examining form and function of synaptic input onto VTA dopamine neurons. Understanding the effects of NL3 depletion on synaptic architecture may provide insight into mechanisms of psychomotor sensitization as well as pathologic alterations that influence human vulnerability to substance use disorders.

Title: Brain plastic changes induced by motivated behaviors in rats

Authors: Z. MIER-QUESADA[1], ***L. GAYTÁN-TOCAVÉN**[2], R. G. PAREDES[2], J. LOZA[1]; [1]INSTITUTO DE NEUROBIOLOGÍA, UNAM, Querétaro, Mexico; [2]Escuela Nacional de Estudios Superiores, Unidad Juriquilla, UNAM, Querétaro, Mexico

Abstract: Synaptic plasticity is the result of changes in the number and strength of synaptic connections due to the processing of different stimuli. Sexual experience can influence synaptic plasticity in the brain in many ways. We used the Partner Preference Task (PPT) and the Sexual Incentive Motivation (SIM) test to evaluate possible plastic changes in different brain areas with the synaptic vesicle marker synaptophysin (SYN). This project aimed to determine by immunofluorescence and stereology, the plastic changes induced by the acquisition of experience in the PPT and SIM in the amygdala (AMY),

hippocampus (HIP) ventromedial hypothalamus (VMH), and nucleus accumbens (ACC), structures related with motivation and sexual reward. 15 Wistar rats (300-350 gr) were used. They were divided into 3 groups: the control group (CG), PPT, and SIM group. After 10 weeks of the behavioral tests, the brains were extracted, 30 µm sections were obtained with confocal microscopy from -2.12 to -3.60 mm for (AMY, HPO, VMH), and from 0.48 to 1.7 for ACC. We average SYN intensity values of 4 coordinates (z = 3 µm each coordinate) in (AMY, HIP, VMH) and (z =10 µm each coordinate) in ACC to determine the volumetric value of each structure. Preliminary results showed a significant increase in SYN expression in the ACC in the PPT and SIM groups with respect to the CG. We also observed a significant increase in AMY and VMH in the SIM group vs the PPT group. Our preliminary data show an increase in SYP intensity in the SIM and PPT groups vs CG in the AMY, VMH and ACC without significant differences in the HIP. We suggest that behavioral experience causes plastic changes involving the expression of synaptic proteins such as synaptophysin, in structures that participate in circuits controlling motivated behaviors.

Title: Microglial BDNF regulates susceptibility to the cognitive and synaptic effects of stress

Authors: *S. WOODBURN[1], J. L. BOLLINGER[2], E. S. WOHLEB[3];
[1]Univ. of Cincinnati, Cincinnati, OH; [2]Pharmacol. and Systems Physiol., [3]Dept. of Pharmacol. and Systems Physiol., Univ. of Cincinnati Col. of Med., Cincinnati, OH

Abstract: Chronic unpredictable stress (CUS) causes synapse loss in the prefrontal cortex (PFC), leading to working memory impairments and adaptations in stress coping. Previous work showed that deficient brain-derived neurotrophic factor (BDNF) signaling increases susceptibility to the behavioral and biological effects of CUS; however, these studies focused on neuronal sources of BDNF. Recent studies indicate that microglia are an important source of BDNF in physiological and pathological conditions. Consistent with this work, experiments from our lab showed that 14 days of CUS reduced *Bdnf* levels in PFC microglia. To further examine the role of microglial BDNF in stress susceptibility, we generated transgenic mice with a microglia-specific *Bdnf* depletion ($Cx3cr1^{Cre/+}:Bdnf^{fl/fl}$) and genotype controls ($Cx3cr1^{Cre/+}:Bdnf^{+/+}$). Mice were supplied with a tamoxifen diet for 3 weeks to drive Cre-induced gene recombination, then were left undisturbed for 14 days to allow peripheral monocytes to turnover, while *Bdnf*-depleted microglia remained. Mice were then exposed to 7 days of CUS or handled intermittently, followed by behavioral testing via forced swim test (FST) and temporal object recognition (TOR). Following this, synaptosomes were isolated from the PFC to assess synaptic protein expression. Interestingly, microglial BDNF depletion impaired TOR performance compared to genotype controls, which coincided with altered expression of proteins involved in glutamate signaling in PFC synaptosomes. These results indicate deficient microglial BDNF increases susceptibility to the neurobiological and behavioral effects of stress.

Title: Perisynaptic Schwann cells undergo a myriad of morphological changes yet remain at neuromuscular junctions during aging

Authors: *R. HASTINGS[1,2], A. O'YOUNG[1], J. PERES DA SILVA[1], G. VALDEZ[1,2];
[1]Brown Univ., Providence, RI; [2]Ctr. for Translational Neurosci., Brown Inst. for Translational Sci., Providence, RI

Abstract: Age-related changes in the pre-synaptic axon terminal and post-synaptic endplate of the neuromuscular junction (NMJ) have been well-documented. In contrast, little is known about the effect of aging on Perisynaptic Schwann cells (PSCs), which are essential for the function and stability of NMJs. In this study, we examined PSCs in young adult, middle-aged, and old mice. We visualized PSCs in transgenic mice expressing GFP in all Schwann cells and in wild type mice immunostained for S100B. Our data show that PSCs are more abundant at NMJs in the soleus and extensor digitorum longus (EDL)

muscles of aged mice. PSCs are increased at NMJs exhibiting age-related blebbing of the axon terminal or polyneuronal innervation. We provide data suggesting that PSCs may be increased because of migration of non-synaptic Schwann cells to aged NMJs. Additional analysis revealed that PSCs undergo a myriad of morphological alterations during aging in both the soleus and EDL muscles, including increased terminal sprouting and the formation of bridges between NMJs. These findings demonstrate that PSCs are similarly affected by aging in the soleus and EDL muscles, which have different functional demands and fiber type composition. To determine if PSCs undergo age-related changes regardless of location and susceptibility of a given muscle to aging, we examined PSCs in extraocular muscles (EOMs). Unlike the soleus and EDL muscles, EOMs and their NMJs remain largely unchanged in aged mice. Not surprisingly, the number and morphology of PSCs were also unchanged in aged compared to young EOMs. Altogether, these data will help unravel the intrinsic drivers of PSC aging as well as the contribution of these synaptic glia to NMJ and muscle aging.

Title: A progressive motor learning task for studying neural circuit remodeling in the primary motor cortex

Authors: P. ADHIKARI, S.-Y. CHUEH, P.-Y. WU, R.-N. WU, *Y.-W. WU;
Inst. of Mol. Biology, Academia Sinica, Taipei, Taiwan

Abstract: The dynamic adaptations in the synaptic plasticity of the neuronal circuits in the brain enable us to process, learn, and retain a wide range of information. During motor skill learning, there is the rapid formation of new spines, and it is followed by the elimination of existing spines in pyramidal neurons of the primary motor cortex (M1). Combining *in vivo* two-photon imaging with forelimb motor learning tasks -- including lever pushing, food pellet reaching, and water droplet reaching -- has become a robust tool for studying learning-associated neural circuit remodeling. However, these tasks are either too easy or lack precise control of the progress of learning. Here, to explore the step-by-step circuit remodeling in learning multiple forelimb movements with increased difficulty, we have established a progressive learning paradigm. This progressive learning task is quantifiable, readily comparable, and also having a different spectrum of difficulty. We adopted a programmable joystick (Wagner et al. 2020), enabling pre-determining movement trajectories. Delving into mouse motor performance has provided an insight into the level of complexity of different trajectories. We observed reduced trial attempts and success rates with increasing linear distance and viscosity (artificial friction). In addition, mice performance for trajectories with turn is highly dependent on the turning angle, i.e., the performance of inward turning is significantly better than outward turning. We trained the mice to perform two task modules of progressive learning:

Module I: 4-mm forward, 8-mm forward, 4-mm forward + 4-mm outward turn, and Module II: 4-mm forward, 4-mm forward + 4 mm inward turn, 4-mm forward + 4 mm outward turn. We found that the learning time required for the subsequent tasks within each module is significantly faster than the first 4-mm forward task. After the training session, we monitored the apical dendrites of the sparse-labeled layer 2/3 and layer 5 pyramidal neurons in the M1 with 2-photon imaging through a chronically implanted cranial window. We could observe synaptic remodeling over different tasks within each module. In conclusion, the new insights gained from applying the progressive motor learning task will enable us to understand the underlying mechanism of circuit remodeling and its correlation with multi-task learning in the brain.

Title: Functional Inactivation of Hippocampus during memory consolidation of mixed choice task applied through the first learning trials is sufficient to suppress the use of Hippocampal strategy for the subsequent trials

Authors: *H. SEMWAL[1], W. PETTIBONE[1], A. SERGEEVA[3], K. UZHCA[4], G. R. POE[2], L. URPA[5], B. A. GROSS[2];
[2]Dept. of Integrative Biol. and Physiol., [1]UCLA, Los Angeles, CA; [3]Anesthesiol., Univ. of Michigan, Ann Arbor, MI; [4]NYU, Albany, NY; [5]Inst. for Mol. Med. Finland, HELSINKI, Finland

Abstract: The hippocampal network plays a crucial role in the formation and encoding of novel environmental cues. The locus coeruleus (LC) is the source of noradrenergic innervation and projects throughout the forebrain and the hippocampus, influencing learning and memory. Normally, LC neurons go silent before a spindle in non-rapid eye movement sleep, and are actively inhibited from firing during rapid eye movement (REM) sleep. However, disorders such as PTSD are associated with increased NE during sleep, which suggests an increased presence of NE due to an overactive LC. Norepinephrine specifically influences hippocampal plasticity, including long term potentiation and depotentiation, which restructures memory networks during the learning process. Activation of the LC has been shown to interfere with sleep-dependent memory consolidation, and optogenetic stimulation of the LC during REM results in deficits in memory. We trained Long-Evans rats to search for rewards hidden in constant positions on a mixed-choice food reward task using an eight-box octagonal maze. To highlight the contribution of different memory systems, the maze was randomly rotated after each trial, and the rat's starting position was changed. We refer to rats who made no more than one error per lap as hippocampal learners. Rats who did not use a hippocampal strategy were still able to find food on every lap, albeit with two or more errors. Each group of rats was divided into four treatment groups that temporarily inhibited

hippocampal learning: (1) two hours of sleep deprivation, (2) isoflurane anesthesia, (3) intrahippocampal norepinephrine infusion, or (4) optogenetic stimulation of the LC during sleep. Each treatment suppressed hippocampal strategy, both during sessions following treatment and for the next six days of training. However, we show that the number of errors in the control groups was significantly lower than the hippocampal-suppressed groups. These findings suggest that the functional inactivation of the hippocampus temporarily impairs cognitive flexibility. To ensure that the treatment did not cause permanent damage to the hippocampus, treated animals were re-trained on the same task in a different environment and maze, and reached below one error per lap showed functional hippocampal strategy indicating treatment did not cause irreversible damage.

Abstract: Recent evidence shows that intracellular calcium dynamics of hippocampal astrocytes encode information about the animal's position and that information encoded in astrocytic signals is complementary to that encoded in the spike output of surrounding neurons. Given that changes in the intracellular concentration of calcium in astrocytes profoundly modulate the activity of nearby synapses and neurons, this recent evidence raises the possibility that calcium dynamics in hippocampal astrocytes may influence the neuronal representation of space. To test this hypothesis, we combined astrocyte-specific pharmacogenetic manipulation, two-photon functional imaging, and information theory analysis in the CA1 hippocampal region of head-fixed mice navigating in a virtual environment. Using adeno-associated viral injections, we first expressed the Gq-coupled hM3Dq receptor and the calcium indicator GCaMP6f selectively in CA1 astrocytes and controlled that activation of the hM3Dq receptor by

clozapine N-oxide (CNO) interfered with ongoing calcium dynamics into astrocytes *in vivo*. We then expressed the hM3Dq receptor in astrocytes and GCaMP6f in neurons and performed two-photon functional imaging of neuronal place cells before and after CNO application in mice navigating a virtual corridor. Analysis of spatial information content at the single-cell and at the network level under control conditions and upon CNO application is currently ongoing. The results of these experiments and analyses will provide important insights about the contribution of hippocampal astrocytes to the modulation of the neuronal representation of space.

Title: Calcium event-independent spontaneous ATP release in astrocytes in cortical slice

Authors: *Y. HATASHITA[1], Z. WU[2], Y. LI[2], T. INOUE[1];
[1]Life Sci. and Med. Biosci., Waseda Univ., Tokyo, Japan; [2]Sch. of Life Sciences, Peking Univ., Beijing, China

Abstract: Astrocytes are the most abundant glial cell type in the central nerves system, tiling the brain with their highly ramified structures. Recent studies revealed that calcium transients in astrocytes play crucial roles in synaptic modulation by releasing chemical substances, called gliotransmitters, including ATP, glutamate and D-serine. Although the spatiotemporal properties of calcium transients in astrocytes have been well investigated, the dynamics of gliotransmitters at subcellular resolution remain poorly understood due to the lack of appropriate techniques to visualize. A recently developed genetically encoded extracellular ATP sensor, $GRAB_{ATP}$ (G protein-coupled receptor activation-based ATP sensor), showed a high sensitivity in monitoring ATP release *in vitro* and *in vivo*, however, spatiotemporal correlation between ATP release and intracellular calcium activity in astrocytes has not been investigated. Using $GRAB_{ATP}$, we investigated spatiotemporal dynamics of ATP release simultaneously with intracellular calcium activity in astrocytes in hippocampal primary culture and cortical acute slices. In neuron-astrocyte coculture, tetrodotoxin (TTX) insensitive ATP release events were detected, while calcium activation by high K^+ or thrombin did not induce detectable ATP release. In acute slice experiment in which cortical astrocytes expressed $GRAB_{ATP}$ sparsely by means of *in utero* electroporation, ATP release events observed, which were TTX-insensitive and inhibited by astrocyte specific metabolic inhibitor, fluorocitrate, indicating that astrocytes in acute slice also spontaneously release ATP. Typical ATP release events in slice occupied approximately 50-200 μm^2 with durations of 10-60 seconds. Extracellular ATP concentration ranged roughly 0.5-5 μM, implying that the spontaneous ATP release from astrocytes may be capable of activation of purinergic receptors in nearby synapses. Simultaneous extracellular ATP and intracellular calcium imaging with $GRAB_{ATP}$ and genetically encoded calcium sensor, REX-GECO1 or Lck-REX-GECO1 in cortical slice, revealed that the two events

rarely co-occurred, thus most of the spontaneous ATP release in astrocytes were independent of intracellular calcium events. In conclusion, our findings suggest that astrocytes in acute slice release ATP independently of surrounding neuronal activity as well as *in vitro*, which may affect nearby synapses depending on the size and amplitude of released ATP. And, spontaneous calcium transients may not be responsible for this gliotransmission.

Title: Role of astrocytic Ca^{2+} signaling in synaptic transmission, plasticity and memory: implications for neurodegenerative diseases

Authors: *E. MOUKARZEL, C. AGULHON;
Paris Univ. - CNRS - Integrative Neurosciences & Cognition Ctr., Paris, France

Abstract: Astrocytes are the most abundant glial cells in the central nervous system and are in close contact with synapses. In response to neurotransmitters, they increase their intracellular Ca^{2+} levels, leading to the release of neuroactive molecules. In addition, astrocytic Ca^{2+} signaling is respectively increased and decreased in Alzheimer's and Huntington's neurodegenerative diseases. Patients' memory is also altered in both diseases. Our main hypothesis is that chronic modulation of astrocytic Ca^{2+} signaling leads to altered release of glutamate or pro-inflammatory factors from astrocytes, and consequent deficits in synaptic transmission, long-term potentiation, and memory formation. We have tested this hypothesis *in vivo* using the mouse primary visual cortex as a model system, combined with electrophysiology, chemogenetics, genetic tools, immunohistochemistry, and behavior. We found that chronically increasing or inhibiting astrocytic Ca^{2+} leads respectively to a depression or potentiation of visual recognition memory formation. The mechanisms underlying such changes are currently under investigation.
Our study could have profound implications in the clinic, as it may lead to a better understanding of the astrocyte role in memory deficits and in the etiology of neurodegenerative diseases.

Title: Satellite glial cells modulate proprioceptive neuron function

Authors: *C. AGULHON, Y. RABAH;
Integrative Neurosciences & Cognition Ctr. - CNRS, Paris Univ., Paris, France

Abstract: Proprioceptive neurons are crucial for coordinating the activity of motoneurons and skeletal muscles to achieve essential motor tasks, such as posture, locomotion, manoeuvring one's way around obstacles or reacting rapidly to external perturbations. They arise from muscle spindles and tendons, and synapse onto ventral horn motoneurons in order to deliver information about the length and contraction of muscles. Proprioceptor cell bodies reside within the dorsal root ganglia (DRGs) and are tightly enwrapped by a thin sheath of glial cells, called satellite glial cells (SGCs). SGCs control the homeostasis of sensory neurons through the clearance of extracellular glutamate and potassium. Additionally, they express a number of Gq protein coupled receptors (G_q GPCRs), which are activated by ATP, glutamate or acetylcholine, leading to SGC intracellular Ca^{2+} elevations. There is evidence that transmitters released from sensory neuron cell bodies activate receptors at the surface of SGCs. Both SGCs and somata of sensory neurons express a plethora of receptors, including G_q GPCRs, supporting the hypothesis that SGC-to-neuron communication also takes place in DRGs. However, only a few studies have investigated SGC-to-sensory neuron interactions and no study has specifically investigated SGC-to-proprioceptor interactions. We hypothesized that activation of SGC G_q GPCR-mediated Ca^{2+} signaling induces the release of neuroactive molecules from SGCs to modulate proprioceptor functions. Using 2-photon microscopy, chemogenetics, and novel genetic tools, we have shown that selective activation of DRG SGC G_q GPCR signaling induces P2R-mediated Ca^{2+} increases in proprioceptors. These data demonstrate that SGCs are able to modulate proprioceptor activity, which, to our knowledge, has not yet been reported. To test whether SGC G_q GPCR activation is sufficient to cause sensory-motor deficits, we are setting up an experimental approach to locally infuse CNO selectively in DRGs.

Neurobio. (ZMNH), Univ. Med. Ctr. Hamburg-Eppendorf, Hamburg, Germany

Abstract: In the hippocampus, neural place cells encode spatial information through the modulation of their firing rate as a function of the animal's position, providing a cellular substrate for spatial cognition. Whether spatial information is encoded beyond neural circuits is currently unknown. Using simultaneous two-photon calcium imaging of astrocytes and neurons in the CA1 hippocampal area of mice navigating in a virtual environment, we demonstrate that astrocytic calcium signals are actively involved in the encoding of information about the animal's position in virtual space. Calcium events carrying spatial information occurred in topologically-restricted and topographically-organized regions of the astrocyte, including the cell body and the proximal processes. Astrocytes had larger spatial fields, which were centered in different positions compared to those of neurons. Moreover, astrocytes encoded spatial information which was complementary and synergistic to that carried by neurons, improving decoding performance when considering astrocytic signals in addition to neuronal signals. These results reveal a fundamental new level of organization for spatial information encoding in the hippocampus: local CA1 non-neural elements provide an additional reservoir of spatial information, which complements that encoded in the spike output of projecting CA1 neurons, expanding hippocampal network population-coding capacity.

Abstract: Glia, or glial cells, are considered a vital component of the nervous system, serving as an electrical insulator and protective barrier from the interstitial (extracellular) media. Certain glial cells (i.e. astrocytes, microglia, and oligodendrocytes) within the CNS have been shown to directly affect neural functions, but these properties are challenging to study due to the difficulty in selectively activating particular glia. To overcome this hurdle, we used selectively expressed light-sensitive ion channels (i.e. channel rhodopsin, ChR2) in glia of larvae and adult *Drosophila.* Upon activation of ChR2, both adults and larvae showed a rapid contracture of body wall muscles with the animal remaining in contracture even after the light was turned off, deactivating the channel rhodopsin. Furthermore, recovery of function once in the dark was related to the duration of light exposure. During ChR2 activation, electrophysiological recordings of evoked excitatory junction potentials within body wall muscles of the larvae confirmed a train of motor nerve activity. Additionally, when segmental nerves were transected from the CNS and exposed to light, there was no noted difference in quantal or evoked responses. This suggests that either there is not a high expression of ChR2 in the glia around the distal regions of segmental nerves, or there's not enough expression to influence the segmental axons to detect in our paradigm. Activation of the glia within the CNS is sufficient to excite the motor neurons. Studies are underway to see how repetitive activation of glia can influence neural circuity and neural development in the Drosophila model.

Title: Inhibitory effect of Apolipoprotein E (ApoE) on axonstimulating effect of astroglial exosomes

Authors: *S. JIN[1], R. JARVIS[1], V. PROMES[1], Y. YANG[2];
[1]Neurosci., Tufts university, Boston, MA; [2]Neurosci., Tufts Univ. Sch. of Med., Boston, MA

Abstract: Exosomes, a major type of Extracellular vesicles (EV), are originated from the endosomal compartment and are known to be released by most cell types, including neurons and glia cells in the CNS. These nanovesicles are typically 50-200 nm in size and carry specific proteins, RNAs and lipids. Exosomes have been shown to function as new type of messengers involved in neuron-glia communication and participate in various physiological and pathological functions. In our current study, by selectively isolating astroglial exosomes using size-exclusion chromatography (SEC), we defined a new astroglial exosome-dependent mechanism for promoting axon growth of primary cortical and spinal

(motor) neurons. RNA-seq analysis of gene expression changes in cortical neurons following astroglial exosome treatment showed a dramatic decrease in cholesterol synthesis pathways compare to control neurons. We then tested the hypothesis that astroglial exosomes carry lipids such as cholesterol that can be uptaken by neurons to facilitate neuronal axon growth. In contrast to our hypothesis, direct treatment of cortical neurons with cholesterol, high-, or low-density lipoproteins (HDL or LDL) have no stimulatory effects on axon growth. In the CNS, Apolipoprotein E (ApoE) is a major transporter of extracellular lipids and cholesterol by binding to its receptor LDLR to transfer lipid to recipient cells. Consistently, direct treatment of human ApoE or other Apolipoproteins (ApoB or ApoJ) also has no stimulatory effect on neuronal axon growth. Co-treatment of astroglial exosomes with RAP, a selective LDLR inhibitor, has no effect on astroglial exosome-mediated stimulation on axons. Surprisingly, Astroglial exosome-induced axon growth is completely inhibited when ApoE is added together with astroglial exosomes onto cortical neuronal cultures. This inhibitory effect appears to be specific to ApoE but not to other Apolipoproteins. In addition, all commonly known human ApoE isoforms ApoE 2, 3, and 4 are able to equally inhibit astroglial exosome-induced axon growth. Immunoblotting of ApoE also showed that more than 98% of astroglia secreted ApoE is expressed in exosome-free astrocyte conditioned medium (ACM). Consistently, mixture of exosome-free ACM is able to completely abolish the stimulatory effect of astroglial exosomes on neuronal axon growth. Taken together, our study uncovered a new inhibitory interaction between astroglia secreted ApoE and neuronal protective effect of astroglial exosomes, providing a new insight on astroglial modulation of neuronal functions in the CNS.

Title: Pyramidal cell myelination is region-dependent and predicted by local axonal morphology in mouse and human neocortex

Authors: *M. PASCUAL-GARCIA[1], S. HIJAZI[1], M. A. W. UNKEL[1], J. A. SLOTMAN[2], A. BOLLEBOOM[3,4], B. L. J. BOUWEN[3,4], A. B. HOUTSMULLER[2], C. M. F. DIRVEN[4], Z. GAO[3], S. A. KUSHNER[1];
[1]Psychiatry, [2]Pathology, [3]Neurosci., [4]Neurosurg., Erasmus Med. Ctr., Rotterdam, Netherlands

Abstract: Myelin enhances axonal conduction velocity and provides metabolic support to neurons. The myelination profile of pyramidal cells is highly diverse and depends on their electrical activity and long-range connectivity. However, there is still insufficient knowledge about the cellular determinants underlying the distribution of internodes along the axon of neocortical pyramidal cells. Our recent studies of fast-spiking interneurons have shown that local axonal morphology is highly predictive of segmental

myelination. Whether pyramidal cell myelination adheres to similar parameters or other mechanisms are involved, is yet to be determined. Here, using wild type and tuberous sclerosis complex 1 (*TSC1*) floxed mice, we investigated the relationship between pyramidal cell axonal morphology and myelination in layer II/III of mouse somatosensory and prefrontal cortices. We performed whole-cell patch-clamp recordings together with biocytin labelling and structured illumination microscopy (SIM). Next, we measured the axonal diameter and interbranch distance of myelinated and unmyelinated segments along layer II/III pyramidal cell axons. Using receiver-operating characteristic (ROC) analysis, we found that the joint combination of axonal calibre and segment length was strongly predictive of segmental myelination, and a better predictor than either parameter alone. The optimal predictive thresholds for axonal diameter and interbranch distance in the somatosensory cortex of wild-type mice were 237 nm and 19.7 µm, respectively (AUC 0.98). In the prefrontal cortex, we found that few pyramidal cells were myelinated at the same neurodevelopmental time point (postnatal weeks 8 - 12). Conversely, enlargement of pyramidal cells by local viral Cre recombinase-mediated cell-specific deletion of *TSC1* robustly increased axonal myelination in the prefrontal cortex. Lastly, we confirmed that these findings extend to human *ex vivo* neurosurgically resected tissue, in which the optimally predictive thresholds for pyramidal cell axonal diameter and interbranch length were 269 nm and 19.0 µm, respectively (AUC 0.91). Similar to neocortical fast-spiking interneurons, local axonal morphology of pyramidal cells appears to explain a substantial proportion of the variance underlying segmental myelination and might function as a causal biophysical constraint for oligodendrocytes to initiate axonal myelination.

Title: ATP-mediated H+ efflux from cultured mammalian astrocytes: a role for monocarboxylate transport.

Authors: *M. KREITZER[1], ***M. KREITZER**[1], R. LEININGER[1], R. MERILLAT[1], R. P. MALCHOW[2]; [1]Indiana Wesleyan Univ., Marion, IN; [2]Dept. Biol. Sci. & Ophthalmology, Univ. of Illinois at Chicago Dept. of Biol. Sci., Chicago, IL

Abstract: Alterations in H+ levels can profoundly impact synaptic transmission by regulating neurotransmitter release, removal of neurotransmitter from synaptic cleft, and post-synaptic receptor

activation. We have previously reported that low micromolar levels of extracellular ATP induce a significant increase in extracellular H+ flux from Müller cells isolated from the retinae of tiger salamanders and other vertebrates, including human. The ATP-induced acidification in Müller cells is mediated by activation of purinergic receptors, leading to calcium release from internal stores and activation of sodium/hydrogen exchange (NHE). Cryopreserved mammalian astrocytes from the cortex and hippocampus of rat can also be provoked by exogenous ATP to release H+ via activation of a purinergic receptor, and H+ release from these cells also depends on release of intracellular calcium. Here we report further observations on H+ fluxes from cultured mammalian astrocytes using H+-sensitive self-referencing microelectrodes (see Tchernookova et al., 2018 and Choi et al., 2021). Our observations suggest that only a small fraction of ATP-induced increases in H+ flux from astrocytes may be mediated by activation of NHE, based on the ability of 2 mM amiloride to partially reduced the increase in H+ efflux. An additional large contribution of ATP-mediated extracellular acidification appears to be mediated by activation of monocarboxylate transporters (MCT), which are expected to co-transport H+ along with lactate (or other substrates) out of the cells. The monocarboxylate transporter inhibitor 4-cin (1 mM) significantly reduced 100 μM ATP-mediated increases in H+ efflux from both cortical and hippocampal astrocytes. Also, we detected extracellular akalinizations around astrocytes following extracellular application of 10 mM lactate, which would be expected to result in the inward movement of lactate and H+ into the cells. These observations lend support for a significant role of MCT transporters in mediating ATP-elicited changes in extracellular H+ from astrocytes. Given the very high sensitivity of synaptic transmission to extracellular H+, we hypothesize that ATP-mediated extrusion of H+ from astrocytes (and glia more broadly) may play a key role in regulating signaling at synapses within the nervous system.

Title: Norrin modulates neuronal network communication and synaptic biology via a cortical astrocyte-subgroup signaling pathway

Authors: *E. G. THOMPSON, S. VIDENSKY, T. WESTERGARD, J. D. ROTHSTEIN;
Neurol., Johns Hopkins Sch. of Med., Baltimore, MD

Abstract: Astrocytes are the most abundant cell type in the central nervous system (CNS) and are essential for brain function. As such, astrocytes play critical roles in ionic and glutamate balance, providing metabolic support to neurons, and regulating neuronal communication. In recent years there has been a newfound appreciation for the heterogeneity of astrocytic functions within sub-regions of the brain

and the emergence of astrocyte subtypes. Our group recently identified one such subpopulation of astrocytes in the cerebral cortex that can be distinguished based on the expression of alternative Wnt receptor ligand Norrin. While previously Norrin has been studied as a protein critical for vascular development in the retina and as a driver of the rare neurodevelopmental genetic disorder Norrie Disease (ND), the characterization of Norrin's effects within the cerebral cortex has been limited in breadth. We found that the selective expression of Norrin in astrocytes within layer II/III and V of the adult cerebral cortex influenced neural network communication and synaptic structure. Specifically, adult Norrin-null (Ndp-/-) animals had a significant decrease in synaptic length and density, that accompanied behavioral deficits. *In vitro* experiments also demonstrated that Norrin significantly increased firing frequency and neuron connectivity in primary cortical neuron cultures when evaluated with multi-electrode array (MEA) analysis. Moreover, we found that Norrin modulates the expression of various synaptic components *in vitro* and *in vivo*. We also generated two novel mouse models of ND that carry the human equivalent of the V43E and H41X *NDP* mutations for evaluation of cortical elements in ND. Initial characterization of these mice has revealed synaptic structure abnormalities and behavioral deficits that recapitulate the human disease. Collectively, these findings suggest that astrocyte-derived Norrin plays a significant modulatory and functional role within the cerebral cortex neuronal network.

Title: Exploring the role of microglia during CNS demyelination in the DTA mouse model

Authors: S. SINGH[1], M. RIITANO[1], H. ZHANG[2], *M. TRAKA[1,2];
[1]Chicago Col. of Osteo. Med. Midwestern Univ., Downers Grove, IL; [2]Anat., Col. of Grad. Studies Midwestern Univ., Downers Grove, IL

Abstract: To investigate the demyelination and remyelination processes in the central nervous system (CNS), we have developed the *DTA* mouse model that specifically targets the ablation of oligodendrocytes by activating the expression of the diphtheria toxin A subunit (DT-A) in these cells through tamoxifen injections into young adult *PLP/CreER^T;ROSA26-eGFP-DTA* (*DTA*) mice (Traka et al., 2010). The tamoxifen-treated *DTA* mice develop severe neurological symptoms by 35 days post-induction (dpi) that correlate with widespread oligodendrocyte death and demyelination in the CNS. Remarkably, these animals fully recover from disease symptoms and they display extensive oligodendrocyte replenishment and widespread remyelination of the demyelinated areas by adult oligodedrocyte progenitor cells (OPCs) at approximately 70 dpi. Given the robust remyelination potential of the young adult tamoxifen-treated *DTA* mice, it is unclear why remyelination fails in CNS

demyelinating diseases such as multiple sclerosis (MS). Microglia are the resident macrophages of the CNS that have been shown to be beneficial for remyelination in various myelin mutants by clearing the inhibitory myelin debris and by secreting cytokines that promote the differentiation and maturation of OPCs. Nevertheless, microglia activation can also play a detrimental role in myelin repair. To better understand the role of microglia in CNS demyelinating diseases, we monitored disease progression and recovery in tamoxifen-treated *DTA* mice fed with PLX3397-chow or normal chow (controls), starting from 14 dpi and continuing till 35 dpi (n= 6 mice/group). PLX3397 is a small molecule CSF-1R inhibitor, that can cross the blood brain barrier and thus rapidly deplete microglia in mice fed with PLX3397-chow. Only male *DTA* mice were used in each group since females develop severe disease symptoms and they die by 21 dpi (Traka et al., 2010). Experiments and data analyses were blinded. Interestingly, our findings showed that microglia elimination in tamoxifen-treated *DTA* mice fed with PLX3397-chow slightly improved their recovery from disease symptoms as compared to control mice, indicating a potential negative role of microglia in CNS remyelination. Further studies on these mice are currently in progress.

Title: Astroglial CXCL12 regulates the demyelinating process and the response of oligodendrocyte progenitor cells

Authors: *T. CHU[1], W. ZENG[1], Y.-P. ZHANG[3], G. N. BARNES[2], C. B. SHIELDS[3], J. CAI[1];
[1]Pediatrics, [2]Neurol., Univ. of Louisville, Louisville, KY; [3]Norton Neurosci. Inst., Louisville, KY

Abstract: Multiple sclerosis (MS) is the most common demyelinating disorder with no cure to stop its progression. Oligodendrocyte progenitor cell (OPC) response and glial network communication determine the pathogenesis of MS. As a vital chemokine, CXCL12 is significantly increased in reactive astrocytes within MS plaques. Little is known about its roles in glial interaction and how it affects the demyelinating process. This study is to reveal its mechanism in astrocyte-OPC interaction, which may offer promising therapeutic targets to modulate lesion microenvironment and alleviate demyelination. To examine the spatiotemporal change of CXCL12 expression during the demyelination-remyelination process, focal demyelination was induced by microinjecting lysophosphatidylcholine into the dorsal funiculus of spinal cord in female C57BL/6J mice. CXCL12 expression was up-regulated at the demyelinating and initial-remyelinating stages, and returned back to the normal when remyelinated. CXCL12 was expressed primarily by astrocytes and by microglia/macrophages (M/M) at a relatively low

level, while its receptor CXCR4 was widely expressed in all glial cells. To reveal the roles of astroglial CXCL12, we created $GFAP^{creER}$;$CXCL12^{fl/fl}$ mice to selectively ablate CXCL12 from astrocytes after tamoxifen administration. CXCL12 was sharply diminished in $GFAP^{creER}$;$CXCL12^{fl/fl}$ mice during the demyelinating process, confirming that astrocyte is mainly responsible for CXCL12 synthesis. Demyelination was alleviated as accessed by the reduction in lesion area and the improvements in fine sensorimotor function and somatosensory evoked potential. Astroglial CXCL12 deletion also reduced the recruitment of OPCs. We therefore generated $Pdgfr\alpha^{creER}$;$CXCR4^{fl/fl}$ mice to specifically delete CXCR4 from OPCs. Consistently, OPC recruitment was greatly disrupted with fewer OPCs distributed along the lesion. These evidences indicate that astroglial CXCL12 is a major chemokine that recruits OPCs via CXCR4. Moreover, we created $GFAP^{creER}$;$CXCR4^{fl/fl}$ mice to explore astrocyte self-activation via CXCR4 based on the finding of reduced Brdu-labelled astrocytes after astroglial CXCL12 deletion. Demyelination was alleviated and astrocytic proliferation was limited when CXCR4 was ablated from astrocytes, suggesting a feedback loop in astrocyte activation that exacerbates myelin damage. These findings suggest that therapies designed to regulate CXCL12-driven responses of astrocyte and OPC, as well as their interactions, may ameliorate neurological impairments by alleviating demyelination and restraining astrogliosis.

Title: Selective oligodendrocyte ablation in the optic nerve induces deficits in nerve function and altered retinal connectivity

Authors: *A. BALRAJ, R. H. MILLER;
Anat. & Cell Biol., George Washington Univ., Washington, DC

Abstract: The survival of individual neurons within neural networks is dependent on successful signal propagation. In white matter tracts like the optic nerve, the myelin sheath provides critical insulation for axonal conduction and when disrupted, can result in the block or delay of neural signals. Because optic neuritis, characterized by the inflammation and demyelination of the optic nerve, results in persistent visual deficits and thinning of retinal layers, we hypothesize that demyelination disrupts normal axonal signaling in retinal ganglion cells (RGCs) and drives changes in upstream retinal network connectivity. In the MBP-iCP9 transgenic, the myelin basic protein (MBP) promoter drives expression of an inducible caspase 9 (iCP9) sequence and a DsRed reporter. Eye injection of the chemical inducer of dimerization (CID) results in the selective apoptosis of oligodendrocytes and subsequent demyelination with minimal inflammation. MBP-iCP9 mice were injected at P14 with either CID or vehicle (EtOH/PBS) for three consecutive days. Two weeks post-injection, oligodendrocyte ablation and retinal cell density were quantified by immunohistochemistry. Optic nerves were assessed using an ex vivo extracellular recording

method, where electrical stimulation induces simultaneous action potentials of RGC axons, generating a compound action potential (CAP) waveform. Axon populations with distinct conduction speeds were identified as peaks. Within-nerve controls used tetrodotoxin to eliminate the stimulus artifact. A significant loss of oligodendrocytes, identified as DsRed+ CC1+ cells (n>5, p=0.0433), was observed in CID-treated nerves when compared to controls (vehicle or non-injected nerves). The number of functional axons, measured as the CAP area, was lower in CID-treated mice (n>3). The slow-conducting axon populations present in control responses, were absent in CID-injected ones, however the fastest-conducting populations were maintained. Comparison of the corresponding retinas of CID-injected and control nerves demonstrated a significant loss of Brn3a+ cells in CID-treated mice (n>4, p=0.0243). The oligodendrocyte loss and demyelination in the MBP-iCP9 transgenic was sufficient to block normal axonal conduction in a subset of RGC axons and preferentially affected the slowest-conducting axons. Loss of alpha-retinal ganglion cells suggests that functionally-relevant demyelination can impact the survival of individual neurons and disrupt upstream network connectivity. Future studies to characterize affected retinal cell types will identify susceptibility to demyelination-induced damage and cell death.

Title: Developing an in vitro model of Autosomal Dominant Leukodystrophy using patient-derived induced pluripotent stem cells

Authors: *T. DEFRANCESCO-ORANBURG[1], Q. S. PADIATH[2];
[1]Human Genet., [2]Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Autosomal Dominant Leukodystrophy (ADLD) is an adult-onset demyelinating disease with no cure. Tandem duplications involving the *LMNB1* gene (ADLD-dup) and deletions upstream of *LMNB1* (ADLD-del) have been identified in ADLD patients. These mutations lead to overexpression of the ubiquitously expressed nuclear lamina protein, laminB1. Why the overexpression of a ubiquitously expressed protein such as laminB1 should cause a specific demyelination phenotype remains unknown. A mouse model in which *LMNB1* overexpression is driven specifically in oligodendrocytes, the myelinating cells of the central nervous system (CNS), shows a similar phenotype to ADLD patients, including vacuolar degeneration of the spinal cord. Using luxol fast blue, we have found that in these mice peripheral myelin is also affected, presumably due to *LMNB1* overexpression being driven by a promotor that is also expressed by Schwann cells, the myelinating cells of the peripheral nervous system. These data suggest that oligodendrocytes are not uniquely susceptible to the effects of laminB1 overexpression. Further, peripheral myelin is not affected in ADLD patients suggesting a disease mechanism that targets *LMNB1* overexpression to CNS cell types including oligodendrocytes. Since these CNS tissues cannot be

studied in living patients, we are utilizing induced pluripotent stem cells (iPSCs) from patients with the different classes of mutations. We have shown that the known *LMNB1* expression levels and genotypes at a single nucleotide polymorphism (SNP) in the region are maintained in these cells, thus they prove to be a valid and accurate *in vitro* model. We have shown that we can use CRISPR-Cas9 to correct the tandem duplication and restore *LMNB1* levels to normal. To assess cell specificity, we are differentiating these patient-derived iPSCs into neurons, astrocytes, and oligodendrocytes, and assessing *LMNB1* expression. This in vitro model will prove critical in identifying a cell specific mechanism that leads to disease and establish a platform in which to evaluate personalized medicine therapeutic options for these patients.

Title: Monocyte infiltration underlies sexual dimorphism in neuromyelitis optica pathogenesis

Authors: *T. CHEN, V. A. LENNON, L.-J. WU;
Mayo Clin., Rochester, MN

Abstract: Neuromyelitis Optica (NMO) is an inflammatory autoimmune demyelinating disease of the central nervous system. Women are more prone to develop NMO. However, the mechanism of sex difference in NMO is still unclear. We recently developed a new murine model which continuously infuses AQP4-IgG intrathecally and induces NMO liked pathology and motor impairment (Chen et al., JCI, 2020). Interestingly, we observed AQP4-IgG infusion causes more substantial functional impairment in female mice when compared with males. The pathological investigation indicated that AQP4 loss and astrocyte activity have no difference between male and female mice after AQP4-IgG injection, indicating similar AQP4 internalization and astrocyte reactivity in both sexes. However, $Iba1^{+}$ microglia/macrophages are much abundant in females than in male mice after AQP4-IgG infusion. Using CyTOF mass cytometry technology, we found that monocytes number dramatically increased in female AQP4-IgG recipients, not males. Consistently, monocyte depletion in female mice but not in males significantly reduced the motor impairment, indicated that AQP4-IgG induced monocyte infiltration is female-specific. Finally, in female mice with ovariectomy, AQP4-IgG infusion induced less monocyte infiltration and better motor function. In summary, our results revealed that monocyte infiltration underlies sex dimorphism in NMO pathogenesis and suggest monocyte a potential target for NMO therapeutic intervention.

Title: Clonal NG2-Cell Response and Proteomic Profile in Two Experimental Models of Multiple Sclerosis

Authors: *S. BARRIOLA[1], L. M. DELGADO-GARCÍA[2,1], N. SALVADOR[1], E. LÓPEZ MARTÍNEZ[1], A. C. OJALVO-SANZ[1], R. SÁNCHEZ-GONZÁLEZ[1], L. LÓPEZ-MASCARAQUE[1];
[1]Inst. Cajal, Madrid, Spain; [2]Lab. of Mol. Neurobio., Univ. Federal de São Paulo, São Paulo, Brazil

Abstract: Multiple sclerosis (MS) is an autoimmune and neurodegenerative disorder of the central nervous system (CNS). The variability in the pathophysiology of this disease makes difficult its study. Nevertheless, the use of different animal models gives a more holistic comprehension of this disease. Here we used both the experimental autoimmune encephalomyelitis (EAE) and toxin-induced demyelination by cuprizone (CPZ), to simulate the relapsing-remitting and the primary progressive MS courses respectively in human. NG2-glia, also known as oligodendrocyte precursor cells (OPC), are of great interest in demyelinating diseases due to their remyelination potential. Here we investigate their differential clonal response to CPZ and EAE brain lesions by combining the StarTrack, a genetic lineage-tracing tool, along with a single-cell morphometric cluster analysis. Data from the morphometric analysis allowed us to unravel different NG2-cells clusters categorized by morphological parameters related, not only to their ontogenic origin, but also to their changes due to the different demyelinating scenarios. In addition, to address the differential altered neural pathways, we compared the proteomic profile of EAE mice (during the disease peak), and CPZ mice (during the acute phase) in two different brain regions: somatosensorial cortex and spinal cord. Bioinformatics analysis revealed changes and protein regional differences between the EAE and CPZ models. In addition, the detailed morphometric analyses of NG2-glia clusters sheds light on the NG2-glia heterogeneity, relevant to deciphering the physiological role of these cells in response to MS.

Title: Amino acid dependent metabolic reprogramming of microglia/macrophages regulates CNS remyelination

Authors: *M. BAYDYUK[1], J. HU[1], E. LI[1], H. WANG[1], S. H. WAKELIN[1], N. V. SHULTS[1], S. G. GYCHKA[2], J. K. HUANG[1];
[1]Biol., Georgetown Univ., Washington, DC; [2]Dept. of Pathological Anat., Bogomolets Natl. Med. Univ., Kyiv, Ukraine

Abstract: Successful remyelination in multiple sclerosis (MS) depends on resolution of pro-inflammatory microglia/macrophage activity in demyelinated lesions. In progressive forms of MS, inflammation and slow myelin degeneration persist leading to neurodegeneration and accumulating neurological disability. It remains unclear how proinflammatory microglia/macrophages prevent remyelination and whether strategies to reprogram activated microglia/macrophages to a pro-regenerative state would be beneficial to the repair process in MS. Here, using metabolomic analysis of lysolecithin-mediated focal demyelinated lesions in the mouse CNS, we show that amino acid levels were significantly increased following demyelination and returned to baseline during remyelination. The amino acid increase in demyelinated lesions was accompanied by the upregulation of Slc7a5, a neutral amino acid transporter, expressed in activated microglia/macrophages. Pharmacological inhibition of Slc7a5 activity or the conditional deletion of *Slc7a5* in microglia/macrophages dramatically decreased the expression of several pro-inflammatory markers including iNOS and Ly86 and phagocytic-related marker CD68 in lesions after demyelination. Moreover, blocking Slc7a5-mediated amino acid transport inhibited mTOR pathway in microglia/macrophages, resulting in significantly decreased appearance of amoeboid microglia/macrophages, while increasing the density of ramified, homeostatic microglia, marked by increased P2RY12 expression. Importantly, inhibiting Slc7a5 in microglia/macrophages led to increased density of mature oligodendrocytes and enhanced remyelination in focal lesion and cuprizone models of demyelination. Furthermore, we found that therapeutic administration of the Slc7a5 inhibitor in mice with experimental autoimmune encephalomyelitis (EAE) prevented the accumulation of clinical disability, reversed the course of the disease, and significantly improved motor function. Together, our results suggest that metabolic reprogramming of microglia/macrophages through Slc7a5-mediated mTOR activation regulates CNS inflammation in demyelinating lesions. Therefore, pharmacological inhibition of Slc7a5 may be a novel treatment option for preventing the expansion of chronic inflammatory lesions, allowing for endogenous myelin repair in progressive MS.

Title: Gli2 regulates the recruitment of adult neural stem cells for remyelination via Slit2

Authors: *A. JOHNSON, D. RADECKI, E. CLAWSON, D. NIEVES-TORRES, J. SAMANTA; Univ. of Wisconsin, Madison, Madison, WI

Abstract: Enhancing repair of myelin is an important therapeutic goal in many neurological disorders characterized by demyelination. In the healthy adult brain, ventral neural stem cells (vNSCs) residing in the subventricular zone, marked by Gli1 expression, do not generate oligodendrocytes. However, in response to demyelination, their progeny are recruited to lesions where they differentiate into oligodendrocytes, and ablation of Gli1 further enhances remyelination. Genetic ablation of Gli1 in vNSCs also increased Gli2 expression, and combined loss of both transcription factors decreased the recruitment of their progeny in demyelinated lesions, suggesting that Gli2 plays an essential role in recruitment of Gli1 vNSCs to the demyelinating lesion. To understand the molecular mechanisms involved in recruitment of vNSC to the demyelinating lesion, we performed an RNAseq analysis to compare the genes expressed in vNSCs expressing Gli1 to those lacking Gli1 expression following demyelination. Through this analysis, we identified Slit2 as a positive regulator of recruitment of vNSCs since it was significantly upregulated in vNSCs in the absence of Gli1 expression. Consistently, expression of Slit2 was reduced in the subventricular zone following demyelination and genetic loss of Gli1 prevented this reduction. Furthermore, pharmacological inhibition of Gli2 in vNSCs in vitro resulted in downregulation of Slit2 expression. Slit2 is a ligand that interacts with Robo receptors on the cell surface to induce a signaling cascade leading to an upregulation of actin polymerization genes and increased cell migration. Thus, our data indicate that, loss of Gli1 induces Gli2 expression which in turn enhances the recruitment of vNSCs to the demyelinating lesion by upregulating Slit2. This could lead to development of therapeutic strategies for enhancing remyelination by regulating the recruitment of vNSCs.

Title: Ferroptosis, an iron-dependent form of cell death in chronic experimental autoimmune encephalomyelitis

Authors: *P. JHELUM, J. ZARRUK, S. DAVID;
The Res. Inst. of the MUHC, Montreal, QC, Canada

Abstract: A relatively new form of regulated, non-apoptotic cell death called “ferroptosis” was identified first in cancer and recently in various neurodegenerative diseases. Ferroptosis requires iron-mediated free radical generation that triggers lipid peroxidation in the absence of sufficient levels of the antioxidant glutathione. Oxidative stress and iron toxicity play a key role in the Multiple Sclerosis (MS) and Experimental Autoimmune Encephalomyelitis (EAE), an animal model used to study MS. We, therefore, assessed if ferroptosis plays a role in EAE. Previously, we reported on the role of ferroptosis in cuprizone (CZ) -induced demyelination in mice. We found that CZ-induced oligodendrocyte (OL) cell death is seen as early as 2 days after the start of CZ diet, which was accompanied with the expression of several markers of ferroptosis. In addition, treatment with ferrostatin-1 (a ferroptosis inhibitor) prevents this loss of OL and demyelination. Currently, we assessed the mRNA expression of several ferroptosis markers in the spinal cord tissue of both relapsing-remitting (RR-EAE) and chronic EAE (CH-EAE) mice. We found that the expression of ACSL4, ACSF2, IREB2, TfR1, and NCOA4 is greater in CH-EAE compared to RR-EAE. Expression of NCAO4, a cargo receptor that shuttles ferritin to autophagosome for degradation (ferritinophagy) and releasing redox-active iron is also increased in CH-EAE. We also found an increase in lipid peroxidation (a hallmark of ferroptosis) as assessed by 4HNE at the peak and progressive stages of CH-EAE. Importantly, treatment with UAMC-3203 (inhibitor of ferroptosis) started at the peak of disease (grade3) improved clinical outcome and reduces lesion volume in CH-EAE. These results provide strong evidence that ferroptosis plays a role in CH-EAE.

Abstract: X-linked Charcot Marie Tooth Disease (CMT1X) is associated with hundreds of mutations in *GJB1*, the gene encoding the gap junction forming protein connexin 32 (Cx32). Cx32 is a component of

the myelin sheath and localizes to the paranodes and Schmidt-Lanterman incisures of myelinating Schwann cells. Though Cx32 is expressed only in the Schwann cell in the peripheral nervous system, CMT1X is characterized by early and prominent axonopathy, and the mechanism by which disruption or loss of Cx32 leads to CMT1X neuropathy is poorly understood. Study of both the phenotype in patients with CMT1X and in animal models generated in our laboratory and by others, suggest that most if not all mutations in Cx32 lead to loss of function of Cx32. We used CRISPR/Cas-9 technology to generate targeted transgenic mice expressing the p.T55I or p.R75W mutations in *Gjb1*. These mutations lead to abnormal accumulation of Cx32 in the Golgi (p.R75W) or ER (p.T55I) and represent the observed abnormal subcellular distributions of Cx32 for at least half of the mutations known to cause CMT1X. Phenotypic profiling of these mice showed that they are authentic models of CMT1X. We then employed a label-free quantitative proteomic profiling of axons isolated from sciatic nerve of age-matched Cx32T55I- and Cx32R75W-CRISPR mutant mice along with wild-type (WT) and *Gjb1*-knockout littermates to identify potential cellular functions altered in axons from CMT1X models. Analysis of differentially regulated proteins revealed changes in proteins involved in RNA processing, axon regeneration, and other axonal cellular functions. Candidate proteins from the quantitative proteomic analysis are currently being studied for transcriptional differences in spinal cord, sciatic nerve, and dorsal root ganglia of WT and mutant mice. Our work illustrates that loss or mutation in Cx32 leads to axonal changes in protein expression, enhancing our understanding of underlying mechanisms of regulating the neuropathy associated with CMT1X, and should lead to improved ability to design potential therapeutics for patients.

Abstract: Glioblastoma is the most frequent malignant tumor of the central nervous system (CNS) and the over-all survival has not increased significantly since the introduction of standard of care therapy at

the beginning of the Century. The search of new therapeutics with anti-carcinogenic effects is of vital importance to improve the quality of life of patients. Hops α-iso-acids are one of the principal bitter compound present in beer and it gives its signature taste. Prior studies had showed it promising bioactive potential and potent cytotoxic activity. In the present work we evaluate the possible induction of cytotoxicity by α-iso-acids-rho over human glioma cell lines U87, U373, LN18 and A172 by MTT reduction assay. Each assay was carried out in triplicate and three repetition of each experiment were performed. The IC_{50} at 72 hrs were calculated for U87 = 20.040 ± 1.990 µg/mL; U373 = 27.190 ± 3.565 µg/mL; LN18 = 7.598± 1.129 µg/mL; A172 = 23.560 ± 5.542 µg/mL. All statistical analysis were made using GraphPad Prism 8. Our result are similar to those reported in literature in other cancer cell lines and gives us the proof of concept where this bioactive compounds could be explore further as potent anticarcinogenics in the CNS.

Title: Mitochondrial metabolic efficiency as a requirement for the proliferation of glioblastoma multiforme cells

Authors: H. BAE[1], A. M. MILLET[1], M. TSUJISHITA[1], G. GUL[1], N. MACHARD[1], G. NOSOVITSKAYA[1], T. S. TIERNEY[1], P. J. S. SMITH[2], *K. N. ALAVIAN[1];

Abstract: Gliomas are among the most common and deadly brain tumors. Current therapeutic methods, including surgery, radiation, and chemotherapy, fail to yield a significant clinical outcome in the malignant types of this disease, including adult and pediatric glioblastoma multiforme (GBM). A prominent feature of cancer cells, including these aggressive tumors, is their high metabolic demand and their reprogramming of energy metabolism. De novo ATP production through mitochondrial oxidative

phosphorylation and production of the intermediates of the tricarboxylic acid cycle, required for anabolic growth, are both dependent on the generation of an electrochemical gradient of protons across the mitochondrial inner membrane and are modulated by the mitochondrial inner membrane ion leak currents. The evidence for the involvement of mitochondrial "efficiency" (as a requirement) for the growth of cancer cells has been lacking. Here we demonstrate a direct role for mitochondrial efficiency, modulated by the anti-apoptotic molecule, Bcl-XL, and the mitochondrial inner membrane leak currents in the proliferation of GBM cells. We also demonstrate the potential for the use of this mechanism as a druggable therapeutic target for GBM.

Title: Rfx1 is a potential target of hypoglycemic drugs to affect cell growth and migration in glioblastoma cells

Authors: *Z. ZUO[1], **W. SHAN**[2];
[1]Univ. of Virginia, Charlottesvle, VA; [2]Univ. of Virginia, Charlottesville, VA

Abstract: Regulatory factor X1 (RFX1), a transcription factor, is a member of the regulatory factor X family. Our previous studies have found that RFX1 play an important role in glioblastoma development. But about how RFX1 is regulated is still unknown. From NCBI Gene Expression Omnibus (GEO) Profiles, we found that three hypoglycemic drugs (pioglitazone, rosiglitazone and WY-14643) might regulate the expression of RFX1. In this study, we tested that RFX1 contributed to the effects of these three hypoglycemic drugs on the proliferation, survival, invasion and migration of glioblastoma cells. The human glioblastoma U251 and U87 cells were incubated with various concentrations of pioglitazone, rosiglitazone and WY-14643 for 72 hours in the presence or absence of siRNA for RFX1. They were then used for assays of cell growth, survival, invasion and migration. Western blotting analysis of RFX1 expression and matrix metallopeptidase 2 (MMP2) activity assay were performed. We found that the growth, survival, migration and invasion of glioblastoma cells were inhibited by the three hypoglycemic drugs. The expression of RFX1 were elevated after treatment of three drugs. MMP2 activity in the U251 and U87 cells was inhibited after treatment with these three drugs, the inhibitory function was blocked when co-cultured with siRNA of RFX1. And also, the hypoglycemic drugs' inhibitory effects on the growth and invasion of glioblastoma cells were eliminated by siRNA of RFX1. To validate the *in vitro* results, U87 cells were implanted into mouse brain and these mice were treated with 5 mg/kg pioglitazone for 8 days before used for immunofluorescence staining. Dual luciferase assay was performed and showed that the three hypoglycemic drugs boosted RFX1 promoter activity. Our results suggest that pioglitazone, rosiglitazone and WY-14643 inhibit the cancer cell behaviors of glioblastoma cells through

RFX1. MMP2 is a potential target of RFX1 to inhibit the migration of glioblastoma cells. RFX1 is a potential target for treating glioblastoma.

Title: Reactivation of p53 plays a dual role in controlling glutamate pathophysiology in glioblastoma

Authors: *A. MINER[1], R. A. UMANS[2], H. SONTHEIMER[3];
[1]Virginia Tech. Carilion Sch. of Med., Roanoke, VA; [2]Fralin Biomed. Res. Inst., Roanoke, VA; [3]Sch. of Med., Univ. of Virginia, Charlottesville, VA

Abstract: Glioblastoma (GBM) is the most common primary malignant brain tumor in adults and has an extremely poor prognosis with a median overall survival of 15 months. The cysteine-glutamate exchanger (system x_c^-, SXC) is upregulated in many GBM tumors, and overactive SXC results in high levels of extracellular glutamate linked to excitotoxicity, seizures, and enhanced tumor survival and invasion. SXC expression has been found to correlate with p53 mutation status, raising the possibility that p53 has a non-canonical role as a transcriptional regulator of the SXC gene *SCL7A11* and may be a more effective therapeutic target than the transporter itself. p53 restorative agents have emerged as a promising treatment for many cancers but their specific mechanism and utility in GBM has yet to be extensively explored. To better understand the mechanism behind system x_c^- regulation, we treated established patient-derived glioma xenolines with known wt-p53, mut-p53, and null-53 genotypes with the p53 restorative agent PRIMA-1^{MET} at a 30µM concentration for 48 hours. Trypan blue assays were used to assess cell survival and expression of putative targets were assessed via western blot. Glutathione levels and ROS staining were used as functional measures of SXC and redox activity. Treatment with PRIMA-1^{MET} resulted in significant glioma cell death independent of p53 mutation status, with a higher sensitivity in wt-p53 and null-p53 cell. Analysis of post-treatment samples did not show significant changes in p21 or SXC protein levels regardless of p53 status. PRIMA-1^{MET} induced cell death was fully rescued by exogenous glutathione in all cells lines and mut-p53 cells were found to express higher levels of enzymes involved in glutathione metabolism in comparison to wt-p53 and null-p53 lines. Measurement of endogenous glutathione production was decreased after PRIMA-1^{MET} treatment *in vitro*, but analysis of *in vivo* flank tumor samples did not show any significant changes. The observed effect of PRIMA-1^{MET} on glioma cells independent of p53 status suggests the existence of a primarily off-target mechanism of action for p53-restorative agents in glioma. Glutathione studies support the existence of alternative direct PRIMA-1^{MET} redox targets with a potential ROS-resistant phenotype associated with p53 mutation. This novel off-target mechanism holds implications for applicability of the drug class to a wider range of glioma patients

and the potential to modulate tumorgenicity through direct and indirect impacts on redox dynamics and tumor metabolism.

Title: Glial Scar Causing Drug Resistance and Inhibiting Glioblastoma Growth in a 3D Human Glioblastoma Microenvironment

Authors: *Y. N. DIEP[1,2], H. Y. KO[3], W. LIM[4], S. PARK[4,5], M. YUN[3], H. CHO[1,2];
[1]Inst. of Quantum Biophysics, Dept. of Biophysics, Sungkyunkwan Univ., Suwon, Korea, Republic of; [2]Dept. of Intelligent Precision Healthcare Convergence, Suwon, Korea, Republic of; [3]Dept. of Nuclear Medicine, Yonsei Univ. Col. of Med., Seoul, Korea, Republic of; [4]Dept. of Biomed. Engineering, Sungkyunkwan Univ., Suwon, Korea, Republic of; [5]Sch. of Mechanical Engineering, Sungkyunkwan Univ., Suwon, Korea, Republic of

Abstract: Glial scar formation is an innate immune response confining injured regions in a central nervous system. In the scar formation in response to glioblastoma (GBM), microglia (MG) are found both inside and outside the GBM tumor mass, while astrocytes (AC) mainly encapsulate the tumor. There are reports about the promotion of immunosuppressive environment and tumor aggressiveness induced by reactive astrocytes and microglia in brains. However, their role during scar formation is still under investigation. Here, we construct an in vitro 3D human GBM microenvironment reconstituting the glial scar formation. GBM spheroids were preformed and then co-cultured with glial cells (AC+MG) in 3D Matrigel. We found that activated AC formed a glial scar around GBM with linear-shaped morphology. Chemokines from GBM spheroids, such as CCL2, GM-CSF, G-CSF, and MIF, induced preceding microglial recruitment, followed by astrocytic scar formation. A wide spectrum of cytokines associated with tumor progression, invasion, and angiogenesis were also measured, such as IL-6, IL-8, and CXCL1. Activation markers, including GFAP for AC and CD206 (M2) for MG, were upregulated in our GBM microenvironment. We also validated that the glial scar significantly restricted the cross-sectional area of GBM spheroids by 2.2 times compared to GBM spheroids without the scar. Moreover, the scar encapsulation acted as a physical barrier limiting drug penetration into GBM spheroids and leading to the drug resistance, shown by a no significant reduction in the cross-sectional area of GBM spheroids with scar even with TMZ treatment, while those without the scar were decreased in area by 1.4 times. Taken together, our 3D human GBM microenvironment has a potential for understanding the gliosis process and the GBM-glia crosstalk, facilitating drug discovery targeting aggressive GBM.

Title: Investigation and regulation of TREM1-positive microenvironment in glioblastoma.

Authors: *N. FILIPPOVA, D. NAMKOONG, E. HAYWARD, X. YANG, B. NABORS;
Univ. of Alabama At Birmingham, Birmingham, AL

Abstract: The harmful contribution of the uncontrollable inflammatory systematic immune response to the development of glioblastoma heterogeneity and recurrence is recognized in recent years and is likely associated with tumor infiltrated immunosuppressive myeloid-derived cells with activated TREM1-dependent cell signaling pathways. Infiltration of TREM1- positive cells to the glioblastoma microenvironment has a negative impact on the patient's overall survival according to the R2: platform. TREM1 appearance in the glioma microenvironment, along with the infiltration of myeloid-derived cells, is grade-dependent and enhanced with tumor grade. The weight of the TREM1- positive cells increases from 21.3% in primary GBM to 36.8% in the recurrent GBM that implies the TREM1-positive population of cells in tumor recurrence. We utilized two immunocompetent mouse glioblastoma models based on the intracranial injection of established mouse glioblastoma GL261 cell line and mouse TRP cell line of transformed astrocytes (truncated SV40 T antigen, Kras G12D mutation, Pten deletion) and performed isolation and analysis of tumor infiltrated immune cells; C57Bl/6 mice without tumor implantation were utilized as control. Our results suggest that the main sources of the TREM1-positive cells in the glioblastoma microenvironment consist of monocytes, macrophages that emerged from monocytes recruited to the tumor bed, neutrophils, and at a low degree activated resident microglia and endothelial cells. 70-90% of de novo formed tumor/host cell hybrids detected in the glioblastoma microenvironment acquire TREM1 expression. Such overwhelming selection of the TREM1-positive hybrid cells in the glioblastoma microenvironment could be explained i) by selective activation and migration of TREM1-positive peripheral immune cells to the ischemic and inflammatory tumor microenvironment favorable for cell fusion, ii) by selective survival of fussed cells acquiring TREM1 expression due to TREM1-dependent activation of anti-apoptotic Bcl2-family proteins and mitofusin molecules that support mitochondria function at stress conditions, iii) by TREM1- dependent local magnification of inflammatory cytokine cascade triggering fusogen expression and causing rearrangement of cytoskeletal architecture essential for cell fusion. We utilized recently developed by our group BBB permeable HuR dimerization inhibitor and found that the HuR inhibition was associated with a significant reduction of TREM1- positive glioblastoma microenvironment, cell fusion, and glioblastoma progression.

Title: Cytomegalovirus-induced metabolic reprogramming of glioblastoma cells disrupts lactate homeostasis and enhances the potential for paracrine manipulation of the tumor microenvironment

Authors: *M. A. A. HARRISON[1], E. M. HOCHREINER[2], B. P. BENJAMIN[2], S. E. LAWLER[3,4], K. J. ZWEZDARYK[2];
[1]Tulane Univ. Grad. Neurosci. Program, New Orleans, LA; [2]Tulane Univ., New Orleans, LA; [3]Neurosurg., Brigham and Women's Hosp., Boston, MA; [4]Neurosurg., Harvard Med. Sch., Cambridge, MA

Abstract: Glioblastoma (GBM) is an aggressive central nervous system neoplasia with limited therapeutic options and very poor prognosis. Following initial reports of cytomegalovirus (CMV) transcripts and proteins in and around GBM tumors, the use of anti-viral drugs in conjunction with the standard of care was shown to significantly increase longevity for GBM patients. A mechanism for the role of CMV in tumor progression has yet to be fully elucidated. We hypothesized that CMV infection induces metabolic reprogramming of GBM or the surrounding microenvironment and that these alterations may account for enhanced tumor progression. We infected LN-18 GBM cells with CMV and employed a Seahorse Bioanalyzer to characterize metabolic function. We observed increases in mitochondrial respiration and glycolysis relative to uninfected controls. Changes were accompanied by increased levels of reactive oxygen species and lactate, respectively. Increased intra- and extra-cellular lactate concentrations led us to investigate enzymes and transporters central to lactate homeostasis. We found increased levels of monocarboxylate transporter 4, a lactate exporter, following CMV infection. Extracellular lactate is a potent paracrine signaling molecule which can promote tumor progression in myriad ways. To examine the paracrine effects of CMV infected GBM cells we conducted indirect co-culture experiments using stromal cells. Our results indicate that, independent of viral transmission, the secretome of infected cells altered expression of metabolic proteins and epigenetic markers in neighboring cells. These results suggest a potential role for CMV as an oncomodulator in the context of GBM and the tumor microenvironment.

Title: Impaired hippocampal spatial coding in aging and neurodegenerative disease

Authors: *Y. FANG, G. J. AUGUSTINE;
Lee Kong Chian Sch. of Med., Nanyang Technological Univ., Singapore, Singapore

Abstract: Spatial memory is degraded both in normal aging and in neurodegenerative diseases, such as Alzheimer's disease (AD). Spatial memory is encoded in hippocampal circuits, both via the activity of place cells as well as in neuronal ensemble activity. Although it is known that place cell properties are altered during aging and in AD, the effects of these processes on neuron ensemble encoding are unclear. We therefore characterized hippocampal spatial coding in both aged and AD disease model mice by performing *in vivo* two-photon calcium imaging of the activity of CA1 neurons while mice travelled on a treadmill. Bayesian decoding methods determined how accurately neuron ensemble activity could predict mice position; the degree of decoding error was used to quantify spatial coding in CA1 neuron ensembles. The effect of aging on spatial coding was examined by comparing spatial coding in young (4-6 months) and aged (13-15 months) mice. Young mice exhibited good spatial coding performance: neuron ensemble activity accurately decoded mouse position on the treadmill. However, aged mice had larger position decoding errors, indicating a decline in spatial encoding. We next characterized spatial coding in young and aged AD model mice. These mice had three human AD-related mutations knocked-into their amyloid precursor protein gene (APP-TKI; Nature Neurosci. 17: 661). An aging-related decline in spatial coding performance was also observed in APP-TKI mice. Further, in comparison to wild-type control mice, APP-TKI mice tended to have larger position decoding errors, a smaller fraction of place cell neurons, and wider place fields. Thus, spatial coding appears to be disturbed in APP-TKI mice. In summary, our results indicate that hippocampal spatial coding declines during aging and that this process is accelerated in AD.

Abstract: Late-stage Alzheimer's disease (AD) is characterized by progressive and broad synaptic loss and cell death across neural circuits. Pre-symptomatic changes in neural connectivity and function have been understudied, in part because of the difficulty of tissue collection in prospective studies in humans. However, both human and animal studies indicate that neuronal hyperexcitability and hyperactivity in the hippocampus are common features of preclinical AD, suggesting that there may be early changes in circuit connectivity that are associated with the disease. Here we used molecular-genetic methods for synapse labeling targeted to CA1 pyramidal neurons to assess progressive alterations in synapse distribution in the transgenic APP/PS1 mouse model of AD. Stereotaxic injections of virus encoding the pan-synaptic labeling reagent (FAPpost) were targeted to the dorsal hippocampal CA1 region, and synapse distribution between wild-type and transgenic mice was compared at three different ages. Digital reconstruction of fluorescently-labeled pyramidal cells and dendrites were carried out for quantitative synaptic analysis across dendritic and somatic compartments. Surprisingly, we found that CA1 pyramidal neurons showed a site-specific increase in the number of synapses in the apical dendritic compartment attributed to inputs from CA3 neurons from 3 to 6 weeks of age. Synapse density in the apical tuft of CA1 pyramidal neurons was decreased at 6 weeks, suggesting progressive modification of the hippocampal-entorhinal circuit over time. Analysis of aged transgenic animals (13-16 months) showed a uniform loss of synapses across all compartments. Expression of the activity-dependent transcription factor c-fos was enhanced in both CA3 and CA1 at 3 and 6 weeks of age, suggesting hyperactivity of the hippocampal circuit during early development. These data indicate that increase in AD-associated amyloid-β load in the APP/PS1 transgenic line is sufficient to drive aberrant circuit activity and connectivity, and suggest that early detection of abnormal circuit function may facilitate interventional strategies to delay or prevent AD.

Title: Tgf344-ad rats display differing levels of gabra5 transcript in single neurons of the ca1 during disease progression

Authors: *J. GEORGE, A. TIPTON, D. FARB, S. RUSSEK, V. KUMARESAN, M. RATNER; Boston Univ., Boston, MA

Abstract: In the United States, 5.5 million individuals suffer with Alzheimer's Disease (AD). This neurodegenerative dementia is characterized by a decline in cognition and the eventual lethal disruption

of all brain functions. There is no cure for AD and current treatments can only temporarily improve symptoms. The pharmacological administration via oral gavage of the cognitive enhancer a5IA, a negative modulator of the γ-aminobutyric acid A receptor ($GABA_AR$) that contains the α5 subunit, increases sharp wave ripple oscillations in wild-type rats but not in the transgenic AD (TgF344-AD) rat. TgF344 was created by injecting rat pro-nuclei with two human AD-associated genes: Swedish mutant human APP (APPsw) and Δ exon 9 mutant human presenilin-1 (PS1ΔE9). We hypothesize that the loss of sharp wave ripple modulation by a5IA in the TgF344-AD rat reflects a molecular reorganization of trisynaptic hippocampal function, which may contribute to deficits in memory consolidation over time. Determining the underlying mechanism of circuit reorganization will provide insight on AD and lead to the development of cognitive enhancers for the successful treatment of this debilitating disease, increasing the length and quality of life. Towards this goal, we used a novel fluorescent *in situ* hybridization technique, RNAscope, to interrogate the spatial expression of *Gabra5* in dissected brains of TgF344-AD and littermate control wild-type rats (Ct), n=4, at two different ages, 9mo and 16mo, to determine if there is a change in transcript abundance in the hippocampus. Our results show that in the CA1 of 16mo TgF344-AD rats, the expression of *Gabra5* across all neurons is decreased compared to Ct and 9 mo animals. Interestingly, 16mo TgF344-AD rats display a decrease in the average number of *Gabra5* transcripts per cell. This decrease in the amount of *Gabra5* containing neurons occurs in the 16mo TgF344-AD rats and not 9mo and was not due to an overall decrease in the number of CA1 neurons which did not change between groups, indicating that the decrease in *Gabra5*$^+$ neurons in the aged TgF344-AD rats was due to a decreased *proportion* of *Gabra5*$^+$ neurons in the CA1 population. In contrast, 9mo TgF344-AD rats presented with an increase in *Gabra5* when compared to Ct, suggestive of a homeostatic response to the beginnings of circuit dysfunction that we will be exploring in our ongoing studies using immunohistochemistry and immunoprecipitation to determine $GABA_AR$ subunit composition in select neurons of the TgF344-AD hippocampal formation.

Title: Early impairment of hippocampal synaptic plasticity in the TgF344-AD rat model for Alzheimer's disease

Authors: *Y. SUN[1], J. GIGG[2], M. HARTE[1];
[1]Div. of Pharm. and Optometry, [2]Div. of Neurosci. & Exptl. Psychology, Univ. of Manchester, Manchester, United Kingdom

Abstract: Hippocampal hyper-excitability has been associated with cognitive decline in early Alzheimer’s disease (AD). The TgF344-AD transgenic rat expresses age-dependent beta-amyloid (Aß) aggregation, tauopathy and neuroinflammation, becoming a useful AD model to study pre-symptomatic

changes in synaptic strength. Here, we sought to determine whether hippocampal excitability changes also occur in this model. For the first part of this study, in vivo evoked field excitatory post-synaptic potentials (fEPSPs) were recorded in the hippocampal CA3 to CA1 projection of the 9-month-old TgF344-AD (TG) and wild-type (WT) rats (males; n=8), to determine the induction properties for short- and long-term synaptic plasticity. Accordingly, the TG rats demonstrated diminished paired-pulse facilitation (PPF), as well as weaker long-term potentiation (LTP) following high-frequency stimulation (HFS) compared to the WT. Interestingly, TG rats also showed larger CA1 fEPSPs with an upwardly-shifted input-output (I/O) curve. These results indicate a baseline increase of presynaptic transmitter release in the hippocampal CA3 to CA1 synapse at this age; this synaptic hyper-excitability then limits the scope for induced synaptic plasticity. To determine whether changes can be seen at an earlier stage of pathology in the model, the same protocol for evoked fEPSPs was applied on the TG model at the younger age of 6 months when soluble Aß oligomers can first be detected (Cohen et al., 2013). As a preliminary result, these TG rats also showed significantly lower LTP after HFS compared to the control (males; n(WT)=6, n(TG)=7), but the magnitude of responses was reduced gradually instead of reaching a steady plateau. In addition to the previous stimulating protocol, low-frequency stimulation (LFS) was applied after LTP to determine the capacity for downregulation of plasticity. Consequently, the response magnitude of the TG rats was markedly smaller compared to the WT, and fell to below the pre-HFS baseline. Further work is underway to analyse PPF and I/O to test for changes in short-term plasticity and baseline connectivity. Collectively, the current results suggest synaptic dysfunction in the hippocampal CA3 to CA1 projection of the TG model for AD. Next, Aß oligomers and other pathologies will be measured using the post-mortem tissue of TG rats and WT littermates at corresponding ages. Since the animals do not show abundance of Aß plaques at the age tested here (Cohen et al., 2013), these results could reveal a possible mechanism for the effect of soluble Aß oligomers that contributes to the memory impairment in AD diagnosis.

Title: Targeting histone 3 K4 trimethylation for treatment of cognitive and synaptic deficits in mouse models of Alzheimer’s Disease

Authors: *Q. CAO, W. WANG, J. B. WILLIAMS, F. YANG, Z. WANG, Z. YAN;
State Univ. of New York at Buffalo, Buffalo, NY

Abstract: Alzheimer's disease (AD) is a multifactorial neurodegenerative disorder characterized by significant memory impairment and cognitive decline. Epigenetic dysregulation of gene transcription plays a key role in mediating gene-environment interactions relevant to AD pathophysiology. Here we show that the permissive histone mark, histone 3 K4 trimethylation (H3K4me3) and its catalyzing enzymes, SET1/MLL family of methyltransferases, are significantly elevated in the prefrontal cortex (PFC) of human and mouse models of AD. Importantly, the cognitive deficits and impaired PFC synaptic transmission in mouse models of AD are substantially recovered by selective inhibition of SET1/MLL. H3K4me3 is associated with transcriptional activation, including gene targets we found to be enriched in neurodegenerative-related pathways. We also discovered that aberrant H3K4me3 elevation and its corresponding dysregulated genes are reversed by the SET1/MLL inhibitor WDR5-0103. Among the upregulated genes linked to increased H3K4me3, one identified top-ranking target, the protein kinase Sgk1, is reversed to normal levels after administration of WDR5-0103. Furthermore, we found that selectively inhibiting Sgk1 directly reduced hyperphosphorylated tau, restored synaptic function, and ameliorated cognitive deficits in an AD mouse model. These findings provide potential mechanistic insights that aberrant epigenetic modifications associated with gene dysregulation in Alzheimer's-related pathophysiology could be a promising strategy for therapeutic intervention.

Title: Synaptic new protein synthesis and Akt1/mTOR signaling pathway is dysregulated in hippocampus of Alzheimer's disease mouse model

Authors: *R. KOMMADDI[1], R. GOWAIKAR[2], K. SINGH[2], A. HASEENA P[1,3], V. RAVINDRANATH[1];

Abstract: Akt/mammalian target of rapamycin (mTOR) signaling pathway is one of the major signaling pathways and it is activated by BDNF that facilitates new protein synthesis at the synapse which lead to the formation of long-term memory in the hippocampus. Recently, we have shown that BDNF stimulated Akt1 mediated new protein synthesis is abolished in primary cortical neurons from APP_{Swe}/PS1ΔE9 (APP/PS1) mice compared with wild type (WT). However, the molecular mechanisms underlying the impairment of new protein synthesis at the synapse is still elusive. Our aim is to understand the molecular mechanisms early by assessing the phosphorylation of Akt1 and the mammalian target of rapamycin (mTOR) signaling cascade molecules and new protein synthesis in hippocampus of WT and APP/PS1

male mice. Intriguingly, pAkt1, pGSK3β, pmTOR, p70S6K, pS6 ribosomal protein, p4E-BP1 levels were significantly decreased in both post nuclear supernatant (PNS) and synaptosomal fractions isolated from hippocampus of one month old (presymptomatic) APP/PS1 male mice compared to WT male mice. Further, activity dependent protein synthesis at the synapse was impaired in synaptoneurosomes isolated from hippocampus of presymptomatic APP/PS1 mice, and this deficit was sustained at young adults (three months). However, no impairment was observed in basal protein synthesis at both ages in APP/PS1 male mice compared to WT male mice. Thus, we conclude that dysregulation of Akt1/ mTOR and its downstream signaling molecules in hippocampus contributes to synaptic dysfunction in Alzheimer's disease, observed as loss of activity dependent new protein synthesis at the synapse in hippocampus which is essential for synaptic plasticity and maintenance.

Title: Presynaptic susceptibility to glutamate spillover in a mouse model of alzheimer disease

Authors: *K. J. BRYMER[1], J. R. BARNES[2], M. P. PARSONS[2];
[1]Biomed. Sci., Mem. Univ., St. John's, NL, Canada; [2]Biomed. Sci., Mem. Univ., St John's, NL, Canada

Abstract: Tight control over the spatiotemporal dynamics of extracellular glutamate is necessary to prevent the toxic effects associated with excess glutamate accumulation. This control is mediated by glutamate transporters located on astrocytes and neurons, with GLT-1 responsible for the majority of glutamate clearance. Previous literature has described an asymmetrical distribution of glutamate transporters in the hippocampus, with presynaptic sites having less glial coverage than postsynaptic sites of the synapse. We reasoned that such an asymmetry would make the presynapse prone to slowed glutamate clearance. To test this hypothesis, we developed a novel approach to quantify the unique glutamate clearance dynamics in presynaptic and postsynaptic microenvironments in the hippocampus of the C57 mouse through a combination of intensity-based glutamate sensing fluorescent reporter (iGluSnFR) and two-photon microscopy. Interestingly, presynaptic microenvironments in acute hippocampal slices were more susceptible to slowed glutamate clearance from a low concentration of DHK than postsynaptic microenvironments. Having established that this asymmetry in the form of glial coverage makes the presynapse vulnerable to slowed glutamate clearance, we next asked what the consequences of this asymmetry are in a brain disease with compromised glutamate uptake, such as Alzheimer disease (AD). We utilized the same iGluSnFr and 2-photon microscopy approach described above in male and female 3xTg and control mice. By 6 months, an age corresponding to the emergence of an AD-like phenotype in the 3xTg mouse, glutamate clearance in presynaptic microenvironments was

impaired while postsynaptic clearance was unimpaired. Remarkably, at 12 months, presynaptic glutamate clearance remained impaired while no evidence of a postsynaptic clearance deficit emerged despite advanced disease pathology. We confirmed that the glutamate clearance impairment in presynaptic microenvironments is mediated by GLT-1, as DHK application to acute hippocampal slices increases glutamate clearance time in presynaptic microenvironments but the magnitude of this increase is less than in WT mice. Moreover, GLT-1 overexpression via ceftriaxone speeds up glutamate clearance in presynaptic microenvironments. These results strongly suggest that glutamate transporters have different capabilities depending on the specific microenvironment within a given region, and that impaired glutamate clearance in presynaptic microenvironments may set the stage for synaptic pathology characteristic of AD.

Title: PSD-95 palmitoylation in Alzheimer's model mice

Authors: K. MERRITT, A. PHAM, ***K. DORE**;
Neurosciences, UCSD, La Jolla, CA

Abstract: The first change in the brains of Alzheimer’s patients and the best biomarker of the disease is synaptic loss. Several studies have shown that PSD-95 (a major scaffolding protein at the synapse) is significantly depleted in brain tissue of Alzheimer’s patients as well as in neurons exposed to Aβ. Consistently, we recently discovered that elevated levels of PSD-95 can prevent synaptic weakening by Aβ (Dore et al, Cell Reports, 2021). The amount of synaptic PSD-95 is controlled by a process called ‘palmitoylation’ which mediate the insertion of PSD-95 in post-synaptic membranes. In the hippocampus of 6-month old APP/PS1 mice, we observed a 50% reduction in palmitoylated PSD-95 while total PSD-95 amounts were reduced by only 10%. This suggests that loss of PSD-95 palmitoylation would happen before reductions in total PSD-95 in this mouse model. Moreover, we characterized PSD-95 palmitoylation in male and female mice of different ages to assess the time course of this decrease and how it is affected by the presence of amyloid plaques. The specific enzyme responsible for PSD-95 depalmitoylation, ABHD17, which removes PSD-95 from synapses, was recently identified. We thus started to test the potential of a novel drug target, ABHD17, as a new therapeutic avenue against Alzheimer’s. Our preliminary *in vitro* and *in vivo* results, using a commercially available inhibitor of that enzyme (Palmostatin B), are very promising. *In vitro* experiments showed that this drug could rescue Aβ-induced synaptic depression and Aβ-mediated effects on dendritic spines. Notably, using immunohistochemistry, we saw that Palmostatin B injections in the intraperitoneal cavity rapidly rescued palmitoylated PSD-95 in a dose dependent manner in APP/PS1 mice, which indicates that this drug can

access brain synapses *in vivo*. We observed similar results using a biochemical approach to quantify PSD-95 palmitoylation (APEGS assay). Moreover, we now have new preliminary data showing that blocking PSD-95 depalmitoylation with Palmostatin B can rescue memory deficits in the Morris Water Maze test and also improve synaptic physiology deficits in APP/PS1 mice. Our data show that PSD-95 palmitoylation is significantly reduced in 6-month old APP/PS1 mice, which might indicate a previously unknown step in the pathophysiology of Alzheimer's disease. Furthermore, pharmacological blockade of PSD-95 depalmitoylating enzyme rescued palmitoylation levels in the hippocampus of APP/PS1 mice and also had promising effects on behavioral and synaptic physiology deficits. Consequently, PSD-95 depalmitoylating enzyme could be an exciting new drug target against Alzheimer's disease.

Title: Suppression of AMPKα2 aggravates cognitive deficits in a mouse model of Alzheimer's disease

Authors: *H. JESTER[1], S. GOSRANI[2], H. R. ZIMMERMANN[3], X. ZHOU[1], T. MA[1];
[1]Intrnl. Medicine-Geriatrics, Wake Forest Sch. of Med., Winston-Salem, NC; [2]Emory Univ., Atlanta, GA; [3]Northwestern Univ., Chicago, IL

Abstract: AMP-activated protein kinase (AMPK) is a cellular energy censor that plays a critical role in protein synthesis regulation, metabolism, autophagy, and mitochondrial biogenesis. Dysregulation of AMPK signaling has been implicated in the pathophysiology of Alzheimer's disease (AD). The catalytic α isoforms (α1 and α2) of AMPK are normally expressed in a homeostatic equilibrium but are differentially expressed in AD brains. Roles of AMPK isoforms in development of AD pathophysiology remain elusive. In this study, AMPKα2 and α1 were conditionally knocked down in excitatory forebrain neurons in the Tg19959 AD mouse model to create heterozygous AMPKα2/Tg19959 and AMPKα1/Tg19959 double mutants. At 3-5 months of age, before cognitive impairments become evident in AD model, the mice were subjected to the Novel Object Recognition (NOR) task and the Morris Water Maze (MWM) that measure hippocampus-dependent spatial learning and memory. In addition, immunohistochemistry, and transmission electron microscopy of the hippocampus were performed to determine alterations in plaque deposition, post-synaptic densities, and polyribosomes. The double mutant AMPKα2/Tg19959 mice showed significant memory impairments in both the MWM and NOR task compared to Tg19959, and α1/Tg19959 genotypes. The AMPKα2/Tg19959 double mutant mice also showed significant decreases in post-synaptic density size and in the number of polyribosomes. An

increase in amyloid plaque deposition was also observed. Taken together, these findings suggest that reduction of AMPKα2 may accelerate cognitive decline and AD pathogenesis. This finding could provide a future therapeutic target and/or diagnostic/prognostic biomarkers for AD.

Title: In vivo imaging of dendritic excitatory-inhibitory synapse imbalance in mouse models of Alzheimer's disease

Authors: *S. NIRAULA[1], J. DODERER[1], S. INDULKAR[1], J. DENG[1], G. KEETER[1], K. BERRY[2], S. YAN[1], J. SUBRAMANIAN[1];
[1]Dept. of Pharmacol. & Toxicology, The Univ. of Kansas, Lawrence, KS; [2]Dept. of Pediatrics, Cincinnati Childern's Hosp. Med. Ctr., Cincinnati, OH

Abstract: The ratio of excitatory and inhibitory synapses is balanced (E/I balance) locally in the dendrites. Local dendritic E/I balance regulates dendritic depolarization and may influence neuronal plasticity and memory. Excitatory synapse loss is the strongest correlate for cognitive decline in Alzheimer’s disease (AD). It is unclear whether excitatory synapse loss triggers compensatory loss of inhibitory synapses to maintain E/I balance. Alternatively, excitatory synapse loss could be a compensation for a prior reduction in inhibitory synapses. Using multicolor two-photon imaging, we map the distribution and dynamics of excitatory and inhibitory synapses in the same neurons *in vivo* in a mouse model of AD (J20 mice). We show that neurons in the visual cortex of J20 mice display a spatially restricted reduction in dendritic E/I balance. Using a genetically encoded calcium sensor GCaMP6, we found that neuronal response plasticity associated with repeated experience of a grating stimulus is impaired in the visual cortex of J20 mice. Consequently, J20 mice are deficient in forming visual recognition memory of the grating stimulus. We test whether E/I imbalance in J20 mice is due to a deficiency in sensing changes to neuronal excitability and whether increasing E/I balance improves plasticity and memory despite lost synapses.

Title: Alzheimer's disease risk gene CD2AP modulates synaptic structure and plasticity

Authors: *M. PAVESKOVIC, S. OJELADE, B. PEKAREK, M. KOCHUKOV, B. ARENKIEL, J. SHULMAN;
Baylor Col. of Med., Houston, TX

Abstract: *CD2-Associated protein (CD2AP)* is associated with increased risk of late-onset Alzheimer's disease. We have previously shown that loss of *CD2AP*'s *Drosophila* homolog, *cindr*, exacerbates Tau toxicity and impairs synaptic maturation and function at the neuromuscular junction. However, little is understood about *CD2AP* at the central mammalian synapse. The present study demonstrates conservation of *CD2AP* function at the pre-synapse from fly to mouse, as well as characterizes *CD2AP*'s role in maintaining post-synaptic structure and function.
We examined short- and long-term plasticity using electrophysiologic measurements and synaptic structure and morphology using confocal imaging. Experiments were performed on homozygous *CD2AP* knockout mice and heterozygous *CD2AP* knockout mice to investigate potential haploinsufficient requirement. Mice constitutively expressing Cas9 endonuclease were used for brain-specific *CD2AP* knockout.
We found that homozygous and heterozygous *CD2AP* knockout mice exhibit increased paired-pulse facilitation, a form of short-term plasticity. This matches data from *Drosophila*, implying conservation from fly to mouse, and indicates decreased probability of presynaptic vesicle release with *CD2AP* loss. We found no change in long-term potentiation (LTP) at 4 to 6 weeks; however, our preliminary experiments demonstrate decreased LTP in aged heterozygous *CD2AP* knockouts. Ongoing experiments are investigating age as a factor in *CD2AP* function. Lastly, *CD2AP* knockout neurons exhibit increased dendritic branching and homozygous knockout mice have increased expression of postsynaptic density protein 95.
In sum, our analyses implicate *CD2AP* in modulation of synaptic plasticity and structure, suggest a conservation of CD2AP function from flies to mice, and support *CD2AP* haploinsufficiency. Going forward, we will investigate how *CD2AP* loss affects existing Alzheimer's pathogenesis in a tauopathy mouse model.

Title: Synthetic and natural conformational variants of misfolded Aβ induce different pathological features in susceptible mice.

Authors: *R. MORALES[1], R. GOMEZ-GUTIERREZ[1], U. GOSH[2], K. DO[1], W.-M. YAU[2], C. DURAN-ANIOTZ[1], I. MORENO-GONZALEZ[1], N. GAMEZ[1], J. SCHULZ[1], C. KRAMM[1], R. TYCKO[2], C. SOTO[1];
[1]The Univ. of Texas Hlth. Sci. Ctr. at Houston, Houston, TX; [2]NIH, Bethesda, MD

Abstract: Compelling evidence in humans and experimental rodents suggest that Alzheimer's disease (AD) -associated Aβ exists in a variety of conformational strains. Unfortunately, current research has not addressed the biological significance of Aβ strain variation in AD. This issue acquires additional relevance considering that mixtures of Aβ strains seems to exist in the brains of patients. Aβ strain variation may explain the pathological and clinical differences observed among people afflicted by AD. Here, we used brain-derived and synthetic Aβ strains to assess for potential differences in propagation and pathological manifestations. In a first set of experiments, two synthetic-$A\beta_{40}$ strains (2F and 3F) that have been thoroughly studied for their structural motifs, were biochemically characterized and injected in the brains of 50 days old Tg2576 mice. We assessed prion-like transmission of these materials by analyzing Aβ deposition 250 days later. A second set of experiments involved the administration of AD brain homogenates from individuals displaying diverse amyloid pathology. These human brain extracts were intra-cerebrally injected into 30 days old APP/PS1 mice that were sacrificed 150 days later. Pathological differences in both experiments were found at different levels, including the type and anatomical distribution of the aggregates, $A\beta_{40}/A\beta_{42}$ ratios, reactivity of amyloid deposits to dyes able to discriminate among misfolded protein conformations, among others. Importantly, differences in astro- and micro-glial activation were also observed. Our data support the concept and biological relevance of conformational strain variation in non-prion protein misfolding disorders. In addition, these results provide a good correlation between structural motifs and biological activity. Our findings may pave the way to identify the most deleterious particles responsible for AD and help in the design of conformation-specific strategies for diagnosis and treatment.

Title: In-tissue structure of Alzheimer's Disease pathology in the mammalian brain by cryo-electron tomography

Authors: *C. M. LEISTNER, R. A. W. FRANK;
Univ. of Leeds, Leeds, United Kingdom

Abstract: Senile plaques composed of amyloid-β (Aβ) are a major pathological hallmark of Alzheimer's disease (AD). Aβ fibrils prepared *in vitro* or purified from post-mortem tissue have been investigated extensively revealing their atomic structure. However, the native architecture of Aβ plaques and the organisation of Aβ fibrils within the brain itself is currently unknown.
Here, we developed a workflow to determine the *in situ* architecture of Aβ plaques using cryogenic correlative light and electron tomography (cryoCLET) in the brain of a knock-in mouse model of AD (1 year old male *App* NL-G-F, n=2). After injecting mice with Methoxy-X04, a fluorescent dye that labels Aβ plaques, fresh cortical tissue biopsies were vitrified by high pressure freezing. Next, tissue cryo-sections were collected on cryoEM grids and Methoxy-X04 stained plaques were mapped by correlative imaging to direct the collection of cryo-electron tomographic data.
3D reconstructions revealed the in-tissue molecular architecture of Aβ plaques. Aβ fibrils were organised within multiple distinct domains of varying densities, including a meshwork and parallel bundles. Interestingly, this correlative imaging approach revealed apparent conformational differences of Aβ fibrils in central versus peripheral regions of the plaque. Numerous other macromolecular features were observed within the plaque, including liquid-like droplets. Subcellular compartments interdigitated the pathology, within and between Aβ parallel bundles. These included membranes containing higher-order protein networks, C-shaped membranes, and membrane nanopodia. The boundary of Aβ plaques was characterised by cells in close proximity to Aβ fibrils that contained an abundance of mitochondria, endoplasmic reticulum, ribosomes and microtubules. Overall, these results reveal the molecular heterogeneity of Aβ plaques and the rich diversity of cellular constituents that define the amyloid pathology of AD.

Title: Hippocampus Specific Knock-Down of PPARα Aggravates Plaque Pathology in 5xFAD Mice

Authors: *M. MCKAY, S. RAHA, R. KUMAR, K. PAHAN;
Rush Univ. Grad. Col., Chicago, IL

Abstract: Peroxisome proliferator-activated receptor alpha (PPARα) is a transcription factor that regulates fatty acid metabolism. Although, metabolically active organs like the liver is rich in PPARα, we and others have demonstrated that PPARα is constitutively expressed in hippocampal neurons. To delineate the role of PPARα in the hippocampus in relation to Alzheimer's disease (AD), we generated 5xFAD mice lacking PPARα in the hippocampus (5xFAD$^{\Delta Hippo}$) via complex breeding among PPARα$^{Flox/Flox}$, calcium/calmodulin-dependent protein kinase II alpha (Camk2a)^{Cre} and 5xFAD mice. Although, phenotypically, 5xFAD$^{\Delta Hippo}$ mice looked similar to 5xFAD mice, we observed aggravated amyloid plaque pathology and enhanced glial activation in the hippocampus of 5xFAD$^{\Delta Hippo}$ mice as compared to 5xFAD mice. Accordingly, 5xFAD$^{\Delta Hippo}$ mice also exhibited decreased spatial learning and memory in comparison to 5xFAD mice. These results suggest that hippocampal PPARα plays an important role in the manifestation of AD-related pathologies and symptoms, and that activation of hippocampal PPARα may be beneficial for AD.

Title: Doxorubicin treatment did not affect AB plaque accumulation in a mouse model of APOE and amyloid.

Authors: *C. NG, M. F. LANFRANCO, G. W. REBECK;
Neurosci. Dept., Georgetown Univ., Washington, DC

Abstract: Cancer survivors often experience cancer-related cognitive impairment (CRCI), which is characterized by problems of attention, working memory, and other domains of cognition following chemotherapy. APOE4, the strongest genetic risk factor for Alzheimer's Disease (AD), is also a risk factor for CRCI. Apolipoprotein E (apoE) is involved in lipid metabolism, synapse regeneration, immune modulation, and clearance and degradation of amyloid β (Aβ) deposition; functions that vary across apoE isoforms. Here we tested whether doxorubicin, a chemotherapeutic drug commonly used for breast cancer treatment, increases AD-related neuropathogenesis in a mouse model expressing familial AD mutations (5XFAD) and the human APOE genotypes (EFAD). Six-month-old female E3FAD (control n=5, treated n=5) and E4FAD (control n=6, treated n=6) mice were treated with either doxorubicin (5 mg/kg) or DMSO vehicle twice, one week apart. Six weeks after the second injection, mice were euthanized, and brains were perfused and collected; one hemisphere was fixed for immunohistochemistry and the other was dissected into cortex, hippocampus, and cerebellum for biochemical assays. The fixed hemispheres

were sliced into 30 μm coronal sections. Immunostaining with 6E10 antibodies to analyze APP and Aβ accumulation in the cortex and hippocampus showed no differences in plaque accumulation after doxorubicin treatment in either APOE genotypes. As expected, we observed greater levels of plaques in regions of the E4FAD mouse brains compared to the E3FAD mouse brains. Sequential protein extraction with Tris-buffered saline (TBS), TBS with 1% Triton-X (TBSX), and formic acid (FA) was performed for measurements of Aβ42 in the hippocampus. No effects of doxorubicin treatment were seen for Aβ42 levels in TBS, TBSX, nor FA fractions. In addition, glial reactivity to the presence of Aβ accumulation was determined by co-staining with either GFAP, an astrocytic marker, or Iba1, a microglia marker, with Moab2 antibodies for the detection of Aβ plaques. These data show no effects of doxorubicin on select aspects of AD pathogenesis, specifically Aβ accumulation; other aspects are being analyzed in these EFAD mice.

Abstract: Effect of sex hormones on the kinetics of amyloid-β in an awake behaving mouse
Hannah M. Edwards, Carla Yuede, John R Cirrito
Washington University, Department of NeurologyKnight Alzheimer's Disease Research CenterHope Center for Neurological DisordersSt. Louis, MO 63110
Alzheimer's disease (AD) is a neurodegenerative disease that is hallmarked by the accumulation of amyloid-beta (Aβ) and tau, followed by a progressive decline in cognitive acuity. Interestingly, AD affects women at a higher rate than men, even when controlling for differences in lifespan. Clinical trials utilizing hormone replacement therapy in older women have yielded conflicting results. To explain this difference, we looked at the direct effect of sex hormones on the temporal kinetics of brain interstitial fluid (ISF) Aβ using in vivo microdialysis. With probes implanted in the hippocampus of awake, behaving mice, we measured Aβ levels over a three-day period. Female animals were injected intraperitoneally with beta-estradiol. An increase in Aβ was seen after 12 hours. Animals were also dosed with norethindrone, a progesterone receptor agonist, using reverse microdialysis to focally target the hippocampus. Interestingly, a decrease in Aβ was seen almost immediately with Aβ levels returning to

baseline after administration of the drug was ceased. These novel results suggest a differential effect of the two most prevalent sex steroids in females, and work is ongoing to uncover the cause of this effect.

Title: Isoform- and dose-dependent effects of apolipoprotein E in the deposition of Abeta in the brain of APP transgenic mice

Authors: *T. HASHIMOTO[1], A. KOKAWA[2], M. TANAKA[1], Y. OHNO[1], M. KASHIWAGI-HAKOZAKI[1], T. IWATSUBO[1];
[2]Dept. of Neuropathology, [1]The Univ. of Tokyo, Tokyo, Japan

Abstract: Deposition and spreading of amyloid-β (Aβ) in the brain is an early and central event in the pathogenesis of Alzheimer's disease (AD). However, the molecular mechanisms underlying Aβ accumulation in the brain are not fully elucidated. Apolipoprotein E (apoE) is one of the lipid carriers in the brain and apoE is also known as Aβ binding protein. There are three common alleles of the human *APOE* gene, ε2, ε3, and ε4, encoding the apoE2, apoE3, and apoE4 isoforms, respectively. Among the three alleles of *APOE*, the ε4 allele is associated with a 6-folds increased risk for developing Alzheimer's disease compared with the most common ε3 allele. The density of Aβ deposition in the brains of *APOE*ε4carrier AD patients is significantly higher than that in *APOE*ε3 carrier, suggesting that apoE might impact the accumulation of Aβ in an isoform-dependent manner. In this study, we have generated APP tg mice expressing human apoE3 by crossing APP transgenic (tg) mice with human *APOE*ε3 knock-in (KI) mice. Gel filtration analysis showed that the level of lipidated apoE in the brains of APP tg/apoE3 KI mice was comparable with that in APP tg mice. *In vivo* microdialysis also revealed that the concentrations of Aβ42 in the brain interstitial fluid of APP tg/apoE3 KI and APP tg mice were at similar levels. By immunohistochemical analyses, APP tg/apoE3 KI mice exhibited a significantly lower Aβ burden in the brain compared with APP tg mice. These data suggest that human apoE3 suppresses the deposition of Aβ more strongly than mouse apoE. To test this hypothesis, we carried out an *in vivo* seeding experiment, which allows the induction of deposition and spreading of Aβ in the brain of APP tg mice by a single inoculation of Aβ seeds. Intra-hippocampal inoculation of TBS-soluble fraction from brains of Aβ-laden APP tg mice significantly induced the deposition of Aβ in the brains of APP tg mice. Notably, the seed-induced Aβ deposits in APP tg/apoE3 KI mice was less than that in APP tg mice. Furthermore, almost no Aβ deposits was observed in the brains of apoE-deficient APP tg mice in *in vivo* seeding experiments. Our findings implicate apoE in the deposition of Aβ by facilitating the seeding activity or spreading of Aβ seeds in the brain, suggesting that human apoE3 and murine apoE may have

different abilities to the facilitation of Aβ seeding. *In vivo* seeding experiments in the APP tg/apoE2 or apoE4 KI mice are underway to elucidate the isoform-dependent effects of apoE in the deposition of Aβ.

Title: Knock-in versus transgenic insertion of mutant amyloid precursor protein leads to early differential spatial deposition of amyloid-β plaques in mouse models of Alzheimer's disease

Authors: *D. HART, R. PELZEL, S. LESNÉ;
Dept. of Neurosci., Univ. of Minnesota, Twin Cities, Minneapolis, MN

Abstract: Animal models are commonly used to study the pathological mechanisms of Alzheimer's disease (AD). The overexpression, knock-out, and introduction of gain-of-function mutations allow for functional investigations of disease relevant proteins such as amyloid precursor protein (APP) and its metabolite amyloid-β (Aβ). Knowing the spatial development of pathology in different models is critical in understanding the potential and relevant translational ability of findings from these animals. To this end, we investigated the extent of Aβ deposition in the well-established transgenic APP J20 line and the newer knock-in App^{NL} and App^{NL-F} (n=6 of each genotype, including wild-type mice) at 9 months of age. All animals were maintained on the C57BL/6J background, and the cohort was made of both male and female mice. Sagittal sections throughout the left hemispheres from these animals were immunostained with 6E10, a commonly used marker for amyloid plaques. Aβ deposits were first registered at 10x and individually validated at higher 40x magnification. In the J20 line, we found cortical, hippocampal, and fiber tract Aβ plaques along with previously unreported subcortical deposition in the striatum. In comparison, knock-in App^{NL-F} mice displayed substantially more cortical deposition with no subcortical plaques. Consistent with previous reports, no Aβ plaques were found in the App^{NL} animals. The discrepancy of subcortical deposition between the J20 and App^{NL-F} lines mirrors that of human AD, whereby individuals with familial AD (fAD) develop subcortical Aβ plaques before hippocampal pathology, a phenotype not seen in sporadic AD (sAD). As such, J20 and App^{NL-F} mice may separately be useful models of fAD and sAD, respectively. Further studies will be needed to better understand the

functional role of these differences and their subsequent behavioral consequences, such as in spatial reference learning and memory and decision making.

Title: Discrete Spatiotemporal Trajectories of Aβ and Tau Pathologies in the Early Stages of Accumulation

Authors: *S. HOJJATI[1], D. DEVANAND[2], J. LUCHSINGER[2], Y. STERN[2], R. RAZLIGHI[1];
[1]Weill Cornell Med., New York, NY; [2]Columbia Univ. Irving Med. Ctr., New York, NY

Abstract: The aggregation of two misfolded proteins intracellular neurofibrillary tau tangles and extracellular amyloid-β (Aβ) plaques are the best-documented pathologies for Alzheimer's disease (AD). Spatiotemporal discrepancies between these two proteinopathies in initial stages of accumulation and their consequences for the brain structure and function are key unresolved challenges in understanding the pathogenesis of AD. In this study, we aimed to show that each pathology is associated with a unique alteration in brain structure (cortical thickness) and function (functional connectivity (FC) networks). Participants were selected from four separate research cohorts at Columbia University Irving Medical Center, and Weill Cornell Medicine. We identified 381 healthy controls with age of 50 years and older with three imaging modalities (T1-weighted structural, resting-state fMRI, 18F-MK-6240 positron emission tomography (PET), and 18F-florbetaben PET) acquired within 12 months. An in-house developed fully automatic quantification method has already been implemented and evaluated using histopathological data used for the quantification of PET scans. To trace the spatial and temporal characteristics of these two pathologies, first we categorized the participants to three groups based on their tau uptake in the regions involved in each Braak stage using the K-means clustering method. Then we performed vertex-wise linear regression models in each group to investigate the relationship between the two pathologies and cortical thickness as well as functional connectivity when age, gender and intracranial volume (ICV) are controlled. Results showed that the tau accumulations were independentely related to cortical atrophy in different brain regions (e.g. medial temporal lobe, posterior cingulate), whereas such relationship was missing for Ab accumulation. On the other hand, the Aβ accumulation were related to significant disruption in the functional connectivity of the Defualt mode network (DMN) as well as dorsal attention network (DAN), whereas tau had a weak association with DMN FC and almost no association with the DAN FC. These unique Aβ and/or tau related alterations in the structure and function of the brain suggests a discrete spatiotemporal trajectory in the early accumulation of the pathologies that are considered as hallmark of the AD. In other words, while later accumulation and coincide of the two pathologies seems to facilitate the brain alterations causing AD, the early accumulation seems to be initiated independently and follow unique trajectory. These findings suggest AD pathways that can be investigated in future studies.

Title: Melanopsin ganglion cell morphology in the 3xTg mouse model of Alzheimer's disease

Authors: *M. A. SMITH[1,3], S. DEWAN[4], C. M. DENGLER-CRISH[2], J. M. FERRELL[1]; [2]Pharmaceut. Sci., [1]Northeast Ohio Med. Univ., Rootstown, OH; [3]Akron Children's Hosp., Akron, OH; [4]Univ. of Akron, Akron, OH

Abstract: Circadian rhythm abnormalities are reported in AD patients very early in the course of the disease including abnormal timing and duration of the sleep cycle, the reduction of melatonin levels during the night, and alternating expression profile of clock genes. These deficits could arise from dysregulation within several brain sites, however, the retina has been postulated as one of the earliest neural structures affected in AD and melanopsin expressing retinal ganglion cells (mRGCs) are responsible for maintaining circadian rhythms, thus making the retina it an attractive target for investigating pathological mechanisms. In other neurodegenerations such as Parkinson's, Alzheimer's, and glaucoma loss of mRGCs, have been detected. While amyloid-β accumulation, mRGC loss, and gliosis in the retinas of mouse models of AD are evident, little is known about the progression of pathology in mRGC axons. Using a combination of immunohistochemistry, and high-resolution florescent microscopy, we examined the mRGC morphology in 4-7 month old 3xTg mice, a commonly used murine model of Alzheimer's disease. We found substantial decreases in in dendritic field complexity, dendritic area, and soma size in the retina of 3xTg mice. Importantly, mimicking the progression of other age related neurodegenerations, these changes occurred independent from a reduction in total RGC and mRGC somata density in the corresponding retinas. In conclusion, the 3xTg mouse exhibits early changes in mRGC morphology in the absence of cell body loss. The accessibility, isolation, and simplicity of the anterior visual system may provide a useful framework for studying the mechanisms of axonopathy in AD.

Title: Visual dysfunction in Alzheimer's disease: investigating the role of the parabigeminal nucleus

Authors: *G. FRAME, C. M. DENGLER-CRISH;
Pharmaceut. Sci., Northeast Ohio Med. Univ., Rootstown, OH

Abstract: The parabigeminal nucleus (PBGN) is an accessory visual structure that in rodents, communicates with the superior colliculus (SC) to mediate an escape response to overhead looming stimuli. While the PBGN seems to be important for defensive survival behavior in rodents, there is very little research on this nucleus in humans or how its structure/function may change with age or disease. However, what is known about this structure suggests it may be selectively damaged in Alzheimer's disease (AD). Clinical observations from AD patients report early, nuanced deficits in response to visual stimuli and movement perception, and accumulations of pathological AD proteins have been identified in the primary visual projection of both patients and experimental AD models (i.e. 3xtg mice) from retina > optic nerve > brain. In rodents, the primary projection target of the retina is the SC, with which the PBGN has strong, bidirectional connections. Additionally, the PBGN is predominantly a cholinergic nucleus—and these neurons are selectively vulnerable to the Alzheimer's disease process. Therefore, the overall goal of our research is to characterize PBGN structure, collicular connectivity, and function across age in both healthy mice (C57BL6) and disease (3xtg Alzheimer's mice) using a comprehensive set of neurohistochemical and behavioral-testing techniques. Here, we present data from our structural analyses comparing PBGN composition across age, sex, and disease state.

Title: CPL500036 - a novel inhibitor of phosphodiesterase 10A - attenuates parkinsonian-like and L-DOPA induced dyskinetic effects in 6-OHDA lesioned rats

Authors: *M. MATLOKA[1], T. LENDA[2], K. OSSOWSKA[2], K. BERGHAUZEN-MACIEJEWSKA[2], D. BIAŁA[2], A. GAJOS-DRAUS[1], P. PANKIEWICZ[1], K. MULEWSKI[2], A. JANUSZ[1], D. SMUGA[1], M.

GORKA[1], J. PIECZYKOLAN[1], M. WIECZOREK[1], J. KONIECZNY[2];
[1]Celon Pharma S.A., Kazun Nowy, Poland; [2]Maj Inst. of Pharmacology, Polish Acad. of Sci., Krakow, Poland

Abstract: Background: Parkinson's disease (PD) is a progressive neurodegenerative disorder characterized by the loss of dopaminergic neurotransmission. Dopamine replacement therapy, e.g. with levodopa (L-DOPA), remains the gold standard of therapy. Unfortunately, following years of exposure, L-DOPA causes motor complications such as L-DOPA-induced dyskinesias (LIDs). Phosphodiesterase 10A regulates cAMP/cGMP downstream signaling thus having a key role in the regulation of dopaminergic signaling in striatal pathways and seems to be of special interest as a potential therapeutic target in PD.
In the presented studies we examined the influence of CPL500036 (CPL036), a novel PDE10A inhibitor, on: 1) sensorimotor deficits and therapeutic effects of L-DOPA and 2) L-DOPA-induced dyskinesias in hemiparkinsonian rats.
Methods: Animals were unilaterally lesioned with 6-hydroxydopamine (6-OHDA). For antiparkinsonian assessment, CPL036 (0.1 and 0.3 mg/kg) was administered either acutely or chronically (2 weeks), alone or in combination with L-DOPA/benserazide (6 mg/kg/6 mg/kg) and sensorimotor deficits were examined in the stepping, cylinder, vibrissae and catalepsy tests. To assess antidyskinetic properties, dyskinesias were induced by L-DOPA/benserazide (6 mg/kg/6 mg/kg) (15 days). Dyskinetic animals were treated additionally with CPL036 (0.03, 0.1, 0.3mg/kg) for next 17 d. The severity of dyskinesia was assessed by Dyskinesia - Abnormal Involuntary Movements scale (AIMs). cAMP and cGMP level was assessed by HPLC method.
Results: Acute treatment with CPL036 reversed the lesion-induced impairments of contralateral forelimb use. Moreover, chronic treatment with CPL036 did not diminish the therapeutic effects produced by L-DOPA. Combined treatment with L-DOPA and CPL036 (0.03, 0.1 and 0.3 mg/kg) dose-dependently attenuated the L-DOPA-induced dyskinesia, and the beneficial effect of CPL036 increased with repeated doses. The level of cAMP and cGMP increased significantly for a dose of 0,3 mg/kg of CPL500-036 in dyskinetic animals.
Conclusion: CPL036 attenuated effectively L-DOPA induced dyskinesias in combination therapy with L-DOPA, without negative impact on the therapeutic antiparkinsonian efficacy of the latter drug, in a rat model of PD.

Title: Sex & brain region-based variation in paraoxonase-2 (PON2) expression in African green monkeys: Impact of pioglitazone treatment and implications for its use in Parkinson's disease

Authors: *S. JAMWAL, J. K. BLACKBURN, J. D. ELSWORTH;
Yale Univ. Sch. of Med., New Haven, CT

Abstract: The neuropathology of Parkinson's disease (PD) involves decreased mitochondrial performance and enhanced oxidative stress as a result of increased production of reactive oxygen species; however, none of the drugs used to treat PD targets these mechanisms. Previous studies have established that PON2 is a mitochondrial enzyme with potent antioxidant and anti-inflammatory properties and a promising target for drugs to impart protection to dopamine neurons and stem the progression of PD. This is supported by studies from our lab that identified a decline in PON2 expression with age in nonhuman primates (NHPs), which correlates with the sensitivity of dopamine neurons to oxidative stress induced by parkinsonian toxins. The value of activating PON2 as a strategy to halt PD progression would be enhanced if the enzyme was highly expressed in dopamine-rich regions and also displayed a sex bias in its distribution in NHP brain, as PD is 2-2.5 times more prevalent in males than females. First, we investigated the sex as well as region-based variation in PON2 expression in NHP brain, using St Kitts African green monkeys. We found a 2-2.5-fold greater PON2 expression in striatum compared with other brain regions and that females exhibit 2-3-fold higher expression compared with males. Second, we studied in vivo pharmacological stimulation of PON2, which has not been demonstrated before. Preclinical studies indicate that the PPARγ activator, pioglitazone, is neuroprotective in PD models by reducing oxidative stress and/or inflammation and clinical studies suggest it may reduce the risk of PD, however, its precise mechanism has not been elucidated. We hypothesized that pioglitazone's action depends on PON2 activation. Indeed, we found that sub-chronic pioglitazone treatment significantly augmented striatal expression of PON2 in mice. To determine the effect of pioglitazone on PON2 expression in a more translatable species, male African green monkeys were treated with oral pioglitazone (5 mg/kg/day) or vehicle for 1 or 3 weeks. Pioglitazone significantly increased PON2 expression in substantia nigra, striatum, dorsolateral prefrontal cortex and hippocampus, but after 3-weeks of treatment the effect on PON2 had subsided. Identifying the mechanisms responsible for the short-term

effect on PON2 is crucial for optimizing the use of pioglitazone and other PPARγ agonists in PD. This study establishes the existence of sex and region-based variation in PON2 protein expression in primate brain and provides a novel mechanism for pioglitazone-induced neuroprotection. We anticipate that these outcomes will contribute to the development of neuroprotective treatments for PD.

Title: Regionally selective effects ofpirepematon catecholamine neurotransmissionupon local administration in cortical and subcortical brain areas

Authors: *S. WATERS[1], **D. ANDERSSON**[1], C. SONESSON[1], A. FAGERBERG[1], L. ROUSK[1], J. TEDROFF[1,2], N. WATERS[1], S. HJORTH[1,3];
[1]Integrative Res. Labs., Goeteborg, Sweden; [2]Dept of Clin. Neurosci., Karolinska Institutet, Stockholm, Sweden; [3]Pharmacilitator AB (inc.), Vallda, Sweden

Abstract: Pirepemat (IRL752), is a new phenyl-pyrrolidine derivative with regio-selective effects on CNS transmission. It is currently in Phase II clinical development for the treatment of postural instability and prevention of falls in Parkinson's disease. Upon systemic administration, pirepemat produces dose-dependent increases in extracellular levels of dopamine, norepinephrine, and acetylcholine in cortical, but not subcortical areas, as measured by in vivo brain microdialysis. It is procognitive in preclinical assays, e.g. NOR and RL, and reverses tetrabenazine-induced hypoactivity but does not stimulate basal locomotor activity in normal animals. (JPET 2020 Sep;374(3):404-419). These in vivo effects have been attributed to antagonism at alpha2c-adrenoceptors, as well as 5HT7 receptors.
To further elucidate the pharmacological mode of action of pirepemat, we studied the effect of local administration of the compound in several brain regions: prefrontal cortex (PFC), hippocampus, striatum, nucleus accumbens (NAc), and locus coeruleus (LC). Using a dual microdialysis probe set-up, pirepemat 1-100 µM was applied by reverse-dialysis into the region of interest. Microdialysis samples were simultaneously collected in the same region, and in one additional region (ipsi- or contralaterally). The alpha2c adrenoceptor antagonist ORM12741 was tested in a similar fashion, however limited to application in the PFC and sampling in the PFC and the striatum. Systemic administration studies were performed for comparison.
Pirepemat produced marked increases in PFC catecholamines upon local administration, without concomitant effects in subcortical areas. Local application in the striatum or the NAc had no effect on catecholamine levels. Application in the LC produced a local concentration-dependent increase of NA, but no concomitant increase in catecholamines in the PFC, neither contra- nor ipsilaterally. The alpha2c adrenoceptor antagonist ORM12741 did not produce similar effects when administered locally, and elicited but a slight regio-selective increase in PFC catecholamines upon systemic administration (0.3 mg/kg, s.c.).

In conclusion, the local PFC effects of pirepemat parallel the effects seen after systemic administration; i.e., the effects are qualitatively similar. This suggests that local cortical mechanisms are the main drivers of the pharmacodynamic effects of the compound. An alpha2c adrenoceptor-selective antagonist failed to produce similar effects, suggesting that the overall in vivo effects of pirepemat may derive from interactions of the agent at several receptors and/or circuits impacting PFC catecholamine output.

Title: Non-clinical pharmacology of YTX-7739, a clinical stage stearoyl-CoA desaturase inhibitor being developed for Parkinson's disease

Authors: *D. TARDIFF[1], M. LUCAS[1,2], I. WRONA[1,2], B. CHANG[1,3], C. CHUNG[1], B. LE BOURDONNEC[1,4], K. RHODES[1,5], R. SCANNEVIN[1,6];

Abstract: Unbiased phenotypic screening and target deconvolution identified stearoyl-CoA desaturase (SCD) as a potential therapeutic target for Parkinson's and related neurodegenerative diseases. SCD inhibition ameliorated neuronal toxicity caused by aberrant α-synuclein, a lipid-binding protein implicated in Parkinson's disease. Inhibiting SCD depletes monounsaturated fatty acids, which may modulate α-synuclein conformations and membrane interactions. Herein, we have characterized the pharmacokinetic and pharmacodynamic properties of YTX-7739, a clinical-stage SCD inhibitor.

Administration of YTX-7739 to rats and cynomolgus monkeys for fifteen days caused a dose-dependent increase in YTX-7739 concentrations that were well-tolerated and associated with concentration-dependent reductions in the fatty acid desaturation index (FADI), the ratio of monounsaturated to saturated fatty acids. An approximate 50% maximal reduction in the carbon-16 desaturation index was observed in brain, with comparable responses in plasma, and skin. In rats, the plasma and skin FADI responses were mitigated by diet supplementation with SCD products. The brain, however, was more resistant to diet effects, as reductions in fatty acid desaturation persisted, consistent with local SCD inhibition and a more limited contribution of systemic fatty acids to brain lipids. Assessment of pharmacodynamic response onset and reversibility kinetics indicated that approximately seven days of dosing were required to achieve maximal responses, which persisted for at least two days after cessation of dosing. YTX-7739 thus achieved sufficient concentrations in brain to inhibit SCD and produce pharmacodynamic responses that were well-tolerated in rats and nonhuman primates. These results provide a framework for evaluating YTX-7739 pharmacology clinically as a disease-modifying therapy to treat synucleinopathies.

Title: The Effects of Vilazodone, YL-0919 and Vortioxetine in L-DOPA treated hemiparkinsonian rats

Authors: S. SMITH[1], ***K. ELDER**[1], M. COYLE[1], A. CENTNER[1], S. COHEN[1], N. LIPARI[1], A. CRUZ-HARRIS[2], C. SHERMAN[3], C. BISHOP[1];

Abstract: Parkinson's Disease (PD) is a debilitating, neurodegenerative disorder characterized by motor symptoms, including bradykinesia, tremor, stiffness, and postural instability, that result from significant nigrostriatal dopamine (DA) loss. The current gold standard treatment for PD involves replacement therapy via the DA precursor L-3,4-dihydroxyphenylalanine (L-DOPA); however, 90% of patients eventually experience choreic and dystonic side effects termed L-DOPA induced dyskinesia (LID). An experimentally supported driver of LID is neuroplasticity within the serotonin (5-HT) system leading to the unregulated release of L-DOPA-derived DA from 5-HT terminals into the motor circuits, including the striatum and substantia nigra. Previous work has implicated coincident 5-HT1A receptor agonism and 5-HT transporter (SERT) blockade as an effective therapeutic method for attenuating LID while maintaining L-DOPA efficacy. The present study examined 3 similar drugs, Vilazodone, YL-0919, and Vortioxetine, that act as 5-HT1A agonists and SERT blockers to test this approach. Adult female Sprague-Dawley rats received unilateral injection of 6-hydroxydopamine into the medial forebrain bundle -to lesion nigrostriatal DA neurons. Thereafter they received 2 weeks of daily L-DOPA treatment (6 mg/kg) until they developed stable abnormal involuntary movement (AIMs) akin to LID. Rats were also assessed for motor performance with the forepaw adjusting steps (FAS) test at baseline and on treatment. Results revealed that Vilazodone and Vortioxetine significantly reduced AIMs and maintained L-DOPA's beneficial prokinetic effects. In contrast, YL-0919 unexpectedly had no effect on LID but did not counteract L-DOPA efficacy. Overall, these findings support pharmacological targets within the 5-HT system that reduce LID. They also provide evidence for unique features of Vilazodone and Vortioxetine, both FDA-approved compounds, as potential adjunct therapeutics to optimize L-DOPA treatment for PD patients.

Title: Evodiamine Suppress Inflammatory Cascade and Potentiate Neuronal Survival in Parkinson's Disease allied Depressive-like Behavior: In-vitro and In-vivo Study

Authors: *M. KWATRA, V. NAIDU;
Pharmacol. and Toxicology, Natl. Inst. of Pharmaceut. Educ. and Res. (NIPER) Guwahati, Guwahati, India

Abstract: Preclinical and clinical data evidently suggested the devastating impact of stress on progressive and accelerating damaging effects on the nigrostriatal pathway in PD. However, the underpinning mechanism elaborating stress mediated-MPTP-induced redox dysregulation, SIRT1/AMPK, ASK1-related apoptosis signaling in cellular and mice models is not explained and validated to date. Moreover, we also studied the neuroprotective effect of EVD *in-vitro* and *in-vivo*. In first phase, we established and validated impact of prolonged restraint stress (168h; 7h/day, 1d-14d, 22d-28d; 3h/day, 15d-21d) on subacute MPTP doses (23.6 mg/kg, i.p. for 7 consecutive days, 15d-21d) injected in mice. We observed severe behavioral changes in the RS+MPTP group compared to RS and MPTP grouped mice for the enhanced reduction in brain vascularity, disrupted redox balance, highly activated apoptotic signaling in substantia nigra pars compacta (SNpc) region of mice brain. Secondly performed *in-vitro* studies for evaluating neuroprotective effects of EVD on LPS stimulated N9 microglial cells and MPP^+ induced neurotoxicity in N2a cells. Anti-inflammatory effect of EVD via repressing active NF-κB signaling while activating Nrf2 regulated Peroxiredoxin-5 (Prx-5) antioxidant axis in N9 cells. Moreover, EVD pretreatment suppresses inflammation and degenerated N2a cells by conditioned media of LPS stimulated N9 cells and further EVD caused inhibition of MPP^+ mediated neurotoxicity via its anti-apoptotic, antioxidant, and activation of neuronal survival (SIRT1/AMPK) mechanism in N2a cells. Lastly, we assessed the neuroprotective benefits of EVD (50 mg/kg and 100 mg/kg) against the RS+MPTP-induced neurobehavioral and neurochemical anomalies. Moreover, we also utilized 3H-1,2-Dithiole-3-thione (D3T); Nrf2 activator alone and in combination with EVD (100 mg/kg) to conclude its Nrf2 pathway activation. EVD, higher dose ameliorates blood flow to the brain on 28th day, increased the level of monoamines, lowered corticosterone level, mitigated the raised oxido-nitrosative stress, and restored the SOD, catalase, reduced NAD level in SNpc of mice. EVD potentially downregulated the NF-κB mediated inflammatory, apoptotic signaling mediators and activated SIRT1/AMPK/Nrf2 provoked anti-inflammatory signaling in SNpc of mice. Moreover, EVD also reversed the IBA-1, TH immunoreactivity, altered ultrastructural architectures to normal control in SNpc of mice. EVD with anti-inflammatory, anti-apoptotic, and neuroprotective properties may be used as adjunct therapy or nutraceuticals to clinically subside the motor and depressive-like behavior in Parkinson's disease.

Title: Investigating the anti-dyskinetic effects of co-administered serotonin- and glutamate-acting compounds, Vilazodone and Amantadine, in hemiparkinsonian rats

Authors: S. COHEN[1], M. TERRY[1], M. COYLE[1], A. CENTNER[1], J. GLINSKI[1], S. SMITH[1], E. WHEELIS[1], C. BUDROW[1], F. P. MANFREDSSON[2], C. BISHOP[1];
[1]Psychology, Binghamton Univ., Binghamton, NY; [2]Neurobio., Barrow Neurolog. Inst., Pheonix, AZ

Abstract: Parkinson's disease is a progressive, neurodegenerative movement disorder caused by loss of nigrostriatal dopamine (DA) neurons. DA replacement therapy using L-3,4-dihydroxyphenylalanine (L-DOPA) improves motor functioning but often results in L-DOPA-induced dyskinesia (LID) typified by abnormal involuntary movements (AIMs). In states of DA depletion, striatal serotonin (5-HT) hyperinnervation and glutamate overactivity are implicated in LID. To capitalize on these co-mechanisms for LID reduction, this study investigated the anti-dyskinetic effects of FDA-approved Vilazodone (VZD), a 5-HT transport blocker and partial 5-HT1A agonist, and Amantadine (AMAT), an NMDA glutamate antagonist, using 6-hydroxydopamine lesioned hemiparkinsonian Sprague-Dawley rats in a series of experiments. First, dose-response curves for each drug against L-DOPA-induced AIMs were determined to identify threshold effective doses. Next, a second cohort of rats was tested with those threshold doses of VZD (1, 2.5 mg/kg, s.c.) and/or AMAT (40 mg/kg, s.c.) to examine their combined acute effects on LID. In a third cohort, AMAT and/or VZD were given daily with L-DOPA during the 14 day priming period to see whether these compounds could prevent LID development. In a final cohort, VZD and/or AMAT were chronically administered in rats with established LID for 2 weeks to examine their interventional properties. For all experiments, AIMs monitored dyskinesia severity and forepaw adjusting steps (FAS) recorded L-DOPA efficacy maintenance. Results revealed a significant decrease in AIMs and maintained FAS with acute, prophylactic and chronic VZD+L-DOPA compared to L-DOPA alone. AMAT+L-DOPA did not exert any significant effects on AIMs or FAS, but the combined administration of VZD and AMAT demonstrated intermediate effects relative to each drug across experiments. These results suggest co-administration of VZD and AMAT with L-DOPA does not synergistically reduce LID in hemiparkinsonian rats. Rather, our results suggest that AMAT may counter the anti-dyskinetic efficacy of VZD when co-administered. Importantly, even very low doses of VZD reduce the development and expression of LID while maintaining L-DOPA efficacy supporting its potential re-purposing as an already FDA-approved drug.

Title: Usmarapride (SUVN-D4010): A 5-HT_4 receptor partial agonist alleviates haloperidol-induced Parkinson's disease associated cognitive dysfunction

Authors: V. GRANDHI, H. TALAKANTI, N. GANUGA, V. GOURA, J. TADIPARTI, R. MEDAPATI, R. ABRAHAM, S. GAGGINAPALLY, D. KANCHARLA, *P. JAYARAJAN, R.

Suven Life Sci. Ltd., Hyderabad, India

Abstract: Haloperidol is a classical antipsychotic drug known for its propensity to cause extrapyramidal symptoms and cognitive impairment, due to the blockade of striatal dopamine D_2 receptors. Drug-induced Parkinson's disease (PD) is indistinguishable from the pathological PD, as the symptoms are similar for both the conditions. PD patients experiences progressive cognitive decline over the years. Cognitive decline further deteriorates the health related quality of life (hQOL) in these patients. Although, rivastigmine is approved for PD related dementia by FDA, it has its own disadvantages, viz. dose limiting side effects, tremor at rest, and lack of efficacy over time etc. Hence, there is an unmet medical need to find effective yet, safe interventions. Usmarapride, a 5-HT_4 receptor partial agonist was evaluated for its potential to alleviate haloperidol-induced PD associated dementia. Haloperidol was supplemented in water feeder bottles at to induce PD associated dementia. Following one week of haloperidol supplementation, treatment with either usmarapride or rivastigmine was initiated. Rats were evaluated in the social recognition task (SRT). Familiarization and recognition trials were conducted with a trial delay of 30 min. Social investigation time spent by adult rat with either familiar or novel juvenile rat was assessed during recognition trial and compared among the juveniles. Discriminative index was calculated and compared among the groups. Chronic treatment with haloperidol produced PD dementia like state with social memory deficits in SRT task. However, preventive treatment with usmarapride alleviated haloperidol-induced PD dementia. Positive control, rivastigmine also significantly ameliorated PD related cognitive deficits. Significant increase in novel juvenile social investigation time or discriminative index was observed for the groups treated with usmarapride or rivastigmine, relative to familiar juvenile or vehicle control group, respectively. Usmarapride ameliorated PD related dementia in an animal model, thus it could be a future promising therapeutic strategy for PD associated dementia, thereby to improve the patients' hQOL.

Title: SB-0107, a Protein Kinase A II potentiator identified through machine learning, treats Parkinson's disease motor disability and levodopa-induced dyskinesia in rat and primate models

Authors: *A. BORDBAR[1], B. BLOEM[1], K. MERCHANT[2], D. M. WEINER[3], M. P. HILL[4], J. M. BROTCHIE[4], J. S. SCHNEIDER[4], T. H. JOHNSTON[4], I. FAMILI[1];
[1]Sinopia Biosci., San Diego, CA; [2]Transthera Consulting Co, Portland, OR; [3]Independent, San Diego, CA; [4]Atuka Inc., Toronto, ON, Canada

Abstract: Levodopa plus carbidopa (L/C) represents the most effective treatment for motor deficits of Parkinson's disease (PD). However, the efficacy of L/C diminishes with PD progression and L/C's chronic use often leads to the debilitating side effect termed levodopa-induced dyskinesia (LID). Thus, clinical management of PD requires a therapeutic regimen that can reduce motor symptoms without inducing dyskinesia. Using a machine learning approach trained on gene expression data from striatonigral neurons of 6-OHDA lesioned mice exposed to various levels of L-DOPA, we identified two genomic signatures associated with levodopa's motoric efficacy and dyskinesia liability. Computational analysis of *in vitro* transcriptomic profiling data of ~20,000 small molecules resulted in selection of SB-0107 as a candidate for follow-up as the compound induced a gene expression pattern similar to that associated with LC's motoric efficacy while reversing the pattern associated with LID. SB-0107 selectively potentiates protein kinase A II, a kinase downstream of dopamine receptors. Thus, we characterized SB-0107's effects in highly translatable rat and primate models of PD disability and LID. In 6-OHDA lesioned rats, the combination of SB-0107 and sub-therapeutic doses of L-DOPA resulted in anti-parkinsonian effects that are equivalent to or greater than high doses of L-DOPA alone, while not inducing LID-like behavior after repeated dosing. Further, SB-0107 significantly reduced expression of several genes associated with LID *in vivo*. In the MPTP-lesioned macaques, SB-0107 showed a dual benefit; it significantly enhanced L/C's effects on PD disability, while also significantly decreasing LID by ~50%. Additional studies with the chronic low dose MPTP macaque model of PD cognition indicated that SB-0107 significantly improved performance in cognitive tasks at certain doses. The unique mechanism of action and preclinical results warrant further development of SB-0107 for PD.

Abstract: *Abstract Body Max 2300 character*
Brain-penetrant structurally targeted allosteric regulators for glucocerebrosidase (GCase) show promising *in vivo* pharmacological activity in animal models of Parkinson's diseaseB. Guzman[1], N. Pérez[1], A. M. García-Collazo[1], E. Cubero[1], X. Barril[1], S. Morales[1], A. Ruano[1], A. Delgado[1], T. Rosa[1], M. Bellotto[1], R. Maj[1*1*] *Gain Therapeutics, Lugano (Switzerland) and Barcelona (Spain).*
ObjectiveDeficiency of glucocerebrosidase (GCase) activity due to mutations in the corresponding *GBA1* gene leads to toxic accumulation of sphingolipids and, in some cases, α-synuclein pathology. Due to the latter, GCase has recently attracted increasing attention given its potential role in Parkinson's disease (PD) pathophysiology: evidence shows that misfolding and loss of GCase activity causes pathologic accumulation of α-synuclein while GCase overexpression in brain reduces pathology and memory deficits in synucleinopathy mouse models. GCase activity is also diminished in cases of idiopathic PD without *GBA1* mutations and correlates with earlier disease onset and worse cognitive and non-motor symptoms. These findings suggest that decreased GCase activity may contribute to pathogenesis in many forms of PD and that enhancing the activity of both mutant and wild-type GCase may represent a potential therapeutic strategy.
MethodsGain Therapeutics has applied its innovative proprietary drug discovery platform, Site-directed Enzyme Enhancement Therapy (SEE-Tx™), to the development of small-molecule structurally targeted allosteric regulators (STAR[s]) that can stabilize misfolded GCase by binding to a site different from its active site, ultimately avoiding its degradation while facilitating its maturation and trafficking to the lysosomes.
ResultsOur orally bioavailable and brain penetrant lead STAR[s] have shown promising effects in different *in vitro* and *in vivo* models of PD. Here we report recent *in vivo* evidence of their beneficial effects towards rescuing GCase activity and protein levels in a dose-dependent manner as well as ameliorating α-syn pathology and behavioral phenotypes in rotenone and other pharmacologically induced animal models.
ConclusionAltogether, the allosteric regulators identified with the proprietary SEE-Tx™ drug discovery platform support the restoration of key biological activities found to be impaired in *GBA1*-related Parkinson's disease, thus warranting further development towards the clinic.

Title: Montelukast Therapy Improves Brain Function with Modulation of Neuroinflammation in a Model of Chronic Gulf War Illness

Authors: *S. ATTALURI, B. SHUAI, M. KODALI, L. MADHU, J. GONZALEZ, X. RAO, A. SHETTY;
Inst. For Regen Med. Texas A&M Univ. Coll Med., College Station, TX

Abstract: Gulf War Illness (GWI) is a multi-symptom illness afflicting ~30% of veterans who served in the first Gulf War. Epidemiological studies suggested that exposure to a combination of chemicals such as the nerve gas prophylactic drug, pyridostigmine bromide (PB), and pesticides during the war caused GWI. Indeed, concurrent exposure to low doses of chemicals used in the GW and mild stress for 28 days in rats leads to symptoms akin to those observed in veterans with GWI. GWI is associated with persistent cognitive and mood impairments, associated with chronic neuroinflammation, and decreased neurogenesis in the hippocampus. We investigated the efficacy of Montelukast (MLK), an FDA-approved drug for asthma with robust anti-inflammatory properties through the inhibition of cysteinyl leukotriene signaling, for improving brain function and modulating neuropathological changes in animals exposed to GWI-related chemicals and stress (GWI rats). We first exposed young rats to low doses of GWI-related chemicals such as the nerve gas prophylactic drug pyridostigmine bromide (PB), mosquito repellant DEET, insecticide permethrin (PM), and moderate stress for 28 days. Four months later, GWI rats received vehicle or MLK at 5, 10, 15, or 20 mg/kg (5 days/week) for eight weeks. A significant cognitive and mood dysfunction was observed in GWI rats receiving the vehicle when interrogated with behavioral tests such as the object-in-place test (OIPT), pattern separation test (PST), and the sucrose preference test (SPT). However, GWI rats receiving different doses of MLK exhibited improved cognitive and mood function, which was evident from their ability for spatial recognition memory in an OIPT, pattern separation in a PST, and no anhedonia in an SPT. Analysis of brain tissues revealed decreased neuroinflammation in GWI rats receiving MLK, evidenced by the reduced number of activated microglia. Additional biochemical studies assessing neuroinflammation and cysteinyl leukotriene signaling are currently in progress. The results suggest that MLK treatment has promise for improving brain function by modulating neuroinflammation.

Title: In vivo striatal activity during motor skill learning and spontaneous behaviour in Huntington's Disease mice

Authors: *E. T. KOCH[1], J. CHENG[1], M. D. SEPERS[3], L. A. RAYMOND[2];
[2]Dept Psychiatry and Ctr. for Brain Hlth., [1]Univ. of British Columbia, Vancouver, BC, Canada; [3]Dept. of Psychiatry, UBC, Vancouver, BC, Canada

Abstract: Huntington's disease (HD) is a neurodegenerative disorder characterized by motor, cognitive and psychiatric deficits. The dorsal striatum is the major site of neurodegeneration in HD, particularly the D2-expressing spiny projection neurons (D2-SPNs) early on, and the D1-expressing SPNs (D1-SPNs) late in the disease. Studies have shown aberrant cortico-striatal signalling in HD mice, including changes to the evoked and spontaneous activity of D1- and D2-SPNs, aberrant glutamatergic and dopaminergic signalling, and deficits in cortico-striatal plasticity. Although there has been extensive research on changes to cortico-striatal signalling *in vitro*, there has been relatively little research on how these changes correlate with behaviour *in vivo*. We combined the accelerating rotarod and open field tasks with calcium imaging using fiber photometry in the striatum of HD mouse models (YAC128 and Q175). This includes imaging of overall striatal activity with GCAMP7f, as well as population specific imaging of D1-SPNs and D2-SPNs simultaneously, using green and red calcium sensors (GCAMP and RCAMP). When imaging GCAMP7f expressed in all striatal neurons, we found that both WT and YAC128 HD mice showed increased striatal activity over baseline when they performed on the rotarod, and this activity reduced over days of training. In both genotypes, there was an inverse correlation between striatal GCAMP7f activity and latency to fall off the rotarod. In our 2-3 month age group, YAC128 mice showed no deficit in latency to fall from the rotarod, however, the correlation between striatal activity and behaviour on the rotarod and in the open field in these mice was significantly weaker. This indicates that striatal signalling is altered in YAC128 mice even at early stages before obvious behavioural deficits are present. We also have used the deep learning networks DeepLabCut and B-SOID to analyze behavioural patterns and kinematics, and correlated these behavioural measures with striatal calcium activity. We discovered changes to paw kinematics during rotarod in YAC128 mice, even in the 2-3 month age group when mice had no differences in latency to fall. This work begins to bridge the gap between our understanding of changes to signalling in the direct and indirect pathways determined from in vitro studies and the behavioural deficits observed in vivo.

Title: Corticostriatal changes associated with the human-specific FOXP2 variant dampen striatal degeneration in Huntington's disease zQ175 knock-in mice

Authors: A. E. MOLERO[1], ***Y. M. ALTUN**[1], G. S. DEVAKANMALAI[1], M. F. MEHLER[2];
[1]Neurol., Albert Einstein Col. of Med., Bronx, NY; [2]Dept Neurol, Neurosci, Psychiat, Albert Einstein Col. Med., Bronx, NY

Abstract: Cumulative investigations have identified a novel class of diverse hominid-specific genes and gene variants with key rostral lateralized neural developmental functions. Given their roles in enhancing neurogenesis, neural circuit formation and complexity, these genes not only optimize brain form and function, but may also differentially modify the progression of neurodegenerative disorders. Such is the case of a human-specific gene variant in the forkhead box P2 gene, h*FOXP2*, which induces a human-like enlargement of dendritic arbors of cell types that comprise cortico-striatal circuitry, one of the primary targets of Huntington's disease (HD). To examine the effects on HD-associated striatal degeneration and motor deficits of h*FOXP2*-dependent corticostriatal 'humanization', we launched an exploratory study in which we introduced h*FOXP2* in HD knock-in mice (the zQ175 model). Nissl-stained sections of 12-month old zQ175 specimens showed anticipated reductions in the number of striatal cells. By contrast, hFoxp2;zQ175 mice did not show significant striatal cell loss (80.3±21.4 vs 103.9±17.4, for hFoxp2;zQ175 and wild-type mice, respectively, Mann Whitney test exact $p = 0.2$). In line with histological preparations, electron microscopy studies revealed that the proportion of striatal cells with degenerative morphology was significantly reduced in hFoxp2;zQ175 compared to wild-type mice (19.3%, 95%CI = 16.4-22.6, vs 56.8, 95%CI = 51.1-62.3, Fisher's exact test $p < 0.0001$). Conversely, the introduction of the h*FOXP2* gene did not modify motor deficits in HD mice, as motor performance was comparable between 6- and 12-month old hFoxp2;zQ175 and zQ175 mice. These observations suggest that the human-specific *FOXP2* variant is a modifier of striatal degenerative changes but not of motor deficits in HD mice. Overall, these findings identify the *FOXP2* gene network as a target for therapeutic interventions aimed at remediating or even reversing neurodegeneration in HD.

Title: Chronic upregulation of endocannabinoid signalling in vivo with JZL184 normalizes impaired striatal synaptic plasticity and motor learning in YAC128 Huntington disease mice.

Authors: *M. D. SEPERS[1], C. WOODARD[1], M. N. HILL[2], L. RAYMOND[1];
[1]Univ. of British Columbia, Vancouver, BC, Canada; [2]Hotchkiss Brain Inst., Univ. of Calgary, Calgary, AB, Canada

Abstract: Huntington disease (HD) is a dominantly inherited neurodegenerative disorder characterized by extensive degeneration of the striatum, a key structure of the basal ganglia involved in motor function and reinforcement learning. Prior to the onset of neurodegeneration, studies in animal models of HD have found significant dysfunction at a synaptic and circuit level including alterations in the expression and signaling of the CB1 cannabinoid receptor, a key component of the endocannabinoid system. Recent work from our lab has suggested that endocannabinoid-mediated long-term depression (LTD) at cortico-striatal synapses is impaired in YAC128 HD mice. As plasticity at corticostriatal synapses is thought to be critical for motor learning, it's possible that disruption of this plasticity contributes to the early symptoms of HD. In *ex vivo* brain slices from YAC128 mice, we found that LTD induced by high-frequency stimulation (HFS) could be rescued by application of JZL184, a drug that blocks degradation of the endocannabinoid 2-arachidonyl glycerol (2-AG), thereby increasing the activation of cannabinoid receptors. To determine whether *in vivo* treatment with JZL184 was able to rescue impaired synaptic plasticity and reverse behavioural phenotypes, we treated 5-month-old YAC128 mice with JZL184 daily for several weeks and performed behavioural and electrophysiology experiments. Two weeks of JZL184 treatment was sufficient to normalize motor coordination deficits in YAC128 mice on the rotarod test but did not rescue 'depressive' behaviour on the forced swim test. Interestingly, in brain slices collected from both treated and untreated WT mice, striatal HFS resulted in long-term potentiation (LTP) rather than LTD. While no significant HFS-induced plasticity was observed in control YAC128 mice, treated YAC128 mice showed comparable LTP to WT animals, indicating that chronic JZL184 treatment was able to rescue impaired synaptic plasticity in these mice. These results provide evidence that targeting impairments in endocannabinoid signaling may be an effective strategy for recovering neuroplasticity and treating the early motor symptoms of HD.

Title: Pharmacologic inhibition of the classical complement pathway enhances neuronal function and HD R6/2 mouse survival

Authors: *A. TASSONI, V. MATHUR, J. VEREEN, E. CAHIR-MCFARLAND, S. SANKARANARAYANAN, T. YEDNOCK, Y. ANDREWS-ZWILLING;
Annexon Biosci., South San Francisco, CA

Abstract: BACKGROUND: Huntington's disease (HD) is an autosomal dominant neurodegenerative disorder caused by expansion of CAG repeats in the *Huntingtin (HTT)* gene. Increased expression of early classical complement components, including C1q, C4 and C3, have been observed in striatal tissue from HD patients, and C1q has been implicated in synapse elimination and neuronal damage in HD mouse models.**AIM**: To examine complement expression, neuronal damage and the potential therapeutic benefit of classical complement inhibition in an HD animal model. **METHODS**: We used the R6/2 transgenic

mouse model of HD expressing a ~ 120 CAG expansion, and measured classical complement components in the plasma and cerebral spinal fluid (CSF) of transgenic vs. wild type mice. We also measured the levels of Neurofilament Light Chain (NfL) as a biomarker of neuronal damage. To test the role of the classical complement pathway in neuronal damage, we pharmacologically blocked C1q activity with an inhibitory antibody (ANX-M1), administered via intraperitoneal injection, and assessed NfL, behavioral function and animal survival. **RESULTS**: We found increased plasma levels of C1q and multiple complement components. NfL was increased in both the plasma as well as the CSF of R6/2 mice and there was a significant positive correlation between CSF NfL levels and plasma C1q, suggesting a potential role of the classical complement cascade in neuronal damage. Treatment of animals with anti-C1q fully blocked C1q in the plasma and normalized levels of complement components. Consistent with a role for the classical cascade in neuronal damage, anti-C1q treatment significantly reduced CSF levels of NfL, improved motor behavior in the open field assay, and increased R6/2 mouse survival.CONCLUSIONS: The results of this study suggest that inhibiting C1q protects against neuronal damage in mice with expanded CAG repeats in the HTT gene and that C1q is a potential pharmacological target in HD. A Phase 2 study of ANX005 anti-C1q therapy in HD patients is ongoing (clinical trials.gov NCT04514367).

Title: Vitamin D3 attenuates oxidative stress and rescues motor dysfunction, neuromuscular impairment and spatial memory deficits observed in 3-nitropropionic acid induced mouse model of Huntington’s disease

Authors: *S. VENKATA MANJARI[1], P. KOMAL[2], S. MAITY[2], S. YU KU[3];
[2]Dept. of Biol. Sci., [1]Birla Inst. of Technol. and Sci. - Pilan, Hyderabad, Telangana, India; [3]The Hong Kong Polytechnic Univ., Kowloon, Hong Kong, Hong Kong

Abstract: Vitamin D3 attenuates oxidative stress and rescues motor dysfunction, neuromuscular impairment and spatial memory deficits observed in 3-nitropropionic acid induced mouse model of Huntington’s disease Manjari SKV[1], Shuvadeep Maity[1], Sonata Yu Ku[2] and Pragya Komal[1*2]Associate professor, The Hong Kong Polytechnic University, Hong Kong, kowloon Hong Kong [1]Department of Biological Sciences, Birla Institute of Technology and Sciences – Pilani, Hyderabad, Telangana, India – 500078; **** Corresponding author-pragya@hyderabad.bits-pilani.ac.in Background:*** Vitamin D3 is a neurosteroid known to have neuroprotective function across a range of mental disorders like Alzheimer’s

disease, Parkinson's disease, dementia and schizophrenia. However, limited evidence shows its beneficial effect in Huntington's disease (HD). In the present study, we aim to explore the neuroprotective effects of Vitamin D3 (VD) supplementation in 3-nitropropionic acid (3-NP) induced mouse model of HD. ***Methodology:*** For present study C57BL/6 male mice (3-4 months of age; n=8-15 animals per group) were divided into four different groups namely; **Group I**: Vehicle treated with sterile saline, **Group II**: animals were induced intraperitoneal (i.p) with 75mg/kg of 3-NP in three consecutive doses as described previously by Fernagut *et al*. **Group III**: animals injected i.p with only 500IU/kg of VD for 15 days and **Group IV**: 500IU/kg (12.5 μg/kg) of VD was given for 15 days through i.p to post 3-NP (75mg/kg) injected animals. Behavioral tests like locomotor activity, gait analysis, rotarod analysis, and morris water maze were carried out for a total period of 30 days. After 30 days, animals were decapitated and striatal tissues were isolated to check the mRNA expression of neurotrophins (nerve growth factor (NGF), brain derived neurotrophic factor (BDNF)) and antioxidative enzymes (superoxide dismutase (SOD), glutathione peroxidase (Gpx) and catalase (Cat)).***Results:*** Our behavior and mRNA results reflect that post VD treatment to 3-NP animals **(Group IV)** significantly rescued spatial memory deficits, locomotion dysfunction and neuromuscular coordination when compared with 3-NP induced HD mice **(Group II)**.***Conclusion:*** Overall, our current study infers that VD may rescue striatal neuron degeneration in HD and changes in the expression of antioxidative enzymes corroborate with the antioxidative property of VD.

Title: Toll-like receptor 4 is involved in the phenotypic manifestations observed on the R6/1 mouse model for Huntington´s disease.

Authors: *P. E. MARTÍNEZ-GOPAR[1,2], C. GONZALEZ-ESPINOSA[2], F. PEREZ-SEVERIANO[1]; [1]Neurofarmacología Mol. y Nanotecnología, Inst. Nacional de Neurología y Neurocirugía, Mexico, Mexico; [2]Farmacobiología, Ctr. de Investigaciones y Estudios Avanzados del IPN, México, Mexico

Abstract: Toll-like receptors (TLRs) are pattern recognition receptors that can respond to internal damage-associated molecular patterns (DAMPs). Activation of TLRs stimulates a complex signaling cascade and triggers inflammatory responses. Different TLRs are expressed in glial cells and neurons and its overactivation leads to the production of pro-inflammatory molecules, neuroinflammation, and neural tissue damage associated with many neurodegenerative diseases such as Huntington´s disease (HD). HD courses with loss of GABAergic neurons in basal ganglia, oxidative damage, and neuroinflammatory processes. Disruptions in the TLR-4 signaling pathway have been reported in both, immunological cells of HD patients and in mice models . The transgenic R6/1 mouse expresses the first exon of human mutant

Huntingtin (mHtt), which causes. R6/1 mice shows a motor deficit at 18 - 20 weeks of age. The objective of this work was to study the participation of TLR-4 in the phenotype expressed in the R6/1 mice. For this purpose, we crossed B6CBA-Tg(HDexon1)61Gpb/1J mice (R6/1) and B6.B10scN-TLR4lps-del mice (TLR4-deficient), and we evaluated motor coordination, weight loss, and expression of feet-clasping weekly from 15 to 25 weeks of age. The body weight of R6/1 mice with normal TLR4 levels (TLR4+/+) and heterozygous TLR4 (TLR4+/−) did not show any difference. However, a delay in motor coordination and a significant lower rank of feet clasping were observed in R6/1 mice heterozygous for TLR4. Previously we had observed that TLR-4-deficient mice showed less neurological and oxidative damage in the neurochemical model of HD, and in this work, we show evidence that indicates that TLR-4 receptor participates in phenotypic motor alterations in the R6/1 model of HD. Taking these results together, we suggest that TLR-4 receptor could be a therapeutic target for the treatment of some deleterious reactions observed in HD. Supported by Conacyt (Grant CF-2019-51488).

Title: Effects of environmental enrichment on modulation of behavioral and hippocampal neuroplasticity in the yac128 mouse model of huntington's disease

Authors: *E. PLÁCIDO[1], C. P. N. CASTRO[1], P. G. WELTER[1], M. FARINA[1], J. GIL-MOHAPEL[2], A. L. S. RODRIGUES[1], A. F. DE BEM[1], P. S. BROCARDO[1];
[1]Federal Univ. of Santa Catarina, Florianópolis, Brazil; [2]Univ. of Victoria, Victoria, BC, Canada

Abstract: Huntington's disease (HD) is a genetic neurodegenerative disease characterized by motor, psychiatric, and cognitive deficits. Emerging evidence has suggested that some of the emotional and cognitive deficits associated with this disease may be related to hippocampal dysfunction. To investigate this hypothesis we used the YAC128 mouse model of HD. We performed a temporal characterization of behavioral dysfunction in early and late symptomatic animals. Moreover, we investigate the effects on behavioral and neuroplasticity of environmental enrichment (EE) exposure in early symptomatic animals. The aim of this study was to perform a temporal characterization of behavioral alterations and determine if EE exposure for 60 days in early symptomatic animals has positive effects on HD symptoms and hippocampal neuroplasticity in YAC128 mice.
Wild-type (WT) and YAC128 mice (n=8-14) were behaviorally evaluated at early (3-4 months) and late (11-13 months) symptomatic stages of disease progression. The animals underwent to Open Field Test, Tail Suspension Test (TST), and T-maze Swimming Test (TMST). To analyze the effects of EE exposure on behavioral modulation and hippocampal neuroplasticity, a cohort of early symptomatic animals was

exposed to EE (2-4 months). After behavioral testing, brain sections were used to immunohistochemistry for cell proliferation (Ki-67 and PCNA) and neuron differentiation (DCX) in the hippocampus (HC). The total number of immunoreactive cells was counted. The tests were analyzed using a two-way analysis of variance and chi-square test. CEUA approved this project under n. 4502210318.
Early (3-4 months) and late (11-13 months) symptomatic YAC128 mice exhibited depressive-like behavior as demonstrated by increased immobility time in the TST. In addition, YAC128 mice presented cognitive deficits in the TMST during the late symptomatic stage. Exposure to EE in the early symptomatic animals reverted the depressive-like behavior in the YAC128 mice and improved their performance on the TMST. Moreover, EE increased HC-Ki-67 positive cells ($p < 0.05$) in the WT mice and decreased ($p < 0.05$) in the YAC128 mice. There were no differences in the number of HC-PCNA positive cells among groups. Also, EE increased HC-DCX positive cells) in WT and YAC128 mice ($p < 0.01$).
Our results show a temporal characterization of behavioral deficits and hippocampal neuroplasticity alterations in the YAC128 transgenic mice. In particular, the present study has further characterized the positive effects of EE on HD symptoms and modulating hippocampal neurogenesis in WT mice and YAC128 mice. EE may play a potential therapeutic role in the treatment of HD symptoms.

Title: Post-acute SARS-CoV-2 infection in non-human primate olfactory system and pyriformcortex/amygdala

Authors: *R. BOOZE[1], H. LI[1], C. MACTUTUS[1], K. MCLAURIN[1], P. DATTA[2], J. RAPPAPORT[2]; [1]Univ. South Carolina, Columbia, SC; [2]tulane national primate research center, Covington, LA

Abstract: Adverse neurological and psychiatric outcomes (i.e., post-acute sequelae of SARS-CoV-2 infection (PASC)) persist in adults clinically recovered from SARS-CoV-2. However, viral invasion and persistence in the brain following full clinical recovery has not been elucidated. We examined the distribution of SARS-CoV-2, angiotensin-converting enzyme 2 (ACE2), and transmembrane serine protease 2 (TMPRSS2) in clinically recovered SARS-CoV-2 infected (2019-nCoV/USA-WA1/2020) primates (8) and controls (4) using RNAscope technology. The olfactory epithelium and pyriform cortex/amygdala exhibited abundant SARS-CoV-2, ACE2, and TMPRSS2 mRNA. SARS-CoV-2

expression in the olfactory epithelium was limited to non-neuronal cells, including sustentacular cells, basal stem cells, and Bowman's gland cells. Strong co-localization between platelet-derived growth factor receptor β and SARS-CoV-2 mRNA supports pericytes as the predominant cell type to harbor the virus in the pyriform cortex/amygdala. Persistence of SARS-CoV-2 mRNA in the pyriform cortex/amygdala was independent of acute clinical symptoms, and included detection of anti-sense (minus) strand in addition to sense strand mRNA. Results support a potential mechanism underlying PASC including long-term neurovascular disruption in specific brain regions.

Title: Neurological Manifestations and Covid-19

Authors: *A. THAPLIYAL[1], **A. SRIRANJANI**[1,2], K. PANT[1], M. THAPLIYAL[2];
[1]Graphic Era Univ., Dehradun, India; [2]Zoology, Government PG Col. Maldevta, Raipur, Dehradun, Dehradun, India

Abstract: As the serious intense respiratory condition Covid 2 (SARS-CoV-2) pestilence spreads, it is turning out to be progressively clear that Covid infection 2019 (COVID-19) isn't restricted to the respiratory framework, and that different organs can be influenced. Specifically, infection related neurological manifestations are being accounted for increasingly more often in the literature. We focused our study on the relationship between COVID-19 and neurological disorders. Our analysis suggests that in terms of per-clinical examination, SARS-CoV-2 could be responsible for a large number of neurological manifestations, and sum up the biochemical pathways that could underlie each neurological manifestation. However, the COVID-19 pandemic fundamentally influences pneumonia and cardior-renal functions, numerous medical practitioners and healthcare professionals noted the detailed neurological inclusion of SARS-CoV-2 in combination with either with either per-existing metabolic abnormalities, medical conditions, infections or even chronic to acute inflammatory episodes of the nervous system. Understanding the systems that lead to neurological manifestations in patients with COVID-19 and how these manifestations correlate with clinical results will be instrumental in directing the ideal utilization of targeted therapeutic techniques Normal 0 false false false EN-IN X-NONE HI /* Style Definitions */ table.MsoNormalTable {mso-style-name:"Table Normal"; mso-tstyle-rowband-size:0; mso-tstyle-colband-size:0; mso-style-noshow:yes; mso-style-priority:99; mso-style-parent:""; mso-padding-alt:0in 5.4pt 0in 5.4pt; mso-para-margin-top:0in; mso-para-margin-right:0in; mso-para-margin-bottom:8.0pt; mso-para-margin-left:0in; line-height:107%; mso-pagination:widow-orphan; font-size:11.0pt; font-family:"Calibri",sans-serif; mso-ascii-font-family:Calibri; mso-ascii-theme-font:minor-latin; mso-hansi-font-family:Calibri; mso-hansi-theme-font:minor-latin; mso-ansi-language:EN-IN; mso-bidi-language:AR-SA;} <![endif]-->

Title: Imaging before and after COVID-19: increased brain temperature and spectroscopic markers of brain injury in regions neighboring the olfactory neural-mucosa interface.

Authors: *A. SHARMA[1], J. P. SZAFLARSKI[2];
[1]Dept. of Neurol., [2]Departments of Neurol. and Neurobio., Univ. of Alabama at Birmingham, Birmingham, AL

Abstract: BACKGROUND. Fatigue, depression, and other post-COVID-19 (C19) symptoms of "brain fog" disproportionately impact patients who had mild infection. These symptoms may stem from neuroinflammation that outlasts active C19 infection. Most neuroimaging studies to date have investigated neurological manifestations in patients with severe C19 manifestations and in post-mortem brains. Prior work has also centered on analyzing structural brain scans, though tools such as volumetric magnetic resonance spectroscopic imaging and thermometry (MRSI-t) may offer a more comprehensive view. This study combined pre- and post-C19 MRSI-t data from the same participants to map virus-induced changes in brain temperature and metabolite markers of CNS injury. **METHODS**. Participants (N=3; 24 to 26 years old) with history of mild C19 and self-reported "brain fog" were scanned at three times each at 3T: two times before infection (t_1/t_2 12 weeks apart) and at 12 weeks post-C19 (t_3). The Metabolite Imaging and Data Analysis System software package was used for spatial reconstruction and spectral processing of MRSI-t data. This included frequency alignment, B_0 inhomogeneity correction, lipid suppression, lipid suppression, spectral fitting, normalization, and integration with water reference data. Voxelwise brain temperature was calculated using the following equation: $T_{CRE} = -102.61(\Delta_{H20\text{-}CRE}) + 206.1°C$. Regions with high gliosis and/or white matter injury were localized by deriving the myo-inositol/creatine (mI/CRE) and choline/CRE (CHO/CRE) ratios, respectively. **RESULTS**. All 3 participants demonstrated post-C19 T_{CRE} increases (p=0.0001), with regional variations in magnitude (p<0.0001). Mean global T_{CRE}=37.49°C at t_1, 37.48°C at t_2, and 37.69°C at t_3. Significant post-C19 increases in mI/CRE were found in the cerebellum and left (L) hippocampus. T_{CRE} and mI/CRE were both increased post-C19 in the L postcentral gyrus. Significant post-C19 T_{CRE} increases were found in the R hippocampus, fusiform, and putamen. Despite small variations in voxelwise T_{CRE}, T_{CRE} was uniformly higher in the orbitofrontal, temporal, and entorhinal cortices. **CONCLUSIONS**. Elevated T_{CRE} and mI/CRE levels were localized to regions neighboring or connected to the olfactory mucosa. This is consistent with current hypotheses regarding viral entry and progression of neuroinflammation. The incorporation of more multimodal imaging data to existing datasets would be valuable, especially for delineating microstructural changes that underlie increased T_{CRE} and mI/CRE in these regions.

Educ. and Res., Chandigarh, India

Abstract: Introduction: COVID-19 has prominent neurological manifestations including psychiatric symptoms, indicating significant synaptic pathology. Surprisingly, existing evidence suggests negligible expression of the key SARS-CoV-2 host cell entry receptor—ACE2 in human brain, which complicates understanding of the etiomechanism of the psychiatric neuropathology in COVID-19. Along with ACE2, the cellular expressions of host proteases such as TMPRSS2 and furin, which cleave the viral spike protein are considered essential for SARS-CoV-2 infection. Recent studies suggested that an alternative host cell entry receptor, NRP1, can mediate entry of furin cleaved SARS-CoV-2 spike proteins into the host cells. However, the role of NRP1 and furin in mediating SARS-CoV-2 entry in human brain cells has been least explored and remains a lacuna in the literature. **Methods:** We performed an *in silico* analysis of the transcriptomic and proteomic expressions of SARS-CoV-2 host cell entry receptors and associated tissue proteases in human brain tissue using publicly available databases. **Results:** ACE2 and TMPRSS2 were found undetectable in both transcriptomic and proteomic analyses, whereas NRP1 and furin were found detectable with low regional specificity across the human brain. Significant protein expressions of NRP1 and furin were detectable in neuronal cell, neuropil, and glial cells of the brain tissue. NRP1 showed significantly higher expression in hippocampal formation. **Conclusion:** Based on the expression analysis, SARS-CoV-2 entry in human brain cells is likely to be mediated through NRP1 and furin. The significant expression in neuronal cells, and a higher expression in hippocampal formation, suggests NRP1 may have a role in the etiomechanism of synaptic pathologies and psychiatric manifestations in COVID-19. Further studies are warranted to validate our findings.

Abstract: SARS-CoV-2 coronavirus disease 2019 (COVID-19) impacts many biological systems, including the brain. Individuals report symptoms of fatigue, brain fog, sensory and cognitive deficits, and psychiatric complaints, which can linger for months post- infection. The potential neural effects of COVID-19 led to the April 2020 creation of NEUROCOVID-19, investigating chronic brain effects associated with COVID-19. NEUROCOVID-19 comprises a comprehensive evaluation including multiparametric MRI, EEG, sensory and cognitive tests, and neuropsychiatric assessments of individuals with different clinical courses of the disease. Here we report preliminary EEG results from individuals who tested positive for COVID-19 (COV+) and self-isolated at home, and controls who self-isolated with flu-like symptoms but tested negative for COVID-19 (COV-). Resting-state EEG (rsEEG) was collected at an initial visit (~118 days post infection) from 41 COV+ participants (mean age: 41, range: 1 -61, 41% female), and 14 COV- participants (mean age: 42.7, range: 26-70; 57% female); to date, 24 COV+ participants and 11 COV- have returned for a second assessment 3-months later. EEG data were collected during five minutes with eyes closed and eyes open using a portable EEG headband (Muse, InteraXon) containing two frontal (F) and two temporoparietal (TP) channels. After artifact rejection and removal of eye blinks, data were divided into 2 second epochs and average spectral power was extracted in the delta (2-4Hz), theta (4-7Hz), alpha (7-14Hz), and beta (14-30Hz) bands. Left and right F and TP electrodes were averaged, and group differences were examined in linear-mixed-effects models for each condition and visit, controlling for age and sex. At initial visit, spectral power was lower overall during eyes closed for COV+ vs COV- at TP channels ($p = 0.04$), with reliable differences in the theta ($p=0.02$) and alpha ($p=0.04$) bands, and a trend in delta ($p=0.06$); COV+ also showed reduced theta at F channels ($p=0.03$). During eyes open, COV+ showed reduced beta power in TP channels ($p=0.04$) and a trend for alpha ($p=0.06$); as well as reduced alpha ($p=0.05$) and theta ($p=0.01$) power, and a trend for delta ($p=0.08$) in F channels. No reliable group differences were observed at the 3-month follow up in the current sample, although follow-up assessments are ongoing so we have reduced power at this point in time. Our results show COVID-19 can have a protracted impact on brain function, over at least 4 months, with some potential resolution over 7 months. Future work will examine within-subjects analyses and relationships between EEG and sensory, cognitive, neuropsychiatric, MRI, and self-report symptom measures.

Title: Sensory and autonomic ganglia of the peripheral nervous system are permissive to infection with SARS-CoV-2 and may provide an avenue of neural invasion in K18-hACE2 mice

Authors: *J. D. JOYCE[1], G. A. MOORE[3], E. HENRY[1], A. S. BERTKE[2];
[1]Translational Biology, Medicine, and Hlth., [2]Virginia Tech., Blacksburg, VA; [3]Biomed. and Vet. Sci., Virginia Maryland Col. of Vet. Med., Blacksburg, VA

Abstract: Symptoms of nervous system involvement are increasingly associated with infection with SARS-CoV-2, the causative agent of pandemic COVID-19. These symptoms span both the central nervous system (dizziness, headache, impaired consciousness) and the peripheral nervous system (impaired taste/smell/vision, neuralgia, paresthesia). Recent studies have focused on central nervous system invasion via neuronal transport through the olfactory bulb or hematogenous entry through infection of endothelial or epithelial cells in the blood-brain or blood-cerebrospinal fluid barriers, respectively, with subsequent spillover into the parenchyma. To date, the potential for infection of and invasion through the peripheral nervous system has yet to be investigated. We intranasally infected transgenic mice (K18-hACE2 mice) expressing angiotensin-converting enzyme 2 (ACE2) which is used by the virus for cellular binding and entry, and their wild-type counterparts with SARS-CoV-2 isolate USA-WA1/2020 and monitored them for six days post infection. Peripheral nervous system sensory ganglia (dorsal root ganglia, trigeminal ganglia) and autonomic ganglia (superior cervical ganglia) along with individual brain regions (olfactory bulb, cortex, hippocampus, brainstem, cerebellum), whole brain hemispheres, and spinal cord samples were collected three- and six-days post infection to assess for neural invasion. Viral RNA was detected via RT-qPCR, viral antigen via immunofluorescence, and infectious virus via plaque assay. We detected viral genome and viral antigen in the sensory (trigeminal and dorsal root) and autonomic (superior cervical) ganglia of K18-hACE2 mice and their wild-type counterparts. These results show that sensory and autonomic ganglia of the peripheral nervous system are permissive to invasion via SARS-CoV-2. Additionally, we also report the spatiotemporal replication dynamics of the virus, using genome copy number and infectious virus titer, within specific brain regions in K18-hACE2 mice, which has yet to date been assessed. Taken together, our data indicate that sensory and autonomic ganglia of the peripheral nervous system are permissive to infection with SARS-CoV-2, and suggest that they may provide alternative routes of central nervous system invasion, which may contribute to nervous system associated sequelae.

Title: Sars-cov-2 induces formation of tunneling nanotubes to facilitate dissemination of viruses and viral factors.

Authors: *D. AJASIN[1], E. EUGENIN[2];
[1]Neuroscience, Cell Biol. and Anat., Univ. Of Texas Med. Br. (UTMB)., Galveston, TX; [2]Neuroscience, Cell Biol. and Anat., Univ. Of Texas Med. Br. (UTMB), Galveston, TX

Abstract: SARS-CoV-2 induces formation of tunneling nanotubes to facilitate dissemination of viruses and viral factors.
David Ajasin[1] and Eliseo Eugenin[1].[1]University of Texas Medical Branch (UTMB), Department of Neuroscience, Cell Biology and Anatomy, University of Texas Medical Branch, Galveston, TX, USA.
The emergence of SARS-CoV-2 and the resulting COVID-19 disease has significantly impeded human activities worldwide. While recent development of efficacious vaccines and vaccination has reduced the spread and severity of the disease, the mechanism of viral spread within cells is just being examined. Here, we show new data that indicates SARS-CoV-2 and its protein can spread to other cells *via* cell to cell-mediated mechanism after initial receptor-mediated viral entry. We observed that viral components, and maybe the virus, can be transmitted through tunneling nanotubes (TNT), thereby avoiding extracellular immune factors such as neutralizing antibodies and other extracellular immune components. TNT is a long cytoplasmatic bridge that accomplishes long-range directed communication between cells. The proposed function for TNT is a cell-to-cell transfer of large cellular structures. TNT may serve as an additional way for Coronaviruses to spread infection between connected human microglia/macrophages, in addition to the classical receptor-mediated extracellular infection route. In agreement with this, we detected that SARS-CoV-2 spreads at a significantly higher rate when compared to HIV and other human Coronaviruses.
We hypothesize that Coronaviruses, including SARS-CoV-2 and 229E, use TNTs as a mechanism for spreading to accelerate lung and CNS disease. Thus, further investigation is necessary to identify the specific mechanism by which SARS-CoV-2 and other coronaviruses induce the formation of TNTs and utilize these processes. Also, identifying the mechanism of TNT induction can aid in the design of new therapies to reduce the viral spread of SARS-CoV-2 and other new Coronaviruses that might emerge in the future. Our study will examine the cellular, molecular and viral factors and mechanisms that induce the formation of TNTs and the mechanisms of virus trafficking across TNT. Title: Meta-analysis of the mechanisms underlying alcohol elevation of amyloid precursor protein expression upon SARS-CoV-2 infection

Authors: S. ALABED[1,2], W. HUANG[1,2], H. ZHOU[2], R. CAMACHO[2], S. ALI[1], *S. CHANG[1,2];

Abstract: Meta-analysis of the mechanisms underlying alcohol elevation of amyloid precursor protein expression upon SARS-CoV-2 infectionSedra Alabed*, Wenfei Huang*, Heping Zhou, Ryan Camacho, Syed Ali and Sulie L. Chang
SARS-CoV-2 infection is responsible for COVID-19 in over 120 million people. Alcohol consumption has significantly increased during COVID-19 pandemic. Despite the sparse drinking records of COVID-19 patients, our in-silico network meta-analysis studies found that that IL-1β, IL-6, JUN, NR3C1 (GR), TNF, IFNG, STAT, NFKB, HIF1A. PPARG and PPARG-RXT may play an important role in mediating alcohol augmentation of SARS-CoV-2-induced systemic inflammation and COVID-19 pathologies. Neuroinflammation signaling pathway may be involved in alcohol modulation of amyloid precursor protein (APP) production, and that TNF, IFNG, STAT1, IL-1β, IL6, and STAT3 may act as upstream regulators to increase APP production during developed COVID-19 via. With these premises, we hypothesized that exposure to ethanol (EtOH) enhances buildup of APP expression induced by SARS-CoV-2 infection. Meta-analysis using QIAGEN IPA was conducted. Applying both IPA networking and Molecule Activation Predictor (MAP) tools on each of the 11 common inflammatory mediators between alcohol and COVID-19, we found that IL-1β, IL-6, JUN, NR3C1 (GR), TNF and IFNG would activate, PPARG and PPARG-RXT would inhibit, while STAT, NFKB and HIF1A would have no effect on APP expression. However, the overall effects of concurrent activation of these 11 genes would result in strong activation of APP expression holistically. IPA Core Analysis of these 11 genes revealed a series of canonical pathways, of which the Neuroinflammation signaling and IL-10 signaling pathways were among the top 5. Subsequently, we used the MAP tool to simulate increased ethanol exposure on expression of the 11 genes, which jointly led to further activation of APP expression. By showing EtOH augmentation on APP expression upon SARS-CoV-2 infection, our studies call attention on long-term complications of alcohol and COVID-19 on Alzheimer disease and other possible neurodegenerative complications (*equal contribution).

Title: A Novel Human ACE2 BAC Transgenic Mouse Model Reveals Multiple Neuropathogenic Routes of SARS-COV-2 to Inflict Neurological and Neurocognitive Sequelae

Authors: K. KEYS, *H. ZHANG, X. TIAN, H. LI, A. YUROCHECKO, X. LU;
Louisiana State Univ. Hlth., Shreveport, LA

Abstract: Given the increasing global-spread of SARS-CoV-2, many questions remain regarding the clinical outcomes of COVID-19, including the possibility of the development of neurological disorders. Evidence of the severity and persistence of neurologic manifestations of SARS-CoV-2 infection have been recognized and is increasing. Virus infection has been speculated as the trigger of neurodegenerative diseases such as Parkinson's disease. In order to provide causal evidence and to study neurological and neurocognitive sequelae from SARS-CoV-2 infection and COVID-19 in vivo, we developed a humanized transgenic mouse model with full-length human ACE2 regulatory regions. We determined the transgene copy number and confirmed human ACE2 mRNA expression in the cortex, striatum, midbrain, cerebellum, and olfactory bulb, lung, spleen, intestine, heart, and muscle. A recombinant pseudotyped vesicular stomatitis virus (rVSV) containing rSARS-CoV-2 Spike protein with GFP or mCherry was propagated in the Vero cell line to trace the neuronal entry routes. To reveal the possible routes of SARS-CoV-2 Infection to impact CNS, we performed intranasal inoculation or intravenous systemic administration of the pseudotyped virus in the transgenic mice. We observed fluorescence protein expression in multiple organs, including CNS. Our results suggest that SARS-CoV-2 may impact CNS through direct ross the blood-brain barrier, hijacking monocytes, or invoking cytokines to elicit persistent neuroinflammation. We describe for the first time the presence along axons of viral particles, suggesting axonal transport to distant brain regions is a valid propagation strategy. The constant presence of the virus in the neurons and axons and the concomitant inflammation are destined to cause long-term or chronic sequelae related to the development or aggravation of chronic neurological diseases. Thus, our study established a small animal model with full-length human ACE2 regulatory regions that faithfully recapitulated structure, tissue distribution, and gene regulation of human ACE2 that is more valuable than most of the existent non-full-length human ACE2 mouse models for studying pathogenesis, clinical complications, and developing countermeasures for SARS-CoV-2 infection. Exploiting knowledge on the routes of SARS-CoV-2 to inflict neurological and neurocognitive sequelae will enhance our ability to address the long-term clinical neurologic outcome of viral infection, as it will shed light on underlying mechanisms of neuropathogenesis and uncover potential druggable molecular virus-host interfaces.

Title: Sars-cov-2 spike protein alters firing activity of medial prefrontal cortex pyramidal neurons in a concentration-dependent manner

Authors: *S. L. CASSODAY[1], L. CHEN[2], V. NGUYEN[4], A. DONNER[4], M. G. DEMARCO[4], L. AL-HARTHI[3], X.-T. HU[2];
[1]Rush Univ. Grad. Col., Chicago, IL; [2]Microbial Pathogens and Immunity, [3]Dept. Immunology/Microbiology, Rush Univ. Med. Ctr., Chicago, IL; [4]Rush Univ., Chicago, IL

Abstract: The Coronavirus disease 2019 (COVID-19) global pandemic caused by infection of the severe acute respiratory disease coronavirus 2 (SARS-CoV-2) not only results in respiratory complications, but also commonly induces long-lasting neurological and neuropsychiatric deficits, including but not limited to headache, ageusia/anosmia, seizure and delirium. Many of these neurological/neuropsychiatric manifestations can be related or attributed to hyperexcitability and neurotoxicity in key brain regions that regulate neurocognition, such as the prefrontal cortex (PFC; and others that are anatomically and functionally connected to PFC). However, the direct impact of SARS-CoV-2 on functional activity of living neurons in such key brain regions is unknown; and has not been studied. Moreover, the COVID-19 pandemic has also impacted the US urban arears where the HIV-Associated Neurocognitive Disorders (HAND, a.k.a. neuroHIV) and Substance Use Disorders (SUD) are prominent. Abnormal neuronal hyperexcitability in the PFC, which is associated with neurotoxicity and cognitive dysfunction, also occur in people living with HIV/AIDS (PLWH), especially those diagnosed with HAND, and SUD (including cocaine use disorders, CUD); both cause neurotoxicity in the PFC. But it is unknown whether, how, and to what extent SARS-CoV-2 worsens neuroHIV or SUD-induced neuronal dysfunction and ultimately the brain dysfunction, and vice versa, in the synergistic epidemic (syndemic) of COVID-19, neuroAIDS and CUD. Such knowledge gap prohibits us to advance our understanding for the impact of COVID-19 on neuroAIDS and CUD, and to define the mechanism underlying long-tern neurocognitive consequences in the syndemic of COVID-19/HAND/CUD. To fill this gap, we assessed the effects of SARS-CoV-2 Spike protein (S1 and S2; 5nM, 10nM, and 20nM in bath) on pyramidal neurons in rat brain slices containing the medial PFC (mPFC) using patch-clamping. Responses of mPFC pyramidal neurons to S1/S2 were

evaluated. We found that S1 initially facilitated firing of mPFC neurons at lower concentration (5nM) but suppressed it at higher levels (10-20nM; n=4-5/ea). Combined S1/S2 also caused a similar inhibition of firing. Larger sample size is needed to confirm these findings. Next, we will determine how and to what extent SARS-CoV-2 exacerbate mPFC neuronal dysfunction in the context of neuroHIV and/or CUD (modeled by cocaine self-administration) using HIV-1 transgenic (Tg) vs. non-Tg rats. Together, our novel findings suggest that SARS-CoV-2 induces abnormal hyperexcitability in mPFC pyramidal neurons, which may contribute to the neurocognitive deficits in COVID-19 patients.

Title: Mild carotid stenosis creates gradual,progressive,lifelong brain and eye damage:An experimental laboratory rat model

Authors: *A. S. SOLOMON[1], A. TZAMERET[1], Y. PIONTKEWITZ[2], A. NITZAN[1], N. RUDOLER[1], M. BRUZEL[1], S. PRI-CHEN[1];
[1]The Goldschleger Eye Res. Inst., [2]Straus Imaging Ctr., Tel Aviv Univ., Tel Hashomer, Israel

Abstract: <META NAME="author" CONTENT="אריה">**Abstract**
Purpose:In humans, carotid stenosis of 70% and above might be the cause of clinical symptoms such as transient ischemic attack and stroke. No clinical or animal studies have evaluated mild carotid stenosis ,and few examined unilateral occlusion Asymptomatic Carotid Stenosis. **Methods :** Here,Westar rats underwent bilateral or unilateral carotid occlusion of 28%-45%.Long term effects were evaluated 9-11 months later. We conducted cognitive evaluation using spatial learning in a water maze and exploration behavior in an open field.Morphology of the brain was examined by MRI using diffusion -tensor imaging (DTI) and immunohistochemistry staining of vthe brain and eyes,**Results**: Cognitive deficit was found in spatial memory and explorartion behavior in both occluded groups,brain and eyes histology presented severe damagein the bilateral group,compared to the unilateral one.DTI revealed an increase in mean diffisivity(MD) in the ventral thalamus,and decrease in fractional anisotropy in optic nerve and optic tract in bilateral occluded rats.Unilateral occluded rats showed only an increase in MD in the ventral pons.In those areas,a significant change in astrocytes , microglia,and number of apoptotic ,cells were found.**Conclusion:** We found that mild carotid stenosis, bilateral and even in unilatera locclusion,creates behavioral abnormalities presented by brain and eye histopathology. The results support our hypothesis that gradual formation of mild carotid stenosis along the life course leads to progressive damage that may create different degenerative diseases at a later age.

Title: Confined plasma leak from capillary by laser irradiation in mouse brain

Authors: *H. KUBOTERA[1], O. KUTOMI[2], S. TAKEDA[2], H. IKESHIMA-KATAOKA[1], T. INOUE[1]; [1]Waseda Univ., Tokyo, Japan; [2]Yamanashi Univ., Yamanashi, Japan

Abstract: In the central nervous system, molecular transport to the brain parenchyma is restricted by blood-brain barrier (BBB). The integrity of BBB is supported by endothelial cells, pericytes and astrocytes. Under physiological conditions, endothelial cells play a key role as a physical barrier of BBB by tight junction through expressing specific proteins, and their expression is regulated by pericytes and astrocytes. However, whether alternative physical barriers exist in the case of endothelial disruption under pathological conditions is not known. In this study, we observed very restricted leakage of blood plasma in mouse brain *in vivo*, after laser irradiation by imaging with Evans Blue or FITC-conjugated dextran (4 kDa) as plasma tracers. It was not coagulant, as fluorescence of Alexa 488-conjugated fibrinogen was undetectable in the extravascular plasma leakage. To investigate cellular mechanisms which prevented the extravascular plasma from diffusion, endothelial cells, pericytes and astrocytes were labeled with tomato lectin, NeuroTrace 500/525 and Sulforhodamine 101 (SR101), respectively. Transgenic mouse line expressing EGFP under the control of Iba1 promotor was used to examine the involvement of microglia. Endothelial cells, microglia or pericytes did not appear to serve as physical constraints to have leakage confined. However, astrocytic endfeet circumscribed the leakage in some cases, which was observed by an electron microscopy. These results suggest that astrocytic end-feet may serve as a physical barrier to restrict the diffusion of extravascular plasma into cerebral parenchyma, where endothelial barricade are disturbed. This would be a kind of fail-safe system of BBB in pathological conditions such as stroke.

Abstract: Cerebral small vessel disease (CSVD) is the second most common cause of stroke and a major contributor to dementia. CSVD manifests in a variety of pathological mechanisms including cerebral microbleeds, intracerebral hemorrhages (ICH), lacunar infarcts, white matter hyperintensities (WMH) and enlarged perivascular spaces. Chronic hypertensive models have been found to reproduce most key features of the disease. Nevertheless, no animal models have been identified to reflect all different aspects of the human disease. Here, we describe a novel model for CSVD using salt-sensitive 'Sabra' hypertension-prone rats (SBH/y), which display chronic hypertension and enhanced peripheral oxidative stress. SBH/y rats were either administered deoxycorticosteroid acetate (DOCA) (referred to as SBH/y-DOCA rats) or sham operated and provided with 1% NaCl in drinking water. Rats underwent neurological assessment and behavioral testing, followed by *ex-vivo* MRI, biochemical and histological analyses. SBH/y-DOCA rats show neurological decline and cognitive impairment, and present multiple cerebrovascular pathologies associated with CSVD such as ICH, lacunes, enlarged perivascular spaces, blood vessel stenosis, BBB permeability and inflammation. Remarkably, SBH/y-DOCA rats show severe white matter pathology as well as WMH, which are rarely reported in commonly used models. Our model may serve as a novel platform for further understanding the mechanisms underlying CSVD and for discovery of novel therapies for this disease.

Title: Endogenous zinc protoporphyrin formation critically contributes to hemorrhagic stroke-induced brain damage

Authors: *R. PAN, S. YU, H. ZHANG, G. TIMMINS, J. WEAVER, Y. YANG, X. ZHOU, K. LIU;
Univ. of New Mexico, Albuquerque, NM

Abstract: ABSTRACT Hemorrhagic stroke is a leading cause of death. The causes of intracerebral hemorrhage (ICH)-induced brain damage are thought to include lysis of red blood cells, hemin release and iron overload. These mechanisms, however, have not proven very amenable to therapeutic intervention, and so other mechanistic targets are being sought. Here we report that accumulation of endogenously formed zinc protoporphyrin (ZnPP) also critically contributes to ICH-induced brain damage. ICH caused a significant accumulation of ZnPP in brain tissue surrounding hematoma, as evidenced by fluorescence microscopy of ZnPP, and further confirmed by fluorescence spectroscopy and supercritical fluid chromatography-mass spectrometry. ZnPP formation was dependent upon both ICH-induced hypoxia and an increase in free zinc accumulation. Notably, inhibiting ferrochelatase, which catalyzes insertion of zinc into protoporphyrin, greatly decreased ICH-induced endogenous ZnPP generation. Moreover, a significant decrease in brain damage was observed upon ferrochelatase inhibition, suggesting that endogenous ZnPP contributes to the damage in ICH. Our findings reveal a novel mechanism of ICH-induced brain damage through ferrochelatase-mediated formation of ZnPP in ICH tissue. Since ferrochelatase can be readily inhibited by small molecules, such as protein kinase inhibitors, this may provide a promising new and druggable target for ICH therapy.

Title: Role of ageing in intracerebral haemahorrhage outcome

Authors: *T. LAM, G.-K. LEUNG;
Univ. of Hong Kong, Hong Kong, Hong Kong

Abstract: [Background] Intracerebral haemorrhage (ICH) has a heavy disease burden globally. ICH represents 15% of the strokes, and it has a high mortality (50%) and poor recovery. From clinical data, old age is associated with higher mortality and poorer recovery after ICH. To pave way for clinical trials targetting ageing-specific pathophysiological pathways, this study aims to explore the role of ageing in ICH. **[Method]** C57BL/6N mouse is used to model intracerebral haemorrhage. To investigate the role of ageing, C57BL/6N mouse of 8 weeks old and that of 50 weeks old are used. To induce ICH in mouse, type IV collagenase is injected intrastriatally, 0.2 cm lateral to and 0.02 cm rostral to bregma. To evaluate the severity of ICH, modified neurological severity score is calculated for each mouse. Rotarod test is used to evaluate the mouse's motor deficit. Corner turn test and cylinder test are used to evaluate loco-motor asymmetry, as well as spontaneous forelimb usage.

Histology is used to fix the mouse brain and measure haematoma size. MRI is used to follow haematoma size in a living mouse continuously over time.
To evaluate the immune response, cytokine assays are used. Oxidative stress is measured by radical oxidative species measuring assay. **[Results]** In this study, we discover that aged mice have higher mortality, poorer functional outcome, and slower recovery. Histology reviewed that aged mice have larger haematoma size in brain and slower haematoma clearance. In aged mice, higher pro-inflammatory cytokines are reported. **[Conclusion]** Our findings suggest that ageing is associated with an attenuated immune response in the brain. This includes prolonged neuroinflammation and increased inflammatory cytokines. As this is an ongoing study, further efforts will be placed on in vitro immune cell response. Immune cells from aged and young mice will be compared.

Title: Cx3cr1 Deletion Promotes Neuroinflammation in Experimental Intracerebral Hemorrhage Female Mouse Model

Authors: *T. ZHU[1], R. C. KOEHLER[2], X. LAN[3];
[1]Dept. of Anesthesiol. and Critical Care Med., Johns Hopkins Med. Institutions, Baltimore, MD; [2]Dept Anesthesiol Critical Care Med., Johns Hopkins Univ., Baltimore, MD; [3]Johns Hopkins Med., Baltimore, MD

Abstract: Objective: Fractalkine receptors (Cx3cr1) and its sole ligand Fractalkine (Cx3cl1) mediate inflammatory responses between neurons and microglia during neurologic disorders. Recent studies on Cx3cr1-gene knockout (KO) mice illustrated a controversial role in acute brain injuries of male mice. Herein, we studied the functions and mechanisms in female intracerebral hemorrhage (ICH) mice to explore the role of Cx3cr1 after ICH. Methods: We used ICH-subjected $Cx3cr1^{gfp/gfp}$ (Cx3cr1 KO) and wild-type (WT) female mice to investigate the role of Cx3cr1 in post-ICH recovery. The ICH models were established via collagen injection, which lysed the mice's brain blood vessels in the striatum. Post-ICH neurologic deficit behavioral tests, including the 24-point scoring system and the wire-handling task, assessed the animals' ability to control body and limb movements. Subsequent immunostaining of the extracted brain tissues (3 days post ICH) was performed to study the microglia and astrocyte activation, and Fast blue staining was applied to determine the lesion volume on day 3 post-ICH. Results: The behavior tests showed slight improvements of motor function in $Cx3cr1^{gfp/gfp}$ female mice, but no

significant differences were detected. Immunostaining of the CD68, CD68/Iba1 and GFAP illuminance around the lesion area demonstrated significant increases in the number of activated microglia and the activation level of astrocytes in Cx3cr1$^{gfp/gfp}$ mice compared to WT. There were no significant differences in the lesion volumes between the two groups. Conclusion: Cx3cr1 deficiency facilitates the up regulation of astrocyte and microglia activation in ICH female mice, which might contribute to neuroinflammation in the acute phase of ICH in females. The mechanisms of Cx3cr1 regulating glial activation in females and the gender differences of Cx3cr1 modulating ICH outcomes need to be further studied in the future.

Title: Proteomic Differences in Intracranial and Systemic Blood of Smokers and Patients with Hypercholesterolemia Undergoing Endovascular Treatment (EVT) for Emergent Large Vessel Occlusion (ELVO)

Authors: *D. HOUSE[1], K. PENNYPACKER[2], J. FRASER[3];
[2]Neurosci., [3]Neurosurg., [1]Univ. of Kentucky, Lexington, KY

Abstract: Background: Smoking and hypercholesterolemia are risk factors for ischemic stroke (IS) development. Blood cholesterol levels and smoking status have also been associated with differing outcomes following EVT. Therefore, we propose that patients from these populations differ compared to patients without these exposures, specifically in proteomic expression at time of IS. **Objective:** Examine intracranial and systemic arterial blood, collected via Blood and Clot Thrombectomy Registry and Collaboration (BACTRAC) protocol, to determine how smoking, hypercholesterolemia, and age affect proteomic expression sampled at time of IS. **Methods:** Systemic and intracranial arterial blood from 61 IS subjects underwent a proximity extension assay to detect proteomic expression of 182 proteins. Smoking status, clinical hypercholesterolemia diagnosis, and age were used in categorizing each subject. Statistical analysis was employed to evaluate proteomic differences within demographic subsets. **Results:** 61 subjects were included in our analysis, of which 36 (59%) were female. 16 (26%) were previous smokers and excluded from our analysis, 16 (26%) were smokers, mean age 63.06, while 29 (48%) were non-smokers, mean age 69.81. 14 (23%), mean age 71.29, had a clinical diagnosis of hypercholesterolemia, while 47 (77%), mean age 66.79, did not. Significant differences were observed when examining proteomic expression in intracranial or systemic arterial blood, with 106 proteomic markers varying between at least one group, 48 between smokers and non-smokers, 51 between cholesterol groups, and 46 varying in expression with age. Proteins found to be significant have established mechanisms in inflammation, neurotrophic mechanisms, and blood brain barrier function. **Conclusions:** Smoking status, blood cholesterol levels, and age are associated with varying protein expression in both systemic and

intracranial arterial blood at time of IS. We are examining the functions and relationships of these proteins. Further evaluation of this data could result in personalized biomarker identification, revealing novel information about IS development, IS severity, or clinical outcome prediction.

Title: Vitamin D deficiency is associated with worse mortality and behavioural outcome after experimental intracerebral hemorrhage

Authors: *A. CHAN, G. K. K. LEUNG;
Univ. of Hong Kong, Hong Kong, Hong Kong

Abstract: Background.
Vitamin D deficiency (VDD) is a globally common endocrinological finding that has been increasingly implicated in exacerbating various common pathologies such as ischemic stroke and myocardial infarction. Intracerebral hemorrhage (ICH) remains the most common subtype of haemorrhagic stroke worldwide, with high mortality and rarely full functional recovery. While VDD is proposed to cause blood-brain barrier (BBB) weakening, the consequence of its deficiency in ICH is unclear. Owing to its involvement in other vascular diseases, we hypothesized that a pre-existing VDD state may worsen outcome in ICH. **Methodology.** ICH was induced via stereotaxic injection of collagenase type IV into the right striatal region of C57BL/6N mice. VDD was induced via special diet for 3 weeks pre-stroke, while normal group was fed regular chow. Deficiency was validated by serum 25-hydroxyvitaminD_3ELISA. Mortality was assessed up to seven days post-stroke. Functional outcome post-stroke was assessed by a battery of neurological tests. T2*-weighted MRI was acquired with 7T MRI scanner post-surgery to visualize intracranial lesions. **Results.** VDD mice showed significantly greater mortality compared to normal mice within 24 hours post-surgery. Surviving VDD mice demonstrated significantly worse functional outcome compared to normal mice. T2*-weighted MR imaging showed a significantly larger lesion size in VDD mice compared to normal mice. **Conclusions.** VDD mice exhibited worse mortality and functional recovery on almost all outcome measurements evaluated as compared to normal mice. Results on MRI indicate an increased initial lesion size to be the likely cause of increased mortality in VDD mice. This pilot study serves to inform future mechanistic studies on VDD and BBB integrity. More attention should be directed to VDD as an exacerbating factor in ICH.

Title: Sexually Dimorphic Amygdala Dysfunction in a Mouse Model of Cardiac Arrest Cardiopulmonary Resuscitation

Authors: *J. VIGIL[1], N. CHALMERS[2], E. TIEMEIER[2], P. HERSON[3], N. QUILLINAN[2];
[1]Univ. of Colorado, Anschutz Med. Neurosci. Grad. Training Program, Aurora, CO; [2]Anesthesiol., Univ. of Colorado, Anschutz Med. Campus, Aurora, CO; [3]Neurosurg., Ohio State Sch. of Med., Columbus, OH

Abstract: Advances in modern medicine have greatly increased chances of survival following traumatic events such as cardiac arrest, stroke, or heart attack. With more people able to recover from these ischemic insults, it is becoming apparent that survivors experience long-term effects, particularly, as it relates to brain function. Our lab has previously identified memory dysfunction in a mouse model of cardiac arrest/cardiopulmonary resuscitation (CACPR) and has attributed this dysfunction to hippocampal damage and impaired hippocampal plasticity. However, no study has attempted to identify amygdala dysfunction post CACPR, despite clinical and animal model evidence of emotional dysfunctions, such as anxiety and PTSD, following global ischemia. Therefore, it is important to identify the effect that CACPR has on the amygdala, to further understand the effects of the ischemic event on the patient, and to perhaps find ways to improve quality of life. I hypothesize CACPR results in deficits in amygdala- dependent learning tasks and circuit specific deficits of long-term potentiation (LTP), the cellular mechanism of learning and memory. Experimental CA was induced in adult (8-12 week) C57BL6 mice for eight minutes via injection of potassium chloride and subsequently resuscitated by injection of epinephrine and mild chest compressions. Seven days post CA, an amygdala-dependent, delay fear conditioning paradigm was used to assess the extent to which amygdala dependent learning and memory is disrupted and field excitatory post-synaptic potential recordings were performed in the basolateral amygdala. Thus far, we have revealed a sexually dimorphic deficit in amygdala dependent fear learning and memory. Both male and female mice display a previously reported contextual fear deficit (Male: 78.6% sham freezing vs. 51.2% CACPR freezing; Female 73.8% sham freezing vs. 40.6% CACPR freezing), however, only male mice display a diminished freezing response to cued fear (56.4% sham freezing vs. 31% in CACPR). Similarly, plasticity involving cortical inputs to the basolateral amygdala is also disrupted in a sexually dimorphic manner, with only males displaying diminished LTP relative to sham controls (202% of BL in controls vs. 99% of BL in CACPR). Interestingly intra-amygdala recordings revealed no disruption of LTP in this circuit. These results support the role of the amygdala in cognitive-affective impairments after CA and provide new insights into the role that biological sex plays in mediating brain dysfunction following CA. In the future, we will continue to unravel the mechanisms by which this sexually dimorphic impairment occurs and identify therapeutic targets.

Title: Connectome Reorganization in Aneurysmal Subarachnoid Hemorrhage: A Graph Analysis

Authors: S. E. NELSON[1], **C. WEINER**[2], A. SIGMON[2], J. HUA[3], H. I. SAIR[3], J. I. SUAREZ[4], *R. D. STEVENS[4];
[1]Neurol., Mount Sinai Hlth. Care Syst., New York City, NY; [3]Radiology, [4]Anesthesiol. and Critical Care Med., [2]Johns Hopkins Univ., Baltimore, MD

Abstract: Background and Purpose: Aneurysmal subarachnoid hemorrhage (aSAH) is a distributed type of brain injury which may disrupt the connectome. In this exploratory study, we hypothesized that connectivity changes would occur in canonical brain networks in the acute phase of aSAH, and be associated with outcome at 6 months.Methods: Patients with aSAH were enrolled in a single-center prospective cohort. Study subjects underwent diffusion tensor imaging (DTI) as part of a multimodal MRI scan. A weighted undirected structural connectome was created from each DTI volume using 176 regions of interest (ROIs) defined by the Johns Hopkins Eve atlas. ROIs were sorted into four networks: Default Mode Network, Executive Control Network, Salience Network, and Whole Brain. Each ROI was characterized using three graph theoretic features: Node Strength (NS), Betweenness Centrality (BC), and Node Degree (ND). Clinical and DTI graph theoretic features were used separately and in combination to train Random Forest (RF) and Logistic Regression classifiers for the prediction of functional outcome at hospital discharge and at six months after discharge, measured using the dichotomized modified Rankin Score (mRS), with favorable outcome mRS 0-2 and unfavorable outcome mRS 3-6. Model performance was determined by the Area Under the Receiver Operator Characteristic Curve (AUROC) and the Area Under the Precision Recall Curve (AUPRC). Results: In total, 56 aSAH patients underwent DTI a median (IQR) of 7 (8.5) days after admission. The best performing model (RF) combined clinical variables with NS and BC from the Whole Brain and had a mean AUROC of 0.88 ± 0.00 and AUPRC of 0.95 ± 0.00 over 500 trials for the prediction of outcome at hospital discharge. The combined model performed better than the clinical model alone (AUROC 0.81 ± 0.01, AUPRC 0.91 ± 0.00), with p-value = 0.03. NS ranked higher than BC. The predicted labels from the RF model were added as a feature: estimated discharge mRS. A second RF model was built, identical to the first but with this one added feature. This model had a mean AUROC of 0.95 ± 0.00 and an AUPRC of 0.96 ± 0.00 over 500 trials for the prediction of outcome at 6 months. Conclusions: Results indicate significant reorganization of the connectome early after aSAH, which may be linked to future changes. Performance of clinical prognostic models was increased significantly by the inclusion of DTI-derived graph connectivity metrics.

Title: Evaluation of 4-aminopyridine as an acute therapy for white matter injury after experimental traumatic brain injury

Authors: *K. L. RADOMSKI[1], X. ZI[1], M. D. NOBLE[2], F. LISCHKA[1], R. C. ARMSTRONG[1];
[1]Uniformed Services Univ. of the Hlth. Sci., Bethesda, MD; [2]Univ. of Rochester, Rochester, NY

Abstract: Currently, there are no effective treatments to prevent axon damage and myelin loss resulting from traumatic brain injury (TBI). Axon damage is a major pathology in all forms of closed head TBI. Demyelinated axons are vulnerable to further damage, aberrant potassium currents, slowed or failed action potential conduction, and impaired information processing in neuronal networks. 4-aminopyridine (4-AP), an inhibitor of voltage-gated potassium (Kv) channels, is FDA-approved to treat chronic stage walking disability in patients with multiple sclerosis. We tested the hypothesis that acute 4-AP treatment, as compared to vehicle control, may protect viable axons and myelin after TBI in male and female mice. Starting 1 day after TBI or sham procedures, mice were treated intraperitoneally with a clinically relevant low therapeutic dose of 4-AP (0.5 mg/kg) twice a day through day 7. Quantification of serum drug levels confirmed 4-AP dosage met the human clinical target range (20-100 ng/ml). Transmission electron microscopy was used to quantify axon damage and myelin loss in the corpus callosum (CC) under the impact site. After TBI in C57BL/6 mice, 4-AP treatment significantly reduced axon damage and demyelination. In addition, 4-AP treatment significantly reduced axon damage after TBI in Thy1-YFP reporter mice with fluorescently labeled CC axons that exhibit YFP-filled swellings as a sensitive indicator of axon damage by confocal microscopy. Furthermore, in vehicle treated Thy1-YFP mice, TBI disrupted CC axon node of Ranvier molecular organization where myelin attaches at Caspr-labeled paranodes and Kv1.2 channels are localized in juxtaparanodes. 4-AP significantly reduced formation of abnormal heminodes and asymmetrical paranodes, and improved Kv1.2 channel localization. Ex vivo electrophysiology was conducted to directly assay CC axon function at 7 days post-TBI. TBI slowed conduction velocity and reduced the compound axon potential amplitude of the myelinated axon population. However, these conduction deficits were not improved with 4-AP treatment. These results demonstrate significant 4-AP benefit on axon and myelin neuropathology and molecular organization while recovery of axon function may require a longer 4-AP treatment period or involve additional mechanisms. This analysis at 7 days post-TBI clearly demonstrates benefit from 4-AP therapy at an acute stage post-injury. Further analyses are warranted to further evaluate and optimize 4-AP effects to sustain axonal viability and promote myelin plasticity as a therapeutic strategy to enhance functional recovery and mitigate post-traumatic neurodegeneration.

Title: Rolipram loaded PgP nanocarrier reduced secondary inflammation marker after murine brain injury

Authors: C. E. JONES[1,2], C. D. PERNICI[1,3], J. S. LEE[2], *T. A. MURRAY[1];
[1]Biomed. Engin., Louisiana Tech. Univ., Ruston, LA; [2]Bioengineering, Clemson Univ., Clemson, SC;
[3]Col. of Pharm., Univ. of Utah, Salt Lake City, UT

Abstract: Traumatic brain injury (TBI) causes an evolving secondary injury resulting in worsening neurological impairments in patients. Injury-induced activation of phosphodiesterase IV causes excessive degradation of cAMP. This impairs second messenger signaling which affects cell metabolism, survival, and memory. Rolipram (Rm), a phosphodiesterase IV inhibitor, loaded on the amphiphilic nanocarrier poly(lactide-co-glycolide)-graft-polyethenimine (PgP) effectively reduced neuronal damage in spinal cord injury. In this study, PgP loaded with Rm (Rm-PgP) was evaluated for its potential as a controlled delivery agent and targeted therapy for TBI. To visualize the PgP, a red hydrophobic dye, DiR, was loaded in PgP (DiR-PgP) and injected it into the frontal cortex in live, adult C57BL/6 mice. We counterstained the vasculature with FITC-dextran to serve as a fiduciary marker for imaging. Using multiphoton microscopy through a cranial window we observed that DiR-PgP spread through the parenchyma and around blood vessels and that it remained for at least 3 days post injection. Next, we performed intraventricular injections in the same strain of mice using PgP complexed with a plasmid encoding β-galactosidase (PgP/pβ-gal). Sections were harvested and IHC staining performed against β-gal which revealed transfection of periventricular and cortical cells. To determine if PgP passes across the blood brain barrier (BBB), we delivered PgP/pβ-gal using clinically relevant intravenous (IV) and a less invasive intranasal (IN) methods of administration. At 3 days post administration, brain tissue was harvested, fixed, and sectioned. We observed β-gal-stained cells in brain sections from both IV and IN delivery. After confirming that PgP passes through the BBB, we treated mice with Rm-PgP within 1 hour of midline fluid percussion injury using the least invasive IN mode of delivery. Mice were sacrificed at 7 days post-injury, and IHC was performed on sagittal brain sections which revealed that Rm-PgP-treated mice had significantly less astroglial activation ($p=0.028$) in the external capsule than vehicle-treated mice. Thus, we have taken the first step in validating Rm-PgP as a potential therapy to reduce secondary inflammation after traumatic brain injury. Funding was provided by NINDS grant NS114723 to TAM and partly supported by NIH/NINDS 5R01 NS111037-02 to JSL. The authors declare no competing interests.

Title: Nano-pulsed laser therapy prevents working memory dysfunction in rats subjected to blast-induced neurotrauma.

Authors: *N. GUPTA[1], K. JOHNSON[1], S. SELL[2], I. PETROV[1], Y. PETROV[1], D. DEWITT[1], D. PROUGH[1], M. MICCI[1];
[1]Univ. of Texas Med. Br., League City, TX; [2]Anesthesiol., Univ. of Texas, Med. Br., Galveston, TX

Abstract: Traumatic brain injury is a chronic disease process which is initiated by a head trauma and persists over time leading to debilitating and potentially life changing brain damage. A potential TBI therapeutic may arise from photobiomodulation; the non-invasive and non-heat generating use of light for therapeutic advantage. We have previously reported that Nano-Pulsed Laser Therapy (NPLT), which combines near-infrared light (which is neuroprotective but has limited penetration in the human brain) and optoacoustically generated low intensity ultrasound waves (which travel throughout the entire brain), significantly reduce neuronal death and microglial activation in a rat model of focal bTBI. More recently we have found that naïve rats treated transcranially with NPLT show a significantly greater expression of brain derived neurotrophic factor (BDNF) in the hippocampus as compared to untreated animals. Based on these data, we set up to test the exploratory hypothesis that NPLT could be an effective preventative treatment for combat soldiers at high risk of bTBI. Male adult Sprague-Dawley (N=12) rats were randomized to receive NPLT or sham treatment and further randomized to receive bTBI or sham injury 24 hours after treatment. Blast TBI was delivered using the Advanced Blast Simulator that models diffuse bTBI. On post injury days 1-5 the rats underwent vestibulomotor and neurological function assessments through Beam Balance and Beam walk, and Neuroscore behavioral assays. On post injury days 13-17, the animals were tested in a modified Morris Water Maze paradigm to assess for working memory. Beam Balance, Beam Walk and Neuroscore assessments did not reveal any significant differences among the 4 experimental groups (sham treatment + sham injury, sham treatment + bTBI, NPLT + sham injury, NPLT + bTBI). The working memory Morris Water Maze test showed that bTBI rats have a reduced T1-T2 latency (indicative of memory impairment) when compared to sham-injured rats on post-injury day 17 (sham=41.208±4.960, bTBI=15.958±6.731 p=.0084; mean+/-SEM, ANOVA). On the other hand, bTBI rats pre-treated with NPLT and sham-injured rats pre-treated with NPLT showed no significant difference compared to sham animals.These results show that, while bTBI did not affect vestibulomotor and neurological functions, it significantly impaired working memory. Moreover, pre-treatment with NPLT prevented bTBI-induced working memory deficits. Further studies are ongoing to determine the effect of NPLT pre-treatment on bTBI-induced histopathological changes.

Title: Neuroimmunomodulatory Treatment Prevents Post-Traumatic Hydrocephalus in Rats

Authors: *L. JANTZIE, **Y. KITASE**, M. FOUDA, S. HAMIMI, S. ROBINSON;
Johns Hopkins Univ. Sch. of Med., Baltimore, MD

Abstract: Young adults who suffer moderate to severe traumatic brain injury (TBI) are at risk of developing subacute post-traumatic hydrocephalus (PTH). In clinical studies, systemic inflammation increases the risk of PTH. We hypothesize that systemic inflammation precipitates the transition from TBI to PTH, and that neuroimmunomodulation after TBI can prevent PTH. On postnatal days 21 (P21) and P23, rats received 3mg/kg lipopolysaccharide (LPS) or sterile saline i.p. On P25, under anesthesia, rats received scalp incision and blunt cranial impact. Sham rats received anesthesia and incision without impact. For treatment, rats were randomized to a regimen of erythropoietin (EPO) plus melatonin (MLT) or sterile saline from P26-P36. Both sexes were used. At P45, opening pressure (OP) were measured. Brains underwent *ex vivo* MRI for structural T2 imaging. Ventricular volumes were quantified. Serum, CSF, and brains were collected. To quantify mRNA and proteins levels, qPCR, electrochemiluminescent assays, and immunoblotting were performed. Observers were blinded to experimental groups. Differences were compared with Kruskal-Wallis test with Dunn's posthoc, with $p<0.05$ indicating statistical significance. Results show that compared to controls (n=13) at P45, PTH-veh rats (n=19) had higher OPs ($p<0.001$), while PTH-EPO+MLT rats (n=8) had lower OPs ($p=0.04$). Ventricular volume was also larger in PTH-veh rats (n=5, $p<0.001$). mRNA levels of transcription factor YAP (yes-associated protein), which regulates ependymal motile cilia maturation and is modulated by inflammation, were reduced by half in PTH brains (n=7, $p<0.001$). Serum CCL2 (MCP-1), IL-1β, lipocalin 2 (NGAL) and TIMP (tissue inhibitor of metalloproteinases) were elevated in PTH rats and normalized with EPO+MLT treatment (n=7-10, all $p<0.05$.) Activity of the protease, calpain, was also elevated in ependyma from PTH rats, and normalized with EPO+MLT treatment (n=7-10, $p<0.05$). In conclusion, PTH complicates the recovery and burden of young adults with TBI. Systemic inflammation alters cerebrospinal fluid (CSF) dynamics, including ependymal motile cilia propulsion of CSF. Initial studies with our novel model of PTH support that chronic inflammation can be modulated by post-TBI treatment with the endogenous neurorestorative agents EPO and MLT.

Title: Intercellular adhesion molecule-1 antagonistic peptide protects the brain from the transmigration of leukocytes and formation of neutrophil extracellular trap and promotes functional recovery after traumatic brain injury

Authors: *P. M. ABDUL-MUNEER, S. BHOWMICK, D. CARUSO;
Hackensack Meridian Hlth. JFK Univ. Med. Ctr., Edison, NJ

Abstract: Traumatic brain injury (TBI) causes the blood-brain barrier (BBB) dysfunction and transmigration of inflammatory blood cells into the brain, an important mechanism underlying neurovascular damage and neuroinflammation. Exploring therapeutic methods against TBI is imperative because several clinical trials that have been performed in recent years have failed to demonstrate significant improvement in outcomes for TBI. We hypothesize that inhibition of intercellular adhesion molecule 1 (ICAM-1) using ICAM-1 antagonistic peptide (IAP) remodels the vascular system and promotes functional recovery after TBI. We are uncovering and targeting the significant roles of ICAM-1 in the transmigration of leukocytes to the brain, Neutrophil Extracellular Traps (NET) formation, and neovascularization. The experimental TBI was induced *in vivo* by fluid percussion injury (10 and 20 psi) in wild-type and *ICAM-1*$^{-/-}$ mice and *in vitro* by stretch-injury (3 psi) in human brain endothelial cells. We manipulate ICAM-1 pharmacologically and genetically and conducted several biochemical analyses to gain insight into the mechanisms underlying ICAM-1-mediated transmigration of leukocytes to the brain, and NET formation. We demonstrated the mechanisms of transmigration of blood cells across the BBB due to brain injury that IAP-mediated ICAM-1 inhibition mitigates leukocytes transmigration by disrupting the paxillin-FAK signaling pathway. Since we hypothesized that the adhesion and transmigration of blood cells lead to the formation of NET, depletion of NET and promoting faster neovascularization are of great therapeutic interest in treating a wide range of central nervous system diseases. Next, we tested whether IAP reduces ICAM-1 expression in neutrophils and inhibits NETs forming ICAM-1+ neutrophils promoting neovascularization. We used a cohort of behavioral tests that include sensorimotor functions, memory, and psychological stress analyses to validate the role of IAP in promoting functional recovery following TBI. Therefore, to validate the central hypothesis, we target a subset of events towards unraveling a larger picture of neurovascular remodeling and functional recovery after TBI by attenuating ICAM-1 activity using a novel small cyclic peptide developed in the PI's lab. Title: Novel Cannabidiol (CBD)-Infused Absorbable Implant Delivery System for Neurotrauma

Authors: *L. K. FRIEDMAN, H. PENG, R. J. ZEMAN;
Cell Biol. and Anat., New York Med. Col., Valhalla, NY

Abstract: Brain and spinal cord injuries result in profound local hypoperfusion which restricts drug delivery to the site of impact so that peripheral treatment alone would have limited access to the site of injury during the most critical phases of neurotrauma. Cannabidiol (CBD), the major non-psychotropic cannabinoid constituent, has anti-convulsant, anti-inflammatory, anti-nociceptive, anti-oxidant, and immuno-suppressive properties which may abate neurotrauma-induced pathophysiology. Treatment of either neurotrauma with CBD would be restricted due to the acute hypoperfusion at the site of impact. We *hypothesized* that continuous local delivery of CBD directly to the contusion site overlying the dura of brain or spinal cord can attenuate the risk of excitotoxic Ca^{2+} dysregulation that causes progressive cell death leading to long-term behavioral and neuropathological sequelae, such as paralysis, locomotor impairment, memory and attention deficits, depression, as well as onset to intractable seizures. Therefore, we devised a patent pending CBD delivery system for brain and spinal cord in a pre-clinical rodent model of contusion. A controlled weight drop stereotactic apparatus was used to induce cortical or spinal cord injury. CBD was delivered over the dura at the contusion site in an infused gelfoam matrix followed by subcutaneous (s.c.) injection at 20 mg/kg 3x/week. Brains and spinal cords were paraffin sectioned, processed and analyzed with Nissl, NeuN and GFAP staining methods. In both brain and spinal cord trauma models of injury, post-administration of the CBD-infused implant with s.c. administration greatly reduced lesion volume that was associated with reduced levels of anxiety and restored locomotor function. In addition, CBD decreased the loss of neurons in the ipsilateral hippocampus, reduced the number of acidophilic injured neurons of the contralateral hippocampus, and inhibited astrocyte activation in the hippocampus bilaterally, which corresponded with improved learning and memory function in the alternating T-maze and increased time with novel objects compared to contusion alone consistent with restored cognitive function. The results suggest that dual therapy by targeting the site of injury internally with an infused CBD medical carrier that is supplemented systemically can offer a more effective countermeasure than systemic or implant treatment alone for opposing the deleterious effects of penetrating head and spinal cord wounds. Whether the beneficial effect of the dual CBD treatment was due to anti-inflammatory, anti-convulsant and anti-oxidative stress properties or other undefined mechanisms is yet to be elucidated.

Title: Mitigation of pain and associated oxidative and neuroinflammatory pathology post-traumatic brain injury with photobiomodulation

Authors: *K. E. BOSSE[1], S. C. LLOYD[1], A. GOODWIN[1], J. I. MALEWICZ[1], B. A. BERKOWITZ[2], A. C. CONTI[1];
[1]Detroit VA Med. Center/Wayne State Univ., Detroit, MI; [2]Wayne State Univ., Detroit, MI

Abstract: Chronic pain is a common complication post-brain injury, impacting and impairing the recovery of over 50% of traumatic brain injury (TBI) patients. Conventional therapies, such as opioids, have proven inadequate, often promoting risk of misuse, overdose, and suicide in these patients. Prolonged presence of reactive oxidative species (ROS) and pro-inflammatory mediators occurs across pain and TBI pathology, making them attractive targets for improving TBI pain management. Photobiomodulation (PBM), a non-invasive light therapy, attenuates excessive ROS production and inflammation, raising its possibility as a non-opioid intervention strategy. Our hypothesis is that PBM mitigates TBI-induced oxidative stress, inflammatory markers, and pain responsivity. C57Bl/6 mice (10-12 weeks old, n = 8-12/group) received a moderate closed-skull impact or sham surgery and were assessed for mechanical pain using von Frey (VF). TBI induced persistent, heightened VF sensitivity to at least 6 months post-injury that was comparable in males and females. Cortical and thalamic tissues showed concomitant, marked elevations in levels of both ROS and a host of pro-inflammatory cytokines (interleukin(IL)-1 beta, IL-12, and tumor necrosis factor alpha), determined using a fluorometric assay and ELISA. Repeated, but not a single, application of PBM (whole-body, 670 nm LED, 50 mW/cm^2, 90 sec/day for 7 consecutive days), initiated 24 hours post-injury, significantly reversed the pronociceptive response detected in TBI mice compared to controls and normalized cortical and thalamic ROS and IL-1 beta levels. In defining the trajectory of this therapeutic effect, a reduction in VF responding was still evident in TBI subjects 48 hours after PBM cessation but they returned to a state of heightened nociception following a protracted (7 days) termination of PBM. These findings highlight processes that govern hypernociception following TBI and promote PBM as a clinically-translatable strategy to address pain post-TBI. Title: Challenges and limitations of CatWalk XT: analyzing gait and locomotor parameters in spinal cord injured mice.

Authors: *A. M. HALLIBURTON, A. N. STEWART, E. P. GLASER, R. H. HAMMONS, J. C. GENSEL;
Spinal Cord and Brain Injury Res. Ctr., Univ. of Kentucky, Lexington, KY

Abstract: Up to 500,000 people sustain a spinal cord injury (SCI) annually. Consequently, locomotor abilities are reduced as a result. Locomotor abilities are the most frequently used outcomes to assess SCI injury and recovery in preclinical rodent models, of which subjective open field rating scores are the predominant test used. The Basso Mouse Scale (BMS) and Basso, Beattie, and Bresnahan (BBB) scales of locomotor recovery dominate the SCI outcome testing for thoracic SCI in mice and rats respectively. Unfortunately, this assessment has limitations such as being ordinal and not-continuous, as well as relying on the fallibilities of the human eye. The CatWalk XT objectively analyzes gait parameters and locomotor activity in mice and rats and has been used in models of SCI. However, there are major limitations to the use of Catwalk XT for SCI that require optimization to acquire efficient and useful results. This project used quantitative approaches to optimize methods for acquiring and analyzing data from SCI-mice using the Catwalk XT. We identified that the regularity index and base of support obtained from Catwalk XT were significantly correlated with functional improvements on the BMS. However, the ability of mice to cross the platform in a consistent uninterrupted pass was a major limitation to data acquisition, which became worse over subsequent days of testing. This poster will discuss our data-driven approach to circumvent difficulties with incompliant trials on the Catwalk XT that have allowed for acquiring regularity index as the best correlate to SCI injury severity. Specifically, this project has identified protocols to obtain the minimum standards for trial number, length of walkway, number of step cycles, and speed variance to obtain reliable, robust, and reproducible outcomes.

Title: Gait assessment in spinal cord injured mice by kinematic synergy

Authors: *Y. SATO[1,3], T. KONDO[4], H. OKANO[4], J. USHIBA[2];
[1]Grad. Sch. of Sci. and Technol., [2]Dept. of Biosci. and Informatics, Fac. of Sci. and Technol., Keio Univ., Kanagawa, Japan; [3]Riken Ctr. for Brain Sci., Saitama, Japan; [4]Dept. of Physiol., Keio Univ. Sch. of Med., Tokyo, Japan

Abstract: Spinal cord injury (SCI) research to develop effective treatments has typically used rodent models whose gait functions are mainly assessed using subjective scoring or univariate kinematic parameters. However, these assessments may not correctly reflect gait deficits. Coordinated joint movements, called kinematic synergies, are known as a procedure to evaluate the basic components of gait (Courtine and Schieppati, *J. Neurophysiol.* 2004), but few studies have examined synergies in rodents. In the current study, we investigated whether kinematic synergies can be used to assess gait function in mice. Kinematic data were recorded from intact (n = 7) and SCI (n = 17) mice walking on a treadmill. Spinal contusion injuries were performed at Th10 with 70 kdyn. Then principal component analysis was applied to extract kinematic synergies from the coordinates of each joint tracked using DeepLabCut (Mathis et al., *Nat. Neurosci.* 2018). Extracted synergy patterns of SCI were classified based on the similarity of the synergy components. Locomotor function was also scored using the Basso Mouse Scale for locomotion (BMS) (Basso et al., *J. Neurotrauma* 2003). Finally, the degree of spared tissue in each group was compared to verify if the differences in synergy patterns reflect the underlying SCI neuropathology. In intact mice, we identified three synergy components: forward propagation, forward/backward bent, and upward/downward movement. The synergy patterns in SCI mice were categorized into three groups using hierarchical cluster analysis based on spatial components. We identified the different spatial components compared with those in intact mice in two groups, however in the remaining group, the spatial components were the same as in intact mice, but the temporal components were different. Moreover, a significant difference was observed between these three groups in histological damage of spinal cord ($F(2,15) = 18.93$, $p < 0.001$; one-way ANOVA with Tukey's post-hoc). On the other hand, a significant difference was not observed in BMS ($F(2,16) = 1.91$, $p = 0.184$). These results suggest that kinematic synergy reflects underlying SCI neuropathology and may provide a new assessment system in the gait of mice with SCI.

Title: A Placebo-Controlled Phase I Study in Healthy Subjects Assessing NVG-291, which Targets CNS Receptor Protein Tyrosine Phosphatase Sigma (PTPσ)

Authors: *M. DEPAUL, B. LAWRENCE, N. COLLETT, J. TOEWS, **D. MIKOL**;
NervGen Pharma, Vancouver, BC, Canada

Abstract: Background: There are no approved neurorestorative treatments following damage to the CNS, whether due to trauma (e.g. spinal cord injury [SCI]) or disease-specific mechanisms (e.g. multiple sclerosis [MS], Alzheimer's disease [AD]). Substantial data from animal models of SCI, MS and AD support that chondroitin sulfate proteoglycans (CSPGs), the major plasticity-inhibiting component of the perineuronal net, are increased at sites of CNS damage and inhibit endogenous repair mechanisms. The inhibitory effect of CSPGs is mediated through protein tyrosine phosphatase sigma receptor (PTPσ), which is the principal receptor for CSPGs in the CNS. NervGen is developing a novel, first-in-class PTPσ inhibitor, NVG-291, a systemically administered peptide for treatment of nervous system damage due to trauma or disease. In animal models, NVG-291 and NVG-291-R (rodent analogue) improved functional outcomes by promoting axonal regeneration, remyelination and neuroplasticity, and were shown to cross the blood brain barrier, by virtue of their cell-penetrating tag.
Objectives: This randomized, triple-blind, placebo-controlled trial will assess the safety, tolerability, and PK of single (SAD) and multiple ascending doses (MAD) of NVG-291 administered subcutaneously once-daily in healthy subjects.
Materials and methods: Part 1 (SAD portion), which began in May 2021, is being conducted in up to 32 healthy adult volunteers randomly assigned into 6 cohorts of placebo or NVG-291 (doses ranging from 0.032 mg/kg to 0.864 mg/kg). The doses being tested are in the (human equivalent) range of doses that showed efficacy in several animal models including SCI and MS. Part 2 (MAD portion) will proceed after Part 1, and dose up to 18 subjects randomly assigned into 3 dose cohorts to receive NVG-291 or placebo once-daily for 14 days. CSF will be collected in additional subjects for analysis of NVG-291 concentration.
Results and Discussion: NVG-291 has been safe and well-tolerated to date. Parts 1/2 are expected to complete in October 2021 and March 2022, respectively. The study will establish the safety and tolerability of NVG-291 and will measure exposure in the plasma and CSF, to support advancement to clinical trials in patients with SCI, MS, and AD in 2022.

Title: Investigating sex differences in mouse neuropathic pain after spinal cord injury

Authors: E. K. GREENOUGH, S. E. LEE, *A. D. GAUDET;
Univ. of Texas at Austin, Austin, TX

Abstract: Spinal cord injury (SCI) causes neuropathic pain in ~65% of injured individuals. Sex differences in neuropathic pain have been observed in patient populations and animal models. Previous studies investigating sex differences in neuropathic pain following SCI have not been in agreement; however, it remains unknown how pain symptoms are affected by injury severity or neuroinflammation. Here, we aimed to establish whether there are sex differences in mouse neuropathic pain symptoms, lesion size, and neuroinflammation after SCI. 20 male and 20 female mice received either T9 contusion SCI (60 kDyn) or T9 laminectomy (sham surgery). Pain symptoms were assessed over 28 days after sham or SCI surgery using established pain measures: von Frey and Hargreaves testing for mechanical allodynia and heat hyperalgesia, respectively. Both female and male mice showed similar locomotor deficits and recovery after SCI (Basso Mouse Scale). Thermal and mechanical pain symptoms were present in both male and female SCI groups after injury. Male mice with SCI exhibited increased mechanical sensitivity compared to females. Sex differences in heat sensitivity appeared at day 21 with females showing increased sensitivity compared to male SCI animals. Tissue will be analyzed to determine the effect of sex on lesion size and neuroinflammation after SCI. These findings highlight that sex differences in neuropathic pain are present in a moderate-severity SCI model, and suggest that sex differences in pain following SCI are dependent on injury severity. Continued investigation into the underlying mechanisms of sex differences in neuropathic pain will aid development of more effective pain-relieving treatments for SCI.

Title: A novel heat-light conflict test for mice unmasks latent anxiety behavior in females after spinal cord injury

Authors: *S. E. LEE[1], E. K. GREENOUGH[2], L. K. FONKEN[3], A. D. GAUDET[2];
[1]The Univ. of Texas at Austin/Dell Med. Sch., Austin, TX; [3]Div. of Pharmacol. and Toxicology, [2]Univ. of Texas at Austin, Austin, TX

Abstract: Anxiety disorders affect 32% of individuals across their lifetime, with a nearly 2x higher prevalence in females. Anxiety exhibits high comorbidity with chronic pain, which implies that anxiety and pain disorders may also share underlying physiological mechanisms. We aim to explore the relative salience of anxiety versus pain using our novel Thermal Increments Dark-Light (TIDAL) conflict assay. The TIDAL conflict assay allows mice to move freely in an apparatus with two connected chambers: one light chamber, maintained at 31°C; and one dark chamber, which starts at 31°C but then increases incrementally from 39 to 44°C. In the first experiment, we reveal that C57BL6/J mice displayed sex differences in the salience of heat vs. anxiety. Specifically, female C57BL6/J mice preferred the dark plate more than male mice despite increasingly hyperthermic temperatures. In the second experiment, we observed distinct TIDAL preference differences in mice with spinal cord injury vs uninjured mice; both male and female mice with spinal cord injury exhibited increased dark-heated plate preference on the TIDAL assay at all tested temperatures (31°C-44°C). Our new TIDAL conflict test unmasks increased salience of stimuli that elicit anxiety-like behavior (vs. heat) in females and after spinal cord injury. Therefore, conflict assays with freely moving mice can illuminate behavioral phenotypes that are concealed at baseline; these strategies could have important implications for understanding the relative salience of anxiety, pain, and other conditions in combination with sex or neurologic disorders.

Title: Quantifying Mouse SCI-related behavior changes using ELAN annotation software

Authors: *A. CHUANG[1], H. KLOEFKORN[2], S. HOCHMAN[3];
[1]Emory Univ., Decatur, GA; [2]Physiol., Emory Univ., Atlanta, GA; [3]Dept Physiol, Emory Univ. Sch. Med., Atlanta, GA

Abstract: Spinal Cord Injuries (SCIs) may cause physical disability, regulatory dysfunction, and chronic pain, which may alter behavioral phenotype. Changes in motor behavior may indicate underlying dysfunction while also providing predictive value in pathogenesis and therapeutic efficacy. While altered behavior is monitored after SCI clinically, pre-clinical analogues are cumbersome and expensive. We tested use of a freely available annotation software (ELAN) as a simple method to quantify rodent behavior to show SCI-related behavioral changes.
We videoed five adult female C57BL/6 mice for 12 hours (noon to midnight) in individual home cages before SCI (baseline, n=5) and twelve weeks after receiving a moderate (50kDyne impact, infinite

horizon impactor) T12 contusion SCI (SCI, n=5). As an initial proof of concept, one hour (3-4PM) of motor behaviors were manually scored before and after SCI. Behaviors (exploration, rearing, eating, drinking, grooming, resting) were quantified using the ELAN linguistic annotation software,[1] an open-source tool able to flexibly assign annotations to video and export in several formats. Video was imported then scanned frame-by-frame. Behavior transitions were video-tag and assigned the appropriate description. Once a video was fully annotated, it was exported to Excel for analysis.
Data were analyzed using two-tailed student's t-tests. SCI animals decreased the number of behavior transitions per hour relative to their baseline values ($p=0.03$), suggesting animals consolidate their behaviors after SCI. Additionally, rearing and exploration events lasted longer after SCI compared to their baseline values ($p=0.02$ and $p=0.02$, respectively) but were less frequent ($p=0.04$ and $p=0.03$, respectively). This may indicate initiating rearing may be more costly than maintaining rearing posture. As exploration includes myriad sub-behaviors (e.g. burrowing, sniffing, locomotion, and nesting), more detailed scoring will be needed to understand these changes. Eating event duration increased after SCI relative to their baseline values ($p=0.02$), however, cumulative eating time and animal weight did not change.
We conclude that ELAN is a simple and robust method to annotate mouse movement-related behaviors and their changes in relevant disease models. Here it enabled us to identify several significant differences in a SCI model (contusion) known to elicit neuropathic pain. Additional studies are planned to use ELAN-derived behavior scoring to develop algorithms that enable automated behavior scoring methods.

Title: Molecular MRI and PET imaging link changes in neuroinflammation to locomotion deficits in contusion injured spinal cord

Authors: C. MU[1], *J. REED[2], M. N. TANTAWY[2], F. WANG[2], J. C. GORE[2], L. M. CHEN[2];
[1]Biomed. Engin., Vanderbilt Univ., Nashville, TN; [2]Vanderbilt Univ. Inst. of Imaging Sci. & Dept. of Radiology and Radiological Scienc, Vanderbilt Univ. Med. Ctr., Nashville, TN

Abstract: Spinal cord injury (SCI) severity and recovery are influenced by complex pathological mechanisms, including demyelination/remyelination, glutamate excitotoxicity, scar formation, and inflammatory responses. The overall goal of this study is to develop and validate noninvasive, mechanism-based imaging biomarkers of these processes to assist evaluation of injury severity, guide interventions, predict recovery, and provide objective measures of treatment outcomes. We used

quantitative chemical exchange saturation transfer imaging (CEST) MRI and translocator protein (TSPO) PET to quantify dynamic molecular changes associated with neuroinflammation over 8 weeks in a contusion lumber (L1) SCI rodent model. 14 SCI and 5 sham control rats were studied. Standard measures including BBB scores, open field, Von Frey filaments, gait analysis, and hot plate test were used to correlate behavioral deficits to the imaging measurements. Data from ROIs in high resolution CEST images were converted to Z-spectra and were fit to a 5-pool Lorentzian peak model. The peak amplitude of the nuclear Overhauser effect (NOE) pool (at RF offset -1.6 ppm) during the 1st week post-op was significantly lower for SCI compared to the sham rats, and amplitude increased progressively through 8 weeks post-injury. The NOE (-1.6 ppm) pool has been linked to mobile macromolecules, such as lipid and membrane proteins, that could be disrupted due to neurodegeneration effects triggered by elevated release of glutamate and pro-inflammatory cytokines at the injury site. PET images acquired within 10 days post injury demonstrated elevated TSPO at and rostral to the injury epicenter. BBB scores for the hindlimbs decreased during the first week of injury, along with decreased normalized open field movement. Motor function began improving within 7-10 days post-injury, while sensory deficits were detected well past 10 days post-injury, with minimal responses to filament strengths up to 60g. Hot plate responses indicated increased pain sensitivity, with decreased hot plate withdrawal times for SCI rats. BBB scores, open field activity, and Von Frey measurements strongly correlated with the -1.6 ppm NOE peak amplitude decrease during Week 1 and subsequent recovery over time. The results indicate that the molecular information provided from CEST and PET measures can be used as biomarkers of neuroinflammation dynamics. These imaging biomarkers for SCI severity and longitudinal recovery progress can be readily translated for human clinical applications. The novel information will help further development of treatments targeting specific pathological mechanisms in preclinical studies.

Title: Depression like behavior following spinal cord injury in male and female rats is associated with a decline in cognitive performance

Authors: *A. STEFANOV, R. M. JOSEPH, A. HEMPHILL, R. DUNDUMULLA, K. BRAKEL, J. RAU, K. S. MONTGOMERY, M. HOOK;
Neurosci. and Exptl. Therapeut., Texas A&M Hlth. Sci. Ctr., Bryan, TX

Abstract: Each year, the global incidence of traumatic spinal cord injury (SCI) is estimated to number in the hundreds of thousands. On top of the disruption of physical and physiological function already complicating their recovery, 26% of SCI patients also suffer from major depressive disorder (MDD) and

60% experience impairments in cognition. Evidence suggests that these comorbidities may share molecular and neuroanatomical correlates. We aimed to investigate the association of depression and cognitive deficits following a lower-thoracic contusion SCI in young and middle-aged male and female Sprague-Dawley rats. Before spinal injury, and at acute and chronic time points after, components of depression-like behavior such as anhedonia, decreased sociability, and learned helplessness were tested using our behavior ethogram. We found that depression-like behavior manifests within a month post-SCI in 30-45% of subjects, commensurate with the clinical incidence, and persists into the chronic phase of recovery. To examine cognition during this phase, we trained rats in the Barnes Maze. We found that the subset of SCI subjects displaying depression-like behavior also demonstrated poor spatial learning strategies compared to their non-depressed SCI and sham counterparts. Our findings suggest an association between depression in acute spinal cord injury and cognitive decline in chronic stages of recovery, and indicate that our rodent SCI model is a powerful tool to investigate the molecular mechanisms underlying these outcomes.

Title: Role of MRI Biomarker in Prognosticating Recovery Following Spinal Cord Injury In a Yucatan Animal Model

Authors: J.-W. KIM[1], M. SHARMA[2], *M. NEGAHDAR[3], R. J. BERT[3], M. L. MORGAN[2], R. U. AHMED[2], D. R. HOWLAND[2], S. E. DAVISON[4], L. C. SHERWOOD[4], M. D. BUDDE[5], J. XU[1], **M. BOAKYE**[2];
[1]Dept. of Radiology, Baylor Col. of Med., Houston, TX; [2]Dept. of Neurolog. Surgery, [3]Dept. of Radiology, [4]Comparative Med. Res. Unit, Univ. of Louisville, Louisville, KY; [5]Dept. of Neurosurg., Med. Col. of Wisconsin, Milwaukee, WI

Abstract: Background and Objectives: The Yucatan minipig model has increasingly been used as a large animal model of SCI. However, in vivo imaging using this model is lacking. Our goal is to investigate the role of MRI biomarkers in prognosticating recovery following spinal cord injury (SCI) in a large animal model. **Materials and Methods:** Eleven minipigs were scanned after 1 week from thoracic contusion injury (short-term). Four of them were scanned again after 12 weeks from injury (long-term). Anatomic Imaging. Three anatomic sequences were acquired: T1, T2, and STIR. Each sequence was performed with a sagittal large FOV to evaluate the whole spine, a sagittal small FOV for higher resolution to cover the site of injury, and axial imaging in several locations distal and proximal to the injury site. Inner-volume-imaging DTI data were collected superior to the site of the injury centered at T3

vertebra including 12 axial slices with 5 mm thickness each. DTI data acquisition was gated to oxygen saturation signal (SpO2) to reduce motion artifact. After the DTI volumes of each axial slice were registered using 2-dimensional x- and y-translation and DTI maps were generated. White matter regions of interest (ROIs) were manually defined based on mean b0 images, mean diffusion-weighted images, and DTI fractional anisotropy (FA) maps. Average DTI measures were calculated for the whole slices, inferior half slices, and superior half slices. **Results:**For short-term scans, the mean: standard deviation (SD) of FA across inferior half, superior half, and all slices were 0.74:0.05, 0.70:0.04, and 0.72:0.05, respectively, and those of radial diffusivity (RD) were 0.46:0.11, 0.51:0.09, and 0.48:0.09, respectively. For long-term scans, those of FA were 0.64:0.05, 0.74:0.03, and 0.68:0.02, respectively, and those of RD were 0.65:0.13, 0.39:0.05, and 0.52:0.04, respectively. In the inferior half slices, the FA values at long-term scans decreased > 7% for all 4 subjects ($p < 10^{-4}$) while RD values increased > 27% for 3 subjects ($p < 10^{-8}$) as compared to short-term scans. In the superior half slices, 2 subjects showed increased FA (> 9%, $p < 10^{-4}$) and decreased RD (> 29%, $p < 10^{-8}$) as compared to short-term scans. Others did not have statistically significant change over time. **Conclusion:** The decreasing FA and increasing RD distal to the injury region implies Wallerian degeneration. The normalization of FA and RD proximal to the injury region from 2 subjects indicates possible recovery after 12 weeks from injury. These data provide preliminary DTI data in a well-described thoracic contusion model in Yucatan minipigs.

Title: Longitudinal neuromuscular connectivity and muscle function following spinal cord injury

Authors: *M. HARRIGAN, M. BALCH, W. D. ARNOLD, J. M. SCHWAB;
Neurol., The Ohio State Univ. Wexner Med. Ctr., Columbus, OH

Abstract: Objective electrophysiological measures are needed for effective cross-species translation, as prior work has uncovered pronounced fundamental differences in the anatomical and functional characteristics of the motor systems in primates versus rodents. The ability to factor neurobiological differences has been limited and constitutes an obstacle for the translation of rodent models to patients. The ability to assess different spinal cord regions and pathologies may be of particular benefit to SCI research. Additionally, low replicability and robustness of behavioral assays of functional recovery limit translation of findings in preclinical SCI models. Therefore, objective electrophysiological measures will optimize predictive value of experimental SCI studies. Compound muscle action potential (CMAP) and motor unit (MU) number estimation (MUNE) allow longitudinal monitoring of MU integrity in patients.

In analogy we refined these methods for assessing spinal MU input in the mouse hindlimb. We longitudinally applied these electrophysiological techniques over a period of five weeks in mice with thoracic SCI. Muscle contractility was also measured and compared to electrophysiological measures. Moving forward, CMAP and MUNE measures are putative electrophysiological biomarkers of forelimb and hindlimb MU integrity poised to guide and improve bi-directional translation in experimental spinal cord disease models.

Title: Sex-dependent cortical volume changes in patients with Degenerative Cervical Myelopathy

Authors: *T. C. OUGHOURLIAN[1], C. WANG[2], N. SALAMON[2], L. T. HOLLY[3], B. M. ELLINGSON[2];
[1]Neurosci. Interdisciplinary Grad. Program, [2]Dept. of Radiological Sci., [3]Dept. of Neurosurg., Univ. of California Los Angeles, Los Angeles, CA

Abstract: Degenerative cervical myelopathy (DCM) is a chronic condition involving the progressive deterioration of osseocartilaginous structures within the cervical spine resulting in compression of the spinal cord and is the most common spinal cord impairment in people over the age of 55. Chronic cord compression from DCM can lead to neck pain, weakness in the upper limbs, loss of fine motor skills, and/or limb dyscoordination. Compared to healthy controls (HCs), studies have shown DCM patients experience structural and functional reorganization in somatosensory, motor, and cerebellar brain regions; however, sex-dependent cortical differences in DCM patients remains largely unexplored. In the present study, we investigate the role of sex differences on the structure of the cerebral cortex in DCM and determine how structural differences may relate to clinical measures of neurological function. T1-weighted structural MRI scans and modified Japanese Orthopedic Association (mJOA) scores were acquired in 85 patients with DCM. Structural MRI scans of 90 age-matched HCs were obtained from the Parkinson's Progression Markers Initiative database (www.ppmiinfo.org/data). Cortical segmentation, gray matter volume (GMV) computation, brain surface smoothing, standard space registration, and whole-brain GMV analysis were completed using FreeSurfer. A general linear model was used to determine vertex-level significant differences in GMV between the following groups 1) HC males and HC females, 2) DCM males and DCM females, 3) DCM males and HC males, and 4) DCM females and HC females. We observed no significant difference in GMV between HC males and females. However, DCM males exhibited larger GMV in motor, language, and vision related brain regions compared to female patients. In female subjects, DCM patients exhibited smaller GMV than HCs in the pericalcarine and lingual cortices, whereas in males, patients observed larger GMV in vision and language related

cortices compared to HCs. Both males and females demonstrated a significant positive correlation between GMV and mJOA score, in which patients with worsening neurological symptoms exhibited decreasing GMV primarily across somatosensory and motor related cortical regions. Interestingly, females exhibited a similar association, albeit across a broader range of cortical areas including those involved in pain processing. In sensorimotor regions, female patients consistently showed smaller cortical volume compared with male patients. Results from the current study suggest strong sex-related differences in GMV in patients with DCM, which may reflect hormonal influence or differing compensation mechanisms.

Title: Disconnection of Stress from Visceral Pain in a Contusion Injury Model of Spinal Cord Injury

Authors: *A. JOHNSON;
VA Hlth. Care Syst., Oklahoma City, OK

Abstract: Introduction: The Veteran Affairs (VA) health care system is the largest single network of spinal cord injury (SCI) care in the nation. Many SCI patients develop complications involving the gastrointestinal (GI) tract including constipation and chronic visceral pain. We have previously demonstrated that activation of limbic brain areas can enhance colonic motility and sensitivity, but it is unknow if the brain-gut connection is maintained following SCI. Our hypothesis is that brain-gut connections can be re-wired following SCI and that activation of specific central networks may offer treatment opportunities for patients with SCI-induced bowel problems. **Methods:** Male Fischer 344 rats were randomized to receive a contusion (300 kdyne impact, Infinite Horizons model 400) SCI at T10 or Sham-SCI (incision without damage). The Basso, Beattie, Bresnahan (BBB) scale was used to assess locomotion one day prior to injury and weekly following the injury. Fecal pellet output in the home cage was assessed daily. On day 21-post injury, rats were randomized to receive 7 days of water avoidance stress (WAS) or Sham-WAS. Colonic sensitivity to distension was measured at 28-days after injury. Results were analyzed with a repeated measure two-way ANOVA with Bonferroni's post-hoc analysis (mean ± standard deviation). **Results:** Rats with SCI displayed a persistently low functional score in injured animals (median BBB score: 3/21 at one week, 7/21 at four weeks in rats with SCI, 21/21 at all weeks for Sham-SCI), indicating impairment of hindlimb function. While there was only any acute decrease in fecal pellet output during the first week after injury, rats with SCI could still elicit increased fecal pellets in response to WAS, suggesting that a connection between the brain and gut could be stimulated by stress despite the SCI. Assessment of colonic sensitivity measured by the visceromotor

response following T10 SCI was not possible due to the lack of hindlimb control. **Conclusions:** We demonstrated that stress-induced colonic motility was maintained following SCI, suggesting that some brain-gut connections can be remodeled to promote GI function following SCI. These finding support further studies using central modulation as a potential option for restoring GI function in in veterans with SCI.

Title: Noninvasive measurement of gastrointestinal motility following spinal cord injury in pigs

Authors: *R. U. AHMED[1], **C. A. KNIBBE**[1], F. WILKINS[1], J. ETHRIDGE[1], M. V. VADHANAM[1], C. M. MOORMAN[1], M. L. MORGAN[1], S. E. DAVISON[2], L. C. SHERWOOD[2], S. S. BARVE[3], D. R. HOWLAND[1], J. SEMLER[1], T. L. ABELL[3], M. BOAKYE[1];

Abstract: Autonomic nervous system disruptions after SCI (spinal cord injury) lead to severe gastrointestinal (GI) dysfunction that directly impact quality of life and chronic morbidity. The SmartPill™ (Medtronic, MN) is a novel, non-invasive tool that actively transmits pH, temperature, and pressure when ingested. We administered the Smartpill™ with normal diet in three pigs that underwent direct T10/T11 SCI impact with contusion from a 10cm drop height to assess feasibility of the SmartPill as a tool to assess GI functionality. Pigs were administered the SmartPill™ with a regular diet, both before injury and at two and six weeks post-injury. Tributyrin, a triglyceride reported to influence the gut microbiome and improve gut dysbiosis, was administered to pigs 1 and 2 post-injury. Gastric Emptying Time (GET), Colon Transit Time (CTT), Small Intestine Transit Time (SITT), antrum maximum pressure (AMP), and minimum pH (min pH) were recorded by MotiliGI®software and analyzed. We observed the following pre-injury transit times in animals 1 and 2, respectively: GETs of 4:06:30 and 7:21:10 and CTTs of 19:55:55 and 17:27:30. We observed the following times at two weeks post-injury in animals 1, 2, and 3, respectively: GETs of 12:06:35, 99:07:37, 8:36:10 and CTTs of 21:58:18, 26:25:03, and 18:08:05. At six weeks post-injury, we recorded the following times in animals 1, 2, and 3, respectively: GETs of 6:58:00, 8:13:51, and 8:41:40 and CTTs of 36:29:15, 22:00:27, and 86:13:05. We observed pre-injury min gastric pHs of 0.4 and 0.3, 2-week post-injury min gastric pHs of 0.5, 0.3, 0.2 and 6-week post-injury min gastric pHs of 0.5, 0.5, 0.3 in pigs 1, 2, and 3, respectively. We also noted pre-injury AMPs of 13451.92 and 8624.08, 2-week post-injury AMPs of 7204.76, 5920.24, and 11208.56, and 6-week pressures of 12609.13, 5928.46, and 7358.97 mmHg*sec for pigs 1, 2, and 3, respectively. These

findings suggest delays in GETs and CTTs post-injury but have minimal impact in SITTs or on minimum gastric pH. The prolonged GET and CTT can influence absorptive capacity in the gut, though it is unclear with the addition of Tributyrin how absorption is influenced and further studies are needed. The min gastric pHs indicate there is no notable changes in gastric acid secretion, though upper duodenal pH due to the interplay of bicarbonate and acid secretion is still of interest. There are decreases in AMP after injury, which could indicate autonomic dysfunction of the pyloric sphincter. These preliminary results support the utility of the Smartpill™ in pigs to assess GI function by reliably collecting metrics that accurately reflect post-injury conditions.

Title: The changes in systemic monocytes in humans undergoing surgical decompression for degenerative cervical myelopathy may influence clinical neurological recovery

Authors: *P. VIDAL VERA[1,2], A. ULNDREAJ[3], L. TETREAULT[4], J. HONG[2], M. FEHLINGS[2]; [1]Univ. Catolica De La Santisima Concepcion, Concepcion, Chile; [2]UHN, Div. of Genet. & Development, Krembil Neurosci. Ctr. and Spine Program, Canada, ON, Canada; [3]UHN, Div. of Genet. & Development, Krembil Neurosci. Ctr. and Spine Program, Canada, ON, Canada, Canada, ON, Canada; [4]Grad. Entry Medicine, Univ. Col. Cork, Ireland, Ireland

Abstract: Background: Degenerative cervical myelopathy (DCM) is the most common cause of non-traumatic spinal cord injury worldwide. Surgical decompression is recommended as the preferred treatment strategy for DCM as it halts disease progression and improves neurologic symptoms. We previously demonstrated that neuroinflammation, including monocytes, plays a critical role in the pathobiology of DCM and in ischemic-reperfusion injury (IRI) following surgical decompression. Monocytes are able to enter the spinal cord and brain tissues due to damage to the blood spinal cord and blood brain barrier following injury. Studies have demonstrated that stroke patients and individuals undergoing hip replacement surgery have increased systemic levels of monocytes. Additionally, changes in the signalling responses of monocytes are associated with post-surgical recovery or with ischemic neural tissue damage. Herein, we investigated the role of systemic monocytes as a predictive biomarker for clinical recovery following decompressive surgery for DCM. **Findings:** There was a 2-fold increase in the number of monocytes in DCM patients at 24 h following decompression as compared to baseline levels, which was associated with a significant improvement in the modified Japanese Orthopedic

Association scale (mJOA) at 6-months after surgery ($p < .0001$). In a mouse model of DCM, depleting acute monocytes reduced the non-classical ($Ly6C^{low}$) subset from circulation ($p < .05$) and resulted in a 1.8-fold increase in CD11b expression in the spinal cord at 5 weeks following decompression. Acute monocyte depletion was accompanied by a modest decline in long-term overground locomotion, as evidenced by significantly reduced hindlimb swing speed. **Conclusions:** This work demonstrated that decompressive surgery leads to an acute increase in peripheral monocytes in human DCM patients, which is modestly associated with clinical recovery. We anticipate that this work could contribute to the implementation of routine measurements of blood monocyte subsets, their activation state, and production of cytokines following decompressive surgery. This information could help to select perioperative anti-inflammatory treatments that can enhance the beneficial effects of decompressive surgery and reduce the incidence of post-operative complications, while avoiding a reduction in systemic monocytes.

Title: Urinary biomarkers in persons with chronic spinal cord injury

Authors: *S. KAPP[1], S. C. ASLAN[3,1], B. UGILIWENEZA[3,1], D. WANG[3,1], E. WYLES[3,1], K. JOHNSON[3,1], J. CAI[1,2], M. MERCHANT[2,1], T. CUMMINS[2,1], A. H. HERRITY[3,1];
[1]Kentucky Spinal Cord Injury Res. Ctr., [2]Dept. of Medicine, Div. of Nephrology and Hypertension, Univ. of Louisville, Louisville, KY; [3]Dept. of Neurolog. Surgery, Univ. of Louisville, Louisville, KY

Abstract: Neurogenic bladder dysfunction after spinal cord injury (SCI) results in involuntary bladder contractions and simultaneous contractions of the urinary sphincter, producing high internal bladder pressure, which can lead to urinary reflux into the kidney, potentially damaging the upper urinary tract. A loss of normal elasticity in the bladder results in poor compliance and is one of the greatest risk factors for long-term complications to the kidneys, such as hydronephrosis and renal failure. The inability to effectively empty the bladder also increases the risk of urinary tract infections (UTIs), which are the single most common secondary medical complication after SCI. Urinary proteomics can be used to investigate the intracellular molecular pathways perturbed after SCI and reveal the protein component directly reflecting the dysfunction of cells within the urinary tract. In the current study, a total of 22 participants (non-disabled, n=10; SCI, n=12) provided clean-catch second morning urine samples. Urine samples from those with SCI were collected midstream, via urethral catheterization. Quantitative proteomic analysis of urine samples was conducted with qualitative and quantitative LC-MS/MS approaches implementing a urine-modified Filter-Aided Sample Preparation (U-FASP) method. Up and downregulated proteins were measured in comparison with non-disabled (ND) controls. In total, 1314

urine proteins were identified and quantified using a strict 1% FDR (false discovery rate) cutoff and 2-peptide identification for further bioinformatics analysis. Informatic analysis using Metaboanalyst 5.0 and PANTHER classification revealed that urine immunoglobulin and calmodulin-related proteins were significantly upregulated in samples from individuals with SCI relative to ND controls. Immunoglobulins can play an important role in the body's immune response mechanisms to bacteria, such as from chronic UTIs. Importantly, urinary excretion of calcium binding proteins may be related to stone formation, which can be attributed to the alkaline pH of infected urine as well as due to chronic catheterization. The data indicated significant changes in the urinary protein concentrations of from individuals with SCI relative to controls, suggesting the potential presence of early biomarkers within urine samples. Since the majority of the urinary proteins are generated by the kidney, the diverse urinary composition provides a comprehensive view of the local and systemic physiology. Current studies are investigating differences in the urinary proteomic profile between those intermittently catheterizing versus those using suprapubic catheters.

Title: Evaluation of recombinant GABAergic cells releasing MVIIA in models of chronic pain in rats

Authors: K. LIEBMANN*, S. JERGOVA, M. HERNANDEZ, B. MARIN, D. QADIR, J. SAGEN; Univ. of Miami, The Miami Project, Miami, FL

Abstract: The underlying mechanisms of chronic pain are caused by pathophysiological processes within multiple pain signaling pathways. Clinical treatment of chronic pain is negatively affected by development of various side effects to pharmacological agents and often provides only moderate pain relief for many patients. Recombinant cell-based therapy provides a new avenue for the management of chronic pain because it can continually produce and secrete analgesic substances at local pain processing sites in the spinal cord.
Transplantation of GABAergic neuronal cells may restore the inhibitory potential in the spinal cord and replace dysfunctional interneurons. Grafted cells may also release analgesic peptides by means of genetic engineering to further enhance the benefits of a cell-therapy approach. The omega-conopeptide, MVIIA, an N-type Ca2+ channel blocker, was one of the earliest tested treatments for severe pain in animal models and is in clinical use marketed as FDA approved Prialt (Ziconotide). However, due to its poor penetration through the blood brain barrier it must be delivered intrathecally. The goal of this project is to develop transplantable recombinant GABAergic cells releasing MVIIA that can alleviate pain-like behavior following peripheral and spinal cord injury.

Rat models using chronic constriction of the sciatic nerve and spinal clip compression injury were used to induce chronic neuropathic pain. Male and female Sprague Dawley were tested weekly for the presence of tactile, cold and heat hypersensitivity. Rat embryonic E14 neuronal progenitors were harvested from medial ganglionic eminence and transfected with p_lenti_MVIIA. Their viability, proneuronal phenotype, and the ability to release recombinant MVIIA were confirmed via immunostaining and FLISA analysis. Recombinant and control cells were intraspinally injected into animals when signs of chronic pain were detected.
An analgesic effect of the transplant treatment was observed in both pain models in both sexes, with a stronger and longer lasting outcome in the recombinant group compared with non-recombinant control neural progenitor cells. Conditioned place preference with gabapentin revealed significant reduction of ongoing pain in animals with the grafts. Inflammatory biomarkers Iba-1, IL1-β, and TNF-α were reduced in treated animals compared to controls. The recombinant cells were detected up to 1 mm distance from the injection site. FLISA analysis confirmed the presence of MVIIA in the spinal homogenate.
Our results demonstrate the beneficial and targeted effect and potency of recombinant cell-based therapy in the management of chronic pain.

Title: Sex and dose-dependent antinociceptive effects of the JNK (c-Jun N-terminal kinase) inhibitor SU 3327 are mediated by CB_2 receptors in female, and CB_1/CB_2 receptors in male mice in an inflammatory pain model

Authors: *J. GUINDON[1], M. MCHANN[2], H. BLANTON[1];
[2]Pharmacol. and Neurosci., [1]Texas Tech. Univ. Hlth. Sci. Ctr., Lubbock, TX

Abstract: Activation of c-Jun N-terminal kinases (JNKs) has been implicated in the development and persistence of inflammatory and neuropathic pain in animal models. Moreover, JNKs have been involved in the maintenance of chronic pain, as well as development of tolerance to antinociceptive agents in the opioid and cannabinoid class of compounds. In this study, we evaluated the antinociceptive effects of the JNK inhibitor SU 3327 (0.3 to 30 mg/kg) in the formalin pain model with an emphasis on the sex-specific actions of this compound. In wild-type C57BL6J mice, SU 3327 produced strong antinociceptive effects in the formalin pain model which were mediated by CB_2 receptors in females, and both CB_1 and CB_2 receptors in males. SU 3327 at a dose of 10 mg/kg produced antinociception, hypothermia, motor impairment, and hypolocomotion to a similar extent in both males and females. The antinociceptive effects of SU 3327 were more potent in males at lower doses (1 and 3 mg/kg), however hypothermia,

motor impairment and hypolocomotion were absent in both sexes at this lower dose range. Analysis of spinal cords, using qPCR following SU 3327 administration in the formalin test, revealed changes in cannabinoid, tolerance and inflammatory markers in females only, and only in the high (10-30 mg/kg) doses conditions. Indeed, females shown increase in mRNA levels of cannabinoids (CB_2), but a decrease in tolerance (β-arrestin 1) and inflammatory (TNF-α, IL-1β, IL-6)-associated markers. The differences between males and females, in this study, support sex as an important factor in nociception and antinociceptive responses mediated by JNK and the endocannabinoid system.

Title: Spinal dopaminergic D1-like receptors contribute in a sex-dependent manner to fibromyalgia-like pain in rats

Authors: *Y. DE LA LUZ-CUELLAR[1], F. MERCADO[2], V. GRANADOS-SOTO[1];
[1]Ctr. De Investigación Y De Estudios Avanzados, Ciudad DE Mexico, Mexico; [2]Dirección de Investigaciones en Neurociencias, INPRFM, Ciudad de Mexico, Mexico

Abstract: Fibromyalgia (FM) is a chronic widespread pain syndrome that mainly affects women. It is believed that reduced serotonin, noradrenaline and dopamine (DA) levels in serum and cerebrospinal fluid in FM patients leads to an aberrant transmission of nociceptive stimuli. Activation of D2-like receptors in spinal cord produces antinociceptive effects while stimulation of D1-like receptors is related to pronociceptive effects in inflammatory and neuropathic pain models. However, the role of spinal DA receptors in FM-like pain is unknown. Moreover, gonadal hormones are known to drive sex differences in chronic pain. The aim of this study was to investigate the role of spinal DA receptors and their possible sex-dependent modulation in a reserpine-induced model of FM in rats. FM-type pain was induced by reserpine (RES) injections (1 mg/kg, s.c. for 3 days) in adult female and male Wistar rats (n=6). Tactile allodynia and muscular hyperalgesia were assessed with Von Frey filaments and the Randall-Selitto test, respectively. RES-treated rats were intrathecally (i.t.) injected with the D2-like receptor agonist pramipexole (15 nmol), or the D1-like receptor antagonist SCH-23390 (30 nmol). To study a possible hormonal influence over DA receptors function, estrous cycle of reserpinized rats was monitored by vaginal smears before drug injection so they were divided in two groups: high 17β-estradiol (E2, proestrus and estrous) and low E2 (metestrus and diestrus). In addition, we injected RES in ovariectomized (OVX) rats and reconstituted them with E2 24 h before the treatment with dopaminergic drugs. To further confirm the influence of E2, another group of OVX reserpinized rats were i.t, injected with estrogen receptor α (ERα) inhibitor MPP before the treatment with drugs. RES produced tactile allodynia and muscle hyperalgesia 5 and 7 days after last injection, respectively, in male and female rats.

I.t. injection of SCH-23390 and pramipexole had a small antinociceptive effect on male rats but reversed RES-induced nociceptive behaviors in female rats. Both drugs showed a greater antiallodynic effect in rats with high E2 compared to those with low E2. Accordingly, ovariectomy depleted SCH-23390-induced antiallodynic effect whereas that systemic reconstitution with E2 restored it. MPP treatment, but not vehicle, blocked E2-restored antiallodynic effect of SCH-23390, suggesting that its anti-nociceptive effect depends on E2-induced ERα signaling. Results suggest that spinal D1-like receptors contribute in a sex-dependent manner to the nociceptive hypersensitivity induced by RES in rats. Moreover, the pronociceptive D1-like receptors function is modulated by E2.

Title: Influence of sex on ACEA antinociception in inflammatory and chronic pain models

Authors: *H. DE SELLE, C. L. DANCEL, M. C. MCHANN, H. BLANTON, J. GUINDON; Pharmacol. and Neurosci., Texas Tech. Univ. Hlth. Sci. Ctr., Lubbock, TX

Abstract: Inflammatory and chronic pain continues to be a common complication associated with patients. Currently, sex differences and its connection to the endocannabinoid system is an ongoing focus of preclinical and clinical research. Indeed, there is evidence that pain, response to analgesics and tolerance is influenced by sex (Blanton et al., 2021). Cannabinoid (CB) receptor agonists are promising therapeutic agents in the alleviation of inflammatory and chronic pain. Selective activation of CB1 receptors via arachidonyl-2-chloroethylamide (ACEA) administration causes anti-nociception and reveals important sex differences in several rodent pain models. In this study, we investigated the dose and sex-dependent role of ACEA in alleviating inflammatory and chemotherapy-induced pain in male and female wild-type mice. In these experiments, we used the formalin test (2.5 % formalin intraplantar) to evaluate inflammatory pain and chemotherapy-induced peripheral neuropathy using cisplatin (5 mg/kg i.p.) as a chemotherapeutic agent. Our results demonstrate that there are sex differences in the response to ACEA alleviating inflammatory (formalin test) pain when used at different doses (between 0.1 - 1 mg/kg i.p.) in male and female WT mice. Furthermore, we evaluated the effect of ACEA on alleviating mechanical (Von Frey) and cold (acetone) allodynia induced by the chemotherapeutic agent cisplatin. We found that ACEA reverse mechanical and cold allodynia in both male and female WT mice. Our results also show that females developed tolerance faster than male. Indeed, females are tolerant to the antinociceptive effect of ACEA after 5 days whereas the males become tolerant after 8 days. Moreover, we also evaluated the oestrous cycle and found that ACEA disrupt the oestrous cycle toward the metestrus stage of the cycle. Taken together, our results suggest a clear interaction between sex, pain and analgesia. In order to shed light on these differences and better understand the mechanisms of action involved, we need to

scientifically recognize the importance of sex in influencing pain responses in order to develop better therapies and improve treatment of chronic pain in patients.

Title: Acea dose and sex dependent antinocicpetive effects in cisplatin induced peripheral neuropathy and changes in the estrous cycle

Authors: *M. MCHANN[1], H. BLANTON[1], I. CASTRO-PIEDRAS[2], J. GUINDON[2];
[1]Pharmacol. and Neurosci., Texas Tech. Univ. Hlth. Sci. Ctr., Lubbock, TX; [2]Pharmacol. and Neurosci., Texas Tech. Hlth. Sci. Ctr., Lubbock, TX

Abstract: Introduction: Chemotherapy induced peripheral neuropathy (CIPN) is a chronic painful experience that has minimal treatment options. Cannabinoids have shown great promise for future treatment of CIPN. Sex differences in pain have been demonstrated by numerous studies and are also found during treatment with cannabinoids (Blanton et al., 2020). In this study, we used S426A/S430A mutant knock in mice. These mice have a mutation at the CB1 receptor for GRK and β-arrestin, showing delay in tolerance to cannabinoids. The 426 and 430 serines are turned into alanines preventing GRK from phosphorylating CB1, therefore the CB1 receptor is not desensitized as quickly.**Methods**: The objective of our current work is to find the efficacy of three different doses of the CB_1 selective agonist ACEA (0.25mg/kg- 0.75mg/kg) in alleviating chemotherapy-induced peripheral neuropathy using cisplatin (5mg/kg i.p.) in KI (S426A/S430A) male and female mice, which was administered once a week for four weeks. Mechanical and cold allodynia was evaluated with the von Frey and acetone tests respectively in S426A/S430A mutant knock-in mice. The sex differences were evaluated at the different doses of ACEA in respect to efficacy and tolerance. Additionally, we evaluated vaginal smears of the vehicle cisplatin females and the 0.75mg/kg females to see if ACEA interfered with the normal estrous cycle of the female mice. **Results**: We found that all doses of ACEA had an anti-nociceptive affect in both males and females, with 0.25 mg/kg showing a partial reversal of neuropathy and 0.5 mg/kg - 0.75 mg/kg showing full reversal of neuropathy. However, mechanical allodynia demonstrated sex differences in tolerance; the 0.25mg/kg dose showed that females developed tolerance two days before the males, the 0.5mg/kg and 0.75 mg/kg dose showed that females developed tolerance three days before the males. The cold allodynia also demonstrated sex differences in the development of tolerance to ACEA, with the 0.25mg/kg dose females developing tolerance two days before the males, the 0.5 mg/kg dose females developing tolerance one day before the males and the 0.75mg/kg females developing tolerance three

days before the males. **Conclusions**: In this study, we demonstrated that ACEA is effective at alleviating partially (low dose) or completely (high doses) chemotherapy-induced peripheral neuropathy at three different doses (0.25mg/kg- 0.75mg/kg) in S426A/S430A mutant mice. Sex differences in response to cannabinoids is demonstrated by ACEA since females develop tolerance to mechanical and cold allodynia faster than males and there is changes oestrous cycle with a predominance of the metestrus-diestrus phases.

Title: Urinary volatiles from pregnant mice produce stress-induced analgesia in male mice

Authors: L. V. LIMA[1], S. ROSEN[1], C. CHEN[1], R. NEJADE[1], M. ZHAO[1], E. TOPRAK[1], S. N. TANSLEY[1], **A. S. ZUMBUSCH**[1], S. SOTOCINAL[1], J. MOGIL[2];

Abstract: Stressors in the laboratory environment have a significant impact on the reproducibility of experiments. While testing mice for pain sensitivity, we observed that male mice being tested in the same room as pregnant females had elevated pain thresholds (hypoalgesia). Here we show that this hypoalgesia is a stress-induced olfactory-mediated phenomenon that is testosterone dependent. The olfactory chemosignal is mediated by volatile compounds found in the urine of pregnant and lactating female mice and that the compounds alone, even without an actual female mouse, can produce stress and stress-induced hypoalgesia. Chemical and behavioural testing of the specific compounds elevated in the urine of pregnant female mice revealed that *n*-pentyl-acetate, banana odorant, produced a concentration-dependant increase in hypoalgesia and plasma corticosterone levels. This olfactory cue likely signals potential female aggression aimed at preventing attacks from stranger males. Research examining rodent chemosignaling has primarily focused on the effects of such signalling from male-to-female or female-to-female mice and how olfactory signals relate to sexual behaviours. Thus, the results presented here represent a novel female-to-male chemosignal, mediated by a urinary volatile, that is important both as a finding in and of itself and as a consideration for avoiding experimental confounds in preclinical research.

Title: Chemokine CCL2 prevents opioid-induced inhibition of nociceptive synaptic transmission in spinal cord dorsal horn

Authors: *M. HELES, P. MROZKOVA, D. SULCOVA, P. ADAMEK, D. SPICAROVA, J. PALECEK;
Inst. of Physiology, Czech Acad. of Sci., Prague, Czech Republic

Abstract: Opioid analgesics remain widely used for acute and neuropathic pain treatment, despite serious side effects such as opioid tolerance and opioid-induced hyperalgesia (OIH). Increased levels of inflammatory chemokines such as C-C motif chemokine ligand 2 (CCL2) in the spinal cord dorsal horn and their interaction with μ-opioid receptors (MOR) may play a significant role in modulation of nociception and side effects development during pathological conditions. Here we report results suggesting the presence of crosstalk between CCL2, MOR, and transient receptor potential vanilloid 1 (TRPV1) receptors in the spinal cord dorsal horn. To study the modulation of acute opioid-induced depression of excitatory synaptic transmission by CCL2 and TRPV1 we used whole-cell patch-clamp recordings of miniature (mEPSC) and dorsal root stimulation-evoked excitatory postsynaptic currents (eEPSC) from superficial dorsal horn neurons in rat spinal cord slices. To investigate the modulation of opioid-induced analgesia in vivo we measured paw withdrawal latency (PWL) to thermal stimulation after intrathecal (i.t.) application of MOR agonist DAMGO ((D-Ala2,N-Me-Phe4,Gly-ol5)-enkephalin) (0.01 μg) and CCL2 (1.4 μg). DAMGO (1 μM) decreased frequency of mEPSC to 60.8 ± 4.0 % ($P<0.001$, n=16) and amplitudes of eEPSC to 33.0 ± 5.3 % ($P<0.001$, n=15) while induced increase of eEPSC amplitudes 15 minutes later in a subpopulation of recorded neurons (166.6 ± 21.5 %, $P<0.01$, n=9). CCL2 (10 nM) diminished the DAMGO-induced inhibition of mEPSC (82.4 ± 3.9 %, n=11) and eEPSC (97.4 ± 10.7 %, n = 11). Minocycline (100 μM), a commonly used inhibitor of microglial activation, attenuated the CCL2-induced effect on eEPSC amplitudes (56.4 ± 8.4 %, $P<0.001$, n=8). TRPV1 antagonist SB366791 (10 μM) prevented the delayed DAMGO induced increase of eEPSC (98.8 ± 16.3 %, n=9). In behavioral experiments, i.t. DAMGO application increased PWL (196.9 ± 12.5 %, n=5) and this thermal hyposensitivity was diminished by i.t. CCL2 injection before DAMGO (121.7% ± 10.2%, n=5). Minocycline (intraperitoneal, 45 mg/kg) prevented the effect of CCL2 on DAMGO induced analgesia. In conclusion, TRPV1 receptors may mediate the development of hypersensitivity described as OIH during opioid withdrawal. CCL2 diminishes the inhibitory effect of DAMGO on nociceptive synaptic transmission *in vitro* and analgesia *in vivo* and this effect is at least partially dependent on activation of microglia. Our results suggest that increased levels of cytokines during pathological conditions may lead to substantial attenuation of opioid-induced analgesia.

Title: Low frequency stimulation of TRPV1-expressing peripheral afferents enhances the excitability of spino-periaqueductal gray projection neurons

Authors: *C. L. BREWER, J. A. KAUER;
Dept. of Psychiatry and Behavioral Sci., Stanford Univ., Stanford, CA

Abstract: Inflammatory injury potentiates peripheral sensory neuron synapses onto spinal neurons projecting to the midbrain periaqueductal gray (spino-PAG PNs). Although this suggests that inflammation strengthens excitatory spinal input to the PAG, the output of spino-PAG PNs after peripheral inflammatory injury has not been examined in depth. Investigating C fiber-induced action potential (AP) firing in spino-PAG PNs can reveal how inflammatory injury affects the output of these neurons to the PAG, a region critical to pain processing. To stimulate C fibers, we used 3-6 week old male and female mice expressing Cre recombinase driven by expression of TRPV1 gene, which is expressed in virtually all C fibers, and Cre-dependent channelrhodopsin. Spinal PNs were retrogradely labeled from the dorsal/lateral PAG using diI. We performed whole-cell patch-clamp recordings in spino-PAG PNs using a semi-intact spinal cord preparation. Current-clamp recordings included spontaneous activity—and intracellular current injections to measure AP threshold and evoked firing. Stimulation of TRPV1-expressing (TRPV1+) peripheral afferents induced burst firing in virtually all spino-PAG PNs sampled. Inflammation increases the spontaneous firing rates of nociception-associated C fibers to 1-2 Hz; therefore, we used low frequency stimulation (LFS; 1 ms 470 nm LED pulses at 2 Hz for 2 mins) to replicate inflammatory injury. LFS induced a long-lasting (at least 20 min) increase in the number of APs within a C fiber-induced burst (n=10, p=0.029), rise in the frequency of synaptically evoked afterdischarge (n=10, p=0.0004), and decrease in intraburst afterhyperpolarization (n=10, p=0.037). Furthermore, LFS induced a transient membrane depolarization (n=12, p<0.0001). These LFS-induced effects may be dependent on G protein signaling, as they were blocked using GDPβs in the intracellular solution. Finally, these effects may in part be driven by altered intrinsic excitability in spino-PAG PNs—as the AP threshold (measured via intracellular current injection) decreased after LFS (n=14, p=0.015). However, LFS had no effect on the membrane potential, spontaneous firing frequency, or evoked firing frequency of spino-PAG PNs. Taken together, these results suggest that LFS increases G protein-dependent TRPV1+ afferent-induced excitability in spino-PAG projection neurons, likely leading to a lasting increase in the activation of supraspinal PAG circuits.

Title: Interleukin-1beta attenuates mechanical allodynia and GluN1 phosphorylation in a murine model of neuropathic pain: involvement of sigma-1 receptor

Authors: *S.-R. CHOI[1,2], H. HAN[2], A. J. BEITZ[3], J.-H. LEE[2];
[1]Dept. of Pharmacol., Catholic Kwandong Univ. Col. of Med., Gangneung, Korea, Republic of; [2]Dept. of Vet. Physiol., Col. of Vet. Med. and Res. Inst. for Vet. Science, BK21 Plus Program for Creative Vet. Sci. Research, Seoul Natl. Univ., Seoul, Korea, Republic of; [3]Dept Vet & Biomed Sci., Univ. of Minnesota Col. of Vet. Med., Saint Paul, MN

Abstract: The sigma-1 receptor (Sig-1R) plays an important role in spinal pain transmission by increasing phosphorylation of the *N*-methyl-D-aspartate (NMDA) receptor GluN1 subunit (pGluN1). As a result Sig-1R has been suggested as a novel therapeutic target for prevention of chronic pain. Here we investigated whether interleukin-1β (IL-1β) modulates the expression of the Sig-1R in spinal astrocytes, and whether this modulation affects the development of central sensitization and neuropathic pain following chronic constriction injury (CCI) of the sciatic nerve. Repeated intrathecal (i.t.) administration of IL-1β from days 0 to 3 post-surgery significantly reduced the increased pGluN1 expression at the Ser896 and Ser897 sites in the ipsilateral spinal cord, as well as, the development of mechanical allodynia and thermal hyperalgesia in the ipsilateral hind paw of CCI mice, which were restored by co-administration of IL-1 receptor antagonist with IL-1β. Sciatic nerve injury increased the expression of Sig-1R in astrocytes of the ipsilateral spinal cord dorsal horn, and this increase was suppressed by i.t. administration of IL-1β. Agonistic stimulation of the Sig-1R with PRE084 restored pGluN1 expression and the development of mechanical allodynia that were originally suppressed by IL-1β in CCI mice. Collectively these results demonstrate that IL-1β administration during the induction phase of neuropathic pain produces an analgesic effect on neuropathic pain development by controlling the expression of Sig-1R in spinal astrocytes.

Title: Slc7a5 (Lat1) inhibition alleviates neuropathic pain in rodent models

Authors: *S. R. A. ALLES[1], A. E. GOINS[1], K. GOMEZ[2], M. AFAGHPOUR-BECKLUND[1], M. MONTERA[1], A. MOUTAL[2], R. KHANNA[2];
[1]Dept. of Anesthesiol. and Critical Care Med., Univ. of New Mexico Sch. of Med., Albuquerque, NM; [2]Pharmacol., Univ. of Arizona, Tucson, AZ

Abstract: High-impact chronic pain is suffered by 1 in 5 patients in the US and globally. Effective, non-addictive, non-opioid therapeutics are urgently needed for the treatment of chronic pain. Slc7a5 (Lat1), also known as system L-neutral amino acid transporter, is involved in a number of physiological processes related to inflammation. Transcriptomics studies have shown that Slc7a5 and its binding partner Slc3a2 are expressed in neurons of the dorsal root ganglia (DRG) and spinal dorsal horn, which are critical to the initiation and maintenance of nociception and pathophysiology of chronic pain. In addition, Slc7a5 is a transporter for the first-line anti-allodynic gabapentinoid drugs and binds to ion channels implicated in nociception and chronic pain including the voltage-gated sodium channel Nav1.7 and the voltage-gated potassium channels Kv1.1 and Kv1.2.
Our preliminary data show that blocking Slc7a5 with intrathecal or intraperitoneal administration of the drug JPH203 alleviates allodynia in the spared nerve injury (SNI) rodent model of neuropathic pain. Western blot studies show an increase in Slc7a5 protein levels in the spinal cord of SNI mice compared to naïve mice and a reduction in mice treated with an anti-allodynic drug. We performed whole-cell electrophysiology from small (<30 µm) cultured DRG neurons from SNI mice and established that excitability of neurons was reduced following JPH203 treatment in agreement with its behavioral effects. We also showed that JPH203 reduces peak tetrodotoxin-resistant (TTX-R) sodium current recorded from naïve rat DRG neurons. These results demonstrate that Slc7a5 is dysregulated in chronic neuropathic pain and can be targeted to provide relief of hypersensitivity.
Therefore, Slc7a5 is a promising target for neuropathic pain. Future work will involve the design of more selective Slc7a5 inhibitors for chronic pain and screening using human/human-derived neurons.

Abstract: Deep brain stimulation (DBS) is a promising therapy for various neurological disorders, and many available devices for DBS can operate in both an open- and closed-loop mode. Using a closed-loop protocol mitigates many drawbacks of open-loop stimulation. We offer a practical guide for the implementation of a closed-loop DBS system, using examples from patients with chronic pain. Focusing on two research devices from Medtronic, the Activa PC+S and Summit RC+S, we provide details on the steps involved in closed-loop programming from a clinician's perspective. These devices contain many adjustable parameters that control how the closed-loop system operates, and these often require a combination of empirically and clinically informed decision making to optimize. As such, we provide an example of combining our understanding of chronic pain with data-driven heuristics in the context of selecting some of the most significant parameters. Additionally, we discuss other practical considerations that a clinician must be aware of when programming a closed-loop device.

Title: Antinociceptive effects of α_2/α_3-selective $GABA_A$ receptor positive allosteric modulators on opioid-induced hyperalgesia

Authors: *K. L. WOODHOUSE[1], J. M. COOK[2], J.-X. LI[1];
[1]Pharmacol. & Toxicology, Univ. at Buffalo, Buffalo, NY; [2]Univ. of Wisconsin-Milwaukee, Milwaukee, WI

Abstract: Opioids have been increasingly prescribed to treat chronic pain since the 1980s, despite evidence that long-term use of opioids may lead to tolerance and pain sensitization called opioid-induced

hyperalgesia (OIH). OIH has been demonstrated in both preclinical models and healthy human volunteers, but is understudied and there is need for novel analgesics capable of mitigating OIH. α_2/α_3-selective $GABA_A$ receptor positive allosteric modulators (PAMs) act specifically at subunits of the $GABA_A$ receptor found to mediate analgesia, and have demonstrated antinociceptive effects in models of chronic inflammatory and neuropathic pain. However, the efficacy of these compounds at relieving opioid-induced pain hypersensitivity have not yet been investigated. This study systematically examined the antinociceptive effects of α_2/α_3-selective $GABA_A$ receptor PAMs alone and in combination with acetaminophen in an OIH rat model wherein repeated treatment with the opioid fentanyl induces mechanical hyperalgesia. The von Frey test was used to measure mechanical nociception. Duration of actions of α_2/α_3-selective $GABA_A$ receptor PAMs (KRM-II-81, NS16085, HZ-166) alone were studied, and combinations of KRM-II-81 and acetaminophen were also studied at fixed ratios (1:1, 1:3, 3:1). Dose-addition analysis was used to assess the antinociceptive interactions between KRM-II-81 and acetaminophen. α_2/α_3-selective $GABA_A$ receptor PAMs were able to fully reverse mechanical sensitivity caused by OIH. Furthermore, KRM-II-81/acetaminophen combinations produced additive to supra-additive interactions depending on the drug mixture ratios. These findings support the idea that α_2/α_3-selective $GABA_A$ receptor PAMs could serve as novel analgesics for treating OIH, and may interact favorably with other non-opioid analgesics.

Title: Select Androgen Receptor Modulator Microparticles Reverses Pain in Mouse Model of Chronic Widespread Muscle Pain

Authors: *J. LESNAK[1], D. S. NAKHLA[2], A. K. SALEM[2], K. A. SLUKA[1];
[1]Physical Therapy and Rehabil. Sci., [2]Pharmaceut. Sci. and Exptl. Therapeut., Univ. of Iowa, Coralville, IA

Abstract: Currently, there is a need for the generation of non-opioid analgesics for treating chronic pain. Preclinical and clinical studies demonstrate the analgesic effects of testosterone. However, treatment with testosterone is not clinically feasible due to unwanted adverse effects. Select androgen receptor modulators (SARM) have been developed to overcome these limitations by selectively activating androgen receptors associated with anabolic effects while minimizing androgenic effects. The purpose of the current study was to develop a SARM-loaded microparticle formulation with a long-term release profile and test its efficacy in a preclinical model of chronic muscle pain. Chronic muscle pain was induced by 2 intramuscular injections of acidic saline (20µl, pH 4.0±0.1) into one gastrocnemius muscle 5

days apart in C57/BL6J male and female mice. Muscle withdrawal thresholds (MWT) were assessed with force sensitive tweezers applied to the gastrocnemius muscle before and weekly for 4 weeks after induction of the model. Efficacy of the SARM ((s)-3-(4-cyanophenoxy)-n-(4-cyano-3-(trifluoromethyl)phenyl)-2-hydroxy-2-methylpropanamide) was tested by daily systemic injections of the drug dissolved in vehicle (25mg/kg, s.c.) or 2 injections of SARM loaded into Poly(lactic-*co*-glycolic acid) (PLGA) microparticles (200mg, s.c.; 24h, 1wk) and compared to vehicle. Drug release profiles from the SARM microparticle formulation were assessed both in vitro and in vivo via HPLC-UV. To test for safety, liver and cardiac toxicity was analyzed from serum samples from animals receiving SARM microparticle or its vehicle. Statistical analysis for MWT was performed with repeated measures ANOVA. Daily systemic administration of SARM reversed the decreased MWT bilaterally ($p<0.01$) when compared to vehicle. Similarly, 2 injections of the SARM microparticle formulation reversed the decreased MWT in the gastrocnemius muscle bilaterally ($p<0.02$) when compared to vehicle. In vitro release studies showed SARM was steadily released from microparticles for up to 4 weeks. In vivo pharmacokinetics studies in mice detected SARMs in the systemic circulation for up to 5 weeks following a single SARM microparticle injection. Toxicity panels revealed no adverse effects of SARM microparticle treatment. The current study shows that SARMs can relieve muscle pain with daily administration. Long-term relief was observed with SARM microparticles with two injections, thus increasing its clinical utility. Future work will test SARM effectiveness in other pain models and clinical populations.

Title: Suvn-1301102, preclinical pharmacokinetic and pharmacodynamic profiling of a p2x7 receptor antagonist

Authors: V. GOURA, *V. PALACHARLA, R. KALLEPALLI, N. ASHTIKAR, V. MEKALA, N. MUDDANA, L. GUTTIKONDA, A. DAS, S. RAVELLA, A. MOHAMMED, P. JAYARAJAN, R. NIROGI;
Suven Life Sci. Ltd, Hyderabad, India

Abstract: Purine receptors play roles in peripheral and central sensitization, and are associated with neuropathic pain. Among all purine receptors, the P2X7 receptors (P2X7R) are well-defined therapeutic target for inflammatory and neuropathic pain. P2X7 receptors are widely expressed by several cell types involved in pain transmission, including the neurons, microglia, satellite glial cells and astrocytes located in the dorsal root ganglia, the trigeminal ganglia, and in the dorsal horn of the spinal cord. Existing P2X7 receptor antagonists are marred with low *in vitro* potency, poor pharmacokinetic properties and inadequate brain penetration. Herein, we describe the *in vitro* efficacy, pharmacokinetics and *in vivo* efficacy of SUVN-1301102. *In vitro* evaluations suggested SUVN-1301102 is a potent P2X7antagonist.

Pharmacokinetic evaluations carried out in male Wistar rats suggested good bioavailability with excellent brain penetration. SUVN-1301102 was evaluated for analgesic activity in neuropathic pain models such as streptozotocin (STZ) induced diabetic neuropathic pain (DNP) and chronic constriction induced (CCI). Paw withdrawal thresholds were evaluated using Vonfrey filaments. SUVN-1301102 showed significant increase in paw withdrawal thresholds at all the tested time points, when compared to vehicle group. SUVN-1301102 showed analgesic like activity in the rodent models. Further, SUVN-1301102 was evaluated in rota rod task for motor coordination. In this assay, SUVN-1301102 did not show decrease in latency to fall. Additional efficacy and safety profiling for this compound and similar compounds from this series is currently in progress.

Title: Terpenes from Cannabis sativa induce anti-nociception in chemotherapy-induced peripheral neuropathy (CIPN) via activation of the adenosine A2a receptor

Authors: *A. SCHWARZ[1], A. I. KERESZTES[2], J. M. STREICHER[2];
[2]Pharmacol., [1]Univ. of Arizona, Tucson, AZ

Abstract: The terpenes α-Humulene, β-Pinene, Linalool, β-Caryophyllene (BCP), and Geraniol are found in medium to high quantities in *Cannabis sativa*. We have observed that when administered, these terpenes elicit decreased pain response and antinociception in mice and have the potential to be used as therapeutic agents for pain relief. Previous work from our lab suggests these terpenes activate cannabinoid receptor 1 (CBR1) and adenosine receptor A2a (A2a). However, it is not clear if these ligands will produce pain relief in chronic pain models. We thus induced chemotherapy-induced peripheral neuropathy in male and female CD-1 mice by injection of paclitaxel (2 mg/kg, days 1-7). We measured mechanical allodynia using Von Frey filaments. The terpenes geraniol, linalool, α-humulene, β-pinene and BCP were injected at a 200 mg/kg dose IP on day 8, with the role of the CB1R and A2a tested

by pre-treatment with the CB1R inverse agonist rimonabant (10mg/kg, IP), the A2a antagonist istradefylline (3.2-10mg/kg, IP), or vehicle control. All terpenes produced robust acute anti-nociception in the CIPN model; mice treated with the CB1R inverse agonist rimonabant showed no significant difference in mechanical sensitivity to vehicle treated animals for any of the terpenes. This suggests no CB1R involvement in this pain model. However, istradefylline treatment partially or fully blocked β-Pinene, BCP, and Geraniol anti-nociception for both lower (3.2mg/kg) and higher (10mg/kg) doses. This suggests that the terpenes β-Pinene, BCP and Geraniol activate A2a receptors to contribute to anti-nociception in CIPN, while all terpenes produce anti-nociception in this pain model. We plan to confirm the action of the terpenes of interest on A2a receptors using a CRISPER-Cas9 Adenosine A2a knock down in the chronic pain CIPN model. These findings suggest that terpenes could be efficacious non-opioid, non-cannabinoid treatments for chronic pain, and further suggest specific receptor mechanisms in different pain models.

Title: Targeting two-pore-domain potassium channels by mechanical stretch instantaneously modulates action potential transmission in mouse sciatic nerves

Authors: *J. LIU[1], N. GANESHBABU[2], N. SHALABY[1], L. CHENG[1], T. GUO[1], B. FENG[1];
[1]Biomed. Engin., [2]Physiol. and Neurobio., Univ. of Connecticut, Storrs, CT

Abstract: Blocking action potential transmission in peripheral nerves effectively suppresses pain arising from the periphery without causing adverse off-target effects on the central nervous system. Despite centuries of research, the exact composition of ion channels that participate in action potential transmission in mammalian peripheral nerves remains undetermined. Recent reports indicate dominant roles of TRAAK and TREK-1 channels, i.e., mechanosensitive two-pore-domain potassium channels (K2P) at the nodes of Ranvier for action potential repolarization in mammalian peripheral nerves. Changes in peripheral nerve conduction by mechanical stretch were previously studied by recording compound action potentials, which lack the necessary resolution to detect the subtle neuromodulatory effects of mechanical stretch. In this study, we developed a novel in vitro approach that enables single-fiber recordings from individual mouse sciatic nerve axons while delivering computer-controlled stepped stretch to the sciatic nerve trunk. Axial stretch instantaneously increased the conduction delay in both myelinated A-fibers and unmyelinated C-fibers. Increases in conduction delay linearly correlated with

increases in axial stretch ratio for both A- and C-fibers. The slope of the increase in conduction delay versus stretch ratio was steeper in C-fibers than in A-fibers. Moderate axial stretch (14-19% of in vitro length) reversibly blocked 37.5% of unmyelinated C-fibers but none of the 8 myelinated A-fibers tested. Application of arachidonic acid, an agonist to TRAAK and TREK-1 to sciatic nerve blocks axonal transmission in both A- and C-fibers. Also, the application of an antagonist ruthenium red showed a tendency of suppressing the stretch-evoked increase in conduction delay. These results could draw focused research on pharmacological and mechanical activation of K2P channels as a novel neuromodulatory strategy to achieve peripheral nerve block.

Title: Deciphering spinal mechanisms of green light-induced antinociception: A step towards an innovative complementary pain therapy

Authors: *L. MARTIN, K. CHENG, S. WASHINGTON, T. KRANZ, A. PATWARDHAN, M. M. IBRAHIM;
Univ. of Arizona, Tucson, AZ

Abstract: Numerous studies have shown how light exposure benefits multiple conditions such as seasonal affective disorders, circadian rhythm dysregulations, and neurodegenerative diseases. However, little is known about its potential benefits in pain management. Postoperative pain severely impacts quality of life and functionality, especially in the elderly. While current pharmacologic methods of pain management are effective in many cases, the associated side effects in elderly patients can limit their use. Non-pharmacological methods could minimize drug reliance, facilitating a reduction of the opioid burden. Green light therapy has been shown to be effective in reducing chronic pain in both humans and rodents; however, the underlying mechanisms of this therapy remain incompletely defined. This study unveils the potential of green light exposure in combination with drugs commonly used in pain management. Through behavioral and pharmacological assays in a postoperative pain model in aged rodents, we have demonstrated that exposure to green light potentiates opioid- and NSAID-induced pain relief. This can ultimately minimize dose requirements to achieve antinociception. Furthermore, these results provided directions to delve into the underlying mechanisms of green light in the spinal cord. We have shown that green light increased spinal endogenous opioid release, concomitant with reduced spinal inflammation. Through 3D-modelling analyses of microglial morphology, we have shown that a 4-day exposure to green light resulted in changes demonstrating evidence for deactivation of these immune cells. Following exposure, microglia soma volumes decreased by 30% with simplified arborization, which is characteristic

of resting states. Consistent with this deactivation, TNFα levels were decreased in the cerebrospinal fluid of the rats. Altogether, these results shed light on the mechanisms of green light therapy and provide crucial information about its use in combination with other drug therapies. This evidence is the foundation for future complementary therapies that will reduce drug prescription and consumption alongside their side effects.

Title: In vivo profile and therapeutic potential of a CB1 positive allosteric modulator (ago-PAM)/CB2 agonist dualsteric ligand

Authors: *J. WIRT[1], S. GARAI[2], G. A. THAKUR[3], A. G. HOHMANN[4];
[1]Indiana Univ. Program in Neurosci., Bloomington, IN; [2]Pharmacol. Sci., [3]Dept. of Pharmaceut. Sci., Northeastern Univ., Boston, MA; [4]Indiana Univ., Bloomington, IN

Abstract: Identification of safe and effective therapies for pain remains an urgent medical need. Activation of cannabinoid CB1 and CB2 receptors suppresses pain in animal models. However, unwanted side effects of direct acting CB1 agonists limits therapeutic use. Both CB1 positive allosteric modulators (PAMs) and CB2 agonists alone have been shown to reduce chemotherapy-induced peripheral neuropathy (CIPN) in rodents without producing tolerance or physical dependence (Slivicki *et al*. (2018) *Biological Psych* 84, 722-733; Deng *et al*. (2015) *Biological Psychiatry* 77: 475-487). In this study, we asked whether GAT1102, which behaves as a dualsteric CB1 PAM/CB2 agonist in vitro, would suppress behavioral hypersensitivities produced in models of paclitaxel-induced neuropathy or incisional injury. We also evaluated whether receptor mechanism of GAT1102 anti-allodynic action would differ based upon the specific pathological pain state or route of drug administration. GAT1102 attenuated paclitaxel-induced mechanical allodynia following either intraperitoneal or intraplantar administration in mice. GAT1102 did not produce tolerance following once daily injections over 10 consecutive days. The observation of elevated pre-injection mechanical paw withdrawal thresholds provided evidence that anti-allodynic efficacy of GAT1102 was maintained 24 h following each prior injection. Mice were also challenged with either the CB1 antagonist AM251, the CB2 antagonist AM630 or the combination of both antagonists to ascertain the relative contributions of CB1 and CB2 receptors to GAT1102-induced therapeutic efficacy. CB1 ago-PAM properties appeared to dominate the in vivo profile of anti-allodynic

efficacy in the paclitaxel-induced neuropathy model. However, the combination of CB1 and CB2 antagonists fully reversed the anti-allodynic effects of GAT1102. GAT1102 also suppressed paclitaxel-induced allodynia following local injection into the paw, consistent with a peripheral antinociceptive mechanism. GAT1102 was also effective in suppressing mechanical allodynia induced by intraplantar incisional injury. Efficacy of GAT1102 in the incisional injury model was reversed by either AM251 or AM630 alone, as well as by the combination of AM251+AM630 mixture. These observations suggest that GAT1102 behaves as a dualsteric ligand, exhibiting anti-allodynic efficacy consistent with both CB1 positive allosteric modulation and CB2 agonism. This favorable therapeutic profile of GAT1102 is observed in the absence of cardinal signs of CB1 activation.

Res. & Develop., New Mexico VA Hlth. Care Syst., Albuquerque, NM

Abstract: Trigeminal neuropathic pain (TN) is a chronic pain condition that leads to a serious decline in quality of life with partial or no improvement from currently available treatments. Although not recommended, opioids are still prescribed to more than 40% of TN patients in the US, contributing to the opioid overdose crisis. Here, we investigated the role of the endogenous anti-opioid system mediated by cholecystokinin-B receptor (CCKBR) in TN. We hypothesized that CCKBR overactivity contributes to the nociceptive propagation in TN and that targeting CCKBR can serve as a novel efficacious non-opioid therapy for TN. Microarray gene expression profiling in an established mouse trigeminal nerve constriction model of TN revealed a 4.0- and 2.7-fold increase in CCKBR expression in the trigeminal ganglia (TG) on day 3 and day 21, respectively, after trigeminal nerve injury. Single-chain fragment variable (scFv) antibodies were generated as preferred non-opioid targeting therapy to block CCKBR. Engineered scFv antibodies feature binding affinity similar to monoclonal antibodies but increased tissue penetrability due to their smaller size. A mouse scFv antibody library recognizing a fifteen amino acid extracellular peptide fragment of the human CCKBR was generated from the immunized spleen.

Ribosome display was used for recombinant antibody selection and antibodies with high affinity, high specificity, superior stability, and solubility were developed further for *in vivo* and *in vitro* efficacy testing. A single intraperitoneal dose was given 3 weeks or 7 weeks after induction of trigeminal neuropathic chronic pain in mice. Mechanical and cold hypersensitivity was permanently reduced in both male and female mice through 10-12 weeks of testing. These preliminary data provide proof-of-concept that anti-CCKBR scFv improves the behavioral functionality in a murine TN model and support our hypothesis that CCKBR plays a role in nociceptive propagation in TN. To identify the mechanism of CCKBR-mediated analgesia, we investigated the expression of the μ-opioid receptor (MOR) and CCKBR in SH-SY5Y neuroblastoma cells using immunocytochemistry. MOR and CCKBR co-localized on the same neurons. These data support the notion that CCKBR may functionally antagonize endogenous MOR, thereby eliciting its pronociceptive effects. Our current work focuses on extending our mechanistic studies on the functional antagonism of MOR by CCKBR, and evaluating the feasibility of targeting CCKBR using an anti-CCKBR scFv as a novel efficacious non-opioid therapy in TN.

Title: Investigation of brain areas involved in delayed-action during olfactory tasks

Authors: *J. K. REINERT, S. LINDEMAN, S. NATH, I. FUKUNAGA;
Sensory and Behavioural Neurosci. Unit, Okinawa Inst. of Sci. and Technol., Onna, Japan

Abstract: Delayed actions, and the underlying neuronal activity that holds the information over time, are integral to behaviours across sensory modalities and typically involve higher cortical areas to achieve high task performance. However, it is not yet clear which anatomical regions are causally involved in rodents performing corresponding, odour-guided tasks. Here, we explored the involvement of several brain areas in mice performing a delayed-response task, discriminating binary odour mixtures of varying complexity.
We first sought to reveal two modes in which mice perform olfactory discrimination tasks, first, when

water arrives with a delay, and second, when reward arrives as soon as an action is taken. Towards this aim we first trained head-fixed mice to discriminate binary odour mixtures in a go/no-go paradigm with reward delivery occurring at a fixed delay of 3.5 seconds after offset of the 'go'-odour (mean reaction time 1436 ms, n = 25 mice). Upon reaching high discrimination accuracy, the timing of reward delivery was changed from this fixed delay to a variable delay, so that the reward was delivered as soon as mice licked on rewarded trials. This resulted in mice altering the onset of anticipatory licks to earlier time-points (mean change: -53.3%, n = 2 mice), similar to findings described for related go/no-go tasks and even classical conditioning experiments. Yet, when the delay was shortened but not under the animals' direct behavioural control, mice also altered the onset of anticipatory licks but to a lesser degree (mean reaction time 1063 ms, n = 16 mice vs. 730 ms, n = 13 mice; $H(3) = 17.3$, $p = 0.002$) Together this indicates that given no further incentive, mice will natively withhold reacting during a delay task.
To clarify which brain regions may maintain the odour-task related information during the delay period, we used *Vgat-Cre::Ai32* mice expressing the light-activated ion channel channelrhodopsin in GABAergic interneurons to selectively inhibit different brain regions during various timepoints of the delay phase. We found, that perturbing the activity in the anterior piriform cortex as well as in the ventral striatum altered the lick response of the mice significantly in a dose-dependent manner. In contrast, this was not observed when perturbing either the olfactory tubercle or the dorsal striatum activity.
Together our results indicate that olfactory-task related information is maintained not only in primary olfactory areas but may be distributed across brain regions at different stages throughout the delay period.

Title: Odor-evoked behavioral signal map in each olfactory cortex subarea: ventral tenia tecta, the nucleus of the lateral olfactory tract, and anterior cortical amygdaloid nucleus

Authors: *Y. TANISUMI[1,2], K. SHIOTANI[3], Y. OSAKO[1,2], T. OHNUKI[1,2], S. TAKAMIYA[1,2], J. HIROKAWA[1], Y. SAKURAI[1], H. MANABE[1];
[1]Grad. Sch. of Brain Science, Doshisha Univ., Kyoto, Japan; [2]Res. Fellow of the Japan Society for the Promotion of Sci., Tokyo, Japan; [3]Ritsumeikan Univ., Kyoto, Japan

Abstract: The olfactory cortex (OC), which consists of some distinct areas, receives both olfactory sensory signals from the olfactory bulb, and top-down signals from higher-order regions. It is unclear whether how each area of the OC codes for sensory and behavioral-related information from higher-order

regions. We specifically addressed this issue in rodents, especially focusing on three areas of the OC: the ventral tenia tecta (vTT), the nucleus of the lateral olfactory tract (NLOT), and anterior cortical amygdaloid nucleus (ACo). Here, our recent work has provided the first recordings of neuronal activity in the vTT, NLOT, and ACo of freely moving mice performing an odor-guided go/no-go task. First, we found some vTT neurons fired to both the go-cue and no-go-cue odor during the odor presentation phase without any preference for a particular cue odor. In contrast, many NLOT and ACo neurons showed cue odor selective responses. Second, we found neurons in the vTT NLOT, and ACo responded to not only the odor presentation phase but also the following odor-evoked behavioral scenes: the movement to the reward port, the waiting for the rewards, and the consumption of the rewards. Individual vTT neurons showed an excitatory response to a specific behavioral scene, with inhibitory responses relative to other scenes. On the other hand, NLOT neurons showed characteristic cue-associated behavioral responses: most of the go-cue preferred neurons excited during reward drinking behaviors. ACo neurons showed two types of odor-evoked anticipation signals: one neuron type exhibited gradual increases of activity toward reward delivery, while another type exhibited a phasic go cue-preferred activity during odor sampling as well as another phasic anticipatory activity for rewards. These results suggest that each area of the OC codes different sensory and behavioral-related signals. Finally, we anatomically elicited the possibility that the medial prefrontal cortex (mPFC)-to-vTT-to-OC pathway may be important as a candidate for the top-down input to the olfactory cortex. To test this hypothesis, we expressed inhibitory opsin Arch in the mPFC and recorded from vTT neurons with and without optogenetic inactivation of mPFC axons while head-fixed mice conducted the odor-outcome association task. Without mPFC-to-vTT inputs, the vTT state representations were degraded and less integrated. Taken together, our data suggest that vTT acts as a hub that sends context-dependent signals from the mPFC to broad olfactory areas.

Title: High-throughput sequencing of olfactory single neuron projections reveals non-random spatial organization

Authors: *Y. CHEN[1], X. CHEN[1], B. BASERDEM[3], H. ZHAN[1], Y. LI[2], M. DAVIS[1], J. M. KEBSCHULL[4], A. M. ZADOR[1], A. KOULAKOV[1], D. F. ALBEANU[1];
[1]Cold Spring Harbor Lab., Cold Spring Harbor, NY; [2]Cold Spring Harbor Lab., COLD SPRING HARBOR, NY; [3]Stony Brook Univ., Stony Brook, NY; [4]Johns Hopkins Sch. of Med., Baltimore, MD

Abstract: In most sensory modalities, neuronal connectivity reflects behaviorally relevant stimulus features, such as spatial location, orientation, and sound frequency. In contrast, the prevailing view of the olfactory system, based on reconstructions of dozens of neurons, is that it lacks structured connectivity, as suggested by reports of broad and distributed connections both from the olfactory bulb (OB) to the piriform cortex (PC) and within the cortex. These studies have inspired computational models of circuit function that rely on random connectivity. It remains, nonetheless, unclear whether the olfactory connectivity contains spatial structure. Here, we use high throughput methods (MAPseq and BARseq) to analyze the projections of 5,309 bulb (8 mice) and 30,433 piriform cortex (5 mice) output neurons in the mouse (C57BL6J, male, 8-10-week old) at single-cell resolution. Surprisingly, statistical analysis of this much larger data set revealed that olfactory connectivity is not random. We identify previously unrecognized spatial organization in connectivity along the anterior-posterior (A-P) axis of piriform cortex at 200 μm resolution. We find that both the bulb projections to the cortex and the piriform cortex outputs form orderly gradients along the A-P axis of piriform cortex. We further identify signatures of local connectivity within the piriform cortex. Specifically, we have uncovered a novel, but simple, principle of olfactory circuit organization and information processing: a triad. Thus, for example, a neuron in the olfactory bulb that targets the anterior portion of the piriform cortex likely also projects to the anterior olfactory nucleus (AON); and neurons in targeted (anterior) piriform locus complete the triad by also projecting to the AON. Moreover, the same triadic organization is replicated at different positions within the piriform cortex, along its anterior-posterior axis, for other functionally distinct targets, such as the cortical amygdala and lateral entorhinal cortex. The matched connectivity, reminiscent of residual neural networks (ResNet) architecture, enables parallel computations and further cross-referencing, since olfactory information reaches a given target region via both direct and indirect processing pathways. This triadic organization suggests that, as in other sensory modalities, olfactory information is routed at the earliest stages of processing in a coordinated manner to behaviorally appropriate targets.

Title: Gamma-synchronization enhances transmission of sensory information in the brain

Authors: T. DALAL, ***R. HADDAD**;
Bar Ilan Univ., Ramat Gan, Israel

Abstract: Although gamma-oscillatory activity is ubiquitous across brain areas, how it contributes to sensory processing and cognitive function remain unclear. We investigated this in the mouse olfactory system, where local GABAergic granule cells in the olfactory bulb shape mitral/tufted cell (MTC) excitatory output from the olfactory bulb to the piriform cortex. By optogenetically modulating granule cell activity, we managed to dissociate MTC gamma-synchronization from firing rates. Recording odour responses in downstream piriform cortex neurons, we found that increasing MTC gamma-synchronization enhanced cortical odour-evoked firing rates, reduced their response variability, and improved the odour ensemble representation. These changes occurred despite a reduction in MTC firing rates, indicating that increased spike-synchrony can compensate for the reduction in spike rate. Furthermore, reducing MTC gamma-synchronization without a decrease in firing rates degraded piriform cortex odour-evoked responses and ensemble odour representation. Finally, direct optogenetic suppression of MTC firing rates reduced their gamma-synchronization and degraded piriform cortex odour responses. Thus, consistent with theoretical predictions, these findings provide the first causal evidence that increased gamma-synchronization enhances the transmission of sensory information in the brain. This may also point to a mechanism by which gamma-synchronization can affect cognitive functions in health and disease.

Title: Mapping the Connectivity and Microstructure of the Human Lateral Olfactory Tracts Using Diffusion MRI

Authors: *S. ECHEVARRIA-COOPER[1], G. ZHOU[1], C. ZELANO[3], F. PESTILLI[4], T. B. PARRISH[2], T. KAHNT[1];
[1]Dept. of Neurol., Northwestern Univ., Chicago, IL; [2]Dept. of Radiology, Northwestern Univ., Evanston, IL; [3]Dept. of Neurol., Feinberg Sch. of Medicine, Northwestern Universi, Chicago, IL; [4]Psychology, Neuroscience, Cognitive Sci. and Network Sci., Indiana Univ., Bloomington, IN

Abstract: Understanding the anatomy of the human olfactory tracts is important to understanding their function in health and disease. This is especially important in cases of neurodegenerative disease, such as Alzheimer's and Parkinson's diseases, where olfactory dysfunction is prevalent and predictive of future cognitive impairment. Historically, susceptibility and motion artifacts have prevented accurate characterizations of the human olfactory tracts *in vivo*, using diffusion MRI (dMRI). To address this, we

used an optimized dMRI method with readout segmentation of long variable echo-trains (RESOLVE) to reduce susceptibility artifacts, and individualized head stabilizers to prevent motion artifacts. Using these methods, we successfully segmented the olfactory tracts of 25 healthy young adult participants, using probabilistic tractography.Participants underwent olfactory perceptual testing with Sniffin' Sticks, a 1.5mm resolution RESOLVE dMRI scan (90 directions, b=1000s/mm^2, and 12 B0 volumes), and T1- and T2-weighted anatomical scans. We used a constrained spherical deconvolution model to perform probabilistic tractography. We placed seeding regions in the olfactory bulbs and at a midway point in the olfactory sulcus to segment the olfactory tracts.We successfully segmented the olfactory tracts in all subjects, but in most subjects we observed a small area of signal drop-out near the sphenoid sinus, resulting in two disjointed olfactory tract segments. We used natural cubic spline interpolation to estimate the path between the two segments. Using these data, we generated a probabilistic olfactory tract template in MNI space, which will be made publicly available.All subjects showed olfactory tract connectivity with the anterior olfactory nucleus, the piriform cortex, and the olfactory tubercle in at least one hemisphere, while 76% showed connectivity with the amygdala. Using our atlas, we calculated fractional anisotropy and mean diffusivity in the olfactory tracts and found that mean diffusivity measures were correlated with subjects' scores on an olfactory discrimination task. Our atlas may be used in future research to investigate the microstructural properties of the olfactory tracts in neurodegenerative diseases.

Title: Binge eating suppresses flavor representations in the mouse olfactory cortex

Authors: *H. LO[1,4], A. SCHOENHERR[1], M. L. TANTIRIGAMA[2,5,6], R. N. SACHDEV[3,6], K. STUMPENHORST[7], M. RIVALAN[7,5], Y. WINTER[7], D. SCHMITZ[3,4,5,8], F. W. JOHENNING[1,4]; [1]Neurosci. Res. (DZNE), Berlin, Germany

Abstract: Energy homeostasis is achieved by the complex regulatory network that involves a feedback circuit between dietary intake behavior and nutritional state. The uncoupling of dietary intake and nutritional state results in overeating. Hedonic overeating can escalate into binge eating, a heritable trait associated with binge eating disorder and bulimia. One factor that modulates this feedback loop is the sensory perception of flavors. Olfaction is a critical element of flavor perception and greatly influences the qualitative and hedonic evaluation of foods. Patients with olfaction deficits commonly report a

reduced appreciation of food items. Current evidence also suggests that the olfactory system is necessary for triggering fasting-induced overeating. However, it is unclear how adaptations related to binge eating are reflected by the olfactory flavor responses.

To understand the relationship between olfactory perception and binge eating, we developed a hedonic feeding paradigm that repeatedly delivers hedonic food (flavored milk) to mice. We controlled the duration of inter-trial intervals so that mice can only activate the lick sensors and feed themselves with slow or fast paces. Implementing this paradigm with a head-mount miniaturized microscope allows us to measure neural responses upon slow eating or binge eating in the olfactory cortex (anterior piriform cortex, aPC) in freely moving mice (Fig. A). During slow eating, we observed distinct populations of excitatory piriform neurons responding to flavored milk and water (Fig. B). Surprisingly, during binge eating, we found the majority of excitatory neurons are rapidly suppressed in the aPC (Fig. C). Further investigation in inhibitory interneurons revealed both PV^{+} and SOM^{+} interneurons are not major contributors to this binge-induced global suppression. Whether this implies the involvement of neuromodulations during binging and/or whether the flavor representation adapts during the escalation of binging are the next steps of our examination.

Title: Taste-odor Integration in the Piriform Cortex of the Rat

Authors: *A. A. IDRIS[1], E. M. WALKER[2], J. X. MAIER[1], B. CHRISTENSEN[3];
[1]Neurobio. & Anat., Wake Forest Sch. of Med., Winston Salem, NC; [2]Neurobio. and Anat., Wake Forest Univ. Sch. of Med., Winston Salem, NC; [3]Vanderbilt Univ., Nashville, TN

Abstract: Flavor perception is the amalgam of taste and odor qualities. During consumption, stimulation from gustatory and retronasal olfactory signals are combined to create it. Although the multisensory nature of flavor perception has been known and described in literature, its neural basis remains unknown.Previous work from our lab suggests that the piriform olfactory cortex (PC) may act as a site of flavor integration, as single PC neurons have responded to both taste and retronasal odor inputs. In this study we further quantified taste-odor convergence on single PC neurons, and characterized how bimodal inputs interact to influence their responses and information processing.To address this, we recorded spiking activity directly from single PC neurons of awake rats in response to taste, odor, and mixture stimuli using chronic electrode implants. Stimulus solutions were delivered via intraoral cannulae. Taste stimuli included all taste qualities; odor stimuli, a variety of monomolecular odorants (0.025%); multisensory stimuli, of binary mixtures of taste and odor stimuli.We recorded from 256 neurons in PC of 25 rats, 118 (46.1%) of which were responsive to intra-oral stimuli (response to all stimuli versus baseline). For these neurons, we analyzed responses to 408 mixture stimuli and their components. A total of 85 (20.8%) mixtures were associated with a significant odor response; 98 (24.0%) with taste response; and 31 (7.6%) with both components, demonstrating convergence of taste and odor inputs onto single PC neurons. To determine if bimodal inputs interact to influence the response, we compared unimodal component responses to mixture responses. For 53 (13.0%) mixtures, we found that neurons only responded to the mixture. For 43 (10.5%) mixtures, neurons only responded to at least one of the components. Thus, bimodal mixtures caused some neurons to become active, and others lost responsiveness relative to the unimodal component, suggesting nonlinear interactions between the two. We also compared mixture responses to the strongest unimodal component response for each mixture. A total of 24 (6.9%) mixtures showed direct evidence of multisensory interactions. Our data shows multisensory convergence onto single PC neurons, extending previous findings that PC is a site of multisensory convergence to both taste and odor stimuli. PC neurons also integrate their bimodal inputs, affecting responses to mixtures as compared to their components, resulting in unique spatial ensembles

activated by mixtures. Ongoing experiments will quantify the effect of taste context on discriminability of cortical odor representations, and determine the source of taste input to PC.

Title: Dynamical properties of interareal coherence and spike patterning in olfactory bulb and piriform cortex oscillations

Authors: *M. G. MARISCAL, T. A. CLELAND;
Psychology, Cornell Univ., Ithaca, NY

Abstract: The coordinated timing of neuronal action potential firing, as evidenced by local field potential (LFP) oscillations, encodes information and facilitates interareal communication. During odor processing, a transition from gamma (50-90 Hz) to beta (12-32 Hz)-band LFP oscillations is observed in the olfactory bulb, with gamma thought to be generated within the olfactory bulb, and beta hypothesized to be generated either by the piriform cortex (after excitation by the olfactory bulb), or by the two structures together. Still, how exactly the olfactory bulb and piriform cortex generate beta, and what causes these oscillations to arise, is not yet known. Here, we analyze simultaneous multielectrode recordings from the olfactory bulb and piriform cortex collected as mice (n=13) were presented with 6 different odors for 10-15 trials each. In addition to the previously reported gamma-to-beta transition of oscillatory activity, we report a brief but consistent early beta oscillation in both olfactory bulb and piriform cortex. While late beta (>200ms after inhalation) arises simultaneously in the olfactory bulb and piriform cortex, this early beta (<150ms after inhalation) first arises in the olfactory bulb, prior to the onset of gamma. Granger causality analysis indicates though this early beta may begin in the olfactory bulb, the piriform cortex drives this oscillation. These early beta oscillations also co-occurred with strong spike patterning: a burst in firing in the olfactory bulb, followed immediately by a burst in firing in the piriform cortex, leading to a wave of inhibition in both areas. This pattern then repeats for multiple cycles on a beta timescale. Additionally, the strength of each oscillation differs between the brain areas. Gamma power is strongest in olfactory bulb, and olfactory bulb principal neurons synchronize strongly to gamma whereas piriform cortical neurons couple only weakly. In contrast, beta power is stronger in the piriform cortex; with both piriform cortical neurons (strongly) and olfactory bulb principal neurons (moderately) synchronizing to beta. Interareal coherence also is strongest for the beta oscillation, suggesting that beta may reflect communication between the two areas. These results further characterize the oscillatory dynamics of the olfactory bulb and piriform cortex during odor processing, and the mechanisms that drive the transitions

between these oscillatory modes. The recordings analyzed are drawn from the publicly available NSF CRCNS pcx-1 dataset (doi: 10.6080/K00C4SZB) by Bolding and Franks (2018).

Title: Top-down processing in body image processing: individuals with higher MMPI scale 1 (Hypochondriasis) showed greater activation in fusiform gyrus during evaluation of ideal body image

Authors: *Y. HAMAMOTO[1], S. SUZUKI[3], S. YAMAZAKI[2], K. MOTOKI[4], K. OBA[1], R. KAWASHIMA[5], M. SUGIURA[5];
[2]Inst. of Development, Aging and Cancer, [1]Tohoku Univ., Sendai, Japan; [3]Dept. of Finance, The Univ. of Melbourne, Melbourne, Australia; [4]Dept. of Food Mgmt., Miyagi Univ., Sendai-Shi, Japan; [5]IDAC, Tohoku Univ., Sendai, Japan

Abstract: Body image disturbance, overestimating and negative feelings toward one's body image, is known to be one of the greatest risk factors for eating disorders. Two independent body image processing are related to body image disturbance: actual body image processing (estimation of one's actual body size) and ideal body image processing (estimation of one's ideal body size). It is also suggested that different psychopathological personality traits influence each body image processing. Minnesota Multiphasic Personality Inventory (MMPI) can assess 10 psychopathological traits and we hypothesized the following relationships with each body image processing. Hypochondriasis and Hysteria scales are related to somatization, which is the tendency to experience psychological problems in the form of physical symptoms, and thus would influence the processing of actual and ideal body images. Psychasthenia scale would influence actual body image processing because Psychasthenia is related to obsession and the fixation of being overweight would influence the actual body image processing. Psychopathic Deviate and Social Introversion scales would influence ideal body image processing because these scales relate to sociability and ideal image is influenced by interaction with others. We investigated these relationships in 35 healthy young women by a task-based fMRI experiment. Participants viewed their silhouette images one by one in an MRI scanner that were distorted in width and performed two tasks: one in which they judged if each silhouette image was larger than their actual body (actual body task) and the other in which they judged if each silhouette image was larger than their ideal body (ideal body task). Based on the hypotheses, we conducted multiple regression analyses to examine relationships between particular MMPI scales and brain activities. We found that activation in the fusiform gyrus was positively correlated with Hypochondriasis during the ideal body task, which supported our hypothesis about the relationship between somatization and ideal body image processing.

Given that the fusiform gyrus is thought to process whole body image and higher Hypochondriasis scales represent greater concerns for one's body image, emotional and cognitive processing derived from concerns for body image may influence visual processing. The current study reveals part of the mechanism of body image disturbance.

Title: Sculpting new visual concepts into the human brain

Authors: *M. IORDAN[1], V. J. H. RITVO[2], K. A. NORMAN[2], N. B. TURK-BROWNE[3], J. D. COHEN[1];
[1]Princeton Neurosci. Inst., [2]Psychology Dept., Princeton Univ., Princeton, NJ; [3]Psychology, Yale Univ., New Haven, CT

Abstract: Humans continuously learn through experience, both implicitly (e.g., statistical learning) and explicitly (e.g., instruction). As humans learn to group distinct items into a novel category, neural patterns of activity for those items become more similar to one another and, simultaneously, more distinct from patterns of other categories. We hypothesized that we could leverage this process using neurofeedback to devise a fundamentally new way for humans to acquire conceptual knowledge. Specifically, sculpting patterns of activity in the human brain that mirror those expected to arise through learning of new visual categories may lead to enhanced perception of the sculpted categories, relative to similar, control categories that were not sculpted. To test this hypothesis, we implemented a closed-loop system for neurofeedback manipulation using fMRI measurements recorded from the human brain in real-time (every 2s) and used this method to sculpt/create new neural categories for complex visual objects. After training, participants exhibited behavioral and neural biases for the sculpted, but not for the control categories, and we observed a significant positive correlation between the increase in behavioral discrimination and the increase of neural separation of the categories. Neural sculpting provides causal evidence (through direct experimental intervention) that distributed patters of activity evoked by complex visual stimuli can be formed de novo in high-level visual cortex to create categories that didn't previously exist in the brain or behavior. The ability to sculpt new conceptual distinctions in the human brain has broad relevance to many domains of cognition such as perception, decision-making, memory, and motor control. This also broadens the possibility for non-invasive clinical intervention in humans with fMRI (e.g., brain-machine interfaces, neuroprosthetics, neurorehabilitation) and hints at the distant possibility of

sculpting more extensive knowledge or complex concepts directly into the human brain, bypassing experience and instruction.

Title: Perceptual dissimilarity analysis distinguishes grapheme-color synesthetes from non-synesthetes

Authors: *S. LACEY, M. GRAVENER, K. SATHIAN;
Penn State Col. of Med., Hershey, PA

Abstract: Synesthetes can be distinguished from non-synesthetes on a variety of experimental tasks because their concurrent synesthetic experiences can either facilitate or inhibit task performance if these experiences either match or conflict, respectively, with some aspect of the stimulus. Here, we tested grapheme-color synesthetes and age- and gender-matched non-synesthetic control participants (n = 20 in each group) using an online perceptual similarity task (Kriegeskorte & Mur, Front Psychol, 2012) to assess whether synesthetes' concurrent color experiences influence perceived grapheme similarity.

Participants iteratively arranged graphemes and, separately, their associated synesthetic colors in an online display, such that similar items were placed close together and dissimilar items further apart. The resulting relative inter-item distances were used to calculate the pair-wise (dis)similarity between items in the set, and thence to create separate perceptual representational dissimilarity matrices (RDMs) for graphemes and colors. On the assumption that synesthetes' similarity judgments for graphemes would be influenced by their concurrent color experiences, we predicted that grapheme and color RDMs would be more strongly correlated for synesthetes than non-synesthetes. We found that the mean grapheme-color RDM correlation was indeed significantly higher in synesthetes than non-synesthetes. In addition, synesthetes' grapheme-color RDM correlations were more likely to be individually statistically significant, even after correction for multiple tests, than those of non-synesthetes. Importantly, synesthetes' grapheme-color RDM correlations scaled with the consistency of their grapheme-color associations as measured by their Synesthesia Battery (SB: Eagleman et al., J Neurosci Meth, 2007) scores, thus providing a measure of convergent validity. By contrast, SB scores for non-synesthetes were only weakly, and non-significantly, related to their grapheme-color RDM correlations. Thus, perceptual dissimilarity analysis successfully distinguishes synesthetes from non-synesthetes, in a way that meaningfully reflects a key aspect of synesthetic experience.

Title: Behavioral Oscillations in Rapid Face Detection

Authors: *X. LIU[1], E. BALESTRIERI[2], D. MELCHER[3];
[1]New York Univ. Abu Dhabi, Abu Dhabi, United Arab Emirates; [2]Univ. of Muenster, Muenster, Germany; [3]Univ. of Trento, Rovereto, Italy

Abstract: Theories of rhythmic perception propose that perceptual sampling operates in a periodic way, with moments of high and low responsiveness to visual stimuli interleaving with each other. This rhythmic sampling seems to be modulated by brain rhythms and leads to oscillations in behavioral outcomes. Previous studies have revealed consistent theta-band behavioral oscillations in low-level visual tasks and object categorization. However, less is known about the oscillatory effect in face perception, for which the human brain has a highly dedicated network. To investigate this, we adopted a dense sampling technique and the dual-target rapid serial visual presentation (RSVP) paradigm. In each trial, a stream of object images was briefly presented at 30 Hz. Two identical face images (the target) were embedded among the baseline images with a randomly selected interstimulus interval (ISI) in between. The ISI varied from 0 to 646 ms in steps of 34 ms. The task was to indicate the presence of the target and its gender if present. There were 165 participants (mean age: 26.29 years old; 84 females; self-identified ethnicity: 46 Asian, 46 Black, 27 Latino, 46 White). We performed a Fourier transform and computed the phase-locked amplitude as an indicator of behavioral oscillations. Non-parametric permutation test was

used to test significance. A strong oscillation was found in the face detection task at 7.5 Hz (p = .005). Combining with previous studies, the results indicate a theta-band based oscillatory temporal organization underlying visual perception. The exact frequency differs from a previous study testing rhythms in face identification, suggesting the involvement of different feedback pathways in different face processes. Grouping the trials by target's gender, we found a significant oscillation at 7.5 Hz in male face detection (p = .023) and a trend to significant oscillation at 10.5 Hz in female face detection (p = .055), providing preliminary evidence that people might rely on different facial features in the rapid detection of female and male face.

Title: Representation comparisons between human brains and hierarchical deep convolutional neural network in face perception reveal a fatigue mechanism of repetition suppression

Authors: *Z. LU[1,2,3,4], Y. KU[1,3];
[1]Dept. of Psychology, Sun Yat-sen Univ., Guangzhou, China; [2]Inst. of Cognitive Neuroscience, East China Normal Univ., Shanghai, China; [3]Peng Cheng Lab., Shenzhen, China; [4]Dept. of Psychology, The Ohio State Univ., Columbus, OH

Abstract: Repetition suppression (RS) for faces have long been studied, yet, the underlying primary neural mechanisms of RS remains debated, for example, fatigue or sharpening of neuronal activities. The present study used a hierarchical deep convolutional neural network (DCNN), which achieve the performance of face recognition at human level, as a tool to simulate the neural mechanism of facial repetition suppression as fatigue or sharpening of neurons and compared representations between human brains and DCNNs. First, pre-trained DCNN was better at distinguishing between different types of faces at human level than randomly-weighted DCNN. Afterwards, we constructed two RS models, fatigue model and sharpening model, to modify the activations of DCNNs, and conducted cross-modal representational similarity analysis (RSA) comparisons between dynamic processing in human EEG signals and layers in modified DCNNs. We found that facial representations of human brains were more similar to facial representations in fatigue-modified DCNN than sharpening-modified DCNN. These results indicated that the facial RS effect in face perception was more likely caused by the fatigue mechanism, which suggested that the activation of neurons with stronger responses to face stimulus would be attenuated more in facial RS. Also, human brains showed stronger and more consistent similarities with the fatigue-modified DCNN as the layer increased. Therefore, the current study supports the fatigue mechanism as a more plausible neural mechanism of facial RS. The comparison between

representations in the human brain and hierarchical DCNN provides a promising tool to simulate and infer the brain mechanism underlying human behaviors.

Title: Degraded macroscale cortical hierarchy is unitary correlate ofhuman unconsciousness

Authors: *Z. HUANG, A. G. HUDETZ;
Univ. of Michigan Med. Sch., Ann Arbor, MI

Abstract: Background. Noninvasive neuroimaging in humans reveals that both pharmacological and neuropathological unconsciousness is associated with an extensive disruption of the functional connectome of brain networks. Here we ask whether these network alterations may relate to a system-level change in macroscale hierarchy affecting integration and segregation of unimodal and transmodal networks. Recent gradient mapping techniques in neuroimaging provide topological representations of human macroscale hierarchy in an abstract low-dimensional space by embedding the functional connectome into a set of axes (Huntenburg et al., Trends Cogn. Sci., 2018; Margulies et al., Proc. Natl. Acad. Sci. U. S. A., 2016; Murphy et al., Neuroimage, 2018; Vos de Wael et al., Commun. Biol., 2020). **Methods.** We analyzed fMRI datasets collected from participants and patients with various unconscious states induced by pharmacological (propofol and ketamine anesthesia, with distinct molecular targets) and neuropathological (unresponsive wakefulness syndrome, UWS) etiologies (Huang et al., Sci. Adv., 2020). We used gradient mapping methods to transform macroscale connectomes into a three-dimensional cortical gradient space (i.e., unimodal to transmodal, visual to somatomotor, and paralimbic to multiple-demand). We also applied a set of measures to quantify the range of each gradient, network eccentricity, and dispersion of global, within and between functional communities. **Results.** We found that unconscious states are associated with an overall degradation of macroscale hierarchy, which is characterized by a reduced functional distance from unimodal to transmodal regions. Further network analyses indicated dose-dependent, anesthetic-agent-dependent, and neuropathology-dependent effects. Moreover, the ventral attention network was most vulnerable to a change in the state of consciousness, of which decreased eccentricity of the cortical gradient space were consistently found during unconsciousness. **Conclusions.** These findings advance our understanding of functional reorganization in the unconscious brain, and offer a reference frame to accommodate conscious and unconscious states of diverse etiologies into a shared low-dimensional cortical gradient space.

Title: Prestimulus fMRI activity predicts subjective Gestalt perception

Authors: *M. WILDING[1,2], C. KÖRNER[1,2], A. ISCHEBECK[1,2], N. ZARETSKAYA[1,2];
[1]Inst. of Psychology, Univ. of Graz, Graz, Austria; [2]BioTechMed-Graz, Graz, Austria

Abstract: The constructive nature of human perception sometimes leads us to perceiving rather complex impressions from simple sensory input. Bistable stimuli give us a rare opportunity to study the neural mechanisms behind this process. Such stimuli can be visually interpreted simple or more complex on the basis of the same sensory input. Previous studies demonstrated that the superior parietal cortex is selectively active when participants perceive a more complex illusory Gestalt impression compared to a simpler interpretation of individual elements. Here we tested whether activity related to the illusory Gestalt percept can be detected not only *during*, but also *prior* to it, by examining the slow fluctuations of resting-state fMRI activity before the stimulus onset. We presented 25 participants (10 women; mean age=24, SD=3.37) with a bistable motion stimulus, which can be perceived either as four moving dot pairs (local) or two moving illusory squares (global). This allows the isolation of specific neural mechanisms that accompany the experience of an illusion under matched sensory input. We used fMRI to measure brain activity in a combination of resting-state and event-related experimental design. The stimulus appeared around the fixation dot for 1s with a jittered inter-stimulus interval of 25-50s. Participants were required to respond either 'local' or 'global' depending on their subjective perception of the stimulus immediately after its presentation. We then performed a FIR-GLM analysis, which enabled us to examine the fMRI signal before and after the stimulus onset in both conditions. We observed that left superior parietal, precentral, and supramarginal areas were more active after the stimulus onset when participants perceived the stimulus as illusory squares compared to when they perceived it as local motion. This is in line with previous studies that examined activity related to perceptual grouping. Crucially, superior parietal areas were also more active for the global compared to the local condition *before* stimulus onset. Additionally, we found that global percepts were preceded by increased activity in the right putamen, which has also been linked to perceptual grouping before. Our results indicate that spontaneous fluctuations of activity in the parietal cortex and the putamen may bias the interpretation of subsequent sensory input in favor of illusory Gestalt perception. They also show that areas that are active during the illusion perception and areas that spontaneously increase activity prior to it partially overlap, suggesting that preactivation of the illusion-selective neural machinery is decisive for the subsequent illusion formation.

Title: Memorability is more than typicality or atypicality: evidence from brain, behavior, and computational modeling

Authors: *M. A. KRAMER[1], M. N. HEBART[2], C. I. BAKER[3], W. A. BAINBRIDGE[1];
[1]Psychology, Univ. of Chicago, Chicago, IL; [2]Vision and Computat. Cognition Group, Max Planck Inst. for Human Cognitive and Brain Sci., Leipzig, Germany; [3]Lab. Brain and Cognition, NIH, Bethesda, MD

Abstract: A growing body of research has demonstrated that certain stimuli are consistently remembered more often than others, even across large heterogenous populations (Isola et al, 2011), leading many to ask, "what makes something memorable?" Recent studies targeting memorability - an intrinsic property of stimuli - suggest that memorability is not explained by single factor models (Bainbridge et al, 2017; Isola et al, 2014) or by linear combinations of traits (Bainbridge et al, 2013). Many of these studies hypothesize that memorability relates to typicality, with some indicating that less typical stimuli are more often remembered (Bylinskii et al, 2015; Lukavský & Děchtěrenko, 2017), some indicating that more typical items are more often remembered (Bainbridge, Dilks, & Oliva, 2017; Bainbridge & Rissman, 2018), and others suggesting a more nuanced relationship between the two (Koch et al, 2020). Here, to fully characterize the relationship between stimulus typicality and memorability, we examined THINGS, a large naturalistic object image database of 26,107 images across 1,854 categories with an associated 49-dimensional representational space consisting of both low-level visual features and high-level semantic features (Hebart et al, 2019). We leveraged the hierarchical structure of THINGS to analyze both image-to-concept typicality (e.g. the typicality of a specific penguin to the concept of a penguin) as well as concept-to-broader-category typicality (e.g. the typicality of penguins as an example of birds). We computed typicality in three ways: 1) similarity scores across visual and semantic dimensions, 2) behavioral judgments, and 3) similarity across layer activations from a deep neural network (DNN) as a proxy for visual processing. We uncovered a semantic primacy in the 49 dimensions with relatively low visual and shared variance, suggesting that the dimensions are semantically biased. We found that within-category typicality derived from the 49 dimensions correlated marginally with memorability, while behavioral within-category typicality and DNN based within-concept typicality values did not. Overall, we observe both positive and negative memorability-typicality relationships across concepts in all cases, suggesting that the relationship between memorability and typicality is more complicated than indicated by previous studies. We further characterize this memorability-typicality relationship by examining THINGS-fMRI/MEG (Contier et al, 2021), a neuroimaging dataset using the THINGS stimuli.

Title: An eye tracking investigation of Rubens' version of Titian's "Fall of Man"

Authors: *R. G. ALEXANDER[1], A. VENKATAKRISHNAN[1], J. CHANOVAS[2], S. L. MACKNIK[1], S. MARTINEZ-CONDE[1];

Abstract: We conducted a psychophysical and eye-tracking study aimed at quantifying gaze dynamics during the free viewing of Rubens' version of Titian's "Fall of Man," as well as during the viewing of other similar paintings. Rubens' copy of Titian's masterpiece is very similar to the original in many ways, and virtually identical in some regards. By comparing gaze behavior during viewing of the two paintings, presented on a computer screen, we assessed the effects of Rubens' changes to Titian's composition on the viewer's experience. An EyeLink 1000 was used to record gaze binocularly from 33 participants as they viewed each of the images for 45 seconds. We analyzed multiple gaze parameters, including fixation duration, saccade and microsaccade production, fixation consistency across subjects, and others, as well as the natural image statistics of each painting. We found that participants gazed for longer durations at Eve's face in the Rubens' version of the painting than in Titian's original. In addition, gaze positions were more dispersed for the Titian painting than for the Rubens painting, indicating different allocations of viewer interest for each painting. Our combined results suggest that the above differences in gaze behavior can be attributed to critical variations in composition between the two paintings. Notably, Rubens changed the depicted characters' body arrangement and gaze direction, providing powerful joint attentional cues for viewers to focus their central vision on Eve's face. Thus, joint attention may be a key element in the viewer's experience of "The Fall of Man" as imagined by Rubens—though not by Titian.

Title: Is Perceptual Adaptation Impaired in Healthy Individuals with Schizotypal Personality Traits?

Authors: *A. O. GIARRATANA[1,2], M. KALIUZHNA[3], S. KAISER[3], P. N. TOBLER[2];
[1]Rutgers Robert Wood Johnson Med. Sch., Piscataway, NJ; [2]Zurich Ctr. for Neuroeconomics, Univ. of Zurich, Zurich, Switzerland; [3]Dept. of Psychiatry, Univ. of Geneva, Geneva, Switzerland

Abstract: Introduction and Background: Schizophrenia can be understood to exist on a spectrum; from non-clinical individuals with higher levels of schizotypal personality traits to patients with schizophrenia. Studying schizotypy in non-clinical populations can be extremely informative, given that schizotypy is positively correlated with an increased liability for the eventual development of a schizophrenia spectrum disorder. By studying schizotypy, researchers may be able to detect biomarkers for early detection of psychosis. To this end, we have developed a novel task that can be used either behaviorally only or together with neuroimaging. We previously found that neural adaptation to reward range is impaired in both healthy individuals with stronger schizotypal personality traits and in patients with schizophrenia. However, it remained unclear whether adaptive coding impairments in the schizophrenia spectrum are limited to reward or affect also other domains. **Specific Experimental Aims:** 1. To develop an fMRI friendly visual perceptual decision-making task with a measureable behavioral output that captures adaptation with narrow versus wide ranges of perceptual inputs. 2. To investigate if the adaptive coding performance in this task correlates negatively with levels of schizotypal personality traits in the healthy control population. **Methods and Design:** In each trial of our novel object discrimination task, participants decide whether a presented image is a face or a house. We present these morphed images in wide range blocks (2.50% - 97.5% face), and in narrow range blocks (27.5% - 72.5% face) to healthy individuals with different levels of schizotypy. **Results:** We find that participants behaviorally adapt to the range, such that for similar images, performance is more accurate in the narrow range blocks compared to the wide range blocks. With regard to the link between perceptual range adaptation and schizotypal personality traits, preliminary results reveal a trend-level negative relation. **Conclusions:** Our findings will speak to the generality of adaptive coding deficits in individuals with schizotypal personality traits, by investigating the perceptual domain with our novel task and its relation to the reward domain using fMRI. The results may provide leads for an early biomarker of schizophrenia burden.

Title: Quantitative analysis method of color-odor association using Bayesian estimation

Authors: *K. TAMURA[1], T. OKAMOTO[2];
[1]Fukuoka Inst. of Technol., Fukuoka, Japan; [2]Kyushu Univ., Fukuoka, Japan

Abstract: Olfactory inputs can influence human behavior and cognition. Odors can be associated with colors, even in the absence of visual information. While some color-odor associations seem to be shared widely (e.g., lemony smells and yellow), other odors can remind different people of different colors. The individual variance of a color-odor association likely indicates association strength, which could be estimated by observing the variation of associated colors and odors. We hypothesized that by observing the variation of associated colors with odor, we could estimate the strength of color-odor association. An appropriate measurement method was required, and the effect of verbal description also needed be considered. We proposed a quantitative method to measure the association between odor and color. Bayesian estimation was used for the statistical analysis because it facilitates the prevention of a type II error, which is caused by frequent hypothesis testing.
We estimated the variances of color responses by measuring associated colors with 13 types of odors as continuous variables in color space, CIEL*C*h*. This space comprises a hue axis (h), a chroma axis (C*), and a lightness axis (L*). It is created by converting Cartesian space, CIEL*a*b*, to a polar coordinate. Language descriptors for each odor were also examined. The Bayesian estimation method using Markov chain Monte Carlo (MCMC) was introduced to summarize color and descriptor responses. A total of 23 university students (female, n = 11, male, n = 12; mean age ± SD = 20 ± 1.6 years) participated in the experiment twice (on two separate days). They were instructed to sniff 13 different odorants and answer questions about the color and semantic descriptors associated with each odor. Their responses were quantified as continuous values and each odor's reproducibility and variability of associated colors were calculated.
This method enabled us to record colors associated with an odor as a continuous variable. Our measurement of associated colors revealed no significant variations between participants. These results supported the consistency of the measurement of associated colors with odor. In order to evaluate their variance, we measured the mean resultant vector length for hue data because CIEL*C*h space is a polar coordinate. Our method assessed the strength of intrinsic association of color-odor pairs by estimating the resultant length of associated color hues.

Title: A Novel Electro-prosthetic Proprioception Reduces Visual-Proprioceptive Matching Error for Finger Aperture Control

Authors: R. RAVICHANDRAN[1], J. L. PATTON[2], *H. PARK[1];
[1]Texas A&M Univ., TX, TX; [2]Sensory Motor Performance Prog, Rehab Inst. Chicago, Chicago, IL

Abstract: Finger motor tasks often need high manipulation accuracy because the fingers are frequently used in sophisticated tasks. Finger aperture control in a finger reaching task is one of the critical maneuvers, especially in applications requiring right amount of force when touching a target object (e.g., a delicate tissue structure in surgery). The planning and execution of such a finger reaching task to control the finger aperture are based on proprioceptive feedback when vision on the fingers is blocked or occupied by other tasks. However, the visual-proprioceptive matching error, which is the mismatch between visually perceived distance and proprioceptively perceived distance, limits the capability of replicating the visual distance by the fingers and results in an error in the motor output. To address the visual-proprioceptive matching error and improve the control accuracy of the finger aperture, we introduce a novel technique, electro-prosthetic proprioception (EPP) that works as a new sensory reference, bridging vision and proprioception. EPP was rendered by electrical stimulation applied to the fingertip with a frequency inversely proportional to the finger aperture distance. We tested EPP could enhance accuracy in a conventional visuomotor training in a finger closing task without vision. We observed that aperture control accuracy significantly improved with EPP ($p<0.001$). More importantly, this accuracy was retained at 2 days post training ($p<0.001$) where conventional visuomotor training does not show any lasting effect at 2 days post training ($p=0.655$). We speculate that EPP affords a new schema of representing visual targets in working memory that reduces visual-proprioceptive matching errors, and may have broad application in enhanced feedback training paradigms, such as neurorehabilitation.

Title: The role of superior colliculus in affective experiences during visual and somatosensory stimulation

Authors: *D. CHEN[1], P. A. KRAGEL[2,3], A. B. SATPUTE[1], P. SAVOCA[4], L. L. WALD[4], M. BIANCIARDI[4], T. D. WAGER[5], K. S. QUIGLEY[1,6], L. F. BARRETT[1,4], J. THERIAULT[1];

Sch., Boston, MA; [5]Dept. of Psychological and Brain Sci., Dartmouth Col., Hanover, NH; [6]Ctr. for Healthcare Organization and

Implementation Res. (CHOIR) and the Social and Community, Edith Nourse Rogers Mem. VA Hosp., Bedford, MA

Abstract: The superior colliculus (SC) is a small deep-brain structure in the midbrain. Non-human animal evidence shows that SC has strong anatomical connections with many sensory regions in the brain, including areas typically involved in vision, somatosensation, and interoception. Physiological and lesion studies also indicate SC involvement in multisensory stimulation that localized to specific layers, with visual activity localized to superficial layers and somatosensory activity to deep layers. SC intermediate and deep layers also receive inputs from brain regions that are implicated in affective experience. Despite this evidence, prior human studies have primarily focused on its role in visual processing and spatial attention. With limited previous human research, we hypothesize that, human SC plays an important role in affective experiences during multisensory stimulation through its widespread anatomical projections with the interoceptive-allostatic system and its multimodal responses. Using 7-Tesla ultra-high-field fMRI at 1.1mm resolution, we measured changes in BOLD activity within the SC during two affect-evoking stimulation, one using visual stimuli (picture viewing, N = 40, Sample 1) and another using somatosensory stimuli (pressure to left thumb; N = 40, Sample 2). Greater activity of whole SC was observed during unpleasant compared to neutral trials in both tasks. Notably, voxel-wise analysis of SC activity was localized to different SC subregions based on task modality: greater activity in bilateral *dorsal* SC was observed during the visual task, whereas greater activity in the right lateralized *ventral* SC was observed during the somatosensory task, consistent with the sensory organization of superficial-to-deep layers of non-human animal SC. Whole-brain functional connectivity from the SC was also examined across trials using subject-specific SC ROIs. Pending a full, planned preregistration of the connectivity analyses, preliminary results (N=3 for each task) showed that, for both tasks, whole SC demonstrated strong functional connectivity with the visceromotor hubs within the interoceptive-allostatic system, many of which have direct anatomical connectivity to the SC (e.g., anterior and mid cingulate cortex, amygdala, insula, periaqueductal grey, hypothalamus, nucleus accumbens, and thalamus). Narrowing the gap between non-human and human research, the results support our hypothesis that SC is involved in affective experience elicited through multiple sensory modalities, and to our knowledge, are the first to show human functional dissociation within SC through multimodal stimulation using high-resolution fMRI.

Title: Seeing the Face of the Talker Normalizes BOLD Pattern Responses to Noisy Speech

Authors: *Y. ZHANG, J. F. MAGNOTTI, A. SONIG, M. S. BEAUCHAMP;
Univ. of Pennsylvania, Philadelphia, PA

Abstract: Viewing the talker's face improves comprehension of noisy speech. To investigate the neural computations underlying this perceptual benefit, we measured BOLD fMRI pattern responses in the posterior superior temporal gyrus and sulcus (pSTG/S) of 14 healthy participants who were presented with 2-second audiovisual recordings of single words (297 words from 12 different talkers) in 5 formats: clear audiovisual (AcV); noisy audiovisual (AnV); clear auditory-only (Ac); noisy auditory-only (An); and visual-only (V).fMRI data was collected with words presented in a silent interval inserted between acquisitions of the multiband pulse sequence. Participants reported whether the word was intelligible ("Y") or not ("N") with a button press after each presentation. For noisy auditory speech, seeing the face of the talker produced a large increase in intelligibility (odds-ratio = 7.0, $p = 10^{-8}$; 38% intelligible for An *vs.* 71% for AnV). The fMRI data from noisy auditory trials was *post hoc* sorted into "Y" and "N" trials, allowing for a comparison between trials that were physically similar but perceptually different. Voxel time series were analyzed using a GLM with 7 regressors of interest (AcV, AnV-Y, AnV-N, Ac, An-Y, An-N, V) in AFNI. The mean percent signal change across conditions was calculated for each voxel and subtracted from the response to each individual condition in order to increase the dynamic range of the fMRI pattern correlation. The fMRI pattern similarity between each pair of conditions was calculated by correlating the normalized percent signal change across the pSTG/S voxel in each of the 28 hemispheres. The response pattern evoked by AnV-Y speech was very similar to the response pattern evoked by AcV speech, even though they were physically very different, r(AcV, AnV-Y) = 0.66 +- 0.04 (mean ± SEM across hemispheres). In contrast, the response patterns evoked by AnV-Y and AnV-N speech were very different, even though the stimuli were physically similar, (AcV, AnV-N) $r = 0.13 \pm 0.13$. Intelligibility had a weaker effect on the response patterns for auditory-only speech, r(Ac, An-Y) = 0.49 ± 0.09 *vs.* r(Ac, An-N) = 0.45 ± 0.10, as confirmed by a significant interaction between intelligibility and stimulus format in a linear mixed-effects model. This demonstrates that intelligibility and the presence of visual speech are both important drivers of response patterns in pSTG/S. When noisy audiovisual words are intelligible, the pattern of brain response in pSTG/S is similar to that observed during clear audiovisual speech, suggesting that normalization of response patterns could be responsible for the perceptual benefit of seeing the face of the talker.

Title: Depth-dependent somatovisual responses in human superior colliculus using 9.4T fMRI

Authors: *D. RESS[1], **A. QURESHI**[1], F. MOLLA[2], K. R. SITEK[3], M. HIMMELBACH[4], G. HAGBERG[5], K. SCHEFFLER[5];
[1]Neurosci., Baylor Col. of Med., Houston, TX; [2]Univ. of Tübingen, Tübingen, Germany; [3]Communication Sci. and Disorders, Univ. of Pittsburgh, Pittsburgh, PA; [4]Hertie-Institute For Clin. Brain Res., Tuebingen, Germany; [5]Max Planck Inst. for Biol. Cybernetics, Tübingen, Germany

Abstract: OBJECTIVE: The superior colliculus (SC) plays an important role in representing the external environment across multiple sensory modalities. Ultra-high field MRI enables imaging and characterization of SC with a greater signal-to-noise ratio in smaller voxels. We investigate the role of deeper layers of SC in somatovisual integration (SVI) that uses tactile cues to guide a visual task. These responses are compared to a visual-only (VO) version of the same task. **METHODS:** MRI data were collected at 9.4T using a 16 (31)-channel transmit (receive) array. T1-weighted anatomical images were acquired with an MP2RAGE sequence (0.6 mm isotropic voxels). fMRI data were collected with 1-mm cubic voxels and 1.5-s TR (8 runs). A level-set scheme (Truong et al., Hum Brain Mapp 41, 2020) was used to quantify depth-dependence of the fMRI signal. Surfaces of each SC were divided into a 3x3 grid to allow across-subject averaging. Data were bootstrapped across subjects to quantify its reliability. Eight individuals participated in SVI and VO sessions, at least one each. Air puffs were delivered to their fingers during the SVI task to cue them to attend to a quadrant of the visual field. Subjects reported the total number of '+' patterns that appeared in this quadrant after each 6-min run, while ignoring other patterns. Single puffs were alternately presented to the index and ring fingers; a random double puff cued visual attention to the upper (index finger stimulation) or lower (ring finger stimulation) visual fields. Stimulation alternated between the left and right hands (cuing left and right visual fields) every 15 seconds, enabling coherence analysis. During the VO task, the target visual quadrant was cued by a color change without tactile stimulation.
RESULTS: We found that somatosensory stimulation drives lateralized responses in SC fairly globally. In rostral SC, responses were largely superficial. Deeper lateralized responses were found in caudal SC, as expected for forelimb stimulation. Compared to the VO responses, deep caudal SC responses were stronger in the SVI task, reaching significance at some depths. However, the SVI responses were noisier than those evoked by VO, and additional evaluation of noise sources is underway. **CONCLUSION:** We probed multisensory responses and studied the depth dependence of sensory processing within human SC using 9.4T fMRI, demonstrating its utility for investigating sensory responses within human midbrain structures. Consistent with prior animal studies, results suggest that the deeper layers of the SC represent multisensory information in a retinotopic fashion.

Title: Three is better than two: how trimodal sensory information integrate in the double-flash illusion.

Authors: *A. TONELLI, A. BOLLINI, M. GORI;
Fondazione Inst. Italiano Di Tecnologia, Genova, Italy

Abstract: The world, as we perceive it, is the result of integration among all our senses. In most cases, the combination of two senses allows improving the sensitivity of a perceived stimulus. However, in other situations, this combination can result in illusions. This is true for the 'Sound-Induced Flash Illusion' (SIFI), in which the rapid presentation of a single visual stimulus associated with two auditory 'beeps' produces the perception of two flashes, demonstrating that sound can alter vision even when there is no ambiguity in the visual input. Similarly, this happens also with tactile stimuli where a double touch induces the perception of two flashes, the 'Tap induced flash illusion' (TIFI). The specific time synchrony of this illusion is considered an indicator of multisensory integration, but what happens when more than two modalities are involved? Can sensory redundancy increase the effect of the illusion or interfere with it? In the present experiment, we tested whether the redundancy of sensory information could influence the visual illusion traditionally found in the SIFI and TIFI. During the experiment, we presented randomly three possible combinations of multisensory stimuli: (1) a single visual stimulus associated with two auditory 'beeps' (SIFI); (2) a single visual stimulus associated with two vibrations (TIFI); (3) a single visual stimulus associated with two vibration and two auditory 'beeps' (TMIFI - TriModal Induced Flash Illusion). The task was to count the number of flashes, regardless of the combination of stimulations. Results show around ~60% of illusion for both SIFI and TIFI conditions, in line with other studies in the literature; while in the tri-modal condition, in which there were two vibrations and two beeps with a single flash, participants perceived the illusion on ~75% of the trials. This result suggests that the redundancy of sensory information can boost the illusion effect. Moreover, we found that the effect in the TMIFI condition correlates positively with the illusion in both SIFI and TIFI, meaning that people with higher illusions in the bimodal conditions perceive a higher illusion in the tri-modal condition. Interesting, there is no correlation between SIFI and TIFI conditions. This result may indicate that when both tactile and auditory cues are presented with the visual stimulus, their influence is not a simple summation effect but rather an integration of the two that changes their effectiveness compared to the only tactile or auditory condition.

Title: A temporally correlated visual signal improves the neural representation of auditory objects.

Authors: A. R. NIDIFFER, E. C. LALOR;
Biomed. Enginerring, Univ. of Rochester, Rochester, NY

Abstract: The auditory system is capable of processing complex acoustic environments, binding features of auditory signals into meaningful units called objects while also segregating objects from background noise and distractors. One cue that aids in this process is the common temporal dynamics of an object's features. Evidenced by behavioral, fMRI, and EEG data, humans can form objects from acoustic signals, called stochastic figure-ground (SFG) stimuli, based solely on temporally coherent frequency changes within that signal, despite spectro-temporal overlap between the stochastic figure and the background in which it is set. It is rare that events in the environment produce energy in a single sensory modality, and so we asked how a visual stimulus might affect object formation when observing these SFG stimuli. Specifically, we sought to determine how auditory object formation was affected by the presence of a temporally correlated, but otherwise uninformative, visual stimulus. While recording high-density electroencephalography (EEG), we presented these stimuli along with one of two visual streams: one with flashes timed to match frequency changes in the auditory object and one with independent flashes with similar temporal statistics. Via forward encoding models, we found neural representations of the object and the background in EEG in fronto-central electrodes typical of auditory signals. When the visual signal was correlated, the figure representation was enhanced relative to its background. Preliminary results from a second experiment suggest that alpha power tracked the correlation between the object and visual stimulus. Taken with previous findings, these results support a complex relationship between multisensory integration, attention, and binding that is susceptible to consistency across sensory features.

Abstract: Combining information from our different senses into a single, coherent percept in a process known as multisensory integration helps us make sense of our surroundings. The benefits of multisensory integration are especially clear when the incoming sensory information is degraded, such as in cluttered, noisy environments. While previous studies have investigated how static multisensory stimuli are processed, less is known about the principles underlying the integration of dynamic, ecologically valid

stimuli such as those that move. Here, we investigate the interaction between auditory and visual apparent motion cues as a function of stimulus reliability. To address this behaviorally, we employed apparent motion stimuli (i.e. random dot kinematograms and auditory motion embedded in noise) in a two-alternative forced choice reaction time task in which participants judged the direction of motion of unisensory alone (i.e., visual, auditory), directionally congruent audiovisual, and directionally incongruent audiovisual stimuli. By parametric manipulation of auditory and visual motion coherence in this task, we investigated their impact upon perceived motion direction and evidence accumulation. We found that adding directionally congruent, low-coherence visual motion to auditory motion decreased sensitivity to auditory motion, whereas adding congruent auditory motion of any coherence to visual motion increased sensitivity to visual motion. Additionally, we found substantial inter-participant variability in sensory cue weighting when auditory and visual motion was directionally incongruent. To determine how strength of visual and auditory motion cues affected rate of multisensory evidence accumulation during motion direction discrimination, we modeled reaction times and accuracy from congruent multisensory trials using a hierarchical Bayesian estimation of drift diffusion modelling (HDDM). We found that adding congruent auditory motion to visual motion increased the rate of evidence accumulation across auditory and visual stimulus coherences. In contrast, adding visual motion that was more coherent than the auditory motion present increased the rate of evidence accumulation, while adding visual motion that was less coherent than the auditory motion present decreased the rate of evidence accumulation. Taken together, our results suggest a greater reliance upon visual information than auditory information when discriminating the direction of audiovisual motion, but with striking inter-individual differences in the respective weighing of the auditory and visual cues.

Title: One-hour interval induces the adaptation to the driving scene that causes simulator sickness.

Authors: *M. HAYASHI[1], Y. ITAGUCHI[3], M. MIKI[4], T. KIMURA[4], M. MIYAZAKI[1,2];
[1]Grad. Sch. of Integrated Sci. and Technol., [2]Dept. of Computer Science, Fac. of Informatics, Shizuoka Univ., Hamamatsu, Japan; [3]Dept. of literature, Keio Univ., Tokyo, Japan; [4]YAMAHA MOTOR Co.,Ltd, Iwata, Japan

Abstract: Driving simulators can be used to safely evaluate the behavior of drivers under various virtual conditions but they often cause simulator sickness. To use driving simulators more effectively, this problem needs to be addressed. In this study, we focused on adaptation as a strategy to reduce simulator sickness. Previous studies showed that simulator sickness is reduced by repetitive experience of

simulators with intervals of one day or more. If the adaptation occurs in intervals shorter than a day, simulator sickness is more effectively reduced. In our previous study, we tested whether adaptation can be induced by a six-minute interval between two sessions in a motorcycle simulator (Hayashi et al., 2021, SfN Global Connectome). However, this six-minute interval did not reduce simulator sickness, suggesting that six-minute intervals are too short to induce adaptation. In the current study, we tested whether a time interval of one hour can induce adaptation. Twenty students participated in the experiment. The participants sat on the chassis of a motorcycle and watched two six-minute motorcycle driving scenes on a winding road from a first-person perspective using a head-mounted display. There was a one-hour interval between the first and second driving scenes. During the experiment, the participants verbally reported the degree of simulator sickness every 30 s using a number from 0 (no sickness at all) to 20 (severe sickness) (Fast Motion Sickness scale, FMS). The FMS scores during the second driving scene were significantly lower than those during the first driving scene. Moreover, we compared the FMS scores between our current (one-hour interval) and previous (six-minute interval) experiments. For the first driving scene, there was no significant difference in the FMS scores between the two experiments, indicating that there were no difference in baseline sickness before the intervals between the two experiments. For the second driving scene, however, the FMS scores were lower in the current experiment with the one-hour interval than in the previous one with the six-minute interval. These results indicate that the one-hour interval induces adaptation to the driving scene and reduces simulator sickness. We discuss a possible mechanism of our results based on the sensory conflict theory and the consolidation theory for sensorimotor learning.

Title: Functional development of extraocular motor neurons in the larval zebrafish

Authors: *P. LEARY[1], D. GOLDBLATT[2], S. HUANG[1], K. HAMLING[1], D. SCHOPPIK[1];
[1]Otolaryngology, Neurosci. & Physiology, & the Neurosci. Institute., [2]Ctr. for Neural Science, Otolaryngology, Neurosci. & Physiology, & the Neurosci. Institute., New York Univ., NEW YORK, NY

Abstract: To stabilize gaze, extraocular motor neurons are tasked with correctly contracting particular eye muscles. Individual motor neurons must therefore encode parameters associated with head and body movements. While much is known about eye movement behavior and the spatial organization of extraocular motor neuron pools, the factors influencing motor neuron activity development remain unclear. We will present results that define the response of developing zebrafish extraocular motoneurons to vestibular stimulation. We first generated transgenic lines that permit targeted expression of the calcium indicator GCaMP6s in the oculomotor (nIII) and trochlear (nIV) nuclei. We next performed whole-body vestibular stimulation in the pitch and roll axes while we measured motor neuron activity

during multiphoton imaging. We investigated changes to activity patterns by repeatedly recording from the same cells over early development. Preliminary findings are as follows: We observed reliable responses that increased in magnitude following stimulation in the preferred direction. The slope of the relationship between stimulus amplitude and increasing activity varied considerably between cells. Further, individual motor neurons had different response kinetics, such as timescale of response, basal activity levels, and post-inhibitory rebound. Between 3 and 10 dpf, we observed systematic changes to the motor neurons. These included changes to the slope of the relationship between stimulus amplitude and activity, indicating changes in sensitivity to body tilts, as well as changes in the sensitivity to pitch vs roll axis stimulation.Taken together, this suggests developmental changes due to cell-specific properties or extrinsic properties, such as establishment of new inputs into motoneuron pools. Work is underway to characterize molecular correlates of these developmental changes using transcriptomic approaches and targeted photoablations of motor neuron inputs. Our work will speak to the factors that shape extraocular motor neuron activity for gaze stabilization.

Title: The Role of Oculomotor Proprioception in the Accommodative Reflex and Vergence Eye Movements

Authors: S. E. STELLA[1], M. E. GOLDBERG[2], S. G. LOMBER[3], *L. D. SUN[1];
[2]Neurosci., [1]Columbia Univ., New York, NY; [3]Dept. of Physiol. and Pharmacol., Univ. of Western Ontario, London, ON, Canada

Abstract: Previous research has shown that cortical ocular proprioception is implicated in fixation stability and alignment of interocular eye position, but it is unknown if it plays a role in the accommodation reflex. This reflex allows the eyes to focus on near targets and involves three simultaneous motor movements in what is known as the “near triad” which includes: binocular convergence, pupillary constriction (miosis), and lens accommodation. We hypothesized that ocular proprioception controls eye position alone and that it would have no effect on accommodation as

measured by pupil size. To test this, we reversibly inactivated area 3a of the somatosensory cortex via a cooling probe implanted in the right central sulcus of a single head-fixed rhesus macaque while tracking interocular angles and pupil diameter. LED fixation targets were presented at near (27 cm) and far targets (1-2 m). Physiological responses were monitored during an alternate-cover task and compared in control, cooled, and warmed states. We assessed approximately 250 trials for each state over five different recording days for the response of the covered and uncovered eye. There were differential contralateral and ipsilateral effects on the pupil during unilateral inactivation of cortical ocular proprioception for near targets. For the covered contralateral eye, there was a significant 3.4% increase in pupil diameter during inactivation which returned to baseline after rewarming (two-tailed Wilcoxon Signed-Ranks Test, $Z=7.93$, $p<1e-14$). The pupil diameter of the covered ipsilateral eye increased by 0.25% during inactivation of area 3a which was not significantly different from the control condition ($Z=0.30$, $p=0.76$). Thus our experiment showed that the contralateral eye saw interference of pupillary constriction during fixation to near targets while cortical proprioception was inactivated (the covered contralateral pupil enlarged and the eye moved laterally). But there was no significant interference ipsilaterally, showing contra-ipsilateral differential control. These results suggest that cortical ocular proprioception plays an additional underlying role in the near triad by modulating pupil and vergence tone, disproving our initial hypothesis of only eye position involvement.

Title: Neuronal populations trajectories during smooth pursuit and motion perturbations in area MT

Authors: K. K. NONEMAN[1], *J. MAYO[2];
[1]Carnegie Mellon Univ., Pittsburgh, PA; [2]Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Natural vision involves unexpected moving objects, self-induced motion, and expectations about motion in the world. The medial temporal area (MT), a sensory response region of the primate visual cortex, plays a critical role in visual motion processing and consists of direction- and speed-sensitive neurons. MT neuronal responses to motion are often described by a dominant sensory component, driven by the presented stimulus, that is modulated by top-down cognitive factors such as visual attention. But the sensory and cognitive aspects of the neuronal mechanisms involved in rapid sensory-motor transformations (~100 ms), such as smooth pursuit eye movements, are unclear. One possibility is that the oculomotor response to motion onset during pursuit is rapid enough to dampen or preclude the effects of top-down modulation. Alternatively, extrasensory signals unrelated to stimulus identity may be an unavoidable part of most behaviors. To begin to address these issues, we designed a task that allowed us to define a ***sensory axis*** based on the responses of neurons to brief motion pulses at various speeds, as well as a ***cognitive axis*** based on well-characterized changes in temporal attention (i.e., expectation) during fixation. We first asked if these two axes were meaningfully separable across

recording sessions. We then evaluated the potential cognitive contributions of pursuit initiation by measuring changes in population trajectories relative to the sensory axis caused by 1) stimulus motion onset, and 2) subsequent eye movement-induced motion. We recorded from small populations of neurons in macaque area MT using linear multi-contact electrode arrays and analyzed neuronal responses to brief motion pulses (50 ms duration) during sustained periods of fixation and pursuit (15 deg/sec). We asked if motion pulses of various speeds (i.e., sensory input) during fixation drive population activity along a similar trajectory as eye movements (i.e., sensory and reafferent input). To find the relevant dimensions for understanding the data, we employed dimensionality reduction techniques to transform the high-dimensional spiking data into lower-dimensional space. Our overarching goal is to delineate the differences in sensory processing and cognition that are at times not readily apparent at the level of individual neurons by using simultaneously recorded populations of MT neurons to better understand the neural mechanisms of motion perception in the natural world.

Title: Fixational drift is driven by diffusive dynamics in central neural circuitry

Authors: N. BEN-SHUSHAN[1], N. SHAHAM[3], M. JOSHUA[2], *Y. BURAK[2,1];
[1]Racah Inst. of Physics, [2]Edmond and Lily Safra Ctr. for Brain Sci., Hebrew Univ. of Jerusalem, Jerusalem, Israel; [3]Ctr. for Brain Sci., Harvard Univ., Cambridge, MA

Abstract: During fixation and between saccades, our eyes undergo diffusive random motion called fixational drift. In the foveal region of the visual field, where receptive fields are dense, fixational drift causes stimuli to move across many receptive fields. The role of this motion in visual coding and inference has been debated in the past few decades. On one hand, it has been proposed that fixational motion may assist high acuity vision. On the other hand, it has been argued that fixational drift poses a challenge for high acuity visual inference, as it precludes the possibility to overcome spiking noise by simple temporal averaging. While the consequences of fixational drift have been extensively studied from a normative perspective, the mechanisms that underlie this motion remained unknown. In particular, it has been unclear whether fixational drift arises from peripheral sources, or from central sources upstream of the muscles. To address this question, we analyzed simultaneous recordings of neural activity of ocular motoneurons (OMNs) in the Rhesus monkey, alongside precise measurements of eye position obtained using implanted eye coils. Single OMNs are too noisy to identify a correspondence between spiking

activity and eye position during fixation over a single trial, but by analyzing data from 58 OMNs over hundreds of eye trajectories for each cell, we show that the two are correlated, and that on average, the correlated component of the single OMN activity accounts for a large fraction of the eye motion variability during fixation. Several lines of reasoning indicate that most of the motion must arise from a central origin, upstream of the motoneurons. This is the first demonstration that fixational drift is correlated with central neural activity. We propose that the primary source of the motion resides in noise-driven random diffusion within the oculomotor integrator. We support this hypothesis by constructing a mathematical model of central and peripheral contributions to eye dynamics: the stochastic dynamics of the oculomotor integrator, combined with the dynamics of the ocular motoneurons and ocular plant. With biologically plausible parameters this model accounts both for the magnitude of the fixational motion and for its detailed statistics, as measured from the data. Thus, we propose that fixational ocular drift provides a direct observation of diffusive dynamics in a neural circuit responsible for storage of continuous parameter memory in persistent neural activity.

Title: Spiking activity and local field potentials along the dorsoventral axis of the superior colliculus during visually-guided eye movements: instantaneous correlational analysis

Authors: *N. J. GANDHI, C. BOURRELLY;
Univ. of Pittsburgh, Pittsburgh, PA

Abstract: The superior colliculus (SC), a neural structure involved in the sensorimotor transformation, is functionally organized along its dorsoventral axis: neurons in superficial layers exhibit a visual response, neurons in deeper layers present a movement response, and neurons in intermediate layers show both responses. Whereas it is known that the action potentials are the output of neurons, local field potentials (LFP) are believed to reflect the input. However, the exact nature of the LFPs remains unclear. In our companion abstract we state that the LFP signal shares general properties with spiking activity - visual response for the most superficial layers, a movement response for the deeper layers, and both visual and movement responses for intermediate layers - and that the onset of LFP modulation occurs earlier than the onset of visual burst in superficial layers. Recently, in the macaque visual cortex, a trial-by-trial correlation analysis has shown that the LFP activity is coupled to the spiking activity. This study showed that the spiking activity is a good predictor of the LFP amplitude occurring later. We hypothesized that, in the superficial layers, after the onset of its modulation, the LFP signals are coupled with preceding

spiking activities. Using multi-contact laminar electrode, we simultaneously recorded LFPs and spikes in the SC in two rhesus monkeys performing a visually guided delayed saccade task. We computed correlations between instantaneous LFP and spiking modulations as a function of depth around the time of the visual burst. We regressed the time-series signals of the residual spiking activity with the residual LFP activity for each trial ("within trial" analysis). The strongest correlations were observed when the LFP activity lagged the visual spiking activity by ~10 msec. Also, the magnitude of the correlation decreased with depth. To study the instantaneous correlation during the visual burst, the residual spiking activity across all trials at one time point was regressed against the residual LFP activity at different delays ("across trials" analysis). We found that, throughout the visual burst, the instantaneous residual spiking activity was correlated with later instantaneous residual LFP activity. The preliminary results of both within trial and across trials analysis on the motor response seem to show similar trends. Altogether, our results support the idea that, after its onset, the LFP modulation could be driven by the spiking activity.

Title: Spiking activity and local field potentials along the dorsoventral axis of the superior colliculus during visually-guided eye movements: visuomotor features and response onset

Authors: *C. BOURRELLY, N. J. GANDHI;
Dept. of Bioengineering, Univ. of Pittsburgh, Pittsburgh, PA

Abstract: The superior colliculus (SC) is a brain structure involved in the visuomotor transformation. Previous studies have shown that the SC is functionally organized across depth: neurons in superficial layers present a visual response, neurons in deeper layers exhibit a movement response, and neurons in intermediate layers show both visual and movement responses. It is known that the spiking activity is the output of neurons. In contrast, local field potentials (LFP) presumably represent the input. The nature of LFP signals in the SC remains largely unexplored. Previous studies, based on single electrode recordings, have shown that LFP signal shares spatial and temporal properties with spiking activity. Moreover, it has been shown that in both frontal eye fields and lateral intraparietal region, the onset of LFP modulations precede the spiking activity during the visual burst, whereas the spikes lead the LFP modulations during the motor response. Using multi-contact laminar electrode, we simultaneously recorded across depth spiking activities and LFPs in the SC in two rhesus monkeys performing a visually guided delayed saccade task. We hypothesized that the same general spatial properties described for the spiking activity

will be found in the LFP signal as a function of depth. We predict that the onset of the LFP modulation will precede the visual burst in the superficial channels whereas the motor burst will occur before the onset of LFP modulation in the deeper channels. As observed for spiking activity, the categorization of the LFP on each channel revealed a visual preference for the most superficial channels, a movement preference for the deeper channels, and both visual and movement responses for intermediate channels. Interestingly, the switch from the visual to the motor preference is observed on deeper channels on the LFP signal. Then, we examined the temporal properties of LFP modulations as a function of depth during the visual response. The analysis of the relative timing between the onset of LFP modulations and the onset of the spiking activity revealed a spatiotemporal pattern: the onset of LFP modulation occurred earlier than the visual burst on superficial channels. A preliminary analysis on the motor response seems to show a similar pattern: the motor burst strongly leads the LFP onset for deeper channels. All together, these results are consistent with the spatiotemporal representation of the input-output transformation in the SC. Nevertheless, it is still unclear if the spiking activity lags (or leads) the LFP activity throughout the visual (or motor) burst or solely at the earlier stage i.e. its onset. This question is addressed in a companion abstract.

Title: Microsaccade dynamics in a spatial attention task with neutral cuing and varied stimulus configurations

Authors: *S. WILLETT, J. MAYO;
Dept. of Ophthalmology, Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Microsaccades are thought to be a behavioral measure of covert attention. Attentional cues can modulate the frequency and direction of microsaccades, as well as attention-related changes in firing rate across visual cortical areas. However, the precise relationship between attention and microsaccades remains unclear. First, many studies probe the microsaccade-attention relationship by using cues that always predict the target location (100% cue validity). This approach assumes the effects of attention remain constant at a single location, complicating the interpretation of the microsaccade-attention relationship for multiple items in more naturalistic settings. Second, because attention fluctuates as a function of cue validity and stimulus configuration, the dynamics of the microsaccade-attentional relationship are confounded by multiple interacting cognitive processes that are sometimes not experimentally manipulated. Here we analyzed monkey behavior in cued vs. neutral blocks of trials to measure attention in relation to microsaccades. Specifically, we investigated a) the frequency and direction of microsaccades aligned to stimulus onset, and b) changes in microsaccades as a function of stimulus configuration (e.g., one stimulus in each hemifield vs. two stimuli in a single hemifield). Monkeys were trained to perform an orientation change-detection task. Two oriented Gabors, sinusoidally

counterphased at 10 Hz, were presented simultaneously. Monkeys fixated (500-5000 ms) and reported an orientation change by saccading to the changed stimulus. Attention was cued to a stimulus location via a visual cue on instruction trials at the start of each block of trials. During cued blocks, the change occurred with 80% probability at the cued location and 20% probability at the other location. During neutral blocks, visual cues were presented at both stimulus locations during instruction trials, and the change occurred with 50% probability at each location. 5% of the total trials were catch trials in which no change occurred and monkeys were rewarded for maintaining fixation. This study investigated microsaccade frequency and direction in response to stimuli that varied in their location and their likelihood to change in orientation. Establishing the distribution of microsaccades across time, cue validity, and stimulus configurations helps elucidate the extent to which microsaccades can be used as a non-invasive indicator of visual spatial attention and the limitations of this approach. In future work, we hope to determine how changes in the moment-by-moment neuronal correlates of attention relate to the timing and direction of microsaccades.

Title: Properties of visual search strategies based on eye-head coordination in athletes

Authors: *S. ONO[1], Y. YOSHIMURA[2], T. KIZUKA[1];
[1]Hlth. and Sport Sci., [2]Comprehensive Human Sci., Univ. of Tsukuba, Ibaraki, Japan

Abstract: In various sports situations, it is necessary to execute appropriate movements in response to visual targets such as a ball or opponent's movements. Visual motion information plays an important role in control of movements. In particular, skilled ball players are thought to acquire accurate visual information by using an effective visual search strategy with eye and head movements. For example, when tracking a moving object, the visual image is first captured in the central or peripheral visual field, and based on this visual information, the speed, trajectory and spatial location of the ball are estimated. In previous studies on visual search, eye movements were mainly analyzed to evaluate gaze, and the distribution of gaze was clarified from the viewpoint of where the gaze is mostly placed in the visual field. However, in actual sports situations, visual search based on the interaction between eye and head (whole body) movements are required. Therefore, the purpose of this study was to determine the characteristics of visual search strategies based on eye and head movements during a ball catching task in comparison between athlete and non-athlete groups. We examined the different patterns of gaze movement, head and eye movements among subjects during a catching task. Participants were fifteen tennis players (athlete group) and fifteen college students who are not experienced in ball sports (non-athlete group). The participants performed a one-handed catching task using a tennis ball-shooting

machine, which was placed at a distance of 9 m in front of the participants, and two conditions were set up: a low-speed condition (ball speed, 24 km/h) and a high-speed condition (ball speed, 32 km/h). Their head and eye movements were detected using gyroscope and electrooculography (EOG) during the task. Our results showed that peak eye and head velocities were lower in the athlete group than in the control group. In particular, when the head was tilted upward, downward eye velocity was induced in the non-athlete group. This result indicate that the non-athlete group shows vestibulo-ocular reflex (VOR) during head movements, whereas the VOR is suppressed in the athlete group. Furthermore, athletes showed smaller arm movements when catching the ball, suggesting that arm movements and head movements are linked to catching skills. Taken together, skilled ball players have relatively stable head and eye movements, which may lead to an effective visual search strategy.

Title: Dissimilarity of finger individuation behavior between flexion and extension

Authors: *O. RAJCHERT, Y. MELUL, F. MAWASE;
Biomed. Engin., Technion - Israel Inst. of Technol., Haifa, Israel

Abstract: The ability to individuate fingers imparts high motor flexibility and requires accurate coordination of different finger flexor and extensor muscles. Although most everyday hand movements involve coordination of flexor muscles for both gross and fine activities (e.g., grasping, typing), the role that extensor muscles play in these types of movements is unclear. Here, we investigated two aspects of independence of the digits during single and multi-finger isometric force assessments, *individuation* - the degree to which all uninstructed digits remain still during instructed movement of a particular digit, and *stationarity* - the degree to which a particular uninstructed digit remains still during movements of all instructed digits. The study was split up into 2 experiments. In Exp. 1, participants (n=13) used a hand robot (Tyromotion's Amadeo®) and producing finger forces, each time with a different single finger, to maintain one of four levels (20,40,60,80% of the maximal voluntary contraction) in both the extension and flexion directions. Participants then performed multi-digit chords (2-digit, 3-digit, and 4-digit) in each direction. We found that during single-digit tasks, individuation and stationarity were significantly lower for extension ($p<0.0001$). Interestingly, we found dissimilar involvement of the opposite muscle direction for uninstructed digits when comparing extension and flexion. While exertion of single-digit extensor forces revealed that in the uninstructed fingers extensor muscles were primarily involved, single-digit flexor forces involved flexors of the adjacent uninstructed digits and extensors of the non-adjacent uninstructed digits. In the multi-digit task, accuracy was reduced for fingers during exertion of force in

the extension direction ($p<0.0001$) and chords with 2 or 3 digits were less accurate for both flexion and extension compared to chords with 1 or 4 digits. Next, we studied the extent to which mechanical coupling between muscle extensors and flexors limits finger independence by studying passive individuated finger movements (Exp. 2). Our data suggest that when the robot passively moved each of the fingers, the reduced mechanical coupling for the extensors could not fully explain the reduced individuated extensor muscles' behavior we encountered during Exp. 1. Overall, our data suggest that finger individuation is dissimilar for extension and flexion and that this disparity is attributed to neuromuscular control, rather than passive mechanical coupling. This study sheds light on characterization of a more complete mechanism of hand function taking into account not only flexion, but also extension.

Title: Use of Immersive Virtual Reality for Assessing Gross Hand Dexterity

Authors: *S. PARKER[1], E. BUCKLEY[2], K. COULTER[2], B. RICKS[2], J. ZUNIGA[1], B. KNARR[1]; [1]Biomechanics, [2]Computer Sci., Univ. of Nebraska, Omaha, Omaha, NE

Abstract: Virtual Reality (VR) is a promising technology that allows for tasks to be performed in a virtual environment that uses less physical space. Previous studies have reported increased functional outcomes with screen-based VR systems[1-5]. However, it is not well known whether immersive VR elicits similar functional outcomes and brain activation as conventional manual therapy. The purpose of this study is to assess the use of immersive VR as a modality for testing total hand dexterity in adults while performing the Box and Block (BBT) test under observation with functional near-infrared spectroscopy (fNIRS). We hypothesize that there will be no difference in the magnitude of contralateral motor cortex (CM1) activation between Manual and VR condition for both the left and right hands. The contralateral activation was chosen in accordance with previous studies that support CM1 activation during arm & grasping tasks[6,7]. Ten participants (5M/5F, age: 26.9±6 years, height: 1.7±0.3 m, weight: 80.1±21 kg, hand dominance: 8 right/2 mixed) were included in analysis. Participants were asked to complete the BBT Manually and in VR (Oculus Rift, Oculus) with their left and right hands for 3 one-minute trials each. A block study design was implemented with one-minute breaks given between trials and three-minute breaks between hands and conditions. The order of BBT condition and hands were randomized for each participant. fNIRS (NIRSport2, Nirx) was used to record levels of CM1 activation for each condition. CM1 activation was calculated using a group level general linear model (GLM) analysis with the NIRS AnalyzIR toolbox[8,9]. The beta values were used in a 2x2 Anova to determine the main effect difference

between VR and Manual conditions for both hands with significance correction. The behavioral outcome measure was BBT score for each condition. Two paired t-tests were performed using BBT scores comparing the Manual and VR conditions for both hands. All statistical analyses were performed in Matlab R2018a (Mathworks) with significance at $\alpha \leq 0.05$. The Manual condition exhibited a significantly higher BBT score compared to the VR condition for both left (Manual: 61±10, VR: 40±13, $p = 0.003$) and right (Manual: 62±7, VR: 42±10, $p < 0.001$) hands. This reduction in functional VR BBT score may be a result of reduced tactile input from the VR controllers combined with the VR being a novel task. There is no significant interaction in CM1 activation between the Manual and VR BBT conditions (all channels $q > 0.05$). CM1 activations were comparable between Manual and VR conditions, suggesting that VR systems may elicit similar cortical responses compared to the conventional Manual BBT.

Title: Horizontal target size perturbation during grasping movements modifies sizes perception and saccade amplitude

Authors: P. SANZ DIEZ[1,2], *A. BOSCO[3,4], P. FATTORI[3,4], S. WAHL[1,2];
[1]Carl Zeiss Vision Intl. GmbH, Aalen, Germany; [2]Inst. for Ophthalmic Res., Eberhard Karls Univ. Tuebingen, Tuebingen, Germany; [3]Dept. of Biomed. and Neuromotor Sci., [4]Alma Mater Res. Inst. for Human-Centered Artificial Intelligence (Alma Human AI), Univ. of Bologna, Bologna, Italy

Abstract: Action and perception are crucial aspects of our daily activities. Based on the dual-visual stream theory, it is now accepted that action and perception are not separated processes, but they interact and influence each other. However, it is still unknown how object perception may be affected by unpredictable changes in object size during grasping movements. In this study, we aimed to determine whether size perception and related saccade amplitude before and after grasping movements were modified by horizontal perturbations of target size during movement execution and under the presence (TF) or absence (NoTF) of tactile feedback exerted on the fingerprints by vibration motors. We have tested twenty-one participants (mean 25.05±4.08years) in 4 blocks of 30 trials where the blocks were divided into two categories: TF and NoTF. Trials consisted of 3 sequential phases: pre-grasping size perception, grasping, and post-grasping size perception. During pre- and post- phases, participants were required to execute a saccade towards a horizontal bar and to perform a manual size estimation of the bar size by extending the index finger and thumb. During the grasping phase, participants were asked to execute a saccade towards the bar and to make a grasping action towards the screen matching the edges of

the displayed bar by extending the index finger and thumb. During the grasping phase, 3 horizontal size perturbation conditions were applied after the onset of the grasping movement: non-perturbation, shortening, and lengthening. 30% of the trials presented perturbation, meaning a symmetrically shortened or lengthened by 33% of the original size. Participants' hand and eye positions during the estimation phases were assessed by a motion capture system and a mobile eye-tracker, respectively. In both NoTF and TF, the difference between perceptual responses in pre- and post- phases revealed significant adjustments. After grasping, size estimation was significantly reduced in lengthening ($p=0.002$; Wilcoxon) and non-perturbation conditions ($p<0.001$; Wilcoxon), whereas shortening condition did not induce significant adjustments ($p=0.86$; Wilcoxon). After grasping, saccade amplitude became significantly longer in shortening condition ($p<0.001$; Wilcoxon) and significantly shorter in lengthening condition ($p<0.001$; Wilcoxon). Non-perturbation condition did not display significant adjustments ($p=0.95$; Wilcoxon). These results suggest that the horizontal size perturbation occurring during the grasping action is reflected on size estimation and saccade amplitude measured in the subsequent perceptual phase.

Title: Humans modulate gripping forces on a stationary, handheld object in response to mere expectation of rapid movement

Authors: *A. S. NAIK, S. AMBIKE;
Hlth. and Kinesiology, Purdue Univ., West Lafayette, IN

Abstract: Recent studies show that while manipulating hand-held objects, the grip force (GF) is not as tightly coupled with the load force (LF), as previously thought. Rather, the predictability of the LF imposed by volitional object movement influences the GF magnitude and the GF-LF coupling. Here, we study the anticipatory modulation of GF to understand further the sensorimotor control of prehension. Previous studies explored the GF-LF coupling while the object was in motion. Hence, we studied GF control during the *foreperiod* of a choice reaction-time (CRT) task, when an object is held static, but participants expect to move it in response to a visual cue. The goal was to identify how GF exerted on a static object changes in response to a mere expectation of object movement. Since GF increases with task uncertainty, we hypothesized that GF would increase when participants expect to move but are uncertain about the time and direction of movement. Healthy adults ($N = 16$; 24 ± 4 yrs.) held an object in a pinch grasp in their dominant right hand and tracked a target provided on a computer screen by moving the object vertically. Digit forces and object position were measured using force transducers and motion capture. Visual feedback of the object's position was provided as a cursor on the screen. In steady tasks, participants were aware that the target will not move. They did not expect to move the object, and held the object static so that the cursor remained inside the target. CRT tasks began like steady tasks, but

participants expected the target to jump either up or down at any moment. They were required to track the target as quickly as possible by moving the object. We compared the mean GF for steady tasks and during the foreperiod of CRT tasks before object movement began. As predicted, the GF increased by 13% when movement was expected versus when it was not expected ($t_{(15)} = 3.1$, $p < .01$). This is a novel finding: GF increased in response to mere expectation of movement, even as the LF remained constant. By increasing GF, the central nervous system (CNS) may increase tactile feedback to improve predictive control of digit forces. Tactile feedback is thought to be intermittent for predictable manipulation tasks. However, when upcoming movements are uncertain and involve significant state changes, more frequent feedback will yield superior current state estimates, which, in turn, would facilitate motor planning and execution. Also, when upcoming movements are uncertain, the CNS may prepare and optimize multiple plans associated with possible movements. Increased GF may be a manifestation of such optimization since the GF eventually increases after the foreperiod during both up and down movement.

Title: Individuated finger control in fine manipulation introduces a cost of decreased trajectory smoothness

Authors: *J. XU[1], T. MA[2], S. KUMAR[3], K. OLDS[4], J. BROWN[4], J. CARDUCCI[4], A. D. FORRENCE[5], J. W. KRAKAUER[4];

Abstract: Humans possess remarkable skills in fine object manipulation. This ability is presumably enabled by increased individuated finger control due to enlarged corticospinal tract (Lawrence & Kuypers, 1968). In the motor control field, it's been established that good control manifests as smooth trajectories (Flash & Hogan, 1985, Harris & Wolpert, 1998). However, what is the role of individuation ability in smooth control in object manipulation is not clear. Here we investigated this question by directly comparing people's finger individuation and their trajectory qualities in precision grip. We developed a sensitive device to measure subtle isometric forces at all fingertips in three-dimension (3D), and designed 3D individuation and three precision-grip tasks. We hypothesize that increased finger individuation may be an important factor of smooth manipulation.
Healthy college-aged participants (N=22 for Individuation and Grip 1, N=17 for Grip 2&3) placed their hands in the device in a comfortable resting posture. In the individuation task, participants were required to move a dot in a 3D virtual cartesian space by exerting isometric forces at one of the fingertips while keeping other fingers immobile. Movement of the dot along virtual xyz axes reflected forces exerted by

MCP ab/adduction, PIP flexion/extension, and MCP flexion/extension, respectively. In the 3 grip tasks, participants attempted to grasp a small spherical object in the 3D virtual space with their thumb and index/middle finger (max force < 3N). The object was placed in the middle of the straight line between the two fingers. In Grip 2 task, the two fingers had to enter tunnels before the grip; in Grip 3 task, they attempted to first grasp a small dial of the same diameter and then turn the dial with +/-20 or +/-45 degrees to match the 12 o'clock position.
From the force traces recorded during the entire trial, we derived Individuation Index, initial and final grip angles, and trajectory smoothness (jerk cost). Our results showed that individuation ability did not play a role in final grip angles ($p = 0.27$) but was a significant factor in the initial positioning of fingers in Grip 2&3 tasks ($p<0.001$), where individuation ability was demanded. Contrary to our prediction, in these two tasks grip trajectory were jerkier than those in simple grips (Grip 1 task) ($p = 0.008$), and individuation ability were negatively correlated with smoothness ($p < 0.01$). In the dialing task, trajectories became jerkier when the angle to be adjusted was smaller (20 deg.) ($p = 0.00005$). We conclude that the evolutionarily new finger individuation system entails a cost of increased movement variability in fine manipulation tasks.

Title: Re-optimization processes to gravitational perturbation in reach-to-grasp movements

Authors: *L. ANDO[1], Y. ITAGUCHI[2];
[1]Grad. Sch. of Integrated Sci. and Technol., Shizuoka Univ., Hamamatsu, Japan; [2]Fac. of letters, Keio Univ., Tokyo, Japan

Abstract: In a daily life, we often experience arm weight changes when using tools or lifting of objects. Most of the studies of motor adaptation in force-field have investigated adaptation processes to force applied in the horizontal plane, but not to force in the gravitational direction. In this study, we investigated the re-optimization processes to forearm-weight increase in the trajectory planning of reach-to-grasp movement. We hypothesized that the height of movement trajectory is modulated to reduce disturbances due to signal-dependent noises in the gravitational direction. To confirm this hypothesis, we conducted 400 trials of reach-to-grasp movement tasks under three weight conditions; no-weight 200 g, 400 g weight condition, which was also supposed to induce muscle fatigue. Signal-dependent noise can be increased by two factors: increased muscle force against the forearm weight and muscle fatigue. We thus set two predictions; first, the movement trajectory will be higher in the weight conditions than the

no-weight condition, and second, the movement trajectory will continue to increase as a function of trials in the 400 g weight condition.In the experiment, right-handed 14 participants performed reach-to-grasp movements on a desk. They reached for and grasped a target object located 30 cm in front of the starting point and transported it 10 cm right of target position with their right-hand. The participants performed eight blocks per each condition, and one block consisted of 50 trials. They experienced each of the three weight conditions alternatively every other month. Under the no-weight condition, the participants performed the movements without any weight. Under the 200 g and 400 g weight conditions, they performed the movements with 200 g or 400 g weight attached to their forearm except in the first and last block. We calculated max height and MGA (maximum grasp aperture); max height was defined as the maximum height of the wrist position from the desk, and MGA was defined as the maximum distance between the tips of the thumb and index finger. The results showed that max height was evidently higher compared with the baseline block in the 200 g and 400 g conditions and continued to increase as function of trials only in the 400 g condition. These results support our hypothesis that participants might re-optimize their movement trajectories to the increase in forearm weight by raising the height, which can reduce disturbances due to signal-dependent noises attributed to increased muscle force against the forearm weight or muscle fatigue.

Title: Grip dynamics during object manipulation on the International Space Station

Authors: *L. OPSOMER[1,2], J.-L. THONNARD[1,2], F. CREVECOEUR[1,2], J. MCINTYRE[3,4,5], P. LEFEVRE[1,2];

Abstract: During object manipulation, the brain must predict the consequences of arm movements to adjust grip force anticipatively and ensure a stable grasp. Parabolic-flight studies have shown that the temporal coordination between grip force and load force is preserved during object manipulation in extreme gravito-inertial environments, such as Mars, Moon, hyper- or micro- gravity (Augurelle et al., 2003; White et al., 2005; Crevecoeur et al., 2009; Opsomer et al., 2018). However, it was also observed in these studies that participants tend to increase the grip-load force ratio in microgravity, probably to increase the safety margin against accidental slips. But what are the characteristics of the grip force/load force coupling in microgravity after long-term adaptation, i.e. when this environment is not novel

anymore? Do astronauts tune the grip force to the object mass and movement-induced inertial loads with the same accuracy as they do on Earth? To address this question, we asked six astronauts to perform rhythmic arm movements with an object held in precision grip, both on Earth and during long-term (>5-months) missions on the International Space Station. Various masses were used, as well as various oscillation frequencies. Corroborating the results from previous studies, a steady grip force/load force correlation was rapidly acquired, both on the ground and during space flight. Strikingly, the grip-load force ratio at the time of maximum load was independent of object mass, movement frequency or gravity level. This constant force ratio was achieved by offsetting the grip force as a function of load force range, consistent with the ability to estimate the slip ratio properly and suggesting that tactile and proprioceptive feedback are integrated quickly to update the anticipatory control of grip force. Interestingly though, even after several months of exposure to microgravity, up/down asymmetries were observed in the grip force modulations, despite symmetrical load force fluctuations.

Title: A method to study prehension in primates

Authors: *A. R. SOBINOV[1], C. M. GREENSPON[2], E. V. OKOROKOVA[1], Y. YAN[1], S. J. BENSMAIA[2];
[2]Dept. of Organismal Biol. & Anat., [1]Univ. of Chicago, Chicago, IL

Abstract: A hallmark of primate behavior is the exceptional ability to dexterously grasp and manipulate objects. Investigation of the neural mechanisms that support manual dexterity has been hindered by technical challenges. First, tracking the time-varying posture of the hand is difficult given its many articulated segments and the susceptibility of individual segments to occlusion. Second, characterizing the contact forces exerted on objects with sufficient precision is challenging given the exquisite sensitivity and spatial resolution of the sense of touch. Third, contact forces propagate down the limb in the form of joint torques and alter muscle activity. Measurements of limb state and object interactions is thus critical to understanding the neural mechanisms that mediate manual object interactions.
With this in mind, we have developed an experimental apparatus to overcome these challenges. First, the apparatus allows us to place an object anywhere in the workspace. Second, the objects size and orientation can be systematically manipulated. Third, the object is sensorized with thousands of pressure-sensitive elements that allow us to measure the forces exerted at each point of contact. Fourth, hand and arm movements are tracked using eight high-speed cameras, whose output is then processed using machine vision algorithms to track the positions of 34 markers on the limb in 2D for each camera. The

positions of the markers are then triangulated based on the 8 planar estimates (on from each camera) and used to obtain time-varying joint angles using a musculoskeletal model of the limb. Finally, we solve an optimization problem in a physics engine to adjust the object's position with respect to the hand to reproduce the pattern of exerted forces. Having reconstructed contact forces, applied to the corresponding contact locations on the hand, and reconstructed the posture of the entire limb, we can then calculate the torque at each joint using inverse dynamics. Together, these measurements provide a characterization of primate manual behavior with exceptional precision, which opens the door to an unprecedented investigation of the neural mechanisms of manual dexterity.

Title: Human and monkey hand kinematics during prehension

Authors: *Y. YAN[1], A. SOBINOV[3], S. J. BENSMAIA[2];
[2]Dept. of Organismal Biol. and Anat., [1]Univ. of Chicago, Chicago, IL; [3]West Virginia Univ., Morgantown, WV

Abstract: HUMAN AND MONKEY HAND KINEMATICS DURING PREHENSION Yuke Yan, Anton R. Sobinov, & Sliman J. BensmaiaThe human hand is a remarkably precise and versatile manipulative organ, enabling interactions with objects that range from the mundane – like grasping an object – to the extraordinary – epitomized by virtuosic instrumentalism. Our understanding of the neural mechanisms that mediate manual dexterity has relied heavily on experiments with non-human primates, and in particular macaques, whose hands and sensorimotor systems are similar to their human counterparts. Indeed, the anatomy of human and macaque hands is largely similar and homologs to the neural structures that support the sensorimotor control of the hand in humans have been identified in macaques. Qualitatively, manual behavior is also similar in humans and monkeys. Like humans, monkeys preshape their hand before grasp in an object-specific way and are capable of some degree of finger individuation. However, to our knowledge, human and monkey manual behavior has never been compared using detailed quantitative approaches that have been used to characterize manual behavior of either species separately. With this in mind, we systematically compared the prehensile behavior of humans and rhesus macaques using an identical experimental paradigm. In brief, humans and monkeys grasped a set of 35 objects handed to them by a robot while we monitored the time-varying joint angles of their hands using a computer vision algorithm. We then compared the hand kinematics of human and monkeys using a variety of quantitative approaches. First, we analyzed the range of motion, velocity, and acceleration of the kinematics. Second, we quantified the degree to which the kinematic subspaces of humans and monkeys are similar. Third, we assessed the interdependence of human and monkey joint movements. Finally, we decomposed the variance in hand postures into different task-dependent and

independent components. We found that, while hand kinematics of prehension are similar in humans and monkeys, these differ in subtle but systematic ways. For example, although thumb is the most independent digit in both species, other human fingers move more independently and adopt postures that are more tightly dependent on the object to be grasped. This careful comparison of human and monkey manual behavior provides a further assessment of the validity of the macaque sensorimotor system as a model of human manual behavior.

Title: Joystick-based Motor Control Task During Sympathoexcitation via Cold Pressor in Healthy Humans

Authors: *T. REISSMAN[1], P. KOMPA[2], K. DUFFY[2], S. COLLINS[2], M. REISSMAN[1], A. CRECELIUS[2];
[1]Dept. of Mechanical Engin., [2]Dept. of Hlth. and Sport Sci., Univ. of Dayton, Dayton, OH

Abstract: Motor control performance is important in tasks that require piloting of a vehicle and thus it is of interest to understand the physiological changes that may impact motor control. Little work to date has been done that attempts to couple physiological measurements such as cerebral blood flow to motor control tasks, particularly in situations of enhanced autonomic nervous system activity. Here, we utilized a joystick-based virtual beam rotation task to assess motor control performance. After a familiarization trial, 24 young, healthy subjects (12M, 12F, age: 21±1 yrs) performed the task in either control conditions or with concomitant sympathoexcitation via cold pressor (CP; foot submerged in 4°C ice slurry), with the order counterbalanced across subjects. Throughout each trial, heart rate (HR; 3-lead ECG), beat-beat arterial blood pressure (BP; finger photoplethysmograph), end-tidal CO_2 (nasal cannula) and middle cerebral artery velocity (MCAv; transcranial doppler), an indicator of cerebral blood flow, were measured. The motor control task consisted of a virtual horizontal beam with a circular ball on its upper surface. A target section of the beam (one of 4 options, near and far on right and left of center) was identified with lines. Subjects were instructed to rotate the joystick in order to tilt the beam and cause the ball to both roll and slow down within the target area. The total motor control task consisted of 10 blocks, where the 4 locations were randomized within each block. Differences between control and CP were assessed with a paired t-test and differences across all timepoints were assessed via repeated-measures ANOVA with post-hoc pairwise (Sidak) test with *a priori* $p<0.05$). The CP elevated HR and BP as anticipated (74±11 vs 84±13 bpm, p=0.0002; 93±8 vs 95x±8 mmHg, p=0.00004). At 30 sec, MCAv significantly increased with motor control task in control (Δ 4.8±7.0%, p=0.007) and CP conditions (Δ 8.7±7.8%, p=0.0001), and this increase was greater for CP vs control (p=0.01). Results did not vary if

separated by sex. Motor control performance was quantified according to the tasks for the 2 near targets and the 2 far targets, as each pairing had the same difficulty level as per Fitts' law. Statistical differences were observed only within the first 30 sec. Total task completion time increased with CP vs control for both the near targets (Δ 0.89s or 21%, $p<0.001$) and the far targets (Δ 0.55s or 11.6%, $p=0.007$). Results indicate these increases were not due to changes in movement initiation but increased movement corrections. Taken together, we demonstrate that sympathoexcitation can negatively impact motor control performance despite increased cerebral blood flow.

Title: Control of manipulative forces on the leg during walker ambulation is hard for human trainers

Authors: J. MANCZUROWSKY, *C. HASSON;
Northeastern Univ., Boston, MA

Abstract: To provide effective physical assistance clinicians must implicitly know how to apply forces to patients' bodies to generate desired motions. This mapping between forces and motion can be framed as an internal model of patient dynamics. In gait rehabilitation these models can be complex, but nevertheless can be learned by non-experts as previously shown. One may expect that the clinical experiences of physical therapists (PTs) provides a foundational set of internal models that can be rapidly adapted to new patients. This study tests the hypothesis that PTs adapt to novel locomotor dynamics faster than non-PTs. We asked two groups of trainers (21-65 yrs), PTs and non-therapists, to reproduce a time-varying pattern of manipulative forces on the leg of a healthy individual walking on a treadmill (the walker). For experimental control all participants interacted with the same walker. The walker wore a right ankle brace that served as an attachment point for a force sensor sandwiched between the brace and a handle the trainers grasped. Walker leg motion and assistive force templates were created from data collected while a PT provided manual assistance to increase the (same) walker's step length. Trainers (PTs and non-PTs) first practiced two randomly presented control conditions without walker dynamics present: 1) trajectory-matching in which trainers tried to match the walker leg motion template while moving their hands in free-air, 2) force-matching where the trainers tried to match the force template by pushing on the walker's leg while the leg remained stationary. Next, trainers practiced two randomized conditions in which success depended on appropriately compensating for external forces from the walker's leg: 1) exerting zero force while holding onto the moving walker's leg, 2) producing forces to match the force template (on a moving leg). In these conditions the walker attempted to maintain the same

locomotor kinematics, aided by a real-time visual display of their motion overlaid with a target trajectory. Data collection is ongoing; preliminary results suggest that without needing to account for walker dynamics, both PTs and non-PTs can move their arms in the requisite leg trajectory and can apply time-varying forces that match the force template. However, both PTs and non-PTs had difficulty adjusting their motor commands to match the force template when the walker ambulated, with high force errors. Both trainer types adapted and improved with practice. Whether PTs have faster adaptation rates than non-PTs should become clear with additional data. Knowledge of how PTs interact with patient dynamics may help develop future approaches to enhance PT performance.

Title: Social-context-dependent activation of the social behavior network in zebra finch songbirds

Authors: *K. L. ANDERSON, J. URAGA, O. WHITNEY;
Biol., City Col. of New York, New York, NY

Abstract: As the environment presents both obstacles and opportunities to organismal fitness, the nervous system functions to evaluate stimuli encountered and generate context-appropriate, adaptive behavioral responses. Such decisions in animals involve brain mechanisms that are not well understood. Recent studies of species-specific adaptive behavior implicate evolutionarily conserved and reciprocally connected brain regions, termed the social behavior network (SBN). However, few studies have investigated the genomic response of regions within the SBN to social behavior stimulation of naturally behaving animals (i.e., not hormonally manipulated). Here, using zebra finch songbirds, we measure activity-dependent gene expression to investigate SBN activation during a non-social context of undirected singing and a social context of female-directed singing. We performed fluorescence *in situ* hybridization to map the transcription of cellular activity marker *EGR1* within the SBN of zebra finches. Three adult males from each experimental group (non-social undirected singing; socially directed singing) were housed individually in acoustic attenuation chambers. Singing males sang spontaneously for 45 mins at the beginning of their 14:10 light cycle in either the presence or absence of a female. Subsequently, brains were quickly excised and freshly frozen for serial coronal cryosectioning. Tissue sections were thaw mounted onto slides and hybridized to FITC-labeled *EGR1* RNA probes. Antibody detection of FITC revealed *EGR1* within regions of interest, which was quantified using ImageJ2 and standardized against DAPI nuclear DNA staining. Similar to previous studies, we found higher levels of *EGR1* in all cerebral vocal-control regions of undirected singing males (HVC, RA, lMAN, and Area X) compared to that in Area X and RA of directed singers. Compared to non-social undirected singing

controls, we found an upregulation of *EGR1* in the VMH, AH, and LS of socially directed singing males. Additionally, we found increased *EGR1* in the PVN, an area with known direct projections to the SBN, in socially directed singing males compared to non-social undirected singing controls. No hemispheric differences were found. These findings suggest that the social behavior network of zebra finches may be part of a larger social decision-making network regulating adaptive behavior in response to environmental challenges. Furthermore, the molecular signatures and epigenetic mechanisms in the SBN that are associated with socially motivated behavior may have a fundamental role in maintaining the neural circuits that direct organismal decision-making.

Title: Social interaction shapes selective memory in the higher auditory area through the neuronal activities of Locus Coeruleus

Authors: *J. KATIC, Y. MOROHASHI, Y. YAZAKI-SUGIYAMA;
Okinawa Inst. of Sci. and Technol. (OIST) Grad. Univ., Okinawa, Japan

Abstract: Juvenile zebra finches learn to sing by engaging in social vocal communications with their fathers (tutors). Being socially exposed to a tutor singing is crucial for juveniles to learn songs. Here we show by recording extracellular single-unit activities in free-moving juvenile zebra finches that neurons in the locus coeruleus (LC), an attention control area, exhibited greater activities when juveniles vocally communicate with tutors. The LC neurons responded stronger to live tutor singing (LIVE TUT) than to playback of pre-recorded tutor songs (TUT playback) (mean response strength (RS) to TUT playback: 1.6 ± 0.4 (spikes/s), to LIVE TUT: 15.98 ± 2.8(spikes/s)). The LC neurons which were activated by LIVE TUT sent axons to the zebra finch higher auditory cortex, the caudomedial nidopallium (NCM), where early tutor song memories form. Previously we showed that a fraction of NCM neurons, which had broader spiking shape, responded selectively to TUT playback (TUT-selective neurons). Here we exposed juveniles to a live tutor for five days (60~90 min /day) and tracked auditory responsiveness of NCM neurons to LIVE TUT and TUT playbacks. We found TUT-selective neurons exhibited greater response to LIVE TUT than to TUT playback only in the first two days of tutoring. After hearing LIVE TUT (> 60 min) those neurons showed greater responses even to TUT playbacks for hours (mean RS before: 0.4 ± 0.2, after: 4 ± 0.67 (spikes/s)). We further found that proportions of TUT-selective neurons increased only for the first two days of tutoring. After the 3rd day of tutoring the neurons which showed responses to TUT playbacks did not increase response strength to LIVE TUT. To ask whether LC neurons directly influence song perception in the NCM, we optogenecially blocked LC terminal activities in the NCM

every time juveniles heard LIVE TUT and recorded NCM neuronal activities. The NCM neurons, which responded to TUT playbacks, showed reduced responses to LIVE TUT when paired with LC terminal inhibition (mean RS to TUT playback: 7.9 ± 0.88, to LIVE TUT with LC inactivation: 3.3 ± 0.73 (spikes/s)). Those neurons showed a reduced response to TUT playback hours after LC terminal inhibition but showed no response reduction to playbacks of other song stimuli. Finally, juveniles, which were hearing LIVE TUT for three days with LC terminal inhibition failed to copy tutor songs (similarity to TUT = 33.7 %, N=6), while control juveniles learned tutor songs well (similarity to TUT = 71.3 % N=6). Taken together, our data suggest that social vocal communication with a tutor modulates song perception in the auditory cortex and shapes selective auditory memories through neuronal activities of the LC.

Title: Dopamine neurons evaluate natural fluctuations in performance quality

Authors: A. DUFFY[1], K. W. LATIMER[2], J. H. GOLDBERG[3], A. L. FAIRHALL[1], ***V. GADAGKAR**[4]; [1]Dept Physiol & Biophys, Univ. Washington, Seattle, WA; [2]Neurobio., Univ. of Chicago, Chicago, IL; [3]Dept. of Neurobio. and Behavior, Cornell Univ., Ithaca, NY; [4]Zuckerman Mind Brain Behavior Inst., Columbia Univ., New York, NY

Abstract: Many motor skills are learned by comparing ongoing behavior to internal performance benchmarks. Dopamine neurons encode performance error in behavioral paradigms where error is externally induced, but it remains unknown if dopamine also signals the quality of natural performance fluctuations. Here we recorded dopamine neurons in singing birds and examined how spontaneous dopamine spiking activity correlated with natural fluctuations in ongoing song. Antidromically identified basal ganglia-projecting dopamine neurons correlated with recent, and not future, song variations, consistent with a role in evaluation, not production. Furthermore, dopamine spiking was suppressed following the production of outlying vocal variations, consistent with a role for active song maintenance. These data show for the first time that spontaneous dopamine spiking can evaluate natural behavioral fluctuations unperturbed by experimental events such as cues or rewards.

Title: Further exploration of the activation of the mTOR cascade throughout development in juvenile zebra finches.

Authors: *R. M. BUTLER[1], S. E. LONDON[2];
[2]Dept of Psychology, [1]Univ. of Chicago, Chicago, IL

Abstract: Early life experiences can result in long-term patterns of behavior when they occur when the brain is sufficiently mature to encode them as memories. An example is a Critical Period (CP), a restricted period of development during which a specific experience has profound and permanent effects on brain function and behavioral patterns. Here, we use a CP in sensory song learning in zebra finch songbirds to study mechanistic connections between juvenile maturation and experiential processes, and the emergence of adult brain function and behavior.
Adult male zebra finches sing a song that reflects a sensory memory of a "tutor's" song they formed during a CP. The process of forming this memory is known as Tutor Song Memorization (TSM) and requires the auditory forebrain. As adults, after the closure of the CP, the auditory forebrain's function changes to support song recognition learning. Females cannot sing, but behave in ways as adults that demonstrate they also form sensory song memories during development. The function of the adult female auditory forebrain appears equivalent to that of the male. But, we recently showed using phosphorylation of ribosomal protein S6 (pS6), a necessary step for protein translation and thus long-term memory formation regulated by the mTOR cascade, that male and female juveniles may in fact use different mechanisms to perform sensory learning, even if they are indistinguishable in adulthood. This prompts the question: what elements of development – maturational progression, experiential accumulation, and genetic sex – contribute to the observed change in molecular response to hearing song?
To answer this question, we used immunohistochemistry to quantify pS6+ cells within the auditory forebrain after males and females, aged to span the CP, heard song. We included males that allowed us to specifically test the role of accumulated tutor song experience, a crucial determinant of the CP close. We found the greatest density in pS6+ cells after hearing song at the onset of the CP compared to all other ages. We confirmed the previously reported sex difference at the onset of the CP, but found that this sex difference does not persist at older ages. We found that hearing song led to a greater increase in pS6+ cells in birds without prior song exposure compared to the birds that had accumulated song experience. These data suggest that a fundamental mechanism of developmental learning and memory, the phosphorylation of S6, is modulated by all elements of development, which need to be considered in studies linking early life experiences and adult behavioral patterns.

Title: Female vocalizations during song learning shape song performance by altering premotor neuron activity in juvenile zebra finches

Authors: *L. BISTERE, D. VALLENTIN;
Max-Planck-Institute for Ornithology, Seewiesen, Germany

Abstract: Learned motor behaviors are often shaped by social influences. For instance, human infants learn to speak through the process of observation learning, imitating and observing parental feedback. Similarly, young zebra finches learn their song from their fathers. To some extend young birds are also able to learn to imitate from playbacks of tutor song without direct feedback. So far, a possible contribution of female zebra finches to song learning has been largely neglected. To understand whether the presence of a female supports song learning, we raised two groups of juvenile males to match the same tutor song in an operant conditioning paradigm. Juvenile birds in each group were either exposed to a female bird or kept socially isolated during the song learning phase. We found, that female zebra finches have an impact on the learned song tempo. Male zebra finches raised with a female copied the tutor song tempo more accurately compared to birds, that were raised socially isolated. We then wanted to characterize the vocal feedback of female birds in respect to songs with different tempos. Therefore, we exposed female birds to playback of a song that was modified to match three different tempos. Female birds responded most to adult song with slow tempo, which suggests that females change their feedback depending on the temporal aspects of song. Next, we wondered how this vocal feedback is processed in the song production pathway of juvenile zebra finches. The premotor nucleus HVC is known to be involved in song learning and song production, but whether auditory feedback by females can also impact this circuitry to support song learning is not known. We performed intracellular recordings of premotor neurons in HVC in awake and listening juvenile zebra finches while presenting playbacks of female calls alone and bird's own songs that were accompanied by female vocalizations. We found that female calls in both contexts had the potential to alter the activity of premotor neurons. Taken together, these findings support the notion that auditory feedback by females contributes to neural plasticity within a premotor circuit which leads to improved learning of the song tempo in juvenile zebra finches.

Title: Axon retraction within a sensory-motor circuit coincides with the closure of a critical period for song learning

Authors: M. I. M. LOUDER[1], M. KURODA[1], Y. MOROHASHI[2], D. TANIGUCHI[1], ***Y. YAZAKI-SUGIYAMA**[2,1];
[1]Intl. Res. Ctr. for Neurointelligence, the Univ. of Tokyo, Tokyo, Japan; [2]Okinawa Inst. of Sci. and Technol. (OIST) Grad. Univ., Okinawa, Japan

Abstract: Young male zebra finches listen and memorize the songs of tutors (normally their father songs) during the auditory learning phase, and then in the following sensory-motor learning phase, match their vocalization to the memorized tutors' songs. Cumulative studies have suggested that the caudomedial nidopallium (NCM) serves as a primary site for the storage of auditory memories of the tutor song. Yet whether the stored auditory memory of the tutor song in the songbird auditory forebrain guides song development remains unknown. Here we investigated the anatomical connections for the subset of NCM neurons which were activated by hearing the tutors' song (Yanagihara & Yazaki-Sugiyama, 2016), and their functional relationship to song learning. We injected in the NCM of juvenile male zebra finches (40-45 DPH) with the adeno associated viral vector (AAV9-cFos-TetOn-EYFP-PEST) and induced EYFP expression in the activated neurons with playback of their tutor's song in the presence of doxycycline at 55-60 DPH. Using whole-brain tissue clearing and light-sheet microscopy, we identified axons of tutor-responsive NCM neurons with long-range projections to song system nuclei, including the song premotor nucleus HVC. We confirmed that NCM-HVC axonal projections were observed in juvenile males (2% area ± 1%, n=6) but not in adult male zebra finches (> 90DPH; 0.1% area ± 0.1%, n=6) in conventional brain sections. To test whether the stored memory in the NCM is involved in song learning, we selectively lesioned the tutor-responsive NCM neurons in juvenile males with a cocktail of viral vectors (AAV9-cFos-TetOn-CaCasp3 and AAV9-cFos-TetOn-dT) which induces apoptosis upon hearing the tutor song playback. After lesioning, we isolated the males and measured the song similarity to the tutor song at 70 DPH. Juveniles with lesions of tutor song-responsive NCM neurons produced songs with less similarity to the tutor song than controls, brothers which were not exposed to tutor songs ($p=0.03$, $d=0.86$, $n=18$). Consistent with the observation of a developmental retraction of NCM-HVC axonal connections in adults described above, lesions of tutor-responsive NCM neurons after the sensory-motor learning phase (> 90 DPH) did not affect song learning ($p=0.74$, $d=0.22$, $n=6$). Taken together, our results suggest that the auditory memory of the tutor song stored in the NCM is involved in instructing motor learning but is developmentally limited by axon retraction upon the closure of the critical period for sensory motor learning.

Title: Optogenetic manipulations of HVC interneurons in adult zebra finches lead to changes in song production

Authors: *F. HEIM[1], E. MENDOZA[2], C. SCHARFF[2], D. VALLENTIN[1];
[1]Max Planck-Institute for Ornithology, Seewiesen, Germany; [2]Freie Univ. Berlin, Berlin, Germany

Abstract: Juvenile male zebra finches learn their song from an adult tutor. They start babbling around one month after hatching, undergo a variable plastic song phase and after three months, a more or less accurate copy of the tutor's song is established and changes little thereafter. The premotor nucleus HVC (proper name) plays a key role in this process and also in adult song production. HVC contains four main cell types, including premotor neurons and inhibitory interneurons, which participate in song production and song learning. As the juvenile's song is being consolidated and becomes more similar to the tutor's song, GABAergic interneurons selectively inhibit premotor neurons during the presentation of song elements a juvenile has already mastered while inhibition is lower during elements that require more practice. Presumably, auditory-induced plasticity of HVC premotor neurons is selectively repressed by GABAergic interneurons. As a result, juvenile song plasticity is reduced and adult male zebra finches sing a stereotyped series of song elements, called motifs, which are strung together in a song bout. To investigate the specific contributions of HVC interneurons to adult song production and test whether altered inhibition can induce song changes in adult birds, we used a viral strategy to activate or inactivate HVC interneurons in male zebra finches. We bilaterally injected mDLX-driven AAVs in HVC to transduce GABAergic inhibitory interneurons and express light-sensitive depolarising or hyperpolarising channel proteins. This approach allowed us to use light stimulation to manipulate neural activity in a cell-type specific manner and assess its impact on song plasticity in freely moving birds. Depolarisation of inhibitory interneurons in HVC during song production resulted in shorter bouts containing fewer motifs. The magnitude of shortened song bouts was positively correlated with the viral transduction efficiency in individuals. Moreover, as predicted, new song elements were added to motifs when light-induced inactivation of interneurons was accompanied by song playbacks. These new song elements were preferentially added towards the end of the existing song. Our results suggest that the inhibitory network in HVC plays an important role in the maintenance of performance stability in adult song production. Precise and cell-type specific manipulations of this network might have the potential to alter and re-open a critical period for sensorimotor learning.

Title: Assessing the effect of tutor song structure on avian vocal learning strategies

Authors: *A. F. TANNER, A. H. BAHLE, M. S. FEE;
McGovern Inst. for Brain Res., MIT, Cambridge, MA

Abstract: In both human infants and juvenile songbirds, vocal learning progresses from an unstructured 'babbling' phase to highly structured sequences that typify adult birdsong and human language. To produce these ordered vocal sequences, young pupils store a memory of adult vocalizations and compare this memory to their own productions, making continuous adjustments until their own productions form a close match with those of adults. One of the earliest signs of the transition from babbling to song is the emergence of "protosyllables" - acoustically variable vocalizations with a characteristic duration - from the random variations in vocalization length that occur in the babbling stage. Songbirds then alter these protosyllables to imitate the tutor's song. Songbirds use different learning strategies to achieve vocal imitation. For example, earlier work has suggested that some birds develop new syllables by hierarchical splitting of the protosyllable and simultaneous differentiation of multiple syllables (motif learner). More generally, we are interested in the role of the acoustic structure of the tutor song in biasing vocal learning toward different strategies. Do acoustically similar tutor syllables promote a splitting strategy, and where are the decision boundaries for such a process? Does the duration of the tutor syllable, in relation to the protosyllable, impact vocal learning? In cases where birds are tutored early, does the rhythmicity of the tutor song constrain the duration of emergent protosyllables? To study the effect of the temporal and acoustic structure of the tutor song on learning strategies, we built an automated audio-video tutoring device for presenting artificial songs with a range of rhythmic and acoustic properties to juvenile zebra finches. Preliminary experiments reveal that juvenile birds rapidly produce a protosyllable that is well matched to the rhythmic properties of the tutor song. In ongoing work, we are using carefully controlled stimuli to ask how different acoustic and temporal properties affect the trajectory of vocal learning. The form in which a tutor song memory influences the process of juvenile song learning may give us insights into the developmental course of complex motor behaviors.

Title: Validation of a vitamin A deficiency (VAD) songbird model

Authors: *C. OLSON, **C. JAMES**;
Midwestern Univ., Glendale, AZ

Abstract: Vitamin A deficiency (VAD) is a global health problem with effects on brain development and cognition, particularly in young people. However, the specific effect of VAD on complex vocal-motor learning has not been studied. Songbirds possess a cortical brain circuit for vocal learning that relies on vitamin A signaling during the critical period of vocal learning. To study VAD in a vocal learner we developed a special diet from white rice and sunflower seed, two grains that are naturally low in vitamin A and carotenoids, with other essential vitamins and minerals added back. This diet was provided to zebra finch family groups during chick rearing to evaluate the ability of parents to feed the diet to their chicks and the effects of a VAD diet on serum and brain retinol, chick growth and development. We found that adult birds readily consumed the rice/sunflower seed diet and fed it to their nestlings. Adults that consumed the diet maintained the same caloric intakes compared to when fed the seed mix and although these birds showed some decline in body mass it remained within a normal range. Surprisingly, we detected a 28% decline in serum retinol after three weeks on the diet in adult finches, a response that makes songbirds a highly useful model to study VAD. Juveniles that were fed the diet by the adults beginning at hatch also were able to consume the food and thrive on it. Compared to controls, chicks on the VAD diet showed no effects on growth rate between 10-65 days, but the chick survival rate was 63% lower than that of controls with no chicks surviving beyond 65 days old. Chicks that were on the VAD diet did not exhibit sub-song behavior between 35-50 days (72 total hours of monitoring), whereas chicks that were on a seed diet or a rice/sunflower seed control diet (with retinol added back) showed song development. We also noted that VAD affected eye shape and appearance, consistent with what is found during VAD of non-avian models. Serum retinol of chicks on the VAD diet showed a 57% decline compared to controls. Further development of this model will require titration of the VAD to moderate levels that allow for song development and high chick survival. This study lays the groundwork for the use of modified diets in the songbird model to examine how VAD or other micronutrients may modulate neural development in the vocal circuit of a vocal learner, as well as open the door for the use of the model in high-fat diet nutrition experiments and lipid transport studies.

Abstract: Research has shown that childhood maltreatment is associated with increased risk for trauma- and stressor-related disorders in adulthood. This increased risk might be caused by maltreatment-induced changes in the neural circuitry underlying fear learning, which results in pathological responses to adulthood trauma. To begin testing this hypothesis, we assessed whether childhood stress was associated with altered fear learning and fear generalization in adults. One hundred and ninety-nine undergraduate students learned to associate one geometrical shape (CS+), but not another (CS-), with an aversive stimulus (US) in a fear-potentiated startle paradigm. The next day, participants were tested for their fear generalization by measuring their fear responses to a variety of stimuli (generalization stimuli, GSs) that were similar to, but different from, the shapes observed on Day 1. Childhood stress was quantified using the Childhood Trauma Questionnaire, and participants were divided into high and low childhood stress groups based on methodology employed in previous work. According to the results, participants with high childhood stress reported significantly greater anxiety sensitivity, state and trait anxiety, symptoms of depression, and symptoms of post-traumatic stress disorder than participants with low childhood stress. Female participants with high childhood stress demonstrated significantly enhanced fear acquisition for the CS+ and significantly greater fear generalization than female participants with low childhood stress and male participants with high or low childhood stress. Moreover, during generalization testing, female participants with high childhood stress exhibited significantly greater US expectancy ratings for the CS+ and some GSs than female participants with low childhood stress. These findings suggest that, in females, exposure to childhood stress could result in greater fear learning and an overgeneralization of fear, which could increase the risk for certain psychological disorders in adulthood.

Abstract: Early life stressing experiences are associated with brain and behavioral alteration during adulthood. This study evaluated how perceived abuse and care during childhood and adolescence impacts on some psychiatric symptoms during adulthood. For this purpose, 115 university students were recruited and answered the Parental Bonding Inventory (PBI), the Childhood Trauma Questionnaire, short form (CTQ), the Beck Anxiety and Depression Inventories (BAI and BDI, respectively), the Insomnia Athens Scale (IAS), the Resilience Scale for Mexican population (RESI-M), and a detection of use of psychoactive substances (tobacco, alcohol, cannabis, stimulants, opiates, cocaine, inhalants, and prescribed tranquilizers). Participants also provided their academic achievement (AA) in each level of education completed; and a cortisol and oxytocin sample during baseline and after watching a video of an ocular surgery, to cause discomfort or stress. Based in PBI and CTQ, Subjects were classified in those who perceived have been raised with optimal care (OC) by both parents, therefore with absence of any type of abuse (physical, emotional and/or sexual abuse, physical and/or emotional negligence); those who did not perceive have been raised with OC by both parents (i.e., negligent care, NC) albeit reported absence of abuse; and those who perceived have been raised with NC and at least one type of abuse (NC+A). Subjects in the OC group had better outcomes in PBI, CTQ, BAI, BDI, AIS, RESI-M and AA compared to those in NC and NC+A groups. Furthermore, according to odds ratio analysis, NC and NC+A were risk factors for presenting mild, moderate, and severe symptoms of depression and anxiety, and to suffer from insomnia, as compared with OC. Regarding to OC, NC+A was a risk factor for the intake of three or more drugs. No changes in cortisol or oxytocin were detected. Our results further support the relevance of Optimal Care during childhood and adolescence to prevent negative outcomes during adulthood.

Title: From biomarkers to novel treatments: a multi-domain analysis of the developmental consequences of early life adversity and the role of therapeutic ketamine

Authors: S. N. ELLIS[1], A. CHEN[1], E. NOEL[1], S. BONAUTO[1], E. MCCUE[2], ***J. A. HONEYCUTT**[1];
[1]Bowdoin Col., Brunswick, ME; [2]Southern Maine Community Col., South Portland, ME

Abstract: An individual's early life environment critically shapes the developmental trajectory of brain and behavior, thereby influencing later-life outcomes. Early life adversity (ELA) via caregiver deprivation can set the course for increased risk for later emerging mental illnesses, particularly those characterized by affective dysfunction (i.e., anxiety, depression), with females showing higher prevalence rates than males. Individuals with a history of ELA exhibit disturbances in processing affective information and can exhibit contextually inappropriate hypervigilance and anxiety-like behaviors. Limbic regions, such as the basolateral amygdala (BLA) and the bed nucleus of the stria terminalis (BNST), are important for processing emotionally salient information. Specifically, they are thought to be involved in the initiation (BLA) and maintenance (BNST) of anxiety-like states in response to potential threat, with both regions receiving regulatory inputs from other cortical regions (i.e., prefrontal cortex). Our work utilizes a novel aversive ultrasonic vocalization (USV) playback paradigm to probe subtle psychosocial effects of ELA on excitatory/inhibitory neural recruitment in these regions, as well as on sex-specific behavioral outcomes and hypervigilance in rats in response to ambiguous threat. We then use a multi-domain approach to investigate the neural and epigenomic drivers of ELA-associated changes in anxiety-like behavior. In recent years the dissociative anesthetic, ketamine, has been of increasing interest for the treatment of persistent and treatment-resistant anxiety and depression in clinical populations; however, the neural mechanisms by which it has its effect remain poorly understood and the degree to which it shows therapeutic efficacy within ELA populations is understudied. Here, we provide evidence of sex-specific changes in anxiety- and depressive-like behaviors in rats following ELA, and their possible mitigation by an acute therapeutic dose of ketamine. In addition to behavioral outcomes, we also present preliminary evidence of epigenetic changes (specifically, changes in regional DNA methylation and inhibitory/excitatory neuron-specific methylation patterns) following ELA in both males and females, as well as their interaction with ketamine treatment. Taken together, these findings provide critical information regarding the lasting consequences of ELA across development as measured at the behavioral, neural, and genomic levels which will allow for the identification of key markers of behavioral risk/resilience, as well as predictions toward efficacy of ketamine treatment.

Title: Early life stress results in atypical defensive behavior in mice

Authors: *C. R. CODY, A. KISNER, A. M. POLTER;
The George Washington Univ., Washingon, DC

Abstract: Defensive behaviors are a crucial aspect of survival and conservation of species. The ability to correctly develop and execute defensive strategies in response to threats is a complex process. Adverse experiences during early life significantly enhance the risk for the development of emotional and threat-related pathologies. One paradigm used to study ELS in the mouse is the limited bedding and nesting (LBN) model, in which dams and pups are placed in a low resource cage for seven days. This leads to disrupted maternal care, and results in behavioral, anatomical, and physiological changes in the brains of pups (Walker et al). It remains unknown how these adaptations affect naturalistic defensive responses and contribute to the development of fear-related disorders, as well as how sex may contribute to these adaptations. In order to test the effects of ELS on defensive behaviors, we utilized a Looming Disk (LD) behavioral assay. In the mouse, looming stimuli mimic the approach of aerial predators, and evoke innate, species-specific defensive behaviors such as running and freezing. Our data indicates that ELS affects the selection of defensive responses in mice. We have identified a relationship between ELS and an increase in passive responses such as freezing, as well as atypical defensive responses such as darting. Control animals exhibited an increased preference for a flight response, with 50% of male and 79% of females engaging in flight. ELS mice show a decreased preference for flight, with only 34% of males and 50% of females utilizing this coping strategy. Conversely, ELS mice show an increased preference for passive and atypical responses, with 30% of male mice freezing and 23% engaging in darting, compared to only 11% and 19% of controls engaging in these respective behaviors. Female ELS treated mice show an even greater preference towards passive and atypical strategies, with 26% exhibiting freezing behavior and 24% exhibiting darting behavior, compared to only 9% and 12% of control females engaging in these respective behaviors. The results of this work indicate that atypical defensive responses to threatening stimuli occur as a result of ELS, and that ELS causes a shift in the preferred behavioral response in both sexes. This work is relevant for increasing our understanding of how altered early life environmental conditions may affect the development of stress related responses in humans later in life.

Title: The role of early life adversity and pubertal timing in the development of the acoustic startle response in rats

Authors: L. E. GRANATA, A. E. R. PARAKOYI, H. C. BRENHOUSE;
Psychology, Northeastern Univ., Boston, MA

Abstract: Early life adversity significantly increases the risk of developing anxiety disorders later in life, particularly during and following adolescence. Hormonal changes during puberty affect the development of neural circuits subserving cognitive and affective regulation, creating a window of vulnerability.

Anxiety-related psychopathologies in humans are often characterized by increased sensitivity to potential threats, which can be modeled in rodents via the acoustic startle response, a reflex modulated by neural systems associated with anxiety disorders. Implementing the acoustic startle test in rodent models enables scrutinization of the relationship between early adverse experiences, pubertal development, and threat responsivity over the lifespan. The current study investigated the development of the startle response across the pubertal transition (postnatal days 25, 35, and 55) and assessed the impact of maternal separation (MS) on startle progression in males and females. Furthermore, we assessed the startle response after presentation of a social threat: a pre-recorded conspecific's ultrasonic vocalization alarm call. Similar to the potentiating effects on anxiety when humans are presented with a fearful face, the alarm call is a species-specific signal of potential danger in the environment that may differentially modulate the acoustic startle response. With evidence that MS-exposed females experience accelerated pubertal development and the notion that pubertal timing can impact mental health outcomes, we also investigated whether the timing of puberty was associated with startle amplitude. Understanding how the startle response develops across puberty will contribute to our understanding of anxiety-related disorders to identify opportunities for intervention during critical transitional windows.

Title: Sex Effects of Early Corticosterone Exposure on LPS Later in Life

Authors: *H. RODGERS[1], K. GILLEY[2], P. SHARMA[3], E. CASTRO[3], D. COLE[3], E. G. VICHAYA[3]; [1]Baylor Univ. Grad. Psychology & Neurosci., Waco, TX; [2]Psychology, [3]Baylor Univ., Waco, TX

Abstract: Depression is a prevalent psychiatric disorder affecting over 200 million people worldwide. It is a complex and multifactorial disease involving many risk factors, including inflammation. There is now compelling evidence that chronic low-grade inflammation is associated with depressive symptoms. While depression and inflammation are more common in women, most animal models we use show male mice to be more susceptible. For example, in response to 0.5 mg/kg lipopolysaccharide (LPS) female mice show blunted sickness behavior and a reduced neuroinflammatory response as measured by qPCR. Our inability to replicate the sex-bias in pre-clinical depression models may be related to our failure to account for potential lifetime stress history. There is evidence that women experience a higher stress burden, which may impact the responsivity of their hypothalamic-pituitary-adrenal (HPA) axis and innate immune system. We sought to examine this possible relationship using a maternal corticosterone exposure model, in which 75 µg/mL of corticosterone is provided in the drinking water to dams from postnatal days 2-8 and is transferred from dam to pups via maternal milk. We hypothesized that maternal corticosterone would increase inflammation-induced depression-like behavior in early adulthood and female mice would

be more sensitive to these effects. We used a 2 (+/- early corticosterone) x 2 (+/- LPS). Maternally treated mice were treated with saline or 0.5 mg/kg LPS at 8-9 weeks of age. The next day we evaluated locomotor activity, forced swim (FST), tail suspension (TST), and spontaneous alterations in the Y-maze to explore depressive-like behavior and cognitive effects. We observed an interaction between corticosterone and sex, such that female mice exposed to corticosterone early in life showed mildly reduced immobility while male mice showed an elevation. This is potentially indicative of a protective effect in female mice. Murine models of early life stress have shown that sex, timing, and stressor severity play a role in determining whether the stress enhances depression risk or promotes resiliency. Further research is needed to confirm risk result and determine if there if a different manipulation that may improve our capacity to replicate the sex bias observed in human populations.

Title: Chemogenetic activation of gi signalling within excitatory neurons of the forebrain in postnatal or juvenile windows of life does not influence the emergence of anxiety or despair like behaviour in adulthood

Authors: *P. TIWARI, D. KAPRI, A. PRADHAN, A. BALAKRISHNAN, P. CHAUDHARI, V. A. VAIDYA;
Tata Inst. of Fundamental Res., Mumbai, India

Abstract: Early life experience plays an important role in shaping functional and behavioural responses. It is known that during this early window, serotonin (5HT) receptors, in particular the Gi-coupled 5HT1A and the Gq-coupled 5HT2A receptor function, play a crucial role in programming anxiety and depressive behavioural states in adulthood. Studies suggest that stimulation of Gi-coupled 5HT1A receptor in this window may serve to program a reduction in trait anxiety, and pharmacological blockade of 5HT1A receptor has been shown to evoke an anxiogenic phenotype in adulthood. To address the role of Gi signalling in this early life window we used a bigenic line in which hM4Di DREADD was expressed exclusively in CamKII-alpha positive excitatory neurons in the forebrain. Previous work done in the lab shows that increased Gq signalling in excitatory neurons in the forebrain in the early postnatal window (P2-P14) increases vulnerability to anxiety and despair-like behaviour in adulthood. The comparative question was to ask whether enhanced Gi signalling promotes the possibility of either resilience to adult onset stress or baseline changes in trait anxiety and despair. We carried out reflex behaviour in neonates that suggested no developmental defects. Anxiety and despair related tests carried out in adulthood also show no difference in behaviors in animals that were subjected to CNO administration in either postnatal

(P2-P14) or juvenile (P28-P40) windows of life, indicating that increasing Gi signalling in these windows may not be sufficient to modulate anxiety and despair like behaviors.

Title: The Long-term impact of early-life stress on anxiety and depression-like behaviors and mRNA expression of CRH receptor 1 in the hippocampus of BALB/c and C57BL/6NCrl male and female mice

Authors: R. MONTOYA[1], F. DELGADO[1], C. BECERRA[2,1], A. ZEVALLOS[1], G. E. PARDO[1], J. M. IGLESIAS-PEDRAZ[1], L. F. PACHECO-OTALORA[1];

Abstract: Background: Several Preclinical and epidemiologic studies associate early-life stress (ELS) with emotional and cognitive disorders later in life. However, susceptibility to stress and the development of stress-related disorders differ substantially among individuals due to the influence of numerous endogenous and exogenous factors. The use of inbred mouse strain could provide a relatively stable and narrow range of genetic and environmental variability to unravel the gene-stress interactions. The neuropeptide corticotropin-releasing (CRH) system is crucial for neuroendocrine and behavioral responses to stress. The CRH plays a key role in the integration of neuroendocrine, autonomic, and behavioral responses to stress acting via corticotropin-releasing hormone receptor 1 (Crhr1). In the present study, we explore the potential behavioral differences in anxiety and depression and measured Crhr1 expression level in the hippocampus between BALB/c and C57BL/6NCrl strains mice after exposition to ELS. **Methods:** Litters from both strains were exposed to ELS by transferring dam and pups from their standard cage condition to a cage with a wire mesh floor and limited bedding and nesting material during postnatal days (PND) 2-9. On PND 10, litters were returned to their standard housing condition, where they remain until weaning at PND 23. Effects of ELS on anxiety and depressive-like behaviors were assessed during PND 73-76 using the elevated plus maze and forced swimming test, respectively. One day after the last behavioral test mice were decapitated and their hippocampi dissected for gene expression analysis of Crhr1. **Results:** Males and females of BALB/c presented higher basal anxiety and depression-like behaviors than males and females of C57BL/6NCrl strain. The ELS increased considerably basal anxiety profile in male BALB/c and reduced in males C57BL/6NCrl with no significant effects on depression-like behavior profile. Conversely, ELS increased markedly depression-

like behavior profile in females BALB/c with no changes in female C57BL/6NCrl and males from both strains. Our preliminary data show that the exposition to ELS also increased significantly the mRNA expression of Crhr1 in the hippocampi of male BALB/c compared to C57BL/6NCrl, with no changes in females from both strains. **Conclusion**: Our data suggest that early adverse experiences increase susceptibility to stress and development of anxiety and depression-like profiles in a stable phenotype animal with a preexisting genetic vulnerability to stress, anxiety, and depression. Furthermore, the development of an anxiety-like phenotype seems to be related to a long-term alteration in Crhr1.

Title: Hippocampal CA2 development under the influence of prenatal spironolactone

Authors: *S. J. SLEIMAN[1], K. E. MCCANN[1,2], S. A. FRY[1], E. K. SHAUGHNESSY[1,3], S. M. DUDEK[1];
[1]Natl. Inst. of Envrn. Hlth. Sci., Durham, NC; [2]Emory Univ. Sch. of Med., Atlanta, GA; [3]Neurosci. Grad. Program, Georgia State Univ., Atlanta, GA

Abstract: Mineralocorticoid receptors (MRs; *Nr3c2*) are highly expressed in hippocampal area CA2, where they regulate CA2 gene expression and social memory. In addition, mutations in *Nr3c2* can cause a syndromic form of autism in humans. Previous work by our lab and others has shown that MR knockout (KO) in mice causes disruption of social recognition memory and increased responses to novelty and in addition, disrupts expression of CA2 'plasticity brake' genes resulting in an abnormal capacity for LTP in CA2. Although our previous studies using conditional MR KO mice provided valuable information relevant to genetic disruption of MRs, pharmacological blockade of MRs could provide a clinically and translationally relevant model of stress-related disorders, given that MRs bind corticosterone/cortisol. Thus, we set out to test our hypothesis that chronic, prenatal exposure to the MR antagonist spironolactone would disrupt CA2 gene expression and social behavior similar to what we observed using conditional MR KO mice. To do this, we implanted subcutaneous 21-day release pellets in two dam groups—Vehicle and Spironolactone—at approximately gestational day 12 (+/- 3 days), alongside a no-surgery Control dam group. Using immunofluorescence, we examined CA2 marker development in the resulting litters at postnatal days (PNDs) 12, 14, and 21. A separate set of pups was allowed to grow until adulthood (PND 60 or PND 170) to investigate the impact of prenatal MR blockade on behavior. We tested mice in the open field, novel object exposure, novel social interaction, and social discrimination. In both males and females, we found that prenatal MR antagonism with spironolactone did not cause overt effects on the development of CA2. However, prenatal spironolactone exposure did cause an increase in

anxiety-like behavior (F(1, 41)=6.104, p=0.0177) and increased reactivity to novel objects (F(1,41)=4.919, p=0.0322), comparable to that of the embryonic MR KO model, without detected disruptions in social memory. As spironolactone is currently used clinically, and there is some evidence that offspring become feminized (in rodents), future studies will be focused on behaviors with known sex differences, such as aggression.

Abstract: Depressive disorder is one of the most distressing disorders, affecting over 300 million people around the world. Numerous studies have been conducted in an attempt to identify the critical brain regions implicated in the major depressive disorder (MDD) etiology. However, the neurological underpinnings of these atypical behaviors remain unknown. Gestational stress has been shown to raise the probability of developing anxiety and depression in early adulthood. Antidepressant treatment during pregnancy has a significant effect on the offspring's neurobehavioral development. Currently, we examined modifications in physiological, morphological, and biochemical characteristics in mice offspring exposed to CTM during the third trimester of pregnancy. We studied behaviors such as depression, anxiety and locomotion deficits in CTM-exposed mouse offspring. We used Golgi-Cox staining to examine the neuronal structure of prefrontal neurons, and there was a substantial reduction in dendritic length and the number of dendritic branches in CTM-exposed mice following altered protein expression levels relative to controls. We found that maternal CTM exposure causes explicit changes in the brain, particularly those regions involved in cognition and drug reinforcement.These findings highlight further research to elucidate the essential pathways and translational potential of therapeutic significance of CTM during pregnancy.

Abstract: Endocrine-disrupting chemicals (EDCs) are pervasive in the environment. These chemicals are known to interfere with hormone synthesis and metabolism although their effects on behavior are not well studied. Importantly, gonadal hormones are known to modulate emotional behaviors including anxiety and depression. To better understand how phthalate exposure during development impacts measures of anxiety-like behaviors we treated pregnant CD-1 dams with vehicle (tocopherol-stripped corn oil) or an environmentally relevant phthalate mixture (20, 200 μg/kg/day, and 200 mg/kg/day) daily from gestational day 10.5 to birth. The mixture was composed of 35% diethyl phthalate, 21% di(2-ethylhexyl) phthalate, 15% dibutyl phthalate, 15% diisononyl phthalate, 8% diisobutyl phthalate, and 5% benzylbutyl phthalate. Activity in adults was tested in the light-dark box, open field, elevated plus maze, and running wheels. Preliminary analyses reveal that prenatal exposure to phthalates significantly increased the number of transitions that adult mice exhibited between the illuminated and dark zones in the light-dark box test ($p=0.004$). More specifically, control animals had fewer transitions than 200 μg or 200 mg groups despite showing similar levels of time spent in the light or dark box areas. Interestingly, females showed more transitions at relatively lower phthalate doses compared to males suggesting higher levels of activity when exposed to a novel environment. When we examined the daily distribution of running wheel activity, we found phthalate exposed animals had more activity in the dark relative to the light period of the day compared to controls. Future analysis will examine gene expression in brain regions critical for anxiety-like behavior and hormone responsiveness. Collectively, our preliminary data suggest that prenatal exposure to an environmentally relevant phthalate mixture disrupts aspects of anxiety-like behavior and this effect is differentially impacted by sex.

Title: Modulation of depression-like behavior by FOXP3^{+} T cell: a causal link to Alzheimer's disease pathophysiology

Authors: *E. YANG, G. M. PASINETTI;
Dept. of Neurol., Icahn Sch. of Med. at Mount Sinai, New York, NY

Abstract: Alzheimer's disease (AD) is the most common form of dementia among the elderly and the number of individuals with AD continues to increase. Among the various causative factors, depression has emerged as a critical factor, increasing the risk of developing AD by 2 to 4-fold. Thus, mitigating depression-like behavior at early-life could lessen the risk of AD at later stages; and that elucidating underlying molecular mechanisms linking depression to AD would offer feasible target for preventing AD progression. We have recently reported the involvement of Forkhead box P3 (FOXP3), a transcription factor modulating the function of regulatory T cells (Tregs) in peripheral immune system, in inducing depression-like behavior in mice following chronic unpredictable stress. We have also identified peripheral FOXP3-Treg cascade as a molecular pathway regulating such behavior. However, it is not known if alleviating depression by modulating FOXP3 could reduce the risk of developing AD-like pathologies. In the present study, we utilized a FOXP3 conditional knockout mouse model [FOXP3-Diptheria Toxin (DT) Receptor] by treating with DT, which causes a reduction of FOXP3 expression. We have observed depression-like behavior following downregulation of FOXP3, accompanied by a significant reduction in Treg/Th17 ratio in the blood. To examine the relevance of this mechanism in AD, we generated a double transgenic mouse model by breeding FOXP3 conditional knockout mice with 5xFAD. We are investigating whether reduction of peripheral FOXP3 in AD model mice alters blood brain barrier (BBB) permeability leading to neuroinflammation, and thereby exacerbating brain cognitive behaviors. In conclusion, our data suggest FOXP3 as a causal link in the peripheral immune system mediating depression like behavior, leading to exacerbation of AD type brain cognitive deterioration.

Abstract: Adolescence is an important period for brain maturation. Isolation during adolescence increases the incidence of mental disorders in adulthood. Anxiety, characterized by a state of hypervigilance and pacing is the most prevalent mental disorder. Exercise is used as a care strategy to treat several mental disorders. In this study we investigated the effects of exercise in mitigating anxiety produced by single housing in adolescent rats. After weaning (day 23), male and female rats were divided into one of the following groups: group-housed, single-housed, or single-housed with exercise. Exercise training started the day of single housing and consisted of running 30 minutes at speed up to 10 m/min on a treadmill once a day, five times a week until day 33. The rats were tested for anxiety-like behavior on day 34 in an Elevated Plus Maze test. Rats reared in isolation spent less time in the open arm than group-housed rats. However, single-housed rats that exercised spent the same time than group-house and made more entries into the open arms than the other two groups, regardless of the sex of the animals. In conclusion, the increased anxiety observed after 12 days of social isolation in single-housed animals was ameliorated in rats that exercised. These findings indicate that running exercise training is effective in diminishing the detrimental effects of social isolation on anxiety in males and females adolescent rats.

Title: Microbiota transfer therapy causes a stable reversion of early life stress-induced behavioral and neuroendocrine alterations

Authors: *R. RUIZ, A. ROQUE, N. LAJUD;
Inst. Mexicano del Seguro Social, Morelia, Mexico

Abstract: Early life stress (ELS) disturbs microbiota composition and it has been shown that the use of probiotics and prebiotics can prevent some of ELS-induced behavioral and neuroendocrine alterations. However, the effect of reversing microbiota dysbiosis in animals that already present the alterations commonly associated to ELS has never been studied. In here, we evaluated whether microbiota transference from healthy animals restores the alterations caused by ELS in “dirty rats”. For this, control (CONT, n = 20) and maternally separated (MS, 3 h/day from postnatal day 1 to 14, n = 20) male Sprague Dawley rats were utilized. At 2 months of age, half of the individuals in each group were treated with oral

antibiotics for 30 days. Subsequently, microbiota transfer therapy was performed by housing receptor animals with intact donors for 60 days. Transference was interrupted and animals were allowed to recover from 30 days. Our results show that MS decreased the discrimination index in the in the object-location test; as well as a decrease in the struggling time and an increase in the immobility time of the forced swimming test, when compared to the CONT group. In the glucose tolerance test, we observed that MS caused an increase in glucose concentrations 30 and 120 min after administration of a glucose load. MS also increased plasma corticosterone concentrations when compared to controls. Furthermore, MS caused a decrease in hippocampal DCX+ cell number. One month after interrupting microbiota transference, all this ELS-induced alterations were reversed and MS group no longer differed from CONT. In conclusion, our results indicate that microbiota transfer therapy reverses behavioral and neuroendocrine ELS-induced alterations, this effect remains stable even one month after interrupting the transference. Our findings provide evidence of the importance of the intestinal microbiota in regulating the HPA axis in adult animals that already present ELS-induced behavioral and neuroendocrine alterations.

Title: Cardiovascular Deconditioning Increases GABAergic Signaling in the Nucleus Tractus Solitarii

Authors: *L. LIMA-SILVEIRA, E. M. HASSER, D. D. KLINE;
Univ. of Missouri, Columbia, Columbia, MO

Abstract: Cardiovascular deconditioning increases GABAergic signaling in the nucleus tractus solitarii Ludmila Lima-Silveira, Eileen M Hasser, David D Kline.Dept. Biomedical Sciences and Dalton Cardiovascular Research Center, University of Missouri, Columbia MO 65211. Hindlimb Unloading (HU) in rats induces dysautonomia and cardiovascular deconditioning (CVD) similar to that seen in bedridden individuals. The autonomic alterations in CVD and HU are related to plasticity within the central nervous system. The nucleus tractus solitarii (nTS) is the major integrative brainstem region for autonomic modulation and processing of the cardiovascular reflex. GABA and Glutamate are the main inhibitory and excitatory neurotransmitters within this nucleus. HU increases nTS glutamatergic neurotransmission yet decreases neuronal excitability. In this study, we investigated the role for GABA in counter-balancing glutamatergic signaling in the nTS. We hypothesized that HU increases GABA synaptic modulation of nTS neurons, which contributes to impaired autonomic and cardiovascular control. HU was induced by placing stainless wire rings in the tail of male Sprague-Dawley rats (3 weeks

old), and after one week of recovery suspending rats at an angle of 30–35° for two weeks with free access to food and water. Control animals were maintained in normal postural conditions. After HU or the control period, coronal brainstem slices were generated and whole-cell patch clamp was performed to evaluate GABA neurotransmission and electrophysiological properties of nTS neurons. The magnitude of GABA release was evaluated via an intensity-based GABA sensing fluorescence reporter (iGABASnFR). Block of GABAA receptors (Gabazine, 20μM and Bicuculline, 20μM) depolarized membrane potential in HU but not in Control, suggesting greater tonic GABA inhibition in HU. In response to GABA interneuron stimulation the evoked IPSC amplitude and its area, as well as iGABASnFR fluorescence, was greater in HU than Control. HU also elevated the frequency of spontaneous miniature IPSCs but not their amplitude. Puffer application of GABA (100μM, 50ms) produced similar postsynaptic current response in nTS neurons of HU and Control. These results indicate that HU increases GABAergic signaling in the nTS likely via augmented release of GABA from presynaptic terminals. This synaptic plasticity may be part of the mechanisms underlying the autonomic and cardiovascular alterations following CVD. Title: Role of the paraventricular hypothalamic nucleus in the cardiogenic sympathetic afferent reflex in spontaneously hypertensive rats

Authors: *M. R. ZAHNER[1], M. C. BROWN[2], M. J. CHANDLEY[1];
[1]Hlth. Sci., [2]East Tennessee State Univ., Johnson City, TN

Abstract: The Cardiogenic Sympathetic Afferent Reflex (CSAR) is a reflex characterized by increased sympathetic activity and blood pressure during myocardial ischemia. Metabolites such as bradykinin (BK), stimulate cardiac spinal sensory afferents causing chest pain and increase sympathetic activity in the CSAR. It has been shown that conditions that increase sympathetic-related cardiovascular activity can augment the CSAR and this is mediated in part by the paraventricular hypothalamic nucleus (PVN). Glutamatergic activation of the PVN in the spontaneously hypertensive rat (SHR) drives elevated sympathetic activity. We have previously shown that inhibition of the PVN attenuates the CSAR in normotensive rats. However, little is known regarding neurogenic hypertension in the CSAR. In this study, we tested the hypothesis that “the sympathetic response to epicardial BK is augmented in the SHR and that this is mediated by glutamatergic PVN neurons”. Renal sympathetic nerve activity (RSNA) and blood pressure was recorded in anesthetized Wistar Kyoto (WKY) and SHRs during epicardial application of BK (10 μg/ml) before and after bilateral microinjection of vehicle, muscimol (0.5 nmol in

50 nl), or kynurenic acid (50 nmol in 50 nl) into the PVN. Vehicle microinjection into the PVN of WKY (N=8) and SHRs (N=8) did not affect basal RSNA or blood pressure, and epicardial BK elicited a significant ($p < 0.05$) RSNA and blood pressure response. Microinjection of the $GABA_A$ receptor agonist muscimol in WKY rats significantly reduced basal blood pressure and the BK-induced RSNA and blood pressure responses ($p < 0.05$, N=10). Microinjection of muscimol in the SHRs significantly reduced basal RSNA and blood pressure and the BK-induced responses compared with controls ($p < 0.05$, N=8). Microinjection of ionotropic glutamate receptor antagonist kynurenic acid in WKY rats had no significant effect on basal RSNA or blood pressure ($p > 0.05$, N=10). However, the BK-induced blood pressure response in this group of rats was significantly reduced ($p < 0.05$) while the RSNA response was unaffected. In the SHRs, kynurenic acid microinjection significantly reduced basal blood pressure and attenuated the BK-induced response ($p < 0.05$, N=8). Neither the basal RSNA nor the RSNA response to BK was significantly reduced compared with controls. These data provide new evidence that the CSAR is augmented in the SHR and that the elevated hemodynamic response to epicardial BK is mediated in part by glutamatergic input in the PVN. GABAergic inhibition decreased basal and reflex responsiveness to epicardial BK demonstrating that the PVN activity plays an important role in the full manifestation of the CSAR in SHRs.

Title: Activation of A5 noradrenergic neurons increases visceral sympathetic nerve activity and blood pressure in rats.

Authors: *S. B. G. ABBOTT, D. S. STORNETTA, R. L. STORNETTA, G. M. P. R. SOUZA;
Dept. of Pharmacol., Univ. of Virginia, Charlottesville, VA

Abstract: A5 noradrenergic neurons in the ventrolateral pons are the principal source of noradrenaline for preganglionic neurons in the spinal cord that regulate the peripheral sympathetic nervous system. A5 neurons are thought to contribute to the sympathetic response to stress, however the nature of A5's role in sympathetic regulation is not well understood. We examined the effects of chemogenetic activation of A5 neurons on cardiovascular function, breathing and metabolism in freely-behaving male and female rats. A5 neurons were targeted by local injection of AAV encoding Cre-dependent HM3Dq, a Designer Receptor Exclusively Activated by Designer Drug (DREADD), in 3 models including 1) transgenic Tyrosine Hydroxylase Cre (Th-Cre) rats, 2) in-bred Sprague Dawley rats with Cre targeted to A5 using a lentivirus that drives Cre expression from an artificial *Phox2b*-promoter, PRSX8, and 3) in-bred Sprague Dawley rats with Cre targeted to spinally projecting A5 neurons with injections of AAV-Cre with a retrograde serotype in the thoracic spinal cord. Data is presented as mean ± SEM. Intraperitoneal

injections of HM3Dq agonist clozapine-N-oxide (0.3 mg/kg, i.p.) increased blood pressure in rats in which A5 neurons expressed the HM3Dq (model 1- 15.5 ± 1.5 mmHg, N=9; model 2- 12.7 ± 2.0 mmHg, N=5; model 3- 18.0 ± 3.1 mmHg, N=7), whereas CNO had no effect on BP in HM3Dq-negative controls (0.4 ± 1.5 mmHg, N=9, P<0.0001 for control vs model 1, 2 & 3 by Dunnett's multiple comparison test following 1-way ANOVA). Stimulation of A5 neurons produced no change in locomotor activity, metabolism or breathing. In anesthetized Th-Cre rats, chemogenetic activation of A5 neurons increased greater splanchnic sympathetic nerve activity (SNA) (HM3Dq vs. control- 61.5 ± 7.1% vs. -7.3 ± 6.3%, N= 8 vs. 7, P<0.0001 by unpaired t-test) and had no effect on lumbar SNA (HM3Dq vs. control- 7.6 ± 5.6% vs. -6.6 ± 3.2%, N= 8 vs. 7, P=0.88 by unpaired t-test). Activation of A5 increased maximum splanchnic SNA during baroreceptor unloading with sodium nitroprusside (P=0.0016), but did not consistently increase the slope of baroreflex function curve (P=0.99). These results indicate A5 neurons promote visceral vasoconstriction while preserving the regulation of SNA by the arterial baroreflex. Hence, activation of A5 neurons may contribute to the redistribution of blood flow away from splanchnic beds to skeletal muscle, the brain and heart during stress.

Title: Investigation of cardiovascular response to trigeminal nerve electrical stimulation

Authors: *C. KIM[1], S. LIM[2], H. KIM[1], Y. PARK[3], D. KIM[3], D. JANG[2];
[1]Div. of Biomed. Engineering, Hankuk Univ. of Foreign Studies, Youngin, Korea, Republic of; [2]Dept. of Biomed. Engineering, Hanyang Univ., Seoul, Korea, Republic of; [3]Nu Eyne Corporate Limited, Seoul, Korea, Republic of

Abstract: Recently, the modulation of the autonomic nervous system, especially the parasympathetic nervous system, using non-invasive electrical stimulation has been investigated in various fields such as rehabilitation and treatment. The trigeminal nerve has been known as the cranial nerve that could regulate the activity of the parasympathetic nervous system with the connection to the vagus nerve through the brainstem. Although various studies reported the modulation in cardiovascular response according to trigeminal nerve stimulation, few studies showed cardiovascular physiological responses in the normal subject depending on the trigeminal electrical stimulation frequency. This study conducted the trigeminal stimulation experiments on four groups (sham, 2Hz, 20Hz, and 200Hz stimulation frequency groups) of 61 normal subjects with three consecutive 2 minutes on and off protocols. During the protocol, electrocardiography (ECG) from the chest and abdomen and photoplethysmography (PPG) from the left finger were obtained, and heart rate (HR) and pulse transit time (PTT) were calculated from them. As a

result, the HR and PTT significantly decreased in all three 2Hz, 20Hz, 200Hz groups except for the sham group ($P<0.001$). Among the three groups, the 200 Hz evoked the most significant change in the HR and PTT. One of the interesting points is that the decrease of HR and PTT just after stimulation got back to the normal state with different delay time (10 seconds and 15 seconds, respectively). These results indicated that the activity of the parasympathetic nervous system could be modulated through the trigeminal nerve, but the recovery time from changes could be different from physiological measurements. In conclusion, these studies demonstrated the possibility that the cardiovascular responses on the trigeminal nerve stimulation with 200Hz frequency could be utilized as validation tool for the autonomic nervous system.

Title: Utilizing transcutaneous auricular neurostimulation to reduce heart rate

Authors: *M. DARROW[1], I. BAUMGART[1], D. GABRIELI[1], N. KHODAPARAST[2], A. COVALIN[2], S. WASHBURN[2], E. MEYERS[1], P. D. GANZER[1];
[1]Battelle Mem. Inst., Columbus, OH; [2]Spark Biomed. Inc., Houston, TX

Abstract: Every year, over 600,000 Americans die from heart disease, making it the leading cause of death in the United States. People living with cardiovascular disease can struggle with everyday activities as these can put too much load on their heart. Currently there is no well-established non-invasive method to reduce cardiac stress specifically during events that can require a higher cardiac load. However, recent evidence suggests that stimulation of cranial nerves (vagus and/or trigeminal) may reduce cardiac stress during these events. Battelle has developed a completely non-invasive system, the CardioHub™, to track many cardiovascular physiological signals to predict in real-time when elevated cardiac stress is about to occur. This triggers transcutaneous auricular neurostimulation (tAN) using the Spark Biomedical Sparrow™ device to reduce cardiac output. The CardioHub is designed to incorporate many wearable and non-invasive sensors to measure biosignals like electromyography (EMG), electrodermal activity (EDA), electrocardiogram (ECG), blood pressure, and more. The CardioHub, using machine learning (ML), extracts features from these biosignals and is able to make informed predictions about when elevated cardiac output is about to occur in order to trigger tAN. In order to test out the efficacy of tAN, we developed an experimental design where participants repeatedly perform the sit-to-stand (STS) maneuver. This causes an average heart rate elevation of ~50% for approximately 5-15 seconds and currently, we have observed an average reduction of heart rate of ~9% during the STS transition period. We have also observed a modest effect of reducing heart rate by ~4% (~3-6bpm) while the participant is sitting at rest. This data demonstrates a novel, completely non-invasive method, to reduce cardiac stress and improve the

everyday lives of people with cardiovascular disease. We are also further investigating the effects of tAN in other applications including reducing symptoms of psychological stress and opioid withdrawal.

Title: The effect of three different pulse lengths (100 μs, 250 μs, 500 μs) and two different frequencies (10 Hz, 25 Hz) of taVNS on heart rate variability in healthy volunteers.

Authors: *P. ATANACKOV, U. KOVAčIč, K. ELERSIč, F. BAJROVIć;
Inst. of Pathophysiology, Fac. of Medicine, Univ. of Ljubljana, Ljubljana, Slovenia

Abstract: Transcutaneous electrostimulation of the auricular vagus nerve (taVNS) is gaining attention as a potential therapy for modulating the autonomic nervous system. Most commonly used parameters have been derived from experience with cervical vagus stimulation. Because the auricular and cervical vagus branches are morphologically and functionally distinct, optimal taVNS parameters are unknown. Heart rate variability (HRV) is an indirect metric of autonomic nervous system activity. In our study, we used HRV to compare the effectiveness of 6 different combinations of electrical pulse length and pulse frequency to modulate the vagus nerve activity. **Methods:** 35 healthy volunteers (mean age 35.5 years, 60% females) completed 7 visits, separated by at least 3 days. During each visit, they received one of 6 different taVNS parameters or sham treatment in a random order. During the visit participants were

placed in a semi supine position. Each visit consisted of an accommodation phase (5 min), a baseline rest phase (10 min), a stimulation phase (15 min), and a recovery phase (10 min), during which ECG data was acquired. TaVNS stimulation was applied at the cymba conchae of the left ear. Participants received monophasic stimulation with 3 different pulse lengths (100 μs, 250 μs, and 500 μs) and 2 different frequencies (10 Hz and 25 Hz), for a total of 6 combinations. RR intervals were recorded from ECG data, using the Ahlstrom and Tompkins algorithm. Last 5min windows of RR intervals from the baseline resting phase, the stimulation phase and the recovery phase were used to calculate rmSSD, SDNN, and HF HRV parameters. **Results:** Factorial rmANOVA showed no difference in the effect of different pulse lengths and frequencies (including sham) on the HRV parameters tested. There was a significant difference in the effect of phase of the experiment (baseline, stimulation, recovery) on HRV parameters. Pairwise post-hoc analysis revealed that SDNN was significantly different between all three phases ($p<0.05$), rmSSD was significantly different between baseline and stimulation phase ($p<0.05$), while HF was significantly different between baseline and recovery phase ($p<0.05$). These differences in HRV between phases of the experiment were not significantly different between stimulation groups (including sham). **Conclusions:** The results presented here suggest that taVNS does not have the ability to significantly alter HRV during or shortly after stimulation. This could be due to either a) a weak or absent effect of taVNS, b) the use of suboptimal stimulation parameters, c) HRV not being a sufficiently sensitive marker. A larger sample size is needed before any conclusions can be drawn.

Title: Lesion of the OVLT impairs the development of hypertension and polydipsia in 2-kidney, 1-clip hypertensive rats

Authors: *M. R. LAUAR[1], **N. PESTANA-OLIVEIRA**[1,2], D. VAN HELDEN[1], J. P. COLLISTER[2], J. W. OSBORN[1];
[1]Dept. of Surgery, Univ. of Minnesota, Minneapolis, MN; [2]Dept. of Vet. and Biomed. Sciences, Col. of Vet. Med., Univ. of Minnesota, Saint Paul, MN

Abstract: Hypertension (HTN) is a multifaceted condition that affects one-third of the population of western countries. It is well established that renal ischemia results in secondary renovascular HTN. Experimental renovascular HTN is induced in rats by creating stenosis of the left renal artery, thereby decreasing perfusion pressure of the clipped kidney (2K1C-HTN), leading to increased renin-angiotensin system activity which may act centrally to increase arterial pressure, sympathetic nerve activity, and water intake (Collister et al.,2018). The organum vasculosum of the lamina terminalis (OVLT) is a circumventricular organ which is responsive to blood borne substances such as angiotensin II, and has

been implicated in the regulation of arterial pressure, sympathetic activity and thirst. Previous studies have shown that OVLT lesion attenuates development of the DOCA-model of hypertension, but does not modify the water intake. In the present study we tested the hypothesis that the OVLT is required for the development of 2K1C-HTN as polydipsia is observed in this model. Male Sprague-Dawley rats (n=3-5/group) were randomly selected to receive either electrolytic lesion of the OVLT (OVLTx) or sham operation. After one week, they were instrumented with telemeters to measure mean arterial pressure (MAP). Two weeks after OVLTx, the left renal artery was stenosed by application of a silver clip. MAP was measured continuously for 6 weeks and, once a week, rats were housed in metabolic cages for 24 hours to measure water intake and urine volume. At the end of the protocol, MAP was significantly ($p<0.001$) lower in OVLTx-2K1C (134 ± 8 mmHg) compared to sham lesion-2K1C (163 ± 6 mmHg) rats. In addition, water intake was significantly ($p<0.001$) lower in OVLTx-2K1C (42 ± 2 ml/day) compared to sham lesion-2K1C (73 ± 2 ml/day) rats. Similarly, urinary volume excretion was reduced in OVLTx-2K1C (25 ± 2 ml/day) compared to sham lesion-2K1C (52 ± 5 ml/day) rats. We conclude that the integrity of OVLT is required for the development of 2K1C hypertension as well the polydipsia observed following renal artery stenosis.

Title: Cardio-vascular modulation by muscarinic antagonists in spinal cord injured rats

Authors: *T. MILLE[1], A. BONILLA[1], C. MENUET[2], S. S. BERTRAND[1], J.-R. CAZALETS[1];
[1]INCIA - CNRS UMR 5287, Bordeaux, France; [2]INMED - INSERM UMR 1249, Marseille, France

Abstract: Spinal cord injury (SCI) is one of the most impairing health problems worldwide. Besides its sensory-motor consequences, SCI induces a hemodynamic instability by interrupting supraspinal regulation of vascular tone, inducing life threatening conditions such as autonomic dysreflexia. Sympathetic preganglionic neurons (SPNs), located in the thoracolumbar segments, are cholinergic neurons controlled by supraspinal structures. SPNs generate slow (2.5s period in rats) oscillations in blood pressure known as Mayer Waves, which are generally used as a marker of sympathetic vasomotor activity. Mayer waves are strongly disturbed after SCI, reflecting the impaired sympathetic vasomotor control, yet their physiological function remains elusive.
To determine if some level of vasomotor sympathetic control of blood pressure persists after high thoracic SCI in rats, we silenced the antagonistic action of parasympathetic cardiovascular regulation. We used methyl-scopolamine (MS), a muscarinic antagonist unable to cross the blood brain barrier. Adult female Sprague-Dawley rats were implanted with a telemetric probe to record cardiovascular parameters. Mean,

systolic and diastolic blood pressure, as well as heart rate, were continuously monitored before, during and after injection of MS or saline. The same recordings and injection procedures were repeated after complete T3 spinal cord transection. A frequency domain analysis (Fast Fourier Transform) of systolic blood pressure and inter-beat interval were used to assess sympathetic/parasympathetic regulation of blood pressure and heart rate, respectively, with a focus on Mayer waves. Correlations between Mayer wave peak and the other physiological variables were computed.
Our preliminary data show that injection of MS after SCI increases the low frequency component (0.3-0.6Hz) of systolic blood pressure, indicative of increased Mayer waves. These preliminary data suggest that in the absence of supraspinal influences, sympathetic regulation can be revealed by peripheral inhibition of muscarinic receptors.

Title: Trigeminal medullary dorsal horn neurons activated during voluntary diving in rats express AMPA glutamate receptors

Authors: *P. MCCULLOCH, K. M. DINOVO;
Midwestern Univ., Downers Grove, IL

Abstract: The diving response is an autonomic reflex characterized by apnea, bradycardia and increased peripheral vascular resistance initiated when animals submerge underwater. Afferent stimulation initiating this response projects from the nasal mucosa via the anterior ethmoidal nerve (AEN) to second-order afferent neurons located within the trigeminal medullary dorsal horn (MDH). The present study investigated the synapse between the AEN and MDH neurons, specifically what glutamatergic receptors are expressed by MDH neurons activated during voluntary diving. In male Sprague-Dawley rats, Fos immunohistochemisty identified MDH neurons activated by repetitive diving through an underwater maze. Further immunohistochemistry identified AMPA receptors subunits expressed by these trigeminal neurons. Within the superficial MDH (laminae I and II), deep MDH (laminae III-V), and Paratrigeminal Nucleus within the spinal trigeminal tract, 26.0%, 68.7%, and 21.2% of Fos-positive neurons, respectively, expressed the GluR 1 subunit; 7.0%, 39.4%, and 19.4% of Fos-positive neurons, respectively, expressed the GluR 2/3 subunit; and 20.8%, 30.07%, and 16.5% of Fos-positive neurons, respectively, expressed the GluR 4 subunit. We conclude the AEN releases glutamate as a neurotransmitter that activates AMPA receptors on second-order MDH neurons during voluntary diving in rats.

Title: Sparc-optical nanosensors detect neurotransmitter release in the peripheral nervous system

Authors: *H. YANG, N. MICOVIC, J. R. MONAGHAN, H. A. CLARK;
Northeastern Univ., Boston, MA

Abstract: Developing methods to monitor the release of neurotransmitters during synaptic transmission would have a significant impact on the diagnosis and the treatment of various neurological diseases. Previously, we have reported a novel DNA-based enzymatic nanosensor capable of detecting acetylcholine (ACh) in the submandibular ganglion (SMG) of living mice with high sensitivity, in vivo reversibility, and dose-dependent response. Equipped with an advanced imaging processing tool, we measured spatially-resolved ACh signal propagation on the tissue level. The ACh nanosensor is based on a bottom-up modular design and assembly process, consisting of DNA as the scaffold, acetylcholinesterase as the recognition component, pH-sensitive fluorophores as the reporters, and α-bungarotoxin as the targeting ligand. The modular design of the ACh nanosensor imparts versatility, enabling easy repurposing for other applications or imaging in different regions of the body. The sino-atrial node (SAN), the pacemaker of the heart, controls the autonomic nervous system in mammals. However, the relationship of SAN with the pathogenesis of cardiovascular disorders is poorly understood due to lack of tools to perform these investigations. Here, we demonstrate the transformation of our nanosensor platform for imaging ACh and norepinephrine (NE) in SAN. For imaging ACh in SAN, we switch the targeting ligand to be the pirenzepine analogue with high affinity to the muscarinic receptors that are highly expressed in the SA node. Our preliminary data illustrate that the new ACh nanosensor can efficiently label the SA node in a living mouse, and rapidly respond to vagus nerve stimulation as confirmed by electrocardiogram. We then redesigned the nanosensor to respond to norepinephrine (NE) by replacing the recognition-reporter pair with tyrosinase and Pt-coproporphyrin, respectively, and the targeting ligand with propranolol analogues. We confirmed successful assembly of the NE nanosensors with UV-Vis spectrophotometry and size exclusion HPLC and the targeting affinity of propranolol-modified DNA scaffold to β1 adrenoreceptors in transfected CHO cells. The NE sensor was designed to emit fluorescence at λem=650 nm, distinct from our ACh nanosensor λem=560 nm, thus facilitating dual imaging of two neurotransmitters in a single organ. We envision such a sensor platform could be compatible with two-photon microscopy and further extend to other organs in the peripheral nervous system with efficient reduction of background noise and a great enhancement in spatial and temporal resolution.

Title: Compromised reactive oxygen species scavenging in Scn1b$^{-/-}$mice, implications for SUDEP.

Authors: J. MURPHY, E. ALEXANDER, ***C. FRASIER**;
Biomed. Sci., East Tennessee State Univ., Johnson City, TN

Abstract: Sudden Unexpected Death in Epilepsy (SUDEP) is one of the most common causes of death in individuals with epilepsy. The exact mechanisms surrounding SUDEP are poorly understood, although cardiac arrhythmias have been implicated. In this exploratory study we used the *Scn1b*$^{-/-}$ mouse model of Dravet syndrome, a severe pediatric epilepsy, to determine how reactive oxygen species (ROS) scavenging is altered during a prolonged oxidative challenge. In heart, ROS balance is largely managed by the glutathione redox couple. During prolonged oxidative stress the ROS scavenging capacity can be overwhelmed, leading to an instability in mitochondrial membrane potential, which may underlie changes to cellular excitability. Our previous work suggests under prolonged oxidative stress induced by diamide, compromises ROS scavenging, can lead to instability in mitochondrial energetics, and cardiac arrhythmias. We hypothesized the Scn1b-/- mice have a decreased ability to buffer increased ROS production during times of stress, making them more susceptible to cardiac arrhythmias. We first isolated primary ventricular cardiomyocytes from *Scn1b*$^{+/+}$ (WT; N=7) and *Scn1b*$^{-/-}$ (KO; N= 8) mice between P15 and P20, loaded them with DCF to detect ROS production, and performed fluorescence microscopy in cells following addition of 80 µM diamide. Diamide oxidizes thiols, depleting the glutathione pool within the cell, ultimately decreasing a major antioxidant pathway in the heart. Our results indicate that cells isolated from KO mice (n=28) have a reduced ability to buffer changes in ROS and die significantly faster than those from WT (n=29). The average time to death was significantly lower in KO cells by 4.25 minutes ($p = 0.03$), with the first cell death occurring within 1 minute of diamide addition in KO cells compared to 5.5 minutes in WT. This was paralleled with a decreased time of onset for increases in the DCF signal, demonstrating that ROS production precedes cell death. Since there were deficits in the ability of KO myocytes to balance increasing oxidative stress, we next performed qPCR on P17 hearts to determine if there were differences in antioxidant gene expression. There was a decrease in the expression of *Sod1* (Cu/ZnSOD, 0.52-fold; $p = 0.03$), but no difference in *Sod2* (MnSOD). In addition, there was a decrease in *Gpx* (glutathione peroxidase) expression in KO mice (0.27-fold; $p = 0.03$), but there were no differences in expression of *Gsr* (glutathione reductase). Taken together our results suggest that cardiac tissue from Scn1b-/- mice have decreased ability to handle prolonged bouts of oxidative stress. This is likely due to a decrease in the availability of the glutathione system.

Title: Stem cell proliferation in the sensory circumventricular organs of adult rats is modified by salt loading

Authors: *S. ZHOU, M. PRAGER-KHOUTORSKY;
Dept. of Physiol., McGill Univ., Montreal, QC, Canada

Abstract: Circumventricular organs (CVOs) are specialized brain regions characterized by a high density of fenestrated blood vessels, thus lacking a complete blood-brain barrier. The organum vasculosum of the lamina terminalis (OVLT) and the subfornical organ (SFO) are sensory CVOs involved in the regulation of body fluid homeostasis and cardiac function. Recent studies reveal that secretory CVOs (the median eminence and the adjacent arcuate nucleus) harbor neural stem cells in the adult rodent brain. However, it remains unknown if sensory CVOs such as the OVLT and SFO also contain neural stem cells. To study if cells in the OVLT and SFO undergo constant proliferation in the adult brain, we intraperitoneally injected Wistar rats with a mitotic marker bromodeoxyuridine (BrdU) and used immunohistochemistry to visualize new-born cells. We have identified that NG2 glia, tanycytes, pericytes and microglia undergo constant proliferation in the adult rat OVLT and SFO. Moreover, a small fraction of BrdU-positive cells expresses a neuronal fate marker, doublecortin. To examine if cell proliferation is attenuated in conditions associated with abnormal fluid balance, we subjected rats to a model of salt-dependent hypertension. Rats were exposed to salt-loading protocol by replacing the drinking water with 2% NaCl for 7 days, leading to an increase in blood pressure. We found increased number of BrdU-positive cells in the OVLT and SFO of rats exposed to 7 days of salt-loading. Our data suggest that OVLT and SFO contain stem cells that undergo constant cell proliferation and might represent an additional neurogenic niche in the adult rat brain; and hypothalamic stem cell proliferation can be modified in response to fluid balance perturbation.

Title: Morphology of subpopulations of stellate sympathetic ganglion neurons in mouse

Authors: M. S. BARRETT, D. M. HEGARTY, B. A. HABECKER, *S. A. AICHER;
Chem. Physiol. & Biochem., Oregon Hlth. & Sci. Univ., Portland, OR

Abstract: Sympathetic nerves innervate the heart, and changes in sympathetic efferent activity can modulate cardiac function. The post-ganglionic sympathetic neurons that innervate the heart are located primarily in the stellate ganglion (SG), which also contains neurons that project to brown adipose tissue (BAT) and other target tissues. We aim to examine morphological changes in SG neurons after myocardial infarction, and characterize the specificity of neural plasticity within the ganglion. To interpret morphological changes induced by cardiac injury, we must first fully understand the normal morphology of distinct groups of SG neurons. To that end, we examined SG neurons following injections of retrograde tracers into cardiac tissue and/or intrascapular brown adipose tissue (iBAT) in adult male and female C57BL/6J mice (ages 23-32 weeks, weighing 24-39 g; The Jackson Laboratory). We examined the number, distribution, and morphology of retrogradely labeled SG neurons using cholera toxin B (CTb) (1 mg/mL in 0.1 M PBS) conjugated to two different fluorophores (Alexa Fluor 488 and AF-555) and we also examined iBAT SG neurons at different times after retrograde tracer injections (n=2 per time point). iBAT-projecting SG neurons were successfully detected 7, 14 and 28 days after injections and could be visualized directly or with antibodies against CTb. iBAT-projecting neurons were located in both left and right SG, predominately ipsilateral to the injection site and were widely dispersed. In contrast, cardiac-projecting SG neurons were more localized near the base of the inferior cardiac nerve within the stellate ganglion and were asymmetrically distributed between left and right SG. In dually injected animals (iBAT + cardiac; n=5), we found that SG neurons were not dual-labeled - supporting the notion that sympathetic innervation to target tissues is specific. We also compared other characteristics of tracer-labeled cardiac and iBAT SG neurons including dispersion, cell count, and soma size within the mouse SG. Our long-term goal is to understand the neural plasticity within post-ganglionic sympathetic neurons that can lead to sympathetic dysregulation after myocardial infarction or heart disease.

Title: Evidence for cholinergic collateral projections between sympathetic neurons in the murine stellate ganglion

Authors: *C. CLYBURN[1], S. L. INGRAM[2], M. C. ANDRESEN[1], B. A. HABECKER[1];
[1]Chem. Physiol. and Biochem., [2]Dept. of Neurolog. Surgery, Oregon Hlth. & Sci. Univ., Portland, OR

Abstract: Cardiac-projecting stellate ganglion (SG) neurons integrate cholinergic signals from preganglionic neurons via T-2 and send noradrenergic projections to the heart to regulate cardiac function. While SG neurons are thought to receive only monosynaptic inputs, early studies hinted at the presence of cholinergic collateral projections between SG neurons. Interestingly, cultured SG neurons use both cholinergic and noradrenergic transmission and can form cholinergic synaptic connections between

one other. The purpose of this study is to test the hypothesis cholinergic collateral projections are present between sympathetic neurons of intact SG in mice.Whole-cell patch clamp recordings were made of intact SG neurons from male and female C57BL/6J mice. $ChAT^{TH\text{-}CreERT2/lox}$ mice allowed for the conditional knockout (KO) of choline acetyltransferase (ChAT) in tyrosine hydroxylase positive (TH+; i.e. noradrenergic) cells. T-2 was electrically stimulated to evoke excitatory postsynaptic currents (eEPSCs) at various stimulation intensities. The jitter (i.e. variability in latency) and amplitude of eEPSCs were assessed in control and ChAT KO mice. The amplitude and frequency of spontaneous EPSCs (sEPSCs) were also examined. Initial studies found that sEPSCs in ChAT KO neurons were lower in frequency compared to controls (0.10±0.03 events/s vs. 1.19±0.24 events/s, respectively, N=5, $P<0.05$), but had similar amplitudes (23.8±2.3pA vs. 31.4±3.1pA, N=5, $P>0.05$), suggesting the loss of presynaptic cholinergic inputs from adrenergic, presumably SG, cells. Preliminary studies also found low and high jitter all-or-none eEPSCs in control ganglia (107.8±3.7μs and 211.6±8.0μs, N=4), but only low jitter eEPSCs in ChAT KO neurons (119.7±6.0μs, N=3), suggesting the loss of polysynaptic inputs in ChAT KO mice. Low jitter eEPSCs in control neurons also had a larger amplitude than high jitter eEPSCs (1445.9±369.5pA vs. 485.9±101.5pA, N=3-4, $P<0.05$). Although preliminary, our results are consistent with the presence of cholinergic collateral connections between postganglionic adrenergic SG neurons. Understanding SG neurocircuitry is critical in deciphering the changes that are observed in cardiac sympathetic neurons and sympathetic activity following myocardial infarction and in heart failure.

Title: The determinants of human circadian phase in two real-life situations

Authors: *A. SILVA[1,2], N. COIROLO[2], J. CASTILLO[2], B. TASSINO[1,2];
[1]Facultad De Ciencias, Univ. de la República, Montevideo, Uruguay; [2]Grupo Cronobiología, CSIC, Univ. de la República, Montevideo, Uruguay

Abstract: Dim light melatonin onset (DLMO) is the most reliable measure of human central circadian timing. The circadian phase, which ultimately depends on the expression of clock genes, is also extremely plastic. Light is the major and best-known circadian zeitgeber, while other non-photic factors such as chronotype, sleep and feeding habits, exercise, and social pressures can also be relevant. Only a few studies have previously addressed the modulation of the circadian phase in non-experimental conditions. In Uruguayan college students (18-30 years old), we evaluated the impact of photic and non-photic factors on the circadian phase estimated by DLMO in two natural scenarios using self-reported data (MCTQ, MEQ) and objective activity and light measurements (actigraphy, GENEactive). First, we evaluated DLMO changes in university students (n=11) between the Antarctic summer (10 days) and the

autumn equinox in Montevideo, Uruguay (10 days). Individual changes in DLMO between both conditions were associated with the change in light exposure in both the morning and the evening, suggesting that those with more light in Antarctica in the morning advanced their circadian phase (R=-0.800, p=0.003), and those with more light in the evening delayed their phase (R=0.747, p=0.008). The change in DLMO also correlated with participants' circadian preferences (R=0.663, p=0.026), and with changes in sleep timing (estimated by the midpoint of the least active 5h period in actigraphy recordings, R=0.693, p=0.018). Second, we evaluated DLMO changes in dance students being trained in two different shifts, morning (8:30 to 12:30, n=7), and night (20:00 to 24:00, n=11) at the National School of Dance in Uruguay. The DLMO of night-shift dancers was later than in morning-shift ones (21:42 ± 0:53 vs 20:32 ± 0:34, p=0.009) and correlated with participants' chronotype (R=0.778, p=0.005) and sleep timing (R=0.563, p=0.072). Interestingly, evening exercise (but not light exposure) delayed the DLMO (R=0.573, p=0.02). Overall, this study contributes real-life examples of the complex integration of photic and non-photic pressures in shaping the plasticity of the human circadian phase.

Title: Natural variations in sleep and circadian rhythm phenotypes, sleep fragmentation, and circadian phase shifts leads to alterations of gene and protein expression in rats

Authors: *A. J. CERWENSKY, S. MOON-KIM, A. M. EGAZARIAN, M. WRIGHT, J. ZEAK, I. H. MIGIAS, M. TORREGROSSA, C. MCCLUNG;
Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Studies show that adolescents are particularly at risk for substance use disorders (SUDs) because they are generally more reward driven, impulsive, and sensation seeking than adults or younger children. Furthermore, genetic, social, and environmental factors can also lead to sleep loss and circadian rhythm misalignment in this population. The Center for Adolescent Reward, Rhythms, and Sleep's (CARRS) general aim is to understand how sleep and circadian rhythm traits and environmental disruptions during adolescence lead to increased vulnerability for substance abuse. In our particular study we aim to determine how natural variations in sleep and circadian rhythm phenotypes, sleep fragmentation, and circadian phase shifts are associated with molecular measures of gene and protein expression in adolescent rats. To approach this, we use Heterogenous Stock (HS) outbred rats obtained from Wake Forest and bred in-facility that are suitable for researching complex traits such as SU-related behaviors both genetically and molecularly. To perform acute sleep restriction, we gently handle adolescent rats for 6 hours starting at Zeitgeiber Time (ZT) 0, the onset of the light phase. For a more mild sleep restriction paradigm, we also restrict the rats by ~40% for 5 days with a 2 day recovery period

for 2-3 cycles. Lastly, to perform circadian rhythm misalignment, we implement a 12 hour light advance every 3 days. Following each of these manipulations, rats are sacrificed at both ZT 2-4 (light cycle) and ZT 14-16 (dark cycle) for tissue analysis. A group of control rats kept on a normal light/dark cycle are also used and sacrificed at the same time points for comparison. Brains are collected and flash frozen to obtain the PFC and NAc for RNA sequencing and differential expression analysis. Based on our pilot data, we expect to find changes in genes involved in neuronal activity (i.e. ion channels) and inflammation in the PFC. We also expect to find changes in genes involved in dopaminergic signalling and MSN activity in the NAc. Overall, the goal of this study is to identify alterations in gene expression as a result of circadian misalignment and sleep restriction in order to further dissect the effects of these specific manipulations and provide a better understanding of how circadian disruption may lead to addiction-like behavior.

Abstract: Eating during the resting phase (reverse feeding) is strongly associated with obesity and metabolic syndrome. In the last decade, chronobiologists have generated several hypotheses regarding the mechanisms that underlie this association. One generally accepted view is that reverse feeding involves an internal conflict between food consumption and the energy-saving state imposed by the endogenous circadian system. However, in rodents, reverse feeding also implies food intake during the light period, which is known to exert metabolic changes as well. This suggests that the metabolic impairments derived from reverse feeding could be influenced by the effects of light on the circadian system. To investigate the conflict between food and the endogenous circadian system without the interference of light, we designed an experiment in which light was absent for most part of the day, but rats were entrained to a 12:12 cycle. For this, we adopted the skeleton photoperiod (SK) in which two light pulses indicated the beginning and end of the subjective day. Under SK conditions, we restricted food intake to either the subjective day or night, carefully assuring that light and food were not available at the same time. After 5 weeks under this protocol, we observed that glucose intolerance was induced by reversed feeding even when animals were not exposed to light. In addition, animals subjected to SK displayed glucose intolerance and increased adiposity regardless of the moment of their food intake. These changes were accompanied by alterations in their daily rhythms of temperature, locomotor activity, energy expenditure, and lipid oxidation, suggesting that the lack of an extended period of light during the daytime deeply alters metabolic rhythms. These data suggest that prolonged daytime light exposure and correct timing of food intake are both essential to maintain metabolic health.

Title: The timing of food intake differentially alters daily rhythms in metabolic rate and ventilation in mice

Authors: *A. A. JONES, K. PROPSOM, L. R. NELSON, D. M. ARBLE;
Biol. Sci., Marquette Univ., Milwaukee, WI

Abstract: To efficiently deal with changes in nutrient availability across the 24-hr day, animals have evolved daily rhythms in energy metabolism and, consequently, a daily rhythm in breathing to mediate metabolic gas exchange. The daily rhythm in minute ventilation, for example, is controlled by the suprachiasmatic nucleus (SCN). However, it is unclear if this ventilatory rhythm is secondary to the SCN-imposed rhythms of metabolic rate or feeding-fasting. Here, we use a desynchronized feeding protocol to determine the extent to which ventilation rhythms are driven by the circadian clock or secondary to

metabolic rate or feeding-fasting. Metabolic rate and feeding patterns were assessed using indirect calorimetry cages and ventilatory function was determined using whole-body plethysmography. As expected, we found that under *ad libitum* and night-time feeding conditions, the daily rhythms in food intake, carbon dioxide production, oxygen consumption, and minute ventilation remained tightly aligned to the dark phase and SCN timing. However, under exclusive day-time feeding, carbon dioxide production shifted to align with food intake while oxygen consumption and ventilation remained coupled to the circadian clock. These results indicate that the daily rhythm in minute ventilation is not primarily mediated by food intake or carbon dioxide production, but instead more strongly linked to oxygen cycles and/or SCN activity.

Title: Using circular statistics to measure degree ofsynchronization of circadian locomotor activity in spiders with two different evolutionary behavioral strategies

Authors: *Y. WU[1], D. MOORE[2], T. C. JONES[2], N. TOPORIKOVA[3];
[1]Div. of Natural and Applied Sci., Duke Kunshan Univ., Jiangsu, China; [2]Dept. of Biol. Sci., East Tennessee St Univ., Johnson City, TN; [3]BIology, Washington and Lee Univ., Lexington, VA

Abstract: Although locomotor activity often is measured as an output of the circadian clock, the mechanism of coordination between the clock and locomotor activity is not fully understood. The phasing of locomotor activity in nature is expressed as the organism's chronotype (for example, anticipation of sunrise, sunset, food availability, predictable presence or absence of predators, etc.) and is assumed to be under selective pressure. For most spiders, there is an optimal time to collect prey from the web but this behavior also must be balanced against predator avoidance. In this work, we analyzed locomotor activity of two spider species, the common house spider *Parasteatoda tepidariorum* and the southern black widow *Latrodectus mactans*. In nature, both species are opportunistic, and capture both diurnal and nocturnal prey. Both species occupy often-shaded rocky crevices or outcrops and are thus subject to variations in onset of local darkness which enables prey capture during daylight hours while providing some protection from visual predators. However, our previous work discovered that both species experience negative masking during the photophase of light/dark (LD) cycles. The inhibited (masked) phase extends through virtually all of the photophase in *L. mactans* but is restricted to late photophase in *P. tepidariorum*. These findings suggest that *P. tepidariorum* is more neurologically primed for attacking prey during the late photophase whereas such neurological arousal in *L. mactans* spans the entire circadian cycle. Using circular statistics, our analyses revealed that *P. tepidariorum* has a higher degree of synchrony between LD cycles and locomotor activity than *L. mactans*. We then measured the distribution of locomotor activity in constant darkness for the same two species. We found that the distribution of mean vectors, indicating the preferred phase of locomotor activity, is highly concentrated for *P.*

tepidariorum. In contrast, mean vectors in *L. mactans* were uniformly distributed throughout the circadian cycle. Thus, our findings suggest that the distribution of locomotor activity throughout the circadian day may correspond to different behavioral strategies in nature.

Title: The Effects of Gut Microbiota on the Developmental Circadian Rhythm in Honey Bees

Authors: *Y. B. KORU[1], Y. ORTIZ-ALVARADO[1], A. A. RUGGIERI[1], E. J. AVILÉS[1], N. RODRIGUEZ[1], R. GIORDANO[2], R. K. DONTHU[3], J. R. LEON[1], T. GIRAY[1], J. L. AGOSTO-RIVERA[1];
[1]Dept. of Biol., Univ. of Puerto Rico, San Juan, PR; [2]Ctr. for Envrn. Sci., Florida Intl. Univ., Miami, FL; [3]Know Your Bee, San Juan, PR

Abstract: Circadian rhythms in honey bees are included in numerous biological processes that influence colony survival and honey bee behavior, such as division of labor. The nurse bees, which show an arrhythmic circadian pattern, take care of brood from 4 to 12 days of age, while forager bees collect resources for the colony from 21 days of age until they die. The gut microbiota of the honey bees is composed of limited number of bacteria species that affect metabolism, physiology, and neurobiological processes. Previous studies show that the honey bee's gut microbiota affects the immune system, learning, and memory. However, postembryonic development of circadian rhythm on honey bees related to changing gut microbiota has not been completely elucidated. This study examines the effects of gut microbiota on the ontogeny of circadian rhythm of young workers under laboratory conditions by using locomotor activity monitor to measure rhythmicity. We hypothesized that changes in gut microbiota are vital to the development of circadian rhythmicity in young workers. We set two groups, consisting of control and antibiotic treatment. We used 50 µg of Tylosin Tartrate inside sugar candy while the honey bees in the control group were fed with only sugar candy. The honey bees were kept at 35 ºC and constant-dark conditions for 13 days inside an incubator. In addition, we used the RNA-Seq technique to investigate the effects of changes in gut flora on expressed genes in the brain by dissecting the brain and gut. Our results show that the honey bees in control reached rhythmicity faster and in greater proportion

than bees in antibiotic treatment. This study presents that the gut microbiota might be an essential factor influencing the ontogeny of circadian rhythm on honey bees. Moreover, honey bees can be used as model organisms on gut-brain axis studies, given their limited number of microorganisms living in their gut. Future studies will examine specific signaling molecules behind the process of ontogeny of circadian rhythm.

Title: The circadian modulation of cognition is disrupted in the 5XFAD mouse model of Alzheimer's disease

Authors: *A. KALIDINDI, K. HOYT, K. OBRIETAN;
Ohio State Univ., Columbus, OH

Abstract: Alzheimer’s disease (AD) is characterized by neurodegeneration and progressive deterioration of memory. AD patients also experience circadian timing system disruptions, with alterations in sleep cycle, core body temperature, activity rhythms, and the phasing of the melatonin rhythm. Recent work has raised the prospect that this circadian timing system disruption could also contribute to the cognitive decline observed in AD. AD pathogenesis has been linked to elevated levels of Aβ peptide, and here we tested whether Aβ disrupts circadian-gated cognition. Further, given that circadian timing is a distributed process, where the master clock in the suprachiasmatic nucleus (SCN) of the hypothalamus functions in coordination with peripheral oscillator populations in the cortex and limbic system that underlie learning and memory, we examined whether Aβ affects clock timing in both the SCN and in cortico-limbic circuits. We used running wheel activity as a readout of SCN timekeeping in the 5XFAD mouse model of accelerated Aβ accumulation at 3-5 months of age (with mild cognitive decline and limited amyloid plaque formation), and at 8-9 months of age (characterized by marked cognitive decline along with amyloid plaque formation). We found no significant difference between 5XFAD mice and WT littermates in their circadian-gated running parameters (e.g., free running rhythms and light-mediated clock entrainment), at any point during the disease process, indicating that key functional properties of SCN clock timing and entrainment are intact in the 5XFAD mouse line. Next, we assessed whether circadian

clock-gated cognitive capacity was altered in the 5XFAD line. Consistent with previous studies, we found that overall cognitive capacity (working memory via the t-maze task, intermediate term memory via the novel object location test and long-term memory via contextual fear conditioning) of 5XFAD mice declined as a function of age. This cognitive decline was observed during both the circadian day and the circadian night. Interestingly, time-of-day analysis revealed that the daily rhythm in the relative efficacy of memory retrieval was significantly diminished in the 5XFAD mice; notably, damping of clock-gated cognitive output was detected early in the AD-like disease process (i.e., 4 months of age). Together, these data raise the prospect that elevated levels of Aβ disrupt cellular timing within forebrain circuits, and that this disruption manifests as a damped daily rhythm in cognition. Current work is focused on an examination of whether Aβ accumulation affects cellular clock timing properties within cortico-limbic circuits that underlie cognition.

Title: Examining Central Circadian Clock Regulation of Extra-SCN Inflammation and Neurodegeneration

Authors: *M. KING[1], E. S. MUSIEK[2];
[1]Neurol., Washington Univ. in St. Louis Neurosci. PhD Program, St. Louis, MO; [2]Neurol., Washington Univ. In St. Louis, Saint Louis, MO

Abstract: Circadian rhythms align cellular and systemic function according to a 24-hour cycle. The central, light-sensitive circadian clock is located within the suprachiasmatic nucleus (SCN) of the hypothalamus, which synchronizes cellular clocks in peripheral tissues by a combination of electrical and humoral cues. Despite the accepted importance of circadian function on neurological health, the mechanisms involved remain an open question. Historically, we and others have examined circadian function by using knockouts of the master circadian protein Bmal1, and our group has shown that Bmal1 deletion has profound effects on glial activation, oxidative stress, and protein aggregation in the brain. However, knockout of Bmal1 both abrogates clock function and causes non-circadian changes in gene expression. A crucial question is which of the effects of Bmal1 deletion in the brain are due to disrupted central circadian rhythms, and which are due to loss of Bmal1 function in a given cell type. Decoupling these two effects will give us a better understanding of how exactly modern circadian disruptions such as jet lag, artificial lighting, and shift work regulate overall brain health and contribute to the pathology of neurological disorders, many of which have a circadian component.
We will address this question using a SCN-specific Bmal1-knockout mouse, which uses the Neuromedin-S promoter (NMS-Cre) to drive expression of Cre recombinase specifically in SCN neurons, disrupting

the central circadian clock without altering Bmal1 expression in cellular clocks elsewhere in the brain. We have confirmed strong Cre expression in the SCN, and negligible expression in other regions such as the cortex and hippocampus. Our actigraphy experiments demonstrate disrupted activity rhythms in NMS-Cre mice in constant darkness, which are exacerbated when subjected to altered light:dark cycles, such as 10h:10h light:dark. We will compare this NMS-Cre mouse with global Bmal1 KO mouse, in which Bmal1 is deleted in both central and peripheral clocks. Ongoing studies involve immunohistochemistry and transcriptomics to characterize the cellular responses to circadian impairment and peripheral inflammation. Finally, disease modeling is underway to understand how these disruptions contribute to the various hallmark pathologies (protein aggregation, oxidative stress, gliosis) of neurological disorders.

Title: Neural correlates of risky decision-making in the periaqueductal gray-amygdala circuit

Authors: E. KIM[1], S. PARK[2], J. CHO[3], *J. J. KIM[1];
[1]Psychology, Univ. of Washington, Seattle, WA; [2]Neurosci. Program, Korea Univ. of Sci. & Technol., Daejeon, Korea, Republic of; [3]Brain and Cognitive Sci., Ewha Womans Univ., Seoul, Korea, Republic of

Abstract: The dorsolateral/lateral divisions of periaqueductal gray (dl/lPAG) and the amygdala (AMYG) are implicated in defensive behaviors. We previously reported that electrical stimulation of the dl/lPAG caused naïve rats foraging for food in a large arena to flee to the nest sans external threats (Kim et al., 2013). This flight behavior was blocked by lesioning/inactivating the AMYG, suggesting the necessity of PAG-->AMYG information flow during escape behavior. We also found that optogenetic stimulation of dl/lPAG cells increased spiking activity of basolateral/central AMYG (BLA/CeA) cells that also responded to the robot predator. This study characterized dl/PAG and AMYG cells involved in antipredatory functions and then examined whether dl/lPAG stimulation altered the firing rates and synchronous firings of AMYG cell pairs. To do so, Long-Evans rats were implanted with tetrodes into the BLA and CeA and injected with AAV-CaMKIIα-hChR2-EYFP (AAV) into the dl/lPAG. After recovery, rats underwent habituation, baseline foraging, optogenetic dl/lPAG stimulation, and robot testing sessions while recording BLA/CeA units. We found distinct types of neurons in both dl/lPAG and BLA/CeA that increased activity to (i) robot activation, (ii) flight onset, (iii) pellet procurement, or (iv) multiple events.

Also, optical stimulation of dl/lPAG cells elicited both escape and neural activity in robot-responsive BLA/CeA cells, not the other cells. We then generated cross-correlograms (CCs) between simultaneously recorded AMYG cell pairs to test whether dl/lPAG stimulation-responsive AMYG cells exhibited synchronous activities during the predator surges. Among the AMYG cell pairs that showed spike synchrony during the robot-surge epochs, stimulation-responsive cell pairs showed higher CC peaks during the robot-surge epochs than the pellet procurement or stimulation epochs. However, there were no reliable CC peak differences across the epochs in the stimulation non-responsive cell pairs. We confirmed strong terminal expressions in the midline thalamic areas (Cameron et al., 1995; Krout & Loewy, 2000) following AAV injection into the dl/lPAG, and found increased fos+ cells in the paraventricular nucleus (PVT) in rats that encountered the robot predator compared to the foraging only controls. Subpopulations of the PVT fos+ cells also expressed Cholera toxin subunit B injected in the BLA or CeA, suggesting the PVT as a potential mediator of dl/lPAG-->amygdala neurotransmission. Taken together, these results suggest that functional interactions between the dl/lPAG and the amygdala neurons, possibly via the PVT, subserve antipredatory defensive mechanisms.

Title: Naturalistic model of posttraumatic stress disorder in rats: effects of active predator assault

Authors: *P. R. ZAMBETTI, J. J. KIM;
Univ. of Washington, Seattle, WA

Abstract: Posttraumatic stress disorder (PTSD) is a devastating psychopathology affecting 8 million people in the US each year, with the incidence rate in women two times higher than in men. PTSD symptoms are multifaceted, including anxiety, avoidance, hyperarousal, and vivid flashbacks. Typically, PTSD develops in individuals after a traumatic event, such as child abuse, domestic violence, sexual assault, combat violence, where there are generally explicit threatening agents (e.g., assailants and enemy combatants). However, most preclinical PTSD research fails to incorporate external agents into animal and human models and focus on limited dependent variables (e.g., freezing in rodents, GSR in humans). To expand the translational relevance of basic PTSD research and provide a paradigm more akin to real-life traumas, we created a single-session inescapable predator-attack encounter in rats. Specifically, hunger-motivated male and female rats implanted subcutaneously with wires at the neck/back region were trained to leave the nest (via a gateway) to forage for a food pellet in a large arena (a purposive behavior) and return to the nest area for consumption (baseline sessions). On the predatory assault encounter session, as the animal approached the food pellet, the nest gateway automatically closed (preventing escape), and a remote-controlled robot surged towards the rat followed by a shock (1 sec, 2.5 mA) to the

animal's neck/back region via a tether cable. This robot+shock attack transpired every minute for 10 minutes. After the last robot surge-shock episode, the gateway opened, and the animal escaped into the nest. Control animals encountered the same surging robot (without shock) in the foraging arena every minute for 10 minutes. On subsequent days, the animals were placed back in the nest and, upon opening the gate, were given 10 minutes to retrieve a food pellet from the foraging area. On the first testing day, robot+shock rats had significantly longer latencies (increased avoidance) to procure the food pellet than those rats exposed to the robot only. Across subsequent testing days, the avoidance behavior of robot+shock males waned at a significantly faster rate compared to robot+shock females. Afterwards, rats underwent Pavlovian contextual fear conditioning (3 footshocks: 1 sec, 1 mA, 1 min apart) to assess fear generalization to a different context. The robot+shock females, but not robot+shock males, displayed heightened contextual freezing during the retention test. This study shows that mimicking real-life uncontrollable traumatic events (i.e., inescapable assault) leads to intensified and generalized fear, particularly in female rats.

Title: Amygdalar protein synthesis supports persistent trauma-induced shifts in perceived negative valence

Authors: *Z. T. PENNINGTON[1], A. R. LABANCA[2], T. R. FRANCISCO[2], D. J. CAI[1];
[1]Neurosci., Icahn Sch. of Med. at Mount Sinai, New York, NY; [2]Icahn Sch. of Med. at Mount Sinai, New York, CA

Abstract: In addition to traumatic stress producing robust associative memories about the traumatic experience, trauma leaves individuals more vulnerable to future stressors. This vulnerability is thought to emerge in part via trauma's capacity to augment subsequent learning about aversive events. However, while much is known about the biology of aversive learning, little is known about how aversive learning is modified by prior traumatic experience. Defining the mechanism through which this change occurs may shed light on new treatment avenues for conditions like post-traumatic stress disorder, which are often predated by a history of traumatic experience. Using a model in which animals are initially given a

strong ‘trauma’, we find that subsequent learning about a second aversive experience is enhanced relative to trauma-naïve animals. Moreover, analysis of the learning curves of the second aversive experience indicates that trauma heightens the perceived valence of aversive stimuli, rather than the speed at which learning occurs, and is independent of peripheral sensitivity to aversive stimuli. Defining the locus of plasticity giving rise to this change in perceived valence, we find that protein synthesis within the basolateral amygdala immediately after trauma is necessary for subsequent enhancements in negative valence. Current work is ongoing to determine how this augmented valence is encoded within the amygdala, using a combination of *in vivo* calcium imaging and immediate early-gene tagging. By dissecting both the psychological process (i.e. enhanced valence), and amygdala activity correlates of trauma-induced changes in aversive learning, this work will hopefully render insights into why some are more vulnerable to trauma than others.

Title: Ensemble reactivation during an offline period links recent experience with past memories

Authors: *Y. ZAKI[1], Z. T. PENNINGTON[1], A. LABANCA[2], Z. DONG[3], K. RAJAN[2], D. J. CAI[1]; [1]Neurosci., [2]Icahn Sch. of Med. at Mount Sinai, New York, NY; [3]Neurosci., Icahn Sch. of Med. At Mount Sinai, New York, NY

Abstract: The compilation of memories, aggregated across a lifetime, defines our human experience. How are memories dynamically updated and integrated across time and experience? Using in vivo calcium imaging (with open-source Miniscopes in freely behaving mice), an activity-dependent cell tagging system, chemogenetics, and novel behavioral designs, we tested how hippocampal networks temporally link memories separated across days. We previously found that contextual memories encoded close in time are linked by directing storage into overlapping hippocampal ensembles, such that the recall of one memory can trigger the recall of another temporally-related memory - termed memory-linking. Here, we first asked whether the strength of an aversive experience affects memory-linking, and found that increasing the negative valence of a memory increases the likelihood of memory-linking. Past literature has shown that hippocampal activity patterns present during learning are reactivated in the hours

following learning, and this has been suggested as a mechanism for memory consolidation. Based on this work, we hypothesized that memory-linking may be driven by the simultaneous reactivation, or co-reactivation, of ensembles representing two experiences. We recorded neuronal activity from the CA1 of hippocampus using Miniscopes during learning of a neutral context, of an aversive context two days later, and during the hour following aversive learning. We found that in the hour after aversive learning, mice that received a weak shock—and didn't display memory-linking—had heightened reactivation of the aversive ensemble, but not of the neutral ensemble from days prior. In contrast, mice that received a strong shock displayed heightened reactivation of both the aversive ensemble and the neutral ensemble following aversive learning, suggesting that this ensemble co-reactivation may underlie memory-linking. Finally, we demonstrate that this transfer of fear from an aversive memory to a previously formed neutral memory can be abolished by inhibiting the reactivation of the ensemble of the neutral memory during the consolidation of the aversive memory. These results collectively suggest that memory-linking is driven by the "co-reactivation" during an offline period of ensembles representing two experiences. Current work is focused on uncovering the specific brain states during which ensemble co-reactivation occurs. These results shed light on the neural substrates underlying how memories are integrated and segregated in the brain.

Title: The nucleus reuniens of the thalamus is necessary for both the retrieval of recent extinction memories and prefrontal-hippocampal theta synchrony

Authors: *M. S. TOTTY, K. R. RAMANATHAN, S. MAREN;
Inst. for Neurosci. and Dept. of Psychological and Brain Sci., Texas A&M Univ., College Station, TX

Abstract: The nucleus reuniens of the thalamus (RE) is a small midline structure interconnecting the medial prefrontal cortex (mPFC) and hippocampus (HPC) that has been proposed to coordinate the precise retrieval of specific memories, such as fear extinction. One mechanism by which the RE may facilitate mPFC-HPC communication is by the coordination of theta oscillations. Previous work has revealed that pharmacological inactivation of the RE inhibits extinction recall, and RE inactivation impairs mPFC-HPC theta synchrony during work memory tasks. However, it is still unknown if the RE is critical for mPFC-HPC theta dynamics associated with extinction recall. Using auditory fear conditioning and extinction, we extend previous pharmacological findings by showing that optogenetic silencing of the RE using a red-shifted opsin (Jaws) impairs extinction retrieval 24 hours after extinction training. Importantly, we demonstrate that increased freezing due to RE inactivation is not non-specific as

inhibiting the RE in animals that were never conditioned had no effect of freezing behavior. In an additional experiment, we show that RE inactivation also impairs mPFC-HPC theta synchrony during extinction recall. These data extend our current understanding of the role of the RE in the retrieval of fear extinction memories and coordinating mPFC-HPC theta synchrony.

Title: Chemogenetic activation of the locus coeruleus modulates neuronal activity in the medial prefrontal cortex of rats

Authors: *A. N. BINETTE, S. MAREN;
Dept. of Psychological and Brain Sci. and Inst. for Neurosci., Texas A&M Univ., College Station, TX

Abstract: The locus coeruleus (LC) is a stress-sensitive brain region that provides noradrenergic input to key nodes in the fear extinction circuit, including the medial prefrontal cortex (mPFC) and basolateral amygdala (BLA). Previous work from our lab has shown that systemic noradrenergic blockade prevents stress-induced deficits in fear extinction memory and stabilizes mPFC firing after acute stress. Additionally, chemogenetic LC activation can drive stress-induced impairments in fear extinction, which are blocked by intra-BLA, but not intra-mPFC, noradrenergic blockade. Based on these data, we hypothesize that stress-induced LC activation dampens mPFC activity via an inhibitory BLA-mPFC circuit to ultimately disrupt fear extinction memory. As a first step toward testing this hypothesis, we examined the effect of chemogenetic LC activation on mPFC calcium dynamics. Long-Evans rats received viral infusions to express excitatory DREADDs in the LC (AAV-PRSX8-hM3Dq-HA) and a CaMKII-driven calcium indicator (AAV-CaMKII-GCamP6m) in the mPFC. A gradient refractive index (GRIN) lens was implanted into the mPFC and a head-mounted miniscope was used to detect mPFC calcium transients. Each session consisted of a 10-min baseline recording followed by injection of vehicle or CNO (3 mg/kg, i.p.) to activate the LC; recording resumed during the 15- to 30-min post-injection time period. Putative neurons and their fluorescent traces were identified with CNMF-E and were matched across sessions using longitudinal registration. Contrary to our hypothesis, CNO treatment increased the calcium event rate in mPFC neurons relative to vehicle treatment. These results suggest that increased LC tonic activity is associated with increased mPFC principal neuron activity in awake and freely moving rats. Future experiments will examine the mechanisms underlying LC-induced modulation of mPFC activity and fear extinction memory.

Title: Relapse of Extinguished Fear After Chemogenetic Reactivation of Hippocampal Fear Ensembles in Rats

Authors: *K. VASUDEVAN, R. RESSLER, S. MAREN;
Dept. of Psychological and Brain Sci. and Inst. for Neurosci., Texas A&M Univ., College Station, TX

Abstract: Recent work in mice has suggested that distinct ensembles of dorsal hippocampal (DH) neurons represent memories of fear and safety after contextual fear conditioning and extinction, respectively (Lacagnina et al. 2019). It is unknown, however, whether similar representations are formed by auditory fear conditioning and whether these representations modulate responding to extinguished conditioned stimuli (CSs). Here, we used an activity-dependent Tet-OFF tagging system ("TetTag") to express an excitatory DREADD (AAV.cfos.tTA9.bGH, AAV.TRE.hM3Dq.mcherry.rBG) in DH neurons active during auditory fear conditioning in rats. Male and female Long-Evans rats were put on doxycycline (DOX) diet prior to infusion of the TetTag AAVs into the DH. Three weeks later, rats were removed from DOX, and the following day were placed in a novel context and presented with 5 tone-shock pairings (n=24) or 5 tone-only presentations (n=8) before being put back on DOX and returning to their homecage. Forty-eight hours later, all animals underwent fear extinction (45 tone-only trials or until fear response sufficiently diminished). Rats then underwent two counterbalanced extinction retrieval tests on subsequent days, in which either clozapine-N-oxide (CNO) or vehicle (VEH) was systemically administered. Freezing was used as an index of fear. During the retrieval tests, CNO administration increased conditioned freezing to the extinguished CS relative to VEH-treated rats or rats that received CNO but were not conditioned. Interestingly, CNO administration did not increase pre-CS freezing to the test context, suggesting that reactivating DH conditioning ensembles did not increase CS freezing by increasing fear to the test context. Rather, chemogenetic reactivation of DH ensembles tagged during auditory conditioning caused a relapse of extinguished fear to an auditory CS. These results imply that contextual representations formed in the DH during auditory fear conditioning can serve to modulate expression of conditioned fear to an extinguished CS.

Title: Differential Contribution of Nucleus Reuniens and Perirhinal Cortex in Pavlovian Trace Fear Conditioning

Authors: *Y.-C. JHUANG, C.-H. CHANG;
Inst. of Systems Neurosci., Natl. Tsing Hua Univ., Hsinchu, Taiwan

Abstract: Pavlovian fear conditioning is a widely used method to study the regulation of fear memory. By repeatedly presenting a conditioned stimulus (CS), such as a tone, with an unconditioned stimulus (US), such as a footshock, animals learn the association between the two events. In trace fear conditioning, the CS and the US are separated by a stimulus-free trace interval. Several studies have shown that the hippocampus (HPC) and the medial prefrontal cortex (mPFC) are both required to encode the association between the CS and the US in trace fear conditioning. Anatomically, the mPFC does not directly project to the HPC, but it can indirectly project to the HPC through the nucleus reuniens (RE) or the perirhinal cortex (PRC). Moreover, these two relay stations reciprocally connect to each other, increasing the complexity of the HPC-mPFC circuitry. Previous studies have shown that the RE and the PRC are both involved in trace fear conditioning; however, the detailed contribution of the two brain regions is still unclear. In this study, we sought to compare the roles of the two areas by pharmacologically inactivating the RE, the PRC, or both, in Long-Evans rats during the acquisition of trace fear memory. Our data suggested that animals could still encode certain level of trace fear under pre-conditioning inactivation of either the RE or the PRC. However, inactivation of both the areas completely abolished the acquisition of trace fear that these animals behaved similarly as the controls that never received footshock during training. Interestingly, we found that RE inactivation resulted in impairment during early retrieval trials, while PRC inactivation led to impairment during latter trials, suggesting their differential importance temporally. Currently, we are examining the effect of PRC activation under RE inactivation and vice versa to investigate whether the impaired acquisition due to loss of function in one relay station could be rescued by enhancing the activities of the other. Our preliminary data suggested that PRC activation did not rescue the impairment produced by RE inactivation. Together, our studies revealed the differential roles of the RE and the PRC in trace fear conditioning.

Title: Differential Delays in between Conditional and Unconditional Stimulus Affect the Associative Strength of Trace Fear Conditioning

Authors: *Y.-J. CHIOU, C.-H. CHANG;
Inst. of Systems Neurosci., Natl. Tsing Hua Univ., Hsinchu (city), Taiwan

Abstract: In classical fear conditioning, two stimuli are presented: the conditional stimulus (CS), such as a tone, and the unconditional stimulus (US), such as a foot-shock. Different from delay conditioning, in which the US is presented after the CS onset and the two stimuli overlap with each other, in trace conditioning, the CS and the US are separated by a stimulus-free temporal gap called "trace interval". Previously, we found that for long trace interval group (trace interval of 120 s), rats showed divergent fear response of either high or low freezing to the tones. In this study, we aimed to examine the hypothesis that as the trace intervals become longer, the association between the CS and the US become weaker. Alternatively, we hypothesized the rats would treat the CS as a safety signal that when the CS is presented, no US follows, and the high fear would peak around the time window when the US should have occurred. On Day 1, the rats received 10 tone (20 s, 85dB, 2kHZ)-foot-shock (2 s, 1.0mA) pairings with an inter-trial interval (ITI) of 240 s. On Day 2, the rats were tested with 10 tones alone (ITI of 240 s). Our results showed that in all experimental groups (DELAY controls and trace intervals of 30 s, 60 s and 120 s), the highest freezing occurred at the time the CS was presented, and the fear level became lower as the trace interval became longer. Because freezing behavior is detected as immobility and animals may decrease their active exploration due to prolonged session time, we next implemented bar pressing for food reward to maintain baseline activities on top of trace fear conditioning. Freezing and bar pressing suppression ratio (SR) were both assessed to measure the fear level. Our result showed the rats showed lower SR as the trace interval became longer, and the highest fear still occurred at the time when the CS was presented. Together, our results suggested that the low fear response to the CS in longer trace interval group is more likely a result of the weaker CS-US association, and we did not find supporting evidence that the animals encode the temporal relationship in between the CS and the US. We are now examining whether the activation level of the fear circuitry would negatively correlate with longer delays of trace intervals.

Title: Borders for Brodmann area 23 determined by quantitative cytoarchitectonic analysis

Authors: K. NWANKPA[1], S. YATES[1], A. RICHARDSEN[1], J. PETLEY[1], S. MARKLAND[1], A. KOSTRYK[1], C. T. CERATO[1], E. ARMSTRONG[1], ***N. PALOMERO-GALLAGHER**[2];
[1]Lake Erie Col. of Osteo. Med., Greensburg, PA; [2]Res. Ctr. Juelich, INM-1, Juelich, Germany

Abstract: The human posterior cingulate cortex (PCC) is of renewed interest stemming from its being an important node in long, intrinsic circuits, such as the default mode network and fronto-parietal control network, as well as local circuits within the cingulate and retrosplenial cortices. With these connections it is no surprise that this region makes important, if as yet poorly understood, contributions to pathologies including but not restricted to Alzheimer's disease, Parkinsonism, depression, schizophrenia, and autism. To better appreciate how molecular characteristics, especially those of receptors and transmitters, relate to more macro observed pathologies, scientists have used architectural maps of cell structures for reference; most commonly those created by Brodmann more than a century ago. We present here the results of using a quantitative and statistically testable cytoarchitectonic mapping protocol, which uses 10 features of cortical laminae to group and subdivide cortex. This study reports on divisions within the PCC between the retrosplenial and 'association' cortices, typically called in the Brodmann nomenclature, Area 23. Both hemispheres of five human brains were coronally sectioned. Sections were silver stained for neuronal perikarya, glial cells, and occasional endothelial nuclei (similar to Nissl stains), digitized, and mapped. Four regions corresponding to areas 23a, b, c and d were identified and segregated by this approach. Qualitatively the PCC has a very heterogeneous structure both in terms of cellular architecture and patterns of connections. The cytoarchitecturally defined subregions have defined topographic placements and both sets of qualitative observations, cytology and topography, were used to validate borders defined by the probabilistic protocol. Caudally Brodmann 23a (BA23a) abuts the retrosplenial area BA30m at or slightly distal to the cusp of the callosal sulcus; rostrally it borders BA23d (23dysgranular). BA23a is inferior to BA23b and both span the same rostrocaudal length. The transition between 23a and 23b is usually close to a dimple found midway along the dorsoventral height of the cingulate gyrus. Superiorly and laterally in the inferior lip of the cingulate sulcus, BA23b borders BA31. BA23d is the rostral-most part of PCC, abutting BA24d and also extending into the superior lip of the cingulate sulcus. Laterally in the cingulate sulcus BA24d borders BA23c, another dysgranular cortex. Given the validation with classic observations, there is now a reproducible way to reference and quantify normal and pathological variants.

Title: Impact of reinforcer type on the reversal learning deficits following developmental insult in mice.

Authors: B. Y. JACQUEZ, J. CHANDRASEKARAN, *J. BRIGMAN;
Neurosciences, Univ. of New Mexico SOM, Albuquerque, NM

Abstract: Behavioral flexibility, one of the core dimensions of executive functioning, which is critical for one's survival, allows for the individual to adapt to the everchanging environment. It is impaired in several neuropsychiatric and neurodevelopmental disorders including prenatal alcohol exposure. Touchscreen based discrimination and reversal tasks have been a reliable method across species to test the flexible behavior. Pre-clinical studies employing animal models use reinforcers following correct choice to motivate the animals to learn and perform the task. While there are several reinforcers available, most employed reinforcers are solid reward (food pellets) and liquid reward (strawberry milkshake). Performance on operant task is highly sensitive to reinforcer type. Previous studies have examined the effects of different solid reward or liquid dietary content on learning in instrumental responding and found that rodents on liquid reward with higher caloric content performed better with increased response and task acquisition rates. But the influence of reinforcer type on reversal learning has not been explored. Here, we aimed to test whether reinforcer type during learning or reversal would impact a previously replicated deficit seen in mice exposed to alcohol during gestation. To test this, we used male and female C57BL/6J mice (n=10/sex/ group) exposed to moderate prenatal alcohol exposure (PAE) via a drinking in the dark paradigm (10% EtOH available 4 hours/day throughout gestation; BAC: ~90mg/dL; SAC: saccharine controls). Mice were trained on a visual touchscreen-based discrimination and reversal task using flavorless dustless 14mg pellets or 30 ul strawberry Nesquik as reinforcers. Total number of correction trials when the mice perform under 50% correct, has shown to be a reliable measure of perseveration during early reversal. Our results show that the type of reinforcer predicted perseverative responses in PAE mice. Both male and female mice trained on liquid reward showed reduction in the total perseverative errors during early reversal compared to mice trained on solid reward. Although there were no significant differences in reaction time between the groups, there was a reduction in magazine latency among the liquid reward mice. Interestingly, mice trained on liquid discrimination and switched to pellets on reversal showed increase in the perseverative trials, compared to mice trained on liquid throughout. This data suggest that reinforce type can have a major impact on motivation, and therefore performance, during reversal learning. Highly motivating rewards may mask behavioral deficits seen with more moderately sought rewards.

Title: Winning gains importance from repeated losing: Interpersonal competition, neural reward-processing, and intrinsic motivation.

Authors: *J. C. BARCH, J. M. CARLSON, E. NIEMAN, H. GABOURY, R. MILLER, J. FOLEY, N. MARION;
Northern Michigan Univ., Marquette, MI

Abstract: Self-determination theory postulates autonomy, competence, and relatedness are basic psychological needs for all humans. Decades of research demonstrates that supporting or thwarting one's perception of need fulfillment enhances or impairs intrinsic motivation, respectively. Less clear however, are the neurological processes underlying these effects. A small number of recent EEG studies have assessed how manipulating autonomy to decrease intrinsic motivation influences the feedback-related negativity difference wave (d-FRN), which represents a difference in participants' neuro-cognitive response to win and loss feedback. While we know that thwarting perceptions of competence in participants by way of rigged losses in competitive situations decreases intrinsic motivation, how these perceptions of competence are linked to electrocortical brain activity are less clear. The study aimed to link perceptions of competence to electrocortical measures of feedback processing. Participants (N = 52) were randomly assigned to either a competence-supporting (n = 23) or competence-thwarting (n = 29) condition in which they either won or lost 75% of trials in a reaction time competition task. During competitive trials, the target time was masked after four seconds, and feedback was a predetermined bright green 'WIN' or a bright red 'LOSE' by condition; but, ostensibly it indicated if they were closer to 5 seconds than their opponent. After the EEG session, participants completed a measure of psychological need satisfaction and self-reported intrinsic motivation. Data suggests effective manipulation of competence perceptions, which predict self-reported interest and enjoyment as expected. Participants experiencing thwarted competence displayed an enhanced d-FRN (as well as other feedback related ERPs) relative to the competence-supporting group. In other words, results suggest that repeatedly losing in a competitive situation enhances the reward-processing system while engaged in the competitive trials.

Title: The anterior cingulate cortex is important in mediating motivated behavior based on reward-expectancy and satiety

Authors: *K. K. BODINAYAKE[1], B. HALBOUT[2], C. R. HUTSON[2], K. M. WASSUM[3], S. B. OSTLUND[4];
[1]Neurobio. and Behavior, Univ. Of California, Irvine, Irvine, CA; [2]Anesthesiol., Univ. of California, Irvine, Irvine, CA; [3]Psychology, UCLA, Los Angeles, CA; [4]Dept. of Anesthesiol. and Perioperative Care, UCI Sch. of Med., Irvine, CA

Abstract: The anterior cingulate cortex (ACC) is thought to mediate the ability to exert cognitive control over decision making when faced with conflicting response tendencies. Importantly, the degree of conflict between reward-seeking actions is not fixed, but tends to vary over time based on factors such as reward availability and value. Our lab recently developed a probabilistic Pavlovian-instrumental transfer (pPIT) task to parse the motivational and predictive properties of reward-paired cues. Rats display a general increase in exploratory instrumental reward seeking when presented with a cue that signals a low-probability (30%) of reward but inhibit this behavior to focus their search at the food-delivery port when presented with a high-probability (100%) cue. We hypothesized that the ACC mediates the ability to use reward expectations to adaptively regulate conflict between generalized reward-seeking (motivational response) and food-port search behavior (prediction response). To test this hypothesis, we virally expressed the inhibitory DREADD hM4Di in the ACC of male Long-Evans rats (n = 14) before training them on the pPIT task. At test, we found that inhibiting ACC function with the DREADD agonist CNO disrupted the cue-specificity of pPIT performance, such that press rates were reduced during the 30% cue but elevated during the 100% cue. To further explore this apparent motivational deficit, rats were then tested on a task in which they could choose between performing an effortful lever-press response for a highly palatable sucrose reward or freely consume lab chow from a dish. Choice between these two options is strongly biased toward the high-effort/high-value reward when rats are fully satiated on home chow (as during training), but becomes more even when they are tested in a food-deprived state. We found that inhibiting the ACC had no effect on task performance when rats were sated prior to testing but decreased pursuit and consumption of both foods when tested hungry. These findings reveal that the ACC plays an important role in regulating motivated behavior based on changes in reward expectancy and physiological need states.

Title: Anterior cingulate cortex functional connectivity is associated with tolerance to distress

Authors: *O. DEZACHYO[1], S. KOZAK[1], Y. BAR-HAIM[1], N. CENSOR[1], E. DAYAN[2];
[1]Sch. of Psychological Sci. and Sagol Sch. of Neurosci., Tel-Aviv Univ., Tel Aviv, Israel; [2]Univ. of North Carolina at Chapel Hill, Chapel Hill, NC

Abstract: Psychological resilience, defined as the ability to adapt under significant adversity, is instrumental in preventing stress-related disorders. An important aspect of resilience is distress tolerance, the capacity to endure affective distress when in pursuit of goals. However, evidence that links intrinsic baseline interactions within large-scale functional networks with performance under distress remains missing. We hypothesized that the anterior cingulate cortex (ACC) may engage in distress tolerance due to its involvement in attention and emotion regulation. Accordingly, we tested whether behavioral

performance under distress is associated with baseline resting-state ACC functional connectivity (FC). Distress tolerance was measured in 97 healthy participants using the behavioral indicator of resiliency to distress (BIRD) task. Analyses contrasted participants who quit the task before its designated termination (n=51) with those who persisted throughout it (n=46). Seed-based FC analysis indicated greater connectivity between the ACC and dorsolateral prefrontal cortex in subjects who persisted throughout the task, along with greater FC between the ACC and the precentral gyrus in those who quit before its termination. Differences in FC between the groups were specific to the ACC, and were absent in the medial prefrontal cortex (mPFC), a neighboring non-overlapping region used here as control for spatial specificity. The results shed light on the mechanisms underlying interindividual differences in the ability to handle distress.

Title: The Cost of Flexible Decision Making and Apathy in Traumatic Brain Injury

Authors: *J. HOGEVEEN[1], D. F. ARAGON[1], E. M. CAMPBELL[1], J. ROMERO[1], E. D. PEARSON[1], C. W. SHUTTLEWORTH[2], R. A. CAMPBELL[3], D. GILL[3], M. HUSAIN[5], V. D. COSTA[6], S. PIRIO-RICHARDSON[4], A. R. MAYER[7];

Abstract: The motivation to initiate action is central to adaptive functioning, but is impaired in a variety of neurological and psychiatric disorders. In particular, a significant number of patients with traumatic brain injury (TBI) demonstrate clinically-significant apathy—i.e., a negative change in goal-directed actions—which can significantly impact patients' lives and persist long after the injury event. Yet, the neurocomputational deficits causing chronic apathy in TBI remain underspecified. In normative decision making, an agent flexibly chooses between novel and familiar goals, which are expected to be valuable enough to justify their associated action costs or effort. Here, we merged computational modelling of 'explore-exploit' decision making (i.e., flexibly deciding whether to explore a novel option versus exploiting a familiar one) and effort-based decision making during fMRI in patients with TBI and low- to high-apathy problems in their everyday lives. Behavioral results indicated that TBI patients with elevated apathy demonstrate reduced exploration of novel choice options, and greater effort-based discounting of rewards, suggesting that the anticipated costs associated with flexible decision making may interact to shape apathy in TBI. fMRI analyses are ongoing, but will test the hypotheses that neural computations

critical for explore-exploit decision flexibility and effort estimation are both disrupted in individuals with TBI and increased levels of apathy. A greater understanding of the neurocomputational bases of apathy in TBI could shape the design of more effective brain-based interventions for normalizing goal-directed behavior in patients.

Title: Limited evidence for prioritized loss avoidance during cognitive performance, despite robust loss aversion in decision-making

Authors: C. CHEN, R. LONG, Z. PU, M. W. L. CHEE, ***S. A. A. MASSAR**;
Natl. Univ. of Singapore, Singapore, Singapore

Abstract: Human behavior is thought to be more strongly motivated by the drive to avoid losses than to pursue gains. This tendency biases individuals to accept more risk, longer delays, and higher effort when choice outcomes are framed as a loss rather than a gain. However, studies measuring cognitive performance under loss and gain incentive conditions did not consistently find that people perform better, or exert more effort when losses are at stake. In a recent study (Massar, Pu, Chen, & Chee, 2020), we found evidence that losses motivated cognitive effort more than gains in a working memory task, especially at the highest effort level. As these results deviated from previous studies, we set out to perform a preregistered, replication, and extension study with an increased sample size informed by a power analysis. Eighty-six participants [mean age (stdev) = 21.95 (2.725), 64 females] performed an N-Back task (1 to 4-Back) under Gain and Loss incentive conditions. To assess effort, pupillometry was recorded during task performance, and subjective effort ratings were taken after each task run. Results showed that contrary to our hypothesis, losses did not enhance working memory performance relative to gains, even at the highest load of the N-Back task. Similarly, no differences in effort allocation as measured by pupil diameter were found between the Gain versus Loss conditions on any task level. Although participants rated that they believed they were exerting more effort in the Loss condition of the highest N-Back level, their subjective feelings of the task did not translate to performance differences between Gain and Loss conditions. In contrast to this absence of loss versus gain effects in N-Back performance, almost all participants did show clear loss aversion in a classical mixed-gamble lottery task. These findings suggest that Gain and Loss incentives may differ in their effects on working memory and decision making.

Title: Examining the neural substrates of reward circuitry in the lateral septum

Authors: *J. ISAAC;
Emory Univ., Atlanta, GA

Abstract: The lateral septum (LS) has been implicated in a variety of behaviors ranging from kinship recognition to aggression. Anatomically, it sits at a critical junction between the hippocampus and reward circuitry. Despite numerous anatomical and pharmacological studies that have investigated the function of the LS, how it contributes to such a variety of heterogeneous behaviors remains unknown. This study seeks to elucidate the diverse connectivity of the LS and how its distinct projections contribute to a breadth of behaviors. In order to do this, we focused on three different target populations of the LS that project to downstream regions that have been linked to distinct behaviors: the nucleus accumbens (NAc), the bed nucleus of the stria terminalis (BNST), and the ventromedial hypothalamus (vmH). First, we employed a modified glycoprotein-deleted rabies virus strategy to trace the monosynaptic inputs to these three different projection populations and found that they each received disparate inputs from various brain regions (n = 3). Using whole brain mapping techniques, we found that LS-BNST and LS-vmH recieved inputs from distinct compartments of the hippocampus. The LS-BNST projection appears to receive more inputs from the dorsal CA1 and the ventral subiculum. In contrast, the LS-vmH projection receives more input from the ventral CA1. The LS-vmH projection also receives dense thalamic input. We then performed cellular resolution calcium imaging in freely behaving mice over a variety of naturalistic and reward-dependent assays to better understand how LS neural activity relates to behavior. We found that LS neurons have strong reward responses, including response to multiple naturally rewarding stimuli, such as food and social rewards. Further calcium imaging of the NAc, vmH and BNST projecting LS neurons will allow us to determine how their unique afferents shape their neural activity. Together these data suggest that the LS has distinct projections to diverse downstream targets that receive discrete inputs from upstream brain regions and encode reward-related information.

Title: L-acetylcarnitine (lac) confers metabolic resilience to trauma and mitigates posttraumatic stress disorder (ptsd)-like symptomatology in male mice

Authors: *G. PRESTON, T. L. KOZICZ;
Mayo Clin., Rochester, MN

Abstract: There is growing evidence to suggest that metabolic dysfunction underlies the pathophysiology of several psychopathologies. Mitochondrial metabolic dysfunction has been strongly implicated in the etiology of several psychiatric disorders, including posttraumatic stress disorder (PTSD). We recently identified evidence of profound mitochondrial metabolic reprogramming in mice exposed to a paradigm for the induction of PTSD-like symptomatology. Both reduced brain mitochondrial electron transport chain activity, as well as reduced circulating acetylcarnitine were identified as highly predictive of PTSD-like behavior in these animals. We therefore investigated the efficacy of the novel antidepressant L-acetylcarnitine (LAC) in mitigating PTSD-like behavior in mice. We exposed 96 C57BL/6J male mice age 10 weeks to a PTSD-induction paradigm comprised of two decontextualized sessions of inescapable electric foot shock. Immediately following induction, 48 animals were supplemented with ~100mg/kg/day LAC (0.06% in drinking water ad libitum). All animals were then assayed for light/dark transfer, marble burying, acoustic startle response, and light phase activity, to identify PTSD-like and resilient animals. Animals were sacrificed and metabolomic analysis for mitochondrial organic acids was performed in circulating plasma collected both before and after PTSD induction. Supplementation with LAC confers a metabolic resistance to trauma and PTSD-like symptomatology in mice. Reduced circulating acetylcarnitine was again associated with PTSD-like behavior, and PTSD-like mice supplemented with LAC displayed both reduced severity of PTSD-like behavior and reduced restraint stress corticosterone response relative to PTSD-like animals supplemented with vehicle alone. These effects were observed at a dose below that required for the anxiolytic effects of LAC. Exposure to the PTSD induction paradigm resulted in reduced body mass, multisystem mitochondrial metabolic dysfunction, and increased mitochondrial bioenergetic flux. This mitochondrial metabolic reprogramming was sufficient to discriminate PTSD-like and resilient animals. The mitochondrial metabolic reprogramming associated with trauma exposure was significantly mitigated in PTSD-like animals supplemented with LAC relative to PTSD-like animals supplemented with vehicle alone. Supplementation with LAC appears to improve mitochondrial bioenergetic metabolism through anaplerotic replenishment of the TCA cycle via α-ketoacids, which was associated with resilience to PTSD-like symptomatology.

Title: Dopamine D1 receptors and PTSD symptom expression in rats

Authors: M. DILLERUD, ***T. KOELTZOW**, J. O'RUSSA, A. MABIE, S. BECKES, W. KOELTZOW, D. C. COOPER, *T. E. KOELTZOW;
Bradley Univ., Peoria, IL

Abstract: The identification of the neurobiological factors that underliethe development of Post Traumatic Stress Disorder (PTSD), as well as thedevelopment of increasingly effective pharmacotherapies, remains a central goalof research. The Single-Prolonged Stress Model (SPS) is a well-established,preclinical rodent model of PTSD (Richter-Levin et al., 2018), and represents avalid model for drug discovery. The mesoaccumbens dopamine (DA) system, whichplays a well-established role in reinforcement learning, is also robustlyactivated by unexpected or aversive stimuli. This attribute may serve to informan understanding of the high comorbidity that has been reported for PTSD andsubstance use disorders. The purpose of the present study is to evaluate theimpact of SPS on DA D1 receptor function. Thirty-six, male, adolescent(PND=50), Sprague-Dawley rats (n=18/group) were randomly assigned to a stresscondition (SPS or SHAM). The SPS procedure consisted of two hours of restraintstress, 20 minutes of forced swimming, and CO^2-inducedloss of consciousness (Lisieski et al., 2018). SHAM controls were exposed toidentical contexts and handling, minus stress exposures. Immediately followingthe SPS/SHAM induction, rats were placed in automated locomotor activitychambers. Following a nine-day incubation period, rats were subjected to abehavioral test battery: open field (10 minutes), elevated plus maze (10minutes), and forced swim (10 minutes) tests. A Greenhouse-Geiser-correctedRMANOVA revealed a statistically significant Time x Stress interaction ($F_{(1,11.51)}$=2.49; p <0.005) as SPS-exposed rats exhibited a hyperactive locomotor response duringthe first three hours of the test. Following incubation, independent samples *t*-testsfailed to identify statistically significant main effects of stress on anybehavioral measure. However, a robust trend associated with strong effect sizesfor rearing was observed: SPS elicited enduring decreases in rearing behaviorin both the Open Field ($t_{(34)}$ = 1.63, p=0.11;d=0.54) and the Elevated Plus Maze ($t_{(34)}$ =1.88; p=0.07; d=0.63). Given the well-established role of DAD1 receptors in vertical motor activation, these findings suggest thepossibility that SPS alters dopamine D1 receptor mechanisms. Thus all rats weresubjected to 1 mg/kg SKF 81297 to assess group differences in the sensitivityof to this DA D1 receptor agonist (data collection and analysis in progress).These data may advance an understanding in the individual differences thatcomprise vulnerability to PTSD and may inform novel treatment strategies.

Title: Function of the insular cortex in post-traumatic behavior induced by acute restraint stress

Authors: *S. PARK[1,2], Y. HUH[2], J. CHO[1];
[1]Dept. of Brain and Cognitive Sci., Ewha Womans Univ., Seoul, Korea, Republic of; [2]Dept. of Med. Sci., Catholic Kwandong Univ., Incheon, Korea, Republic of

Abstract: Fear is an integral part of a brain's defensive mechanism that evolved to survive against predation and other ecological risks. Occasionally some fearful events become traumatic lasting for a long period, and dysfunctions of the fear-related circuit are thought to be underlying causes of various post-traumatic symptoms. Recent studies suggested the insular cortex (IC) as an additional component of the fear managing brain network. Functional neuroimaging studies have linked the IC activation to anxiety disorders, such as a simple phobia or post-traumatic stress (PTS). However, the role of the IC leading to PTS have not been understood. Therefore, we investigated the role of the insular cortex in the animal model of PTS. First, we used an animal model of PTS and measured how long the behavioral post-traumatic symptoms lasts. We then investigated the neural activity of IC neurons during post-traumatic behavior. Lastly, we investigated whether the IC is involved in triggering traumatic behaviors by ablating the region. Acute restraint stress was used for our PTS model. Behavioral response to the trauma-reminding object was compared in the restraint and non-restraint control groups. We found that the restraint stress group shows less contacting and more burying of the trauma-reminding object than the control group, confirming that PTS symptoms developed with our model. The restraint stress group maintained these trauma-related behaviors until the 8th week. Single-unit recording in freely moving mice after inducing acute restraint stress revealed a correlation between the neural activity of IC and defensive burying behavior in the restraint stress group. In contrast, the neural activity of IC in the control group showed no correlation with defensive burying behavior. After confirming that acute restraint stress induces trauma-related behaviors and neural activity of IC correlated with defensive burying behavior, the role of the IC in PTS was further tested by making electrolytic lesions. Indeed, traumatic behaviors significantly decreased in IC lesioned group compared to the control, confirming that the IC is involved in inducing traumatic behaviors. Overall, our findings show that the IC is involved in processing trauma-related information and crucial for expressing traumatic behavior.

Title: Acute and chronic ethanol administration exacerbate the long-term behavioral effects of predator stress

Authors: *C. S. GOODMAN, C. R. DEL VALLE, J. L. DODSON, I. F. SMITH, K. M. ELMOUHAWESSE, E. P. HOPSON, H. R. SPARKMAN, M. M. NAYLOR, P. R. ZOLADZ; Psychology, Ohio Northern Univ., Ada, OH

Abstract: Trauma is frequently associated with alcohol use, yet limited work has examined the impact of alcohol ingestion on the development of post-traumatic stress disorder (PTSD) symptoms. In two separate experiments, we examined the effects of acute and chronic alcohol administration on the development of PTSD-like symptoms in Sprague-Dawley rats exposed to predator stress. In Experiment 1, rats were injected intraperitoneally with alcohol (1.5 g/kg, 20% v/v) or vehicle (distilled H_2O) 30 minutes before being exposed to an adult, female cat for 1 hour. One week later, the rats were tested for anxiety-like behavior and symptoms of hyperarousal. Stressed males, but not stressed females, treated with alcohol prior to stress displayed significantly greater anxiety and a trend toward larger startle responses, relative to stressed rats treated with vehicle. In Experiment 2, rats were injected with alcohol (1.5 g/kg, 20% v/v) or vehicle (distilled H_2O) on Mondays, Wednesdays, and Fridays for 7 weeks. On the Monday of the 7th week, the rats were injected 30 minutes prior to cat exposure. During the 8th week, the rats were tested for anxiety-like behavior and symptoms of hyperarousal. Stressed males and females treated with alcohol exhibited significantly greater anxiety than rats treated with vehicle, and stressed females treated with alcohol displayed significantly exaggerated startle responses. These findings suggest that acute and chronic peri-traumatic alcohol ingestion sex-dependently increases the risk of developing some PTSD-like symptoms.

Title: Identifying neuronal circuits mediating MDMA's prosocial effects by brain-wide activity mapping

Authors: *D. RIJSKETIC[1], J. SALGADO[1], N. R. WALL[1], P. LLORACH[1], S. SCHLOZMAN[1], Z. RASTEGAR[1], D. BARBOSA[1], D. CARDOZO PINTO[1], P. A. NEUMANN[1], M. HELL[2], K. T. BEIER[1], R. C. MALENKA[1], B. D. HEIFETS[1];
[1]Stanford Univ., Stanford, CA; [2]Federal Univ. of Juiz de Fora, Juiz de Fora, Brazil

Abstract: MDMA (ecstasy) shows promise in the treatment of PTSD, facilitating psychotherapy via feelings of social connection, empathy and trust. However, MDMA has abuse potential and long-term heavy use can have complications. Improving on MDMA to develop a safe, scalable treatment requires understanding its therapeutic mechanism. We found that supraphysiological serotonin release in the nucleus accumbens accounts for MDMA's prosocial effect. Elucidating how this local pharmacological mechanism alters brain-wide activity could yield novel targets to mimic MDMA's therapeutic effects. To

image brain-wide activity, *TRAP2* mice (Targeted Recombination in Active Populations 2), in which the neuron firing-dependent *Fos* promoter drives CreER expression, were crossed to a reporter line (*Ai14*). In effect, 4-hydroxytamoxifen transiently enables CreER to trigger tdTomato expression. *TRAP2;Ai14* mice were singly housed and i.p. injected with saline or MDMA (7.5 mg/kg) along with 4-OHT. Mice were later regrouped and injected after 2 weeks with saline or MDMA. 90 minutes later mice were perfused, brains were bisected, immunolabeled, made optically transparent (iDISCO+), and imaged via light sheet microscopy. Using Ilastik, MIRAcL, FIJI, and FSL, we detected active cells, registered the Allen brain atlas to images, quantified regional cell densities, and generated voxel-wise corrected p-value maps. For chemogenetic silencing of social ensembles, hotspots in *TRAP2* mice were bilaterally injected with AAV8-DIO-hM4Di-mCherry or AAV8-DIO-mCherry. The MDMA social ensemble was later TRAPed before a 3 chamber sociability test where mice received CNO and saline or MDMA. MDMA (204404 ± 46560 cells; N = 6) significantly increased the total number of tdTomato$^+$ (active) neurons compared to saline (393627 ± 20811 cells; N = 7). In both social and non-social contexts, MDMA enhanced activity in the nucleus accumbens and several prefrontal cortical regions, such as prelimbic and orbital areas. Voxel-wise analyses revealed preferential activation of the dorsal endopiriform nucleus in the social context. Diffuse chemogenetic silencing of the mPFC MDMA social ensemble left MDMA's prosocial effect intact, whereas silencing this ensemble in the dorsal medial shell of the nucleus accumbens significantly blunted MDMA's prosocial effect. Through unbiased whole-brain mapping of neurons differentially activated by saline vs MDMA in social and non-social contexts we identified a novel network of regions that may mediate MDMA's prosocial effects. We plan to test for causal links between these structures' activity and MDMA's effects on sociability and relief from traumatic experiences.

Title: Orexin receptor antagonists reverse neurophysiological and behavioral deficits in a rodent model of stress-induced psychosis

Authors: *H. B. ELAM[1], S. M. PEREZ[1], J. J. DONEGAN[2], D. J. LODGE[1,3];
[1]UT Hlth. San Antonio, San Antonio, TX; [2]Dell Med. Sch. at the Univ. of Texas at Austin, Austin, TX; [3]South Texas Veterans Hlth. Care System, Audie L. Murphy Div., San Antonio, TX

Abstract: Post-traumatic stress disorder (PTSD) is a prevalent condition affecting approximately 8% of the United States population and 20% of United States combat veterans. In addition to core symptoms of

the disorder, up to 64% of individuals diagnosed with PTSD experience comorbid psychosis. Previous research has demonstrated a positive correlation between symptoms of psychosis and increases in dopamine transmission. We have recently demonstrated that the paraventricular nucleus of the thalamus (PVT), which is activated following stressful or aversive events, can regulate dopamine neuron activity in the ventral tegmental area (VTA) through a multi-synaptic pathway that begins with a projection to the nucleus accumbens (NAc). Specifically, inactivation of the PVT leads to a reversal of aberrant dopamine system function and psychosis-like behavior. The PVT receives dense innervation from orexin containing neurons, therefore, targeting orexin receptors may be a novel approach to restore dopamine neuron activity and alleviate PTSD-associated psychosis. In this study, we induced stress-related pathophysiology in male Sprague Dawley rats using a two-day inescapable foot-shock procedure. Following footshock, we observed a significant increase in VTA dopamine neuron population activity, deficits in sensorimotor gating, and hyperresponsivity to psychomotor stimulants. Administration of selective orexin 1 receptor (OX1R) and orexin 2 receptor (OX2R) antagonists (SB334867 and EMPA, respectively) or the FDA-approved, dual-orexin receptor antagonist, Suvorexant, were found to reverse stress-induced increases in dopamine neuron population activity. However, only Suvorexant and SB334867 were able to reverse deficits in behavioral corelates of psychosis. These results suggest that the orexin system may be a novel pharmacological target for the treatment of comorbid psychosis related to PTSD.

Title: Ketamine sex- and dose-dependently mitigates behavioral sequelae induced by a predator-based psychosocial stress model of PTSD

Authors: *C. R. DEL VALLE, C. S. GOODMAN, J. L. DODSON, I. F. SMITH, K. M. ELMOUHAWESSE, E. P. HOPSON, H. R. SPARKMAN, M. M. NAYLOR, P. R. ZOLADZ; Psychology, Ohio Northern Univ., Ada, OH

Abstract: Few pharmacological agents effectively treat the array of symptoms involved in post-traumatic stress disorder (PTSD). SSRIs are the most commonly prescribed medications for PTSD, but they lead to remission rates of barely 50% and take weeks to months before producing symptom relief. Therefore, we examined the impact of ketamine, an NMDA receptor antagonist that has rapid antidepressant effects, on PTSD-like symptom development in rats exposed to a predator-based psychosocial stress model of PTSD. Male and female Sprague-Dawley rats were exposed to psychosocial stress for 31 days. The stress procedure involved two separate cat exposures (Days 1 and 11) and daily social instability. Immediately

after the first cat exposure, rats in the stress groups were injected intraperitoneally with ketamine (10 mg/kg or 15 mg/kg) or vehicle (0.9% saline); rats in the no stress groups were injected with vehicle. Three weeks following the second cat exposure (i.e., Day 32), the rats were tested for symptoms of anxiety and hyperarousal. Stressed males treated with vehicle exhibited heightened anxiety on an elevated plus maze and less activity in an open field. Stressed females treated with vehicle displayed exaggerated startle responses, as well as heightened anxiety and less activity in an open field. These effects were prevented by ketamine treatment, particularly the 10 mg/kg dose. Such findings indicate that peri-traumatic administration of a sub-anesthetic dose of ketamine can prevent the onset of PTSD-like symptoms.

Title: Mechanisms of susceptibility or resilience to traumatic stress: potential influence of the microbiome

Authors: A. TANELIAN, R. NAHVI, B. NANKOVA, *E. SABBAN;
New York Med. Col., Valhalla, NY

Abstract: Post-Traumatic Stress Disorder (PTSD) is a severe and long-lasting outcome of traumatic life event. Exposure to trauma induces PTSD only in a sub-population of individuals while others remain resilient. The mechanisms and contributing factors differentiating between stress resilient and susceptible subjects are still unclear. We hypothesize that inter-individual differences in the microbiome composition and its function contribute to host resilience or susceptibility to stress-induced psychopathologies. This study aimed to characterize differences in gut microbial community structure and functions in the Single Prolonged Stress (SPS) animal model of PTSD. Sprague-Dawley male rats were divided into SPS treated group or unstressed controls. After 14 days, behavioral analyses were performed using Open Field, Social Interaction and Elevated Plus Maze tests. The animals were sacrificed the following day and cecum, colon, hippocampus, and medial prefrontal cortex were collected. Based on the anxiety measures, the SPS group was further subdivided into SPS-resilient (R) and SPS-susceptible (S) subgroups. Prior to SPS and immediately after the Open Field test, fecal samples were collected from each rat for 16S V3-V4 ribosomal sequencing; whereas urine samples were collected before and 90 minutes after SPS to measure urinary epinephrine (Epi) levels. Analysis of fecal microbiota revealed significant differences among the groups before and after SPS stressors. Before SPS, the SPS-S subgroup harbored microbiota with an overall pro-inflammatory phenotype, such as significantly increased levels of Clostridia, and decreased levels of *Lactobacillus* and *Barnesiella* compared to the SPS-R subgroup. After SPS, among the many changes observed was significant decrease in abundance of *Bacteroides* in SPS-S subgroup. In line with

the shifts in microbiota, levels of cecal short chain fatty acids were also altered, with SPS-S subgroup having significantly lower levels of Acetate, Valerate and Caproate along with shortened colon length. Analyses of different brain regions revealed significant increases in blood brain barrier permeability in SPS-S subgroup relative to the SPS-R subgroup as determined by Claudin-5 expression. Urinary Epi levels were also significantly higher in the SPS-S subgroup. Taken together, our results suggest microbiota is a potential factor in predisposing subjects either to stress susceptibility or resilience. Moreover, SPS triggered significant shifts in the gut microbiota, therefore unravelling these mechanisms could lead to new therapeutic possibilities for PTSD through controlled manipulation of the gut microbiota.

Title: Effects of diet & exercise on neurobehaviors in mice

Authors: *M. K. SATYAL, C. BUHLER, D. QUETEL, D. F. ENGLISH, J. C. BASSO;
Virginia Tech., Blacksburg, VA

Abstract: Diet-induced obesity and sedentary behavior are important factors influencing cognitive function decline. Limited research to date has examined the interaction between diet and exercise on exercise behavior and cognitive outcomes. Male and female FVBN/C57B6 mice (N=32) were randomly assigned to consume high-fat (60% kcal fat) or low-fat (10% kcal fat) diet *ad libitum* from weaning. At 9 weeks of age, mice from each diet group were randomized to receive 24-hour access to either an electronic running wheel or a sham locked running wheel for a period of 21 days for a total of 4 groups: (1) low-fat sedentary (LF-S), (2) low-fat exercise (LF-E), (3) high-fat sedentary (HF-S), and (4) high-fat exercise (HF-E). Animal weight and volume of exercise were tracked throughout the intervention period. The open field task and elevated plus maze were used to assess anxiety and blood glycated hemoglobin (HbA1c) was used to assess glucose control at the end of the intervention period.There was a significant interaction effect between time and diet on weight ($F(1.79, 48.36)=3.94$, $p=0.030$). Weekly running distance (km) increased significantly across the 3 week intervention period ($F(1.3, 18.7)=13.692$, $p=0.001$). Additionally, there was a significant effect of diet on running distance ($F(1,14)=4.86$, $p=0.045$) with the high-fat group running more than the low-fat group. There was a significant effect of exercise on time spent in the closed arms of the elevated plus maze ($F(1,26)=10.91$, $p=0.003$) with the sedentary group spending more time in the closed arms. There was no significant main effect of diet or exercise nor an interaction effect of diet and exercise on the time spent in the center of the open field or HbA1c. The distance run in the first week of wheel exposure was negatively correlated with time spent in the center of

the open field (r=-0.532, p=0.034). These findings suggest that high-fat diet and exercise may influence neurobehaviors preceding the onset of metabolic dysfunction.

Title: Non-normative reward biases persist in instrumental information demand

Authors: *I. RISCHALL[1], L. HUNTER[1], G. G. JENSEN[2], J. P. GOTTLIEB[3];
[1]Columbia Univ., New York City, NY; [2]Psychology, Columbia Univ., New York, NY; [3]Neurosci., Columbia Univ. Med. Ctr., New York, NY

Abstract: Curiosity guides us through the world, governing which information we take in and which we ignore. Humans are intrinsically motivated to obtain information, sometimes to reduce uncertainty and sometimes merely to anticipate positive outcomes. Although uncertainty-driven information demand is theoretically optimal and maximizes prediction accuracy, a bias toward positive information can interfere with prediction accuracy and result in suboptimal outcomes. Here we show that this bias, traditionally thought to reflect an affective preference for “savoring” over “dread” (anticipating positive but not negative outcomes), may instead reflect the limitations of heuristics that people use to identify informative observations. Participants (N = 610) performed an online task in which they attempted to predict the sum of two prizes by inquiring about the precise value of one of the prizes. Each prize was randomly drawn from a probability distribution with pre-specified variance and expected value (EV). The normative strategy, which minimized the uncertainty of the sum, was to inquire about the prize with the higher variance regardless of EV. We replicated our previous finding that, when information demand was not incentivized (i.e. information was non-instrumental), participants used non-normative strategies, frequently inquiring about the higher-EV prize. If this bias were due to savoring, it should diminish when participants had monetary incentives for minimizing uncertainty. Contrary to this prediction, the bias persisted in two distinct instrumental conditions, resulting in significant loss of rewards. Only 11% of participants consistently adopted the normative strategy despite the fact that this strategy was constant across different conditions and could be calculated with simple arithmetic. These findings suggest that people identify informative stimuli using heuristics that may approximate ideal performance in some tasks but reliably fail in other conditions.

Title: The neurodevelopment of value-driven attention

Authors: *P. WIWATPHONTHANA[1], P. SOOKPRAO[1], C. CHUNHARAS[6], P. PUVACHAROONKUL[2,1], K. LERTLADALUCK[3,1], S. ITTHIPURIPAT[1,4,5];

Abstract: Reward plays an essential role in prioritizing the processing of sensory information. Past psychological studies in human adults have shown that rewarding stimuli not only facilitate goal-directed behaviors but also cause distraction when they are irrelevant to the current behavioral task. While neural mechanisms underlying value-driven attention have been increasingly well understood, it is still unclear how the human brain develops to support value-driven attention. To address this question, we measured EEG from typically developing adolescents and healthy adults performing a variant of value-driven attention tasks where we assessed the impacts of low and high reward values associated with the colors of task-irrelevant visual stimuli (i.e., low- and high-valued distractors) on the behavioral performance at discriminating task-relevant targets as well as the amplitude of the N2pc, the well-known event-related potential (ERP) index of covert visual attention related to target selection. Consistent with previous reports, in adults, low-valued distractors did not change behavioral performance at discriminating task-relevant targets and did not modulate the amplitude of target-related N2pc. On the other hand, high-valued distractors led to worse discrimination performance and the reduction in the N2pc amplitude compared to the low-valued-distractor and no-distractor conditions. In contrast, teenagers exhibit different patterns of reward modulations at both behavioral and neural levels. While high-valued distractors increased behavioral inference and reduced the N2pc amplitude in a similar degree as the adult group, low-valued distractors produced much higher attentional capture effects in teenagers compared to adults. These resulted in comparable levels of attentional capture effects between low- and high-valued distractors in the younger group. Together, our findings suggest that the differential effects that low and

high rewards have upon attention in adulthood are caused by the reduced sensitivity of the attentional system to visual stimuli associated with low reward values during development.

Title: The relationship between cognitive function and depression in people with and without type 2 diabetes mellitus

Authors: *H. HIBINO[1], S. L. GORNIAK[2];
[2]Dept. of Hlth. & Human Performance, [1]Univ. of Houston, Houston, TX

Abstract: The coexistence of type 2 diabetes mellitus (T2DM) and depression and a bidirectional relationship between two health conditions are reported (Roy & Lloyd, 2012; Semenkovich, Brown, Svrakic, & Lustman, 2015). A substantial body of literature demonstrates cognitive impairment (CI) in both people with T2DM and depression; CI advances as the severity of T2DM and depression progresses (Gatlin & Insel, 2015; McDermott & Ebmeier, 2009). Additionally, domain-specific cognitive deficits, such as working memory, are reported in people with diabetes mellitus (Christman, Vannorsdall, Pearlson, Hill-Briggs, & Schretlen, 2010; Gorniak, Lu, Lee, Massman, & Wang, 2019; McCrimmon, Ryan, & Frier, 2012). The coexistence of T2DM and depression progresses the CI; however, it is unclear whether the level of depression severity is associated with cognitive function in people with T2DM (Demakakos, Muniz-Terrera, & Nouwen, 2017). Cognitive function may be associated with the level of depression severity and the presence of T2DM. To test our hypothesis, we examined the association between cognitive task performance and the level of depression severity in people with and without T2DM. Finally, we examined a regression model to predict the cognitive task performance. A total of 21 people with T2DM (65.2 + 5.8 years old, all female) years old and 21 age- and sex-matched healthy people (66.2 + 5.7 years old, all female) performed an auditory n-back task, in which subjects were instructed to repeat the nth letter back in a sequentially presented list of letters. The difficulty of n-back task was manipulated by asking subjects to repeat the letter further back in the list. Additionally, we asked subjects to perform the n-back task and a constant grip force tracking task to increase the difficulty of n-back task. There were three levels of difficulty: 0-back, 1-back, and 2-back. Response accuracy and response time (RT) of the n-back task were recorded. Hospital Anxiety and Depression Scale (HADS) depression and Montreal Cognitive Assessment (MOCA) were used to quantify the level of depression severity and general cognitive function, respectively. People with T2DM had a higher score of HADS depression ($p < 0.05$) and a lower score of MOCA ($p < 0.05$) compared to healthy control subjects. Overall, the score of HADS depression was related to response accuracy ($p < 0.01$) and RT ($p < 0.05$).

Finally, multiple regressions demonstrated that n-back condition, group, and the score of HADS depression predicted response accuracy ($p < 0.001$, $R^2 = 0.51$), while only group predicted RT ($p < 0.001$, $R^2 = 0.068$). These results underscore the significance of T2DM and depression in the cognitive task performance.

Title: Tumor suppressor gene Fus1 causes sex-dependent effects in memory impairments

Authors: *T. FARRIS[1], A. V. IVANOVA[3], A. SHIMAMOTO[2], A. SHANKER[1];
[2]Neurosci. and Pharmacol., [1]Meharry Med. Col., Nashville, TN; [3]Vanderbilt Univ., Nashville, TN

Abstract: Tumor suppressor gene *Fus1* causes sex-dependent effects in memory impairments
Tonie Farris[1], Alla V. Ivanova, Akiko Shimamoto, and Anil Shanker
Meharry Medical College, Department of Biochemistry, Cancer Biology, Neuroscience, and Pharmacology, Nashville, TN.
Memory impairments contribute to the manifestation of diseases such as amnestic mild cognitive impairment (aMCI). Incidences for aMCI are more reported in women than in men, although some studies have demonstrated otherwise. Fusion 1 (*Fus1*), also known as tumor suppressor candidate 2 (*TUSC2*), was originally identified as a tumor suppressor gene, but now is considered as a mitochondrial Ca^{2+} protein that aids the mitochondrial calcium uniporter (MCU) and mitochondrial sodium-calcium exchanger (mNCX). A deletion of *Fus1* gene augments the production of reactive oxygen species (ROS), oxidative stress, and disturbs the homeostasis of mitochondrial Ca^{2+} ($miCa^{2+}$). We have previously demonstrated that *Fus1* knock-out (KO) mice showed deficits in olfactory and spatial memory. However, these results were only tested in females and sex was not considered as a variable. Here, we assessed a potential sex difference in memory impairments in *Fus1* KO and wild-type (WT) mice. To do this, we executed a battery of behavioral tests including, Y-maze, which was conducted for a duration of 8 minutes with an overhead camera recording the series of arm entries made by each individual mouse; Novel object recognition (NOR) was conducted in an open field arena where each mouse was placed individually with either two identical objects in the familiarization period or with two dissimilar objects in

the exploration period; and open-field test (OFT), in which mice were placed in an open-field arena and allowed to move about freely for a 30 minute test duration. All behavioral tests were performed on 17-weeks old mice. Results show that *Fus1* KO males, but not KO females, exhibited a reduced percentage of correct alternations ($p<0.05$, n = 11-14 per group). By contrast, *Fus1* KO females had increased locomotor activity compared to *Fus1* KO males ($p<0.05$, n =4-11). No gene or sex effects were observed in NOR test. Amyloid β_{1-42} peptide was measured and found to be unaltered in male and female KO mice. Thus, Fus1 deficiency show sex-dependent effects in specific behavioral tasks. The findings of this study corroborate that Fus1 deficiency has a comportment on short-term memory as well as locomotor activity as tested *in vivo*. The outcomes of this ongoing study will provide insights on the potential mechanisms that induce memory impairments to give rise to neurodegenerative diseases such as aMCI.

Title: Trpm8 is important for skeletal acquisition and maintenance in male but not female c57bl6/j mice

Authors: *A. L. LANGLAIS[1,2], R. J. NEILSON[1], B. A. MOHAMED[1], A. L. CARVALHO[1], K. A. BECKER[3], K. J. MOTYL[1,2,4];
[1]Ctr. for Mol. Med., Maine Med. Ctr. Res. Inst., Scarborough, ME; [2]Grad. Sch. of Biomed. Sci. and Engin., Univ. of Maine, Orono, ME; [3]Col. of Osteo. Med., Univ. of New England, Biddeford, ME; [4]Sch. of Med., Tufts Univ., Boston, MA

Abstract: Transient receptor potential cation channel subfamily M member-8 (TRPM8) is the thermo-TRP channel responsible for cold thermosensation within sensory neurons. In rodents, loss of TRPM8 greatly diminishes the ability to sense and respond to cold. This also results in altered core body temperature regulation and metabolism. Other TRP channels of the Vanilloid family have established roles in bone via regulation of Ca^{2+} stores and intracellular Ca^{2+} signaling of osteoblasts (bone mineralizing cell) and osteoclasts (bone resorbing cell), but the role of TRPM8 in bone homeostasis has yet to be clearly defined. Previously, we found that cool temperature housing in aged mice (52 weeks old) caused bone loss, independent of TRPM8, but that male mice null for TRPM8 (*Trpm8*$^{-/-}$) had low bone density and cortical bone defects compared to wildtype (WT) mice regardless of housing temperature. To determine whether this was age-related or due to impaired acquisition, we examined bone in young (8 weeks old) mice when trabecular bone density has peaked, and cortical bone is continuing to grow. Similar to aged mice, *Trpm8*$^{-/-}$ males, but not females, have reduced total areal bone mineral content (mg of bone, -10%) vertebral bone volume fraction (Bone Volume/Total Volume, -13%) and trabecular

number (-4.6%) compared to WT mice. The L5 vertebrae from *Trpm8*$^{-/-}$ males had significantly less % bone surface occupied by osteoblasts, and gene expression of the osteoblast marker *Bglap* (Osteocalcin) was reduced in tibia. Additionally, expression of osteoclast marker *Ctsk* (Cathepsin K) was increased in *Trpm8*$^{-/-}$ males. These results suggest altered differentiation and activity of the bone multicellular unit in the absence of *Trpm8*. Interestingly, expression of neurotrophic factors *Ngf* and *Bdnf* were significantly upregulated in the tibia and *in vitro* cultured osteoclasts of *Trpm8*$^{-/-}$ males, suggesting TRPM8 may influence innervation of the bone microenvironment. However, *Trpm8* expression has been reported in tissues outside the nervous system. Using CRISPR-Cas9 we inserted loxP sites in introns 11 and 14 of the *Trpm8* gene to generate a *Trpm8*$^{loxP/loxP}$ strain. *Sox2*-mediated Cre recombinase successfully deleted exons 12-14, which is predicted to cause a frameshift mutation and premature stop codon. Deletion was confirmed by genotyping and qPCR analysis in the dorsal root ganglion. These mice mimic the low bone mineral content observed in the male *Trpm8*^{tm1Jul} (*Trpm8*$^{-/-}$) mice. We will use these mice to test neuronal and bone cell-mediated origins and effects of TRPM8 signaling, which will expand our understanding of the role of TRPM8 in bone development and maintenance.

Title: Changes in the distraction potential associated with the side of motor onset of motor symptomatology in Parkinson disease

Authors: *Y. MARTÍNEZ-SERRATO[1], R. SOLIS-VIVANCO[2];
[1]INSTITUTO NACIONAL DE NEUROLOGIA Y NEUROCIRUGIA, CIUDAD DE MEXICO, Mexico;
[2]Neuropsychology Dept., Inst. Nacional De Neurologia Y Neurocirugia Ma, Mexico City, Mexico

Abstract: Neurophysiological studies obtained through the distraction potential, composed by the mismatch negativity (MMN), the P3a and the reorientation negativity (RON) have reported that involuntary attention (IA) is impaired since early stages of Parkinson's disease (PD). It is also known that IA mechanisms are automatic or bottom-up and are regulated by the ventral frontoparietal network, which is largely lateralized to the right hemisphere. Due to an asymmetric degeneration of striatal dopaminergic neurons, PD generally initiates its motor symptomatology unilaterally (left-onset side; right-onset side) which has led a growing body of researchers to explore the cognitive, psychological, and clinical differences between left onset PD patients and right onset PD patients. While such alterations have been described from the aforementioned approaches, much less is known about the neurophysiological dynamics underlying impairments in the IA with respect to the onset side of motor symptomatology in these patients. The aim of this study was to analyze and compare the characteristics of the components of the distraction potential between a PD group with left-sided onset (LPD), a PD group with right-sided onset (RPD), and a control group (HC). Twenty-five patients with LPD onset and 31 with RPD onset

were studied, as well as 24 healthy control subjects. All subjects performed an auditory distraction task while a digital EEG was being recorded. The distraction potential was obtained by averaging methodology. Each wave was analyzed with a Repeated Measures ANOVA test. The main finding of this study was the reduction in the P3a showing lower amplitude in the LPD group with respect to the RPD group and the HC, this results suggests that patients with LPD have reduced involuntary attention. Therefore, this finding may be of interest for clinicians involved with the intervention of these patients, since, if the IA is mostly affected in patients with LPD, strategies at the neuropsychological level can possibly be proposed by differentiating the side of motor symptom onset.

Title: Multitasking has a persistent effect on the brake reaction time in simulated car driving

Authors: *O. BOCK[1], R. STOJAN[2], M. MACK[2], C. VOELCKER-REHAGE[2];
[1]German Sport Univ. Cologne, Koeln, Germany; [2]Inst. for Sport Sci., Univ. of Münster, Münster, Germany

Abstract: Distracting tasks degrade drivers' performance on a subsequent braking task. We have shown (SfN 2020) that this degradation can persist even at stimulus onset asynchronies (SOA) of ≈12 s. Our earlier study dealt with performance measures that are relevant for traffic safety: lane keeping and distance keeping. Here we evaluate a performance measure that reflects drivers' initial and intended response: gas-off reaction time (gRT). Earlier research about the psychological refractory period (PRP) effect suggest that a distracting tasks delays subsequent gRT only if SOA is below about 400 ms, not if SOA ≈12 s as in the present data. In a driving simulator, 120 older adults (69.43 ± 3.70 years old) followed a lead car that mostly drove at a constant speed of 70 km/h, but occasionally braked: its brake lights came on, and the car slowed down to 40 km/h. To avoid collisions, participants had to slow down as well. Eleven trials of this braking task were intermixed with 60 trials of distracting tasks (typing, reasoning, and memorizing, each presented visually or auditorily). SOA between a distracting trial and the subsequent braking trial was 11.3 ± 2.4 s. In a control condition, the braking tasks were administered without distracting tasks. For analysis, SOA was binned into terciles (4.0 to 10.5 s, 10.5 to12.1 s, 12.1 to 24.5 s) and was contrasted against the control condition in a linear mixed-effects model. Covariates were Gender, Age, Distance (to the lad car at brake light onset) and SOA * Distance. Participant ID was

included as random intercept. Dependent variable was gRT. The main effect of Distance was significant (p &lt 0.001, est. = 0.04). SOA contrasts were not significant (all p &gt 0.05), but Distance * SOA-contrast interactions were significant for the contrast of short SOA with control (p &lt 0.001, est. = 0.02), medium SOA with control (p = 0.001, est. = 0.02), and long SOA with control (p = 0.014, est. = 0.01). Thus, responses at short, medium and long SOA didn't differ from control when Distance was low, but they increasingly differed from control as Distance increased. We conclude that distracting tasks led to an increase of subsequent gRT, unless Distance was low and braking responses therefore were urgent. Importantly, the increase was observed even though SOA ≈12 s. Thus, effects of distractions on gRT were much more persistent than classical PRP-effects. We posit that distracting tasks can establish a persistent task set, which must be reconfigured before a braking response can be produced, thus increasing gRT. The presumed reconfiguration was swift if braking responses were urgent, which suggests that persistence may be a matter of convenience rather than necessity.

Title: Global and local attention as predictor of intelligence

Authors: *C. D. GUILLERMO-FLORES, E. LOPEZ-GONZALEZ, T. V. ROMAN-LOPEZ, A. LAZARO-FIGUEROA, C. SANCHEZ-GACHUZ, M. MENDEZ-DIAZ, O. PROSPERO-GARCIA, A. E. RUIZ-CONTRERAS;
Natl. Autonomous Univ. Mexico, Mexico City, Mexico

Abstract: Several neuroimaging studies indicate the involvement of the prefrontal areas, especially, the dorsolateral prefrontal cortex (DLPFC) in intelligence, which has also been associated with working memory and executive functions. Switching in attention as well as performance on the task are generally related to DLPFC. Frontal N200 and P300 of the event-related potentials (ERPs) have been associated with working memory and cognitive control, thus both are considered characteristics of intelligence. This study evaluated if switching attention into global and local processing can predict intelligence, using the Navon task (letters or numbers composed of smaller letters or numbers), which requires responding to global or local stimuli through switching attention to certain features of the stimuli and ignoring others. A total of 85 young volunteers (44 males and 43 females) answered the Navon task and the Shipley-2 test, to assess global intelligence and fluid and crystallized intelligence. ERPs were recorded in a subsample of 37 subjects (21 men and 16 women) while responding to the Navon task. Regression analysis showed that accuracy in the Navon task for the local condition predicted crystallized intelligence score (r2= 0.0362, p<0.001), and overall intelligence score (r2=0.0412, p<0.001); while in ERPs, mean amplitude of P300 during global condition predicted crystallized intelligence (r2 = 0.0996, p<0.001) and overall intelligence

score (r2=0.125, p<0.001). These results suggest that subjects who are more efficient at inhibiting irrelevant stimuli had higher intellectual performance, which may indicate that selective attention is necessary to improve performance on tasks that require a higher degree of concentration.

Title: Analysis of information coding and exchange in the multiple demand network in space and time using fMRI-MEG fusion

Authors: *H. KARIMI-ROUZBAHANI[1], A. RICH[2], A. WOOLGAR[1];
[1]MRC Cognition and Brain Sci. Unit, Univ. of Cambridge, Cambridge, United Kingdom; [2]Dept. of Cognitive Sci., Macquarie Univ., Sydney, Australia

Abstract: A multiple-demand network (MDN), composed of frontal and parietal cortices, is activated by, and encodes relevant information in, a wide variety of demanding cognitive tasks. They are proposed to select and integrate task-relevant information from across neural systems (Duncan et al. 2020) but the temporal dynamics of information processing and exchange remain unclear. For example, it is unknown whether information coding arises in sub-regions of the MDN one-after-another or simultaneously. Here, we used fMRI-MEG fusion to obtain spatiotemporal insight into information coding in the MDN during a cognitively demanding task. By comparing the temporal evolution of information (from MEG) to the information contained in different brain regions (fMRI), fusion can reveal the temporal order of information coding across regions. Then, to study the exchange of this information between regions, we developed a novel implementation of Granger-causality-based connectivity analysis using the estimated time-resolved response in each region. On each trial, one of four visual stimuli appeared (white squares on grey background; two in top-right and two in top-left hemi-fields), and participants (MEG: n=24; fMRI: n=30) had to press one of four buttons. They learned two orthogonal stimulus-button mappings (rules; indicated by fixation cross color) in a training phase. Using Representational Similarity Analysis, we fused four aspects of information: coarse stimulus (left vs. right stimuli), fine stimulus (inner vs. outer stimuli), rule and response information. Both coarse and fine stimulus information appeared first in posterior followed by anterior regions of the MDN. Rule information appeared in the same order. Parietal MDN was the region which showed the response information immediately before the response. Our

connectivity analysis showed information transfer from sensory regions to MDN and its circulation within the MDN. Compared to other aspects of information, the fine stimulus information was most dominantly circulated within the MDN. These findings provide evidence for differential roles of MDN sub-regions across different information aspects. The new connectivity method opens opportunities for detailed study of information exchange with high spatial and temporal resolution.

Title: Test anxiety is associated with changes in all three domains of the attention networks task as measured by electroencephalography

Authors: G. M. TALKINGTON[1], *E. A. BOURASSA[2];
[1]Tulane Univ. Sch. of Med., New Orleans, LA; [2]Biol. Sci., Mississippi Col., Clinton, MS

Abstract: Alterations in attentional processes are commonly noted in patients with anxiety disorders as well as in non-clinical populations with trait- or state-anxiety. Test anxiety (TA), although a common entity, is poorly characterized. In this study, the attention networks task (ATN) was used to measure the efficiency of the alerting, orienting, and conflict-resolution domains of attention while simultaneous electroencephalography (EEG) recordings were taken from students with and without TA. It was predicted that students with high test anxiety (HTA) would have poorer conflict-resolution; other attentional networks were expected to be unaffected (in line with other forms of anxiety in most studies). Students were screened for TA using the blue-box stress test; those with and low TA (LTA) were later administered the ATN during EEG recording. Behavioral analysis showed that HTA students had marginally significant lower conflict-resolution efficiency compared to LTA ($p=0.06$); interestingly, HTA students also had lower orienting and increased alerting efficiency compared to LTA. On the alerting domain, both LTA and HTA had larger N1 waves in the central cued condition compared to no cue, but the N1 was larger in HTA than LTA in both conditions. On the conflict-resolution domain, LTA had larger parietal N1 waves in the incongruent condition compared to congruent condition, an effect not seen in HTA. The latency of the N1 was also delayed by approximately 150 ms in HTA compared to LTA in both conditions. The P3b wave was significantly larger in both conditions in HTA. In the orienting domain, the parietal N1 was larger for spatial cues than central cues in LTA, an effect not seen in HTA. In the central cue condition, the P3b was not significantly different between groups, but in the spatial cue condition, the P3b was much larger in HTA compared to LTA; intriguingly, the P3b was smaller in the spatial cue condition in LTA but larger in the spatial cue condition in HTA. Across the attentional domains, event-related spectral perturbations (ERSPs) between conditions and groups showed a variety of theta-power changes in both the parietal and frontal lobes. Taken together, these data suggest that students with TA allocate more attentional resources when alerted to a task and fail to reduce their allocation of attentional resources when less resources are needed. Along with this, orienting of attention requires more

cognitive resources than expected. These changes are consistent with some forms of anxiety (but not others) and also share characteristics with other disorders of attention such as attention-deficit hyperactivity disorder.

Title: Brain network dynamics in the transition from wakefulness to sleep

Authors: *S. KUMAR[1,2], J. GONZALEZ-CASTILLO[1], E. TAGLIAZUCCHI[3], I. FERNANDEZ[1], P. MEDIANO[2], A. ARZI[2], C. BAREHAM[2], P. BANDETTINI[1], T. BEKINSCHTEIN[2];

Abstract: The brain dynamically transitions between distinct states over time that may correspond with ongoing cognition, metabolic processes, vigilance, etc. This work aimed to show how vigilance alters the functional organization and coordination of brain regions in a dynamic and task-dependent way. In two EEG-fMRI experiments, healthy adults were encouraged to become drowsy and fall asleep inside the MRI scanner. In the first study, drowsy participants (n = 22) additionally performed a simple auditory decision-making task, and the second study was a resting-state session in which a different set of participants (n = 25) passively listened to tones. An EEG-based automatic vigilance classification of “alert” or “drowsy”, based on the Hori stages for sleep onset, was assigned to each timepoint. The classification was derived from a support vector machine algorithm that includes frequency band power and cross-regional coherence as predictor variables. fMRI Regions of Interest (ROIs) were extracted using a whole-brain parcellation, and an instantaneous phase coherence was calculated at each timepoint for each ROI pair. K-means clustering was performed on the phase coherence patterns of both datasets combined. Four patterns were determined to be the optimal number of clusters, and a resulting fMRI-derived pattern was assigned to each timepoint. Within each dataset, a vigilance contrast (alert vs. drowsy) was calculated on concatenated data coinciding with each fMRI pattern. We show that task and vigilance have different effects on the brain depending on concurrent fMRI pattern configuration and the complexity of that configuration, with simpler patterns highlighting more task-dependent differences, particularly within-network. These findings suggest spontaneous within-network functional organization may be modulated by drowsiness, and drowsiness may alter more complex brain configurations in a task-independent way. ROIs in a ventral attention network may contribute to a compensatory mechanism when subjects are actively trying to sustain cognitive function and perform a task while drowsy.

Title: Electrophysiological correlates of attention and response inhibition in a food go/no-go task

Authors: *R. GRAHAM[1], V. LEYVA[2], F. DE PALMA[2], N. CEBALLOS[2];
[1]Texas State Univ. San Marcos, San Marcos, TX; [2]Texas State Univ., San Marcos, TX

Abstract: Visual images of food are salient and evocative, making them an effective marketing tool. Yet the neural processes that support this effectiveness are not well understood, especially the role of individual differences such as food preferences, body weight, hunger, dieting behaviors, and general preoccupations with food. These variables may modulate how people initially respond to food images (e.g., cue reactivity) and how more deliberate control processes (e.g., behavioral inhibition) are subsequently engaged. The current study examined whether food tastes and/or preferences play a role in these effects as indexed by event-related potentials (ERPs) using a task involving behavioral inhibition. Twenty-one healthy female college students (mean age = 23.2 years) completed go/no-go tasks with either high calorie sweet or high calorie savory foods as targets (counterbalanced). Self-reported BMI, food preferences, hunger, restrained eating, and state/trait cravings were also assessed. Behavioral analyses revealed greater accuracy for go relative to no-go trials, with no differences for sweet or savory foods. ERP analyses focused on peak latencies and amplitudes of the frontocentral N2 and the centroparietal P3 components. N2 latencies were sensitive to food type and food preferences, with a tendency to peak earlier in response to savory high calorie images but only in people who preferred these foods. In contrast, P3 amplitudes were sensitive to response type such that they were higher during no-go vs. go trials. Follow-up regressions focusing on N2 latencies revealed that latencies during go trials were negatively associated with trait craving, while latencies during no-go trials to preferred foods were positively associated with state craving. Overall, results suggest that the N2 and P3 elicited by food stimuli in a go/no-go task index separate processes. More specifically, the timing of the earlier N2 may be more sensitive to the more automatic, motivational properties of palatable foods, while amplitudes of the subsequent P3 are more sensitive to more controlled processes like behavioral inhibition.

Title: Visual distraction disrupts category-tuned attentional filters in ventral visual cortex

Authors: *L. PIDAPARTHI, B. DUBE, J. D. GOLOMB;
Dept of Psychology, Ohio State Univ., Columbus, OH

Abstract: To compensate for the complexity of our visual environments, we rely on attention to selectively filter goal-relevant information from irrelevant information. During visual search, for instance, attention prioritizes target-matching information in the environment. However, if distracting information appears during this search, spatial attention can be captured, prolonging search. Does distraction also disrupt feature- or category-based attentional filters that prioritize task-relevant information? To examine this, we measured the neural signatures of attentional filtering specific to object category using human fMRI. In this experiment, participants were presented with 2x2 arrays of hybrid face-house images; they performed a 1-back task based on the designated stimulus category (i.e., attend-faces and attend-houses blocks), with the target item's location indicated by a solid white border. On some trials, a salient distractor (a dotted white border) appeared briefly around one of the nontarget locations. On distractor-absent trials, we found the predicted pattern of attentional modulation: greater BOLD activation in the fusiform face area (FFA) during attend-faces blocks and in the parahippocampal place area (PPA) during attend-houses blocks, illustrating the efficacy of attentional filtering for the target category. On distractor-present trials, however, we observed a relative increase in activation reflecting the processing of the nontarget category (i.e., increased FFA activation during attend-houses and increased PPA activation during attend-faces), suggesting a disruption of the attentional filter selective for object category. Overall, these results indicate that visual distraction by abrupt-onset salient stimuli disrupts both spatial and category-tuned attentional filters, failing to restrict processing of task-irrelevant information.

Title: Unpacking the influence of attention on the hierarchical multisensory integration of audiovisual speech

Authors: *F. AHMED, A. R. NIDIFFER, E. LALOR;
Univ. of Rochester, Rochester, NY

Abstract: Seeing a speaker's face significantly improves speech comprehension, particularly in noisy environments. This is attributed to the brain's ability to integrate information from auditory and visual sensory modalities through a process called multisensory integration (MSI). In addition, real-life listening environments are often full of multiple competing sources of speech, although listeners are typically interested in following just one of those - known as the 'cocktail-party problem'. Successful communication involves both MSI of audiovisual (AV) speech and selective attention, but how these processes interact with each other is not well understood. This is because the majority of previous studies examined each of these processes in isolation without considering the interplay between the two. Furthermore, most of those studies used relatively controlled stimuli and paradigms that do not reflect the sensory challenges faced in the real world. Here we present the results of three experiments aimed at examining how attention affects electrophysiological signatures of multisensory integration in the context of natural, continuous audiovisual speech. In particular, we wish to test the hypothesis that such multisensory integration occurs at different hierarchical levels of speech processing, each of which can be differentially influenced by attention. All three experiments involve recording EEG from subjects presented with a cocktail-party-like scenario involving continuous AV speech. Following previous research, all experiments involve comparing models of that EEG based on assuming an underlying multisensory process (AV) with those based on assuming two independent unisensory processes (A+V). The three experiments differ in the number and location (relative to fixation) of the visual speech stimuli in such a way as to allow us to assess the multisensory integration of dynamic, low-level visual cues vs detailed, higher- level articulatory cues. Our modeling results point to a limited influence of attention on indices of multisensory integration at lower hierarchical levels. However, at later/higher-stages of processing, the influence of attention varies substantially based on the visual information available to the subject. Overall, our data support the flexible interplay of attention and MSI at different levels of the speech processing hierarchy, depending on the task and the environment.

Title: Feature-selective priority maps in human cortex are modulated by top-down and bottom-up attention

Authors: *D. D. THAYER, T. C. SPRAGUE;
Psychological and Brain Sci., Univ. of California, Santa Barbara, Santa Barbara, CA

Abstract: The relative importance of a particular location within the visual field can be characterized in a priority map (Itti & Koch, 2001; Wolfe, 1994), which integrates the bottom-up image-computable salience of each location in the scene with the top-down behavioral goals of the observer; the resulting activity profiles across the priority map guide attention to important locations in the environment. Computational priority map models suggest that this map is computed by combining across spatial maps for individual feature dimensions, such as color and motion. At the neural level, previous work has identified retinotopic cortical areas that are sensitive to color (hV4/VO1/VO2; Brewer et al., 2005) as well as motion (hMT+/TO1/TO2; Amano et al., 2009), making these regions strong candidates for 'feature dimension maps'. Here, we used multivariate voxel activation patterns across retinotopic feature-selective cortical regions to characterize spatial feature dimension maps. In Experiment 1, we cued participants to either attend a single feature of a colored moving dot stimulus, or a central fixation cross to assess how activation profiles across maps reflect top-down task goals (under identical visual stimulation). To evaluate how bottom-up feature salience modulates activation patterns, Experiment 2 required participants attend fixation while a salient color or motion singleton was presented in the periphery. If these regions act as feature dimension maps, there would be greater activation corresponding to the location of the stimulus/singleton when attending/shown the preferred feature of a given region (e.g., within color-responsive hV4 when attending color). We found that stimulus and singleton representations within reconstructed priority maps were stronger in color selective regions when color was attended (Expt 1) or salient (Expt 2) compared to motion, and representations in motion selective regions were stronger when motion was attended or salient compared to color. These findings suggest that feature-selective cortical regions support spatial maps of priority indexed for specific feature dimensions, and that top-down and bottom-up inputs can reweight activation profiles across these maps.

Title: Prior dynamic experience regulates spatial attentional rhythm

Authors: *Y.-A. CHENG, H. LUO;
Sch. of Psychological and Cognitive Sci., Peking Univ., Beijing, China

Abstract: The brain efficiently organizes its limited resources over external information through attention. Recent studies demonstrate that attention works in a dynamic way, whereby multiple locations, objects, and features are rhythmically sampled over time. However, it remains largely unknown whether attentional rhythm is inherently hardwired or can adapt to prior experience and changes flexibly. Here we used time-resolved behavioral measurements on 25 human subjects to examine whether externally induced rhythm in prior experience would influence spatial attentional rhythm. Specifically, subjects were first exposed to a rhythmic prime display, i.e., a near-threshold stimulus was presented alternatively between two spatial locations for 2500 ms at 3 Hz or 5 Hz. Next, after a varied time interval (200 to 1000

ms in steps of 33 ms), a near-threshold probe appeared at one of the two locations and subjects needed to detect the target and the accuracies were measured. First, behavioral data shows 2.5 Hz attentional rhythm when there is no prior stimulus, largely consistent with previous findings. Most importantly, the attentional rhythm is modulated by the temporal characteristics of prime stimulation, i.e., increasing to 4.5 Hz for 5 Hz prime and remaining at 2.5 Hz for 3 Hz prime, when the probe was presented in the left visual field. Taken together, our results suggest that visual attentional rhythm is not a fixed clock and could be modulated by and adapt to prior dynamic experience.

Title: A role for paraventricular oxytocin neurons in social recognition memory

Authors: *K. THIRTAMARA RAJAMANI[1], M. BARBIER[1], K. NIBLO[1], S. WAGNER[2], V. GRINEVICH[3], S. NETZER[2], H. HARONY-NICOLAS[1];
[1]Icahn Sch. of Med. at Mount Sinai, New York, NY; [2]Univ. of Haifa, Haifa, Israel; [3]German Cancer Res. Ctr., Heidelberg, Germany

Abstract: Social cognition in mammals is fundamental for several conserved behaviors including distinguishing prey from a conspecific, identification of mating partners and for kinship maintenance. Together these behaviors have a major influence on their ability to maintain evolutionary fitness. Social recognition memory is a form of social cognition that requires the discrimination of a novel from a familiar conspecific. Deficits in social recognition have been reported in several psychiatric disorders including Autism spectrum disorder and Schizophrenia. Thus, identifying the neural and biological correlates of social recognition memory (SRM) can spur a greater underlying of these behaviors in disease. Oxytocin (OXT) is a neuropeptide that is synthesized and released by neurons in the paraventricular (PVN), supraoptic and accessory nuclei of the hypothalamus. It is implicated in social behaviors including maternal care, social bonding, and social recognition memory. Despite a clear role for OXT in SRM, it is still unclear which of the three nuclei within the hypothalamus is necessary for the formation of this form of memory. Furthermore, little is known about what role do downstream neural substrates, targeted by OXT axonal projections, play in SRM. We hypothesized that PVN OXT neurons are necessary for both short- and long-term SRM. To address our hypothesis, we used designer receptors activated by design drugs (DREADDS) to specifically silence OXT neurons (OXT-hM4DGi) in the PVN of male Sprague Dawley rats and assessed their performance on both short and long term social recognition memory. We found that silencing OXT neurons in the PVN, leads to impairments in both long and short-term SRM. In order to identify and investigate downstream targets of OXT neurons

necessary for SRM, we first used an OXT-specific antibody to label OXT projections across the brain. We identified a novel posterior hypothalamic nuclei; supramammillary nucleus (SuM), as a new target of OXT projections. The SuM is known to play an important role in hippocampal learning and memory. We next injected OXT specific anterograde (AAV-OXT-Venus) and retrograde (AAVretro-GFP) viruses into the SuM and confirmed that these OXT fibers originate specifically from the PVN. Finally, we found that blocking OXT receptor activity in the SuM inhibits long but not short term SRM, suggesting that the PVN-SuM may be a novel neural circuit necessary for this form of memory. Taken, together these findings attribute a novel role for PVN-OXT neurons and PVN-SuM neural circuitry in social recognition memory.

Title: A corticothalamic circuit for top-down inhibitory control of social motivation in male mice

Authors: *N. R. MACK, W.-J. GAO;
Neurobio. & Anat., Drexel Univ. Col. of Med., Philadelphia, PA

Abstract: Deficits in social motivation are common in many neuropsychiatric disorders such as depression, anxiety, and autism spectrum disorders. However, the neural mechanisms by which the brain regulates social behavior remain unclear. Previous research has shown that parvalbumin (PV) interneurons in the prefrontal cortex (PFC) are active during social behavior, and enhancing PV interneuron activity can rescue sociability deficits. However, a population of PFC neurons that may be inhibited by PV interneurons during social behavior has yet to be identified. Our study first tested whether neural connections between the prefrontal cortex (PFC) and the posterior paraventricular thalamus (pPVT) play an essential role in regulating social motivation using a chemogenetic approach. We found that chemogenetic activation of PFC-pPVT neurons abolishes social preference in mice without affecting locomotor behavior in the three-chamber sociability task. Moreover, this effect seems to be specific to male mice. These results are interesting because they replicate findings from others showing that activation, but not inhibition, of the PFC, abolishes social motivation. Our conclusion that chemogenetic activation of PFC-pPVT neurons reduces social motivation predicts that PV interneurons may inhibit this population of neurons for effective social interaction to occur. To test this hypothesis, we implement fiber photometry to assess changes in calcium activity in PFC-pPVT neurons during social interaction. These results will provide evidence for a novel circuit mediating prefrontal top-down inhibitory control of social

motivation. A mechanistic understanding of brain activity during social interaction will help develop better biomarkers for symptomology and better treatment options for social deficits.

Title: Nucleus accumbens population neural dynamics encoding social interactions

Authors: *P. ZHAO, X. CHEN, D. AHARONI, A. BELLAFARD, A. MURUGESAN, J. QUAN, P. GOLSHANI;
UCLA, Los Angeles, CA

Abstract: Deficits in social interactions are the main clinical manifestations of autism spectrum disorder (ASD). These deficits may arise because social interactions are not rewarding for individuals with ASD. However, the neural dynamics driving diminished social reward in autism are poorly understood. Though the nucleus accumbens (NAc) is embedded within 'reward pathway', it is still unclear whether and how NAc and its connected brain regions such as medial prefrontal cortex (mPFC) encode and drive social interactions and social reward. Using miniaturized microscopy, we recorded neural activity of NAc core neurons expressing GCaMP6f in animals freely interacting with a conspecific or exploring an object. We identified a larger proportion of neurons activated during social interaction than during object exploration (16.7% vs 5.4%). In NAc, the percentage of D1R neurons engaged in social interactions was higher than that of A2aR neurons (15.1% vs 8.3%). To determine how neural populations encode social interactions vs object explorations, we trained a Partial Least Squares Regression (PLSR) decoder on NAc neural activity. PLSR decoder could predict epochs of social interaction but not epochs of object exploration. Interestingly, social interactions could be decoded from neural activity of D1R, but not A2aR neurons. As mPFC is also a critical hub for social behavior and has projections to NAc, we recorded neural activity of mPFC neurons. Using the same criteria, we identified a far lower proportion of neurons activated by social interaction (6.3%). Decoder performance showed less specificity in predicting epochs of social interaction when trained with mPFC neural activity patterns. To explore the stability of NAc ensemble firing, we recorded the same neural population as animals interacted with the same conspecific across 6 days. By tracking the same neurons, we found that although there was always a significant proportion of NAc neurons activated during daily social interaction sessions, the probability that a neuron was socially activated across sessions decreased across days suggesting that a stable population does not code for social interactions across sessions in NAc. Moreover, the population of NAc neurons responding to social interactions was distinct from the population responding to sucrose reward, suggesting that distinct ensembles encode social and non-social rewards. Therefore, NAc neurons, especially D1R neurons, robustly encode social interactions specifically, but these representations are not stable across days.

Further work will aim at whether these networks are aberrantly activated in models of autism with impaired social interaction.

Abstract: Deficits in in the ability to detect or respond to distress in others are seen many psychiatric disorders including autism spectrum disorders, leading to impaired social functioning. Consolation, or comforting physical contact directed toward a distressed party, is a behavioral output of empathy that has been observed in humans and non-human primates. Recently, our lab reported the first evidence of partner-directed consoling in rodents. Prairie voles (*Microtus ochrogaster*), a socially monogamous and highly affiliative rodent, reliably express empathy-like consoling behaviors by allogrooming their distressed partner. Observing a distressed partner induces neural activity in the anterior cingulate cortex (ACC) and infusing an oxytocin receptor (OXTR) antagonist in ACC eliminates consoling behavior. As a first step toward investigating the neural circuitry of consoling behavior in voles, we traced anatomical neural projections to the ACC in adult prairie voles using viral tracing. Prairie voles received unilateral infusion of AAVrg-hSyn-EGFP to either the left or right ACC. Two weeks later the animals were perfused and their brains sectioned at 30 µM. Immunohistochemistry was performed on sections throughout the brain to detect GFP and sections were imaged on a fluorescent microscope. We found that several cortical and subcortical structures project to the ACC of the adult prairie vole. Projections from cortical structures include the primary somatosensory, visual, auditory, perirhinal, entorhinal, and insular cortices. Projections from subcortical regions include the claustrum, basolateral amygdala, zona incerta, hippocampus, and several thalamic nuclei. Future studies will map inputs specifically to ACC OXTR-positive cells and manipulating projections to those cells using *Oxtr-Cre* prairie voles to better the neural circuit mechanisms of oxytocin-dependent empathic-like consoling behaviors.

Title: The Central Amygdala - a Gate for Visceral Changes In Social Behavior

Authors: *H. LANOVOI[1], I. CARCEA[2];
[1]Rutgers, The State Univ. of NJ - Newark, Newark, NJ; [2]Rutgers Univ., Newark, NJ

Abstract: The Central Amygdala - a Gate for Visceral Changes In Social BehaviorHunter Lanovoi and Ioana Carcea
Somatic health and social behaviors correlate in the human population and in animal models. However, the physiological mechanisms supporting this relationship remain unclear. Social interaction is a dynamic neurobiological process that integrates external social stimuli with internal states. Visceral information about the physiological, immunological, and metabolic state of the internal organs, such as those involved in digestion are directly and indirectly conveyed to the central nervous system. Changes in the composition of microbes residing in the gut, as during indigestion or after antibiotic treatment, can change the inflammatory state of the host through the release of lipopolysaccharide (LPS). These changes have a particularly noticeable effect on engagement in social interactions. These robust behavioral effects likely developed as a safeguard to prevent the spread of disease. A key structure for controlling social engagement is the central amygdala, and particularly its oxytocinergic neuromodulation. We investigate if oxytocin receptor neurons in central amygdala might represent a mechanism for LPS-induced changes in social behavior. For this, we first treated mice with LPS and characterized acute changes in social engagement: social sniffing and approach in a direct social interaction assay and preference for social salience in a salience discrimination task. We find that LPS-treated mice initiate less nose-nose sniffing bouts (Saline: 6.813 +/-0.328, LPS: 2.122 +/- 1.011, $p<0.0001$, n=8) and have no preference for social salience (Saline: -6.870 +/-33.66, LPS: 10.79 +/-13.32, p=1537, n=8). Next, we will manipulate the activity of OXTR+ neurons in central amygdala to determine if they can change behavioral responses to LPS. To determine if OXTR+ cells in central amygdala might receive information about internal visceral state, we performed monosynaptic rabies tracing from these neurons and found inputs from the parabrachial nucleus, a structure that responds to noxious visceral signals. We will determine whether these inputs play a role in the social avoidance and social indifference phenotypes we identified after LPS treatment. This work will contribute to understanding factors that might contribute to disrupted social behaviors in autism and other disorders with a social dimension.

Title: The neural oscillatory signature in the anterior cingulate cortex driving observational fear in the mouse, a rodent model of affective empathy

Authors: S.-W. KIM[1], M. KIM[1], ***J. BAEK**[1], C.-F. LATCHOUMANE[1], G. GANGADHARAN[2], Y. YOON[1], D.-S. KIM[3], Y.-S. KIM[4], H.-S. SHIN[1];

Sch. of New Drug Discovery & Development, Chungnam Natl. Univ., Daejeon, Korea, Republic of

Abstract: The behavioral assay for observational fear in rodents has accelerated in-depth studies of neural circuits and genes underlying vicarious emotional learning. Two alternative behavioral tests for observational fear measures animal's behaviors driven by two different processes: the assay with naïve observer mice measures affective empathy-like responses to other's suffering, and that with prior foot-shocked observers measures adaptive learned responses for self, which is amplified by a similar observation. However, this critical difference has been largely ignored, and consequently, the neural process specifically driving the former, empathy-like behaviors, has not yet been clearly identified. Here, we report that 4-to-8-Hz slow theta oscillations in the right anterior cingulate cortex (ACC) are specifically and causally linked with the emergence of the empathy-like fear responses in mice. These low-frequency neural oscillations in the ACC were selectively increased during socially driven freezing responses but not during self-retrieved responses. Notably, a closed-loop disruption demonstrated that this ACC theta is essential for the observational fear. The oscillations synchronized the ACC and the basolateral amygdala (BLA) activities, and optogenetic inhibition of either the ACC-to-BLA or the BLA-to-ACC pathway selectively impaired the observational fear without affecting classical fear conditioning. The increase/decrease of theta power in these two brain regions induced by optogenetic manipulation of the hippocampal theta also selectively and bidirectionally altered observational fear with the freezing levels correlated with the power. Together, these results indicate that 4-to-8-Hz theta oscillations in the ACC are the selective and essential neural process driving the socially driven empathic fear that is discriminable from the self-retrieved or classical fear.

Title: The Role of medial prefrontal cortex in fear-related behavior with social exposure in adolescent rats: contribution of GABAergic and Oxytocin system

Authors: *M. JANG, T. JUNG, Y. JEONG, Y. BYUN, J. NOH;
Dankook Univ., Yongin-Si, Gyeonggi-Do, Korea, Republic of

Abstract: We have identified the decrease of fear response by a social experience with conspecifics, which is as a phenomenon that can be suggested as a social buffering during the fear conditioning in the adolescent male rats. However, this behavioral changes by social exposure on neural mechanism has not yet been fully investigated, especially for the role of medial prefrontal cortex(mPFC). In this study, we carried out passive avoidance test in the single rat-exposed and the pair rats-exposed condition and determined histological and electrophysiological changes in the mPFC. To clarify a cellular mechanism in the mPFC, several drugs were injected into assigned rats via stereotaxically implanted guide cannula in mPFC. The rats exposed with toy rat showed a significant increase in fear behaviors, such as single rats, suggesting that the social buffering requires the existence of a living rat, not an object. We found that the increasing c-Fos expression in the mPFC in association between fear-related behaviors by social stimuli via pair exposure. Anisomysin and GABAzine stereotaxically treated into the mPFC of pair rats showed a significant increase in fear-related behaviors compared with saline-injected pair rats. Muscimol injection into single rats showed a significant reduction in the fear-related behavior compared with saline-injected single rats. Especially the mEPSC/mIPSC frequency ratio in the PL of mPFC in pair rats was significantly reduced compared with that in single rats. In addition, atosiban, oxytocin receptor antagonist, injected into pair rats showed a significant increase in fear-related behaviors and decrease in c-Fos expression like as single rats, whereas carbetocin, oxytocin receptor agonist, into single rats showed a significant reduction in the fear-related behavior and an increase in c-Fos expression like as pair rats. Taken together, our results suggest that pair exposure with conspecifics during fear-inducing situations induces social buffering, by contribution of the GABAergic system and oxytocin system in the mPFC.

Title: Cortical thinness underpins ingroup bias

Authors: *P. KANG[1], Y. SUN[2], Y. ZHOU[3], B. LINDSTROM[4], J. KIM[5], H. KIM[5], S. SUL[6], G. HEIN[3], P. N. TOBLER[1];

Abstract: Ingroup bias is the tendency to favor ingroup members over outgroup members. It is pervasive in humans and occurs both with ad-hoc groups based on incidental aesthetic preferences and with longer-lasting and more coherent groups based on nationality or race. Although many neuroimaging studies investigated the neural mechanisms of ingroup bias, most of them focused on different neural activity elicited by ingroup versus outgroup conditions. In turn, little is known about the brain structures underpinning or protecting against ingroup bias. Here, we investigated whether the cortical thickness of brain areas thought to facilitate perspective taking (temporoparietal junction (TPJ)) and empathy (insula) accounts for individual variation in ingroup bias. Specifically, we combined two studies, performed in different countries, that tested attitudes towards ingroup and outgroup members. In Study 1, thirty three participants (17 female, 25.48±4.70 years old) from South Korea performed an implicit association task towards South (ingroup) and North Koreans (outgroup) with positive and negative words and rated the warmth and competence of South and North Koreans. We found that the cortical thickness of the right TPJ (rTPJ) was negatively correlated with ingroup bias (r =-.34 p=0.05). In Study 2, thirty Swiss participants (all males, mean age 22.74±2.75) rated how close they felt to other Swiss participants (ingroup) and to Middle Eastern immigrants (outgroup). We found that the difference in closeness rating between ingroup and outgroup (ingroup-outgroup) correlated negatively with rTPJ thickness (r =-.40, p=0.033). Together, our results suggest neural structures important for perspective taking contribute to overcoming ingroup bias. We plan to replicate these exploratory findings with an independent confirmation sample.

Title: Heterozygous loss of KCNQ2 impairs learning and memory in mice

Authors: *G. C. TRACY[1], A. R. WILTON[1], E. C. KIM[1], J. S. RHODES[2,3], H. J. CHUNG[1,3];
[1]Mol. and Integrative Physiol., [2]Dept. of Psychology, Univ. of Illinois At Urbana-Champaign, Champaign, IL; [3]Dept. of Neurosci., Univ. of Illinois At Urbana-Champaign, Urbana, IL

Abstract: Neuronal Kv7/*KCNQ* channels are voltage-gated, slow-activating, and non-inactivating potassium channels. They are critical for the inhibition of neuronal excitability by limiting the repetitive firing of action potentials (APs) and hyperpolarizing the resting membrane potential. Neuronal Kv7 channels are mostly heterotetramers of Kv7.2/*KCNQ2* and Kv7.3/*KCNQ3*. Dominant mutations in *KCNQ2* and *KCNQ3* cause diseases of hyperexcitability, such as Benign Familial Neonatal Epilepsy and Epileptic Encephalopathy. Kv7.2 channels are highly expressed in the hippocampus and cortex indicating a potential role in regulating hippocampal dependent learning and memory.Since mice administered scopolamine to model cognitive deficiencies saw a recovery of cognitive performance when administered XE991, a Kv7 channel antagonist, in this study, we test the hypothesis that a genetic decrease in Kv7.2 expression will lead to an improvement in learning and memory. To test this hypothesis, performed behavior tests with a genetic deletion of a single copy of the *KCNQ2* gene.Using heterozygous knock-out mice (*KCNQ2*$^{+/-}$) we performed learning and memory behavior tasks including the object location test (OLT), novel object recognition test (NORT), contextual fear assay (CF), and passive avoidance test (PA). KCNQ2$^{+/-}$ mice show a systemic reduction in *KCNQ2* expression while our lab has confirmed a reduction in membrane bound Kv7.2 channels in hippocampal neurons. For this study, male and female *KCNQ2*$^{+/-}$ and *KCNQ2*$^{+/+}$ mice performed the passive avoidance test and contextual fear test, which examine learning and memory function dependent on the hippocampus, neocortex, and amygdala. In PA, female *KCNQ2*+/- mice displayed a decrease in memory formation compared to female *KCNQ2*+/+ mice, while male mice showed no difference between genotypes. Male *KCNQ2*$^{+/-}$ show a trend towards a decrease in memory retention compared to male *KCNQ2*+/+ mice during PA while female mice showed no genetic difference in retention. Female mice overall showed increased memory retention over male mice in the contextual fear test. Using the tail flick assay we confirmed there was no difference in heat pain tolerance between *KCNQ2*$^{+/-}$ and *KCNQ2*$^{+/+}$ showing that pain tolerance should not affect foot shock response between the genotypes.In contrast to our initial hypothesis, these findings indicate that genetic down regulation of Kv7.2 impairs learning and memory in mice. This suggests that Kv7.2 could be a potential pharmacological target to treat cognitive impairment dependent.

Title: Follistatin mediates learning and synaptic plasticity via regulation of Asic4 expression in the hippocampus

Authors: *Y.-J. CHEN, S.-M. DENG, C.-H. TSAO, H.-W. CHEN, G.-J. HUANG;
Chang Gung Univ., Taoyuan, Taiwan

Abstract: Intellectual disability is also known as mental retardation, a disorder which may involve a delay in development or a learning disability. The mechanisms underlying learning disability have not been fully characterized. Mounting evidences have been suggested that learning abilities correlate with hippocampal neurogenesis. In this study, we used a high resolution method for identifying loci associated with neurogenesis by combining genetic mapping with sequencing information. We identified a candidate gene, follistatin (Fst), for further study due to its strong expression in the dentate gyrus. Mice with Fst deficient in the central nervous system exhibited impairments of hippocampal neurogenesis, dendritic spine densities, long-term potentiation (LTP), and spatial learning. To rescue the deficits in Fst KO mice, we injected AAV9 CMV::Fst viral vector into Fst KO mice hippocampi and found spatial learning abilities and LTP deficits could be recovered. Utilizing RNA sequencing, we identified Asic4 could be a possible gene regulated by Fst. With injection of AAV9 CMV::Asic4 viral vector in hippocampi, Fst KO mice improved the spatial learning and LTP abilities. Furthermore, we found that lasting high expression level of Fst in hippocampi could delay the cognition declination accompanying by aging. Here, we demonstrated hippocampal follistatain played a crucial role in cognitive function through changing the expression of Asic4.

Title: The effects of ketamine or (2R,6R) hydroxynorketamine treatment on novel object placementtask performance and hippocampal AMPA receptor binding.

Authors: *R. MCNAIR[1], *R. MCNAIR[2], **A. KHAWAJA**[1], A. L. PEHRSON[3,4];
[1]Psychology, [3]Dept. of Psychology, [4]Sokol Inst. for Pharmaceut. Life Sci., [2]Montclair State Univ., Montclair, NJ

Abstract: Many psychological and neurological disorders present with impaired cognitive function across multiple domains including learning and memory. These cognitive impairments greatly impact daily life functioning and are a major contributor to the economic burden associated with these disorders. Currently, there are few options treatment that effectively addresses these issues. Recent studies suggest that ketamine produces rapid and sustained changes in hippocampal synaptic plasticity, including increased long-term potentiation, and α-amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid (AMPA)

receptor expression or membrane insertion. Additionally, the ketamine metabolite (2R,6R) hydroxynorketamine (HNK) has been implicated as a mediator of ketamine's effects. These data may suggest that ketamine or HNK may have effects on hippocampus-dependent cognitive function 24 hours after a single dose, and the effects of these treatments on cognitive function have not been extensively characterized 24 hours after administration. We used 120 adult male Long Evans rats to investigate the effects of an intraperitoneal injection of vehicle, 3, 10, or 30 mg/kg ketamine (24 hr IP) or vehicle, 1, 3, or 10 mg/kg HNK (24 hr IP) on spatial memory performance in the novel object placement (OP) task, which depends critically on the function of the dorsal hippocampus. Immediately after completion of the OP task, we collected brain tissue in order to examine the effects of these treatments on AMPA receptor expression in the hippocampus using *ex vivo* autoradiography. In study 1, rats were randomly administered a dose of vehicle, 3, 10, or 30 mg/kg ketamine (24 hr IP), while in study 2 rats were randomly administered vehicle, 1, 3, or 10 mg/kg HNK. We found that ketamine treatment had no significant effect on spatial memory performance in the OP task, and had no effect on AMPA receptor expression as measured by EVA. Similarly, HNK treatment had no effect on OP treatment, but induced a small but significant increase in [^{3}H] AMPA binding at 10 mg/kg 24 hr IP. These findings suggest that ketamine and HNK have limited functional effects on hippocampally-dependent memory performance and hippocampal AMPA receptor binding 24 hours after treatment in healthy adult male rodents. Further research is needed to investigate the effects of these treatments in disease models featuring cognitive impairment in both male and female rats.

Title: Hippocampal spatial learning deficits induced by chronic inflammation are mediated by 3-hydroxyanthranillic acid dioxygenase in young adult male mice

Authors: *M. N. MITHAIWALA[1], A. M. GARRISON[1], J. R. MORALES[1], A. M. VAIANA[1], S. E. H. KUHN[1], S. N. KHATRI[2], J. R. PUGH[2], J. C. O'CONNOR[1,3];
[1]Pharmacol., [2]Cell. and Integrative Physiol., UT Hlth. San Antonio, San Antonio, TX; [3]Res., Audie L. Murphy VA Hospital, South Texas Veterans Heath Syst., San Antonio, TX

Abstract: The hippocampus regulates several learning and memory processes. It is also particularly reactive to proinflammatory insults, having been described as a highly "immunovigilant" brain region. We have reported that acute peripheral immune challenge with lipopolysaccharide disrupts hippocampal cognitive performance in wild-type (WT) mice, but targeted deletion of 3-hydroxyanthranillic

dioxygenase (3-HAAO) prevented cognitive disruption. In this study, we hypothesized that structural alterations in the hippocampus following chronic inflammation precipitate spatial learning and memory deficits in a 3-HAAO-dependent manner. To this end, we induced chronic inflammation in male 3-6 month old WT or 3-HAAO knockout with *M. bovis*, BCG. We assessed short-term hippocampal working memory in the Y-maze and novel place preference task. Similar to our previous results following LPS, chronic inflammation induced deficits in WT mice but were absent in 3-HAAO mice. Additionally, we identified marked spatial learning deficits in the Barnes maze induced by infection with BCG in WT mice but not 3-HAAO null mice. To assess non-hippocampal learning, we measured fear-conditioning behavior, which is dependent on amygdala and found no deficits in freezing responses between WT and 3-HAAO mice with or without treatment with BCG. Moreover, we did not observe impairments in short-term or long-term contextual fear memory. Using Golgi-Cox staining, we determined that BCG treatment reduced dendritic spine density and neuronal complexity of CA1 apical dendrites independent of 3-HAAO genotype. Interestingly, BCG treatment significantly reduced hippocampal neurogenesis in a 3-HAAO dependent manner. Under whole-cell voltage clamp conditions, BCG treatment did not affect basal synaptic transmission properties of DG or CA1 neurons from the dorsal hippocampus. These results are the first to suggest that chronic inflammation alters hippocampal spatial learning by causing structural and functional disruption to the hippocampal network that are regulated by 3-HAAO activity and implicate quinolinic acid in regulation of neurogenesis in the adult hippocampus.

Title: Neuronal Primary Cilia Regulate Hippocampal Neuronal Priming and Trace Memory Formation

Authors: *Y. ZHOU[1], X. CHEN[1], L. QIU[1], H. WANG[2];
[1]Dept. of Molecular, Cell. and Biomed. Sci., Univ. of New Hampshire, Durham, NH; [2]Dept. of Statistics, Univ. of Connecticut, Storrs, CT

Abstract: Memory is thought to be encoded by sparsely distributed neuronal ensembles in memory-related regions. We utilized a deep-brain *in vivo* calcium imaging to directly visualize real-time calcium dynamics in freely behaving animals, which were subjected to trace fear conditioning. We have reported that the overall activity levels of hippocampal neurons exhibit a right-skewed lognormal distribution, with a small group of highly active “primed neurons” preferably engaged in trace memory formation. This

study, along with other evidence, underscores the importance of neuronal priming for hippocampal memory formation. Primary cilia are microtubule-based sensory organelles present in most vertebrate cells including neurons. Malfunction of neuronal primary cilia is associated with many neurological disorders including cognitive impairment, intellectual disability, and neurodegeneration. It remains elusive how neuronal primary cilia regulate the activity of hippocampal neurons and hippocampus-dependent memory formation. We utilized IFT88- (a protein essential for ciliogenesis) floxed mice to conditionally ablate primary cilia, combined with *in vivo* calcium imaging and trace fear conditioning study or with EEG recording. Here we show that inducible IFT88 global KOs display a markedly impaired learning than their littermate controls. The overall activity levels of hippocampal neurons of the IFT88 global KOs are significantly decreased compared to controls. Moreover, the burst synchronization of primed neurons is drastically suppressed in IFT88 global KOs. Comparison of EEG recordings in the neocortex under isoflurane anesthesia indicates that temporal ablation of primary cilia in adult mice also drastically decreases overall brain excitability. Further, local ablation of neuronal primary cilia in hippocampal CA1 region also decreases hippocampal neuronal priming and trace memory-associated burst synchronization. Together, we conclude that ablation of neuronal primary cilia impairs trace fear memory by decreasing hippocampal neuronal priming and the formation of burst synchronization.

Title: The 5-HT6 receptor of hippocampus tone regulations both Short and Long Term Memory on memory consolidation and amnesia.

Authors: *G. LIY-SALMERON[1], L. APARICIO NAVA[2], R. TELLEZ[3], R. TELLEZ[3];
[1]Hlth. Sci. of UNIDEP, Tijuana, Mexico; [2]Neuropharm., CINVESTAV-IPN, mexico, Mexico;
[3]Chemestry, UNAM, mexico, Mexico

Abstract: To our knowledge, the intrahippocampal serotonergic 5-HT_6 receptor tone on memory and amnesia models remains unexplored. Hence, in the present work, we tested intrahippocampal administration of serotonin or 5-hydroxytryptamine (5-HT)$_6$ receptor experimental molecules with differential intrinsic activity. Methods: In the present study, Automatized Autoshaping memory task was used, useful measuring memory, neural markers, and pharmacological effects. We are hypothesizing that experimental molecules with differential intrinsic activity might reveal serotonergic tone. Particularly, intrahippocampal administration of 5-HT_6 receptor compounds with differential intrinsic activity (i.e., agonistic and antagonistic) might be evidencing a serotonergic tone via this receptor. Bilateral intrahippocampal dose-response curves show that administration of EMD386088 (10 and 100 μg) had no effect or (50 μg) decreased conditioned responses (CR) in short- and long-term memory (STM and LTM, respectively); while SB-399885 (10 or 100 μg) significantly decreased CR in STM and LTM (24 and 48-h) or (50 μg) had no effect; thus suggesting that there is a 5-HT_6 receptor tone regulating both STM and

LTM. Moreover, intrahippocampal inactive doses of EMD386088 (5 μg) plus SB-399885 (0.5 μg) did not affect STM and LTM; however, they partially or completely prevented the scopolamine or dizocilpine-induced amnesia. Thus confirming that both drugs exerted their effects through 5-HT_6 receptor and that there is a hippocampal serotonergic tone under amnesic states, similar to that striatal.

Abstract: The neurotransmitter acetylcholine plays an important role in the brain. Specifically, in the hippocampus, major processes involved in learning and memory are mediated by acetylcholine. Metabolism of acetylcholine by the primary enzyme acetylcholinesterase(AChE), can provide insights on how learning and memory processes are regulated. Knowing that contextual fear learning, a hippocampus-dependent task, differs by genetic background, we investigated acetylcholinesterase activity levels after fear conditioning in male 129S1/SvlmJ, 129S4/SvJaeJ, 129S8/SvEvNimrJ, A/J, AKR/J, BALB/cJ, BTBRT<+>ltpr3<tf>/J, C3H/HeJ, C57BL/6J, CBA/J, DBA/1J, DBA/2J, FVB/NJ, LP/J, MA/MyJ, NZB/BINJ, SJL/J, SM/J, SWR/J and 129S2/SvPasCrl mice. To assess region specificity, we collected and measured AChE levels in dorsal hippocampus, ventral hippocampus, and cerebellum. Additionally, we correlated our AChE activity with publicly available data from the Mouse Phenome Database (MPD). MPD results showed AChE levels in the dorsal hippocampus were correlated with 3 cognitive assessment errors in the Barnes Maze. For ventral hippocampus, AChE activity levels were correlated with emotional behavioral responses in cued fear testing, light-dark box and variants of the elevated maze. Additionally, findings demonstrated that AChE activity levels as well as fear learning varied by mouse strain in all three brain regions. Moreover, AChE levels in the dorsal hippocampus were negatively correlated with fear conditioning outcomes. Interestingly, AChE levels in the ventral hippocampus and cerebellum were not correlated with fear learning. Our results suggest that acetylcholinesterase activity modulates learning in dorsal hippocampus and demonstrates that dorsal hippocampus and ventral hippocampus are functionally distinct.

Title: Vagus nerve stimulation in healthy male rats: Enhanced cognitive performance and hippocampal neuroplasticity

Authors: *L. OLSEN[1], R. MOORE[1], N. BECHMANN[1], S. CUNNINGHAM[1], V. ETHRIDGE[2], J. ROHAN[2], C. HATCHER-SOLIS[1];
[1]Air Force Res. Lab., Wright-Patterson AFB, OH; [2]Naval Med. Res. Unit Dayton, Wright-Patterson AFB, OH

Abstract: FDA approved vagus nerve stimulation (VNS) has been reported to improve learning and memory, but the mechanisms of this cognitive enhancement have yet to be elucidated. Behavioral performance, electrophysiology, and brain derived nerve growth factor (BDNF) expression were measured after VNS administration to investigate VNS mediated changes in cognition and hippocampal neuroplasticity. Healthy male Sprague-Dawley rats (N = 47) aged 10-12 weeks were implanted with a platinum/iridium electrode cuff around the unsheathed left VN. After recovery, successful implantation was confirmed using the cessation of breathing test and VNS was administered as fifteen 100 µs biphasic pulses at 30 Hz, 0.8 mA constant current every 18 seconds for 30 minutes. Novel Object Recognition (NOR) and Passive Avoidance Task (PAT) training was paired with VNS (N = 28). NOR and PAT testing was measured 24 hr after training and *post-mortem* tissue was collected 48 hr after VNS administration. Electrophysiology recordings were obtained using a microelectrode array system to assess functional effects on hippocampus slices 90 min after VNS (N = 19). All sham rats received the same treatment without VNS and experimenters were blinded throughout data collection/analysis. Stimulated rats exhibited enhanced memory performance in NOR ($p < 0.05$, n = 12) and PAT ($p < 0.05$, n = 14). Stimulated rats also exhibited enhanced hippocampal plasticity as an increase in long-term potentiation (LTP) from CA1 neurons was detected ($p < 0.05$, n = 7-12) 90 min after VNS. Immunohistochemical analysis of perfused and fixed hippocampal tissue from the behavioral experiments demonstrated an increase in BDNF expression in the CA1 ($p < 0.05$, n = 8-9) and CA2 ($p < 0.01$, n = 7-8) 48 hr after VNS, indicating that enhanced neuroplasticity can potentially be sustained for days after VNS administration. The results from this study suggest that VNS-induced cognitive enhancement may be due to increased hippocampal neuroplasticity during memory consolidation. Also, there is indication that a single session of VNS may lead to sustained enhancement of hippocampal neuroplasticity via increased neurotrophic factor expression. These findings significantly contribute to a better understanding of the interplay between VNS and hippocampal neuroplasticity, which may improve clinical utilization of VNS for cognitive enhancement.

Title: Cholinergic and Glutamatergic Subcortical Inputs to Dorsal Hippocampus Mediate Stress-Induced Generalization of Negative Memories

Authors: *L. REN[1], A. CICVARIC[2], H. ZHANG[2], M. MEYER[1], Z. PETROVIC[2], V. GRAYSON[1], A. L. GUEDEA[1], X. SUN[3], Y. LIN[4], J. M. RADULOVIC[2];
[1]Northwestern Univ., Chicago, IL; [2]Albert Einstein Col. of Med., Bronx, NY; [3]Stanford Univ., Stanford, CA; [4]Psychiatry, Upstate Med. Univ., Syracuse, NY

Abstract: Memories have specific and general features, which allows them to inform behavioral responses in similar situations. However, these features can sometimes become excessively generalized to dissimilar situations, contributing to maladaptive behavioral responses. This is seen in memory overgeneralization, a key cognitive symptom associated with Major Depressive Disorder, Generalized Anxiety Disorder, and Post-traumatic Stress Disorder. Stress increases negative memory generalization through its interactions with dorsal hippocampal (DH) memory systems, though the mechanisms underlying this remain poorly understood. To better understand these processes, we developed a mouse model of stress-induced generalization of negative memories (SIG) to determine SIG's dependence on DH memory circuits and memory engram populations. Using this model along with chemogenetic and optogenetic approaches, we found that cholinergic medial septum (MS) inputs to the DH and glutamatergic ventral tegmental area (VTA) inputs to the DH are necessary for SIG, and stimulation of cholinergic MS inputs to the DH is sufficient to induce fear memory generalization. Moreover, using activity-dependent labeling of DH engram populations, we found that after stress, cholinergic septohippocampal inputs drive reactivation of dentate gyrus (DG) npas4-dependent ensembles that represent specific features of a fear-inducing memory. These findings suggest that SIG results in part from cholinergic-mediated enhanced retrieval of DG specific memory ensembles that interfere with ongoing behavioral responses. Altogether, these results provide mechanistic insights that can inform future therapeutic targets for treatment of memory overgeneralization.

Title: Evaluating the role of hippocampal inputs to the mammillary nuclei in spatial memory

Authors: *K. MAR[1], J. C. KIM[2,1];
[1]Psychology, [2]Cell & Systems Biol., Univ. of Toronto, Toronto, ON, Canada

Abstract: The mammillary bodies (MB) are implicated in processing spatial information however, the role of hippocampal (subicular) inputs to the MB has remained elusive. In the present study, we set the stage for an investigation into the role of subicular inputs to the MB in egocentric and allocentric navigation. We began by characterizing baseline behaviour of male and femaleC57BL/6 mice 1-3 months of age (n = 11) in an egocentric and allocentric spatial assay in a Barnes maze. To characterize baseline egocentric navigation, escape to a previously memorized shelter location was initiated under a red-light condition with an innately aversive auditory stimulus. We show that memory of the goal location can be encoded following a brief exploration of the shelter and that an animal's position relative to the shelter location is constantly updated for effective path integration at escape onset. To investigate allocentric navigation, mice were trained to navigate to a shelter location based on distal cues motivated by escape from the innately aversive brightly lit open field. Across training days, mice displayed a more robust memory for the shelter location compared to naive animals, suggesting animals are able to effectively utilize distal cues for goal-directed escape. In an effort to understand how subicular inputs are distributed within the MB we conducted an exploratory investigation into the anatomical connectivity using anterograde tracing methods. We found MB-projecting subicular neurons are organized topographically such that axons originating from the dorsal or ventral subiculum terminate in the dorsal or ventral portions of the medial MB respectively, with more posterior ventral subicular neurons projecting to more lateral regions of the MB. These parallel pathways may represent a functional differentiation of subicular inputs to the MB and suggest a potential role for the subicular-MB pathways in processing different types of spatial information that merits further investigation. In current experiments, we are using fibre photometry to characterize patterns of bulk activity from subicular terminals in the MB expressing Ca^{2+} indicators achieved by targeted injection of adeno-associated viral vectors in freely moving animals across both spatial assays.

Title: The role of adolescent omega-3 supplementation on visuospatial memory performance and cognitive flexibility: Sex- and age-specific effects

Authors: *A. MORIN, M. POITRAS, J. RAYMOND, H. PLAMONDON;
Behavioural Neurosci., Univ. of Ottawa, Ottawa, ON, Canada

Abstract: The adolescent period is known for increased neuroplasticity resulting in long-lasting changes to brain integrity and cognition. Additionally, diet plays an essential role in modulating plastic processes during this period. Research has shown omega-3 polyunsaturated fatty acid-rich diets to be linked with enhanced cognitive performance and attention. The goal of this study was to assess the impact of adolescent omega-3 supplementation on visuospatial memory abilities and cognitive flexibility of male and female rats during adolescence and adulthood. To do so, 64 Wistar rats (32 females, 32 males) were supplemented omega-3 rich fish oil (FO) or control soybean oil (CSO) daily by oral gavage (0.3ml/100g body weight) from post-natal day (PND) 28 to 47. Half of the animals in each group (n=8) underwent behavioural testing in the Barnes Maze (BM; 6 acquisition and 3 reversal learning sessions) immediately following the end of supplementation, while the other half underwent testing during adulthood (PND 90). Our results support FO supplementation to reduce the initial distance to find the hidden box compared to CSO-fed rats. As adults, rats used shorter distance to escape than juvenile rats, independently of sex and diet. Overall, distance to the hidden box decreased with trials for all groups. On days 2 and 5 of maze exposure, FO-males' performance was marked by slower travel speed compared to female counterparts during the second trial. When the hidden box was moved (reversal learning trials), rats showed improved performance over days, which was only observed upon re-exposure to the task (the daily trial 2). Overall, these preliminary findings support FO diet to display beneficial effects on cognitive performance, with increased cognitive benefits in females. Consistent with earlier studies, adult rats displayed shorter distance to reach the hidden box, which supports a more rapid acquisition of task contingencies compared to juvenile rats.

Title: Prenatal cannabinoid exposure affects memory through altered glutamatergic and GABAergic receptor expression and function

Authors: *K. U. CHOWDHURY[1], W. D. SMITH[2], K. MCDONALD[1], P. D. PINKY[3], S. BHATTACHARYA[3], M. REED[1], V. D. SUPPIRAMANIAM[4];

Abstract: With the increase in legalization of cannabis, prenatal exposure to cannabinoids has increased significantly and is expected to continue rising. Currently, there are no therapeutic approaches to treating cognitive deficits associated with prenatal cannabinoid exposure (PCE). This project aims to elucidate mechanisms by which PCE causes learning and memory deficits in offspring by assessing alterations in neuronal signaling regulated by excitatory NMDAR (N-Methyl D-Aspartate Receptor), AMPAR (α-Amino-3-Hydroxy-5-methyl-4-isoxazole Propionic acid), and inhibitory GABAAR (Gamma-Aminobutyric Acid receptor subtype A) interaction. Pregnant Sprague Dawley rats were orally gavaged with either sesame oil or 5mg/kg of pure synthetic α9-tetrahydrocannabinol (THC) from gestational day five to post-natal day 9 (GD5-PND9). In immunoblotting experiments performed on hippocampal synaptosomes, PCE offspring exhibited altered ratios of GluN1, GluN2A, and GluN2B-containing NMDARs, as well as GluA1 and GluA2-containing AMPARs, compared to vehicle-treated animals. To further evaluate if these changes in receptor expression translated into functional changes at the cellular level, we recorded whole-cell spontaneous currents from hippocampal pyramidal cells and field activity from hippocampal CA3-CA1 Schaffer collaterals in PCE offspring. Spontaneous postsynaptic currents driven by AMPAR, NMDAR, and GABAAR channels showed alterations in frequency and amplitude between PCE and control animals. PCE offspring also demonstrated impaired long-term potentiation (LTP), the cellular correlate of learning and memory, within CA3-CA1 signaling pathways. To summarize, our study highlights a substantial role of primary excitatory and inhibitory neurotransmitter receptors (AMPAR, NMDAR, and GABAAR) in controlling hippocampal memory deficits caused by prenatal exposure to cannabinoids.

Title: A portion of perigestacional drink consumption with sucrose alters learning and spatial memory in the juvenile progeny of Wistar Rats

Authors: *C. PEREGRINO-RAMIREZ[1], N. CORTES-ALVAREZ[2], R. PEDRAZA-MEDINA[1], C. VUELVAS-OLMOS[1], M. ORTIZ[1], J. GUZMAN-MUÑIZ[1], N. MOY-LOPEZ[1];
[1]Univ. of Colima, Colima, Mexico; [2]Dept. of Nursing and Obstetics, Univ. of Guanajuato, Guanajuato, Mexico

Abstract: In recent years, according from the ENSANUT 2018, 85.8% of the Mexican population over 20 years of age consumes soft drinks with a high amount of sucrose. Learning and memory are cognitive processes vulnerable to high sucrose intake during critical periods such as pregnancy and lactation. The objective of this research is to know the effect of sucrose consumption during the perigestacional period on learning and spatial memory of the juvenile progeny. Twelve female Wistar rats were randomized into two groups: control group [CG] (n = 6), and sucrose consumption group [GS] (n = 6). The CG and GS had *ad libitum* access to diet and standard water throughout the study, additionally, the GS had access for 2 hours a day to a bottle containing a solution of 10% sucrose weight volume in water. In the PND-90, the mating process was carried out. Both groups maintained their dietary regimen throughout the pre-pregnancy (PND 69-90), pregnancy (PND 90-111), and lactation (PND 111-132) periods. Offspring received water and food *ad libitum* throughout the experimental period. The pups were subjected to behavioral evaluation: Morris´s water maze (MWM), applied in PDN 29-34 (learning phase) and PDN-42 (memory); and Novel Object Test (NOT) applied in the PDD-41 (habituation) and PDN-42 (Evaluation). No significant differences were observed in maternal body weight of both groups, however, during the whole period, the food intake of GS was significantly lower than that of CG. In the MWM the GS had a

slower learning process than GC. In the NOT (1h, 2h & 4h), the GS only exhibit a preferential exploration of the new object during the 4h evaluation but not in the 1h & 2h; In contrast, the GC exhibited a significant preference in the two last periods of time (2h & 4h). The results suggest that consumption of sucrose (10%) during the perinatal period contributes to the non-preferential exploration of the new object of the GS, this can be interpreted as a possible alteration in learning & memory acquisition; in agreement with the results presented in the MWM that indicate impairments in learning.

Title: Effects of developmental stage and allosteric AMPA receptor modulators on spatial memory in Juvenile Rats

Authors: *R. OGOE[1], N. R. MILL[1], S. GANJU[1], D. CHEN[1], J. A. PERDOMO[1], S. J. YOON[1], A. SARDANA[1,3], C. L. KIMBALL[1], N. VALIBEIGI[4], D. G. MCHAIL[1], T. C. DUMAS[2];
[2]Psychology, [1]George Mason Univ., Fairfax, VA; [3]Georgetown Univ., Washington, DC; [4]Krasnow Inst. For Advanced Study, Fairfax Station, VA

Abstract: Cognitive health in adulthood and aging, in large part, is a function of proper maturation of forebrain neural systems. Hippocampal maturation is driven in part by modifications to α-amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid receptors (AMPARs) at glutamatergic synapses. Circa the end of the third postnatal week in rodents, AMPAR composition shifts from containing primarily GluA1 subunits to predominantly GluA3 subunits and greater association with transmembrane regulatory proteins (TARPs). These changes lead to greater malleability of synaptic connections by lengthening excitatory synaptic responses and decreasing the threshold for the induction of long-term changes triggered by patterned activity. This receptor subunit switch and the accompanying physiological changes coincide with the emergence of more mature spatial navigation in rats. We have previously demonstrated that delivery of positive allosteric modulators of AMPARs (drugs that extend the excitatory synaptic responses) to rats younger than three weeks lowers the threshold for induction of activity dependent synaptic strengthening and produces more mature Y-maze alternation patterns. Electrophysiological studies revealed age-dependent effects of CX614 with rats older than three weeks showing a decrease in the rate of slow gamma oscillations, but younger animals displaying an increase in fast gamma power. However, limitations of the Y-maze preclude the ability to detect differential effects on spatial learning versus spatial memory. As such, we have expanded this research to include the Barnes Maze. Preliminary results from our research indicates that different dosages of the CX614 have divergent effects on spatial memory depending on the age of the rat (older or younger than one week). Higher doses led to fewer

search errors and shorter escape paths to the goal during learning trials for older rats. Our current research suggests a more mature search strategy during probe trials at high doses of CX614 in younger animals. We continue to build upon these findings to further elucidate how changes in AMPAR dynamics can modulate memory related circuit oscillations. Discoveries emerging from these studies shed light on the complex interaction of AMPAR structure and dynamics on spatial memory and learning can provide potential explanatory mechanisms for memory and learning deficits in neurodegenerative disorders. AMPAR dysfunction has been implicated in the etiologies of Alzheimer's Disease, Huntington's Disease, and Fragile X syndrome and these insights could provide possible avenues for improved targeted interventions.

Title: A high fat diet during pregnancy decreased expression of myelin and synaptophysin in the hippocampus and impair spatial learning in the offspring rats.

Authors: *M. ORTIZ-VALLADARES[1], S. RAMOS-MIRAMONTES[1], R. PEDRAZA-MEDINA[1], J. GUZMÁN-MUÑIZ[2], N. MOY-LÓPEZ[1];
[1]Univ. de Colima, COLIMA, Mexico; [2]Univ. de Colima, Colima, Mexico

Abstract: The vulnerable periods during the development of the central nervous system are sensitive to environmental aggressions since they depend on the temporal and regional appearance of critical development processes. Maternal exposure to a high-fat diet (HFD) can alter brain structure and function in offspring. In this study, we analyze the effects of maternal HFD on physical and cognitive development, myelin and synaptophysin optical density in the hippocampus, and memory (SM) and spatial learning (SL) of offspring. Eight litters were used, during gestation four mothers were fed a balanced diet (BD) and four with a high-fat diet. The SL was evaluated with the Morris water maze (MWM) at postnatal day (PD) 28 and the SM at PD42. At PD42, the offspring were sacrificed to take out the brains for myelin and synaptophysin immunohistochemistry and take blood samples for weighs glucose, cholesterol, and triglycerides levels. The results showed effects on physical development, the HFD group had an increased body weight from the fourth week ($p<0.05$), this correlates with food consumption where a significant increase in consumption was observed until the third week ($p<0.01$), in contrast to the BD group. The serum levels only showed increased glucose by the HFD group. Similarly, the HFD group had longs latencies on MWM but not showed significant differences in the memory test. The optical density results revealed decreased expression of myelin on dentate gyrus and corpus callosum

($p<0.01$) and, decreased synaptophysin expression on CA3 and dentate gyrus to hippocampus ($p<0.01$). The results suggest that an inadequate diet as an HFD during pregnancy affects the cognitive development of the offspring and alters to myelination process that could have a relationship with neuronal functionality communication and impairment in synaptophysin expression.

Abstract: Diet-induced obesity is associated with premature cognitive decline and neurodegenerative diseases. Elevated consumption of fats and sugars in human and rodents has been associated with deficits in recognition memory, which is modulated by the hippocampus. Alterations in excitatory and inhibitory neurotransmitters in this area have been observed after hypercaloric diets, but the effects on episodic-like memory are not conclusive. To investigate the effects of hypercaloric diets on memory and their relationship with γ-aminobutyric acid (GABA), glutamate and glutamine in the hippocampus. A control diet (CD), a high-fat diet (HFD) and a combined high-fat-high-fructose diet (HFFrD) were administered to 30 adult mice for 10 weeks. The discrimination indexes and exploration time of the novel object recognition (NOR) task were evaluated, and GABA, glutamate and glutamine concentrations were obtained from the hippocampus. The HFFrD induced lower discrimination indexes, decreased exploration time in the recognition memory task, and lowered the concentrations of glutamate and glutamine in hippocampus. The discrimination indexes of the NOR task were negatively correlated with glutamate in the HFFrD group. These findings suggest that a dysfunction in the hippocampal glutamate and glutamine may underlie the episodic-like memory deficits in mice fed HFFrD diets.

Abstract: Metabolic disturbances, such as insulin resistance, hyperglycemia, and obesity are associated with an increased risk of cognitive impairment and dementia, including Alzheimer's disease (AD). Insulin/IGF1 signaling mediated by insulin receptor substrate 2 (IRS2) regulates homeostasis of nutrients including glucose. Male mice lacking IRS2 display severe type 2 diabetes mellitus (T2DM), characterized by hyperglycemia and insulin resistance, which promotes premature death. We found that young adult male mice lacking IRS2 on a C57BL/6J genetic background ($IRS2^{-/-}$/6J) survived in different experimental environments. Therefore, our study investigated whether IRS2 deficiency-induced T2DM affected hippocampus-associated cognitive function in young male mice. IRS2 deficiency led to aberrant alterations in energy and nutrient sensors in the hippocamps of young male mice with T2DM. Moreover, inactivation of IRS2 in mice reduced core body temperature accompanied by abnormal change in the temperature sensor in the brain. Finally, male mice lacking IRS2 exhibiteddecreased spontaneous activity, an increase in anxiety-like behavior, and impairment of hippocampus-dependent spatial memory. These results suggest that IRS2 deficiency accompanied by T2DM causes impairments of brain energy metabolism and thermoregulation and exerts a negative impact on hippocampal-dependent emotional responses and spatial memory during young adulthood.

Title: Estrogenic protection against dorsal hippocampal D2-type dopamine receptor antagonism in gonadectomized male and female mice

Authors: *N. BASS, M. HICKEY, S. VAN DEN BERGHE, E. CHOLERIS;
Univ. of Guelph, Guelph, ON, Canada

Abstract: Social learning is an evolutionarily adaptive form of learning that may be defined as learning that occurs during social interaction and/or social observation (Galef, 1998). The underlying neuroregulatory mechanisms of social learning are poorly understood and may be tested in mice by utilizing the social transmission of food preference (STFP) paradigm. Multiple systems including the dorsal hippocampus (HPC), estrogens, progesterone, dopamine (DA) and more recently androgens, have been implicated in the STFP. Specifically, dorsal HPC infusions of the D2-type DA receptor antagonist raclopride blocked social learning in gonadectomized male and female mice but not their gonadally intact counterparts suggesting an interaction between dorsal HPC D2-type DA receptors and gonadal hormones during social learning in mice (Bass et al., 2019). This research intends to identify the *specific* hormone(s) involved. In males, gonadal testosterone may act at either androgen receptors (directly) or estrogen receptors, following aromatization to estrogens. In addition, the enzyme 5a-reductase can convert testosterone to the potent androgen dihydrotestosterone (DHT) which also acts on the androgen receptor. In study 1, we implanted subcutaneous slow releasing silastic capsules of either estradiol benzoate (EB) or sesame oil in castrated (CAS) male “observer” (OBS) mice, and in study 2 ovariectomized (OVX) female OBSs received similar hormone treated. Later studies investigate the role of progesterone and DHT hormone replacement in gonadectomized OBSs. OBSs received bilateral infusions of the D2-type DA receptor antagonist raclopride (18 µg/µL for OVX OBSs or 20 µg/µL for CAS OBSs) into the dorsal HPC 10-minutes prior to a 30-minute social interaction with a recently fed, same-sex, familiar “demonstrator” (DEM) followed by an 8-hour OBS choice test. Social learning is determined if OBSs prefer the DEM diet when given the choice between two novel diets. Findings revealed that long term EB treatment protects against the impairing effects of raclopride on social learning in CAS and OVX (preliminary) mice. These findings suggest a possible interaction between dorsal HPC D2-type DA receptors and estrogen receptors in the regulation of social learning in male and female mice.

Title: Hippocampal interleukin-6 affects mnemonic functions and emotionality in a sex-dependent manner

Authors: *F. LONGO[1,2], M. ASKER[1,2], O. A. E. ABUAMRA[1], J. E. RICHARD[1], S. BÖRCHERS[1,2], J.-P. KRIEGER[1], K. P. SKIBICKA[1,3,2];

Abstract: Interleukin (IL)-6 is a central player in the pathogenesis of inflammatory conditions and has been increasingly recognized as a key contributor to central nervous system (CNS) pathophysiology in both adult and developing brain. IL-6 dysregulation contributes to the pathogenesis of a wide range of neuropsychopathologies including autism spectrum disorders (ASD), schizophrenia, and cognitive decline. Recently, increased CNS IL-6 levels were linked to the long-term effects of COVID-19 infection including sleeping difficulties, memory performance, depression, and anxiety. To date, the specific molecular mechanisms, and the brain region through which central IL-6 modulates emotional and cognitive function and exerts its metabolic effects remain poorly understood. The ventral hippocampus (vHPC) represents a critical brain region for the control of memory processes and regulation of emotional/affective behaviors. We found that both IL-6 and IL-6 receptors are expressed in the hippocampus, potentially indicating that local hippocampal IL-6 is positioned to affect hippocampal function. Here we propose that CNS IL-6 contributes to emotional and cognitive behavior through its production, release and action within the vHPC. To evaluate this, we used both neuropharmacological and virogenetic manipulations to alter IL-6 levels in the vHPC of male and female rats. Microinjections of IL-6 into the vHPC impairs memory acquisition and memory retrieval only in female rats, as indicated by reduced novel object exploration in the novel object recognition (NOR) test and reduced ability to locate the platform in Morris water maze (MWM) test. Conversely, reducing hippocampal IL-6 by infusion of the adeno-associated virus (AAV)-siRNA-IL-6 into the vHPC resulted in facilitation of learning and memory process in the NOR and MWM test. Moreover, reduced vHPC IL-6 expression improved anxiety-like and depression-like behavior. Taken together, these results provide new insight into the role of CNS IL-6 highlighting its ability to modulate hippocampus-dependent mnemonic process and affective behaviors in the vHPC. Future studies will evaluate the physiological and pathophysiological conditions, like viral infections or obesity, resulting in activation of this local hippocampal IL-6 actions.

Title: Preceding inhibition organizes hippocampal spike sequences

Authors: *A. NOGUCHI[1], Y. IKEGAYA[1,2];
[1]The Univ. of Tokyo, Tokyo, Japan; [2]Inst. for AI and Beyond, The Univ. of Tokyo, Tokyo, Japan

Abstract: Neuronal spike times are essential for neural coding (Buzsáki et al., 1994; Ferster and Spruston, 1995; Singer, 1993). A subset of neurons often emits a series of action potentials and generate sequential activity. The spike times of neurons during sequential activity are regulated at the millisecond level while preserving flexible modifications to embody diverse sequence patterns. Such spike sequences are exemplified by memory replays during sharp wave–ripples (SWRs) (Buzsáki, 2015). Hippocampal pyramidal cells are sequentially activated during exploration or learning, and these spike sequences are subsequently reactivated in time-compressed manner during SWRs while the animal is immobile or asleep (Lee and Wilson, 2002). This internal replay of sequential activity during behavior has been thought to contribute to memory consolidation, memory recall, and navigational planning (Carr et al., 2011; Ólafsdóttir et al., 2018). In spite of these critical roles, the mechanism for enabling such flexible spike sequencing remains to be clarified. In this study, we conducted *in vivo* whole-cell recordings simultaneously from up to three CA1 pyramidal cells and examined the mechanisms underlying flexible spike sequences at the single-cell level. We found that neurons were transiently hyperpolarized prior to SWRs. The pre-SWR hyperpolarizations varied in magnitude across SWR events and individual neurons, and later spike times during SWRs were preceded by larger pre-SWR hyperpolarizations. Intracellular blockade of Cl^--mediated inhibition eliminated the pre-SWR hyperpolarizations and advanced the spike times, indicating that GABAergic inputs underlie the pre-SWR hyperpolarizations and delay spike times. These results suggest that pre-SWR inhibition coordinates the sequential spike times of CA1 pyramidal cells and diversifies the repertoire of sequence patterns.

Title: Episodic-like memory related activity of hippocampal VIP interneurons in freely behaving mice

Authors: *S. TAMBOLI[1], D. TOPOLNIK[1], A. GUET-MCCREIGHT[2], L. TOPOLNIK[1];

Abstract: Most of the hippocampal vasoactive intestinal polypeptide (VIP) expressing interneurons (INs) specifically target inhibitory neurons, providing a disinhibitory mechanism for ungating the external inputs onto excitatory neurons. CA1 VIP INs have been shown to aid spatial learning and memory but their role in episodic memory is yet unknown. To address this subject, first, we employed a series of behavioral paradigms to assess various aspects of episodic memory and then a unified paradigm to examine What-Where-Which episodic-like memory. Second, we simultaneously performed in vivo calcium imaging of CA1 VIP INs activity in freely behaving mice using wireless fiber photometry. We found that VIP INs were routinely active in all memory tasks throughout the entire period of exploration. During object exploration periods, VIP INs showed evenly balanced rising and dropping activity patterns, which evolved over the course of the object familiarization. Further, examining VIP INs' activity during various behavioral states revealed distinct activity patterns and higher calcium transients (CaTs) during grooming periods than object exploration and rearing. Additionally, grooming-associated CaTs showed a robust correlation with the duration of grooming. Taken together, these results indicate that VIP INs help to encode novelty during episodic-like memory and certain aspects of behavioral states. Ongoing analysis of VIP INs' activity and experiments using behavioral state-dependent optogenetic perturbations will help us better understand the contribution of disinhibitory interneurons in hippocampal memory processing.

Title: The role of inhibition in shaping hippocampal memory encoding sequences

Authors: *J. TAXIDIS[1], B. A. MADRUGA[2], E. PNEVMATIKAKIS[3], M. Z. LIN[4], P. GOLSHANI[5]; [2]Physics, [1]UCLA, Los Angeles, CA; [3]Ctr. for Computat. Biol., Flatiron Institute, Simons Fndn., New York, NY; [4]Neurobio., Stanford, Stanford, CA; [5]UCLA Dept. of Neurol., Los Angeles, CA

Abstract: Hippocampal spiking sequences can encode external sensory cues and internally link them by tiling the gaps in time between them, tracking the passage of our experiences. But the population dynamics of these sequences are unknown. We employed *in vivo* two-photon calcium imaging in the mouse CA1, during learning of an olfactory delayed non-match-to-sample task (DNMS). We previously described pyramidal cell (PY) spiking sequences composed of 'odor-cells' encoding specific olfactory

stimuli, followed by 'time-cells' encoding time-points in the ensuing delay period after a cue. Odor-cells retained robust and stable fields across days and alterations in the trial structure, whereas time-fields were unstable and readily remapped. During DNMS learning, the number of time-cells increased while odor-cells remained fixed (Taxidis et al., Neuron, 2020). What is the role of feedback inhibition by parvalbumin- (PV) or somatostatin-expressing (SOM) interneurons (IN) in shaping these sensory and temporal representations? By expanding our previous analyses to calcium traces from GABAergic cells, we found that a subset of IN yielded significant odor- and time-fields, collectively forming odor-specific sequences. These 'odor-IN' and 'time-IN' had lower odor-selectivity and noisier activation than PY, yielding poor odor-decoding. Moreover, odor-IN had more stable fields than time-IN, as in PY, but those remapped more than PY fields across days or trial alterations. Importantly, unlike PYs, the number of time-cell INs did not increase during learning. Finally, through *in vivo* high-frequency voltage imaging, using the ASAP voltage indicator, we recorded action potentials and subthreshold membrane dynamics from multiple PV- and SOM-expressing IN during DNMS performance. We followed the same cells across multiple days, before and after DNMS training. We found that IN firing rates increased, on average, during locomotion and confirmed that they exhibited odor-fields with reduced odor-specificity compared to PY. Increased spiking during odor-presentation was accompanied by higher theta power in subthreshold traces. Conclusively, PV and SOM interneuronal ensembles in CA1 provide timed but not cue-specific inhibition, potentially increasing the signal-to-noise-ratio of PY sequences by silencing the rest of the PY population.

Abstract: Hippocampal pyramidal cells (PCs) exhibit location-specific spiking patterns (place fields), which have been implicated as the neural basis of a cognitive map of space. The key subcellular compartment for PC action potential generation is the axon initial segment (AIS), which is under exclusive GABAergic control by the 'chandelier' or axo-axonic cells (AACs). On the basis of *in vitro* studies, it has been suggested that chloride-conducting GABAA receptors on the AIS may increase or decrease PC firing, depending on the state of the innervated PCs. Despite the presumed key role of AACs in controlling action potential initiation and timing, the *in vivo* characteristics of AAC activity dynamics and their effect on PC spiking and place fields remained unknown.
We have used fluorescence- and electron microscopy, *in vitro* and *in vivo* electrophysiology, as well as *in vivo* calcium imaging and optogenetics to characterize a transgenic mouse line (Unc5b-CreER) for the inducible labeling of AACs in adult mice of both sexes. We show that AACs in the hippocampal area CA1 of head-restrained mice are synchronously activated by episodes of locomotion, and by whisking during rest. Optogenetic intervention experiments with large-scale electrophysiological (silicone probe) or optical (two-photon calcium imaging) recording of PC activity illustrated that AACs exert inhibitory effects on CA1 PCs in awake, behaving mice, compared to controls. Specifically, extracellular field potentials evoked by optogenetic AAC activation indicated a net inhibitory postsynaptic effect in the pyramidal layer, and photostimulation resulted a transient reduction in average PC spiking, without triggering synchronous network events. Optogenetic inhibition of AACs, in contrast, resulted in increased PC activity, suggesting that natural AAC activity is tonically suppressing PC spiking. Finally, location-specific AAC inhibition induced novel, persisting place fields near the stimulus location in mice performing a random foraging task on a linear treadmill, demonstrating a critical role of AACs in regulating hippocampal place field remapping. These results together demonstrate brain state-specific dynamics of a critical inhibitory controller of cortical circuits.

Abstract: Encoding and retrieval of memory are two processes serving distinct biological purposes but operating in highly overlapping brain circuits. It is unclear how the two processes are coordinated in the same brain regions, especially in the hippocampal CA1 region where the two processes converge at the cellular level. Here we find that the neuron-derived neurotrophic factor (NDNF)-positive interneurons at stratum lacunosum-moleculare (SLM) in CA1 play opposite roles in memory encoding and retrieval. These interneurons show high activities in learning and low activities in recall. Increasing their activity facilitates learning but impairs recall. They inhibit the entorhinal- but dis-inhibit the CA3- inputs to CA1 pyramidal cells and thereby either suppress or elevate CA1 pyramidal cells' activity depending on animals' behavioral states. Thus, by coordinating entorhinal- and CA3- dual inputs to CA1, these SLM interneurons are key to switching the hippocampus between encoding and retrieval modes.

Title: Large-scale AOD-based two-photon imaging of CA2/3 inhibitory network dynamics during spatial navigation

Authors: B. VANCURA[1], A. D. GROSMARK[2], *A. LOSONCZY[3], T. GEILLER[1];
[2]Neurosci., [1]Columbia Univ., New York, NY; [3]HHMI Janelia Farm, Westport, CT

Abstract: The hippocampus is a mammalian brain region responsible for spatial navigation and episodic memory. Both the rapid initial encoding and the consolidation of recently acquired memories are thought to rely critically on the CA2/3 subregions, but precisely how the *in vivo* dynamics of CA2/3 neurons support these cognitive processes remains unknown. In particular, inhibitory GABAergic microcircuits within CA2/3 are hypothesized to regulate many aspects of circuit function that may be critical for memory encoding and consolidation, including the regulation of synaptic plasticity and the generation and control of extracellular network oscillations. However, most available data on the anatomy and physiology of hippocampal inhibitory circuit elements comes from the CA1 subregion. It thus remains unknown how generally the conclusions from CA1 apply to upstream CA2/3, and in particular whether and to what extent the *in vivo* dynamics of CA2/3 interneurons differ from their CA1 counterparts. To close this gap, here we utilize large-scale, AOD-based two photon functional calcium imaging in

combination with *post-hoc* immunohistochemistry to characterize the activity patterns of molecularly-identified CA2/3 interneurons during spatial navigation and awake sharp-wave ripples (SWRs). We observe both region- and subtype-specific differences in interneuron recruitment during behavior, including differences in locomotion modulation, spatial tuning, and responses to contextual manipulations. These results suggest that both the molecular subtype of a given interneuron and its location within the hippocampal network together determine its functional properties during behavior.

Title: Integration of sensory and temporal information in CA3 during working memory

Authors: *S. CHEUNG[1], C. C. DORIAN[3], K. SAFARYAN[2], J. TAXIDIS[1], P. GOLSHANI[4]; [2]Departments of Physics and Astronomy, Neurology, Neurobio., [1]UCLA, Los Angeles, CA; [3]Univ. of California Los Angeles, Los Angeles, CA; [4]UCLA Dept. of Neurol., Los Angeles, CA

Abstract: Memories are temporally organized. When we recall an event, we also recall the relative timing it was experienced. How does the brain compute and store this temporal representation of memory? The hippocampus is a key region for these computations as hippocampal CA1 or CA3 lesions cause impaired coding of sequential events separated by time. The hippocampus bridges stimuli-free gaps between sequential events through neural ensembles that fire sequentially during the delay. These “time cells” fire sequentially encoding successive moments during the delay. Recent work from our lab has shown that the CA1 region of the hippocampus contains neurons that display stimulus-specific sequential firing patterns during the delay period of an olfactory working memory task. CA1 largely lacks recurrent connectivity, so it is unlikely that it generates these sequential firing patterns on its own. CA3 is an upstream region with direct connections through the Schaffer collaterals to CA1, has extensive recurrent connections and is therefore a candidate region that generates these stimulus-specific sequential firing patterns. CA3 also receives input from the lateral entorhinal cortex, which processes nonspatial sensory information and receives direct connects from the olfactory bulb. Given the unique attributes of CA3, we propose that CA3 is where sensory and temporal information is integrated and then this code is passed onto CA1.Using chronic in vivo two-photon calcium imaging, we monitored CA3 neuronal population activity during a delayed non-match-to-sample (DNMS) olfactory working memory task. We have identified stimulus-specific sequentially firing cells that tile the delay period of the DNMS working memory task. We propose that these cells generate robust representations of stimulus-specific time that is

then passed onto CA1 cells. These findings will lay the groundwork for understanding how elements of a memory are unified and coded within CA3 as dynamic attractors.

Title: Signatures of rapid synaptic learning in the hippocampus during novel experiences

Authors: *J. B. PRIESTLEY[1], J. BOWLER[2], S. V. ROLOTTI[1], S. FUSI[1], A. LOSONCZY[1]; [1]Neurosci., [2]Neurobio. and Behavior, Columbia Univ., New York, NY

Abstract: Neurons in the hippocampus exhibit striking selectivity for specific combinations of sensory features, forming representations which are thought to subserve episodic memory. Even during a completely novel experience, ensembles of hippocampal “place cells” are rapidly configured such that the population sparsely encodes visited locations, stabilizing within minutes of the first exposure to a new environment. What cellular mechanisms enable this fast encoding of experience? Here we leverage virtual reality and large scale neural recordings to dissect the effects of novelty and experience on the dynamics of place field formation. We show that the place fields of many CA1 neurons transiently shift locations and modulate the amplitude of their activity immediately after place field formation, consistent with rapid plasticity mechanisms driven by plateau potentials and somatic burst spiking. These motifs were particularly enriched during initial exploration of a novel context and decayed with experience. Our data suggest that novelty modulates the effective learning rate in CA1, favoring burst-driven field formation to support fast synaptic updating during new experience.

Title: An entorhinal cortex instructive signal shapes experience-dependent CA1 representations

Authors: *C. GRIENBERGER[1,2], J. C. MAGEE[1];
[1]Neurosci., Baylor Col. of Med., Houston, TX; [2]Biol., Brandeis Univ., Waltham, MA

Abstract: A crucial function of the brain is to produce useful representations of the external world. Previous results demonstrate that a non-Hebbian type of synaptic plasticity, behavioral timescale synaptic plasticity (BTSP), has a fundamental role in novel place field formation in hippocampal area CA1. BTSP has several distinct characteristics, including that it is driven by dendritic plateau potentials (plateaus) instead of APs. As axons from layer 3 entorhinal cortex (EC) impinge onto the site of plateau initiation and their activity regulates plateau probability, we hypothesized that this EC input might shape CA1 representations during learning. To test this hypothesis, we used two-photon calcium imaging in mice exploring a novel linear track for the first time. We observed the experience-dependent development of place cell representations in CA1, which featured an increased place field density (2-3x) around the reward location. Several findings implicated BTSP: (1) the abrupt appearance of new place cells; (2) the width of the new fields was correlated with the animal's running speed during induction; (3) new fields were shifted forward in space with respect to their induction; (4) the development of the representation was severely attenuated by plasticity and calcium spike blockers, APV and SNX-482. We next performed two-photon calcium imaging of layer 3 EC axons. Individual axon activities fell into three categories, axons that were positively or negatively velocity-tuned and untuned axons. We further found the average population activity to be constant throughout the linear track. However, correcting for the spatial profile of running speed revealed that the EC input rate (df/f per cm) was elevated around the reward location by a factor of 2-3. This result suggests that the EC may provide a signal to CA1 capable of increasing plateau probability and BTSP-driven new place field formation around the reward location. To test this hypothesis, we optogenetically reduced EC axon activity around the reward and this abolished the reward site-associated increase in place field formation. Furthermore, we modified our behavioral learning task in order to generate a peak in EC input at a second location away from the reward site. This manipulation produced a significantly higher number of place fields in this location. Taken together, these two pieces of evidence indicate that EC activity is both necessary and sufficient to shape CA1 population activity. Our results identify the layer 3 entorhinal cortex input as a key signal that instructs CA1 neurons in how to represent an environment.

Title: Population dynamics underlying sharp-wave ripple formation in 3D imaged, molecularly identified CA2/3 interneurons

Authors: *B. VANCURA[1], T. GEILLER[1], A. LOSONCZY[2], A. D. GROSMARK[2];
[2]Neurosci., [1]Columbia Univ., New York, NY

Abstract: The CA2/3 network of the hippocampus is critical for mammalian cognition through both the initial encoding and the subsequent consolidation of episodic memories. The consolidation process is thought to occur largely during sharp-wave ripples (SWRs), fast oscillatory network events initiated by the synchronous activation of CA2/3 pyramidal neurons coordinated by strong inhibitory feedback signals. During SWRs, the time-compressed reactivation of behaviorally-relevant neural trajectories in the hippocampus is thought to underlie the transfer of nascent memories to the neocortex for long-term storage. Despite the significance of SWRs, the circuit mechanisms supporting their formation and maintenance remain only partially understood, largely because the single-cell and population-level activity patterns of identified cell types within the CA2/3 microcircuit during SWRs remain unknown. Here, we take a step towards a mechanistic understanding of SWR formation by utilizing AOD-based two-photon calcium imaging, in combination with simultaneous LFP recordings and post-hoc immunohistochemistry, to provide the first description of the dynamics of populations of simultaneously imaged, molecularly-identified CA2/3 interneurons during physiologically identified offline states. Through these methods we describe the unique CA2/3 inhibitory patterns which predict, and then evolve during, awake SWRs.

Title: Large-scale two-photon calcium imaging in freely moving mice

Authors: *W. ZONG, H. OBENHAUS, E. SKYTØEN, H. ENEQVIST, N. JONG, M. JORGE, M.-B. MOSER, E. I. MOSER;
Kavli Inst. Systems Neurosci, Trondheim, Norway

Abstract: New generations of portable microscopes for calcium imaging enable observation of activity in hundreds-to-thousands of neurons while animals perform experimental tasks, allowing researchers to identify the underlying neural dynamics and computational algorithms, goals that would be out of reach if cells were recorded one by one or a few at a time. For high-resolution imaging *in vivo*, investigators have mostly relied on stationary benchtop two-photon (2P) microscopes where mice are head-fixed under the objective. However, head-fixed protocols are suboptimal for studies of self-guided non-stationary behavior such as navigation, and they preclude, to a large extent, the identification of cells that are inherently spatial in their firing patterns, and that depend on proprioceptive-vestibular information, which is compromised by head-fixation. Due to the unsuitability of benchtop imaging for behavior that requires voluntary movement, investigators have tried, for almost two decades, to develop miniature 2P microscopes - 2P miniscopes - that can be carried on the head of freely moving animals. Early versions of 2P miniscopes did not catch on, however, because they lacked the capacity to image sensitive calcium indicators such as GCaMP6, because their scanning speed was slow, because the miniscopes were heavy and difficult to carry for rodents, or because optical cables were stiff and inflexible. These constraints motivated the development of a new generation of 2P miniscopes (Zong, et al.,2017, Zong, et al.,2021) with 2P benchtop-comparable resolution, fast speed, *z*-scanning capability and large field of view (FOV). However, while these 2P miniscopes represented major advances in imaging quality, their applicability in tasks that require movement remains limited, due to heavy weight, stiff optical cable and low cell yield. We developed a new portable 2P microscope (MINI2P) for fast high-resolution calcium imaging of over 1,000 neurons at a time. Behavior of MINI2P-carrying mice was indistinguishable from that of untethered unimplanted animals on half-hour free-foraging trials. With successive recordings from matrices of neighboring regions, more than 10,000 neurons could be imaged. These advances were achieved through a new optical system design with an increased FOV, a novel technique for successive imaging of adjacent FOVs, a new micro-tunable lens that increased the Z-scanning speed and range, lighter weight, and a new type of flexible connection cable. Large-scale recordings were obtained from visual cortex, medial entorhinal cortex, and hippocampus, and neurons with strong spatial tuning were shown in all areas, including visual cortex.

Title: Grid cell modules remain coordinated after neural activity is dissociated from external sensory cues

Authors: T. WAAGA[1], ***H. AGMON**[2], V. NORMAND[1], A. NAGELHUS[1], R. GARDNER[1], M.-B. MOSER[1], E. I. MOSER[1], Y. BURAK[2,3];

Abstract: The representation of an animal's position in the medial entorhinal cortex (MEC) is distributed across several modules of grid cells, each characterized by a distinct spatial scale. The population activity within each module is tightly coordinated, and jointly restricted to a two dimensional toroidal manifold, which is preserved across environments and behavioral states. Little is known, however, about the coordination of activity patterns across modules. We analyzed the joint activity patterns of hundreds of grid cells, simultaneously recorded in animals that were foraging in light and complete dark conditions to eliminate visual cues. We found that the states of different grid modules are tightly coordinated, even in darkness, when the internal representation of position within the MEC deviates substantially from the true position of the animal. These findings suggest that internal brain mechanisms dynamically coordinate the representation of position in different modules, to ensure that grid cells jointly encode a coherent and smooth trajectory of the animal.

Title: A novel theta-rhythmic directional signal in entorhinal cortex

Authors: *A. Z. VOLLAN, R. J. GARDNER, T. WAAGA, M.-B. MOSER, E. I. MOSER;
Kavli Inst. For Systems Neurosci., Trondheim, Norway

Abstract: A large proportion of cells in the medial entorhinal cortex and parasubiculum (MEC/PaS) show tuning to the animal's head direction (HD), but are distinguished from HD-tuned cells in other regions by their broad tuning curve shapes and their strong theta-modulation. These unique characteristics may indicate that these cells are actually not truly tuned to HD, but rather represent a distinct directional signal correlated with HD. Motivated by this hypothesis, we used Neuropixels silicon probes to record large populations of MEC/PaS cells (n≈1000 per session) in rats exploring 2-D and 1-D environments.
We applied a Poisson Gaussian process latent variable model (P-GPLVM) to population spike trains of MEC/PaS cells, and thus extracted a novel latent directional signal which we term "internal direction" (ID). When we compared cells' relative tuning strength to ID and HD, we found that ID- and HD- tuned cells were from largely non-overlapping populations: ID-preferring cells were more strongly theta-modulated and had broader HD tuning curves than HD-preferring cells.
The extracted ID latent variable displayed unique temporal dynamics which distinguished it from HD. ID was distributed bimodally relative to the animal's head direction, and over consecutive theta cycles it systematically alternated between pointing to the animal's left and right side. Left/right alternation (LRA) was most reliable when the animal ran directly towards a goal in the open-field foraging task - however, we observed the same result on a linear track, where left- and right-going trajectories do not represent possible future paths. Therefore, it appears that ID does not directly represent ongoing or future navigation behaviour.
If LRA is a fundamental characteristic of ID, it may be expected to occur also during REM sleep, when activity in the hippocampal-entorhinal circuit is entirely internally-driven. Indeed, we found that REM contained periods of sustained LRA highly similar to wake, in agreement with the idea that LRA is an intrinsic property of the networks responsible for generating ID.
In summary, we discovered ID, a novel directional signal with theta-rhythmic, left-right-alternating dynamics. The ID signal might be used as a directional input to the grid cell network to generate theta sweeps in arbitrary directions (Gardner et al., this session).

Title: Coordinated direction- and position-coding dynamics during grid-cell theta sweeps

Authors: *R. J. GARDNER, A. Z. VOLLAN, T. WAAGA, M. B. MOSER, E. I. MOSER;
Kavli Inst. Systems Neurosci, Trondheim, Norway

Abstract: During alert states, place- and grid-cell activity is temporally organized within theta waves, which travel from dorsal to ventral poles of the hippocampal-entorhinal system. Neural activity in each theta cycle represents a stereotyped spatial trajectory ("sweep") which travels outwards from the animal's location. It has been proposed that grid cells contribute to generating sweeps, because some theoretical models allow grid cells to generate arbitrary linear trajectories from a directional input. A candidate for this directional input is the "internal direction" (ID, see Vollan et al., this session) represented by cells in medial entorhinal cortex and parasubiculum (MEC/PaS). To investigate this possibility, we examined population recordings of position- and direction-modulated cells in MEC/PaS. Recordings were obtained in rats exploring 2-D and 1-D environments, implanted with Neuropixels silicon probes.
Supposing that ID were the directional driving input for sweeps, ID dynamics should be aligned with the directions of sweeps. We therefore applied a Poisson Gaussian process latent variable model to extract the latent 2-D position representation in the open field. Sweeps, evident as linear trajectories radiating outwards from the animal's location, were reliably aligned to ID. Sweeps were most strongly represented by burst-firing, position-modulated cells, which included grid cells and conjunctive grid-by-direction cells. Furthermore, ID was aligned to grid-cell sweeps during REM sleep, suggesting that grid dynamics may be constitutively coupled with ID across all conditions.
Examining single modules of grid cells revealed that each module represented a restricted segment of the population sweep, with the segment length proportional to the grid spacing. This scale relationship, combined with sequential activation of modules associated with the dorsoventral travelling theta wave, allows for the joint activity of multiple modules to represent a single coherent trajectory.
Finally, if sweeps are generated by grid cells, the periodic nature of the grid pattern may allow sweeps to extrapolate beyond the limits of the physical environment. When we examined 2-D latent position, we observed that, during sweeps which were directed towards nearby environmental boundaries, the latter portion of the sweep represented unvisited, out-of-bounds locations.
In conclusion, we show that coordinated activity of ID and grid cells is consistent with the hypothesis that sweeps are generated by MEC/PaS circuits using ID input: sweeps are reliably aligned to the ID signal, and occur with highly stereotyped geometry independently of the physical context.

Title: Toroidal topology of population activity in grid cells

Authors: *E. HERMANSEN[1], R. GARDNER[2], M. PACHITARIU[3], Y. BURAK[4], N. BAAS[1], *B. DUNN[1,2], M.-B. MOSER[2], E. I. MOSER[2];

Abstract: Entorhinal grid cells, so-called because of their hexagonally tiled spatial receptive fields, are organized in modules which, collectively, are believed to form a population code for the animal's position. One major debate revolves around the possible mechanisms that may underlie the grid pattern. Although multiple alternatives have been hypothesized, the stability of the correlation structure of the activity of grids cells, across environments and arousal states, has favoured a class of recurrently connected models known as continuous attractor networks (CANs). However, because previous samples of co-recorded grid cells have been small, it has remained unclear whether grid cell networks exhibit continuous attractor dynamics, and if so, how such dynamics interface with environmental cues.
Here, we apply topological data analysis to simultaneous recordings of hundreds of grid cells, and show that joint activity of grid cells within a module lies on a toroidal manifold, consistent with a two-dimensional CAN. Each position of the animal in its physical environment maps to a single location on the torus, and each grid cell is preferentially active within a single "field" on the torus. Toroidal firing positions persist between environments, and between wakefulness and sleep - as predicted by CAN models, but not by feed-forward models which generate grid patterns from external inputs by means of Hebbian plasticity.
Finally, we compare the toroidal tuning of three distinct grid-cell subtypes which differ in burst-firing, theta-modulation and spike-waveform characteristics, and we show that the toroidal representation is preferentially carried by a population of burst-firing, weakly-theta-modulated grid cells. Conjunctive grid-by-direction cells also demonstrated selectivity to the torus, but more weakly, in accordance with the higher dimensionality of the conjunctive code.
In conclusion, our present observation of grid-cell ensemble dynamics on a toroidal manifold constitutes the first population-level description of CAN dynamics in grid cells.

Title: Behaviour Of Medial Entorhinal Cortex Cells During A Radial Eight Arm Maze Task

Authors: *Y. BAPATDHAR, J. CSICSVARI;
Inst. of Sci. and Technol. (IST) Austria, Klosterneuburg, Austria

Abstract: Across species the medial temporal lobe region of the brain is known to be involved in spatial navigation. Historically the grid cells of the medial entorhinal cortex (mEC) have been of interest. Their (relatively) rigid, grid-like firing pattern has played a significant role in furthering our understanding of how space is represented in the brain. The mEC, however, has a myriad of other very interesting cells that exhibit spatial properties but are not grid per say. The role of these non-grid spatial cells during navigation is still not well understood. In addition, the mEC has been shown to replay independently of the hippocampus. The role of this independent replay is as yet unknown. The aim of the project is to elucidate the role of this replay and to understand how different cell types in the mEC behave differently during a complex navigation task.
We performed multichannel, extracellular electrophysiology on 4 adult, male Long Evans rats while they performed a radial eight arm maze task. The rats were implanted with microdrives targeting the dorsal CA1 and layers II/III of the mEC. The rats performed an eight arm maze task where, everyday, they were expected to learn which 3 arms (out of the 8 arms) were rewarded. Each trial started with a delay of 1min. Animals performed 30 trials per day. The recorded data was preprocessed and putative single units were isolated using a semi-automated clustering algorithm. All further analysis was then performed on these isolated units using custom code.
We establish how the different kinds of spatial cells in the mEC behave during this task. We show how grid and non-grid spatial cells behave differently at different phases during the task - during the 1min delay period, during the first half of the learning block (when the animal is still learning the reward locations and makes mistakes) and during the second half of the learning block (once the animal has learnt the reward locations). We show how at key moments of immobility (when the animal is at the centre - a decision point; or when the animal is at a reward location) the trajectory replayed by mEC cells isn't always the same as that replayed by hippocampal CA1 cells. Here we show what the role of the independent replay and the non-grid spatial cells of the rodent medial entorhinal cortex is during complex spatial navigation tasks. These results are a demonstration of the influence of non-geometric factors on the firing properties of the mEC space coding cells. The results also demonstrate how the independent replay in the mEC could be part of a parallel memory formation circuit in the brain.

Title: Out of place: the anticipatory nature of the hippocampal cognitive map

Authors: *P. CHAUDHURI-VAYALAMBRONE[1], M. E. RULE[2], M. KRSTULOVIC[1], P. KEREKES[1], M. BAUZA[3], T. O'LEARY[2], J. KRUPIC[1];
[1]Dept. of Physiology, Develop. and Neurosci., [2]Dept. of Engin., Univ. of Cambridge, Cambridge, United Kingdom; [3]Univ. Col. London, London, United Kingdom

Abstract: The hippocampal formation contains a variety of spatially sensitive neurons, thought to form key components of the cognitive map. As a rat moves throughout an enclosure, place cells fire at particular locations, while grid cells fire at each vertex of a triangular grid tiling the entire enclosure. The firing patterns of these cells are normally viewed as functions of an animal's current position. Previous studies have shown that these cells are biased towards encoding position prospectively, as they mostly fire spikes just before the animal moves through the cell's preferred spatial location(s). On shorter timescales, grid cells have been suggested to fire in both prospective and retrospective modes.
We analysed the firing patterns of grid cells and place cells, simultaneously recorded in freely moving rats. We shifted each cell's spike times by fixed intervals back and forth along the animals' trajectories, to see if this sharpened the resulting rate maps. Both types of cells exhibited prospective coding, firing ~100 ms before the animal entered a cell's preferred location. When co-recorded, grid cells generally have smaller time-shifts than place cells (median 80ms and 160ms respectively). There was also no clear correlation between time-shifts in co-recorded grid cells and place cells, suggesting that this prospective offset is not coordinated between the hippocampus and the entorhinal cortex.
To explain the heterogeneity of these time-shifts, we looked at their relationship to the local field potential (LFP) theta rhythm (7-12 Hz). Many grid and place cells exhibit theta precession, where spikes fall on progressively earlier theta phases as the animal traverses a firing field. We found that place cells that are more strongly locked to theta phase show larger time-shifts. We also looked at whether the heterogeneity in these shifts could be explained by latent variables acting at shorter timescales. Such variables may cause momentary fluctuations in the apparent time-shift of a cell's firing, which would be obscured by averaging across a recording session. We expected prospective shifts to correlate between consecutively traversed grid fields. However, we found no evidence for correlated fluctuations in prospective time-shifts.
We conclude that grid cells and place cells show predominantly prospective coding. We conjecture that the difference between their time-shifts reflects a flow of information from place cells to grid cells. These results also suggest that particular phases of the theta rhythm are associated with prospective coding.

Title: Egocentric tuning in hippocampal neurons: Using simulations to estimate misclassification rates

Authors: *J. CARPENTER[1], J. BLACKSTAD[1], B. DUNN[2], E. I. MOSER[1], M.-B. MOSER[1];
[1]Kavli Inst. for Systems Neurosci., Trondheim, Norway; [2]Dept. of Mathematical Sci., Norwegian Univ. of Sci. and Technol., Trondheim, Norway

Abstract: Navigation relies on the integration of incoming sensory information with a stable schema that can be applied to map the current environment. This integration results in a dynamic map of the animal's position based on coordinate systems which have origins centered either on the navigator him/herself (egocentric) or on some distal, world-centered cue (allocentric). In open-field recordings from the hippocampus, neurons have typically been understood to represent information within an allocentric frame of reference, whereas the investigation of spatial information in egocentric reference frames in this brain structure has received little attention. Here, in agreement with previous work (Sarel et al., 2017; Jercog et al, 2019); any other), we find indications for modulation of place cell activity by egocentric bearing using previously defined methods for detection in real data from open field environments. However, our findings also raise the possibility that activity in hippocampal neurons may often be falsely attributed to egocentric orientation as a result of tuning to related covariates. By developing a simulation framework composed of functional cell types with various kinds of spatial tuning and by applying large populations of these simulated neurons to egocentric classification methods, we find higher than expected false positive rates among simulated neurons not tuned to egocentric orientation. False positive rates vary across cell types, behavioral sessions, noise levels, and firing field sizes, pointing to factors that might potentially account for misattribution to egocentric tuning in experimental studies. We propose here that with simple improvements in experimental design and analysis, such issues can be mediated. Further, we suggest that such studies of potential confounding factors should be investigated prior to data collection.

Title: Probing neural representations of spatial memory and navigation in the human hippocampus and thalamus with augmented reality in the real world

Authors: *S. MAIDENBAUM[1], V. KREMEN, JR[2], A. PATEL[5], K. MILLER[2], J. VANGOMPEL[2], B. BRINKMANN[3], V. SLADKY[3], G. A. WORRELL[4], J. JACOBS[6];
[1]Biomed. Engin., Ben Gurion Univ., Beer Sheva, Israel; [2]Neurosurg., [3]Neurol., [4]Mayo Clin., Rochester, MN; [6]Dept. of Biomed. Engin., [5]Columbia Univ., New York, NY

Abstract: Spatial memory and navigation are a crucial part of our lives. However, neural research on spatial navigation and rehabilitation in humans is typically limited by our current imaging technologies. Conventional human brain imaging methods, such as fMRI, MEG or ECoG, do not allow subjects to freely move around a spatial environment, thus limiting the realism of tasks. Other brain recording methods, such as EEG or fNIRs, allow increased mobility but do not offer the signal quality or coverage of deep brain regions.
To address these concerns, we studied data from a rare set of patients (N=4) with drug resistant mesial temporal lobe epilepsy, who were implanted with invasive neural stimulator (INS) enabling continuous wireless brain recording (investigational Medtronic Summit RC+STM), which allowed them to move and navigate completely freely in a real-world spatial environment. We targeted main deep brain structures in the temporal lobe, hippocampus (Hc) and anterior nucleus of thalamus (ANT) bilaterally. To probe the neural basis of real-world navigation in these participants, we designed a custom Augmented Reality (AR) spatial memory task. In this task, augmented treasure chests were placed throughout the room the patient was in. In each trial the patient had to memorise the location and content of the object inside each chest. Then, following a distractor task patients were cued by object and had to return to the location where that object was previously found. Each trial included 4 chests in different locations and patients received feedback after every trial. We also ran this paradigm on a group of healthy participants (N=24) to establish a baseline.
Both healthy participants and patients performed the task significantly well. Patient results were similar to those of the healthy control participants, and both were twice as the baseline established for this task in virtual reality in previous work. In the neural recordings from the patients we found increased oscillatory power in the theta band (5-8Hz) by movement and by task stage. We also found a significant modulation of theta oscillatory power by movement direction in the patients' anterior thalamus. Our findings validate that integrating AR with chronic neural implants can lead to improved techniques for spatial memory research, more precisely identifying movement-related neural signals and revealing new directional neural representations.(note that authors 1 and 2 contributed equally to this work, as did authors 8 and 9)

Abstract: Spatial navigation is recognized to involve the multiple cognitive processes of guiding and determining the trajectory between focusable elements within cognitive maps of a specific environment. Animal and human neuroimaging studies have suggested that the hippocampus and associated brain regions are critical for neural computation of cognitive maps and serve as neural substrates underlying successful spatial navigation. In this human neuroimaging study, we used functional magnetic resonance imaging (fMRI) to investigate whether and how the sustained experiences of using immersive virtual reality with a head-mounted display (HMD) influence the neural processing of visuo-spatial navigation. Thirty-six immersive virtual reality users (VR group) and thirty-eight healthy adults without VR experiences (Non-VR group) were instructed to perform a virtual maze-like task and control task for navigating a virtual environment during fMRI scanning. Behavioral results showed no significant differences in findings landmarks in the virtual environment during maze-like task between VR and non-VR group. The whole-brain fMRI analysis, however, showed that VR group had reduced neural activation in hippocampus, cerebellum, posterior parietal cortex, and supplementary motor area, probably indicating a more efficient spatial-navigation brain network for performing VR-based maze task. Our fMRI results suggested that the sustained experiences in practicing VR may modulate the neural substrates underlying successful spatial navigation and the findings provide supportive evidence for neural efficiency mechanism of the human brain in spatial navigation.

Title: Sex Differences in Head Direction Signals When Learning a Complex Environment

Authors: *Y. CHENG[1], E. R. CHRASTIL[2,1];
[1]Cognitive Sci., [2]Neurobio. and Behavior, Univ. of California, Irvine, Irvine, CA

Abstract: Sex differences have frequently been reported in human wayfinding, but it is unknown whether there are sex differences in head direction signals when navigating in a complex environment. In an fMRI study, we tested 105 participants (55 males, 50 females) in a cardinal-direction-aligned virtual maze. The navigation task consisted of an exploration phase and a test phase. During the 16-minute exploration phase, participants freely explored to find 9 objects located in the environment and were instructed to remember their locations. During exploration, participants made decisions about where to go next while they were stationary at each intersection. The program then showed movement going forward to the next location. For each of the 48 test trials, participants started at one object and were directed to go to another object, without feedback and with a limited time. We conducted an intra-subject multivariate pattern classification for the four head directions (north, south, east, west) in five a priori regions of interest (ROIs): thalamus, retrosplenial cortex, precuneus, extrastriate cortex, and early visual cortex. Our analysis focused on the stationary decision-making period during the exploration phase, parsed by sex. For people who completed the experiment, we were successfully able to discriminate between head directions in early visual cortex in females (n = 45) and in thalamus and precuneus in males (n = 53). Classification strengths in precuneus were higher in males than females. 7 participants (2 males, 5 females) dropped out during the test phase due to motion sickness. There were some indications that head direction classification strength differed for males with motion sickness compared to those without. Overall, this study indicates that there are sex differences in basic head direction signals during navigation. In particular, the head direction signals during stationary decision-making indicated that the ROIs where the classifier could successfully discriminate between the four directions differed between males and females. These findings suggest the primary building blocks of navigation have early differences that differ by sex, which could affect later navigational abilities.

Title: Hippocampal-dependent navigation strategies are associated with increased vicarious trial-and-error in human virtual navigation

Authors: *N. SCHMITZER-TORBERT[1], G. WEST[2], V. D. BOHBOT[3];
[1]Wabash Col., Crawfordsville, IN; [2]Univ. of Montreal, Montreal, QC, Canada; [3]Dept. of Psychiatry, McGill Univ., Douglas Mental Hlth. Univ. Inst., Verdun, QC, Canada

Abstract: Vicarious trial-and-error (VTE) in rodents occurs during deliberation between potential options and is associated with hippocampal activity. VTE is also associated with the use of spatial (e.g.

allocentric, flexible) navigation strategies in rodents, and VTE-like behavioral measures have been observed in humans using allocentric strategies in virtual navigation tasks. To determine if VTE is related to the use of hippocampal-dependent strategies in humans, we examined performance in two radial maze tasks (the 4 on 8 Virtual Maze, 4/8 VM, and the Concurrent Spatial Discrimination Learning Task, CSDLT) developed by our lab to assess the use of hippocampal-dependent memory in healthy adults. Both the 4/8 VM and CSDLT begin with a dual-solution phase, where either spatial (e.g. "choose the path next to the mountain") or nonspatial (e.g. "choose the left path") strategies can be used to find objects hidden in the radial maze paths. After reaching criterion performance, probe trials (removing the extramaze cues in the 4/8 VM, shifting the arms presented in the CSDLT) are administered to assess the use of hippocampal-dependent spatial strategies, and the 4/8 VM also includes a strategy assessment based on the participant's self-report. In a sample of undergraduates and Amazon Mechanical Turk workers tested on the 4/8VM (n = 521, 258 females), and the CSDLT (n = 140, 69 females), measures of VTE were associated with the use of hippocampal-dependent strategies in both tasks on probe trials, and with self-reported use of spatial strategies on the 4/8 VM. VTE was attenuated, but remained elevated, when distal cues were removed during the 4/8 VM probe trial, indicating that VTE was not simply related to scanning the environment for landmarks. Under dual-solution conditions, VTE in participants using spatial strategies was elevated in the first trial of the CSDLT, and throughout the 4/8VM. These behavioral patterns parallel imaging studies, indicating that elevated VTE is observed in spatial learners in each task when hippocampal activity is elevated, suggesting that episodes of VTE may serve as a behavioral index of hippocampal activation as spatial navigation strategies are employed.

Title: Medial temporal codes for distorted spatial memory during virtual navigation

Authors: *K. N. GRAVES[1], B. E. SHERMAN[1], I. H. QURAISHI[3], E. C. DAMISAH[2], N. B. TURK-BROWNE[1];
[1]Psychology, [2]Neurosurg., Yale Univ., New Haven, CT; [3]Dept. of Neurol., Yale Sch. of Med., New Haven, CT

Abstract: As we navigate through the world, we pick up on spatial patterns of locations we encounter. Our prior work has shown that human navigators use such patterns when searching for new locations. How memories of individual past locations are influenced by this pattern extraction process remains unknown. In statistical learning tasks, spatially co-occurring objects are later judged as being closer together in space, suggesting a hypothesis by which extracting spatial patterns during navigation may distort individual locations to be remembered as closer together than reality. These distortions may

originate in the medial temporal lobe, and the hippocampus in particular, which has been linked to both statistical learning and spatial navigation. To test these predictions, we recruited nine epilepsy patients implanted with intracranial electrodes for seizure monitoring. They performed a virtual navigation task in which they moved through a circular, beach-themed arena and learned five locations, with each location marked by a uniquely colored disk. At the beginning of each training trial, participants saw a color word prompt, informing them of the disk color they were going to find. The disk then appeared in the arena and they navigated to it. After repeatedly navigating to each location across training trials, participants completed a test phase. On each test trial, participants again saw a color prompt, but the arena remained empty with no disk appearing. They were instructed to navigate to the remembered location of the cued disk, providing an estimate of its location based on training. Applying an inverted encoding model to intracranial EEG data collected concurrently, we reconstructed spatial representations of the five learned locations from oscillatory activity in the hippocampus. Variation in the reconstructions corresponded to differences in spatial error during the test phase, as well as to a behavioral spatial pattern bias from the distribution of locations. Thus, we show that "place codes" for learned locations can be reconstructed from local field potentials in human hippocampus, and that these reconstructions are subject to cognitive biases acquired during spatial learning.

Title: Human single neuron activity encodes future trajectories

Authors: *T. DONOGHUE[1], S. E. QASIM[1], A. PATEL[1], H. AZAB[2], E. H. SMITH[3], R. MATHURA[2], J. MYERS[2], A. ANAND[2], J. ADKINSON[2], H. G. REY[2], J. D. ROLSTON[4], T. E. J. BEHRENS[5], M. BOTVINICK[6], S. A. SHETH[2], J. JACOBS[1];

Abstract: Navigating through the world, including tracking current location in the environment and using this information to make decisions and move through the world according to one's current goals, is an important task to thrive in dynamic environments. While much prior work has demonstrated how the medial temporal lobe encodes spatial information, including place cells which contain information about one's current location in space, it is unclear how such representations relate to navigational goals and contribute to upcoming decisions. Related to this, in rodent work, place cells have been reported to

encode current positions while also being modulated by future trajectories. To investigate whether this kind of encoding can also be found in humans, we recorded single-neuron activity from the medial temporal lobe and surrounding ventral prefrontal cortex in neurosurgical patients who performed a virtual spatial-navigation and memory task. In this task, subjects navigate a fixed-track virtual world and, at a navigation choice point, are instructed to alternate between choosing to go down either the left or right side of the track. In addition to having to remember previous trajectories, patients are also engaged in a spatial memory task in which they have to learn and then later retrieve the location of treasure chests along the track. By analyzing single-neuron activity while subjects navigate this virtual world, we find both 'place' and 'distance' cells, whose firing reflects spatial position and distance along the track, respectively. In addition, we find 'splitter' cells, whose firing rates are modulated by the future trajectory of the subject, including both 'splitter place cells', in which cells have differential firing at a particular location along the track as subjects move that reflects future left or right turns, and 'splitter time cells', in which cells have differential firing for future left and right turns at particular times during the stationary pause period in which subjects are making the navigation decision. Our results demonstrate how spatial encoding relates to current context and future decisions with human subjects engaged in a complex spatial navigation and memory task. This finding suggests that single neuron activity in human medial temporal lobe and surrounding areas not only encodes one's current position in space, but also systematically relates to upcoming choices about future actions and upcoming trajectories, suggesting these cells are likely involved in processes such as planning and decision making.

Title: The relationship between hippocampal subfield volumes and human spatial navigation

Authors: *A. S. TU, C. MCINTYRE, E. R. CHRASTIL;
Univ. of California, Irvine, Irvine, CA

Abstract: Navigation is a critical skill, important for finding resources and returning to safe locations. Despite its importance, there are large individual differences in human navigation ability. Although studies in navigation experts and older populations have shown a relationship between overall hippocampal volume and navigation ability, this relationship in the healthy, young adult population has recently been called into question. The medial temporal lobe (MTL) regions of the brain, specifically the

hippocampus, relate to learning and memory ability and can aid in successful navigation. However, there are mixed findings on whether volumes of certain hippocampal subfields can explain the variability in navigational performance across the young adult population. This study tested the abilities of 25 young adults to successfully navigate a new virtual desktop maze environment. After freely exploring the maze for 16 minutes, participants were asked to go from one object in the maze to another, while taking the shortest route. T1-weighted, T2-weighted, and high-resolution T2 MRI brain images were collected and automatically segmented into four hippocampal subfields and three adjacent MTL regions via the Automatic Segmentation of Hippocampal Subfields (ASHS) pipeline. The volumes of the segmented hippocampal regions were then used to measure whether individual regions within the hippocampus correlate with navigation ability. We theorize that successful navigation of this maze involves pattern separation ability, since many of the hallways look similar, and participants needed to discriminate between partially overlapping routes to reach the target. Thus, we hypothesize that the Cornu Ammonis 3 (CA3) and Dentate Gyrus (DG) regions, which have been shown to be involved in pattern separation ability, will be correlated with individual differences in navigation of this population. If pattern separation is not important, we still predict that the CA1, CA2/3, and DG volumes are correlated with navigation performance due to their relations with recall of target objects. Our findings suggest that subfield volumes - not overall hippocampal volume - are informative to understanding the link between brain and navigation behavior in the healthy, young adult population.

Title: Creatures of habit? Examining navigation strategies across the lifespan

Authors: *P. MAXIM, S. D. MOFFAT, T. I. BROWN;
Sch. of Psychology, Georgia Inst. of Technol., Atlanta, GA

Abstract: How we navigate our world depends on many factors, however not everyone holds equal expertise or ability. Research suggests that aging negatively impacts flexible navigation performance, perhaps in part due to memory integration and route memory deficits, so it is imperative we understand how memory influences navigation strategies and what factors lead to navigation differences as we age. The present study tested young adults (YA, 18-40) and older adults (OA, 65-80) across two days in a virtual navigation task. Participants are trained on specific paths through six virtual towns, and after a 24-hour period, are tested during fMRI on their memory of these now-familiar routes (FR). Participants are then given novel goals and permitted to reach the goal using any strategy (unbound to the FR). Some trials are designed so that the optimal route (OR, optimal shortcut) follows the same direction as the FR (forward-shortcut), while in others the OR requires traveling backward relative to the direction of the FR

(backward-shortcut) - i.e., greater heading conflict between OR and FR. The relationship between strategy (familiar vs. shortcut) and execution (efficiency of strategy) is not clear-cut. Preliminary analyses show no significant differences in navigation strategy and efficiency between age groups for forward-shortcuts. But during the backward-shortcut trials, when given the choice between a) backtracking or shortcutting in a "conflicting" direction with the FR vs. b) traveling along the familiar forward direction, YAs show a significant bias toward more closely following the FR than the OR that, interestingly, the OAs do not. Unlike YAs, the OAs did not significantly differ in their strategy across forward and backward trials, but group data show they tend to take fewer FRs compared to the YAs when the goal is backward relative to the FR. Parallel analyses suggest nearly every OA underperformed in FR memory tests compared to the YAs, indicative of a more effortful experience when trying to remember the FR. Together, these findings suggest that route familiarity and directional conflict may be important moderators of past evidence that aging leads to decreased flexibility/increased route-based navigation. By examining fMRI correlates in the frontal and medial temporal circuitry, we unpack the neural bases of how these individuals execute their navigational strategies and which factors play a role in these abilities as we age.

Title: Virtual Maze Adaptation to Study Navigation Ability in Children

Authors: *C. O. ZURITA BAUTISTA, I. Y. DEL RIO-PORTILLA, G. D. ORTIZ-LAGUNES;
Lab. de Sueño, Facultad de Psicología, Univ. Nacional Autonoma de Mexico, Mexico city, Mexico

Abstract: There are many paradigms utilized for behavioral experiments with children which use an avatar or the children's body to navigate and guide self-location with landmarks, located inside and outside the environment. Using virtual mazes is common during electroencefalography studies with adults. The virtual arena used by Jacobs et al. (2013) has been utilized to identify the place and grid cells in humans. The characteristics of the labyrinth are an important factor to compare the results obtained. Werweg and Kahana (2018) point out that navigating in circular environments could lack the rotational symmetry associated with the grid cells activity. So, characteristics may play an important role in brain activity. Brain electrical activity (EEG) during navigation has been studied in different species, including adult humans. In children, most navigation studies focus on behavioral variables, and the development of

EEG activity is a wide field to investigate. When working with children, we need to keep in mind the difference in the cognitive development between adults and kids. There are differences in the level of language understanding, attention ability to keep the focus on the task among other cognitive functions between both groups. Throughout time EEG navigation paradigms have been designed for adults. Hence, when testing children some adjustments are required on them. In that way, findings with children may help following changes between EEG activity until they reach mature brain oscillations. Therefore, it is important to assess the virtual environment for navigation, adapted from adult's paradigms, but at the same we need to take in to account the previous findings in behavioral navigational paradigms with children. Consequently, our group adjusted the virtual arena developed by Jacobs et al. (2013) for children. We replaced the landmarks and scenarios of the virtual arena and assessed instructions and duration of trials in three conditions: baseline, encoding, and recall of landmarks. The task was applied to seven children (6-12 years old). In contrast to adult paradigms, we found that children needed an average of 28 s for trials in the baseline condition, 25 s for the encoding, and 28 s in the recall condition. Besides, the scrolling speed to walk and turn right or left through the virtual arena was an important factor for the kid's attention to the landmarks. Regarding the instructions, the participants proposed explanations and word synonyms that were easier for them to understand and keep them interested in the task. Based on the outcomes, we propose modifications to the virtual arena paradigm, useful in EEG research with children.

Ctr., Montreal, QC, Canada

Abstract: When navigating in a novel environment, people can memorize spatial locations using a hippocampus-dependent strategy (learning the relationship between landmarks) or a strategy that recruits the caudate nucleus (using a rigid stimulus-response pattern). The caudate nucleus forms a part of the reward system and supports procedural learning and the formation of habits. Previous work from our lab has shown that healthy young adults who use caudate nucleus-dependent memory to solve a radial arm maze consume higher levels of addictive substances and take more risks in a gambling task. It, however,

remains to be determined if memory performance during childhood is associated with the development of higher levels of substance use and behavioural problems later in life. To test this hypothesis, we examined data from the Quebec Newborn Twin Study (QNTS), a prospective longitudinal study of twins born between 1995 and 1998. When the children were 8 years old, they completed a radial arm maze (4 on 8 Virtual Maze adapted for children [a4/8 VM]) that measures hippocampus-dependent memory, spatial learning and working memory. Hippocampus-dependent memory is measured during a probe trial at the end of the task where all environmental landmarks around the maze are occluded. We compared memory performance in the a4/8 VM at age 8 to self-reported measures of substance use, depressive symptoms and externalizing behavior problems at ages 14 and 16. We found that lower hippocampus-dependent memory as measured by the probe trial at age 8 was associated with higher levels of depression in adolescence. Lower rates of spatial learning at age 8, meaning taking more trials to reach the criterion of no errors, was associated with increased substance use (cigarettes, cannabis and other illicit drugs) and behavioural problems in adolescence. Lastly, working memory errors at age 8 were associated with increased substance use (alcohol, cigarettes, cannabis and other illicit drugs) behavioural problems and increased depression in adolescence. These results suggest that memory performance in childhood, reflecting the integrity of memory systems and reward sensitivity, might have some predictive value in determining future maladaptive behaviors in adolescence.

Title: Relationship of nicotine use and cessation to impulsivity, foraging and hippocampal-dependent navigation

Authors: *Y. WANG[1], J. LAWSON[1], K. WILSON[1], V. D. BOHBOT[2], N. C. SCHMITZER-TORBERT[1];
[1]Dept. of Psychology, Wabash Col., Crawfordsville, IN; [2]Dept. of Psychiatry, McGill Univ., Douglas Mental Hlth. Univ. Inst., Verdun, QC, Canada

Abstract: Why do some people successfully quit nicotine use while others struggle to do so? One obstacle is that nicotine use is associated with altered decision-making, such as increased discounting of future rewards, which is well-known. However, nicotine use has also been associated with a broader range of decision-making correlates, which may be important in supporting nicotine cessation. In this study, we examined the relationship between current nicotine use (cigarettes and e-cigarettes) and decision-making parameters derived from survey measures and virtual navigation tasks. Participants (Amazon's Mechanical Turk, undergraduates, and local community members) completed surveys including measures of delay-discounting and nicotine use. Consistent with the literature, cigarette (but not e-cigarette) use was associated with stronger delay discounting. Discounting rates were also negatively

related to self-reported intentions to quit using nicotine, and positively to self-reported nicotine dependence.Participants also completed a foraging (Movie Row) and a spatial memory (4 on 8 Virtual Maze, 4/8 VM) virtual navigation task. In the Movie Row, participants navigated around a virtual track presented on standard desktops/laptops. Rewards (4-sec video clips presented on movie screens) were offered in four zones (each with a different category of video), available after a variable delay. E-cigarette use was related to greater enjoyment of video rewards, especially in females, but with earning fewer total rewards. Participants typically made slower choices and showed increased vicarious trial-and-error when making poor decisions (e.g. accepting a bad offer), but this relationship was reduced in cigarette users. Unexpectedly, deliberation associated with poor decisions was reduced in nicotine users reporting weaker nicotine dependence. Cigarette users also showed increased deliberation when presented with difficult offers.The 4/8 VM (a radial maze task) was used to assess spontaneous preference for hippocampal-dependent spatial navigation strategies or striatal-dependent response navigation strategies. Nicotine use was not related to navigation strategy (spatial versus response), consistent with previous reports. Exploratory analyses suggested that navigation strategy may moderate the relationship between lifetime years of nicotine use and discounting rates, and to intentions to quit using nicotine.These results suggest that nicotine use is related to disruptions in several decision-making systems, which may differ across the modality of nicotine use, and may relate to motivation to quit using nicotine.

Title: Spatial navigation in amyotrophic lateral sclerosis

Authors: P. M. MAIER[1], D. IGGENA[1], T. MEYER[1], C. FINKE[1], *C. J. PLONER[2];
[1]Dept. of Neurology, Charité Universitätsmedizin Berlin, Berlin, Germany; [2]Dept. of Neurology, Charite Universtätsmedizin Berlin, Berlin, Germany

Abstract: Amyotrophic lateral sclerosis (ALS) is characterized by a progressive degeneration of upper and lower motor neurons. Beyond motor symptoms, up to 50% of patients develop cognitive deficits of executive function, memory, language, and social cognition. Consistent with these impairments, recent studies found ALS-specific hippocampal pathologies including atrophy and shape alterations. However, the behavioral relevance of hippocampal damage remains unclear since it can be observed in patients without overt memory deficits. We investigated hippocampus-dependent behavior in ALS with a spatial navigation paradigm.
Sample: Forty-five ALS patients (13 f., 32 m.) were included. Thirty-four patients were diagnosed with

typical amyotrophic lateral sclerosis (upper and lower MN affected), four with primary lateral sclerosis (upper MN-variant of ALS) and seven with progressive muscular atrophy (lower MN). Patients with fronto-temporal dementia were not included. On average, patients were 60.3 years old and diagnosed 20.2 (0-114) months before testing. All patients had sufficient hand motor function to control a joystick (ALS-functional rating scale (FRS): mean 39.3 (29-46); FRS-progression / month: mean: 0.40 (0.05-2.33)). Additionally, forty-five age-, sex- and education-matched healthy controls were tested.
Methods: Participants performed a spatial navigation task that requires memory-guided navigation based on landmarks and/or memory of movement sequences. Previous studies suggest that these navigational patterns depend on hippocampal integrity. Furthermore, we administered neuropsychological tests for spatial memory, spatial fluency and perspective taking. Results: Contrary to our expectations, we did not find impaired performance in patients relative to controls in landmark-based or sequence-based spatial navigation. We also did not find deficits in neuropsychological measures for immediate and delayed spatial memory, spatial fluency and perspective taking.
Discussion: Our findings argue against clinically relevant spatial memory and navigation deficits in early- to mid-stage ALS patients. Previous studies showed that memory and executive functions remain rather stable during disease progression, suggesting that impairments should present already at disease onset. These and our findings can be reconciled by assuming significant cognitive reserve in ALS patients mitigating the behavioral effects of hippocampal dysfunction, even in behavioral contexts that usually recruit the hippocampus.

Title: The relationship between navigation abilities and mental disorders

Authors: N. HATAMIAN, R. F. WOODRY, B. TRANQUADA-TORRES, A. YEE, E. R. CHRASTIL; Univ. of California, Irvine, Irvine, CA

Abstract: This study examined the relationship between aspects of navigational ability and behavioral traits associated with various mental disorders. We propose that navigational ability may utilize the same brain circuitry that has dysfunction in certain mental disorders and may be a beneficial early marker for these disorders. This study was inspired by the Research Domain Criteria (RDoC), a framework outlined by NIMH to study the basic dimensions of functioning that span the range of behavior from normal to abnormal. For example, we hypothesized that spatial perspective taking, which is important for navigation, could be associated with social perspective taking in disorders such as autism spectrum disorder or eating disorders. To test this question, participants recruited online through Amazon

Mechanical Turk (n>350) completed two web-based spatial cognition tasks and a self-report measure of navigational ability. They also completed a battery of standardized questionnaires to capture non-pathological ranges of mental disorders. The Open Field Task (OFT) is similar to a virtual Morris water maze. It tests an individual's ability to recall, locate, and navigate to four hidden objects scattered in an open field environment from a first-person perspective. The Spatial Orientation Task (SOT) tests spatial perspective taking by imagining different viewpoints in a layout of objects. The Santa Barbara Sense of Direction Scale (SBSOD) is a self-report measure of navigational ability. The behavioral questionnaires assessed pathological and non-pathological levels of mental disorders such as depression, anxiety, autism, and schizotypy to examine individual variability within the healthy population. Preliminary correlations indicate relationships between navigational ability and several mental disorders. In particular, obsessive-compulsive disorder and impulsivity showed relationships with performance errors in the SOT. These preliminary results also identify relationships between apathy as well as eating disorders and errors in the OFT. Together, these findings suggest that the circuitry for navigation and certain mental disorders could overlap, leading to new avenues for understanding these disorders.

Title: The Effect of Aging on Basal Cortisol in Participants using Spatial versus Response-dependent Navigation Strategies

Authors: *G. WEST;
Univ. of Montreal, Montreal, QC, Canada

Abstract: This study examined how the relationship between endogenous cortisol, navigation strategy, and episodic memory is affected by age. We compared cortisol samples collected from a group of healthy younger adults (N = 66; mean age= 21.7) with samples collected from a group of older adults (N= 139, mean age= 65.77). All participants completed the 4-on-8 virtual maze task (4/8 VM) and neuropsychological measures of memory (i.e., Rey-Osterrieth Complex Figure Test (RO); Rey Auditory Verbal Learning Test (RAVLT). The 4/8 VM is solved using one of two spontaneous navigation strategies while learning the new environment. The spatial strategy involves learning the relationship between environmental landmarks and is associated with increased grey matter and activity in the hippocampus. In contrast, the response strategy involves using a rigid pattern of turns and is associated with increased grey matter and activity in the caudate nucleus. Our previous work has shown that basal cortisol is higher in young adult spatial learners compared to response learners. Further, higher basal cortisol levels are associated with increased spatial memory performance amoungst spatial learners while

higher cortisol is detrimental to spatial memory performance of response learners. In the current study, we found that with age, older adult spatial and response learners had equally low basal levels of cortisol, similar to young adult response learners. When comparing the older and younger adult groups, we found that cortisol levels appear to decrease with age uniquely amoungst spatial learners. No significant difference in neuropsychological measures of memory between older spatial and response learners were observed. Results are discussed in the context of previous work demonstrating that older spatial learners display more grey matter in the hippocampus and that a decrease in basal cortisol with age from a previous higher point is associated with better cognitive outcomes.

Title: Reinforcement learning models quantify behavioral dynamics underlying threat learning in anxious and healthy adults

Authors: *J. NAPOLI[1], R. ABEND[1], S. G. RUIZ[1], A. L. GOLD[1], J. C. BRITTON[2], K. J. MICHALSKA[3], T. SHECHNER[4], A. M. WINKLER[1], E. LEIBENLUFT[1], D. S. PINE[1], B. B. AVERBECK[5];

Abstract: Learning about potentially harmful stimuli and events is critical in shaping adaptive behavior in a changing environment. This type of learning, in which one forms an association between neutral stimuli and aversive outcomes, is known as threat learning. Several influential neurodevelopmental theories propose that person-to-person variation in this process can result in varying anxiety symptoms. Here, we studied a sample of people with a wide range of age and anxiety severity on a threat learning task, and used computational models to quantify the mechanisms underlying their behavior. Finally, we tested the parameters estimated by our models to discover links among the threat learning processes, neuroanatomical substrates, and anxiety severity. Our participant sample consisted of 215 individuals, made up of both those with anxiety and healthy volunteers ranging from 8-50 years old. Participants engaged in a threat learning task, in which photographs of two women displaying neutral expressions served as the conditioned threat and safety stimuli (CS+ and CS-, respectively). The unconditioned stimulus (UCS) was a presentation of the same actress displaying fear and co-occurring with a female scream, immediately following the CS+. Structural MRI images of the subjects were taken and skin conductance responses were recorded while the participants engaged in the task. We used the skin conductance data to model the learning effects, and used the parameters estimated from our models to assess associations among this behavior, whole-brain morphometry, anxiety severity, and age. We found

that threat conditioning was optimally modeled with a Rescorla-Wagner model that featured Bayesian learning and response decay terms. A lower threat generalization rate, the rate at which participants acquired a fear response to the CS-, was significantly associated with higher anxiety severity, but only in participants under the age of 13 years. Next, we will be looking at correlations between the parameters of our extinction model with anxiety, age and brain morphometry. Ultimately, these findings relate the dynamic processes underlying threat learning to neuroanatomy and learning theories of anxiety.

Title: Bad from the start: Pupil diameter and fixational eye movements distinguish aversively-associated from innocuous visual locations

Authors: *W. M. FRIEDL, S. R. MILTENBERGER, A. KEIL;
Psychology, Univ. of Florida, Gainesville, FL

Abstract: Learning environmental cues that predict aversive events aids animate beings in avoiding foreseeable harm, promoting survival. To illuminate neural foundations of aversive associative learning outside of the traditional “fear circuit” centered on the amygdala, pupil activity and gaze direction of human participants (N=51, mean age=19.49, 19 male) undergoing classical aversive conditioning were recorded. High-contrast Gabor patches were individually presented at one of five different on-screen locations, with only one spatial location paired with an aversive 90 dB white noise auditory stimulus for the final 200 (out of 350 total) trials. Both pupil activity and rapid, intermittent deviations from fixation (microsaccades) showed responses indicating a binary discrimination between noise-paired and unpaired locations. Bayes factors strongly support a paired-versus-unpaired distinction in pupillary responses beginning approximately 1 second following stimulus onset and persisting throughout the remainder of a trial. Meanwhile, microsaccades towards the spatial location of the aversivly-paired Gabor patch were relatively inhibited from 200-400 milliseconds post stimulus onset. These results indicate that learning aversive associations via classical conditioning impacts perceptual processing from the very earliest stages. Specifically, both the autonomic nervous system-mediated pupillary response and the microsaccade generating circuit featuring the superior colliculus and pontomedullary reticular formation selectively respond to conditioned spatial locations. Furthermore, neither pupillary re-dilation nor microsaccade rate differentiate between non-conditioned locations as a function of distance from the

aversivly-associated Gabor location. Exploratory results presented here enrich previously reported findings of graded response changes in visuocortical population-level activity when viewing conditioned spatial locations.

Title: Identifying the neurocognitive role of associative memory in acute stress-induced craving to smoke

Authors: *J.-H. LEE[1], S. KANG[1], S. U. MAIER[3], S. LEE[2], W.-Y. AHN[1,2];

Abstract: Tobacco use disorder has a chronic course that is characterized by repeated relapse. Previous studies have revealed several triggers of relapse including stress and exposure to drug cues. While literature suggests that both stress and the memory system play a critical role in relapse to tobacco use, it remains unclear (1) how stress affects memory associated with drug cues (2) whether craving for smoking is related to drug-specific associative memory. Here, we developed a novel laboratory task to investigate the effect of stress on smoking-associated memory and the urge to smoke. We first created a controlled set of visual stimuli consisting of pairs of scenes with the same background but differing in their foreground object's association with smoking and plain objects (e.g., a cigarette vs, a pen). In Study 1, a group of smokers was recruited to validate the stimuli set on their arousal, valence, and subjective complexity ratings. In Study 2, an independent group of smokers seeking abstinence were recruited for two visits that took place on two consecutive days. On the first visit, participants performed an encoding task to build associations between smoking/neutral items and the background contextual scenes. On the second visit, participants were tested on their associative memory from the first day and reported their preference for each stimulus. We used the socially evaluative cold pressor test (SECPT) to induce psychosocial stress. Subjective level of perceived stress and salivary cortisol was collected to ensure the manipulation of stress. Based on the preliminary results, we hypothesize that (1) smokers under stress would show better memory of scenes related to smoking and that (2) this memory bias would be associated not only with a bigger urge to smoke but also with a higher preference in smoking-associated neutral stimuli. These findings will shed light on the role of associative memory bias in stress-induced craving for tobacco.

Title: Multimodal interrogation of statistical learning and episodic memory in human epilepsy

Authors: *A. ALJISHI[1], B. E. SHERMAN[2], D. M. HUBERDEAU[2], A. SIVARAJU[3], N. B. TURK-BROWNE[2], E. C. DAMISAH[1];

Abstract: Memory impairment is a direct and leading cause of morbidity in all forms of epilepsy. Prior human studies suggest that Episodic Memory (EM; i.e., ability to remember individual events) and Statistical Learning (SL; extraction of patterns over time and space) both depend on the medial temporal lobe (MTL). EM has been the focus of most memory-related studies in epilepsy, yet it is not known whether SL and EM are equally affected in epilepsy. To address this gap, we developed novel behavioral methodologies combined with structural imaging and functional interrogation of the MTL. 38 epilepsy patients and 29 age- and sex-matched healthy controls underwent computer-based behavioral testing designed to separately evaluate SL and EM. Clinical data, including seizure frequency, seizure onset zone (SOZ), MTL structural abnormalities, and antiepileptic drugs (AEDs) taken, were obtained from the patient cohort clinical profiles. Manual segmentation of MTL was performed in 25 of the patients to obtain volumes of structures using MRI scans. Multivariable regression and analysis of variance for the behavioral scores and clinical characteristics showed that seizure frequency was the most important predictor of SL: patients with poorly controlled seizures performed worse in SL relative to healthy controls and patients with well-controlled seizures. Notably, seizure frequency did not predict EM performance. Rather, consistent with prior literature, anti-seizure medications and the presence of MTL lesions were the most important predictors of EM. Volumetric analysis of MTL demonstrated correlations between SL performance and MTL volumes within epilepsy patients. To assess the causal role of the MTL in SL, a subset (4) of epilepsy patients underwent 1-Hz direct electrical stimulation (DES) designed to temporarily inactivate function in the MTL. Transient DES of the hippocampus during the learning phase of the SL task led to impaired SL performance. This impairment was specific to the MTL: no impairment resulted from stimulating a control non-MTL region. Together, these results suggest that SL is a hippocampal-dependent learning system affected by seizure severity in epilepsy patients. Further, compared to EM, SL was a better predictor of cognitive function in epilepsy. These findings may lead to a more comprehensive understanding of memory impairment in epilepsy, and provide an assortment of patient-centered memory-related endpoints used to evaluate the efficacy of novel treatments.

Title: Modality-specific parameters and interference contribute to better-fitting bimodal associative learning models

Authors: H. D. HUANG[1], F. R. BAUMGARDT[1], B. LAHNER[2], *R. M. G. REINHART[1];
[1]Boston Univ., Boston, MA; [2]MIT, Boston, MA

Abstract: Perceiving and processing different sensory inputs are crucial to understanding adaptive learning. Here, we develop and validate a computational model that combines the prediction-error updating of reinforcement learning with the fast, robust componentry of working memory to examine the role of interference between auditory and visual stimuli. Human subjects performed a bimodal associative learning task, in which, on each trial, a single visual or auditory stimulus was mapped to a button-press response. New stimulus-action pairings were randomly selected at the beginning of each block, and subjects had to learn the correct pairings based on binary feedback at the end of each trial. We adopted a Reinforcement Learning Working Memory (RLWM) framework from previous studies with two major modifications: 1) each modality can take on different parameter values and 2) pairings can interfere with each other between modalities and between blocks. Our results show that model instances embedded with the above modifications can better describe bimodal learning. Learning rates were generally higher at the beginning of each block when new pairings were introduced and later decreased, while perseveration started low and later increased, suggesting that the participants became more adept at the task and more prone to sporadic errors as they reached a steady state of learning. Interestingly, the group of subjects who showed improved learning over time were best fitted by a different model (RLWM with all interference) compared to those who did not (RL with no interference from the opposite modality in the previous block). This suggests that a strategy towards improved learning involves utilizing a broader range of previous knowledge and a balanced mixture of both RL and WM components. For the improved group, the weighting towards WM increased with task familiarization, which likely relates to the higher decay rate of the Q matrices for the RL component compared to the non-improved group. Additionally, learning rate and perseveration seem to have reached a steady state in later blocks for the improved group, while substantial fluctuation upon new pairing introduction was observed for the non-improved group. The results show that the nuance of bimodal learning is better captured by separate sets of parameters, that different kinds of interference (or prior information) play a role in successive learning, and that different learning strategies could be identified by computational behavioral models. Future research seeking to identify the neuroanatomical loci and neurophysiological events associated with key parameters from our model is implicated.

Title: Evolution of problem-solving strategies with learning and architecture in recurrent neural networks

Authors: *B. TSUDA[1,2], B. J. RICHMOND[3], T. J. SEJNOWSKI[2,1];
[1]UCSD, La Jolla, CA; [2]Salk Inst. for Biol. Studies, La Jolla, CA; [3]NIMH, Bethesda, MD

Abstract: Objective and Rationale--Problems can often be solved by multiple strategies. Recent studies of humans and monkeys have provided evidence of such variability in strategy adoption for problem solving, yet the underlying neural basis for the strategy differences is unknown. We adopted a computational modelling approach to help elucidate how two critical network features - network size and amount of experience - may lead to unique problem-solving strategies when encountering the same problem. Following the observation by Wittig et al. (2016, *Learning and Memory*) that monkeys and humans adopt different strategies on a set of working memory tasks, we trained recurrent neural network models of different sizes on the same tasks and analyzed their strategy development and progression throughout learning.
Methods--For our studies, we used recurrent neural networks (RNNs; long-short term memory networks in our implementation) that have been demonstrated in prior works to be useful models of working memory computations in the brain. The networks were trained by reinforcement learning on computational implementations of the three tasks from Wittig et al. 2016. For each task, we varied the size of the RNNs (n=[5,10,25,50,100,200,500]) and the amount of training (task episodes=[0,10,20,30,40,50]x10^3) and ran 10 independent replicate RNNs per condition. We then assessed network strategy by measuring two main metrics derived from results reported in Wittig et al. 2016: non-target yes-response linear fit slope and residual. Using these two metrics we could effectively identify different strategies employed and any switching between them during training.
Results--We found that networks evolve from non-selective to selective response strategies with more experience, while able to achieve relative task proficiency across both strategies. Larger network sizes led to more rapid transitions from non-selective to selective strategy during training, even when overall task performance remained similar. Interestingly, on particular tasks we observed that networks' strategies progressed through an evolution of a random-non-specific response strategy, to a recency-based strategy, and finally to a highly selective strategy.
Conclusions--These results recapitulate key aspects of the strategy differences observed by Wittig et al. between monkeys and humans on these tasks. Our results suggest monkeys may adopt different strategies from those used by humans due to limitations of learning speed and neural capacity that constrain what neural computations they can use to perform the task.

Title: Effects of depressive symptomatology on reversal learning in a probabilistic classification task

Authors: C. Y. FRANCO, H. P. DE GUZMAN, *B. J. KNOWLTON;
Psychology, UCLA, Los Angeles, CA

Abstract: Depression and substance use disorders are highly comorbid, suggesting that common neurocognitive mechanisms may contribute to both. Here we examine the idea that measures of depression may be related to increased habitual responding, leading to increased liability for substance use disorders. To investigate this relationship, 44 young adults (21 ± 3.26 years old) completed a version of the Weather Prediction Task (WPT), a classification task in which cues were associated with two outcomes ("sun" or "rain") probabilistically. After 100 trials, the probabilities were reversed for each cue stimulus unbeknownst to the participant and they completed another 100 trials with the new probabilities. We calculated habitual responding as the preponderance of initial contingency responding during the probabilistic reversal phase, indicating reduced flexibility and goal-directed responding. Participants completed questionnaires examining early-life stress (Childhood Trauma Questionnaire), depression (Beck Depression Inventory [BDI]), state and trait anxiety (State-Trait Anxiety Inventory [STAI]), and subjective SES (MacArthur Scale of Subjective Social Status). Results from linear regression analyses revealed significant interactions concerning subjective SES with BDI (b = -0.007, p = 0.012, η^2 = 0.005) and state anxiety scores (b = 0.006, p = 0.012, η^2 = 0.165) on the measure of habit responding. These results reveal differential effects of depression and anxiety on habit responding dependent on perceptions of socioeconomic status. In particular, among individuals with lower perceptions of SES, individuals with higher BDI scores (b = 0.0134, p = 0.004) and lower state anxiety scores (b = -0.0124, p = 0.006) are expected to exhibit greater habit responding. Results further revealed a significant interaction between subjective SES and BDI scores on lose-shifting behavior in the reversal phase of the WPT (measured as the proportion of response shifting based on previously incorrect answering; b = -0.004, p = 0.023, η^2 = 0.0167), such that among individuals with lower perceptions of SES, individuals with higher BDI scores exhibit a greater proportion of lose-shifting behavior during the reversal phase (b = 0.006, p = 0.027), consistent with previous research suggesting a hypersensitivity to punishment in people experiencing symptoms of depression. These results support the involvement in depression of striatal circuits that have been shown to subserve stimulus-response learning and processing aversive outcomes. Our results also indicate that SES modulates the effect of depression on these behavioral measures.

Title: Oscillatory Mechanisms of Context Dependent Cognitive Maps in Human Memory

Authors: *O. ASHMAIG[1], K. R. SHERRILL[3], N. W. MORTON[5], L. L. COLGIN[4], R. J. BUCHANAN[6], A. R. PRESTON[7], A. WATROUS[2];
[2]Neurol., [1]Univ. of Texas at Austin, Austin, TX; [4]Ctr. for Learning and Memory, [3]Univ. of Texas At Austin, Austin, TX; [5]The Ctr. for Learning & Memory, The Univ. of Texas at Austin, Austin, TX; [6]Neurosurg., Seton Brain and Spine Inst., Austin, TX; [7]The Univ. of Texas At Austin, Austin, TX

Abstract: Everyday choices depend on the situation in which they are made, such as packing for a trip differently based on the destination. Dominant theories posit that context-guided memory relies on both associating and separating representations for objects, values, contexts, and locations. Rodent studies show that the hippocampus (HPC) encodes these cognitive maps in a hierarchy based on their behavioral relevance and that the medial prefrontal cortex (mPFC) then provides top-down signals to refine context-sensitive representations. Much less is understood about the mechanisms that support context-dependent behavior in humans. We analyzed intracranial recordings from epilepsy patients as they performed a VR-based associative memory task with context-dependent reward values. We first identify behavior-dependent theta and high-frequency gamma activity using our recently published oscillatory detection algorithm (ORCA) and then employ a novel, phase-based representational similarity analysis to characterize phase coded representations. We show that theta-gamma phase-amplitude coupling (PAC) within the HPC and mPFC provides temporal coordination for the formation and expression of context-dependent memory. Combining novel behavioral and signal-processing methods with analysis of human recordings, this project suggests that oscillations within HPC and mPFC support context-dependent choice.

Title: Successful context-dependent associative rule learning involves tuning the dimensionality of representational spaces

Authors: *S. S. P. LIAPIS[1,2], A. E. CHANG[2,3], J. T. MCGUIRE[1,2,3], C. E. STERN[1,2,3];
[1]Grad. Program for Neurosci., [2]Cognitive Neuroimaging Ctr., [3]Psychological & Brain Sci., Boston Univ., Boston, MA

Abstract: Prior research has identified a prominent role for prefrontal cortex (PFC) and medial temporal lobe (MTL) regions in context-dependent rule learning. Here, we sought to explore whether these regions mediate flexible learning by maintaining a high-dimensional space for activity patterns encoding possible rules, while simultaneously pruning away irrelevant features from the problem space, effectively tuning the dimensionality of representational space. To test this hypothesis, we re-analyzed an existing dataset from an fMRI study of healthy adults learning context-dependent associations (Morin et al., 2021). Participants (N=30) learned, through trial and error, rules linking cues and associates depending on their spatial context. We employed a data-driven approach to examine the dimensionality of representations for cues and associates (Mack et al., 2020). Voxelwise activity patterns for each presentation of a cue or associate were extracted using beta-series regression (Mumford et al., 2012). We then derived a dimensionality score for these representations using principal components analysis. We predicted greater dimensionality for cue relative to associate representations as well as a decrease in dimensionality over the course of learning. We also expected greater dimensionality for cue representations in participants who learned the task compared to those who failed to do so. Lastly, we anticipated that dimensionality would explain learning by tracking accuracy over the course of the experiment. The results demonstrated higher-dimensional representations for cues relative to associates in PFC and MTL areas. Additionally, cue patterns were higher-dimensional for successful learners, while associate patterns were similar across learners and non-learners. Over the course of learning, PFC and MTL representational spaces were compressed. However, successful learners diverged from non-successful participants over time, limiting compression to maintain higher-dimensional representations. Within PFC, we found that representational dimensionality in orbitofrontal cortex tracked accuracy over time. These findings are consistent with the use of higher-dimensional representations to encode rule relationships while filtering out irrelevant features. The results suggest that PFC and MTL regions facilitate context-dependent associative rule learning by balancing the compression and maintenance of high-dimensional representational spaces and that dimensionality is a key marker of learning.

Title: Mechanisms and dynamics of statistical learning across levels of abstraction

Authors: *B. E. SHERMAN[1], A. ALJISHI[2], K. N. GRAVES[1], I. H. QURAISHI[3], A. SIVARAJU[3], E. C. DAMISAH[2], N. B. TURK-BROWNE[1,4];
[1]Psychology, [2]Neurosurg., [3]Neurol., [4]Wu Tsai Inst., Yale Univ., New Haven, CT

Abstract: We regularly encounter the same objects, people, and places, and they appear in predictable configurations and sequences across experiences. The human brain is deftly attuned to such structure, quickly extracting spatial and temporal regularities via statistical learning. Recent studies have used a technique known as frequency tagging to detect the representation of such structure in the brain during scalp and intracranial EEG. Frequency tagging capitalizes on neural entrainment to stimuli presented at a regular rate, but can also reveal learning by tracking entrainment to the frequency of repeating sequences (even in the absence of segmentation cues). In past studies, these sequences consisted of multiple repetitions of the exact same stimuli in a particular order. However, regularities in the real-world often involve variance across repetitions (e.g., different speakers of the same language, the layout of sections in different grocery stores, traffic patterns and detours on a daily commute). Accordingly, a critical function of statistical learning is to generalize across this variance to represent more abstract regularities. Here we test how the human brain generalizes during statistical learning using frequency tagging in epilepsy patients with intracranial EEG. Patients were presented with series of scene photographs that contained regularities at one of two levels of abstraction. In the exemplar-level condition, the same scene images were presented repeatedly in pairs (e.g., scene A was always followed by scene B). Consistent with prior work, we found reliable entrainment at the frequencies of both the images and pairs, suggesting statistical learning of the pairs. In the category-level condition, all scene images were trial-unique, but certain subcategories were reliably paired (e.g., a beach was always followed by a mountain). We again found reliable entrainment at the frequencies of both images and pairs. Because the pair structure existed at only the level of categories, this demonstrates abstraction during online statistical learning. This extends prior work in which categorical statistical learning was revealed through behavioral tests, which could have been supported by abstraction at test rather than during learning as shown here. We found reliable overlap in the electrode contacts that entrained to image and pair frequencies across conditions, with the effects manifesting primarily in visual cortex. In ongoing work, we are testing the hypothesis that the hippocampus is causally involved in statistical learning, examining whether cortical frequency tagging is altered by hippocampal stimulation.

Title: Altered functional connectivity in late middle-aged and older patients with obstructive sleep apnea

Authors: *G. MARTINEZ VILLAR[1,2], V. DANEAULT[1,2,3], M.-È. MARTINEAU-DUSSAULT[1,2], C. ANDRÉ[1,2], A.-A. BARIL[2,4,5], C. LAFOND[1,2], J. MONTPLAISIR[1,2], J. CARRIER[1,2], N. GOSSELIN[1,2]; [1]Univ. de Montréal, Montréal, QC, Canada; [2]Ctr. for Advanced Res. in Sleep Medicine, Hôpital du Sacré-Coeur, Montréal, QC, Canada; [3]Univ. of Sherbrooke, Montréal, QC, Canada; [4]McGill Univ., Montréal, QC, Canada; [5]Douglas Mental Hlth. Inst., Montréal, QC, Canada

Abstract: Background: Obstructive sleep apnea (OSA) is associated with changes in resting-state functional connectivity (FC) in young and middle-aged adults. These changes especially occur between regions of the Default Mode Network (DMN) and the limbic system, which are known to be crucial for cognitive and memory functions. However, it remains unclear whether these changes are also observed in older adults with OSA, who could be at risk of cognitive decline. **Objective**: To characterize the association between OSA severity indices and resting-state FC among regions of the DMN and the limbic system in late middle-aged and older adults. **Methods:** 97 participants (25 females; 65.8±7.0 years old; 15.3±3.3 years of education) underwent a neuropsychological assessment, full-night polysomnography and 3T magnetic resonance imaging protocol including a 3D T1-weighted (MPRAGE) and 2 resting-state fMRI time series (T2*-weighted). OSA severity was reflected by the apnea-hypopnea index (AHI), the oxygen desaturation index and the microarousal index. The whole sample included 24 controls, 36 participants with mild OSA ($5 \geq AHI < 15$) and 37 individuals with moderate to severe OSA ($15 \geq AHI$). CONN toolbox was used to perform multiple regression analyses between OSA severity variables and FC values between each pair of regions of interests of the DMN (medial prefrontal cortex, posterior cingulate cortex, precuneus and lateral parietal lobes) and limbic system (hippocampi and parahippocampal gyri). All analyses were performed while controlling for age, sex and level of education. **Results:** Greater OSA severity (higher apnea-hypopnea and oxygen desaturation indices) was associated with lower FC between the hippocampi and multiple regions including medial prefrontal cortex, posterior cingulate cortex, precuneus, lateral parietal lobes and parahippocampal gyri ($Fs > 4$; $ps < 0.05$ FDR-corrected). Moreover, higher apnea-hypopnea index was associated with higher FC between the anterior and posterior parahippocampal gyri ($F=5.88$; $p=0.017$ FDR-corrected). No significant association was found between the microarousal index and FC values. **Conclusions:** Greater OSA severity in late middle-aged and older adults is associated with decreased FC between the hippocampi and multiple regions of the DMN and limbic system, and increased FC within the parahippocampal gyri. Further analyses will aim at testing whether these FC changes predict cognitive decline, and whether treating OSA may normalize FC patterns.

Title: Dual-task exercise program for older adults with mild cognitive impairment: a randomized controlled trial

Authors: *S. JUNG;
Dept. of Rehabil. Med., Seoul Natl. Univ. Boramae Med. Ctr., Seoul, Korea, Republic of

Abstract: INTRODUCTION Dual-task (DT) exercise training is a multidimensional exercise intervention that combines motor and cognitive tasks to affect on motor-cognitive interplay. We aimed to investigate the effect of DT exercise program on cognitive, physical, and psychological function of older adults with mild cognitive impairment (MCI). **METHOD** Twelve older adults with MCI (MOCA-K≤25 or K-MMSE≤28) were recruited and randomized either to an exercise group (n=6) or to control group (n=6, Table 1). The exercise group underwent 8-week, 60-minute group exercise sessions, 3 times a week, with moderate intensity exercise combined with simultaneous cognitive tasks. They also performed moderate intensity weekly home aerobic exercises for 60 minutes or longer for 8 weeks. The control group performed 60-minute home stretching and yoga sessions, 4 times a week for 8 weeks after an initial exercise education. DT cost, cognitive function, physical performance, body composition, level of physical activity, health-related quality of life, and exercise psychology were assessed at baseline and after the intervention. Resting state functional brain MRI were also obtained at baseline and after the intervention. **RESULTS** The ratings of perceived exertion was 6.02±0.52 for exercise group. The amount of physical activity during the intervention period was higher in exercise group (35379.0±15785.4 MET min/week) than control group (19833.0±8968.7 MET min/week). Exercise group improved significantly on DT cost (Figure 1), executive function, memory function, physical performance, leg lean mass, and exercise psychology. Exercise group showed significantly higher satisfaction on intervention than control group. There was no adverse event during the intervention. **CONCLUSION** DT exercise program which combined moderate intensity exercise with simultaneous cognitive tasks could improve cognitive, physical, and psychological function in older adults with MCI.

Title: Interaction of APOE ε4 and KIBRA T-allele on cognitive and neuroimaging markers in cognitively unimpaired older adults

Authors: *N. NIKKHAHMANESH[1], M. MALEK-AHMADI[2], Y. SU[2], V. DEVADAS[2], V. GHISAYS[2], J. LUO[2], Y. CHEN[2], H. PROTAS[2], K. CHEN[2], R. CASELLI[3], E. REIMAN[2];
[1]Univ. of Arizona, Scottsdale, AZ; [2]Banner Alzheimer's Inst., Phoenix, AZ; [3]Mayo Clin., Scottsdale, AZ

Abstract: Background: The ε4 allele of the APOE gene is a major genetic risk factor for Alzheimer's disease (AD) and decreased cognitive performance. T allele carriage of the kidney and brain (KIBRA) gene has demonstrated neuroprotective qualities for neuron survival, learning and memory, and network connectivity. Previous studies have demonstrated that KIBRA-T allele carriage is associated with increased hippocampal volume and episodic memory performance, however its interaction with APOE carrier status is unclear. The aim of this study was to assess the interaction of APOE genotypes with KIBRA genotypes on episodic memory and hippocampal volume in cognitively unimpaired (CU) older adults.
Methods: Data from 198 CU older adults age 65 years and older were analyzed from the Arizona APOE

cohort. Delayed Recall (DR) and Total Learning (TL) scores of the Auditory Verbal Learning Test (AVLT) were used as the dependent variables in linear mixed-effects models where a three-way interaction of Time, APOE ε4 carrier status, and KIBRA-T carrier status was used to assess longitudinal cognitive performance. Cross-sectional analyses were analyzed using generalized linear models (GLMs) where neuroimaging biomarkers for hippocampal volume, white matter hyperintensity volume, glucose metabolism, amyloid load, and tau load were used as outcome variables and the interaction of APOE ε4 carrier status and KIBRA-T carrier status was the predictor variable of interest. The LMEs and GLMs adjusted for age, sex, and education.
Results: The time-based interaction of KIBRA-T carrier status and APOE ε4 carrier status for AVLT DR was statistically significant (β = 0.15, 95% CI: (0.03, 0.26), p = 0.01) where ε4 carriers who lacked the KIBRA-T allele had the fastest rate of decline. APOE ε4 carriers who also carried the KIBRA-T allele had rates of decline that were similar to that of APOE ε4 non-carriers. A similar finding was noted for hippocampal volume among APOE ε4 carriers where KIBRA-T carriers had significantly greater volumes relative to KIBRA-T non-carriers (β = 7.35e-04, 95% CI: (8.12e-05, 1.39e-03), p = 0.03). No significant interactions for KIBRA and APOE were noted for the other neuroimaging outcomes. Significant main effects for APOE ε4 status were noted for hippocampal volume and glucose metabolism.
Conclusion: These findings indicate a neuroprotective effect associated with the KIBRA-T allele among APOE ε4 carriers on episodic memory and hippocampal volume. Although this effect was not found for other AD-related biomarkers, KIBRA-T allele carriage appears to mitigate the effects of age-related cognitive decline and hippocampal atrophy.

Title: Enduring memory improvements in older adults using high-definition transcranial alternating current stimulation

Authors: *W. WEN[1,2], S. GROVER[2], V. VISWANATHAN[2], C. T. GILL[2], R. M. REINHART[3];
[1]Peking Univ., Beijing, China; [3]Dept. of Psychological & Brain Sci., [2]Boston Univ., Boston, MA

Abstract: Normal and pathological age-related cognitive decline is characterized by a variety of memory impairments. Neuroscience studies have shown that synchronized activity in the theta-frequency band (3-8 Hz) of intraparietal lobe (IPL) is associated with working memory and synchronized activity in the gamma-frequency band (30-100 Hz) of dorsolateral prefrontal cortex (DLPFC) is associated with long-

term memory. Recent evidence using transcranial alternating current stimulation (tACS) in healthy young adults has suggested that these brain-behavior relationships may be causal. Yet, it remains to be seen whether working and long-term memory improvements can be selectively induced in an older population (65+ year) based on the spatiospectral parameters of tACS, and moreover, whether stimulation applied over multiple consecutive days can confer more potent and enduring memory benefits than a single "dose". Here, we conducted a randomized, double-blind, sham-controlled study (N=60) targeting the memory performance of older adults (68-88 years) with a chronic (4-day) administration of high-definition tACS (HD-tACS) designed to facilitate synchronous cortical activity in the high gamma range (60 Hz) of left DLPFC or the low theta range (4 Hz) of left IPL. During stimulation, subjects performed a classic auditory-verbal free recall task allowing us to isolate changes in long-term memory and working memory, separately, indexed by the canonical primacy and recency serial position curve effects. Memory performance was evaluated at baseline before intervention, on each stimulation day, and 1-month postintervention. Gamma HD-tACS preferentially improved the primacy effect at day 1, day 2, day 3, day 4, and 1 month, while theta HD-tACS preferentially improved the recency effect at day 3, day 4, and 1 month, relative to baseline. The rate of "online" memory improvement over 4 days predicted the size of "offline" memory benefits 1 month later at the group and individual level. Interestingly, baseline general cognitive performance played a significant role in determining stimulation effectiveness with low cognitive functioning older adults experiencing the largest and most enduring memory improvements. The results argue in favor of dual storage theories of human memory and set groundwork for developing circuit-based therapeutics aimed at improving memory in normal and pathological aging populations.

Title: Machine-learning defined precision tES for improving cognitive function in older adults

Authors: *A. ALBIZU[1], R. FANG[2], A. INDAHLASTARI[3], A. O'SHEA[3], S. E. STOLTE[2], K. B. SEE[2], E. M. BOUTZOUKAS[3], J. N. KRAFT[1], A. J. WOODS[3];

Abstract: Transcranial electrical stimulation (tES) is widely investigated as a family of therapeutic tools for enhancing cognitive function in older adults with and without neurodegenerative disease. Prior research demonstrates that direction and intensity of electrical current are essential features for producing favorable outcomes of stimulation. While these features are directly related to electrode placement and injected current, they vary extensively with differences in individual anatomy. This pilot study used machine learning and MRI-derived computational models of tES to define a personalized medicine strategy for transcranial electrical stimulation. Fourteen healthy older adults (age 65-87) received 20 min of 2mA tES stimulation (F3-F4) during a two-week cognitive training intervention. Computational models of tES current density were generated from T1-weighted MRI images to estimate the intensity and direction of the tES electric field. Constructed models were normalized to MNI space using the University of Florida Aging Brain-587 tissue probability map. Normalized maps were passed through a binary support vector machine-learning algorithm (SVM) to identify the critical features for producing tES-based working memory improvements. Weighted Gaussian Mixture Model (WGMM) optimization was used to optimize the electrode placement and injected current by maximizing the likelihood of treatment response in tES non-responders as well as within an independent sample of treatment naïve participants. Optimized models were passed back into the deployed SVM model for reclassification to assess the performance of the GMM. Optimization via GMM reduced inter-individual electric field intensity and direction variability by 61.7%. GMM optimization also produced an average treatment response likelihood estimate of 99.96%. The optimized models successfully converted 100% of non-responder predictions to responders within the deployed SVM. Similarly, 100% of independent treatment naïve optimization solutions were also successfully classified as responders. While clinical applications of tES have grown exponentially, reproducibility of these studies remains a challenge. At present, the optimal stimulation parameters remain unknown, making it difficult to ensure optimal treatment response on an individual basis. Findings from this study clearly demonstrate the advantages of employing personalized stimulation parameters in tES protocols through artificial intelligence and precision dosing. The current study provides a method to build personalized medicine models for a variety of therapeutic tES applications.

Title: Regional Cortical Thickness Predicts Top Cognitive Performance in the Elderly

Authors: *E. DOMINGUEZ[1], Y. REN[2], C. E. STARK[3];
[1]UC Irvine, Irvine, CA; [2]Univ. Of California, Irvine, Irvine, CA; [3]Univ. of California Irvine, Irvine, CA

Abstract: While aging is typically associated with cognitive decline, some individuals are able to diverge from the characteristic downward slope and maintain very high levels of cognitive performance. Prior studies have found that cortical thickness in the cingulate cortex, a region involved in information processing, memory, and attention, distinguish those with exceptional cognitive abilities when compared to their cognitively more typical elderly peers. Others major areas outside of the cingulate, such as the prefrontal cortex & insula, are also key in successful aging well into late age, suggesting that structural properties across a wide range of areas may better explain differences in cognitive abilities. Here, we aim to assess the role of regional cortical thickness, both in the cingulate and the whole brain, in predicting Top Cognitive Performance (TCP), measured by performance in the top 50th percentile of memory & executive function. Using data from National Alzheimer's Coordinating Center, we examined cognitively normal subjects aged 70-89. We found that, while thickness in cingulate regions can predict TCP status with some degree of accuracy, a whole-brain, network-level approach out-performed the localist, cingulate models. These findings suggests a need for more network-style approaches and furthers our understanding of neurobiological factors contributing to preserved cognition.

Title: Age-related differences in memory-guided decisions are driven by a trade-off between multiple decision systems

Authors: *S. M. NOH[1], T. K. KERR[1], I. J. BENNETT[2], A. M. BORNSTEIN[1];
[1]Cognitive Sci., Univ. of California Irvine, Irvine, CA; [2]Dept. of Psychology, Univ. of California, Riverside, Riverside, CA

Abstract: Recent findings have identified a key role in decision-making of memory content, in addition to reinforcement learning. This leaves open the possibility that observed decision-making difficulties in older adults are driven by age-related declines in memory, reinforcement learning, or both decision systems. In the present study, we examined the effect of aging on these memory-guided decisions in a lifespan sample of adults who completed a task that allowed us to separately assess the contributions of recent reinforcement, item memory, and context memory to choices. Participants learned to choose between 3 decks of cards with probabilistic rewards, where each trial was tagged with a unique object image to serve as item-level reminders of each choice (learning phase), and then continued to choose between the same 3 card decks with occasional presentations of a memory probe from the learning phase (test phase). At the group level, we found that these memory probes biased subsequent choices to be more consistent with the reminded trial from the learning phase, with a larger effect in older than younger

adults. Strikingly, however, whereas younger adult decisions were consistently influenced by a combination of both recent reinforcement and memory content, older adult decisions exhibited a marked trade-off between memory and reinforcement learning: Individuals who were more influenced by recent rewards were less influenced by memory, and vice-versa. These findings suggest that age-related differences in memory-guided decisions may stem from a focus on one decision system over another, perhaps reflecting the judicious use of limited cognitive resources.

Title: Baclofen partially rescues MK-801 induced circuit deficits

Authors: *P. JANZ[1], M. NICOLÁS[2], A. HONRUBIA[2], M. VALENCIA[2], R. REDONDO[1];
[1]Hoffmann-La Roche, Basel, Switzerland; [2]CIMA, Univ. of Navarra, Pamplona, Spain

Abstract: Cognitive deficits and impaired sensory processing are hallmarks of neurodevelopmental and neuropsychiatric disorders, such as schizophrenia and autism. N-Methyl-d-aspartate receptor (NMDAR) hypofunction is considered to contribute to these deficits by disrupting excitation-to-inhibition balance in neuronal circuits. Based on preclinical data, activation of GABAB-receptor is hypothesized to restore this imbalance, but its effect on translational electrophysiological circuit readouts is poorly understood.Therefore, we studied the physiology of limbic-auditory circuits under pharmacological NMDAR blockade (using MK-801) and GABABR activation (using Baclofen) in freely-moving rats, implanted with electrodes in key brain areas. The pharmacological effects were assessed using resting-state EEG, auditory-induced oscillation and mismatch-negativity paradigms.Across brain areas, MK-801 increased the power of both resting-state and auditory-induced brain oscillations, mainly in the gamma and higher frequency ranges. Baclofen partially normalized this aberrant oscillatory activity. Coherence analysis indicated that network interactions are substantially altered by MK-801, with increased functional coupling in limbic thalamocortical circuits in the gamma range, and increased coupling of the frontal cortex with the auditory cortex and the amygdala in the theta band. Baclofen normalized the coherence between frontal cortex and amygdala, but augmented the MK-801-driven increase in thalamocortical coherence. Finally, we report that Baclofen intensified the MK-801-induced deficits in auditory mismatch responses.In summary, while GABABR activation normalized gamma abnormalities upon MK-801, it disrupted functional coupling and context-dependent auditory processing. The complex circuit modulation by GABABR activation described in this study invites an updated interpretation of its therapeutic value for neurodevelopmental disorders associated with NMDAR-hypofunction.

Title: A dorsal hippocampus to ventral tegmental area polysynaptic pathway underlies psychomotor behavior in mice

Authors: *J. ZHANG, M. NAVARRETE, Y. WU, Y. ZHOU;
Florida State Univ., Tallahassee, FL

Abstract: The heterogeneity of psychiatric disorders poses major difficulties in deciphering the underlying etiology of these conditions. Thus, delineating clinical features of distinct neural circuits may provide paramount information that will facilitate a better understanding of the underlying pathophysiology. The mesolimbic dopamine (DA) system, which originates from DA neurons in the ventral tegmental area (VTA), is thought to be dysregulated in patients experiencing psychosis. However, the source of the disturbance and the underlying neural circuitry remain unknown. Here, we address these knowledge gaps by utilizing chemogenetics and neuronal activation analysis to dissect a polysynaptic circuit that originates from the dorsal hippocampus (dHP) in mice. We show that inhibition of 14-3-3, a family of schizophrenia-associated proteins, in the dHP activates VTA DA neurons, and such activation is necessary in eliciting novelty-induced locomotor hyperactivity (psychomotor behavior) in mice. We find that an increased activation of the lateral septum (LS) neurons is necessary for over-activation of DA neurons and psychomotor behavior induced by 14-3-3 inhibition in the dHP. Moreover, 14-3-3 inhibition-induced neuronal activations and behavioral alteration can be mimicked by selective activation of LS-projecting dHP neurons. Collectively, these findings demonstrate how loss of function of one pivotal family of proteins in the hippocampus contributes to activity alterations in the dHP-LS-VTA pathway, which may underlie key pathophysiology of schizophrenia-related symptoms.

Title: Phase modulation of resting-state fMRI BOLD signal in cases of schizophrenia with medication

Authors: *C.-Y. YU[1], S.-J. TSAI[1,2,4], A.-C. YANG[1,2,3,5];
[1]Inst. of Brain Sci., [2]Sch. of Med., [3]Digital Med. Ctr., Natl. Yang Ming Chiao Tung Univ., Taipei, Taiwan; [4]Dept. of Psychiatry, [5]Dept. of Med. Res., Taipei Veterans Gen. Hosp., Taipei, Taiwan

Abstract: Background and objectives: Few studies focused on the abnormal phase modulation of the time-frequency analysis in functional magnetic resonance imaging (fMRI) blood oxygenation level dependent (BOLD) signal in schizophrenia. The present research aimed to investigate the instantaneous phase relationship among different brain regions in individuals with schizophrenia (SCZ) on antipsychotic medication. We anticipated finding differences of phase coherence or phase difference from functional connections in certain brain regions between SCZ and healthy controls (HC). The association of antipsychotics with functional BOLD signal might be identified by using this novel signal analysis approach. **Methods:** The data in the study was from Taiwan Aging and Mental Illness Cohort (TAMI), which is an MRI and whole genome sequence study at Taipei Veterans General Hospital and National Yang-Ming University since 2012. The BOLD signals of 200 SCZ and 200 HC acquired from TAMI were analyzed with Hilbert-Huang Transform (HHT) and phase analysis at identified frequency bands. In addition, a two-sample t-test with Bonferroni correction was used for examining between-group differences. Finally, the forward stepwise method for multiple linear regression (MLR) models with significantly different connections and controlled demographic variables were built to predict Chlorpromazine (CPZ) dosage. **Results:** This study showed that six intrinsic mode functions (IMFs) were extracted from BOLD signal with ensemble empirical mode decomposition (EEMD) in HHT. The second IMF from EEMD was selected for analysis based on its neuronal correlates according to the previous study's recommendations. Subsequently, the between-group statistically significant number of connection pairs was 616 in phase coherence and 44 in phase difference, while five in both the two phase patterns. MLR models showed that CPZ dosage was associated with phase coherence between left caudate nucleus and left lenticular nucleus, pallidum, phase coherence between right cuneus and right middle occipital gyrus, phase coherence between right postcentral gyrus and right supramarginal gyrus, and phase coherence between postcentral gyrus and left inferior parietal, but supramarginal and angular gyri. **Conclusions:** Our findings using phase coherence and phase difference analysis of BOLD signal support the notion that antipsychotics are associated with alteration in functional brain network. These brain regions may be related to both treatment and side effects of antipsychotics.

Title: Designing a BCI to improve working memory in patients with schizophrenia

Authors: Y. LIN[1], *I.-W. SHU[2], S.-H. HSU[3], B. CASTILLO[2], R. SEN[2], V. GANDARA[2], J. A. PINEDA[4], E. GRANHOLM[2], F. SINGH[2];
[1]Electrical and Computer Engin., [2]Psychiatry, [3]Swartz Ctr. for Computat. Neuroscience, Inst. for Neural Computation, [4]Cognitive Sci., Univ. of California San Diego, La Jolla, CA

Abstract: *Intro*. Working memory (WM) is critical for optimal cognitive function and often impaired in patients with schizophrenia. Optimal WM performance requires greater neural synchronization in dorsal-lateral prefrontal cortical (DLPFC) areas of the brain (e.g., greater gamma power). Conversely, in patients with schizophrenia, impaired WM is generally associated with attenuated DLPFC activity, including decreased frontal gamma power. We thus hypothesized that training participants with schizophrenia to enhance frontal gamma activity would improve WM. *Methods*. We used EEGLAB (an open-source suite of MATLAB toolboxes) to design a brain-computer interface (BCI) enabling participants to practice increasing frontal gamma activity (i.e., gamma neurofeedback, or NFB). *Results*. To validate BCI effectiveness, we randomized participants with schizophrenia to active (n = 9) or mock (n = 7) gamma-NFB (twice-weekly 30 min sessions for 12 weeks). In support of BCI effectiveness, frontal gamma activity increased by about 0.26 standard deviations (SD) after active NFB, but fell by about 0.50 SD after mock NFB. Furthermore, active NFB improved WM performance by about 0.18 SD, in contrast to a decline of about 0.30 SD with mock NFB. Training-related changes in WM improvement positively-correlated with training-related changes in gamma activity (R = 0.380). Preliminary analyses indicate that active NFB produced greater frontal P3 event-related potentials (ERP), as well as greater frontal gamma and high beta power, during WM (e.g., N-Back); in contrast, mock NFB was associated with declines in frontal P3 amplitudes, no changes in frontal high beta power and a weaker increase in frontal gamma power. *Conclusions*. Gamma-NFB training using a EEGLAB/MATLAB-based BCI effectively increased frontal gamma activity, WM performance and WM-related ERP and high-beta/gamma activity in participants with schizophrenia receiving active NFB, compared to mock NFB. Future studies will focus on identifying neurophysiologic markers of brain changes underlying effective training/learning and improvements in WM performance.

Title: Comprehensive and simultaneous 3-D imaging of interneuron subtypes in CA1 depict deficits in interneuron activity resulting in microcircuit imbalance in a mouse model for the 22q11.2 deletion syndrome

Authors: *S. HERRLINGER, B. RAO, A. TUTTMAN, T. GEILLER, B. VANCURA, J. GOGOS, A. LOSONCZY;
Zuckerman Inst., Columbia Univ., New York, NY

Abstract: Adults and children with the 22q11.2 deletion syndrome (22q11.2DS) demonstrate cognitive, social and emotional impairments. 22q11.2 deletions are also one of the strongest genetic risk factors for schizophrenia (SCZ). Cognitive impairment in 22q11.2DS and in SCZ, in general, include episodic memory dysfunction. Episodic memory encoding is dictated in part by place cell activity and tuning in the CA1 region of the hippocampus. Using calcium imaging to record place cell activity in live behaving mice in a goal-directed learning and memory task our group previously showed that episodic memory and place cell dynamics in a mouse model for the 22q11.2DS (*Df(16)A*$^{+/-}$) are impaired. However, the mechanisms underlying these deficits are still unexplored. The activity of hippocampal place cells is under strong inhibitory control by several heterogeneous subtypes of GABAergic interneurons (INs). A wealth of evidence points toward deficits in local microcircuits and IN dysfunction as a key factor in the pathophysiology of SCZ; however, most studies have focused selectively on reduced parvalbumin-expressing IN activity, which is associated with disorganized network function in various mouse models for SCZ, despite recent studies implicating dysfunction in other IN types, including Somatostatin+, VIP+ and Neuropeptide Y+ expressing INs in various cortical circuits. Preliminary data further examining CA1 principal neuron dynamics and plasticity collected *in vivo* and *in vitro* suggest that inhibitory circuits are either over-compensating *in vivo* or are intrinsically deficient themselves. In addition, we know very little about how specific *in vivo* activity dynamics of hippocampal IN subtypes are affected by 22q11.2 deletions or other SCZ risk mutations, and we lack basic information on the activity dynamics of identified CA1 interneuron types during *in vivo* behavior in SCZ mouse models. We hypothesized that an inhibitory-disinhibitory microcircuit motif which gates CA1 place cell excitability and plasticity is disrupted by 22q11.2 deletions. We have tested these hypotheses by functionally and molecularly characterizing CA1 inhibitory circuits and their influence over CA1 place cell firing field formation during learning by carrying out large-scale, unbiased 3D AOD GCaMP-Ca^{2+} imaging *in vivo* of collective CA1 IN dynamics with post hoc molecular identification of IN types, and assessed baseline and learning-related changes in *in vivo* activity of INs in *Df(16)A*$^{+/-}$ and littermate controls. Preliminary results identify subtype-specific alterations in IN dynamics, contributing to microcircuit imbalances in this model.

Title: Optogenetic inhibition of posterior caudatoputamen indirect pathway neurons causes auditory cortical activation in rodents

Authors: *Z. YELLOWMAN[1], R. YANG[2], T. J. ZAFAR[1], E. M. NIKULINA[1], R. P. HAMMER, Jr.[1]; [1]Basic Med. Sci. & Clin. Translational Sci., [2]Basic Med. Sci., Univ. of Arizona Col. of Med., Phoenix, AZ

Abstract: The "auditory striatum" has emerged as a prominent source for regulating elements of auditory information. Our laboratory has shown that dopamine infusion into a region of the posterior caudatoputamen of rats activates neurons within the primary auditory cortex (Au1). This region of the caudatoputamen in rodents is analogous to the auditory striatum. We utilized optogenetics to explore the involvement of indirect pathway neurons in the context of auditory cortical activity. Indirect pathway neurons of the auditory striatum in adult male Sprague Dawley rats (~250 grams) were identified and unilaterally transfected with retroAAV expressing Jaws-GFP (#65014-AAVrg, Addgene; n=9), ChR2(H134R)-GFP (#58880-AAVrg, Addgene; n=6) or GFP (#50465-AAVrg, Addgene; n=7) by unilateral stereotaxic infusion into the globus pallidus (coordinates: -1.8 mm AP, 3.9 mm ML, -6.2 mm DV; Paxinos and Watson, 2013). Overexpression of the retrograde construct containing Jaws is known to inhibit neurons, while ChR2 overexpression activates neurons upon ontogenetic stimulation. Rats were implanted with an LED fiber optic probe targeting the auditory striatum, and wireless optogenetic stimulation was performed in sound-attenuated chambers for 30 min. Following perfusion and tissue processing, immunohistochemical labeling of Fos in the caudal striatum (-1.8 mm AP) and Au1 (-4.3 mm AP) were quantified and compared using one-way ANOVA. Fos labeling in Au1 was significantly greater in Jaws as compared to GFP ($p<0.001$) or ChR2 ($p<0.01$) groups. Ipsilateral Au1 showed significantly more Fos expression compared to contralateral Au1 only in the Jaws group ($p=0.001$). Significantly greater Fos labeling was present in striatal indirect neurons transfected with ChR2 compared to Jaws ($p<0.01$) or GFP ($p<0.01$), suggesting that ChR2 activated while Jaws inhibited these neurons. Indirect striatal projection neurons are less likely to fire in the presence of dopamine due to their predominant expression of D_2-like receptors. We show here that optogenetic inhibition of caudal striato-pallidal neurons significantly increased Fos expression in Au1. By contrast, Au1 activation present during auditory hallucinations is presumably blocked by antipsychotic drug-induced D_2-receptor antagonism. Therefore, dopamine- or optogenetically-induced inhibition of auditory striatal indirect pathway neurons may lead to activation of Au1 neurons, producing a perception of auditory activity. These findings may elucidate a pathophysiological mechanism underlying auditory hallucinations as defined within a novel auditory striato-pallido-thalamo-cortical brain circuit.

Title: Haloperidol pretreatment reduces auditory cortex Fos expression caused by posterior striatal dopamine infusion in proestrus female rats

Authors: T. J. ZAFAR, Z. YELLOWMAN, E. M. NIKULINA, *R. P. HAMMER, Jr.;
Basic Med. Sci. & Clin. Translational Sci., Univ. of Arizona Col. of Med., Phoenix, AZ

Abstract: Schizophrenia-related brain mechanisms are poorly understood, but a prevalent theory involves dopamine over-stimulation as all major drug treatments block D_2-like dopamine receptors (D2Rs) in the brain. We have shown that 50 nM dopamine infusion into the auditory striatum activates primary auditory cortex (Au1) in male and female rats, and dopamine increases Au1 Fos expression during proestrus, but not other stages of the estrous cycle. To determine whether D2R antagonist pretreatment would block dopamine-induced Fos expression in Au1, haloperidol was administered prior to striatal dopamine infusion in proestrous female rats. We hypothesized that haloperidol pretreatment would inhibit Fos expression in the Au1 after striatal dopamine infusion in female rats. Infusion cannulas were implanted targeting the posterior caudatoputamen (CP; AP: -1.80 mm, ML: 4.4 mm, and DV: 5.0 mm), and daily vaginal smears were conducted to determine the estrous stage. While in proestrus, rats received systemic haloperidol pretreatment (0 or 0.5 mg/kg, IP in saline vehicle). Rats were then transferred to a sound-attenuated chamber with 70 dB background noise and 30 min later received striatal infusion of dopamine (0 or 50 nM in saline vehicle) at 0.2 µl/min for 5 min, then were returned to the sound-attenuated chamber for 90 min (n=6 per group). Twenty µm sections from CP and Au1 were processed for Fos immunolabeling with statistical comparisons by 2-way ANOVA and Tukey's tests. Striatal dopamine infusion following saline pretreatment significantly increased Fos expression in the CP ($p < 0.0001$) and in the Au1 ($p < 0.0001$) compared to saline-saline treatment, as well as compared to haloperidol-saline treatment in the CP ($p < 0.0003$) and in the Au1 ($p < 0.0001$). Haloperidol pretreatment significantly reduced Fos expression in the CP ($p < 0.05$) and in the Au1 ($p < 0.005$) compared to saline-dopamine treatment, although dopamine with haloperidol pretreatment increased Fos labeling in the CP ($p < 0.006$) and in the Au1 ($p < 0.05$) compared to saline-saline treatment. Haloperidol alone did not alter Fos labeling in CP or Au1. The results reveal that pretreatment with a moderate dose of haloperidol significantly reduced Au1 activation caused by striatal dopamine infusion in proestrus female rats, while this dose of haloperidol alone did not induce Fos in the CP. Thus, striatal dopamine probably acts on indirect pathway neurons to produce Au1 activation, as these neurons express predominantly D2Rs which are blocked by haloperidol to reduces this effect. These results provide a better understanding of the brain mechanism which may underlie dopamine-induced auditory hallucinations.

Title: Cell-type and age-dependent bias of PHP.eB serotyped adeno-associated viruses for mouse neocortical cell types

Authors: *J. BENDRICK[1], M. WALKER[2], C. TRADER[1], S. YAO[1], B. TASIC[1], T. L. DAIGLE[1]; [1]Allen Inst. For Brain Sci., Seattle, WA; [2]Univ. of Michigan, Ann Arbor, MI

Abstract: Recombinant adeno-associated viruses (AAVs) are widely used tools in modern neuroscience and have enabled unprecedented access to brain regions and cell-types within the mammalian brain. These AAVs are versatile and can be engineered to deliver a diversity of gene cargoes into the brain via local or systemic injections, to support basic neuroscience research and targeted gene therapy applications. Specifically, PHP.eB serotyped AAVs allow for delivery of virus throughout the central nervous system, which enables access to neuronal cell types throughout the brain. While previous studies elucidated how PHP.eB serotyped AAVs cross the blood brain barrier, little is known about how well these AAVs infect genetically-defined inhibitory and excitatory neurons across the cortical sheath or the critical factors affecting viral transduction following systemic delivery. In this study, we evaluate the efficiency of PHP.eB serotyped AAV transduction in the brain following retro-orbital delivery of virus into mice from seven Cre;Ai14 double transgenic crosses that label major excitatory and inhibitory cell types. We demonstrate that PHP.eB serotyped viruses preferentially infect parvalbumin (Pvalb) and somatostatin (Sst) subclasses, and layer 5 excitatory neurons and are biased against (i.e. least efficiently transduce) vasoactive intestinal peptide (Vip) and layer 4 excitatory neurons. These cell-type specific biases in infectivity were found to be well maintained in the several cortical regions analyzed and could not be improved by delivery of up to ~1.0E+12 genome copies (GC) of virus. Additionally, we found an age-dependent decrease in viral transduction across diverse mouse neocortical cell-types. Collectively, our results reveal the inherent biases of PHP.eB serotyped AAVs for mouse neocortical cell types and identify age as a key factor to consider when delivering these viruses systemically.

Title: Genetically encoded biosensors for typical antidepressants

Authors: *Z. BLUMENFELD[1], A. L. NICHOLS[1], L. LUEBBERT[1], P. M. BORDEN[3], A. K. MUTHUSAMY[2], J. S. MARVIN[3], C. KIM[1], S. GRANT[2], D. P. WALTON[2], H. J. KNOX[2], J. H. WANG[1], L. L. LOOGER[3], D. A. DOUGHERTY[2], H. A. LESTER[1];
[1]Biol. and Biol. Engin., [2]Chem. and Chem. Engin., Caltech, Pasadena, CA; [3]Janelia Res. Campus, Howard Hughes Med. Inst., Ashburn, VA

Abstract: Major depressive disorder (MDD) is often treated with selective serotonin reuptake inhibitors (SSRIs), with the assumption that elevated extracellular serotonin concentration underlies the therapy. That SSRIs bind to the serotonin transporter (SERT) on the plasma membrane (PM) is indisputable; however, SSRIs typically require 2-6 weeks before a response to treatment can be observed, and events during this delay remain elusive. We propose that SSRI-SERT interactions *within organelles* are crucial aspects of the therapeutic mechanism of SSRI treatment, especially within the endoplasmic reticulum (ER). Therefore, we have developed genetically encoded fluorescent biosensors to study the subcellular pharmacokinetics of SSRIs. OpuBC, a monomeric bacterial periplasmic binding protein (PBP), has a ligand-binding site that can be mutagenized for the evolution of biosensors. We inserted a circularly permuted "superfolder" GFP (cpGFP), flanked by several residue linkers, within the PBP interdomain hinge regions. By applying directed evolution of binding pocket residues, we have produced $\Delta F/F_0$ &gt 1 at 1 μM for two sensitive SSRI-biosensor pairs, termed "**i**ntensity-based **Esc**italopram-**S**e**n**sing **F**luorescent **R**eporter" (iEscSnFR) and "**i**ntensity-based **Fluox**etine-**S**e**n**sing **F**luorescent **R**eporter" (iFluoxSnFR). These are selective sensors which bind neither to endogenous molecules - including neurotransmitters - over the range of pharmacologically-relevant concentrations, nor to other exogenous compounds. Results obtained with our biosensors in mammalian cells (HeLa) using targeting and retention sequences that direct the constructs to the ER or the PM show that escitalopram and fluoxetine enter the lumen of the ER at concentrations similar to those detected on the extracellular surface of the plasma membrane, seconds after the SSRI enters the extracellular space. In mouse primary hippocampal neuronal cultures, we likewise measure entry into the ER, though the compounds appear to enter and leave neurons much more slowly. These experiments provide first evidence for the existence and relevance of SSRI inside-out drug action. To probe "inside-out" mechanisms further, we synthesized quaternized (permanently positively charged) derivatives, and we confirmed that these compounds do not enter the ER, though they interact similarly to the parent compounds with both the PM-targeted constructs as well as in purified protein. We hope that further application of these tools will show the initial steps in the pathway of SSRI intracellular pharmacokinetics, helping to elucidate the role "inside-out" neuropharmacology in therapy for MDD.

Title: A protein reporter for recording brain-wide neural activity at the single-cell level

Authors: *D. LIN, X. LI, A. E. COHEN;
Chem. and Chem. Biol., Harvard Univ., Cambridge, MA

Abstract: Behavior emerges from the interacting activity of widely distributed ensembles of neurons. A central goal in neuroscience is to identify the neural ensembles associated with distinct sensory inputs, behaviors or physiological states. To understand the distinct roles of different subsets of neurons in complex brain states, one would like to perform multiple experiments in a single animal, and to identify the neural ensembles activated in each condition, with single-cell resolution. To our knowledge, no such tool exists. Here we present a protein-based approach to map brain-wide dynamics of immediate early gene (IEG) activation. A soma-localized protein reporter (soma-HaloTag) was engineered to form a physical record of IEG *c-fos* activation, which can be labeled at multiple time-points by systemic administration of its different-colored fluorescent substrates (HaloTag ligands). This technology enables labeling of at least three distinct brain-wide neural ensembles, with a time resolution of approximately three hours and single-cell resolution. The tool opens the possibility of multi-timepoint global activity mapping at the single-cell level and provides a promising strategy for identifying the internal representations and connections of different brain states.

Title: Developing Optogenetic Nanobodies to Control Neuronal Signaling Proteins

Authors: *C. WOODS, J. ENGLISH;
Univ. of Utah, Salt Lake City, UT

Abstract: Optogenetic and chemogenetic tools permit the functional modulation of specific neuronal populations *in vivo.* Popular tools for this purpose include genetically expressed light-gated channels (Rhodopsins) or designer receptors exclusively activated by designer drugs (DREADDs). These tools allow manipulation of specific neuronal subsets within complex circuits. These tools do not directly modulate native signaling events, but instead introduce exogenous signaling proteins to impinge on native cell signaling. An improvement on these approaches would be to allosterically modulate native neuronal

signaling proteins during their native, physiological relevant activities. Through mammalian directed evolution with VEGAS (Viral Evolution of Genetically Actuating Sequences), our lab has developed nanobodies to modulate endogenous protein signaling. Nanobodies are small (~15 kDA) antigen binding fragments derived from heavy-chain-only antibodies found in camelids. Their small size and high specificity and affinity for an antigen make them ideally suited for use as an intrabody in living cells to endogenously control various protein functions. However, constitutive and unregulated expression of nanobodies is an undesirable tool for on-demand neuronal circuit control. Recently, Gil et al. (2020) inserted light-oxygen-voltage (LOV) domains into nanobodies, deemed OptoNBs, to enhance or inhibit nanobody binding to a protein of interest upon blue-light illumination. This photoswitchable control is the next step in fine-tuning nanobody research used thus far to dissect signaling pathways and circuits *in vivo*. Here, we generated optically-activatable LOV nanobodies targeting the human G-protein coupled receptor 5-HT_{2A} (serotonin 2A receptor). LOV domains were introduced at multiple positions of a nanobody previously evolved as a positive allosteric modulator of the 5-HT_{2A} receptor. These 5-HT_{2A}-LOV chimeric nanobodies were screened for their ability to optogenetically enhance 5-HT_{2A} signaling upon administration of serotonin. Our preliminary data indicate that these constructs can optogenetically modulate endogenous receptor activity. Using the VEGAS platform, we will develop additional nanobodies targeting neurologically important G-protein coupled receptors as candidates for OptoNB development. We believe our ability to control allosteric nanobody binding with light, in combination with our ability to evolve functional nanobodies against a broad range of cell signaling targets will prove to be essential tools for cell, developmental, and systems neuroscience.

Title: Pulse-chase HaloTag labeling of surface-exposed AMPA receptors reveals the spatial distribution of potentiated synapses in vivo

Authors: *D. KIM, X. LI, H. TIAN, J. D. WONG-CAMPOS, A. E. COHEN;
Chem. and Chem. Biol., Harvard Univ., Cambridge, MA

Abstract: Memories are formed by the strengthening of synaptic connections, predominantly via increases in the density of α-amino-3- hydroxy-5-methyl-4-isoxazolepropionic acid receptors (AMPARs) in the post synaptic membrane. Increases in AMPAR density upon learning have been observed by *in vivo* 2-photon microscopy of a fusion between an AMPA receptor and a pH-sensitive fluorescent protein. This technique required registration of individual synapses at multiple time-points, and the imaging depth was limited by light scattering to superficial cortical layers. We developed an approach to labeling surface-

exposed AMPARs at different time-points via intracortical injection of membrane-impermeable HaloTag-ligand dyes, followed by *ex vivo* multi-color imaging. By separating the *in vivo* encoding from the *ex vivo* readout, this approach enables wide-area mapping of AMPAR dynamics in any brain region. We fused GluA1, a subunit of AMPAR, with the HaloTag, a self-labeling protein which forms a covalent bond to an exogenous ligand (HaloTag-ligand). We expressed HaloTag-GluA1 in mouse barrel cortex pyramidal neurons, and saturated the surface-exposed AMPARs via local injection of a membrane impermeable HaloTag-ligand dye. We stimulated the whiskers and then injected a different-colored HaloTag-ligand dye to label newly surface exposed AMPARs. High-resolution multicolor imaging of layer 2/3 pyramidal neurons in fixed brain slices revealed an increase in AMPAR density upon whisker stimulation. Pulse-chase HaloTag labeling of AMPARs can be a powerful tool to investigate the distribution and time-course of synaptic potentiation throughout the brain. We envision that this method will expand our knowledge of how memories are formed and stored.

Title: Monitoring Neuromodulators by Fluorescence Lifetime Imaging of Neuromodulator Sensors

Authors: *P. MA, P. CHEN, E. TILDEN, Y. CHEN;
Dept. of Neurosci., Washington Univ. in St. Louis, St. Louis, MO

Abstract: Monitoring the dynamics of neuromodulators is key to understand their functions. Engineering of G protein coupled receptor (GPCR)-activation-based neuromodulator optical sensors has enabled us to detect the neuromodulator changes based on the sensor fluorescence intensity changes. However, intensity-based measurement is only able reflect short-term and phasic changes of neuromodulators. In contrast, fluorescence lifetime measurement of the sensors, which is independent to the sensor expression levels, provides the possibility of measuring tonic activities, long-term chronic changes, and absolute concentrations of neuromodulators. Here using fluorescence lifetime imaging, we screened the commonly used GPCR-activation-based neuromodulator sensors and report that some neuromodulator sensors show changes of fluorescence lifetime. By simulation of the sensor fluorescence and autofluorescence of the bio-tissues, we found that autofluorescence contribution difference before and after sensor activation was not sufficient to induce as much fluorescence lifetime change as experimentally observed, indicating the authentic fluorescence lifetime change of the sensor. Using fluorescence lifetime measurement, we detected changes of neuromodulator in acute mouse hippocampus brain slices. Using fluorescence lifetime photometry combined with Electroencephalography (EEG) and Electromyography (EMG) recordings, we measured the long-term neuromodulator changes in the hippocampus along with sleep-wake cycles within 24 hours and across different days in mice. In summary, our study shows the

fluorescence lifetime changes of some GPCR-activation-based neuromodulator sensors and provide some proof-of-principle applications of fluorescence lifetime measurement in vitro and in vivo.

Title: Temporal fidelity and integration of spike activity with the new jGCaMP8f calcium indicator

Authors: *G. J. BROUSSARD[1], F. J. URRA QUIROZ[2], G. DIANA[2], L. A. LYNCH[1], D. A. DIGREGORIO[2], S. S.-H. WANG[1];
[1]Princeton Neurosci. Inst., Princeton, NJ; [2]Neurosci., Inst. Pasteur, Paris, France

Abstract: GCaMPs are indispensable for surveying action potential-associated calcium activity in populations of neurons. However, GCaMP6f and 7f exhibit slow fluorescence rise kinetics and a non-linear calcium-dependence, placing limits on their ability to read out spike timing and number. To compare how these GCaMP variants and the newer jGCaMP8f translate neural activity to fluorescence dynamics, we used stopped-flow fluorimetry of purified GCaMP protein and ex vivo recordings from parallel fiber boutons in brain slices which could be given controlled stimuli. GCaMP6f and 7f responses were largely explained by a slow, calcium-driven process with high cooperativity as indicated by their Hill coefficients (2.3 and 2.1). This cooperativity can account for ex vivo non-linearity of up to a three-fold increase in response to the second of two spikes applied 10 ms apart. In contrast, capturing the faster rise kinetics of jGCaMP8f required an additional fast calcium-dependent activation process, where each process displayed low cooperativity (Hill coefficients = 1.2 for fast and slow processes), and showed a near-linear response to paired spikes. However, jGCaMP8f also showed up to three-fold slower decay times in response to burst-rate (100 Hz) spiking, consistent with cumulative activation of the slow process. Despite this effect, jGCaMP8f's linearity and rapid rise time make it suitable for accurate spike inference using straightforward methods, even at high instantaneous firing rates. Taken together, this work identifies functional attributes of next-generation GCaMP variants that are suited for high-fidelity spike inference.

Title: Dopamine distribution in time and space: effects of methylphenidate

Authors: *J. A. CHOUINARD[1], S. TAKAHASHI[1], N. KITAMURA[1], K. LIYANAGAMA[1], K. KURIMA[1], L. TIAN[2], J. R. WICKENS[1];
[1]Okinawa Inst. of Sci. and Technol., Onna-son, Japan; [2]Biochem. and Mol. Med., Univ. of California, Davis, Davis, CA

Abstract: Methylphenidate is the most widely prescribed treatment for attention-deficit hyperactivity disorder (ADSD). It inhibits the dopamine transporter (DAT) and, by reducing clearance, leads to increased and prolonged dopamine (DA) signal in the extracellular space, but its macroscopic effects are not completely understood. We first investigated the temporal dynamics of dopamine by fast-scan cyclic voltammetry (FSCV) using focal electrical stimulation. In the presence of the DAT blocker, a delayed concentration peak can be observed until after the end of the stimulation. This cannot be explained by a simple time delay due to diffusion time because there is no corresponding delay in onset of dopamine increase at the distant recording site. Diffuse optical stimulation was also used to assess if the initial increase in dopamine could result from an electrical current spread causing release at distant sites, while the delayed peak is due to diffusion delays. However, similar results to focal electrical stimulation were obtained. We finally explored if diffusing waves would occur on a much smaller spatial scale by combining simultaneous FSCV with pre or post-synaptic expression of the genetically encoded dopamine sensors dLight1.3b or dLight2.1 imaging to obtain more spatiotemporal information on dopamine release. A new type of Cre-dependent adeno-associated virus was also engineered to enhance the more sensitive dopamine sensor dLight2.1, which was found to provide bright, easy to locate sensor expression, with a better signal-to-noise ratio at 3 weeks post-injection. Results indicate that the clearance of dopamine is slow in all monitoring modalities used in the presence of DAT blockers, but the delayed peak can only be observed in voltammetry traces. We conclude that dLight reveals dopamine levels in the cell inner compartment - much closer to the source whether it is pre or post-synaptic - while FSCV is sensing diffusion way beyond the synaptic space. In the end, both FSCV and dLight imaging techniques provided different, but useful complementary information. The influence of methylphenidate on apparent diffusion distance of dopamine may be important for understanding its effects on processing of reward signals and its mechanisms of action in the treatment of ADHD.

Title: Development of multicolor fluorescent probes for heterogeneous Aβ deposits in Alzheimer's disease

Authors: *R. AL-LAHHAM, A. MUKHERJEE, C. SOTO;
UT Hlth. Sci. Ctr. at Houston, Houston, TX

Abstract: Accumulation of Aβ into amyloid plaques and tau into neurofibrillary tangles are pathological hallmarks of Alzheimer's disease (AD). AD is also a mixed proteinopathy with α-synuclein, the pathological hallmark of Parkinson's disease, being detected in more than 50% of AD cases. However, there is a significant intra- and inter-individual variability with respect to coexistence, morphology and conformation of these aggregates, which may account for the extensive clinical heterogeneity observed in neurodegenerative diseases. In AD, Aβ can deposit in a spectrum of morphology from diffuse to fibrillar, and dense-cored plaques. The pathological relevance of these varied morphologies in AD is still unknown. In this study, we sought to develop an array of fluorescent dyes to specifically probe Aβ aggregates, in an effort to address their diversity. 10 µm-thick sections of paraffin-embedded frontal or temporal cortex from pathologically confirmed AD patients and healthy control as well as midbrain specimens from pathologically confirmed LBD patients were used for dyes staining, as well as 4G8, AT8, phospho-α-synuclein and α-synuclein immunostaining. APP/PS1 mice brain sections were also used for staining and immunostaining. We screened a small library of benzothiazole-coumarin fluorescent probes and identified three structurally similar fluorescent probes, PMDAM022, PMDAM006, and PMDAM015, that intensely stained Aβ plaques in frontal cortex AD brain sections, both parenchymal and vascular, with no apparent staining in healthy control brain. This was confirmed by immunostaining of mirror image sections with 4G8 antibody. Amyloid plaques in APP/PS1 mouse brain were also recognized by these probes. The set of these three dyes allowed the visualization of Aβ deposits in three different colors (blue, green and far-red). The triple-stained sections display a staining pattern that suggests they bind to different regions of the plaques, and therefore would be valuable to be used for different plaques morphologies. Interestingly, PMDAM0022 also stained NFTs in AD human brain temporal cortex sections and Lewy bodies in LBD human midbrain sections, while the PMDAM006 and PMDAM015 did not. Aβ aggregate-specific dyes identified in this study have the potential to be further developed into Aβ imaging probes for the diagnosis of AD. In addition, the far-red dye we developed in this study may serve as an imaging probe for small animal imaging of Aβ pathology. The present findings have several implications as they will not only facilitate the development of novel and refined diagnostic tools but also will help us address the clinical heterogeneity observed within AD.

Title: Genome editing for non-human primates

Authors: *T. AIDA[1], J. J. WILDE[1], D. ROY[3], Y. ZHANG[1], R. C. DEL ROSARIO[3], M. WIENISCH[1], Q. ZHANG[1], G. FENG[1,2,3];

Abstract: Many of the critical neural circuits and regional neuronal populations at the center of higher human cognitive function are not present in lower mammalian brains and can be studied only in nonhuman primate (NHP) brains. The recent emergence and rapid development of new genome editing technologies, such as the CRISPR/Cas system, have opened the door for generating genetically modified NHP models. These genetic NHP models are transforming our understanding of higher brain functions and facilitating the development of effective treatment for human brain disorders. We have developed a series of CRISPR technologies to specifically manipulate genomic sequences in NHP zygotes in an efficient, precise, and predictable manner for the generation of genetically modified NHPs. Importantly, these genetic NHP models can faithfully recapitulate symptoms of human psychiatric disorders. Finally, we show strategies empowering rapid homozygous animal production and direct in vivo genomic manipulation. Taken together, these genome editing technologies accelerate functional brain research using genetic NHP models.

Title: Cell-specific genome editing in the mouse central nervous system utilizing a novel CRISPR/Cas9 technique

Authors: *M. A. QUINLAN[1], A. C. HUNKER[4], M. X. BERNSTEIN[2], M. E. SODEN[3], L. S. ZWEIFEL[1];
[1]Psychiatry and Behavioral Sci., [2]Neurosci., [3]Pharmacol., Univ. of Washington, Seattle, WA; [4]Allen Brain Inst., Seattle, WA

Abstract: Since the discovery of CRISPR/Cas9 (Clustered Regularly Interspaced Palindromic Repeats/CRISPR associated protein) as an effective means to modify the genomes of plants, animals, and bacteria it has emerged as the method of choice for genome editing and engineering. Although CRISPR/Cas9 methods have been broadly implemented in the *in* vitro setting at the single-cell level, their deployment in targeted gene modification within specific cell types of an intact multicellular organism has been limited by their efficiency in these contexts. Here, we sought to address this limitation by developing and optimizing a new technology for selective gene editing using a CRISPR/Cas9 method in combination with multiple copies of single-stranded DNA (msDNA) that acts as the homology donor template generated by a bacterial reverse transcriptase (RtEc86). Our method, dubbed DNA REplacemnt through AMplification (DREAM) is a viral-based system with the delivery of a cell-specific Cas9 and an RtEc86 that reverse transcribes our homology donor template *in vivo* in the central nervous system (CNS) in an adult mouse. To test the efficacy of this strategy, we targeted gene insertion in the mouse CNS by linking an EGFP coding sequence to homology arms flanking a Cas9-targeted sequence in the tyrosine hydroxylase (*Th*) gene. We previously demonstrated the efficacy of targeting mutagenesis of *Th* in the ventral tegmental area (VTA) utilizing our cell-specific CRISPR/Cas9 loss-of-function tool (Hunker et al. 2020). Using both immunohistochemistry and targeted sequencing, we validated the targeted insertion of EGFP into the TH locus and demonstrate that DREAM editing is highly efficient. We further assessed the minimal homology arm length for targeted insertion and tested the necessity of RtEc86 and Cas9. Based on this data, we conclude that targeted gene insertion *in vivo* in the adult CNS is highly efficient, rapid, and precise. The development of our DREAM technology will allow researchers to easily and precisely edit the genome *in vivo* and future experiments will assess the broad applicability of DREAM editing in other cell types and organisms. In addition to being a valuable molecular tool for basic research, we believe this strategy will have wide therapeutic potential.

Title: Using CRISPR-dCas13 RNA editing technology for novel site-specific manipulations of ubiquitin-proteasome signaling during memory formation

Authors: *K. FARRELL[1], M. MUSAUS[2], T. J. JAROME[1];
[1]Dept. of Animal and Poultry Sci., [2]Sch. of Neurosci., Virginia Tech., Blacksburg, VA

Abstract: The ubiquitin-proteasome system (UPS) controls the majority of protein degradation in cells. This degradation process occurs through the regulatory protein ubiquitin, of which multiple can bind a target substrate and form polyubiquitin chains at 8 different linkage sites that each have unique functions. The most abundant polyubiquitin modifications are K48 and K63, the latter of which is thought to be independent of the degradation process while the former is preferentially targeted for degradation by the 26S proteasome, which is activated by phosphorylation of the RPT6 subunit at serine 120 (S120). Over the last decade, numerous studies have demonstrated that UPS-mediated protein degradation is necessary for memory formation in several brain regions. However, this evidence was obtained through broad manipulations of UPS signaling, such as proteasome inhibitors or knockdown of specific ubiquitin ligases. Due to this, the role of specific proteasome subunit phosphorylation sites and diverse polyubiquitin chains, especially those independent of the protein degradation process, in memory formation has never been directly tested. To address this gap in the field, we adapted the CRISPR-dCas13 (catalytically dead Cas13) system in which the dCas13 is fused with the deaminase protein ADAR (CRISPR/dCas13b-ADAR) to make site-specific modifications on the major ubiquitin coding gene, Ubc, and the RPT6 coding gene, Psmc5. We generated multiple guide RNAs (gRNAs) targeting the S120 codon of the Psmc5 transcript, converting it to glycine. In rat B35 cells we observed reduced levels of phosphorylated RPT6-S120 without any changes in total RPT6 levels (3 biological replicates, unpaired t-test, $P < 0.05$). Using the same experimental design, we targeted the lysine-63 (K63) codon in the Ubc gene to convert this lysine to glutamate and found reduced K63 polyubiquitination levels with no changes in the neighboring lysine-48 linkage site, indicating a site-specific codon edit. Next, we tested whether these plasmids could successfully control memory formation in vivo. We found that editing of K63 polyubiquitination in the amygdala impaired contextual fear memory in female rats ($n = 6$ per group, unpaired t-test, $P < 0.05$). Together, these data demonstrate the efficacy and specificity of this novel approach for generating single mismatches on RNA transcripts in vitro and in vivo, which provides a precise, endogenous method for elucidating the function of the proteasome and individual polyubiquitin linkage sites independently in the adult brain and during memory formation.

Abstract: Single-cell transcriptomics approaches have unearthed a myriad of new cell types within the mammalian brain and have spurred interest in the study of their function. However, genetic access to many of these transcriptomically-defined cell types is limited because the available transgenic lines label relatively broad and heterogenous neuronal populations and the nascent cell types are often highly interrelated at the level of gene expression, making traditional single-gene-based approaches less tractable. To facilitate higher precision genetic access, we have generated a new suite of FlpO transgenic lines for intersectional genetics that are driven by marker genes for major inhibitory subclasses and select excitatory projection neuron types within neocortex. We characterize these lines systematically using a multi-modal approach and provide a roadmap for how the new tools can be combined with one another and existing transgenes or enhancer-driven adeno-associated viruses (AAVs; Graybuck, Daigle et al., Neuron 2021) to target specific transcriptomic cell types. In parallel, to compliment the FlpO driver lines, we have developed the TIGRE3.0 transgenic reporter platform that builds upon our previously published one (Daigle, Madisen et al., Cell 2018) and enables Cre- and Flp-dependent transgene expression in diverse neuronal populations. This new collection of conditional reporter lines includes tools for labeling (both cell-filling and nuclear), optical physiology, and optogenetics. TIGRE3.0 reporters offer several key advantages compared to published TIGRE2.0 reporters such as lower toxicity and functionally relevant levels of transgenes in a broader range of cell types. Together, these transgenic tools and strategies will enable explorations and better understanding of transcriptomic cell types in the mammalian brain.

Title: Exbox: a simple boolean exclusion strategy to drive expression in neurons

Authors: *T. UBINA, T. VAHEDI-HUNTER, A. GUPTA, W. WONG, W. AGNEW-SVOBODA, V. SANTHAKUMAR, M. RICCOMAGNO;
Univ. of California Riverside, Riverside, CA

Abstract: The advent of modern single-cell biology has revealed the striking molecular diversity of cell populations once thought to be more homogeneous. This newly appreciated complexity has made intersectional genetic approaches essential to understanding and probing cellular heterogeneity at the functional level. Here we build on previous knowledge to develop a simple AAV-based approach to define specific subpopulations of cells and temporally control expression by Boolean exclusion logic (AND NOT). This Expression by Boolean Exclusion (ExBoX) system encodes for a gene of interest which is turned ON by a particular recombinase (Cre or FlpO) and turned OFF by another. ExBoX allows for the specific transcription of a gene of interest in cells expressing only the activating recombinase, but not in cells expressing both. We show the ability of the ExBoX system to tightly regulate expression of fluorescent reporters both *in vitro* and *in vivo*, and further demonstrate the powerful adaptability of the system by achieving expression of a variety of virally-delivered coding sequences in the mouse brain. This simple strategy will expand the molecular toolkit available for cell- and time-specific gene expression in a variety of organisms and systems.

Title: Launching NeuroGT: a brain atlas of neurogenic tagging CreER drivers for birthdate-based classification and manipulation of mouse neurons

Authors: *T. HIRATA[1], Y. TOHSATO[2], H. ITOGA[3], G. SHIOI[3], H. KIYONARI[3], S. OKA[4], T. FUJIMORI[4], S. ONAMI[3];

Abstract: Neuronal birthdates are commonly used to classify neurons. However, the current nucleotide-based birthdating method is retrospective in nature and does not allow the manipulation of classified neurons. To overcome this limitation, we developed neurogenic tagging mouse lines that can induce CreER-*loxP* recombination in the neurons with similar birthdates in living animals and enable various experimental manipulations of the classified subsets. To encourage the use of this resource, we constructed a brain atlas of the neurogenic tagging mouse lines (NeuroGT), which includes holistic sections and whole-mount image data of the *loxP*-recombined neurons and their processes across the entire brain that were tagged at each single day during the neurodevelopmental period. This image database is open to the public, offering people the opportunity to find specific neurogenic tagging driver lines and the stages of tagging appropriate for their own research purposes.
Visit NeuroGT database (https://ssbd.riken.jp/neurogt/), and explore the specific brain region of your interest. If you find a neurogenic tagging driver line promising for your research, you can advance your research using the mouse line deposited at RIKEN BDR after completion of MTA.

Title: Increased Efficiency of RapGEF2 Knockout in Drd1-Expressing Medium Spiny Neurons in Mouse Striatum by Cre Amplification

Authors: *H.-Y. ZHANG, W. XU, S. Z. JIANG, L. E. EIDEN;
Sec Molec Neurosci, NIH, NIMH-IRP, Bethesda, MD

Abstract: Cre-loxp technology was introduced in the 1980s (Sauer and Henderson 1988; Sternberg and Hamilton 1981). Many different Cre strains, each containing a Cre transgene under a different tissue-specific promoter, may be crossed with a loxP strain to allow the investigator to study a gene's effects in a tissue-specific manner. The Cre/loxP system is the most powerful tool and widely used to generate a tissue specific or inducible knockout mouse and has been particularly useful to help neuroscientists to study the brain functions within specific cell types and neural circuits. However, not every Cre driver mouse line will produce enough Cre to excise loxp-flanked gene elements to efficiently knock out the gene of interest. We generated a conditional RapGEF2 knockout mouse (Drd1Cre^{+}::RapGEF2$^{fl+/fl+}$cKO) in D1-MSNs by crossing Drd1cre mouse with our interest, RapGEF2 flox mice. No effect on RapGEF2 expression in the striatum of control mice and cKO mice, assessed by immunohistochemistry and Western Blot, was noted. In contrast, a significant decrease in RapGEF2 expression was detected in CA1

and DG subregion of hippocampus by crossing the Camk2α-Cre mouse with RapGEF2 flox mice to generate a RapGEF2 forebrain knockout mouse. These data suggest that the Drd1Cre mouse line does not provide enough Cre recombinase to functionally knock out RapGEF2. To solve this problem, we designed a Cre-dependent Cre (Syn-Flox-Stop-Cre-Venus) construct in C57Bl6 mice, to amplify the Cre expression under the Synapsin promotor, called for short 'Cre-Gone-Wild' (CGW) mice. First, the CGW mice were tested for leakage expression of Cre with Venus indicator by crossing CGW mice with Drd1Cre mice. Data showed that Venus expression was only detected in Syn-flox-stop-cre and Drd1-cre double positive mice, but not in Syn-flox-stop-cre+ only mice, indicating that CGW mice amplify low levels of Cre without non-specific breakthrough. Crossing the CGW mice with $Drd1Cre^{+}$::$RapGEF2^{fl+/fl+}$ mice to generate CGW::$Drd1Cre^{+}$::$RapGEF2^{fl+/fl+}$ cKO mice resulted in significant decrease in RapGEF2 mRNA (around 35%~45%) in both dorsal striatum and nucleus accumbens (NAc) of cKO mice, compared to control mice, by quantitative real-time PCR assay. Treatment of these mice with a single dose of cocaine (20 mg/kg, i.p) resulted in striking attenuation of phospho-ERK expression in the NAc in cKO mice, consistent with our previous reports using AAV-Cre-directed RapGEF2 knockout (Jiang, et al. JN 2021). These data support the successful employment of CGW mice to amplify Cre expression, which will be a useful tool to provide sufficient Cre recombinase to efficiently knockout target gene and knockout gene functions.

Title: Integrated and extensible neuron morphology analysis in python with nGauge

Authors: *L. A. WALKER[1,2], J. S. WILLIAMS[3], Y. LI[4], D. H. ROOSSIEN, JR[6], N. S. MICHKI[1], D. CAI[4,1,5];
[1]Biophysics, [2]Computat. Med. and Bioinformatics, [3]Computer Sci., [4]Cell and Developmental Biol., [5]Neurosci. Grad. Program, Univ. of Michigan, Ann Arbor, MI; [6]Ball State Univ., Muncie, IN

Abstract: As more whole-brain-scale single neuron morphology reconstructions become accessible to the neuroscience community, robust and comprehensive methods to quantify the differences between neurons of different subtypes and animal species are highly desirable. Several software packages have been developed to analyze 3D neuron tracing results stored in the industry standard SWC format. However, they provide relatively simple quantifications and their non-extendable architecture prohibits these software packages from advanced data analysis and visualization. This limitation has arisen as a major

reason large projects opt for bespoke quantification pipelines which can be hard to reproduce and maintain between projects.
To address these challenges, we developed *nGauge*, a Python toolkit currently available in the Python software repositories. *nGauge* consists of tools to perform morphometry of individual neuron SWC files, plot 2D representations of neurons, as well as perform 3D visualizations and quantifications of multiple neurons. To ensure intercompatibility, *nGauge* implements nearly one hundred morphometrics using definitions from previously published studies. As an application programming interface (API), *nGauge* can be referenced by other popular open-source software to create custom informatics analysis pipelines and advanced visualizations. *nGauge* also defines an extendable data structure that handles volumetric constructions (e.g., soma), in addition to the SWC linear reconstructions, while remaining lightweight and capable of exporting to standardized SWC files. Here, we describe the development of *nGauge* through illustrations of the software's design and data structure. To demonstrate the power of the built-in visualization tools, we provide illustrated examples of reanalyzing published datasets. We envision that *nGauge*'s open-source and expandability nature will attract contributions from the community to its public repository to make it an important toolkit of neuroscience research.

Title: Transcriptome Wide Association Study of Individually Imputed Genetically Regulated Gene Expression in the Million Veteran Program

Authors: *S. VENKATESH, W. ZHANG, G. HOFFMAN, P. ROUSSOS, G. VOLOUDAKIS;
Icahn Sch. of Med. At Mount Sinai, New York, NY

Abstract: Most neuropsychiatric disorders are moderately heritable but characterized by many genetic risk variants with weak effects. As such, it is difficult to point to direct causes or elucidate mechanisms of action. Despite the ease in gathering genetic data from humans, genetic data does not easily explain mechanistic effects. Gene expression on the other hand, can more easily explain mechanistic effects, but is harder to gather, especially in brain regions which are critical to the understanding of neuropsychiatric disease. To address this, we developed methods to impute genetically regulated gene expression (GREx) from genotypes and imputed GREx in over four hundred thirty thousand European individuals in the Million Veteran Program (MVP) for a wide variety of tissues and cell types. We use EpiXcan (based on PrediXcan) to develop machine learning models from training genotype, expression, and epigenetic data.

We use custom scripts to impute individual GREx and perform a variety of downstream association analyses, including Principal Component Analysis (PCA), GREx Phenome Wide Association Studies (PheWAS), and Transcriptome Wide Association Studies (TWAS). Results show an overlap in Schizophrenia genes identified by individual level TWAS and those identified by summary level TWAS informed by GWAS. TWAS also identifies genes involved in Major Depressive Disorder and Schizophrenia that are also implicated via other methodologies. Finally, correlation of targeted genes with COVID-19 severity reveals correlations seen in COVID-19 positive individuals. GREx presents a unique solution to integrate effects across the genome and increase sample size in gene expression analyses. We are pursuing the creation of additional EpiXcan models, improved statistical methods for downstream association analyses, and replication efforts across biobanks. We plan to perform these analyses in all ancestries, available EpiXcan and PrediXcan models, and relevant phenotypes.

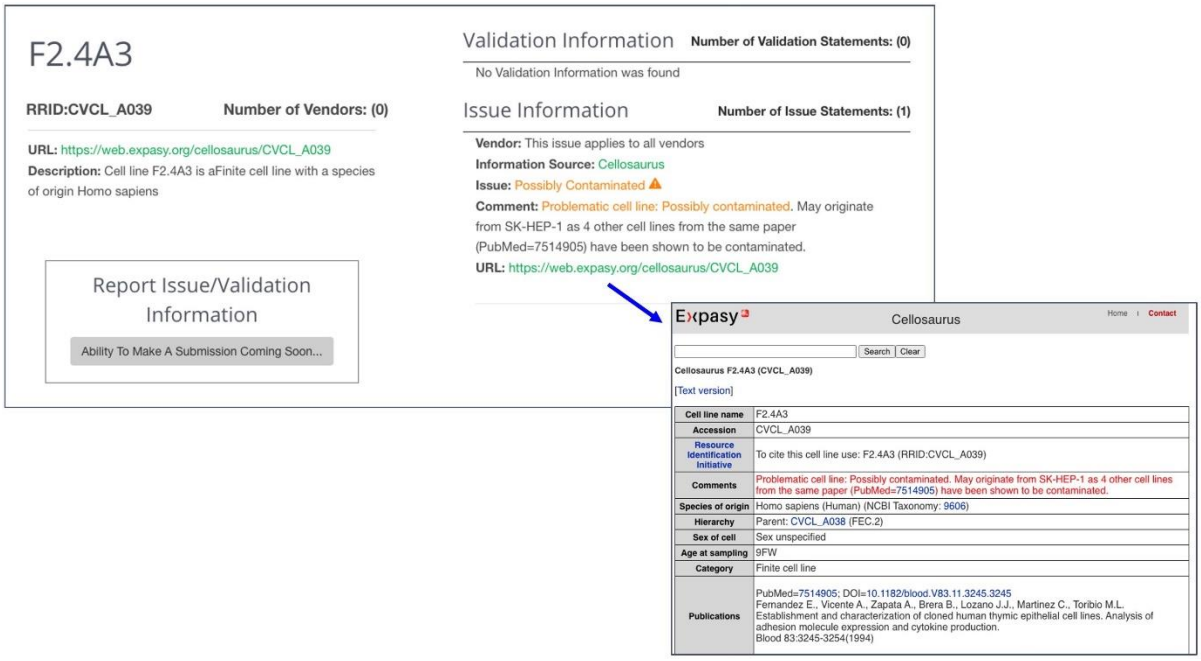
Title: Resource Watch - Making Research Resource Issue, Characterization and Validation Information FAIR



Authors: P. L. PASCUAL, K.-W. LIN, V. GUO, C.-N. HSU, A. E. BANDROWSKI, M. E. MARTONE, *J. S. GRETHE;
Dept. of Neurosciences, Univ. of California San Diego, Sch. of Med., La Jolla, CA

Abstract: Research resources, such as antibodies and cell lines, are a major source of variability in scientific experiments, and if they don't perform as expected, a major source of irreproducibility. Therefore, identifying and tracking the performance of these resources is important for maintaining the integrity of the scientific record. Resource Watch (https://scicrunch.org/ResourceWatch) serves this purpose as a hub for storing performance information (i.e. issues, characterization, and validation) about a variety of research resources within the biomedical domain. Resource Watch is built on the foundation of Research Resource Identifiers (RRIDs) as a means of uniquely identifying key research resources that underlie the findings of scientific studies in the literature. A core part of the content within Resource Watch comes from the community authorities that manage identifiers for specific resources, such as the Antibody Registry (antibodies) and Cellosaurus (cell lines). However, Resource Watch also enables aggregation of information from a number of other sources (e.g. Human Protein Atlas for antibody characterization information and the literature via natural language processing). In addition, the platform

also enables researchers to submit their own claims about a specific research resource. Resource Watch ensures that information on the performance of research resources is F.A.I.R. (Findable, Accessable, Interoperable, Reuseable) and is openly available to the biomedical community.

Title: The OpenBehavior project: RRIDs, video repository, training workshops

Authors: *M. LAUBACH[1], A. V. KRAVITZ[2], L. M. AMARANTE[3], A. E. BANDROWSKI[4], K. CHAVEZ LOPEZ[1], W. FOBBS[1], J. FRIE[5], M. ISAACSON[1], J. KHOKHAR[5], S. R. WHITE[1]; [1]American Univ., Washington, DC; [2]Washington Univ., St Louis, MO; [3]Johns Hopkins Univ., Baltimore, MD; [4]SciCrunch Inc. and UCSD, La Jolla, CA; [5]Univ. of Guelph, Guelph, ON, Canada

Abstract: The OpenBehavior project disseminates information on open source tools and methods for research in the field of behavioral neuroscience. During the past year, the project has received funding from the National Science Foundation with three goals. First, we are creating a database of open source tools and, working with SciCrunch project, are issuing Research Resource Identifiers (RRIDs) for each tool. The initial database has been created based on more than 180 projects posted to openbehavior.com. The database will be used to create a factor for tracking the impact of open source tools, similar to the h factor. We also working with SciCrunch on the development of SciScore, a methods review tool for scientific articles. Second, we have created a repository of raw video files used for computer vision analysis in behavioral neuroscience experiments. The repository currently hosts 12 sets of videos covering a variety of common behavioral designs. The goal of the repository is to enable training on the use of some of the most currently popular open source tools in the field. In addition, we have hosted community conversations with leading developers and users of computer vision methods, and are actively working on a document to propose standards and increase rigor and reliability for the methods. Third, we are hosting training workshops on the most popular open source tools in the field. The first of the workshops is focused on hardware, specifically Arduino microcontrollers. We welcome interactions and discussions with the research community on these topics.

Title: Dandi - a data archive and collaboration space for neurophysiology projects

Authors: *S. S. GHOSH[1], Y. O. HALCHENKO[2], R. CHOUDHURY[3], B. DICHTER[4], M. GRAUER[3], J. T. WODDER, II[2], D. CHIQUITO[3], J. NESBITT[3], B. HELBA[3], M. VANDENBURGH[3], D. JARECKA[1], S. A. ABRAHAM[1];

Abstract: DANDI is a neurophysiology data archive and collaboration hub built to support multiscale, multispecies, and multimodal neuroscience research. The data and resources related to DANDI are supporting theoretical neuroscience, driving biological applications, helping develop new analytic tools through standardized annotation and dissemination. The DANDI infrastructure is built on opensource technologies and in the cloud, to support dissemination, search, visualization, computation, collaboration and coordination in neurophysiology research projects to promote FAIRness and efficiency. DANDI currently contains 32 TB of data from over 70 datasets, across 4 species, and multiple recording modalities spanning intracellular, extracellular, and behavioral timeseries from electrophysiology, optophysiology, and optogenetic experiments, as well as multimodal MRI, OCT and immunostaining data from human ex vivo brain tissue samples. DANDI aims to help make data and software for neurophysiology FAIR. DANDI currently provides neurophysiology data storage for the purposes of collaboration and dissemination of data, easy to use tools for data submission and access, a Jupyter-based computation hub to introspect data in the archive, and integration with other archives and analytic platforms. DANDI is a Web platform for scientists to share, collaborate, and process data from neurophysiology experiments using FAIR principles. DANDI is addressing challenges in standardization, data transfer, storage and access, and improving the culture of sharing through a community of practice. DANDI uses BRAIN Initiative community data standards such as NWB, and works closely with the BIDS and NIDM communities to expand those standards to neurophysiology and microscopy. DANDI has launched an application programming interface server to attract software developers to interact with the archive programmatically and has also contributed to community efforts to provide efficient access to larger datasets in the cloud. With DANDI, researchers can now share, collaborate on, and publish citable datasets, and thereby increase rigor and reproducibility of neurophysiology research.

Title: Early prediction of neurodevelopmental disorders based on de novo coding variation

Authors: *J. CHOW[1], F. HORMOZDIARI[2];
[1]UC Davis Genome Ctr., [2]Biochem. and Mol. Med., Univ. of California, Davis, Davis, CA

Abstract: The early detection and treatment of neurodevelopmental disorders (NDDs) can significantly improve affected patient outcomes. Whole exome and genome sequencing of families have identified rare coding variants, such as *de novo* variations, that are present at significantly higher rates in individuals with NDDs compared to unaffected controls. In particular, the enrichment of *de novo* likely gene-disruptive (LGD) variants in affected individuals relative to controls observed across multiple cohort studies has resulted in the identification of hundreds of NDD risk genes. The differential burden of non-synonymous *de novo* mutation that exists among NDD cases and controls indicates that *de novo* coding variation can be used to identify samples that will likely display an NDD phenotype. Thus, we have developed an approach for the accurate prediction of NDDs with a very low false positive rate (FPR) using *de novo* coding variation for a subset of affected cases.
We use a shallow neural net (SNN) with a custom loss function that specifically seeks to maximize TPR while minimizing FPR and incorporates LGD and missense *de novo* mutation, constraint, and conservation data. The SNN achieves a high (> 0.30129) true positive rate (TPR) at very low FPR (< 0.01) in comparison to traditional classification models (baseline models) such as random forest, support-vector machine (SVM), and logistic regression, corresponding to at least a 5% increase in TPR. The SNN also achieves a high precision recall - area under the curve (PR-AUC) (0.95050). As expected, an ensemble model that averages predictions among the SNN and baseline models is able to achieve increased TPR at FPR < 0.01 (0.30715) and PR-AUC (0.95176). The SNN itself is a major contributor to increased TPR at FPR < 0.01 and PR-AUC metrics observed in the ensemble model; an ensemble model that does not use SNN predictions yields decreased TPR at FPR < 0.01 (0.23347). Trained SNNs enable NDD risk gene ranking, revealing candidate NDD genes enriched in *de novo* non-synonymous mutations in NDD cases relative to controls.
In summary, the described SNN identifies NDD cases at high TPR while minimizing FPR with increased precision at lowered recall thresholds compared to traditional machine learning methods. Several factors contribute to the improved performance of the SNN, namely: the use of genic constraint and

conservation features in LGD-specific prediction, the architecture of the SNN, and the TPR-maximizing and FPR-minimizing custom loss function. The SNN trained on *de novo* coding variation additionally produces a ranked list of prioritized NDD risk genes for future clinical study.

Title: Meta-analysis of neuron cell with single cell RNA-seq of human brain tissue

Authors: *H. WATANABE, W. LIN, Y. KAWASHIMA, T. HOSOYA;
Biomed. business center, Ricoh Company, Ltd., Kawasaki-shi, Japan

Abstract: Introduction: In order to understand the development and role of the human brain, it is important to identify the cell types that compose the human brain tissue and the role of those cells. Recently, single-cell genomic analyses have been performed to human brain tissue, and revealed that there are various types of cells (interneuron, excitatory neuron, neuro precursor cell, microglia) in the human brain tissue. Generally, each cell type specifically express genes which are called cell marker. For example, GAD1 of interneuron and GFAP of astrocyte are well known cell markers. However, the cell markers used in each laboratory are different even for the same cell type. Thus, it is still unclear whether genes are available to use as a cell marker. The cell markers are often used to spatial analysis for human tissues to reveal distribution of each cell types. Likewise, it is important for cell differentiation technology to use cell type classification using cell marker. Above all, the cell markers of cell type in the fetal brain is good information, because ESC (embryonic stem cell) and iPSC (induced pluripotent stem cells) are known to be young cells. Over the past two years, several laboratories have been investigating single cell RNA-seq (scRNA-seq) data which are publicly available. In this study, we combined these data and used human brain single cell data to identify cell markers in fetal brain.Method: The scRNA-seq data which are gene expression data and metadata (cell types) of human brain tissue of fetuses were downloaded from publicly available database. Using these gene expression data and metadata (cell types) of each cells, we identified marker genes in each study to eliminate inter-study bias after that we integrated their gene lists. In addition, gene functional analysis was performed on marker genes.Results: The integration of data obtained from different laboratories revealed highly reproducible cell markers observed between different studies. Furthermore, it was revealed that several gene functions of the marker genes related to neuronal differentiation.

Title: Three-dimensional missense tolerance ratio analysis

Authors: *R. E. PERSZYK[1], A. S. KRISTENSEN[2], P. N. LYUBOSLAVSKY[3], S. F. TRAYNELIS[4]; [1]Emory Univ., Atlanta, GA; [2]Univ. of Copenhagen, Copenhagen, Denmark; [3]Univ. of TexaS, Austin, TX; [4]Dept Pharmacol, Emory Univ. Sch. of Med., Atlanta, GA

Abstract: A wealth of genetic information is available describing single nucleotide variants in the human population that appear to be well-tolerated, and in and of themselves, do not confer disease. These variant datasets contain signatures about the protein structure-function relationship and provide an unbiased view of various protein functions in the context of human health. This information can be used to determine regional intolerance to variation, defined as the missense tolerance ratio (MTR), which is an indicator of stretches of the polypeptide chain that can tolerate changes without compromising protein function in a manner that impacts human health. This approach circumvents the lack of comprehensive data by averaging the data from adjacent residues on the polypeptide chain. We reasoned that many motifs in proteins are comprised of non-adjacent residues, but together function as a unit. We therefore developed an approach to analyze nearest neighbors in three-dimensional space as determined by crystallography, rather than on the polypeptide chain. We utilized members of the GRIN gene family that encode subunits of NMDA-type ionotropic glutamate receptors (iGluRs) to exemplify the differences between these methods. Our method, 3DMTR, provides new information about regions of intolerance within iGluRs, allows consideration of protein-protein interfaces in multimeric proteins, and moves this important research tool from one-dimensional analysis to a structurally-relevant tool. We validated the improved 3DMTR score by showing that it more accurately classified the functional consequences of set of newly measured and published point mutations of Grin family genes than existing methods.

Title: A repertoire of nervous system related genes identified by literature mining showed unambiguous modular expression in brain tissues

Authors: *V. Y. MULEY;
Inst. de Neurobiología, Univ. Nacional Autónoma de México, Queretaro, Mexico

Abstract: Biological systems are inherently modular i.e. they have the ability to organize themselves into multiple sets of discrete individual units, that are relatively autonomous with respect to each other's functional tasks, but together drive specific physiological functions. The examples of discrete units could be sets of genes that execute glycolytic pathway and TCA cycle, which together are part of carbohydrate catabolic pathway. The discrete units of genes are referred to as functional or genetic modules since they have functional and genetic specificity. In the last two decades, several attempts have been made to predict genetic modules using a variety of datasets and techniques. However, our knowledge about genetic modules involved in various physiological functions and their interactions is largely incomplete. Literature databases such as PubMed provide a unique opportunity to mine research text, identify genes, and assemble genetic modules. In this study, I have successfully reconstructed genetic modules involved in nervous system related functions using 2,643,233 research articles published between 1801 to 2018 by querying nervous system related keywords in the PubMed database. Of them, 729,544 publications reported 62,250 unique genes. Hypergeometric distribution test was applied on each gene to assess its over-representation in nervous system related publications in the background of non-nervous system related publications. The 14,672 genes were significantly over-represented in the nervous system related publications at a p-value cutoff of 0.05 or less. In which, human encoded genes were 2,448, while remaining genes were from other species, which were mapped to human genes by best-bidirectional blast searches. This search identified additional 1,855 genes, which were not studied in humans with respect to the nervous system but in other species. In total 3,742 human genes were selected for further analysis, which were frequently reported in nervous system literature. Functional enrichment analysis confirmed their significant association with nervous system related functions, while 66% genes expressed exclusively in brain tissues. Astonishingly, most remaining genes showed a modular expression pattern in a few specific tissues such as blood, testis, and muscles. It indicates that these gene modules, though expressed in other tissues, are likely to form a communication bridge with the brain. Overall, this is a first ever study, which catalogues all genes that are scattered over millions of research articles on the nervous system at one place.

Title: Do arousal fluctuations alter functional connectivity?

Authors: *S. SHAHSAVARANI[1,2], D. N. THIBODEAUX[1], C. J. NWOKEABIA[1], W. XU[1], F. LODGHER[1], D. A. HANDWERKER[2], J. GONZALEZ-CASTILLO[2], P. A. BANDETTINI[2], E. M. C. HILLMAN[1];

Abstract: In functional Magnetic Resonance Imaging (fMRI), researchers often rely on dynamic Functional Connectivity (FC) to investigate ongoing fluctuations in the correlation structure of neural activity. To fully leverage this non-invasive neuroimaging approach, it is imperative to first characterize what drives the underlying neural phenomena that induce the dynamics of functional connectivity as observed in fMRI data. As a first step in that direction, here we asked whether spontaneous changes in neuronal patterns of FC could be explained by behavioral or physiological variables in the awake, behaving mouse. Simultaneous neuronal calcium and hemodynamic signals were recorded from five thinned-skull adult Thy1-jRGECO1a mice, using Wide Field Optical Mapping (WFOM). The mice were free to move on a rotating wheel while their heads were fixed. Concurrently with brain imaging, we monitored the mice's locomotion and whisking patterns to measure changes in behavior. We also recorded pupillometry to measure physiological arousal. Applying pairwise Pearson's correlation coefficient on all temporal segments overlapping with each behavior of interest, we created neuronal FC maps for five distinct behavior and physiological states: (1) locomotion onset, (2) locomotion, (3) locomotion offset, (4) high arousal level right after locomotion offset, and (5) low arousal level 40 seconds after locomotion offset. Next, to predict the temporal evolution of behavioral states during the experimental sessions, we modeled every FC frame as a linear combination of these representative FC brain states. Our results revealed systematic shifts between high and low arousal states when the mouse was not running. Low arousal states were correlated with smaller pupil size and less whisking compared with the high arousal states. Further, our network analyses showed that during the low arousal state, the lateral frontal network and a sensory network, including the barrel cortex, were less synchronized with other brain regions. Additionally, when comparing rest with running, we noted distinct interhemispheric correlations in our brain networks. Specifically, the frontal network and the barrel network exhibited higher interhemispheric correlations during rest, whereas the visual network showed higher interhemispheric correlations during running. Our findings provide evidence that dynamic fluctuations in FC estimated from neuronal data directly relates to our measures of behavior, especially fluctuations in arousal. Future work will assess the hemodynamic correlates of these findings.

Title: Decoding the identities of naturalistic movie clips from human brain hemodynamics using high-density diffuse optical tomography

Authors: *Z. E. MARKOW[1], K. TRIPATHY[3], J. W. TROBAUGH[2], A. M. SVOBODA[4], M. L. SCHROEDER[5], S. M. RAFFERTY[6], E. J. RICHTER[2], A. T. EGGEBRECHT[6], M. A. ANASTASIO[7], J. P. CULVER[8];

Sch. of Med., Saint Louis, MO; [7]Bioengineering, Univ. of Illinois at Urbana-Champaign, Urbana, IL; [8]Radiology, Washington Univ. in St Louis, Saint Louis, MO

Abstract: In the last decade, functional MRI (fMRI) has achieved remarkable success at decoding the identity and content of a wide range of stimuli experienced by human subjects, using their brain activity and machine learning methods. Unfortunately, fMRI employs bulky equipment that cannot be used at the bedside, cannot image many patients with metal implants, and is difficult in young children. More-lightweight non-invasive tools have not accomplished the decoding performance of fMRI. High-density diffuse optical tomography (HD-DOT) non-invasively images blood oxygen fluctuations related to brain activity, like fMRI, but with near-infrared light. HD-DOT is an alternative in fMRI-incompatible patients and settings, and has spatial resolution between fMRI and more-lightweight non-invasive technologies such as NIRS and EEG. To evaluate feasibility of decoding naturalistic movie stimuli with HD-DOT, we first evaluated how well an HD-DOT system could identify which of four 90-second movie clips was being viewed based on imaged brain dynamics. During each session, each clip was viewed 4-8 times (trials) total. For the first half of each session (training set), the brain responses to each clip were averaged to form a "template" response for each clip. For each remaining trial (testing set), our simple decoder guessed that the clip shown was the clip whose template had the highest correlation with the measured response. These guesses were over 80% accurate across 16 sessions from 4 subjects, well above chance (25%) in terms of effect size and statistical significance ($p<0.001$). Next, we attempted to identify clips outside a decoder's training set. To do this, we relabeled two clips and their responses as training trials, and we used these to fit a linear model for predicting the imaged response from wavelet motion energy features in any clip. The model was used to predict the responses to the other two (test) clips and to two "lure" clips never viewed by subjects. This decoder guessed that the clip viewed in each trial was the clip whose predicted response had the highest correlation with the measured data. Across subjects and sessions, average accuracy exceeded 60% and statistically exceeded chance (25%, $p<0.05$). Accuracy

remained above chance even with up to 40 lure clips. Future work will attempt to decode more types of stimuli.

Title: A New Monitoring Method for Detection of Stimulation Regions during HD-tDCS using Effective Connectivity Analysis: An fNIRS Study

Authors: *Y.-H. KIM[1,2,3], G. LEE[1], J. LEE[1], J. KIM[1,2], H. KIM[1,2], S. SHIN[1];
[1]Dept. of Physical and Rehabil. Medicine, Ctr. for Prevention and Rehabil., Samsung Med. Ctr., Seoul, Korea, Republic of; [2]Dept. of Hlth. Sci. and Technology, SAIHST, [3]Dept. of Med. Device Mgmt. & Research, Dept. of Digital Health, SAIHST, Sungkyunkwan Univ., Seoul, Korea, Republic of

Abstract: Transcranial direct current stimulation (tDCS) has been gaining increasing interest as a potential therapeutic treatment in rehabilitation. Although there have been many studies for the effects of tDCS, there are insufficient studies on real-time monitoring methods to give information on the exact location of stimulation personalized to the individual patient for improving the effect of tDCS. In this study, we propose a new method based on functional near-infrared spectroscopy (fNIRS) that can detect the location of stimulation in real-time to provide accurate stimulation location of high-definition tDCS (HD-tDCS) to the functional region of interest of the individual patient. The subjects wear both fNIRS and HD-tDCS devices, which are NIRScout® system (NIRx Medical Technologies, Germany) and Starstim 8 (Neuroelectrics®, Spain). The fNIRS signals around the HD-tDCS electrodes are measured in real-time and the phase-locking values (PLV) are calculated for each fNIRS channel. The PVL has information about not only the connectivity between fNIRS channels, but also the direction of stimulation transmitting by phase analysis. Using this information, the stimulus region can be accurately detected by estimating the location where the stimulus is the most applied. The proposed detection method was loaded into *ActiVeiw*®, which is a real-time brain activity monitoring toolbox, and an experiment was performed with 1 mA HD-tDCS. Real-time responses were observed by calculating the PLV using the fNIRS channels located on the top, bottom, left, and right with the anode of tDCS. Four vectors were created with the magnitudes which were calculated from PLV and the directions estimated from the four positions to each other. Then the summation of the four vectors was represented as the flow of the stimulus transition from the center. This stimulus flow is transmitted from the location of the maximum stimulations to the surroundings by HD-tDCS and the maximum stimulus location can be estimated.

Effectiveness of the proposed method was confirmed by observing the stimulus region according to changes of the cathodal array of HD-tDCS in real-time. Using the proposed method, it was possible to check whether or not the tDCS is being accurately stimulated to the desired regions in real time and was able to give a feedback for correction of the HD-tDCS protocol. This method may be able to improve HD-tDCS effect by providing a personalized stimulation protocol for individual patients**.**

Title: Optical resting state reveals cortical connectivity with columnar resolution in monkeys

Authors: *N. S. CARD[1], O. A. GHARBAWIE[2];
[1]Bioengineering, [2]Neurobio., Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Spontaneous modulations in brain activity (i.e., resting state) reveal fundamental features of brain organization. Measuring resting state with fMRI has gained considerable traction as a non-invasive approach to studying cortical connectivity in humans and animals. Although resting state connectivity (RSC) corresponds with structural connectivity (SC) at the macroscale, it is unclear whether RSC can reveal granular elements of SC. Addressing this problem requires 2 provisions: (1) measuring RSC at cortical column resolution (<200 um), and (2) comparing RSC and SC in the same animal and hemisphere. To meet both provisions, we investigated RSC and SC in motor and somatosensory cortex in 2 squirrel monkeys. We used intrinsic signal optical imaging (ISOI, 630 nm illumination) to measure spontaneous hemodynamic fluctuations under isoflurane anesthesia. High resolution optical images (1312 x 1082 pixels, ~19 um/pixel) were acquired in >12 experiments/animal (15 min/run, 10 frames/s) over 14-16 months. Optical images were processed, temporally filtered (bandpass 0.01-0.1 Hz), then used in cross-correlation analyses between pixels. The field-of-view (~26 x 22 mm) included motor and somatosensory areas, which we mapped extensively (>400 sites/hemisphere) with microstimulation and multi-unit recordings. We used a clustering approach and a seed-based approach to examine spatial patterns in resting state activity. For clustering we applied principal component analysis and k-means to define functionally-related cortical zones. Clustering maps corresponded well with microelectrode maps, which contained anatomical and functional features as they included cortical borders and somatotopic zones. In the seed-based approach, 48 seeds were examined in frontal motor areas (M1, PMd, PMv) and somatosensory areas 3b, 1, and 2. In separate imaging sessions, we used microstimulation + ISOI at the same sites to investigate effective connectivity (EC). Finally, we injected retrograde tracers in 5 of those sites to reveal SC. Thus, for every seed there were 2 connectivity maps (RSC and EC) and 5 of those seeds also had SC maps. All connectivity maps were spatially quantified according to cortical area and

somatotopic zone. Direct comparison of the maps showed excellent correspondence between RSC, EC, and SC. Collectively, the clustering and seed-based approaches showed that resting state ISOI can reveal embedded cortical networks at cortical column resolution. We are now leveraging resting state ISOI to investigate rules that govern connectivity in motor and somatosensory cortex.

Title: Simultaneous, wide-field optical imaging of neural, metabolic and hemmodynamic activity in awake mice

Authors: *X. WANG, A. BICE, Z. ROSENTHAL, J. PADAWER-CURRY, J.-M. LEE, A. BAUER; Washington University, St. Louis, Saint Louis, MO

Abstract: In the healthy brain, local changes in blood flow and brain energy utilization are coupled to changes in local neural activity, phenomenon described as neurovascular coupling (NVC) and neurometabolic coupling (NMC). NVC and NMC evolve during development, abd are altered under anesthesia, and other conditions affecting the central nervous system disrupt individual or multiple pathways involved in NVC. Understanding how different central nervous system. diseases affect different components of NVC will enable linking of changes in neural or metabolic dysfunction to changes in hemodynamic signaling upon which functional neuroimaging methods rely. Genetic engineering techniques in mice have provided new opportunities for extending wide-field optical imaging methods to direct measures of neural activity. Fluctuations in calcium concentration can be imaged and visualized using fluorescent, genetically encoded calcium indicators (GECIs). However, the excitation/emission spectra of commonly used GECIs (e.g. GCaMP) overlap with those of flavin adenine dinucleotide (FAD), an endogenous measure of oxidative metabolism. Red-shifted GECIs allow for parallel imaging of calcium and FAD events and have advantages for in vivo imaging due to reduced tissue scattering and absorption. In addition, unlike GCaMP, excitation spectrum of red-shifted GECI does not overlap with Channelrhodopsin-2(ChR2) spectrum, which makes optogenetics targeting possible. Six mice (7-8 months of age) expressing the red-shifted GECI jRGECO1a with cranial window were used for experimentation. A custom light engine consisting of 470nm, 530nm and 625nm LEDs illuminated the skull. Diffuse reflected light for optical intrinsic signal imaging and fluorescence emission were collected

by a lens, split by a 580nm dichroic and sampled by two CMOS cameras. We developed a dual-fluorophore, wide field imaging system for rapid, simultaneous mapping of calcium, metabolic and hemodynamic activity in awake mice. As a proof-of-concept, we report stimulus-evoked and spontaneous patterns of activity across hemoglobin, FAD and jRGECO1a in awake and anesthetized animals. Contrast-specific patterns of activity differ across state and frequency range examined, providing complementary information along the NVC pathway. This flexible hardware platform allows for integrating optogenetic stimulation for all optical neural circuit interrogation and readout, and for examining the interaction between multiple cell populations. This system can be used to determine how glucose challenge and stroke recovery change the NVC.

Title: Activity-dependent segmentation of wide-field imaging data using spatial independent component analysis (sICA) reveals stable cerebral cortical maps

Authors: *A. K. NIETZ, M. L. STRENG, L. S. POPA, Mr, E. FLAHERTY, R. CARTER, J. D. ARONSON, T. J. EBNER;
Neurosci., Univ. of Minnesota, Minneapolis, MN

Abstract: Recent advances in cranial windows in conjunction with genetically-encoded calcium indicators have allowed chronic, wide-field optical access to non-contiguous brain structures. However, analysis of the (often large) neuroimaging datasets is challenging due the complexity and variability of activation patterns. A fundamental issue is the method used to functionally segment the region imaged, including the stability of that segmentation over different time scales. We implemented spatial Independent Component Analysis (sICA) using the blind source separation algorithm JADER to extract spatial independent components (sICs) on cortex-wide mesoscale calcium imaging data in six mice expressing genetically-encoded GCaMP6f (Thy1-GCaMP6f), a calcium indicator. Spatial ICA segments the cerebral cortex by identifying regions with statistically independent activity based on minimizing mutual information. A surgically implanted transparent polymer skull allowed extensive optical access to the dorsal cerebral cortex. Imaging was performed with the mice head-fixed on a freely moving disk treadmill, allowing for free limb and body movements that included locomotion and grooming. Mice were imaged multiple times over several months, with datasets of approximately 5.5 to 14.5 hours.First, we performed a spatial segmentation of each mouse cortex based on the entire data set, the template map. In all mice, the segmentation showed minimal overlap between sICs and extensive coverage of the imaged cortex. Second, we repeated the analysis using different length time windows of data and compared the resulting sICs with the sICs obtained from the template map using both Gaussian mixture model clustering and a 2D correlation coefficient with a cutoff threshold for similarity. Both methods revealed remarkably similar ICs, in shape and location, across the time windows analyzed. However, not all sICs from the template map were present within the finer time windows, suggesting that certain regions are engaged only at specific times. Intriguingly, ICs from the template map, can split into two components in the finer time windows.These observations argue for two hypotheses. First, the stability of the sICs over different time scales suggests that neural populations in well-defined areas operate in a highly coherent manner, potentially providing the computational building blocks of cortical function. Second, the observation that not every sIC in the template map has a counterpart in finer time windows suggests a temporal dynamic underlies sIC processing and their engagement in behaviors.

Title: Naturalistic stimuli for human brain mapping using high-density diffuse optical tomography

Authors: *M. FOGARTY[1], K. TRIPATHY[1], A. SVOBODA[1], M. SCHROEDER[1], S. RAFFERTY[1], P. MANSFIELD[2], R. ULBRICH[2], M. BOOTH[1], E. RICHTER[1], C. SMYSER[3], A. T. EGGEBRECHT[2], J. CULVER[1];

Abstract: The study of early brain development is challenging due to limitations in both imaging modalities and stimulus protocols. While considered the gold-standard, functional magnetic resonance imaging (fMRI) presents challenges in pediatric populations as the loud, confined space in the bore of the magnet, away from a caregiver, can be frightening for children. Alternatively, high-density diffuse optical tomography (HD-DOT) is an emerging method that uses a dense array of overlapping light measurements to improve image quality over traditional functional near-infrared spectroscopy (fNIRS) as validated against fMRI in adults. The open-air environment of HD-DOT, along with the development of a child-sized imaging cap, makes our preschooler age HD-DOT system conducive for studying childhood brain development. Movie viewing is an increasingly popular naturalistic stimulus as it can reduce head motion and increase engagement in young children. Movies also drive reproducible brain activity despite their complexity and can be used to map multiple processing pathways in parallel using feature regressor analysis. These regressors are time courses for certain features in the movie including low-level features, such as luminance, as well as high-level features like speech or faces, which can be either manually or automatically coded. Movie features often covary, for example speech and faces, prompting the need for a multivariate general linear model (GLM) -based processing approach. To validate the movie regressor maps we compared the maps from speech feature regressors to activation maps from a well-characterized word hearing task. The maps from movies vs isolate maps displayed considerable similarities. However, manually coding these high-level features is a time-consuming and subjective process that severely limits our library of movie clips. Alternatively, a Faster Region-based Convolutional Neural Network (R-CNN) was trained and implemented to detect faces in animated movie clips and automatically code the face regressor. Maps were compared between the automatically and manually coded face regressors and displayed a high degree of similarity based on the Pearson correlation coefficient across the entire field of view. Overall, the establishment of an engaging child-friendly, naturalistic stimuli lays the groundwork for future developmental neuroscience studies in preschool age children.

Title: Observing the Activity of Serotonergic Neurons After Acute Pain Stimulation Using Implantable CMOS Imaging Device and Microdialysis in Freely Moving Mice

Authors: *L. AKBAR, Y. OHTA, M. KAWAHARA, H. TAKEHARA, M. HARUTA, H. TASHIRO, K. SASAGAWA, J. OHTA;
Nara Inst. of Sci. and Technol., Ikoma, Japan

Abstract: Visualizing neural activity using imaging method is recently becoming an intriguing trend in neuroscience. However, current available devices are relatively larger and weightier, make it difficult to employ in a deeper brain region. Furthermore, multiple sites of imaging or combination with other systems to gather valuable information is still limited. In fact, neurons are working within numerous network connections, for instance, acute pain involves diverse neural projections. Serotonin is a neurotransmitter firmly related with pain. Dorsal raphe nucleus (DRN) serves as the major source of serotonergic neurons in the brain which innervates various parts including central amygdala, particularly the capsular-lateral subsection (CeLC), and anterior cingulate cortex (ACC). CeLC and ACC are extensively associated with the affective dimensions of pain. Nevertheless, direct observation of these three different areas concurrently on a living animal remain unexplored. In this study, we aim to demonstrate the design and utility of integrated system of implantable imaging device with microdialysis. Our device is thin and lightweight (~0.2 gram), composed of CMOS image sensor and micro-LED (λ=470 nm) embedded on the flexible printed circuit (FPC) substrate. The absorption filter is applied above the image sensor. The device is coated by Parylene-C for biocompatibility and waterproofing. The design of our device avoids bulky optical compartment while retaining its crucial function for observing neural activity. The imaging device was implanted to DRN, and microdialysis probes in CeLC and ACC. We subcutaneously injected 2% paraformaldehyde (PFA) to the mouse hindpaw to induce acute pain condition. The microdialysis sample were collected every 15 minutes and measured by high-performance liquid chromatographic column-electrochemical detector (HPLC-ECD). Using GCaMP6 transgenic mice, our device was able to detect neural activity. The results suggested that fluorescence intensity increased in DRN after 2% PFA stimulation. Serotonin concentration also elevated both in CeLC and ACC, observably higher in the first 15 minutes after the stimulation which in line with a massive licking behavior in the injected hindpaw. By this experimental scheme, we revealed that our device is feasible for multi-site implantation with less invasiveness and did not hinder the mice movement, an important consideration for *in vivo* investigation. The streamlined structure of our device can be safely combined with other systems, and it also enables us to conduct triple implantation, opening possible way to monitor neural circuits in many locations simultaneously.

Title: Effective correction of physiological noise and head motion artifacts with resting-state fNIRS data

Authors: *P. LANKA[1], T. HUPPERT[2], H. BORTFELD[1];
[1]Univ. of California, Merced, Merced, CA; [2]Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Resting-state functional connectivity (RSFC) with functional near-infrared spectroscopy (fNIRS) is an effective tool to study cortical connectivity across development. However, the presence of motion artifacts (MA) and systemic physiology (SP), including cardiac, respiration, and blood pressure, in the fNIRS signal can lead to incorrect statistical conclusions due to increased false positives (FP) and lowered sensitivity to the underlying neural activity. For example, shared SP between fNIRS channels may lead to spurious correlations due to increased covariance between channels. Moreover, the hemodynamic response (HR) and SP combined with the high sampling rate of fNIRS can lead to temporal autocorrelation of the time series, also producing spurious correlations. Finally, motion corrupted timepoints, whether as spike or shift artifacts, have higher signal intensity than neural activity and thus may also lead to false conclusions. It is imperative for fNIRS researchers to correct for these issues to obtain statistically valid RSFC measures using this technique. Previous studies have shown that pre-whitening and the use of robust methods are effective in reducing temporal autocorrelation and motion artifacts respectively, while the use of short separation (SS) channels that capture signal changes originating in the scalp offers a solution to ameliorate some of the problems with SP in fNIRS data. However, questions remain about the effectiveness of principal component analysis (PCA) for removing shared SP, and the effectiveness of these methods for time-lagged connectivity metrics such as Granger causality (GC) is not well understood. In the current study, we used simulated data with a known covariance structure to mimic the HR associated with neural activity and added shared physiological noise along with spike and shift artifacts to mimic motion artifacts. We used FP rate plots and receiver operating characteristic (ROC) curves to assess the effectiveness of these methods. Our results using simulated data corroborate the use of robust statistics and pre-whitening as effective methods to correct for MA and autocorrelation in fNIRS time series. More importantly, we found that using principal components extracted from SS channels as covariates in partial correlations between channels was effective in reducing spurious correlations due to shared SP. Finally, while our approach is also applicable to GC metrics, it is not as effective in reducing the FP rate as with the zero-lag connectivity metrics. We recommend a combination of pre-whitening, robust methods, and partial correlation for obtaining statistically valid connectivity metrics with fNIRS.

Title: Working with Wilfrid Rall: Origins of computational neuroscience

Authors: *G. M. SHEPHERD;
Yale Med. Sch., New Haven, CT

Abstract: John Moore (2010) has provided a valuable "personal view" of the early development of computational neuroscience with recollections of his work with Kacy Cole in 1950, carrying out the first computer calculations of the Hodgkin-Huxley equations for the action potential on the SEAC, the first "truly functional electronic computer in the US". A decade later I joined Wilfrid Rall when he was creating the compartmental method for representing integration of synaptic activity in neurons. The first application of the Rall method to motoneuron dendrites became a classic of the founding of computational neuroscience (Rall, 1964). The second application was in our work on olfactory bulb neurons, characterized by Moore as a "computational breakthrough; the prediction of the possibility of dendrodendritic synapses (Rall and Shepherd, 1968)." This work, together with Tom Reese and Milton Brightman, has been summarized in "The Theoretical Foundation of Dendritic Function" (Segev et al, 1995). Here I provide background with unpublished documentation for how we extended the Rall method to brain neurons and microcircuits. The Rall method adapted the metabolic approach of Mones Berman describing the movement of tracers through large body compartments to the biophysical representation of synaptic potentials spreading in fine dendritic processes of individual neurons. In our model he added the first representation of simplified HH equations for analysis of active dendritic properties. The antidromically driven mitral cells and synaptically activated granule cells were analyzed as electric dipoles generating successive time periods of extracellular potentials, which served to constrain the interpretation of active vs passive properties of the neurons. My proposed local circuit wiring diagram facilitated testing for the interactions between mitral and granule cells; the model rejected axon collaterals and predicted a sequence of dendrodendritic activation of granule cell dendrites which then inhibit the mitral cell dendrites. Rall recorded our discussion as we created this prediction in his notebook Vol. 4 (August 24, 1964, p.56). The prediction was confirmed by electron microscopy (Rall et al, 1966) as recorded in correspondence between the four investigators at the time. This was a novel brain microcircuit based on neuroanatomy, electrophysiology, electronmicroscopy, and a realistic computational biophysical model. Rall's lab notebooks and our correspondence describing this and other early unpublished work on computational models are openly accessible to scholars at https://medicine.yale.edu/lab/shepherd/.

Title: Super-human cell death detection with biomarker-optimized neural networks

Authors: *J. LINSLEY[1], D. LINSLEY[3], J. LAMSTEIN[1], G. RYAN[1], K. SHAH[4], N. CASTELLO[1], V. OZA[1], J. KALRA[1], S. WANG[1], Z. TOKUNO[2], A. JAVAHERIAN[1], T. SERRE[3], S. FINKBEINER[1];
[1]Gladstone Inst., San Francisco, CA; [2]Gladstone Inst., San Francsico, CA; [3]Brown Univ., Providence, RI; [4]System1 Biosci., San Francisco, CA

Abstract: Many of the cellular events that underlie neurodegenerative disease are best captured by continuously imaging live neurons over time with microscopy. The advent of robot-assisted microscopy has helped scale longitudinal live microscopy to high-throughput regimes with the statistical power to detect transient events. Yet analysis of these experiments still relies on time-intensive human annotation. Cell death in particular is a fundamental biological process commonly found in live microscopy but that is difficult to automatically detect without perturbing experiments with stains, dyes or biosensors that can bias experimental outcomes, lead to inconsistent results, and reduce the number of processes that can be simultaneously labelled. We address this fundamental limitation of live microscopy with biomarker-optimized convolutional neural networks (BO-CNN): interpretable computer vision models trained directly on biosensor activity. We demonstrate the ability of BO-CNNs to detect cell death with super-human accuracy and speed by learning to identify important subcellular morphology associated with cell vitality, despite receiving no explicit supervision to rely on these features. Importantly, these models also uncover novel intranuclear morphology signal that is difficult to spot by eye and has not yet been linked to cell death, but reliably indicates death. BO-CNNs are broadly useful for analyzing any live microscopy and essential for interpreting high-throughput robotic-aided experiments.

Title: Mathematical simulation predicts hyperexcitability of axotomized neurons through decrease in the membrane capacitance (C_m)

Authors: *E. PETROFF, V. SNITSAREV;
Montclair State Univ., Montclair, NJ

Abstract: Axotomy induces considerable changes in the electrophysiological characteristics of sensory neurons and leads to hyperexcitability, which in case of nociceptive neurons may cause chronic pain. We

used a Simulink implementation of nodose neuron action potential firing model developed by Schild et al. *J Neurophysiol* 71, 2338-2358, 1994, and further updated in Schild & Kunze *J Neurophysiol* 78, 3198-3209, 1997, to model changes that may lead to hyperexcitability. In the mathematical simulation of an A-type neuron [https://www.mathworks.com/matlabcentral/fileexchange/18812-nodose-neuron-action-potential-firing], the resting membrane potential (MP_{rest}) settles to -56.0 mV upon initialization. In response to progressively increasing current injections from 0.025 to 0.045 nA with 0.005 nA increments, the model generates 0, 1, 2, 4, and 6 APs, and adapts within 1 second to the membrane potentials of -48.0, -46.4, -44.6, -42.6, and -40.5 mV, respectively. The model behaves similar to an A-type neuron. For example, elimination of conductance of the fast tetrodotoxin-sensitive voltage-gated Na^+ channel, similar to the experimental application of tetrodotoxin, leads to elimination of action potentials in the model. We paid particular attention to the parameter shifts that could increase neuronal excitability, a model of chronic pain elicited by nociceptive neurons after injury and following tissue regeneration. Because C_m is directly proportional to the plasma membrane surface area, we hypothesized that a decrease in C_m may lead to an increase in excitability. A decrease in C_m by 10% from its default value of 32.5 pF results in 0, 1, 4, 10 APs and adaptation to -48.0, -46.4, -44.6, and -42.8 mV in response to 0.025, 0.03, 0.035, and 0.04 nA current injection, respectively; while in response to 0.045 nA a non-adapting train of APs at 25 Hz was elicited. Conversely, an increase in C_m by 10% from its default value of 32.5 pF results in 0, 1, 2, 2, and 3 APs and following adaptation to -48.0, -46.4, -44.6, -42.6, and -40.3 mV in response to 0.025, 0.03, 0.035, 0.04 and 0.045 nA current injection, respectively. Notably, these changes in excitability were not directly related to the changes in the level of depolarizing membrane potentials in response to current injections (model of the receptor potential). This simulation could potentially contribute to further understanding of neuronal hyperexcitability and pain during inflammation, injury and following tissue regeneration to develop tools for pain reduction.

Title: A conductance-based model of intrinsic firing activity in human induced pluripotent stem cell-derived dopaminergic neurons

Authors: *A. L. HANES[1], D. PRE[2], A. WOOTEN[2], A. G. BANG[2], J. M. GEARHART[3];
[1]On contract to AFRL 711 HPW/RHBBA, UES, Inc., Beavercreek, OH; [2]Prebys Ctr., Sanford Burnham Prebys Med. Discovery Inst., La Jolla, CA; [3]On contract to AFRL 711 HPW/RHBBA, Henry M. Jackson Fndn., Dayton, OH

Abstract: Human induced pluripotent stem cell (hIPSC)-derived neurons are an in vitro platform for high-throughput screening that measures the effect of neuroactive compounds in terms of altered firing activity, but not mechanisms. To complement this screening platform, we developed an in silico conductance based model of the intrinsic properties of hISPC-derived dopaminergic (DA) neurons using

the NEURON modeling software, with the intention to later expand the model to simulate small networks. Our objective is to identify hypothetical mechanisms of action for neuroactive compounds by tuning model parameters to reproduce the altered activity caused by those compounds. Ion channels were selected for inclusion in our model via literature search, and the presence of these channels in hIPSC-derived DA neurons was confirmed through RNAseq. The channels' voltage-dependence and kinetic parameters were selected via literature search; a single-cell model was created with representations of these ion channels, as well as intracellular calcium buffering and efflux, and volume transmission and reuptake of dopamine. A simulation of multiple non-networked neurons was created by generating replicates of the single cell model in which the maximal conductances and some kinetic parameters were randomly varied. To obtain the data for model validation, neurons were cultured on microelectrode array plates in the presence of synaptic blockers, such that the resulting firing activity represented the cells' intrinsic pacemaking activity rather than synchronized network bursts. These data were then analyzed via spike-sorting, yielding the spiking activity and firing rates of individual firing units. This process was repeated with neuronal cultures treated with verapamil and gabapentin, which have a known pharmacological effect on some of the ion channels in the cultures. By tuning the model parameters according to these compounds' mechanisms of action, we were able to create simulations that reproduced the approximate range of firing rates seen in all three treatment conditions, indicating that our model is an accurate reproduction of the cellular mechanisms underlying the intrinsic neuronal properties observed in vitro.

Title: Aging Lévy walk with rest model for Arc and β-actin mRNA transport in neurons

Authors: *H. AHN[1], X. DURANG[2], J. SHIM[1], G. PARK[1], J.-H. JEON[2], H. PARK[1];
[1]Dept. of Physics and Astronomy, Seoul Natl. Univ., Seoul, Korea, Republic of; [2]pohang university of science and technology, Pohang, Korea, Republic of

Abstract: Localization of mRNA in neurons is crucial for regulating gene expression for long-term memory formation. mRNAs are recruited to messenger ribonucleoprotein (mRNP), which are packages of mRNAs and proteins, and transported to their target location by motor proteins along cytoskeletons. However, the mechanism by which mRNPs find their target site is not understood well. Here, using the MS2/PP7 mRNA labeling system, we observed endogenous Arc and β-actin mRNA in living neurons as they are known to be localized to activated synapses. After investigating the statistical properties of mRNA movements, we modeled the mRNA movement as an aging Lévy walk which has two dynamic

phases: the motor-involved ballistic run and static localization. This study suggests a theoretical model for the mechanism of neuronal mRNP transport and provides a quantitative comparison between the model and experimental data for the two different mRNAs.

Title: Computational modeling of blocking afferent neural transmission by sub-kilohertz electrical stimulation of dorsal root ganglia

Authors: *N. SHALABY, B. FENG;
Dept. of Biomed. Engin., Univ. of Connecticut, Storrs, CT

Abstract: Chronic visceral pain is a debilitating medical condition that leads to decreased quality of life. Its multifaceted nature and vague identifiable symptoms make it a challenge to treat by conventional pharmacological approaches. Neuromodulation techniques, such as spinal cord stimulation and peripheral nerve stimulation, have emerged as non-drug alternatives to chronic pain management. We recently provided compelling experimental evidence to indicate that dorsal root ganglion (DRG) stimulation can block action potential transmission in peripheral nerves, which potentially alleviates pain without evoking paresthesia. To gain mechanistic insights into DRG stimulation, we report in this abstract computational models of myelinated and unmyelinated sensory afferent neurons and systematical assessment of the effect of extracellular DRG stimulation on action potential transmission and conduction block. NEURON simulation environment is used to build models of sensory afferent neurons consisting of a soma in the DRG, a stem axon, and its bifurcation at the T-junction into a peripheral axon projecting to the target tissue and a central axon projecting to the spinal cord. Action potentials are evoked in the distal end of the peripheral axon and extracellular electrical stimulation is delivered close to the DRG soma. Myelinated A-fibers are modeled with regions of Nodes of Ranvier connected by passive internodal segments. Unmyelinated C-fibers are assumed to have homogeneous ion channel densities in axonal regions. We used the models to assess the following potential mechanisms responsible for the blocking effect by DRG stimulation: activation of calcium-activated potassium channels at the T-junction, increase of intracellular sodium and extracellular potassium concentrations, axonal membrane hyperpolarization by elevated sodium potassium ATPase, and soma membrane hyperpolarization. This preliminary modeling study will not only advance our mechanistical understanding of sub-kilohertz DRG stimulation in afferent conduction block, but also guide the design of new stimulation protocols that target the DRG and other regions of the afferents to effectively attenuate peripheral drives to the central nervous system.

Title: Computational modeling of extracellular microelectrode recordings from A-delta neurons in the dorsal root ganglia

Authors: *L. R. MADDEN[1,2], R. D. GRAHAM[1,2], S. F. LEMPKA[1,2,3], T. M. BRUNS[1,2];
[1]Biomed. Engin., [2]Biointerfaces Inst., [3]Dept. of Anesthesiol., Univ. of Michigan, Ann Arbor, MI

Abstract: Dorsal root ganglia (DRG) are discrete recording targets for closed-loop peripheral neuromodulation, due to the presence of sensory neurons that innervate specific dermatomes. DRG contain pseudounipolar neurons, which have a stem axon protruding from the soma that splits into a peripheral axon that extends out to the body and a central axon that enters the spinal cord. A-type DRG neurons occasionally contain a long, tortuous, unmyelinated axonal pathway at the initial segment, known as a glomerulus. The electrophysiological effects of potential ephaptic coupling - the phenomenon that the electric field generated by a firing axon can influence the firing properties of adjacent axons - has yet to be explored in these neurons. Additionally, in vivo DRG recordings with penetrating microelectrodes can have distinctive “W”-shaped waveforms whose origin is not understood. Here, we built a computational model of an A-delta neuron within a DRG to investigate how the extracellular voltage waveform recorded by a penetrating microelectrode array can be influenced by the neuron’s structure (the trajectory of the glomerulus), electrophysiological properties (ephaptic coupling within the glomerulus), and its location relative to the recording electrode. We built a finite element method model that included general thorax tissue, bone, intraforaminal space, a dural sheath, white matter peripheral and spinal nerve roots, a grey matter DRG, and a penetrating multi-site microelectrode array. We built a multi-compartment double cable model that contained a myelinated stem axon, peripheral and central axon branches, an unmyelinated glomerulus section, and a 40-µm diameter soma. We used a reciprocity-based approach to simulate extracellular recordings at multiple sites on our microelectrode array. Our model demonstrated how the location of the recording contact relative to different components of the neuron influenced the peak-to-peak voltage amplitude and multiphasic properties of the recorded waveform. The results of this model may be used to provide context for in vivo neural recordings, identify features to improve the accuracy of spike sorting algorithms, and give insights into the electrophysiological function of glomeruli in DRG A-type neurons.

Title: Effects of electric field on neuromodulation in transcranial direct current stimulation

Authors: *H. CHUNG[1], C. IM[1], H. SEO[2], S. C. JUN[1];
[1]Sch. of Electrical Engin. and Computer Sci., Gwangju Inst. of Sci. and Technol., Gwangju, Korea, Republic of; [2]Daegu-Gyeongbuk Med. Innovation Fndn., Daegu, Korea, Republic of

Abstract: Noninvasive brain stimulation (NIBS) has increasingly attracted attention from many researchers as a neuromodulation technique because of its application in brain research and treating neurologic and psychiatric disorders. One of the ways to apply NIBS is transcranial direct stimulation (tDCS), which modulates cortical neurons' activities by delivering weak electric currents through two or more electrodes attached to the scalp. However, the results of tDCS are highly variable depending on the inter-subjects and there remains uncertainty about the affected brain areas as well as its cellular mechanisms. In particular, there has been a controversy around the deterministic factors of cortical neurons' response to tDCS. Some studies reported that the orientation of stimulation, which is represented as the radial field (RF), is a crucial factor, while others insisted that electric field (EF) magnitude itself is the key factor. In the midst of this controversy, we aimed to investigate the deterministic factor for neuronal response to conventional (C)-tDCS and high-definition (HD)-tDCS in a computational study by constructing a multi-scale model. We integrated anatomically detailed head models and morphologically detailed multi-compartmental models of three types of cortical neurons. Our neuron models were modified versions of neuron models from the blue brain project and had an anatomically detailed morphology from dendrites to arborized axons. With a multi-scale model, we quantified the neuronal response to the C-/HD-tDCSs and investigated the effects of EF and RF magnitudes on the excitation threshold of neurons. We found that EF was more highly correlated to neuronal response than RF in both C-/HD-tDCSs. In a comparison between C-/HD-tDCSs, the latter's EF and RF had a higher correlation on neuronal response. This is possibly because, as reported by other studies, HD-tDCS has higher EF and RF focalities, compared to C-tDCS. We concluded that EF was a deterministic factor for the excitation threshold. However, RF also had a noticeable impact on the cortical neuronal response to tDCS, even though it is relatively weak. This result might suggest that the strength and orientation of the electric field should be taken into consideration when tDCS is applied. This work allowed us to quantify the effect of EF and RF in the cases of both C-/HD-tDCSs by combining morphologically realistic neurons and an anatomically realistic head model. Further, this work should be helpful in getting us one step closer to settling the controversy surrounding the deterministic factor of the cellular mechanisms of NIBS and cellular mechanisms per se.

Title: Combining neural ODEs and incomplete ODE systems to model complex under-parameterised biochemical networks

Authors: *D. LINKEVICIUS[1], A. CHADWICK[1], M. STEFAN[2], D. STERRATT[1];
[1]Sch. of Informatics, [2]Ctr. for Discovery Brain Sci., Univ. of Edinburgh, Edinburgh, United Kingdom

Abstract: Complex biochemical networks that contain on the order of a thousand unique protein species [3] underpin synaptic function. Such biochemical networks can be modelled as systems of ordinary differential equations (ODEs). However, to date, a detailed dynamical model of synaptic biochemistry contained at most 55 unique proteins [2]. This large discrepancy is due to the dearth of knowledge on the structure and reaction rates of synaptic biochemical networks, making only partial models of the synapse possible. Therefore, there is a need to develop alternative approaches to model synaptic biochemical networks, which are agnostic to the full structure and parameterisation of the biochemical system.
In this exploratory work we propose a method of combining an existing partial ODE model with a powerful novel machine learning approach - neural ODEs [1]. We restrict some of the derivatives in the Neural ODEs to be a partial ODE model of a biochemical system. Our approach can then learn the remaining dynamics necessary to reproduce given physiological data in an efficient, data-driven manner and requires less data on the biochemical reaction structure and rates. By using a synthetic example we demonstrate how the resulting model is more powerful than traditional approaches, yet is partially interpretable via the encoded partial ODE system which represents real biochemical species.
Most dynamical models of synaptic activity are constructed in order to investigate a very limited number of phenomena. Since such models only include a small fraction of the protein species existing within a synapse [2], it is unclear how they would perform in reproducing a broader range of synaptic dynamics. Given our exploratory work, we believe that our semi-black box hybrid approach could ultimately produce a dynamical model that is powerful enough to reproduce a much larger set of empirical studies on synaptic dynamics. Such a model could be an invaluable tool to further both theoretical and empirical understanding of synapses.

Title: A graph neural network approach to neuron classification

Authors: *E. A. SMITH, R. C. GERKIN;
Arizona State Univ., Tempe, AZ

Abstract: The morphology of neurons determines their functional processing capabilities and their role in neural circuits. Constructing biologically realistic computational models of neural circuits will require accounting for a diversity of morphologies -- including from the same nominal neuron type -- and then generating statistically equivalent diverse neuron types in silico. In order to construct a framework for classification and generation of diverse morphologies, we used a graph neural network (GNN) architecture, a deep learning architecture that accounts for connectivity relationships in predicted elements; specifically we used the actual neuronal morphology as the "graph", with reconstructed neuritic segments as nodes and edges. We trained models of this type using complete reconstructions of mammalian olfactory bulb neurons from NeuroMorpho, and evaluated the ability of these models to correctly classify specific cell types. Simulation results indicate that the model performance is comparable to conventional methods of classifying neurons from structure. Because these GNN models develop an internal representation of the relationship between the low-level morphological details and neuron types, future work will allow the operation to be reversed: creating novel neuron morphologies from provided types, while respecting observed variability within and across types.

Title: Characterizing the TMS-evoked EEG responses of the leg, hand, and face areas in the primary motor cortex

Authors: *E. KALLIONIEMI[1,2], S. MÄÄTTÄ[2], L. SÄISÄNEN[2,4,5], J. HYPPÖNEN[2], P. KOSKENKORVA[3], J. SAARI[2,5];
[1]UT Southwestern Med. Ctr., Dallas, TX; [2]Clin. Neurophysiol., [3]Dept. of Clin. Radiology, Kuopio Univ. Hosp., Kuopio, Finland; [4]Inst. of Clin. Med., [5]Applied Physics, Univ. of Eastern Finland, Kuopio, Finland

Abstract: Transcranial magnetic stimulation (TMS) is a non-invasive brain stimulation method. When combined with simultaneous electroencephalography (EEG), TMS-evoked EEG potentials (TEPs) can be applied to evaluate the excitability, connectivity, and oscillatory characteristics of the stimulated cortical

area. So far in the motor cortex, TEPs have been described mainly in the hand motor area. No research exists on whether TMS applied to cortical representation areas for different muscle groups induce similar TEPs to that of the hand TEPs or whether the TEPs are unique for the specific functional area being stimulated. Thereby, we aimed to characterize the TEPs measured from the cortical leg, hand, and face area. The cortical representation area for the leg is near the vertex, the hand slightly more lateral, and the face the most lateral in the primary motor cortex. The study included 9 healthy right-handed subjects (38±11 years, 5 females). First, the cortical representation areas for the right leg (tibialis anterior), hand (first dorsal interosseous), and face (mentalis) were mapped, and the resting motor threshold (rMT) from these areas were measured as the % of maximum stimulator output (%MSO). In total, 150 TEPs from each area were measured using single-pulse TMS at an intensity of 90% of the area-specific rMT. In the analyses, the TEPs for each representation area were averaged. The subject-specific TEP peaks were characterized by their mean latency and polarity (negative, N; positive, P) at the Cz electrode. rMT of the hand was lower than that of the face and leg (p=0.001). The mean ± standard deviations were 56.0 ± 14.0 %MSO (leg), 38.0 ± 4.7 %MSO (hand) and 63.7 ± 19.3 %MSO (face). For leg, the most consistently identifiable peak latencies at single-subject level had a group mean ± standard deviation of P33 ± 5ms, N53 ± 7ms, P66 ± 10ms, N77 ± 10ms, P133 ± 8ms, N178 ± 8ms, and P225 ± 3ms. For hand, the peaks were P30 ± 5ms, N58 ± 5ms, N100 ± 5ms, P154 ± 4ms, and N175 ± 5ms. For the face, the latencies were N20 ± 5ms, P32 ± 5ms, N60 ± 6ms, P78 ± 6ms, N113 ± 7ms, P166 ± 6ms, and N215 ± 5ms. TEPs in all muscle groups had a similar initial waveform, but after about 66 ms after the TMS-pulse, the TEP peaks started to differ, especially that of hand differed from others. Both the hand and face TEPs exhibited the N100 peak, which was not visible in the leg TEPs. Alternatively, the leg N100 could have appeared earlier than in the other muscles, as the leg TEPs involved an additional negative peak at 77 ms after the TMS-pulse. These results suggest that TEPs might be unique to each muscle group.

Title: Neurocognitive biomarkers of TMS response: Modeling the trajectories of change in cognitive control in response to TMS for depression.

Authors: *S. T. OLSEN, C. R. P. SULLIVAN, D. C. COOPER, S. WILSON, A. I. SONMEZ, S. C. ALBOTT, S. C. OLSON, Z. NAHAS, C. B. PETERSON, B. R. RITTBERG, A. HERMAN, A. S. WIDGE;
Univ. of Minnesota Twin Cities, Minneapolis, MN

Abstract: Transcranial magnetic stimulation (TMS) of the prefrontal cortex (PFC) is an effective treatment for depression, though it is time consuming and costly, and only 40-70% of patients respond. TMS suffers from a lack of biomarkers of target engagement that are scalable to general practice. Further, there is a lack of mechanistic understanding; it is unknown how activation of the PFC leads to improvement in depressive symptoms. Cognitive control has been linked to both PFC function and the symptoms of depression, as well as having been shown to improve with TMS. In this way, changes in cognitive control with TMS could be a potential target engagement biomarker, as well as elucidating the mechanism of action of TMS response. Additionally, better (and earlier) prediction of patient response, could further improve treatment outcomes and potentially shorten the number of necessary treatments. We are combining a trajectory modeling approach (latent class mixture modeling) with a battery of cognitive control tasks, measured longitudinally throughout the course of TMS for treatment resistant depression (TRD). We have conducted a replication of the trajectory modeling of clinical response using a naturalistic sample of 155 patients who received TMS for TRD. Results of that retrospective analysis indicated a non-response, and lower and higher baseline symptom response trajectories, partially replicating previous research using this approach. However, it remains unclear whether this modeling can be used to accurately predict response prior to completion of treatment. We have begun data collection on the cognitive battery study, with 6 patients currently enrolled. Tasks are performed at two baseline visits, once weekly throughout treatment, and at a one-month follow-up. Tasks measure different aspects of cognitive control and include: Bandit, Two-Step, Dot-Probe Expectancy, and WebSurf. Additionally, a questionnaire assessing depression symptoms (Patient Health Questionnaire-9, PHQ-9) is taken daily as a part of normal clinical care. For each run of the task, we use established modeling (e.g., drift diffusion, or logistic regression assessing model-based versus model-free learning) to extract a measure of the patient's decision making, which can then be tracked across time using the trajectory modeling approach. We predict that changes in cognitive control will precede changes in depression symptoms, providing evidence of cognitive control as a viable biomarker of TMS response.

Title: Rapid estimation of neuronal activation by transcranial magnetic stimulation using convolutional neural networks

Authors: *A. S. ABERRA[1], A. LOPEZ[2,3], W. M. GRILL[1,2,4,5], A. V. PETERCHEV[1,2,5,6];

Abstract: Transcranial magnetic stimulation (TMS) can modulate neural activity by evoking action potentials in populations of cortical neurons. The TMS-induced electric field (E-field) can be simulated in subject-specific head models derived from MRI data, but the spatial distribution of the E-field alone does not predict the neuronal response. Coupling E-field models to populations of biophysically realistic neuron models has yielded insights into the direct activation mechanisms of TMS (Aberra et al. 2020), but the significant computational cost associated with non-linear neuronal models limits their widespread use and eventual translation to clinical applications. Our objective was to use machine learning approaches to develop computationally efficient estimators of the activation thresholds of multi-compartmental cortical neuron models in response to TMS-induced E-fields. We used a multi-scale model combining anatomically accurate finite element method (FEM) E-field models with layer-specific models of cortical neurons adapted from the Blue Brain library to approximate the properties of human neurons (Aberra et al. 2018). We calculated activation thresholds of model pyramidal cells (PCs) in layers 2/3 and 5 and large basket cells in L4, and we used these data to train 3D convolutional neural networks (CNNs) to predict the thresholds for specific model neurons given their local E-field distribution sampled on a cubic grid. We compared this CNN estimator to an approach using the uniform E-field approximation to estimate thresholds in the non-uniform TMS-induced E-field. Using training and test datasets from different head models, the 3D CNNs were substantially more accurate than the uniform E-field approach, with mean absolute percent error (MAPE) on the test dataset below 2.5% compared to 5.9 - 9.8% MAPE with the uniform E-field approach. Further, there was a strong correlation between predicted and actual thresholds ($R^2 > 0.96$) for all cell types vs. 0.62 - 0.91 R^2 for the uniform E-field approach. The CNNs estimated thresholds with 2 - 4 orders of magnitude computational speedup over the multi-compartmental neuron models. We found a 3D CNN architecture can estimate rapidly and accurately the activation thresholds of biophysically realistic neuron models for TMS using sparse samples of the local E-field, enabling simulation of the response of large neuron populations on a personal computer.

Title: Does transcranial alternating current stimulation modulate cognition? A systematic review and meta-analysis.

Authors: *R. FAYZULLINA[1], S. GROVER[1], B. M. BULLARD[2], V. LEVINA[3], R. M. REINHART[1]; [1]Dept. of Psychological & Brain Sci., Boston Univ., Boston, MA; [2]Dept. of Psychology, The Univ. of California, Berkeley, Berkeley, CA; [3]Dept. of Psychiatry, Yale Univ., New Haven, CT

Abstract: In the past decade research in non-invasive brain stimulation has become more prevalent, drawing attention not only to the opportunity to study causal relationships between brain and behavior but also to the potential of stimulation to improve cognition. A growing body of studies examines the effects of transcranial alternating current stimulation (tACS) on cognitive performance. We aimed to evaluate the evidence accumulated in existing research and quantify the effects of tACS on various cognitive domains. We performed a random-effects meta-analysis of 90 studies (266 experiments) that used tACS to modulate attention, memory, executive control, learning, fluid intelligence, and decision-making, or to improve clinical symptoms. The effect sizes were synthesized using the robust variance estimation method separately for performance and reaction time outcomes. We further performed the moderator analysis that investigated the effects of various parameters of stimulation by the means of meta-regression. Quality assessment, testing for heterogeneity, evaluation of the publication bias, and sensitivity analysis were performed to ensure the robustness of the results. Total sample size included 2656 participants (1159 males, average age 31.4 (SD =16.5)). The results showed a small, but statistically significant overall effect of tACS on performance across all cognitive domains (Hedges' $g = 0.29$, 95% CI [0.2, 0.38], $p < 0.0001$), and an even smaller, yet significant, effect of tACS on reaction time (Hedges' $g = 0.20$, 95% CI [0.08, 0.32], $p = 0.002$). We found significant effects of tACS on performance in executive control ($g = 0.52$), attention ($g = 0.32$), long-term memory ($g = 0.28$), and working memory ($g = 0.26$), but not fluid intelligence or motor learning. Moderator analysis showed a statistically greater offline effect of tACS on cognitive performance compared to the online effect. Exploratory analysis revealed significant interaction of the timing of stimulation effects with the use of current-flow modeling and manipulation of the current phase. No other parameters of stimulation significantly affected the magnitude of the effect size. Our work presents the largest existing meta-analysis of tACS effects on cognition so far, yet it also shows the heterogeneity present in existing research - a typical feature of a young developing field. While the results of the meta-analysis showed a robust effect of tACS on cognitive performance, the optimal features of stimulation setup remain less clear. More research is needed to evaluate an effective combination of stimulation parameters to guide future studies and interventions.

Title: Fronto-occipital phase shift in EEG cross-frequency coupled phase-dependency during working memory performance

Authors: M.-H. AHN[1], H.-S. KIM[2], ***B.-K. MIN**[3];
[1]Lab. of Brain & Cognitive Sci. for Convergence Med., Hallym Univ., Anyang, Korea, Republic of; [2]Biomed. Engin. Res. Ctr., Asan Med. Ctr., Seoul, Korea, Republic of; [3]Dept. of Brain & Cognitive Engin., Korea Univ., Seoul, Korea, Republic of

Abstract: Transcranial current stimulation is a potent neuromodulation technique used to enhance human cognitive function in a non-invasive manner. In this study, we investigated whether a cross-frequency coupling (CFC), after transcranial alternating current stimulation (tACS), was observed differently in the frontal and occipital areas during working-memory performance. Eighteen healthy participants were recruited in this study: nine for a tACS-treated group and nine for a sham group of age-gender-matched controls. Participants were instructed to perform a modified Sternberg task, where a combination of letters and digits (7 items to be encoded) was presented before and after the tACS or sham stimulation. The stimulation group was treated with CFC-tACS for 20 minutes (input channel: F3, return channels: Fp1, Fz, F7, and C3). We analyzed delta-phase/high-gamma-amplitude CFC of electroencephalographic data to find neural correlates for the enhancement of working-memory performance by tACS-treatment. We observed phase-shifts between the frontal and occipital CFC phase-dependency in the second half of the retention period along with tACS-mediated improvement in working-memory performance. This finding implies that their CFC neurodynamics reflect a long-range communication between the frontal and occipital areas during working-memory performance. Our observations provide CFC-mediated neural correlates for working-memory performance.

Abstract: Transcranial direct current stimulation (tDCS) is a non-invasive brain stimulation technique that has shown promise in improving cognitive functioning and as a therapy for neurological disorders. Recent studies have shown that it can modulate widespread neural activity; yet, these effects are highly variable and depend on the areas being stimulated (montage) and the type of stimulation (polarity and intensity). We tested two tDCS stimulation montages (unilateral and bilateral) targeting the nonhuman primate prefrontal cortex (PFC), and examined their influence on spectral power in scalp-recorded EEG and intracranial field potentials. The effects of polarity (anodal or cathodal) and intensity (0.5-1.5mA) were also examined. We found changes in EEG power at parietal scalp sites during tDCS stimulation in the lower frequency bands (<4 Hz). These effects were larger when using the bilateral tDCS montage. No effects of polarity were seen, but intensity of stimulation showed a roughly linear effect on power. Changes in scalp EEG power in parietal recordings did not persist post stimulation, and tended to show decreases in power. Although frontal scalp EEG was not recorded during stimulation, increases in power were seen post stimulation. These results highlight the importance of tDCS electrode placement in order to target specific brain areas. Furthermore, these data allow us to better understand the underlying mechanisms of tDCS and can help translate findings across experimental studies.

Title: Modulation of Motor Sequence Learning with 4mA tDCS

Authors: *G. HSU[1], A. D. SHEREEN[2], L. C. PARRA[1];
[1]Biomed. Engin., City Col. of New York, New York, NY; [2]Advanced Sci. Res. Ctr. at the Grad. Ctr., New York, NY

Abstract: Direct current stimulation (DCS) reliably boosts synaptic plasticity in vitro, but requires fields stronger than those produced in vivo in humans at 2mA with transcranial direct current stimulation (tDCS), the effects of which are still in contention. Through a well established motor sequence learning task, we hypothesize that concurrent tDCS at an increased intensity of 4mA reliably improves task performance. Furthermore, we expect the boosting effect to last at least an hour after initial training and be specific to the trained hemisphere and sequence. Functional magnetic resonance imaging (fMRI) of healthy participants (N = 10) executing simple finger movements was used in a current flow model to formulate a generalized 4x4 focal high definition tDCS (HD-tDCS) electrode montage targeting the hand knob on the contralateral primary motor cortex (M1). In a single-blind design, 72 healthy right-handed adult participants received either anodal (N = 36) or cathodal (N = 36) HD-tDCS while they performed a

sequential finger tapping task (FTT) using their non-dominant hand for 12 minutes. A 1-hour follow-up session measured retention of task performance and included two control tasks with unfamiliar sequences on both the contralateral and ipsilateral hands. Two-sample t-tests of the mean tapping speed and sequence completion indicate a significant difference in performance between the anodal and cathodal groups on the trained sequence. Unexpectedly, we also find a polarity effect on task performance that carries over to the untrained hand as well as an untrained sequence. Discomfort at various time points during the procedure was measured using a visual analog scale (VAS). In both groups the mean VAS values did not exceed moderate levels of discomfort. These results suggest that 4mA HD-tDCS targeted to M1 has a non-specific effect on motor sequence learning. Furthermore, 4mA HD-tDCS is well tolerated.

Title: The roles of the neuronal adaptor FE65 in neurite outgrowth

Authors: *K.-F. LAU, W. CHAN, W. LI;
The Chinese Univ. of Hong Kong, Shatin, NT, Hong Kong

Abstract: Neurite outgrowth is a crucial process in developing neurons for neural network formation. Neurite damage is often observed after brain injuries and in the early stages of many neurodegenerative diseases and in the case of age-related neural degeneration. Understanding the regulatory mechanisms of neurite outgrowth is essential for developing strategies to stimulate neurite regeneration after nerve injury and in neurodegenerative disorders. We have shown that the neuronal adaptor FE65 activates neurite outgrowth by recruiting the small GTPase ARF6 and the Rac1 GEF ELMO1 by its PTB1 domain and N-terminal region, respectively. Interfering with the formation of the multimeric signaling complex attenuates both ARF6-ELMO1-mediated Rac1 activation and neurite elongation. The plasma membrane trafficking of ELMO1 is markedly decreased in cells with suppressed expression of either FE65 or ARF6. Moreover, FE65 is shown to increase the amount of ELMO1 in the recycling endosome, an organelle responsible for returning proteins to the plasma membrane. In conclusion, FE65 potentiates ARF6-Rac1 signaling by orchestrating ARF6 and ELMO1 to promote the plasma membrane trafficking of ELMO1 via the endosomal recycling pathway, and thus, potentiates Rac1-mediated neurite outgrowth.

Title: Dystonia Mutation in TorsinA Impairs Neurite Formation in Hippocampal Neurons

Authors: D. C. MENDEZ[1], G. W. G. LUXTON[2], *T. W. BASTIAN[1];
[1]Univ. of Minnesota, Minneapolis, MN; [2]Univ. of California - Davis, Davis, CA

Abstract: Dystonia is the third most common neurological movement disorder and is characterized by sustained muscle contractions resulting in involuntary twisting of the extremities and abnormal posturing. The most common and severe inherited form is DYT1 dystonia, caused by a loss-of-function mutation ΔE302/303 (ΔE) in the conserved luminal AAA+ protein, torsinA. Brain imaging studies show that mouse and human carriers of ΔE mutation display reduced axonal integrity and coherence in pathways that modulate the sensorimotor cortex, suggesting that DYT1 dystonia is a neurodevelopmental circuit disorder. However, the mechanisms underlying torsinA-dependent neurodevelopment are unclear. Therefore, we asked if torsinA is required for axon and dendrite initiation and/or elongation using developing mouse primary hippocampal neuron cultures. Cells were nucleofected at plating with plasmids expressing EGFP alone or conjugated to 1) wild type torsinA (torsinA^{WT}); 2) torsinA$^{\Delta E}$ (dystonia mutation); or 3) torsinA^{E171Q} (ATP-hydrolysis defective). At 2 days *in vitro* (DIV), when axon specification is complete, neurons were stained for axons (Tau) and dendrites (MAP2). EGFP-positive neurons were imaged and the morphology of their axons and dendrites were analyzed (18-22 neurons per group). Neurons expressing torsinA$^{\Delta E}$ had significantly decreased total neurite length when compared with neurons expressing torsinA^{E171Q} and exhibited a decreasing trend in total neurite number by 2DIV when compared to EGFP alone or torsinA^{WT}. No significant change in total neurite length or number was observed in neurons expressing torsinA^{E171Q} at 2DIV. Together, these data suggest that the expression of torsinA$^{\Delta E}$inhibits neurite extension in polarizing hippocampal neurons, while expression of the ATP-hydrolysis defective torsinA^{E171Q} has no impact on this process. Since localization of the centrosome is necessary and sufficient for the polarization of cultured hippocampal neurons, we hypothesize that torsinA may promote proper neurite development and neuronal polarization in hippocampal neurons by controlling the subcellular localization of their centrosome which will be tested in future work. Here, we provide experimental evidence supporting a role for torsinA in neurite development in developing hippocampal neurons. Elucidating how torsinA functions during this process can help explain how neurons develop functional domains (one axon, multiple dendrites). We are currently assessing effects on axonal and dendritic morphology. This can lay the foundation for developing novel therapies for the treatment of dystonia and other diseases caused by torsinA mutations.

Title: Interactions between the Down syndrome-related genes Dscam and Appl in axon patterning during neurodevelopment

Authors: *S. PIZZANO[1,2], M. VELING[1,3], G. STERNE[1,2], B. YE[1,3,4];
[1]Univ. of Michigan, Ann Arbor, MI; [2]Neurosci. Grad. Program, Ann Arbor, MI; [3]Dept. of Cell and Developmental Biol., Ann Arbor, MI; [4]Life Sci. Inst., Ann Arbor, MI

Abstract: Down syndrome (DS) is a neurodevelopmental disorder caused by trisomy of human Chromosome 21 (HSA21). In patients, the extra chromosome results in higher expression of many of the triplicated genes, including *Down syndrome cell adhesion molecule (DSCAM)* and *Amyloid Precursor Protein (APP)*. 99% of DS patients present with intellectual disability (ID) and DS models show that trisomy causes atypical morphology and connectivity in CNS neurons. Despite the high rate of ID, no single region of HSA21 has been isolated as causal. This could suggest that ID has multiple causal regions or that interactions exist between HSA21 casual genes. However, it is technically challenging in mammals to test the hypothesis that HSA21-genes interact. We used the *Gal4/UAS* system along with other *Drosophila* genetics to model the increased expression of multiple DS-gene homologues during development. This allowed for cell-type specific and temporally-controlled expression. Our work suggests that the *Drosophila* homologs of *DSCAM* and *APP* interact to regulate axon morphology in neurodevelopment. We found that Appl up-regulation or loss of function increases or decreases Dscam expression respectively; This causes axonal overgrowth or restriction in Class IV Dendritic Arborization Neurons (C4Da). Furthermore, Appl regulates Dscam protein but not mRNA, indicating a post-transcriptional regulatory mechanism. We are identifying the underlying mechanisms of this interaction for future study in DS mouse models. This work will 1) provide insight into the mechanisms underlying the neurodevelopmental interactions of Down syndrome-related genes and 2) elucidate the potential link between atypical neurodevelopment and a well-characterized, Alzheimer's-linked gene (*APP*).

Title: The F-BAR protein CIP4 regulates neurite dynamics and cortical neuron migration

Authors: *L. A. ENGLISH[1], R. J. TAYLOR[2], C. J. CAMERON[2], E. J. DISTLER[2], *K. TAYLOR[2], E. W. DENT[2];

Abstract: Neurite initiation from newly born neurons is a critical step in neuronal differentiation and migration. Additionally, neuronal migration in the developing cortex is accompanied by dynamic extension and retraction of neurites as neurons progress through bipolar and multipolar states. However, there is a relative lack of understanding regarding how the dynamic extension and retraction of neurites is regulated during neuronal migration. In recent work we have shown that CIP4, a member of the F-BAR family of membrane bending proteins, inhibits cortical neurite formation in culture. CIP4 knockout neurons initiate neurites earlier than wild-type controls, while CIP4 overexpression results in protrusion of lamellipodia-like veils, which inhibit filopodia formation and neurite initiation. Moreover, CIP4 is predominantly expressed prenatally in cortical tissue. These results beg the question of how CIP4 functions in radial neuron migration and differentiation *in vivo*, including the timing and manner of neurite repression. To examine the effects of modulating expression of CIP4 *in vivo*, we used *in utero* electroporation, in combination with our newly published Double UP technique, to allow for comparison of experimental (knockdown or overexpression) and control cells within the same tissue. We show that either knockdown or overexpression of CIP4 results in the marked disruption of radial neuron migration, by increasing or decreasing neurite number and length, respectively. Further experiments will determine if CIP4 both inhibits extension and promotes retraction of neurites in early developing cortical neurons. Together these results will provide insight into the function of F-BAR proteins in cortical neuronal migration.

Title: Neuron Navigator 1 contributes to neuron morphogenesis via regulation of the cytoskeleton and the plasma membrane

Authors: *R. POWERS, E. DESAI, T. LICHTENBERG, B. CALABRESE, S. HALPAIN;
UC San Diego, La Jolla, CA

Abstract: Proper regulation of the cytoskeleton is essential for neurodevelopment. Cytoskeleton associated proteins integrate extra- and intracellular signals to influence actin and microtubule dynamics in the developing neuron. These cytoskeleton dynamics are necessary for later circuit integration and brain development, but many of the proteins involved have yet to be elucidated. Neuron Navigator 1 (Nav1) is a microtubule +TIP protein highly expressed during brain development. Nav1 is necessary for neuritogenesis, but the underlying mechanisms are relatively unknown. Using RNAi and knockout strategies in primary neurons and cell lines along with live and fixed microscopy techniques, we found that Nav1 is important for coordinating the cytoskeleton of the cell periphery for accurate cell morphogenesis. This includes an unexpected role in regulating F-actin dependent membrane ruffles and endocytosis in the growth cone, as well as a novel role in regulating actin-membrane coupling. These data highlight the importance of Nav1 in cell morphogenesis, as well as reveal new roles of this +TIP protein in regulating actin and plasma membrane to organize the cell periphery.

Title: Cas adaptor proteins are required for cortical axon tract fasciculation

Authors: *J. ESTEP[1], W. WONG[2], M. RICCOMAGNO[3];
[1]Univ. of California Riverside, Riverside, CA; [2]Molecular, Cell, & Systems Biol., [3]Univ. of California, Riverside, Riverside, CA

Abstract: Proper neural circuit organization requires individual neurons to project to their targets with high specificity. While several guidance molecules have been shown to mediate axonal fasciculation and pathfinding, little is understood regarding how neurons intracellularly integrate these cues. Here we provide genetic evidence that the Crk-Associated Substrate (Cas) family of intracellular adaptor proteins are required in a non-neuronal autonomous manner for proper fasciculation and guidance of several cortical white matter tracts, including external capsule (EC) and thalamocortical axon (TCA) projections. These findings build on a growing literature implicating Cas proteins as key mediators of cell motility and adhesion signaling.

Title: Interaction of SPIN90, SH3 protein interacting with Nck, 90 kDa, with miR-135a in neocortical neuronal migration

Authors: *S.-O. HUH, J.-E. KANG, H. PARK, A. SADRA;
Hallym Univ. Med. Sch., Chuncheon, Korea, Republic of

Abstract: Precise coordination of cytoskeleton is required for newly born neocortical neurons to migrate through multiple laminar layers and form normal connections with other neurons. As such, defects in the expression of genes related to cytoskeleton dynamics can lead to detrimental effects in neural proliferation, migration and neural connectivity, which in turn could lead to developmental neural migration disorders including autism spectrum disorder. Here, we investigated roles of SPIN90 (SH3 protein interacting with Nck, 90 kDa) in radial migration. Silencing of SPIN90 expression using RNAi was performed via in utero electroporation. We found down-regulation of SPIN90 resulted in abnormal termination of the neuronal migratory process. New born neurons with reduced expression of SPIN90 failed in reaching their final destination with neocortex and remained and accumulated in IZ. Furthermore, the morphology of these cells exhibited multipolar. In addition, SPIN90-silencing also caused reduction of the numbers of dendrites and neurites, as well as shortening of axon length. In contrast, overexpression of SPIN90 induced a significant increase in the number of migrating cortical neurons, as revealed by transwell assay. To elucidate key regulatory gene networks involved in neocorticogenesis, we sought to identify any regulatory miRNAs modulating the levels of SPIN90, and found that microRNA-135a is capable of regulating SPIN90 message. This microRNA also promoted neuronal migration and axonal elongation in neuronal processing as part of a gene expression regulatory network thought to be active in neocorticogenesis. Together, our observations suggest an essential role of SPIN90 in the neocortical neuronal migration.

Title: Trio interacts with CRMPs and plays a role in the Semaphorin3A pathway

Authors: *E. FINGLETON[1], J. D. PASKUS[2], K. W. ROCHE[3];
[1]NINDS, NIH, Washington, DC; [2]NINDS, [3]RBS/NINDS, NIH, Bethesda, MD

Abstract: The RhoGEF Trio contains tandem GEF domains capable of activating both Rac1 and RhoA, positioning it as a bidirectional modulator of cytoskeletal dynamics in key neuronal processes, such as neuronal migration, axon guidance, dendrite arborization, and structural long-term potentiation. Additionally, de novo mutations in some regions of Trio are highly associated with Autism Spectrum Disorder, suggesting an important role for Trio in early stages of neurodevelopment. In a recent affinity purification/mass spectrometry screen for Trio interactors, collapsing response mediating proteins (CRMPs) 1-4 were identified as Trio-interacting proteins. CRMPs are most well known for their role in mediating Semaphorin3A (Sema3A) induced axon repulsion, but also play key roles in neuronal migration, dendrite arborization, and some forms of synaptic plasticity. Due to their roles as bidirectional modulators of the cytoskeleton and their phenotypic overlap with Trio, we hypothesize that CRMP binding may modulate the activity of either or both of Trio's GEF domains. Here we present data verifying that Trio and CRMP interact in vivo. Additionally, we present new data suggesting that Trio mediates Sema3A-induced neurite retraction in vitro. Additional experiments are necessary to fully dissect the nature of this interaction.

Title: Dual leucine zipper kinase regulates Dscam expression through a non-canonical function of the cytoplasmic poly(A)-binding protein

Authors: *M. SINGH[1], J. KIM[2], B. YE[3];
[1]Biol., UNIVERSITY OF NEVADA, RENO, RENO, NV; [2]Biol., UNIVERSITY OF NEVADA RENO, RENO, NV; [3]Life Sci. Inst., Univ. of Michigan, Ann Arbor, MI

Abstract: Dual leucine zipper kinase (DLK) plays essential role in the development, degeneration, and regeneration of neurons. DLK can regulate gene expression post-transcriptionally, but the underlying mechanism remains poorly understood. *Drosophila* DLK, Wallenda (Wnd) regulates the expression of Down syndrome cell adhesion molecule (Dscam) by the 3' untranslated region (3'UTR) of *Dscam* mRNA. We speculated that Wnd may require an RNA binding protein (RBP) for this regulation, because being a protein kinase, it unlikely affects the 3'UTR of mRNAs directly. In this study, using an unbiased cell-based RNAi screen in cultured *Drosophila* Schneider 2 (S2) cells, we identified, pAbp —*Drosophila* ortholog of cytoplasmic PABP (PABP-C) as an RBP that is required for Wnd-mediated upregulation of Dscam. Subsequent studies showed that pAbp mutations abrogated the increased expression of Dscam as well as the exuberant presynaptic arbor growth by Wnd. PABP-C acts as a general translation activator by interacting with the poly(A) tails of mRNA. Interestingly, pAbp interacts with a non-canonical binding site on *Dscam* 3'UTR. Removing this region significantly reduced Wnd-induced increase in Dscam expression. These suggest that a non-canonical interaction of PABP with the 3'UTR of target transcripts is essential for DLK functions.

Abstract: The Kirrel3 receptor has been implicated in the regulation of multiple processes during the development of nervous system circuitry, including the targeting and coalescence of axons within synaptic fields and the formation of synapses. The function of Kirrel3 in these processes has been proposed to rely on homophilic adhesion between Kirrel3 molecules, but the physiological importance of Kirrel3 homophilic interactions in circuit development remains to be established. To assess the requirement of homophilic adhesion in Kirrel3 function, we first visualized the molecular basis of the homophilic adhesion by solving the crystal structure of the mouse Kirrel3 homodimer complex. These analyses identified the first immunoglobulin domain as the mediator of Kirrel3 homophilic adhesion and identified specific residue substitutions within this region that abolish the interaction. To examine the

importance of Kirrel3 homophilic adhesion in circuit formation *in vivo*, we used the CRISPR-Cas9 technology to edit the *Kirrel3* gene in mice to encode a Kirrel3 protein lacking homophilic adhesion capabilities (*Kirrel3-Q128A*). An analysis of axonal targeting in the accessory olfactory system of *Kirrel3Q128A* mice revealed alterations in the formation of the glomerular map, which phenocopy defects observed in *Kirrel3* null animals. Taken together, our results uncover the homophilic adhesion of Kirrel3 receptors as a key mechanism to regulate axonal targeting during development of the nervous system.

Title: Indirect modulation of synaptic transmission in mouse striatal neurons by synaptotagmin-9

Authors: *M. J. SEIBERT, K. STANLEY, J. BRIGUGLIO, E. R. CHAPMAN;
Howard Hughes Med. Inst. & Dept. of Neurosci., Univ. of Wisconsin - Madison, Madison, WI

Abstract: In many CNS synapses, synaptotagmin-1 (syt1) (NCBI Gene ID# 20979) serves as a calcium sensor that triggers fast, synchronous neurotransmitter release. A closely related but relatively uncharacterized isoform, synaptotagmin-9 (syt9) (NCBI Gene ID# 53420), is also expressed in CNS neurons and has been shown to be a calcium sensor for dense-core vesicle (DCV) exocytosis and neuropeptide secretion in neuroendocrine cells. In this work we attempt to characterize the role of syt9 in neuronal cell biology and synaptic physiology. We use male and female syt9 KO mice and cultured P0-1 mouse neurons - sex differences were not assessed. We show, via quantitative immunoblotting, that endogenous syt9 is expressed in cortical, hippocampal, and striatal neurons at levels that are ~25-fold lower than syt1. We conducted whole-cell voltage clamp experiments and observed that loss of syt9 has no effect on evoked neurotransmitter release in any of these three neuronal cell types. However, upon significant overexpression, we confirmed that syt9 can rescue some degree of fast, synchronous neurotransmitter release in syt1 KO cortical neurons, but this is an artifact due to up-regulation of this protein. Consistent with this observation, immunocytochemistry (ICC) experiments indicated that overexpressed syt9 had a high degree of colocalization with the synaptic vesicle marker, synaptophysin. We went on to observe that miniature inhibitory postsynaptic current (mIPSC) frequency was lower in cultured syt9 KO striatal neurons compared to WT neurons; this effect was striatum specific, as mIPSCs were unchanged in syt9 KO cortical and hippocampal neurons. To begin to elucidate the role of syt9 in regulating mIPSCs in striatal neurons, we used ICC and found that endogenous syt9 colocalized with

Substance P (SP), a neuropeptide that is packaged into DCVs, is enriched in striatal tissue, and is an agonist to the neurokinin 1 receptor (NK1R). To determine whether SP secretion contributes to mIPSC frequency, we supplemented the culture media with this peptide and found that it fully rescued the decreased mIPSC frequency in syt9 KO striatal neurons. Additionally, when WT striatal neurons were treated with the NK1R antagonist SR140333, we observed a decrease in mIPSC frequency that appeared to phenocopy the syt9 KO phenotype. These results suggest that syt9 may serve as a calcium sensor for SP secretion from striatal neurons, thereby indirectly regulating aspects of synaptic transmission. This work posits a novel role of syt9 in neurons and underscores a gap in our understanding of this protein's function in hippocampal and cortical neurons.

Title: Isoflurane reduces brain-derived neurotrophic factor release leading to inhibition of glutamate exocytosis

Authors: R. WILLIAMS[1], K. W. JOHNSON[2], H. C. HEMMINGS, Jr.[1], *J. PLATHOLI[1];
[1]Anesthesiol., [2]Pharmacol., Weill Cornell Med., new york, NY

Abstract: Inhibition of glutamate release is one of many ways general anesthetics depress excitatory synaptic transmission, but the underlying cellular and molecular targets remain unclear. We hypothesized that isoflurane, a common general anesthetic, reduces brain-derived neurotrophic factor (BDNF) release, resulting in decreased presynaptic glutamate release. Dissociated hippocampal neurons from wild-type and loss-of-function BDNF Val66Met knock-in mice with reduced BDNF secretion were used to test this. Isoflurane-induced changes in BDNF release were measured using the genetically encoded biosensor BDNF-pHluorin. Neurons in culture with varying levels of BDNF secretion were used to determine the effect of reduced endogenous BDNF amounts on glutamatergic synaptic vesicle exocytosis using vGlut1-pHluorin. Our results show that isoflurane attenuates BDNF release contributing to inhibition of glutamate release and that this inhibition may be long-lasting in neurons with reduced endogenous BDNF (Val66Met).

Abstract: Retrograde endocannabinoid signaling via presynaptic cannabinoid (CB_1) receptors plays an essential role in the calibration of neurotransmitter release probability in both phasic and tonic manner. However, the role of the major endocannabinoid messengers [2-arachidonoylglycerol (2-AG), anandamide (AEA)] and their predominant synthesizing enzymes [diacylglycerol lipase-α (DAGLα), N-acyl phosphatidylethanolamine phospholipase D (NAPE-PLD)] in tonic endocannabinoid signaling has remained elusive. We utilized patch-clamp electrophysiology with combination of Stochastic Optical Reconstruction Microscopy (STORM), two-photon imaging and liquid chromatography/tandem mass spectrometry to address potential cell-type specific physiological and molecular changes in mice with chronic absence of DAGLα. Despite the reduced basal 2-AG levels, our results demonstrate unaltered morphology and CB_1 receptor expression with unchanged baseline synaptic transmission between inhibitory basket cells and CA1 pyramidal cell pairs in the hippocampus. Pharmacological blockade of CB_1 receptors in both DAGLα- and NAPE-PLD knockout mice revealed elevated inhibitory synaptic transmission, therefore unaltered cannabinoid tone. These findings highlight a ligand-independent persistent cannabinoid signaling which maintained synaptic function at homeostatic levels.

Title: Endocannabinoid Modulation of Synaptic Transmission in the Lateral Habenula

Authors: *N. D. WINTERS[1], M. ALTEMUS[2], K. D. JOHNSON[2], S. PATEL[2];
[1]Pharmacol., [2]Psychiatry, Vanderbilt Univ., Nashville, TN

Abstract: The lateral habenula (LHb) is an epithalamic brain structure critically involved in the processing of aversive stimuli. Despite the increasingly evident role of the LHb in neuropsychiatric disease, the molecular regulators that orchestrate synaptic transmission within this brain structure are poorly understood. Among the plethora of neuromodulatory systems that have been described within the LHb is the endocannabinoid (eCB) system, a lipid-derived retrograde signaling system that dynamically regulates a variety of functions in the brain. Data from other labs have demonstrated the presence of functional CB1 receptors at LHb synapses, that LHb eCBs are recruited by stress, and that intra-LHb CB1 inhibition can produce anxiolytic and antidepressive-like effects, suggesting the hypothesis that eCB signaling within the LHb may serve an activity-promoting function. To mechanistically test this hypothesis, we have begun to examine how eCB signaling modulates synaptic transmission within the LHb. We have found that CB1 activation or blockade produces unexpected effects on excitatory vs. inhibitory spontaneous release. We have begun testing a hypothesis involving an indirect endocannabinoid signaling mechanism and have generated data mechanistically supporting these paradoxical findings. Ongoing studies are aimed at further dissecting the role of this indirect endocannabinoid mechanism in regulating LHb synapses and examining the function of eCBs in regulating evoked release from key stress-related inputs to the LHb.

Title: Activation of the serotonin 2A receptor Inhibits claustrum neurons projecting to anterior cingulate cortex and modulates cognitive flexibility performance

Authors: *T. L. ANDERSON, P. I. ORTINSKI;
Neurosci., Univ. of Kentucky, Lexington, KY

Abstract: The claustrum (CLA) has long been speculated to be fundamental in a variety of brain functions such as attention salience and cognitive flexibility. The CLA also boasts being the most densely innervated structure in the brain and has the highest expression of the serotonin 2A receptor (5HT2AR), the main excitatory G protein-coupled receptor subtype for serotonin (5HT), and the major site of action for psychedelic hallucinogens. The CLA, as well as 5HT and the 5HT2AR, have recently been implicated for playing a role in cognitive flexibility, the ability to adapt behavior to environmental changes, though these relationships remain largely uninterrogated. Because cognitive flexibility is emerging as a testable metric relevant to drug use research, as many drugs of abuse, including cocaine negatively affect cognitive flexibility, we observed the effects of both cocaine, and the potent 5HT releasing agent, MMAI, on rat cognitive flexibility performance using a set-shifting task. We also use whole cell electrophysiological slice recordings to observe effects of serotonin on neuronal activity in the claustrum, first targeting general claustrum neurons, and then using retrograde labeling, to record from CLA neurons projecting to the anterior cingulate cortex (ACC) in the presence of 5HT and the 5HT2AR antagonist, Ketanserin. Spontaneous excitatory post-synaptic current (sEPSC) frequency and amplitude were analyzed, as well as other cell properties such as resting membrane potential, action potential firing rate, and spontaneous inhibitory post-synaptic currents (sIPSCs). Significant decreases in sEPSC frequency and amplitude were observed in both indiscriminate CLA neurons and CLA-ACC labeled neurons after application of 5HT to the slice. Similarly, robust increases in sIPSC frequency and amplitude were observed. Blockade of the 5HT2AR with Ketanserin eliminated the synaptic effects of 5HT, indicating a regulatory role of the 5HT2AR in claustrocortical signaling. Our behavioral preliminary experiments included testing rat cognitive flexibility under the influence of either cocaine, MMAI, or saline in set-shifting tasks to receive sugar pellets. Our results showed that both cocaine and MMAI had profound negative effects on cognitive flexibility performance. These findings provide the first physiological evidence that the large population of CLA-ACC neurons are under strong inhibitory control from 5HT and the 5HT2AR. Our behavior data also confirms that disruption of serotonergic brain signaling can negatively affect cognitive flexibility performance.

Title: Hiv-1 tat protein exacerbates methamphetamine-dysregulated dopamine uptake into vesicular monoamine transporter-2 and potentiates methamphetamine conditioned place preference in hiv-1 tat transgenic mice

Authors: *J. ZHU[1,2], M. J. STRAUSS[1], S. E. DAVIS[1], J. P. MCLAUGHLIN[2];
[1]Drug Discovery and Biomed. Sci., Col. of Pharmacy, Univ. of South Carolina, Columbia, SC;
[2]Pharmacodynamics, Univ. of Florida, Gainesville, FL

Abstract: Methamphetamine (METH) abuse has been shown to increase the incidence of HIV-1 associated neurocognitive disorders (HAND). Perturbation of dopamine (DA) transmission has been demonstrated as a mediating factor in HAND and METH abuse. Our published work has demonstrated that the HIV-1 regulatory protein, transactivator of transcription (Tat), decreases DA transport via the DA transporter (DAT) and vesicular monoamine transporter-2 (VMAT-2). The VMAT-2 transports cytosolic DA into synaptic vesicles and plays a critical role in DA homeostasis. Therefore, this study examined the synergistic effects of Tat and METH on DA uptake through VMAT-2 and associated METH reward through the following three experiments. *Experiment-1*: *in vitro* incubation of isolated mouse whole brain vesicles with recombinant Tat_{1-86} or METH displayed a concentration-dependent inhibition of vesicular [^{3}H]DA uptake, in which a combination of Tat and METH induced an additive reduction of DA uptake via VMAT-2 compared to Tat or METH alone. *Experiment-2*: we determined whether the *in vitro* effect of Tat and METH on VMAT-2 uptake can be replicated in an inducible Tat transgenic (iTat-tg) mouse model. This model recapitulates many aspects of the neurocognitive impairments observed in HIV infected individuals. iTat-tg and G-tg (Tat null) mice were given saline or doxycycline (Dox, 100 mg/kg/day, i.p.) for 21 days, and on day 8 after starting injection of saline or Dox, mice were given saline or METH (3 mg/kg, i.p.) daily until day 21. 24 hours after last injection, all mice were subjected to kinetic analysis of [^{3}H]DA uptake into whole brain vesicles. Results show that 21-day Dox-induced Tat expression caused a 57% decrease in the maximal velocity (V_{max}) value, which was attenuated in G-tg mice. 14-day METH alone induced a 35% and 52% reduction of V_{max} in iTat-tg and G-tg mice, respectively, whereas a greater decrease (66%) in V_{max} was observed in iTat-tg mice of Dox-METH group. Considering that both Tat and METH interact with DAT and VMAT-2, these results provide evidence that Tat and METH could disrupt DA transmission by inhibiting both DAT and VMAT-2 function. *Experiment-3*: following 14-day treatment of Dox, the iTat-tg mice potentiated METH-conditioned place preference 6-fold over saline-treated mice, suggesting that Tat expression potentiates the rewarding effect of METH. The current findings suggest that Tat and METH synergistically inhibit VMAT-2-mediated DA uptake, leading to dysregulation of DA transmission and raises the exciting possibility of a potential therapeutic strategy by targeting VMAT-2 for METH abuse in HIV infected individuals.

Title: Somatodendritic release of cholecystokinin regulates VTA local circuitry and mouse behavior

Authors: *V. MARTINEZ DAMONTE[1], M. B. POMRENZE[2], R. C. MALENKA[2], J. A. KAUER[1]; [1]Dept. of Psychiatry and Behavioral Sci., [2]The Pritzker Laboratory, Dept. of Psychiatry and Behavioral Sci., Stanford Univ. Sch. of Med., Stanford, CA

Abstract: Ventral tegmental area (VTA) dopamine (DA) neurons participate in circuits that underlie diverse behaviors, including motivation, learning, aversion, and locomotion. Somatodendritic DA release is a notable feature of DA cells and decreases spontaneous firing mediated by D2R autoreceptors. Most DA neurons also express the neuropeptide cholecystokinin (CCK), but its role in the VTA has remained elusive.GABAergic inputs are essential for controlling the firing pattern of VTA DA neurons. In electrophysiological recordings in horizontal midbrain slices, we recently found that somatodendritically-released CCK potentiates inhibitory postsynaptic currents (IPSCs) onto VTA DA neurons. This potentiation is triggered by a mild depolarization of the DA neuron, is blocked by the CCK2R antagonist LY225910, and occurs only at specific subsets of inhibitory synapses on DA cells. Here we explore CCK release and its impact on VTA-related behaviors.First, we examined the mechanisms underlying CCK release. Since depolarization of DA neurons releases CCK, we tested whether optogenetic activation of DA neurons alone might release CCK. We found that this also potentiated IPSCs in DA cells. Our preliminary data suggest that ELISA assays confirm this.As Ca2+ chelation prevents CCK-induced LTP, we next explored whether blocking L-type voltage-gated calcium channels, generally associated with dense core vesicle release, prevents depolarization-induced LTP. We bath applied NiCl2 (50μM) and found that depolarization no longer triggered LTP. We are currently evaluating the involvement of other cellular proteins that may be required to support CCK release.Finally, we studied CCK effects on the excitability of DA neurons and on VTA-related behaviors. We infused either CCK or saline bilaterally into the VTA of fasted mice and measured food intake. We found that in the first hour after CCK infusion, food consumption was reduced. However, we also observed in an open field test that CCK delivery decreased the total distance traveled and time spent in the field center, suggesting that locomotor deficits or anxiety could contribute to the food intake results.Our work in VTA DA neurons reveals a novel role for CCK somatodendritic release as an overlooked modulator of the local circuit and its behavioral consequences.

Title: Stress sensitive kappa opioid receptor modulation of excitatory drive onto nucleus accumbens fast-spiking interneurons

Authors: *B. C. COLEMAN[1], K. M. MANZ[2], B. A. GRUETER[3];
[1]Vanderbilt Univ., Nashville, TN; [3]Anesthesiol., [2]Vanderbilt Univ. Sch. of Med., Nashville, TN

Abstract: The dynorphin/kappa opioid receptor (KOR) system within the nucleus accumbens (NAc) contributes to negative affective states following withdrawal from illicit drugs, pain, and stress. In the NAc, parvalbumin fast-spiking interneurons (PV-FSIs) receive similar excitatory input as neighboring medium spiny neurons (MSNs) and robustly inhibit MSN activity via feedforward inhibition, critically regulating NAc circuit dynamics. KORs have been shown to presynaptically inhibit glutamate release onto MSNs, but dynorphin/KOR regulation of excitatory drive onto PV-FSIs remains unknown. To address this gap, here we characterize KORs at glutamatergic synapses onto PV-FSIs in the NAc core (NAcc). Using male and female PV-cre/Ai9(tdTom) mice and whole cell electrophysiology, we show that activation of KORs induces long-term depression (LTD) of excitatory drive onto PV-FSIs. Further characterization shows that the depression is expressed postsynaptically and is mediated by PKA and calcium/calcineurin dependent endocytosis of AMPARs. We also report that KORs preferentially modulate midline nuclei of the thalamus afferents and not prefrontal cortex afferents onto NAcc PV-FSIs. To determine the potential involvement of this mechanism in the response to stress, mice were subjected to restraint stress for one hour, a manipulation shown to increase NAc dynorphin. In stressed animals the KOR agonist no longer elicited LTD. Interestingly, the LTD is rescued by administration of the KOR antagonist, nor-BNI, prior to the stress. This work provides a novel mechanism and synaptic locus by which KORs modulate NAc circuit activity and provides evidence for the recruitment and/or dysregulation of this mechanism following stress.

Title: Corticotropin-releasing hormone and oxytocin augments synaptic activity in the nucleus tractus solitarii of rats subjected to chronic intermittent hypoxia.

Authors: *P. BARCELLOS-FILHO, D. D. KLINE;
Biomed. Sciences/Dalton CRC, Univ. of Missouri, Columbia, MO

Abstract: Hypertension is one consequence in individuals with obstructive sleep apnea. Chronic intermittent hypoxia (CIH) in rodents mimics the hypoxia-induced hypertension seen in sleep apnea. Alterations in synaptic activity within the nucleus tractus solitarii (nTS), the central integration site of sensory afferent, are involved in the CIH-induced hypertension. The paraventricular nucleus of the hypothalamus (PVN) has a modulating role in controlling nTS activity to influence blood pressure and respiration. The PVN sends direct neuronal projections containing oxytocin (OT) and/or corticotropin-

releasing hormone (CRH) to the nTS, and these neuropeptides alter nTS synaptic signaling. During hypoxia, there is an increase in the production of these neuropeptides, yet their contribution to nTS activity is not completely understood. We hypothesized OT and CRH (individual and combined) modulates nTS synaptic activity in normoxia and their influence is enhanced after CIH. Male Sprague-Dawley rats (3-4 weeks) were exposed to 10 days normoxia (21% O_2) or 10 days CIH (30-40 sec of 6% oxygen, 10 episodes/h, 8 h/day). Horizontal brainstem slices were generated, and using whole-cell patch-clamp recordings, we examined synaptic neurotransmission and electrophysiological properties of monosynaptic nTS neurons. Excitatory postsynaptic currents (EPSCs) and current-evoked action potential discharge (APD) were examined during sequential aCSF control, OT (600 nM) alone, CRH (300 nM) alone, and the combination of OT (600 nM) and CRH (300 nM). In normoxia, compared to aCSF baseline, OT alone had no effect on afferent (TS)-evoked EPSC amplitude, spontaneous (s)EPSC amplitude or frequency, or APD. CRH alone tended to increase TS-EPSC amplitude yet decreased APD. sEPSCs were not affected. Co-application of OT and CRH did not alter EPSCs but reversed the CRH-induced depression of discharge. Conversely, after CIH, the response to neuropeptide activation was enhanced. While OT had a tendency to increase TS-EPSCs, CRH alone and its combination with OT significantly augmented TS-EPSC amplitude evoked in response to 0.5 and 20Hz stimulation. The characteristic frequency-dependent depression of TS-EPSCs in the nTS was not altered by any drug combination, suggesting pre-synaptic release was not altered. sEPSCs and discharge were relatively unaffected. In summary, these data show that following CIH, CRH and OT synergistically enhanced afferent-driven neurotransmission to nTS neurons via an increase in their postsynaptic receptors.

Title: The neuropeptide oxytocin: search for its possible neuromodulatory action of dopamine & serotonin in different region of the brain

Authors: *P. THAKUR[1], R. SHRIVASTAVA[2], V. K. SHRIVASTAVA[1];
[1]Biosci., Barkatullah Univ., BHOPAL, India; [2]Zoology, Sathya Sai Women Col., Bhopal, India

Abstract: The neuropeptide oxytocin has been implicated in social behavior and being evaluated as a possible treatment for neurodegenerative disorders *i.e.* schizophrenia, autism spectrum disorders, anxiety, and depression etc., but the neural mechanisms how oxytocin modulates social behavior is unknown. Dopamine and serotonin are important neurotransmitter in central nervous system and disruption in dopaminergic and serotoninergic neurotransmission have been found in the patients of neuropsychiatric

disorder *i.e.* autism, depression etc. Here, we have explored the influence of exogenous oxytocin in the neurotransmission of dopamine and serotonin level in various regions of the brain. Experimental animal, were exposed intraperitoneally (i.p.) to oxytocin 0.0116mg/kg for 30, 60, and 90 days while control animals were treated with normal saline. After the completion of different duration, all the animals of different groups were sacrificed by cervical dislocation; the brains were carefully removed, washed in normal saline, and frozen tissue was divided into seven regions, the medulla oblongata, midbrain, cerebellum, cerebral cortex, striatum, hippocampus, and hypothalamus, adopting the methodology of (Glowinski & Iversen, 1966) for the estimation of dopamine and serotonin in different region of the brain. In the present study we found that, there is significant increase ($p<0.001$, one way analysis of variance [ANOVA]) in dopamine level in hypothalamus, cerebral cortex, and midbrain of the brain region of the animals treated upto 90 days, which indicates the stimulation of dopamine mesocorticolimbic pathway. Furthermore, dopamine level significantly decreased in cerebellum of 30 days oxytocin treated group, while the level of dopamine increased after 60 and 90 days of treatment with oxytocin, which may be due to dose and duration dependent factor of oxytocin. However, oxytocin treatment upto 90 days results significantly increase in the level of serotonin in selected seven region of the brain. This finding is consistent with the effect of exogenous oxytocin on neuromodulation of serotonergic system in different region of the brain and regulates appetite social cognition, homeostasis, and energy metabolism and further paves the way for the identification of novel neurodegenerative drug target.

Title: Properties of astrocyte polarity

Authors: *J. D. ELLIOTT, M. MATHEW, G. ZHANG, J. L. FUCHS;
Univ. of North Texas, Denton, TX

Abstract: Astrocytes are often considered relatively unpolarized, in keeping with the meaning of astrocytes as “star cells.” In this respect, astrocytes contrast with neurons, which are a paragon of polarity, sending action potentials down a single axon from the neuron’s basal pole and receiving dendrites located apically. However, astrocytes do exhibit polarity in the distribution of the intermediate filament glial fibrillary acidic protein (GFAP) and the location of the primary cilium. These features may be polarized beginning with the birth of astrocytes, when newly born pairs of daughter cells are mirror images of each other with the most distant poles having both the primary cilium and the highest concentration of GFAP. The present study is a systematic analysis which addresses these aspects of astrocyte polarity: heterogeneity across brain regions; orientation with respect to migration or region-specific architecture; developmental changes; and influence of cilia deficiency. We developed measures to quantify polarity strength, polarity orientation with respect region-specific architecture, and the occurrence of GFAP polarity relative to the primary cilium location. Polarity strength was the ratio of the distance between the

centers of mass of GFAP concentration and the soma, to the radius of the soma along the same axis. These measures were evaluated in prefrontal and somatosensory cortices, hippocampal CA1, caudate putamen, and corpus callosum of Aldh1L1-EGFP astrocyte reporter mice on postnatal days P30 and P1. On P30, GFAP polarity showed main effect of brain region ($p<0.001$). Mean polarity ratio for the five regions was 0.75 ± 0.01 SEM, ranging from 0.71-0.83. Selective polarity orientation was evident in prefrontal cortex, hippocampus, and corpus callosum only. GFAP polarity strength was greater on P1 than on P30 ($p<0.001$), with polarity ratios of 0.83 ± 0.01 and 0.75 ± 0.01, respectively. GFAP and primary cilia were both located in the same pole of the soma in 94.4% of P30 astrocytes compared to 82.4% on P1. Astrocytes lacked primary cilia in cilium-deficient $Tg737^{orpk}$ mutant mice on P31 and the average GFAP polarity was greater than Aldh1L1-EGFP mice (0.77 ± 0.01 and 0.75 ± 0.01, respectively, $p=0.045$). Our study suggests (1) Polarity via GFAP and primary cilium location is a general feature of brain astrocytes; (2) Polarity strength and orientation vary with brain region; and (3) Polarity may be present in newly born astrocytes and is maintained throughout development. The results lead to questions about the implications of polarity and its potential relationship to the dual role of astrocytes in communicating with both neurons and the circulatory system.

Title: Regulation of astrocytic glutamine synthetase expression through extracellular glutamine

Authors: *Y. NASU[1,2], K. TABETA[2], M. TERUNUMA[1];
[1]Div. of Oral Biochemistry, Fac. of Dent. & Grad. Sch. of Med. and Dent. Sci., [2]Div. of Periodontology, Fac. of Dent. & Grad. Sch. of Med. and Dent. Sci., Niigata Univ., Niigata, Japan

Abstract: <META NAME="author" CONTENT="那須 優介">Astrocytes, one of the major glial cells in the central nervous system, is the only cell types that express glutamine synthetase (GS) to protect neurons against neurotoxicity induced by excess amount of ammonia and glutamate. An increasing number of studies have indicated that GS levels in astrocytes is associated with several brain disorders including Alzheimer's disease, schizophrenia, mesial temporal lobe epilepsy and depression. However, the detailed mechanism regulating astrocytic GS expression remains unclear. According to a recent report, GS expression in the liver is regulated by extracellular glutamine (Nguyen TV et al. *Mol Cell*. 2016). In this study, we investigated whether GS expression in astrocytes is regulated in response to the extracellular glutamine concentration.We used primary cultured astrocytes prepared from rat embryo in this study. We first removed glutamine for 36 hours and then increased extracellular glutamine concentration to 4 mM. We observed a time-dependent reduction in total GS expression. The gene encoding GS, *glul*, was not reduced, suggesting the possible mechanism of enhanced GS degradation in this condition. GS in liver has been reported to be ubiquitylated and subsequently degraded by the proteasome along with extracellular glutamine levels (Nguyen TV et al. *Mol Cell*. 2016). Thus, we used

proteasome inhibitor MG132 and found that glutamine-induced GS down-regulation was attenuated when proteasome degradation pathways are inhibited. In contrast, glutamine-deprived astrocytes dramatically increased GS expression. Interestingly, the application of glutamate and NH_4Cl, the sources of glutamine, in glutamine-deprived astrocytes did not increase GS as much as that of glutamine-deprived astrocytes, suggesting that the amount of intracellular glutamine may be the determinant of GS expression in astrocytes. We are currently investigating the mechanism of GS up-regulation in glutamine-deprived astrocytes.

Title: Dna methylation regulates trkb isoform expression in cns

Authors: *X. WEI[1], M. L. OLSEN[2];
[1]Virginia Tech. Neurosci. PhD Program, Blacksburg, VA; [2]Virginia Tech, Sch. of Neurosci., Blacksburg, VA

Abstract: The tropomyosin receptor kinase B (TrkB), the canonical receptor of Brain-Derived Neurotrophic Factor (BDNF), is broadly expressed in developing and mature brain. Studied for nearly three decades, BDNF/TrkB signaling has been shown to play critical roles in central nervous system (CNS) development, neuronal cell growth, differentiation, synaptogenesis and synaptic plasticity. While dysregulated BDNF/TrkB signaling is implicated in a growing list of neurodevelopmental and neuropathological disorders. TrkB is encoded by the *Ntrk2* gene, a complex gene approximately 330kb in length. TrkB has two main isoforms expressed in the CNS, the full length TrkB (TrkB.FL) receptor and the truncated TrkB (TrkB.T1) receptor. We recently demonstrated that TrkB.T1 is the predominant isoform in the rodent cortex, is almost exclusively expressed in astrocytes, and appears critical for astrocyte morphological maturation. In contrast TrkB.FL is the main isoform expressed in neurons. Given the critical role for this signaling pathway in healthy brain development and mature CNS function, we aim to identify the molecular underpinnings for the cell type specific expression of each TrkB isoform. We isolated astrocytes and neurons from p28 WT male mice cortex with magnetic isolation method and high molecular weight DNA was extracted to construct libraries for four biological replicates of astrocytes and neurons. Using nanopore sequencing, which enables direct, quantitative analysis of the methylation status of Ntrk2 in its entirety, preliminary data indicates marked differences in neuronal and astrocyte methylation. Notably, the majority of differentially methylated sites between astrocytes and neurons were found in intron located after the first coding exon expressed in both TrkB.FL and TrkB.T1 and in regions which flank a unique TrkB.T1 exon, which indicated that DNA methylation may regulate

TrkB isoform expression. Future work is aimed at investigating and manipulating these unique differentially methylated regions to determine in DNA methylation patterns in Ntrk2 regulate cell-type specific expression patterns in unique CNS cell populations.

Title: Uptake of biotinylated spermine in astrocytes: effect of Cx43 siRNA, HIV-Tat protein and polyamine transport inhibitor on polyamine uptake.

Authors: *C. J. MALPICA-NIEVES[1], Y. RIVERA[2], D. E. RIVERA-APONTE[3], O. PHANSTIEL[5], R. W. VEH[6], M. J. EATON[3], S. N. SKATCHKOV[4];
[1]Biochem., Univ. Central Del Caribe-School of Med., Bayamon, PR; [2]Chiropractic, [3]Biochem., [4]Biochem & Physiol., Univ. Central Del Caribe, Bayamon, PR; [5]Med. Educ., Univ. of Central Florida, Orlando, FL; [6]Inst. für Zell- und Neurobiologie, Charité, Berlin, Germany

Abstract: Polyamines (PAs) are polycationic biomolecules containing multiple amino groups. Patients with HIV-associated neurocognitive disorder (HAND) have high concentrations of the polyamine N-acetylated spermine in their brain and cerebral spinal fluid (CSF) and have increased PA release from astrocytes. These effects are due to the exposure to HIV-Tat protein since it produces conversion of SPM in astrocytes to N-acetylated-SPM (Ac-SPM) which has been found to be a novel biomarker predicting the severity of HAND in HIV-infected individuals. In healthy adult brain, PAs are accumulated, but not synthesized in astrocytes suggesting that PAs must enter astrocytes to be N-acetylated and released. Therefore, we tested if Cx43 hemichannels (Cx43-HCs) are pathways for PA flux in control and HIV-Tat treated astrocytes. We used biotinylated spermine (b-SPM) to examine polyamine uptake in cells bathed in a solution containing 2.5 mM Ca^{2+} and 2 mM Mg^{2+}. We found that control astrocytes and those treated with siRNA-Cx43 took up b-SPM similarly suggesting that PA uptake under these conditions is via a transporter/channel other than Cx43-HCs. Surprisingly, astrocytes pretreated with both HIV-Tat and siRNA-Cx43 showed increased accumulation of b-SPM. Using a novel polyamine transport inhibitor (PTI), trimer 44NMe, we blocked b-SPM uptake showing that PA-uptake is via the PTI-sensitive transport mechanism such as organic cation transporters. Our data suggest that Cx43 HCs are not a major pathway for b-SPM uptake in the condition of normal extracellular calcium concentration but may be involved in the release of PAs to the extracellular space during viral infection.

Abstract: Astrocytes are important regulators of neuronal synapse development and function. In the rodent cortex neurons are arranged in layers, each with stereotyped synaptic connectivity. Cortical astrocytes produce several synapse promoting factors, however, what regulates their regional and temporal expression during development is unknown. Here we use RNA sequencing, genetic mouse models, immunohistochemistry and in situ hybridization to determine the expression profile of astrocyte synapse promoting genes, and their regulatory mechanisms in the developing mouse visual cortex. This analysis identified astrocyte signals that show differential temporal and layer-specific expression. The observed expression changes occurred mainly between post-natal days (P) 7 and 14, a time between synapse initiation and maturation. We focused on factors that promote expression of AMPA receptors (AMPARs), crucial components of active excitatory synapses, such as glypican 4 (Gpc4) and chordin like 1 (chrdl1). AMPAR subunit composition undergoes a developmental switch, whereupon GluA1 is prevalent in immature synapses, while GluA2 marks a mature synapse. Gpc4, which promotes expression of GluA1 is highly expressed at P7, and is downregulated at P14 specifically in layer (L) 1, suggesting a role in synapse initiation. Chrdl1, which promotes synapse maturation by regulating expression of GluA2, peaks at P14 in the upper layers. These temporal and regional changes are regulated by visually evoked neuronal activity, as they are absent in mice lacking glutamate release from thalamo-cortical projections, resulting in delayed synapse maturation. Further, expression of synapse regulating genes and synaptic development are also altered when astrocyte signaling is blunted by diminishing calcium release from intracellular stores, as evident from mice lacking the Ip3r2 gene. Single nucleus RNA sequencing identified astrocytic genes from various functional categories, that are regulated by neuronal and astrocyte activity, along with multiple genes that show layer-specific enrichment. These findings provide insight into neuron-astrocyte interaction as it occurs at the level of the distinct cortical connections, and constitute an important frame work for future studies of astrocyte and synapse development in the cortex.

Title: Fibroblast Growth Factor Receptor 1 interacts with diet to impact tanycyte morphology and physiology

Authors: *K. SMITH[1,2], N. A. ESTEVE[2], G. NORA[2], L. HUVAL[2], T. ADOUN[2], H. MAYEUX[2];
[1]Univ. of Louisiana At Lafayette, Lafayette, LA; [2]Biol., Univ. of Louisiana, Lafayette, LA

Abstract: Fibroblast Growth Factor Receptor 1 (FGFR1) is expressed by most astrocytes in the Central Nervous System, including strong expression in hypothalamic tanycytes. Tanycytes are a specialized subtype of astrocyte of the hypothalamus. The cell bodies of tanycytes are located in the ventral wall of the 3rd ventricle, alongside ependymal cell bodies. Tanycytes have long radial projections into the hypothalamus, and previous studies have indicated that the radial morphology of tanycytes aids in their functions of transferring metabolic signals and hormones from the 3rd ventricle and blood stream to the hypothalamic nuclei controlling physiological processes such as appetitive behaviors. Tanycytes are in a privileged position between the CSF in the 3rd ventricle, the blood supply via fenestrated capillaries in the median eminence, and metabolism-influencing nuclei in the hypothalamus. In this study, we utilized a Nestin-Cre Recombinase transgenic adult mice line that conditionally deleted FGFR1 in neural stem cells (NSCs), to investigate the impacts that FGFR1 has in tanycyte morphology and physiology. We also explored differential impacts upon the dentate gyrus (DG) of the Hippocampus. We placed 7-11 mice per group on a one-month long high fat diet to investigate differences in body homeostasis and tanycyte morphology between FGFR1 flox allele controls and Cre+ FGFR1 deficient mice. We found that FGFR1 is a vital contributor to tanycyte morphology and quantity, and a partial promotor of NSC maintenance. Although tanycyte morphology was disrupted in regular diet (RD) KO mice, glucose physiology and body weight was unperturbed relative to RD WT mice. With a combination of FGFR1's deletion and a high fat diet (HFD), NSCs were greatly reduced in both the 3rd ventricle and the dentate gyrus. Although a HFD has be proven to promote a low-grade pro inflammatory environment, microglia were not drastically activated in the HFD mice compared to RD mice; however, they were reduced in number in the DG of HFD mice.

Title: Neuronal activity drives pathway-specific depolarization of astrocyte distal processes

Authors: M. ARMBRUSTER[1], S. NASKAR[2], J. GARCIA[2], M. SOMMER[2], E. KIM[2], Y. ADAM[3], P. G. HAYDON[4], E. S. BOYDEN[6], A. E. COHEN[7], ***C. G. DULLA**[5];

Abstract: Astrocytes are glial cells with elaborate morphological complexity, allowing close physical and functional interactions between nanometer-scale distal astrocyte processes (DAPs) and neuronal synapses. Excitatory amino acid transporters (EAATs), including GLT1 and GLAST, are concentrated in DAPs where they remove extracellular glutamate, providing spatiotemporal control of excitatory neurotransmission. The inward rectifying potassium (K^+) channel Kir4.1 is also present in DAPs, where it mediates K^+ buffering by allowing K^+ influx when extracellular levels are high. Astrocytes have low membrane resistance (R_m, ≈ 5 MΩ) and hyperpolarized membrane potentials (V_m) (≈ -80 mV), near the K^+ reversal potential, thanks to their expression of a cadre of K^+ channels. This has led to the assumption that astrocytes are electrically passive and undergo only very small changes in V_m. Whole cell recordings from astrocyte soma show that astrocyte V_m changes by only a few mVs during neuronal activity and returns to baseline over the course of seconds. Because of low astrocyte R_m and DAP morphological complexity, there is minimal spatial propagation of depolarization in astrocytes. Therefore, measurements made at the soma at best represent a heavily filtered and attenuated version of changes in V_m (ΔV_m) in DAPs. Short bursts of neuronal activity rapidly and reversibly inhibit EAAT function with synapse specificity. Because EAATs are voltage-dependent, we suspected that DAP depolarization may contribute to activity-dependent EAAT inhibition. To address this possibility, we expressed genetically encoded voltage indicators in astrocytes to image astrocyte V_m. Using this approach, we report that neuronal activity induces large, rapid, focal, and pathway-specific depolarization of astrocyte DAPs. These depolarizations are mediated by elevated extracellular K^+ during presynaptic activity, with an additional contribution from EAAT-mediated currents. These depolarizations lead to voltage-dependent inhibition of EAATs which enhances synaptic NMDA currents. This represents a novel form of astrocyte-neuron communication mediated by rapid, spatially specific DAP depolarization and has important implication for understanding the role of astrocytes in shaping extracellular glutamate and K^+ dynamics.

Title: Dynamic actin waves in astrocytes sense environmental cues and cluster into hotspots of activity

Authors: *K. M. O'NEILL[1], E. SARACINO[2], B. BARILE[3], N. J. MENNONA[1], S. PATHAK[1], M. G. MOLA[3], T. POSATI[2], R. ZAMBONI[2], G. P. NICCHIA[3], V. BENFENATI[2], W. LOSERT[1];

Abstract: Astrocytes are recognized as the brain cells that maintain homeostasis and, more recently, as modulators of synaptic transmission. *In vivo* studies have shown that astroglial homeostatic regulation and synaptic modulation occur mainly at the endfeet of astrocytes, in so called “microdomains”. While the effects of transmembrane flux of ions and water molecules on these processes have been deeply investigated, the role of cytoskeleton dynamics has not been explored. Here, we investigate the dynamic function of actin in live astrocytes in response to chemophysical changes to the extracellular environment. To this end, we use confocal microscopy to capture actin dynamics in live primary neocortical rat astrocytes that have been transduced with actin-GFP. We perturb the cells chemically by changing the imaging media from a standard external solution (the control) to a “triggering” solution - either an isotonic high potassium solution (“high K+”; [K+] = 40 mM) or a hypotonic solution (“hypotonic”; ΔOsm = 60 mOsm). We also culture astrocytes on two different surfaces: poly-D-lysine- (PDL-) coated glass as a control or on hydrotalcite nanoparticle films (HTlc), the latter of which is a validated, biocompatible nanotopography that causes astrocytes to differentiate and become more *in vivo* like in morphology and function. We employ an optical flow analysis method to analyze how actin dynamics change after chemical perturbation and how the characteristics of actin dynamics are altered in distinct mechanical environments, specifically investigating the magnitude, probability, and persistence of dynamics. We also identify small regions of especially high activity, which we call “hotspots”. Chemical perturbations (both high K+ and hypotonic) strengthen actin dynamics compare to paired controls, and high K+ causes more dynamics near the boundary of the cell compared to paired controls. Of note, when analyzing actin dynamics within “hotspot” regions, we find that the relative strength of actin dynamics within hotspots compared to the whole cell increases for the high K+ condition but not for the hypotonic condition. We also compare actin dynamics in undifferentiated astrocytes grown on PDL to differentiated astrocytes grown on HTlc substrates, finding that PDL cells display stronger actin dynamics but that HTlc cells display more frequent actin dynamics. Taken together, our results suggest that actin dynamics are a local manifestation of the cellular homeostatic response to chemical and physical changes in the extracellular microenvironment.

Title: A large portion of the astrocyte proteome is dedicated to the perivascular endfeet, including critical components of the electron transport chain

Authors: *B. SHIM[1], J. A. STOKUM[1], W. HUANG[2], M. KANE[2], J. A. SMITH[1], V. GERZANICH[1], J. SIMARD[3];
[1]Neurosurg., [2]Pharmaceut. Sciences, Sch. of Pharm., [3]Neurosurgery, Pathology, and Physiol., Univ. of Maryland, Baltimore, Baltimore, MD

Abstract: Perivascular astrocyte endfeet are specialized, diffusion-limited subcellular compartment that completely envelop the cerebral vasculature. Despite significant efforts to characterizing the structural aspects of the astrocyte endfeet, a clear understanding of the endfoot physiology remains elusive, in part due to the limited studies on the endfoot proteome which may be distinct to the proteome of the greater astrocyte body. To address this, we developed a novel technique to isolate the perivascular endfeet from brain tissue, which we further utilized to identify and compare the proteomes of the endfoot and somata. In our protocol, we isolated the astrocyte endfeet by dissociating these processes from freshly isolated brain microvessels, which have previously been reported to retain the endfeet. The endfeet were further purified using the ACSA-2-based sorting procedure, a method previously reported to isolate ultrapure astrocyte somata from the adult rodent brain. Results from the proteomics study expand the previously known set of proteins enriched at the endfeet from 10 to 516, which comprised more than 1/5th of the entire astrocyte proteome. Importantly, a number of critical electron transport chain proteins was identified to be exclusive to the endfeet while enzymes involved in glycogen storage were localized to the somata, thus suggesting compartmentalization of subcellular metabolic functions. Furthermore, the endfoot proteome also revealed a number of proteins that were previously understood to contribute to maintaining the blood-brain barrier but not known to localize to the endfeet. Our findings in this study identify a number of key astrocyte endfoot-specific proteins, which may extend to a better understanding of the physiological and/or pathophysiological role of the endfeet.

Abstract: Astrocytes have many essential roles in brain function. Underpinning these roles is an elaborate cellular architecture based on frequent, extremely fine, but seemingly haphazard branches, as well as prominent features including tripartite synaptic complexes and perivascular endfeet. How these astrocytic structures combine to form a unified cellular architecture that supports their complex functions in the CNS is unclear. This is largely due to a dearth of high quality, high resolution datasets that reveal these nanoscopic structures, and robust computational approaches that effectively interrogate astrocyte morphology and organization. Here, we produced and analyzed three, high-resolution datasets using focused ion beam serial electron microscopy and computer vision approaches to provide a principled, quantitative analysis of astrocytic ultrastructure. Analysis of changes in process thickness and surface curvature across the astrocytic volumes allowed for the decomposition of the astrocytes into fundamental 'parts.' Network analysis of these connected parts demonstrates the existence of centralized, but infrequent hubs that give rise to many simple branches, as well as large loops in the structure of astrocytes. Interestingly, tripartite synapses were not distributed evenly across these parts. We also directly measured distances through the convoluted astrocytic volumes using fast marching wavefront propagation. This allowed us to define spatial relationships between tripartite synapses, the astrocyte surface, and astrocytic mitochondria. Using these relationships, we found that astrocytes partition the surrounding synaptic population into clusters that are distinct from synaptic clusters defined simply by direct synapse-synapse spatial relationships. Furthermore, astrocytic mitochondria appear to be positioned preferentially closer to specific synaptic clusters, but not to specific classes of synapses. This study reveals that astrocytes have complex anatomical adaptations and provides deployable computational resources to systematically and quantitatively resolve astrocyte nanostructure and architecture in the CNS.

Title: Storm super-resolution imaging of molecules in the fine processes of mouse hippocampal astrocytes

Authors: *M. ZÖLDI[1], K. KENESEI[2], Z. LÁSZLÓ[2], I. KATONA[1];
[1]Psychological and Brain Sci., Indiana Univ., Bloomington, IN; [2]Inst. of Exptl. Medicine, HAS, Budapest, Hungary

Abstract: Astrocytes are now recognized as key players in shaping synaptic signaling between neurons. However, our understanding of how the expression and distribution of astrocytic molecules exert their regulatory control over synapses is still limited owing to the difficulties to localize them inside astrocytes. As the thin astrocytic processes are beyond the diffraction limit and many of the astrocytic proteins are expressed in low copy numbers, the traditionally used confocal and electron microscopic techniques suffering from low resolution and low labeling density, respectively, can not be used to tackle the above questions. As a potential alternative approach, STochastic Optical Reconstruction Microscopy (STORM), a recently developed fluorescence-based super-resolution imaging method, could bridge the gap between resolution and labeling density. The simultaneous visualization of astrocytic plasma membranes along with a target protein in their native tissue context in a way compatible with STORM imaging, however, is still a very difficult task. Therefore, we aimed to develop and present a labeling, imaging and analysis pipeline with which we can better study the nanoscale arrangement of astrocytic molecules and fine processes in relation to synapses. To sparsely label hippocampal astrocytes, we electroporated newborn mouse pups at postnatal age P0-P01 with a plasmid expressing the fluorescent protein mCherry fused to Channelrhodopsin-2 (ChR2). We show that ChR2-mCherry incorporates into the plasma membrane of single electroporated hippocampal astrocytes, and STORM imaging visualizes the intricate spongiform morphology of fine astrocytic processes well below the diffraction limit. Dual-color STORM imaging revealed that our approach has the sufficient resolution to localize astrocytic proteins inside processes and to discriminate them from neighboring synaptic structures. We present important controls to assess the channel crosstalk and chromatic aberration arising in dual-color super-resolution images, and provide analysis methods using tessellation and nearest neighbor distance measurements to validate the astrocytic presence of selected proteins. By combining STORM imaging with confocal microscopy, we also show how astrocytic processes contact the different hippocampal synapse types in non-dehydrated tissue

samples. Our data highlight the importance of studying the nanoscale arrangement of astrocytic proteins and fine processes in their native tissue context.

Program, The Ottawa Hosp. Res. Inst., Ottawa, ON, Canada; [7]Concordia Univ., Montreal, QC, Canada; [8]Child Study Ctr., Yale Univ., New Haven, CT

Abstract: Astroglial cells are emerging as key players in the development and homeostatic maintenance of neurons and neuronal networks. Astroglial cell functions are critical to neuronal migration and maturation, myelination, and synapse dynamics, however little is known about astroglial phenotypic changes over development. Furthermore, astroglial cells express steroid hormone receptors and show rapid responses to hormonal manipulations, however, despite important sex differences in telencephalic regions such as the cortex and hippocampus, few studies have examined sex differences in astroglial cells in telencephalic development. To phenotype cortical astroglial cells across postnatal development while considering potential sex differences, we used translating ribosome affinity purification together with RNA sequencing (TRAPseq) and immunohistochemistry to phenotype the entire astroglial translatome in males and females at key developmental time points: P1, P4, P7, P14, P35 and in adulthood. Overall, we found two distinct astroglial phenotypes between early (P1-P7) and late development (P14-Adult), independent of sex. The astroglial translatome also showed significant sex differences in gene expression patterns over development, with peak sex differences observed at P7. At least part of the sex differences observed at P7 appear to be due to males reaching a more mature astroglial phenotype earlier than females. Together, these data clearly delineate and phenotype astroglia across development and identify sex differences in astroglial developmental programs. Importantly, these developmental sex differences could have an impact on the construction and maintenance of neuronal networks and potential developmental windows of vulnerability to neurologic and psychiatric disease.

Title: Mechanism and function of microvesicle release by GDE3

Authors: *R. LEVY-MYERS, S. SOCKANATHAN;
Johns Hopkins Med. Institutions, Baltimore, MD

Abstract: Neuron-glia communication is critical for proper brain function. Specifically, astrocytes are known to regulate aspects of neuronal health, synaptic function, and disease progression. Extracellular vesicles (EVs) comprise one pathway that astrocytes communicate with neurons. EVs are small (100-500nm) vesicles that are released and received by all cells. EVs contain protein and nucleic acid cargo that can exert large effects on recipient cells. GDE3 (Glycerophosphodiester Phosphodiesterase 3 or GDPD2) is a 6-transmembrane protein expressed on the plasma membrane of astrocytes but not neurons. Mice lacking GDE3 (Gde3-KO) exhibit signs of neurodegeneration suggesting that GDE3 regulates a non-cell autonomous function of astrocytes. We found that GDE3 is necessary and sufficient to release a subclass of EVs called Microvesicles (MVs) from the plasma membrane of astrocytes. We hypothesize that GDE3 promotes the release of specialized MVs from astrocytes that are necessary for neuronal health and survival. To investigate this possibility, we have performed unbiased screens to define the mechanism of GDE3 MV release and to identify cargos of MVs released by GDE3 from astrocytes. Here we investigate the model that GDE3 reorganizes the actin cytoskeleton network via the WAVE Regulatory Complex (WRC) to release MVs and that these MVs are required for neuronal survival and function. This work has potential to identify a novel modifier of MV release from astrocytes and define new subtypes of MVs that play critical roles in regulating neuronal health and function.

Title: The critical role of ARL13B in mechanisms of astrocyte development

Authors: *R. BEAR, T. CASPARY;
Human Genet., Emory Univ., Atlanta, GA

Abstract: Astrocytes are the most abundant glial cell in the brain and are essential for neuron function and neural circuit formation. Astrocytes have an indispensable role in the developing brain, yet our understanding of the mechanisms that allow astrocytes to develop remains behind our growing knowledge of astrocyte function. Several neurodevelopmental disorders that result in intellectual disability are attributed to astrocyte dysfunction during development, highlighting the importance to resolve mechanisms that regulate astrocyte development. Astrocytes contain a critical signaling appendage, the primary cilium, a crucial regulator of neuronal development but overlooked in astrocytes. ADP-ribosylation factor-like protein 13B (ARL13B) encodes a regulatory GTPase enriched in cilia that controls many neurodevelopmental processes, including neuron specification, migration, and axon guidance. Recessive mutations in *ARL13B* result in the ciliopathy, Joubert Syndrome, a disorder characterized by several neurological phenotypes including intellectual disability. Joubert Syndrome motivates studying the relationship between ciliary signaling and astrocytes because they converge in the pathogenesis of neurodevelopmental disorders. The goal of my research is to determine the role of ARL13B in regulating signaling pathways underlying astrocyte differentiation and proliferation. Here, I employ genetic mouse models to specifically and temporally manipulate ARL13B expression and function in developing astrocytes *in vivo*. I show that astrocytes lacking ARL13B have altered rates of proliferation and changed timing in astrocyte stage-specific gene expression. These results indicate a key role for ARL13B during astrocyte development. This work informs a novel relationship of ARL13B and cilia to mechanisms of astrocyte development and reveals previously enigmatic functions of astrocyte primary cilia.

Title: Dark neurons of the rat sensorimotor cortex and changes in neuroglyal relationships after short time occlusion of the common carotid arteries

Authors: A. GORBUNOVA, S. STEPANOV, D. AVDEEV, A. SHORONOVA, L. MAKARYEVA, M. KORZHUK, ***V. AKULININ**;
Omsk State Med. Univ., Omsk, Russian Federation

Abstract: To study the processes of the hydropic dystrophy and gliocytoarchitectonics reorganization during formation of "dark neurons" within the sensorimotor cortex (SMC) in rats after the occlusion of the common carotid arteries. Acute ischemia was modeled on mature Wistar rats via 20- and 40- min occlusion of the common carotid arteries (OCCA). Nissl, hematoxylin-eosin staining, immunohistochemical typing have been used to perform comparative morphometric evaluation of the cyto- and glyocyto- architectonics of the neocortex 1, 3, 7 days after OCCA. Relative area of the edema/swelling zones and numerical density of the normal and hyperchromic (dark) pyramidal neurons, oligodendrocytes (ODC) and microgliocytes (MGC) were determined. The chosen method of the brain fixation significantly affects observed amount of the artifact dark neurons (ADN), which are similar in morphology and tinctorial properties to the degeneratively altered dark neurons (DDN). The appearance of reversibly and irreversibly altered DTN after OCCA in the SMC was accompanied by an increase in the relative area of edema-swelling zones (from 5.4% in the control to 17.6%). The maximum content of DDN (53%) was detected in layer V on the 7 day after ischemia. According to immunohistochemical typing data of NSE, MAP-2, HSP-70, p38, and CASP3, majority of the proteins specific for the DDNs were preserved, ensuring neuron recovery. The total numerical density of SMC neurons in the layer III decreased by 26.4% after 7 days, and in layer V - by 18.5%. The revealed changes were diffuse-focal in nature. The content of astrocytes, MGC and ODC increased in the areas of DDN accumulation. The neuro-astroglial index increased to 2.72 on the 3 day after the OCCA, compared to the control - 1.62. The peak in the MGC density was observed one day, and in the ODC density - 7 days after the acute incomplete ischemia. When compared to 20 min OCCA, 40 min ischemia caused increase in number and density of the dark neurons in the SMC, and, as a consequence, signs of the hydropic dystrophy. On that background, we also observed increase in the number of ODC, astrocytes, and MGC. It is likely that edema/swelling, and active MGCs and astrocytes sanitize neural tissue during first 1-3 days after ischemia, thus, providing for the future (7 days after) structural and functional recovery with the participation of the ODC.

Abstract: Previous studies demonstrated that high intake of the essential nutrient, choline, during gestation, ameliorates hippocampal amyloidosis, reduces gliosis, prevents cholinergic defects and increases hippocampal neurogenesis in hemizygous APPswe/PS1dE9 (APP.PS1) Alzheimer's disease (AD) model mice. Here, we investigated the effects of a similar treatment on behavioral phenotypes in the APP^{NL-G-F} mouse model for AD. These mice express a humanized APP with three mutations that cause familial AD in humans [Swedish (NL), Arctic (G), and Beyreuther/Iberian (F)] under the control of the endogenous mouse APP promotor. The latter permits to overcome problems related to the overexpression of APP observed in the transgenic mouse models for AD (e.g. APP.PS1) and is therefore considered a more physiologically relevant model well suited for studies of the pathophysiology of this disease. We maintained the pregnant and lactating wild type C57BL/6J control mice and homozygous APP^{NL-G-F} mice on a control AIN76A diet containing 1.1 g/kg of choline or a choline-supplemented (5 g/kg) diet. After weaning all offspring consumed the control diet. Mice were examined in a cross-sectional fashion at 3, 6, 9 and 12 months of age using the open field, elevated plus maze, Barnes maze and contextual fear conditioning experimental paradigms. As compared to controls, the APP^{NL-G-F} mice exhibited abnormalities in anxiety-related behaviors at 3 and 6 months of age and learning and memory deficits at 9 and 12 months of age. Perinatal choline supplementation ameliorated some of the memory deficits in the 12-month old APP^{NL-G-F} mice observed in the contextual fear conditioning test. The data suggest that dietary supplementation with choline during fetal development and early postnatal life prevents some of the behavioral abnormalities in the APP^{NL-G-F} AD model mice.

Title: Deficiency of brain-derived insulin-like growth factor 2 (IGF2) promotes seizures and exacerbates cognitive defects in a mouse model of Alzheimer's disease (AD): effects of perinatal choline supplementation

Authors: T. A. BELLIO, S. C. YEE, T. JAYASINGHE, V. CHINTHAREDDY, M. CAMPION, H. JAMIESON, S. DEVARAJ, J. K. BLUSZTAJN, *T. J. MELLOTT;

Abstract: High intake of the essential nutrient, choline, during early life increases brain expression of the growth factor IGF2 and protects Alzheimer's disease model mice from several features of AD-like pathology. The goals of our study are to understand if IGF2 may mediate the beneficial effects of perinatal choline supplementation and to examine the effects of reducing brain-derived levels of IGF2 in AD model mice. We generated wild-type and APPswe/PS1dE9 (APP.PS1) mice with a forebrain-specific *Igf2*$^{fl/fl}$ genotype by crossing mice carrying a tamoxifen-inducible *Camk2a*-promoter-driven Cre recombinase (CAMK2a-ERT2) with transgenic mice with the floxed *Igf2* gene. The pregnant and nursing mothers of these progeny consumed a control- or a choline-supplemented diet, and all offspring consumed a control diet after weaning. The forebrain-specific deletion of the *Igf2* gene was induced on postnatal day 60 with 5 consecutive days of i.p. injections of tamoxifen. At 6 months of age, there was a noticeable reduction (approximately 58-67%) in the levels of IGF2 protein in the hippocampus and cortex in mice with CAMK2a-CreERT2. There were no changes in the IGF2 levels within the liver of these mice suggesting that induction with tamoxifen specifically reduced forebrain-derived IGF2. It is possible that the remaining 40% of IGF2 protein expression in the brain tissues is the result of circulating IGF2 or glial-derived IGF2 rather than neuronal-derived production. As these tamoxifen-induced mice aged, we observed an increased mortality rate within APP.PS1 mice with CAMK2a-CreERT2 in both sexes, which may indicate increased vulnerability to AD in IGF2-deficient mice. Animal subjects were behaviorally tested at 6, 9 and 12 months of age. At 12-months of age, all APP.PS1 mice exhibited a deficit during the acquisition training in the Barnes maze compared to all non-AD model mice, with APP.PS1/CAMK2a-CreERT2 mice being the most impaired during the training. Interestingly, 1-day probe testing in the Barnes maze revealed significantly impaired memory recall in APP.PS1/CAMK2a-CreERT2 mice compared to their IGF2-intact APP.PS1 counterparts. In addition, APP.PS1/ CAMK2a-CreERT2 mice were more prone to seizures during behavioral testing. These results show that long-term reduction of brain-derived IGF2 can be tolerated in non-AD mice but can further impair cognitive function in APP.PS1 mice. This suggests increased vulnerability to AD pathophysiology in these mice and supports the notion of beneficial role of brain-derived IGF2 in later stages of AD progression.

Abstract: Alzheimer's Disease (AD) is characterized by a progressive cognitive decline, loss of synaptic connections and neurons, and the formation of amyloid plaques and neurofibrillary tangles lesions. In addition, numerous studies suggest a strong correlation between a reduced Cerebral Blood Flow (CBF) and Blood-Brain-Barrier (BBB) dysfunction with the development of AD. These cerebrovascular alterations precede the formation of amyloid plaques, tangles, and the onset of cognitive decline, suggesting that impaired cerebrovascular function plays a key role in the onset and/or progression of AD neuropathology. Pro-neuronal cell-based therapies have emerged as a promising alternative strategy for the repair or replacement of deteriorating neurons and neuronal networks in AD, whereas pro-vasculogenic cell-based therapies have also been used to address vascular deficiencies in the brain. However, cell-based therapies face numerous limitations. In many cases, progenitor or stem cell sources are insufficient, difficult to isolate, or pose major risks in terms of uncontrolled differentiation, tumorigenesis, genetic abnormalities, and immunogenicity. To implement safe and efficient cell therapies in AD, here we show a non-viral, nanotransfection-driven strategy to deliver pro-neurogenic and pro-vasculogenic factors to reprogram fibroblasts into therapeutic neurons and endothelial cells to treat females from the triple transgenic murine model of AD (3xTg-AD). In our experimental design, we performed a single intra-hippocampal injection of fibroblast pre-programmed to convert into neurons; or three intra-cerebroventricular injections of fibroblast pre-programmed to convert into endothelial cells. Fibroblasts with no pre-programming were used as control. Our preliminary results indicate that fibroblasts pre-programmed into neurons can survive and express markers of mature neurons inside the brain parenchyma after at least 6 weeks post-injection. Also, assessment of spatial learning and memory with the Barnes Maze significant improvement in long-term memory capacity and reduced aggregation of amyloid-beta peptides. On the other hand, fibroblasts pre-programmed into endothelial cells were detected 5 weeks after the last injection, and analysis of spatial memory with the Barnes Maze shows that the deficits presented by the 3xTg-AD mice were mitigated by the pre-programmed fibroblast. Together, our results indicate that the development of nanotransfection-based cell therapies by direct reprogramming is a promising therapy for AD that could overcome many of the limitations of current cell therapies.

Title: Role of PCDH15 in the neurosensory retina & retinal pigment epithelium along with exogenous retinoid delivery to rescue the dysfunctional photoreceptors activity in a novel preclinical mouse model.

Authors: *S. RIAZ[1], S. SETHNA[2], T. DUNCAN[3], M. REDMOND[3], S. RIAZUDDIN[2], Z. AHMED[2]; [1]Otorhinolaryngology Head and Neck Surgery, Univ. of Maryland, Sch. of medicine, Baltimore, MD; [2]Otorhinolaryngology Head and Neck Surgery, Univ. of Maryland Sch. of Med., Baltimore, MD; [3]Natl. Eye Inst., Bethesda, MD

Abstract: Abstract Purpose Usher syndrome type I (USH1) is characterized by congenital deafness, vestibular areflexia, and progressive retinal degeneration with age. The protein-truncating p.Arg245* founder variant of *PCDH15* has ~2% carrier frequency among Ashkenazi Jews, accounting for nearly 60% of their USH1 cases. We have developed and characterized *Pcdh15*$^{R250X/R250X}$ mouse model (*Pcdh15*^{R250X}; equivalent to human p.Arg245*) to investigate the precise role of protocadherin-15 in the neurosensory retina and RPE including, light transduction and mechanism of visual deficits and rescue of the vision by exogenous retinoid delivery. **Approach***Pcdh15*^{R250X} mice were generated using CRISPR/Cas9 technology. Retinal function was assessed using electroretinography (ERG), while structure integrity was assessed via optical coherence tomography (OCT). Rescue strategies for visual deficits included exogenous retinoids delivery via intraperitoneal injections. **Results**Our results showed that deficiency of *Pcdh15* causes early visual deficits, as evaluated by ERG, similar to USHIF patients. The neurosensory retina is a light-sensitive tissue lining the inner surface of the eye. ERG showed attenuated a- and b-wave amplitudes suggesting dysfunctional photoreceptors, while histology and OCT showed no gross retinal degeneration at early ages. At the molecular level, we found light-dependent mislocalization of arrestin and transducin, key dark cycle proteins, in mutant mice. We also found reduced levels of RPE-specific visual retinoid cycle proteins, RPE65 and CRALBP, and reduced levels of retinoid chromophores. Next we assessed exogenous retinoid delivery to rescue the visual deficits. First, a single intraperitoneal injection of exogenous 9-*cis* retinal, an analog of the naturally occurring 11-*cis* retinal improved ERG amplitudes in mutant mice suggesting improvements in the photoreceptor functional activity which are important part of neural retina. Single injection of 9-*cis* retinal was effective for one week at younger (2-3 months) and older ages (6-7 months) of mice.**Conclusions**Our results showed *Pcdh15*^{KI} mutants recapitulates human p.Arg245* visual deficit phenotype. Functional evaluation revealed a dual role for protocadherin-15 in photoreceptors and RPE. Our current findings support a role for visual retinoid cycle dysfunction in *Pcdh15*^{R250X} mutant mice suggesting a basis for a clinical trial of exogenous FDA approved retinoids to preserve vision in USH1F patients.

Abstract: Familial Alzheimer's disease is caused by dominant mutations in the genes that encode amyloid precursor protein, presenilin 1, and presenilin 2, which affect multiple brain regions. Although targeting mutations using CRISPR/Cas9-mediated genome editing is a promising disease-modifying treatment strategy, brain-wide amelioration of Alzheimer's disease phenotypes using this approach has not been demonstrated. Here, we show that CRISPR/Cas9-mediated genome editing by intravenous administration of a modified adeno-associated virus (AAV) that can cross the blood-brain barrier efficiently disrupts mutated *APP* in various brain regions of the transgenic mouse models that carry the human *APP* Swedish mutation. Systemic delivery of the modified AAV-Cas9 virus decreases amyloid plaque deposition throughout the brain. In addition, this single-dose administration of the modified AAV-Cas9 virus globally alleviates AD-associated pathologies including microgliosis and neurite dystrophy. Moreover, systemic delivery of AAV-Cas9 virus ameliorates the cognitive impairment of the AD transgenic mice, resulting in improved habituation ability, working memory, and risk-taking behavior. Thus, our work on brain-wide gene editing provides a novel approach toward developing a noninvasive, single-administration, disease-modifying treatment for familial Alzheimer's disease and other monogenic diseases that affect multiple brain regions.

Title: Nano-pulsed laser therapy-treated hippocampal neural stem cells differentiate into neurons resistant to amyloid beta oligomer toxicity

Authors: *K. J. JOHNSON[1], A. C. GRANT[2], K. JOHNSON[2], G. TAGLIALATELA[3], R. ESENALIEV[4], M.-A. MICCI[2];

Abstract: Objective Synaptic and mitochondrial dysfunction driven by toxic amyloid oligomers (Aβo and Tauo) are early events leading to cognitive decline in Alzheimer's disease (AD). Transcranial treatment of adult WT mice with near-infrared light (NIL) decreases synaptic vulnerability to Aβo and preserves mitochondrial function after Aβo treatment. Nano-pulsed laser therapy (NPLT) combines photobiomodulatory effects of NIL with optoacoustic ultrasound waves to deliver two therapeutic components with greater penetration than static NIL therapy. We have previously shown that preserved hippocampal neurogenesis correlates with synaptic and cognitive resilience in non-demented individuals with AD neuropathology. Here we sought to determine whether adult rat hippocampal stem cells (NSCs) treated with NPLT differentiate into neurons with decreased synaptic and mitochondrial vulnerability to Aβo toxicity. **Methods** Adult rat hippocampal NSCs were exposed for five minutes to NPLT or sham treatment and allowed five days to differentiate into mature neurons (MN). For analysis of Aβo binding, MNs were incubated with 2.5μM Fluor-647-labeled Aβo for 30 minutes at 37ºC and immunostained for βIII-tubulin (a neuronal marker). Aβo puncta on neurites were quantified using ImageJ. For analysis of mitochondrial membrane polarization, Aβo-treated MNs were incubated with the mitochondrial membrane potential-dependent dye, MitoTracker Deep Red (MTDR) and potential-independent MitoTracker Green (MTG). Flow cytometric analyses of MTDR and MTG was conducted 30 minutes post-Aβo treatment. Mitochondrial respiration was evaluated using Seahorse XF analyzer. **Results** NPLT induced a significant enhancement of major mitochondrial bioenergetic parameters in NSC (ATP production, maximal respiration, and spare capacity). MNs generated from NPLT-treated NSCs showed significantly fewer Aβo puncta per neurite compared to MNs from sham-treated NSCs ($p=0.0049$), and lower percentage of total neurites with bound Aβo ($p<0.0001$). We also found that Aβo treatment induced a significant reduction in total mitochondria and mitochondrial membrane potential in MNs from sham-treated NSCs but not in MNs from NPLT-treated NSCs. **Conclusions** Here we show that adult rat hippocampal NSCs treated with NPLT display enhanced mitochondrial function and generate neurons resistant to Aβo binding and to Aβ-induced mitochondrial dysfunction. These data suggest that NPLT, approved for use in humans for unrelated clinical applications, could be a valuable therapeutic tool for inducing cognitive resilience to AD neuropathology.

Title: Near-infrared light reduces glia activation and modulates neuroinflammation in the brain of diet-induced obese mice

Authors: *S. SAIEVA, A. FRACASSI, M. MARCATTI, W.-R. ZHANG, G. TAGLIALATELA; Mitchell Ctr. for Neurodegenerative Dis. - Dept. of Neurol., Univ. of Texas Med. Br., Galveston, TX

Abstract: Obesity is one of the most prominent risk factors for Alzheimer's Disease (AD); obesity and AD share several pathological features, notably neuroinflammation. Hippocampal neuroinflammation, in rodents, correlates with poor memory performance, while in humans, growing evidence shows that obesity increases three times the risk of developing AD. The overall objective of this work is to reduce the impact of obesity on neuroinflammation, with the long-term goal of reducing the risk of later dementia. Recently, near-infrared (NIR) light has been proposed as potential treatment for cognitive deficits, showing improvement of learning and memory in both humans and animal models. Previous work demonstrated that a transcranial delivery of NIR light reduced Aβ and Tau pathology and improved memory function in mouse models of AD. Here, it was tested whether NIR light may prevent obesity-induced neuroinflammation, in a diet-induced obese mouse model. After 13 weeks of high-fat diet (HFD), the mice received the NIR light treatments for 4 weeks in single daily sessions of 90 seconds each. Using fluorescence immunostaining to evaluate glial activation we found that in both hippocampus and parietal/occipital cortex, HFD caused increased expression of CD68 (activated microglia) and GFAP (astrocytic marker), whereas NIR light reversed this increase. On the other hand, we found no change in frontal cortex either due to HFD or NIR light. Furthermore, using quantitative real-time PCR analyses we evaluated the effects of NIR light on cytokines mRNA levels in hippocampus and frontal cortex and found that in the hippocampus, HFD caused an increase of pro-inflammatory IL-1β and TNF-α, as well as of the anti-inflammatory IL-10, which were brought back to basal levels by NIR light treatment. Also, BDNF mRNA was upregulated in HFD mice treated with NIR light, compared to HFD not-treated mice, thus suggesting that the NIR light triggers neuroprotective mechanisms contributing to reduced neuroinflammation. Collectively, this data suggests that obesity-induced neuroinflammation may be reduced by NIR light and that this is a reversible process that may be targeted to prevent neurodegeneration. These results thus support the notion of NIR light as a potential preventative, non-invasive therapeutic approach against obesity-induced CNS deficits that are known to concur to AD neuropathological cascade.

Abstract: Hippocampus-dependent memory loss is a key symptom of neurodegenerative diseases such as Alzheimer’s disease and related dementias (ADRD). Because the mechanisms underlying memory loss associated with ADRD remain unclear, no effective treatments exist. Fundamental studies have shown that a set of transcriptional regulatory proteins of the nuclear receptor 4a (Nr4a) family serve as critical molecular switches for long-term memory in the hippocampus. Here, we show that Nr4a proteins regulate the transcription of a group of genes encoding chaperones that localize predominantly to the endoplasmic reticulum (ER). Nr4a-driven expression of these chaperones is critical for the trafficking of plasticity-related proteins to the cell surface, as well as for long-lasting forms of synaptic plasticity and long-term memory. Analysis of human ADRD data revealed that pathological progression correlates with downregulation of Nr4a transcription factors in the hippocampus. Further, in a tau-based mouse model of ADRD-associated neurodegeneration, hippocampal levels of both the Nr4a family members and the ER chaperone effector genes were shown to be reduced. Importantly, overexpressing Nr4a1 or ER chaperone Hspa5 ameliorated the long-term memory deficits in this mouse model. Thus, our findings identify ER chaperones and the protein folding pathways that they regulate as key effectors of memory consolidation. This essential molecular switch to long-term memory appears impaired in ADRD, pointing towards novel therapeutic approaches for treating memory loss in these neurodegenerative diseases.

Title: Thermoneutral temperature exposure increases slow-wave sleep in the 3xTg-AD mouse model of Alzheimer's Disease

Authors: *J. WANG[1], D. HUFFMAN[1], A. AJWAD[1], A. D. BACHSTETTER[2], M. P. MURPHY[4], B. F. O'HARA[3], M. J. DUNCAN[5], S. SUNDERAM[1];

Abstract: There is growing evidence that disordered sleep, which is known to be associated with Alzheimer's disease (AD), may accelerate neuropathology, thus promoting a vicious cycle. Strategies for improving sleep quality may slow disease progression. Here we investigate the feasibility of sleep enhancement through ambient temperature regulation and examine the effect on amyloid- pathology. Female 3xTg-AD mice (~12 m.o.) were instrumented for EEG/EMG monitoring. After a week-long baseline, one half of the mice (n=9, EXPT; one animal did not survive for analysis) were exposed to stepwise diurnal increases in ambient temperature (Ta) to reach 30ºC (thermoneutral for mice) during the light phase while the rest (n=8, CTRL) remained at room temperature (22ºC). Vigilance state - i.e., Wake, REM, NREM, and slow wave sleep (SWS) within NREM - was scored in 4-second epochs and sleep metrics computed. SWS and REM were significantly greater ($p<0.05$) in the light phase for EXPT mice. These effects suggest better sleep consolidation and greater sleep depth with thermoneutral warming. After four weeks of treatment, the animals were euthanized, and the brains removed to assay amyloid pathology by ELISA. We found that thermoneutral warming caused a significant reduction in both Aβ40 and Aβ42 in the hippocampus, but not in the cortex. These data imply that thermoneutral warming might have some regional specificity in its effects, the effects appear to be specific to some brain areas more than others, with implications for the cognitive and neuropathologic changes found in AD. Furthermore, since SWS and REM support memory, future studies should investigate the effects of thermoneutral enhancement of SWS and REM on cognition.

Title: Neurodevelopmental deficits as a therapeutic target for adult-onset Spinocerebellar Ataxia type 1

Authors: *C. EDAMAKANTI[1], M. MARTINA[2], P. OPAL[3];
[1]The Ken and Ruth Davee Dept. of Neurol., Northwestern Univ., Morton Grove, IL; [2]Dept. of Physiol., [3]The Ken and Ruth Davee Dept. of Neurol., Northwestern Univ., Chicago, IL

Abstract: Spinocerebellar ataxia type1 (SCA1) is an adult-onset neurodegenerative movement disorder caused by a pathogenic polyglutamine expansion (CAG repeat) in the protein Ataxin-1 (ATXN1). SCA1 is a condition characterized by progressive problem with movement. People with this condition initially experience problems with coordination and balance (ataxia). Main pathological hallmark of the disease is Purkinje cell loss in cerebellum. Since ATXN1 is a transcriptional regulator it is not surprising that transcriptional misregulation appears as the initiating pathogenic event— indeed occurring as early as the first week of postnatal life. It is still unclear whether pathogenic changes occur only in Purkinje cells (PCs), the cells that are especially vulnerable in the disease, or whether other cell types contribute to pathogenesis. Given the importance of this postnatal period for cerebellar development, we asked whether this region might be developmentally altered by mutant ATXN1. We found that mutant ATXN1 — through transcriptionally upregulating the sonic hedgehog pathway—stimulates the proliferation of a relatively understudied cerebellar stem cell niche (defined by prominin-1; also, called CD133). Because these stem cells differentiate into GABAergic interneurons (basket cells and stellate cells) in molecular layer, there is an exaggerated inhibitory synapse formation with Purkinje cells. We have also confirmed the exaggerated GABAerigc interneuron connections in human SCA1 patients. This leads to significant increase in GABAergic interneuron inhibition of PCs, disrupting cerebellar Purkinje cell function in a non-cell autonomous manner. Mutant ATXN1 thus alters the neural circuitry of the developing cerebellum, setting the stage for the later vulnerability of Purkinje cells in SCA1. To interfere with the excessive GABAergic inhibition, we activated the endocannabinoid system (known to tamp down GABAergic inhibition in cerebellum by acting on presynaptic release of GABA) using endocannabinoid receptor agonist. We found that treated SCA1 mice performed significantly better on rotarod assay than untreated mice. This is the first drug that shows such a dramatic and prompt symptomatic improvement. Cannabinoid agonists are already FDA-approved for several disorders and we are optimistic that this might lead to a novel therapeutic treatment for SCA1.

Abstract: Aim : Multiple system atrophy (MSA) is characterized by α-synuclein (α-syn)+ glial cytoplasmic inclusions in oligodendrocytes and demyelination. Primary progressive multiple sclerosis (PPMS) has focal lesions of demyelination due to oligodendrocyte degeneration. Both MSA and PPMS commonly show oligodendrogliopathy, demyelination and glial inflammation. We previously developed a novel mouse model of MSA-cerebellar type (MSA-C) and PPMS by overexpression of mutant α-syn in oligodendrocytes in a temporarily restrictive manner using Tet-off system. We aimed to identify novel drug targets for MSA-C/PPMS using our model. Methods: We generated and analyzed TetO-α-SynA53T Tg/+; PLP-tTA Tg/+ double transgenic mice (A53Tα-syn mice), which express mutant human A53Tα-syn in oligodendrocytes starting at 8 weeks of age when doxycycline was removed from the feed. Results: A53Tα-syn mice developed progressive mono-, hemi-, and paraparesis and ataxia around 22 weeks, culminating in death around 30 weeks. Phosphorylated α-syn (p-α-syn) aggregated mainly in oligodendrocytes showing loss of connexin (Cx)47 and Cx32 in the spinal cord and brainstem/cerebellar white matter. Focal demyelination and oligodendrocyte loss started from the p-α-syn-deposited areas, leading to widespread demyelination. In the lesions, reactive astroglia showed extensive loss of Cx43 and Cx30, and activated microglia had marked up-regulation of arginase-1, colony stimulation factor 1 receptor (CSF1R) and Toll-like receptor 2. Single-cell RNA sequencing reveled the characteristics of microglia involved in the disease. Re-inhibition of A53Tα-syn expression at 23 weeks improved neurological symptoms and glial inflammation, whereas re-inhibition at 27 weeks resulted in only partial improvement. A CSF1R inhibitor administration eliminated activated microglia, but did not improve p-α-syn accumulation, demyelination or symptoms. Conclusion : Our model showed α-syn aggregation in oligodendrocytes and rapid progression with remarkable glial inflammation and demyelination. Early removal of α-syn could be novel therapeutic measures for MSA-C/PPMS.

Title: Exercise acts via BDNF-TrkB signaling to rescue deficits in a mouse model of spinocerebellar ataxia type 6

Authors: *A. A. COOK[1], S. JAYABAL[2,1], J. SHENG[1], T. C. S. LEUNG[1], A. J. WATT[1];
[1]Dept. of Biol., McGill Univ., Montreal, QC, Canada; [2]Dept. of Neurobio., Stanford Univ. Sch. of Med., Stanford, CA

Abstract: Spinocerebellar ataxia type 6 (SCA6) is an inherited neurodegenerative disease, presenting with mid-life onset of motor coordination difficulties and eventual cerebellar degeneration. We used a knock-in mouse model ($SCA6^{84Q/84Q}$) that carries a CAG expansion mutation in the *CACNA1A* gene to characterise the pathophysiology of SCA6 and identify potential treatments. We have previously shown that at 7 months these mice display deficits in motor coordination, as well as abnormalities in the intrinsic firing patterns of the Purkinje cells in the cerebellum. A 1 month program of voluntary exercise was able to rescue both motor coordination deficits and the frequency of intrinsic Purkinje cell firing. In order to identify the mechanism by which exercise acts therapeutically in the $SCA6^{84Q/84Q}$ model, we investigated brain-derived neurotrophic factor (BDNF) since BDNF levels are reduced in post-mortem brain tissue from SCA6 patients[1] and BDNF administration has been implicated in the pathophysiology of other ataxias[2]. We found that $SCA6^{84Q/84Q}$ mice had reduced levels of cerebellar BDNF, but this could be reversed by exercise. To determine whether exercise acts therapeutically in this model via BDNF-TrkB signaling, we administered 7,8-dihydroxyflavone, a small molecule that mimics BDNF as an agonist of the TrkB receptor. Chronic oral administration of 7,8-DHF rescued both motor coordination and Purkinje cell firing frequency deficits in the $SCA6^{84Q/84Q}$ mouse. The rescue of motor coordination deficits was sustained over several months of administration, demonstrating the potential of 7,8-DHF as a long term treatment for SCA6. By identifying a pathway by which exercise exerts its positive effect on cerebellar function, we have identified novel therapeutic strategies for SCA6.

Title: Assessing and mitigating neuroinflammation in X-linked dystonia parkinsonism

Authors: *T. PETROZZIELLO, C. A. VAINE, S. E. KIM, E. B. PENNEY, R. F. SÎRBULESCU, M. C. POZNANSKY, D. C. BRAGG, R. E. TANZI, C. ZHANG, G. SADRI-VAKILI;
Massachusetts Gen. Hosp., Boston, MA

Abstract: X-linked Dystonia Parkinsonism (XDP) is a severe neurodegenerative disease endemic to the Philippines and characterized by generalized dystonia combined with or followed by parkinsonism. Although several genetic studies mapped the XDP locus to TATA Binding Protein (TBP)-Associated Factor-1 (TAF1), the exact molecular mechanisms leading to neuronal loss remain to be clarified. Recently, we have demonstrated an increase in astrogliosis and microgliosis in human post-mortem prefrontal cortex (PFC) from XDP patients indicating an increase in neuroinflammatory processes in XDP. Furthermore, we reported a concomitant increase in the levels of histone H3 citrullination as well as myeloperoxidase (MPO) in XDP PFC. Both histone H3 citrullination and MPO have been linked to inflammatory processes in several pathological conditions, including neurodegenerative diseases. Here, we sought to unravel the molecular mechanisms underlying neuroinflammation in XDP and we hypothesized that mitigating inflammation may provide a potential therapeutic strategy for XDP. Therefore, we set out to assess the levels of known cytokines and chemokines in post-mortem XDP PFC using Meso Scale Discovery (MSD) assay. Our results revealed that several pro- and anti-inflammatory cytokines had differential expression in XDP PFC compared to controls. Additionally, there was a significant increase in the pro-inflammatory chemokines CXCL13 and CXC3L1 in fibroblasts derived from XDP patients compared to unaffected family members as detected by reverse transcription followed by qPCR. Together, our findings provide the groundwork for us to further assess the role of inflammation in XDP pathogenesis and to begin targeting these pathways as a potential therapeutic strategy to mitigate neuroinflammation in XDP.

Title: Gene therapy in the Shaker rat model of Christianson syndrome.

Authors: *C. J. ANDERSON[1], K. P. FIGUEROA[1], S. PAUL[1], W. DANSITHONG[1], M. GANDELMAN[1], D. R. SCOLES[2], S. M. PULST[1];

Abstract: Objective: The objective of this work is to optimize a gene therapeutic treatment strategy in the Wistar Furth *Shaker* rat, a spontaneous model of ataxia based on mutation of the Slc9a6 gene.
Background: Christianson syndrome (CS) is a complex developmental and neurodegenerative disorder characterized by a number of severe symptoms, including ataxia epilepsy, intellectual deficit, autistic features. In recent years, we have worked to characterize a naturally occurring rat model of Purkinje cell (PC) degeneration and ataxia, the Wistar Furth *shaker* rat, and in the process, we tied the shaker phenotype to a loss-of-function mutation in *Slc9a6*.
Design/Methods: We generated an AAV that uses an L7 promoter to target expression of the wildtype Slc9a6 rat gene to PCs along with a GFP tag to evaluate target engagement. We administered this AAV via intracerebroventricular injection prior to PC degeneration and evaluated therapeutic effect in the context of molecular, cellular, and motor phenotype. As NHE6, the gene product of SLC9A6 is widely expressed in brain, in our current work, we are evaluating the use of the ubiquitous CAG promoter for more widespread expression.
Results: Small doses of L7-Slc9a6-GFP AAV (as low as 2.26 x 10^11 vg copies) were well tolerated and sufficient to substantially reduce the ultimate motor phenotype. Interestingly, only a modest molecular improvement was required to generate substantial motor benefit. We will additionally present data evaluating safety and efficacy of the CAGpromoter-based construct.
Conclusions: AAVs are a promising candidate for treatment of the motor symptoms associated with *Slc9a6* mutation. Given the relative ease of targeting different cell types with AAVs through various promoters, we are currently in evaluation of AAVs to treat the developmental and epileptic components of the *shaker* phenotype.

Abstract: Spinocerebellar ataxia type 2 (SCA2) is a neurodegenerative disease caused by expansion of a CAG repeat in *Ataxin-2* (*ATXN2*) gene. The mutant ATXN2 protein with a polyglutamine tract is known to be toxic and contributes to the SCA2 pathogenesis. Here we tested the hypothesis that the mutant *ATXN2* transcript with an expanded CAG repeat (*expATXN2*) is also toxic and contributes to SCA2 pathogenesis. The toxic effect of *expATXN2* transcripts on SK-N-MC neuroblastoma cells and primary mouse cortical neurons was evaluated by caspase 3/7 activity and nuclear condensation assay, respectively. RNA immunoprecipitation assay was performed to identify RNA binding proteins (RBPs) that bind to *expATXN2* RNA. Quantitative PCR was used to examine if rRNA processing is disrupted in SCA2 and Huntington disease (HD) human brain tissue. RESULTS: *expATXN2* RNA induces neuronal cell death, and aberrantly interacts with RBPs involved in RNA metabolism. One of the RBPs, transducin β-like protein 3 (TBL3), involved in rRNA processing, binds to both *expATXN2* and expanded *huntingtin* (*expHTT*) RNA *in vitro*. rRNA processing is disrupted in both SCA2 and HD human brain tissue. These findings provide the first evidence of a contributory role of *expATXN2* transcripts in SCA2 pathogenesis, and further support the role *expHTT* transcripts in HD pathogenesis. The disruption of rRNA processing, mediated by aberrant interaction of RBPs with *expATXN2* and *expHTT* transcripts, suggest a point of convergence in the pathogeneses of repeat expansion diseases with potential therapeutic implications.

Title: Examining the role of NAA transport in Canavan disease pathology

Authors: *V. L. HULL, Y. WANG, D. E. PLEASURE;
Neurol., UC Davis, Davis, CA

Abstract: Canavan disease (CD) is an incurable leukodystrophy which develops in infancy and childhood as the result of *ASPA* mutations which disrupt the functionality of aspartoacylase. Aspartoacylase is an oligodendroglial-enriched enzyme responsible for cleaving the abundant brain amino acid, N-acetyl-L-

aspartate (NAA). Infants and children with CD are therefore unable to metabolize NAA and have extremely elevated levels of brain NAA accompanied by spongiform white matter degeneration, motor and cognitive delays, ataxia, and progressive neuronal atrophy. Attempts at *ASPA* gene replacement have largely proven ineffective, resulting in an urgent need to define new therapeutic targets for this fatal disease. Our lab has previously published studies showing that knockout and viral mediated neonatal knockdown of the neuronal enzyme Nat8l, which is responsible for the synthesis of NAA, is preventative against development of white matter vacuolation and ataxia in the well characterized CD model mouse (*Aspa*$^{nur7/nur7}$, "CD mouse"). Our most recent publication shows that intracisternal administration of an antisense oligonucleotide targeting *Nat8l* is capable of lowering brain NAA concentration, repairing white matter vacuolation and improving motor deficits in adult CD mice. Our current study seeks to further understand what role brain NAA transporters play in the cell specific accumulation and maldistribution of NAA in Canavan disease.

Title: A sporadic case of severe peripheral neuropathy expands the phenotypic range of TUBB2A mutations

Authors: K. SCHERER[1], M. F. HAMMER[2], W. A. DAY[3], W. R. MONTFORT[4], J. H. MILLER[5,6], L. M. JOHNSTONE[2], D. R. ANDREW[1,7], ***L. L. RESTIFO**[1];

Abstract: An 8-year-old boy was evaluated for progressive loss of strength and sensation in his extremities and developmental delay. Birth history was unremarkable and family history was negative. Motor and language milestones were delayed; dysarthria and swallowing difficulties were noted. On exam, the patient had symmetric distal weakness, muscle wasting, and sensory deficits, consistent with sensorimotor peripheral neuropathy. Neurophysiological testing revealed markedly reduced nerve-conduction velocities, consistent with demyelination. Compound motor action potential amplitudes were only moderately reduced, but declined considerably over the next four years, indicating interim axonal loss. At age 11, he lost ambulation. He never had seizures, and EEG was normal. Brainstem auditory evoked responses were abnormal. Neuropsychological testing showed mild intellectual disability affecting many cognitive domains. Brain MRI demonstrated mildly reduced volume of gray matter and

corpus callosum white matter, but no cortical gyration defects or abnormal myelination. Sural nerve biopsy showed reduced axon-fiber density and myelination. Electron micrographs revealed abnormal Schwann-cell processes with onion-bulb formation, reflecting attempted remyelination. Some axons showed abnormal microtubule orientation. Clinical genetic testing (including high-resolution karyotype, copy-number variants, and sequencing of genes commonly altered in peripheral neuropathies) failed to identify a cause of the phenotype. Whole-exome sequencing, using Illumina's massively parallel sequencing-by-synthesis method, was performed on peripheral blood DNA from the patient, his parents, and his unaffected sister. Sequence analysis using custom variant-filtering software revealed the proband has three amino-acid-altering germline variants not shared with any family members; two variants were eliminated as potential candidates to explain his condition. In *TUBB2A*, encoding β-tubulin 2A, the proband has a heterozygous *de novo* mutation at a highly conserved amino acid position, Arg262Pro, which is predicted to be deleterious. Crystal structure of wild-type β-tubulin (Protein Data Bank 4HNA) shows Arg262 lying on the surface, along a contact zone with the kinesin motor domain. Arg262Pro would disrupt an intramolecular hydrogen-bond network through interaction with three other amino acid residues. In the closely related gene, *TUBB3*, mutations at Arg262 also cause neuropathology with PNS and brain components. However, the proband's phenotype is distinct from the cortical dysplasia and epilepsy caused by other dominant *TUBB2A* mutations.

Charcot-Marie-Tooth Association

Title: A comparative study of mouse models of dominant and recessive Charcot-Marie-Tooth disease type 2E

Authors: S. D. KING[1], P. C. MONSMA[1], E. J. STONE[1], A. UCHIDA[1], R. RODRIGO[2], G. OWENDOFF[3], W. D. ARNOLD[2], *A. BROWN[1];
[1]Neurosci., [2]Neurol., [3]Biomed. Sci. Honors Program, Ohio State Univ., Columbus, OH

Abstract: Charcot-Marie-Tooth disease type 2E (CMT2E) is a slowly progressing peripheral neuropathy caused by mutations in the gene for neurofilament protein L (NEFL), which is a component of neurofilaments. Neurofilaments are space-filling cytoskeletal polymers that accumulate in myelinated axons, contributing to the expansion of axon caliber and consequent increase in axonal conduction velocity during postnatal development. CMT2E-causing mutations can be dominant (mostly missense mutations) or recessive (null mutations). The *Nefl*$^{N98S/+}$ mouse, which is heterozygous for the N98S

mutation, is an established model of dominant CMT2E. The *Nefl*$^{-/-}$ "knockout" mouse, which is homozygous for a null mutation, is a potential model of recessive CMT2E. We are characterizing these mice in order to understand how both missense and null mutations in the same gene cause disease. Tail nerve conduction measurements at 4,8,12 and 16 weeks of age revealed that *Nefl*$^{-/-}$ and *Nefl*$^{N98S/+}$ mice had lower compound action potential velocities and amplitudes compared to *wt* mice. Tasked with traversing a horizontal ladder, the *Nefl*$^{N98S/+}$ mice had significantly more footfalls than *wt* mice, whereas the *Nefl*$^{-/-}$ mice appeared normal. Visual assessment of open field locomotion using the Basso Mouse Scale revealed mild locomotor impairment that increased with age in both *Nefl*$^{-/-}$ and *Nefl*$^{N98S/+}$ mice. Histologically, the sciatic nerves of *Nefl*$^{-/-}$ and *Nefl*$^{N98S/+}$ mice were indistinguishable, with a widespread reduction in myelinated axon caliber and g-ratio. Ultrastructurally, myelinated axons in the sciatic nerves of both *Nefl*$^{-/-}$ and *Nefl*$^{N98S/+}$ mice were largely devoid of neurofilaments, whereas unmyelinated axons appeared unaffected. As reported by others, *Nefl*$^{N98S/+}$ mice exhibited neurofilament accumulations in the soma and proximal axons of some neurons in the ventral horn and sensory ganglia. In contrast, no such accumulations are encountered in *Nefl*$^{-/-}$ mice, which lack neurofilaments. In conclusion, the phenotype of the *Nefl*$^{-/-}$ and *Nefl*$^{N98S/+}$ mice appears to converge on a lack of neurofilaments in peripheral myelinated axons, leading to a failure of these axons to expand during postnatal development, but diverge in the soma and proximal axons. The nerve conduction defects likely reflect the reduced axonal caliber, whereas the greater locomotor impairment in the *Nefl*$^{N98S/+}$ mice suggests an additional toxic gain of function. Thus, it is possible that there are multiple disease mechanisms at work in CMT2E that act at different locations in the neuron and/or nervous system.

Title: Aging at the Mouse Neuromuscular Junction and the Therapeutic Effect of a Novel Calcium Channel Modifier

Authors: *Y. LI[1], J. BAROUDI[1], M. PATEL[1], M. WU[1], S. GATTI[2], M. LIANG[3], G. VLADOMIR[3], Y. BADAWI[1], P. WIPF[3], S. MERINEY[1];

[1]Univ. of Pittsburgh Ctr. For Neurosci., Pittsburgh, PA; [2]Tufts Univ., Tufts University, MA; [3]Chem., Univ. of Pittsburgh, Pittsburgh, PA

Abstract: There is still a gap in the literature regarding longitudinal changes of the neuromuscular junction (NMJ) in the process of aging, and such knowledge is vital to discoveries of novel therapeutic treatments and to the timing of prophylactic strategies. In this study, we used electrophysiology and immunohistochemistry to investigate structural and functional changes between 4 and 28 months of age at the mouse NMJ. We observed significant and dynamic changes in neurotransmitter release in the epitrochleoanconeous (ETA) nerve-muscle preparation from both male and female C57/BL6 mice. The changes are time-dependent, leading us to further separate the aging time course into epochs named ”Adult” (4-18 months), “Early Aging” (19-24 months), and “Later Aging” (25-28 months).We have applied these epochs to our morphological data on the motor axons (with antibody against neurofilament-M) and acetylcholine receptors (AChR, with α-Bungarotoxin) at the NMJ and characterized their changes during the aging process. Lastly, we have used forelimb grip strength as the behavioral measurement for muscle strength. Here, we report an increase in action potential-triggered transmitter release in the Early Aging epoch, and a decreased transmitter release in the Later Aging epoch - a biphasic change. During these same epochs miniature end plate amplitude continuously decreases. This suggests a compensatory homeostatic mechanism in the Early Aging epoch that is not maintained in Later Aging. In terms of morphology, we identified a significant decrease in AchR area and synaptic motor axon area. In addition, the ACHR area broke into islands. The average island numbers of AChRs increased from 5 in Adult Epoch to 10 in Later Aging epoch. The percentage of multi-innervated synapses significantly increased from 1% in Adult epoch to 12% in Early Aging epoch, and 30% in the Later Aging epoch. Additionally, grip strength/body weight significantly decreased from 1.75 in Adults to around 1.5 in both Early Aging and Later Aging epochs. Finally, we have treated the aged ex vivo nerve muscle preparation with the small molecule calcium channel gating modifier, GV-58, and found a 1.64-fold increase in quantal content. To summarize, we have studied aging at the NMJ in a longitudinal fashion, identifying important time epochs for development of prophylactic strategies, and shown that our small molecule acutely and successfully rescued loss of transmitter release in aged NMJs.

Abstract: Myasthenia gravis (MG) is caused by antibody-mediated autoimmune responses to muscle acetylcholine receptors (AChRs) that induce complement-mediated destruction of the AChRs and impairment of neuromuscular transmission. Serological testing for the detection of AChR antibodies is currently used for MG diagnosis but does not correlate with disease severity. The main immunogenic region (MIR) at the extracellular end of the AChR α1 subunit contains a cluster of tightly-overlapping B cell epitopes that are targeted by more than half of autoantibodies in MG. Autoantibodies to the MIR passively transfer experimental autoimmune MG (EAMG) in healthy animals, exhibit all the major pathological activities of MG serum: causing focal complement-mediated lysis of the postsynaptic membrane and cross-linking-induced endocytosis of AChRs (antigenic modulation), and show better correlations with disease manifestations in MG. The acetylcholine binding protein (AChBP) from the snail *Aplysia californica* is a structural homologue of the extracellular domain of AChRs. A chimeric AChBP containing the conformational intact MIR exhibits high affinity for mAbs to the MIR and reacts with serum antibodies from cats, dogs, and humans with MG. We found that the iodinated MIR/AChBP chimera, which is used to develop a serological radioimmunoassay (RIA) to detect pathological anti-MIR autoantibodies in sera from MG patients, was destabilized and lost antibody-binding capacity more rapidly than the decay rate of iodine-125, limiting its potential clinical practicality. We hypothesized that the instability results from the steric strain caused by the proximity of the incorporated large iodine atoms and adjacent structural components. Computational analysis revealed that only six of the twelve tyrosine residues on each subunit of the MIR/AChBP chimera are accessible for iodination. We generated three mutants, in each of which two of the six identified tyrosine residues were mutated into phenylalanine. Only two of these mutants showed improved stability after iodination. Studies are currently underway to further pin down those tyrosine residues directly responsible for the instability and generate a stable mutant of the chimera, ideally for use in RIA, by replacing these residues with other amino acids.

Title: Characterization of neuromuscular defects in a Drosophila model of muscular dystrophy

Authors: *J. SIDISKY, D. BABCOCK, R. CARATENUTO;
Lehigh Univ., BETHLEHEM, PA

Abstract: Muscular Dystrophies are a group of diseases characterized primarily by the progressive weakness in muscle and loss of muscle mass. Recent evidence has demonstrated that synaptic defects are among the earliest hallmarks of neurodegenerative diseases, including neuromuscular defects seen in Amyotrophic Lateral Sclerosis (ALS). However, much less is known about synaptic defects in diseases of the muscle, including Muscular Dystrophies. Our work here describes the neuromuscular defects that precede muscle cell loss in an adult Drosophila model of Duchenne Muscular Dystrophy, which is caused by a mutation in the *dystrophin* gene. Through characterization of locomotive behavior, analysis of *dystrophin* mutants, as well as tissue-specific knockdown of *dystrophin*, we demonstrate the progressive loss of functional and structural integrity at adult Neuromuscular Junctions (NMJs) that precede cell death. Additionally, we characterize defects in synaptic proteins in pre-synaptic motor neurons including Bruchpilot (BRP) and Synapsin (Syn). We also investigate changes in post-synaptic muscle cells through staining Glutamate Receptors (GluRs) and post synaptic density (PSD) marker Disc-large (DLG). Together, our results describe the early pre- and post-synaptic deficits present at NMJs in a Drosophila model of Duchenne Muscular Dystrophy and provide insight into the mechanisms underlying synaptic defects that ultimately lead to muscle cell death.

Title: Passive transfer of Lambert-Eaton myasthenic syndrome to mice does not alter the presynaptic AP waveform or reduce BK channel contribution to the AP waveform or transmitter release

Authors: C. KAUFHOLD[1], S. GINEBAUGH[1], K. OJALA[1], M. DAVEY[1], E. MILLER[2], G. ORTIZ[2], ***Y. BADAWI**[1], S. MERINEY[1];
[1]Univ. of Pittsburgh, Pittsburgh, PA; [2]Univ. of California, Berkeley, Berkeley, CA

Abstract: The autoimmune neurological disease Lambert-Eaton myasthenic syndrome (LEMS) is known to attack and remove presynaptic voltage-gated calcium channels and disrupt the normally organized active zone structure at the neuromuscular junction. This leads to a significant reduction in presynaptic calcium entry and transmitter release. We wondered if these pathological alterations would also affect the activation of presynaptic calcium-activated potassium (BK) channels. At the adult neuromuscular junction, BK channels are known to be co-localized with voltage-gated calcium channels in the active zone. The BK channel tight spatial association with voltage-gated calcium channels leads to BK channel activation late in the action potential waveform, locally accelerating the falling phase of the action potential waveform, which decreases the duration of the presynaptic action potential, and subsequently reduces the probability of transmitter release at neuromuscular active zones. Because LEMS reduces calcium entry, we hypothesized that BK channel activation might decrease due to the reduction in the

calcium trigger for activation, broadening the presynaptic action potential waveform. We tested this hypothesis using passive transfer of LEMS to adult male and female mice using daily intraperitoneal injections of LEMS patient serum for 3-4 weeks. As expected, LEMS serum injections greatly reduced action potential triggered transmitter release as has been previously reported. However, using the voltage-sensitive dye BERST-1, we showed that LEMS serum injections did not change the presynaptic action potential waveform. Furthermore, the addition of IBTX (to block BK channels) was still able to broaden this waveform, indicating that BK channels were still present and contributing to action potential shape as observed in control un-injected animals. Furthermore, IBTX increased action potential-triggered transmitter release at neuromuscular synapses of LEMS injected mice, as is observed in controls. Therefore, using a previously validated mouse model of LEMS, we showed that the activation of calcium-activated potassium channels in the neuromuscular active zone and the presynaptic action potential waveform are not significantly affected by the pathological processes that underly LEMS.

Title: Nicotinic acetylcholine receptor PET-MR imaging for skeletal muscle denervation: a preliminary study

Authors: *S. LEE[1], Y.-I. KIM[2], J. CHUNG[2], S.-Y. KIM[3], S. LEE[2], S. OH[2], J.-S. RYU[2], W. KIM[4], D. KO[4], K. KIM[3];

Abstract: Denervated muscle caused by peripheral nerve injury can be visualized by several imaging studies such as MRI and F-18-FDG PET scans. However, invasive needle electromyography is the current gold-standard diagnostic method for peripheral nervous system disorders. Increased expression of nicotinic acetylcholine receptors (nAChRs) of denervated skeletal muscle has been found in previous studies. This phenomenon is thought to be related to acetylcholine supersensitivity after muscle denervation. Therefore, nAChRs imaging study for skeletal muscle could be an imaging method for muscle denervation and used as a new diagnostic method for peripheral neuromuscular disorders. A 10 week old male c57bl/6 mouse was used for this study. The mouse was anesthetized and the left sciatic nerve was exposed by splitting the gluteal muscle. A nerve segment 5 mm long was resected in the proximal part of the nerve.The sham operation, exposing the sciatic nerve without resection, was done at the other side of the mouse. 1 week after the denervation, the mouse underwent micro PET/MR imaging. MR imaging was performed just after the mouse anesthesia for about 12-minutes. After MR imaging,

PET imaging was done after 0.485 mCi of F-18-ASEM intravenous injection for 60-minutes using dynamic mode. The mouse was sacrificed, and lower leg muscles were harvested for autoradiographic evaluation. F-18-ASEM PET showed increased uptake at denervated lower leg muscles, which were matched on signal change of MR. Maximum and mean standardized uptake value of these muscles was 15.07 and 4.77, respectively. In contrast, no significant uptake was observed at sham side muscles. Autoradiography results demonstrated that denervated tibialis anterior muscle has more than 2.79 times of average intensity than contralateral tibialis anterior muscle. In an animal model of sciatic nerve injury, F-18-ASEM PET/MR showed increased nAChRs expression in denervated muscles. Therefore, F18-ASEM PET/MR can be a potential imaging modality for the evaluation of denervation after nerve injury.

Title: Endogenous antigen presentation from damaged muscle cells initiates and sustains autoreactive antibody response in rats - a novel model for myasthenia gravis

Authors: B. S. LAWSON[1], J. WU[1], ***A. PHAM**[1], Q. XU[2], O. A. GARDEN[3], J. LUO[1];
[1]Univ. of Pennsylvania, Philadelphia, PA; [2]Fox Chase Cancer Ctr., Philadelphia, PA; [3]Louisiana State Univ. Sch. of Vet. Med., Baton Rouge, LA

Abstract: Myasthenia gravis (MG) is a chronic autoimmune disease caused by antibodies that target muscle nicotinic acetylcholine receptors (AChRs) and impair neuromuscular transmission, thereby causing muscle weakness. What initiates and sustains MG is still largely unknown. Translation of therapeutic approaches developed in animal models of MG into positive results in humans faces difficulties, partially because of the lack of an ideal animal model. Experimental autoimmune MG (EAMG) is usually induced in mice or rats by immunizing with AChR purified from *Torpedo* electric organ. Immunized mice produce antibodies that cross-react with mouse muscle AChR, causing myasthenic symptoms, but do not induce a self-reactive CD4+ T cell response or a self-sustaining antibody response. EAMG rats develop a self-reactive CD4+ T cell response to rat muscle AChR, but it is difficult to investigate autoimmune responses due to the cross-reaction of anti-Torpedo AChR antibodies. We developed a chronic, self-perpetuated EAMG model in rats using a chimeric acetylcholine binding protein (AChBP) containing the main immunogenic region (MIR), a group of tightly-overlapping B cell epitopes that are targeted by more than half of autoantibodies in MG and EAMG, as an immunogen. Both the chimeras containing the human MIR and the syngeneic MIR were potent in inducing EAMG, though the latter was less potent. Immunizing with either chimera initially induced large amounts of antibodies to the immunogens, which cross-react with rat muscle AChR weakly. Trace amounts of cross-reactive antibodies induced by the chimeras caused focal lysis of the postsynaptic membrane, resulting in shedding of membrane fragments containing AChRs, which, in turn, initiated a secondary antibody response to rat muscle AChRs, as reflected by the development of autoantibodies to AChR cytoplasmic domains. This feedforward cycle of autoimmune stimulation sustained the autoimmune response. Fourteen months later, the mean value for total AChR extracted from these rats was less than 38% of the amount extracted from rats immunized only with adjuvants and more than 72% of the AChR extracted from these rats was complexed with antibody. This novel EAMG model enables us to investigate the autoimmune response to endogenous muscle AChR by measuring antibodies to the cytoplasmic domain of rat muscle AChR that the MIR/AChBP lacks, allowing rigorously assessing the effectiveness of immunosuppressive therapies in suppressing the autoimmune response rather than the immune response to an exogenous immunogen.

Title: Two new mouse models of Charcot-Marie-Tooth Disease Type 1X (CMT1X) caused by mutations in the gap junction beta-1 gene (GJB1)

Authors: C. L. HATTON, A. L. D. TADENEV, R. SCHNEIDER, L. P. BOGDANIK, C. M. LUTZ, *R. BURGESS;
The Jackson Lab., Bar Harbor, ME

Abstract: Charcot-Marie-Tooth Disease Type 1X (CMT1X) is caused by more than 400 X-linked mutations in the gap junction beta-1 gene (*GJB1*), which encodes gap junction protein connexin32 (Cx32). Loss of normal Cx32 function results in the failure of gap junction function, leading to clinical symptoms of demyelination and peripheral neuropathy. Loss of function results from many mechanisms, including severely truncated alleles (nulls), mutations affecting Cxn32 trafficking and localization, and mutations affecting gap junction channel function. These different mechanisms may require different therapeutic approaches, and therefore animal models reflecting the breadth of mutation types are necessary for rigorous preclinical studies. An existing knockout (KO) mouse model develops relevant demyelinating and neuropathy phenotypes, but only accurately models the subset of mutations that result in null alleles. As part of a larger effort to model additional human disease-associated *GJB1* mutations, we created a novel R15Q mouse model, as well as a new null allele, $Gjb1^{del2}$, resulting from an early frameshift caused by a deletion of 2 bases in codon 7.
Hemizygous male or homozygous female $Gjb1^{R15Q}$ mutant mice develop histological signs of demyelination and axonopathy by 6 months of age, which progresses and is more severe at 9 months. The phenotype is more severe in peripheral motor nerves than sensory nerves. The femoral motor branch shows demyelination and decreased axon areas, with increased space between axons, but no reduction in axon number. Nerve conduction velocities show a significant decrease of about 15% in the 9 month old mice compared to controls. The $Gjb1^{del2}$ mutant mice show similar phenotypes in the femoral motor nerves by 3-4 months, which also progress with age and closely resemble the previously reported KO mice. Behavioral testing for both genotypes is on-going, but so far has not shown significant differences in body weight, rotarod performance, or grip strength, for either allele.
Thus, we have successfully created two new models of CMT1X, $Gjb1^{R15Q}$ and $Gjb1^{del2}$. These mice have robust histological signs of disease that progress with age, but milder neurophysiological and behavioral defects. The full characterization of these mice will provide additional models for preclinical studies of CMT1X.

Nacional Autónoma de México, Mexico City, Mexico

Abstract: Excitotoxicity is a common event in the pathophysiology of nerodegenerative disorders. Occurs due to the overactivation of NMDA receptor by agonist such as glutamate, NMDA and quinolinic acid (QUIN), promoting an intracellular overload of calcium and the subsequent impairment of cellular homeostasis, conducing to cell injury and the activation of different cell death pathways which contribute to brain tissue damage. There is evidence indicating that autophagy flux is impaired as a consequence of excitotoxicity, however the molecular mechanism of this impairment is not fully understood. Recent evidence suggests that oligomerization of p-MLKL the last event in necroptosis activation, as well as the increase in caspase 3 activity promotes autophagy disruption, nevertheless the participation of necroptosis and apoptosis in excitotoxic-induced autophagy flux impairment remains poorly explored. Intrastriatal administration of QUIN has been used as an excitotoxic/pro-oxidant model for the study of biochemical events impaired during excitototxicity. QUIN promotes tissue damage and increases neurodegeneration; nonetheless its effect on autophagy remains unexplored. In this work we explore the effect of QUIN on autophagy flux, as well as necroptosis and apoptosis activation. We administrated 1 µL of isotonic saline or QUIN at 120 or 240 nmol in the right striatum of male Wistar rats (260-300 g), and the brain tissue was extracted 7 days after injection. We evaluated ultrastructural change in the mitochondria, endoplasmic reticulum and axons of striatal neurons. Moreover, the autophagy flux, necroptosis and apoptosis were evaluated by western blot. QUIN administration produces mitochondrial crests swelling and fragmentation also decreases ribosomal density in the rough endoplasmic reticulum, as well as myelin sheaths discontinuity in axons. Furthermore, QUIN administration induces autophagy flux impairment observed as the increase in LC3-II and p62 levels, and decrease in mature cathepsin D and Beclin 1 levels. Additionally, QUIN administration increases TNFα and RIPK3 levels suggesting an activation of necroptosis as well as an increase in Bax levels and a decrease in Bcl-2 levels, suggesting an activation of apoptosis. These results indicate that QUIN causes subcellular compartments alteration, blocks autophagy flux and activates necroptosis and apoptosis at 7 days.

Title: Zonisamide pre-treatment alleviates oxaliplatin-induced dorsal root ganglion neuron death in vitro

Authors: *K. SANGO, S. TAKAKU;
Tokyo Metropolitan Inst. of Med. Sci., Tokyo, Japan

Abstract: Oxaliplatin (OHP), a platinum-based agent commonly prescribed for patients with colorectal cancers, has been shown to evoke peripheral neuropathy; however, its pathogenesis remains obscure and no effective remedies for it have been developed. Previous *in vivo* and *in vitro* studies indicate that sensory neurons in spinal dorsal root ganglia (DRG) are the most common target of OHP. Zonisamide, an anti-epileptic and anti-Parkinson's disease agent, exerts neurotrophic activities toward DRG neurons, and therefore its potential efficacy for the OHP neurotoxicity defines the aim of this study. DRG neurons from 3-month-old female Wistar rats were seeded on poly-L-lysine-coated dishes and incubated for 24 h in a serum-free medium (SFM) in the presence or absence of 100 μM zonisamide, then maintained for 24 h in SFM in the presence or absence of 75 μM OHP. The average cell survival ratios (means±SD) determined by trypan blue exclusion were 60±13.5% in [control; n=16], 65.6±18.1% in [pre-zonisamide; n=10], 28.1±11.4% in [OHP; n=16], and 42.9±14.9% in [pre-zonisamide and OHP; n=16], respectively. Zonisamide pre-treatment significantly alleviated DRG neuron death under exposure to OHP, and its activity was attenuated by co-treatment with 25 μM phosphatidyl inositol-3'-phosphate-kinase (PI3K) inhibitor LY294002; the survival rations declined from 43.6±11% in [pre-zonisamide and OHP; n=9] to 35±11.4% in [pre-(zonisamide+LY294002) and OHP; n=10]. These findings suggest that zonisamide alleviates OHP-induced DRG neuronal cell injury and death via stimulating PI3K signaling pathway. Zonisamide pre-treatment may be efficacious against the neurotoxic adverse effects of OHP.

Title: Primary cilia loss renders pyramidal neurons susceptible to perinatal ketamine-induced dendritic degeneration and learning deficits

Authors: N. SARIC, F. SOMAA, *M. STRAUSS, C. FOSTER SADE, S. BEJUGAMA, G. N. RIVERO BALLON, L. WANG, K. HASHIMOTO-TORII, N. ISHIBASHI;
Children's Natl. Med. Ctr., Washington, DC

Abstract: Recent clinical studies have demonstrated a strong link between anesthetic exposure and neurodevelopmental outcomes in children with CHD. Protein-damaging *de novo* gene mutations have been demonstrated to be strong predictors of neurodevelopmental anomalies in congenital heart disease (CHD), and at least 50% of these genes have been found to be associated with primary cilia structure and/or function. Therefore, studying the combined effect of anesthesia and primary cilia gene mutations may shed light on the neurodevelopmental abnormalities observed in CHD children. Using *Emx1cre; Ift88 f/f*, in which primary cilia are lost specifically in cortical excitatory neurons, we administered either PBS or Ketamine at postnatal day 7 (P7). We examined markers of cytoskeletal degeneration at P8 in the medial prefrontal cortex as well as behavioral testing at P30 using water T-maze to assess their spatial memory performance and cognitive flexibility. Separate cohorts were also tested for gross and fine motor deficits using the accelerated rotarod and pellet reach task, respectively. During the reversal learning paradigm, the *Ift88* knockout mice that were exposed to ketamine (cKO+Ket) showed a strongly reduced ability to learn compared to other groups, indicative of a cognitive flexibility deficit. This same group demonstrated significant motor deficits, with a reduced rate of motor learning in both gross and fine motor tasks. To assess pyramidal neuron morphology, we used two other inducible Cre/lox mice to specifically label layer II (*Nes-Cre/ERT2*) and layer V (*ER81-Cre/ERT2*) neurons. We found significant enhancement in immunoreactivity of cytoskeletal degeneration markers in the cKO+Ket mice compared to the other three groups (cHET+PBS, cHET+Ket, and cKO+PBS). The effects of ketamine on dendritic morphology were also specific to this group. To examine if the observed learning-related deficits were related to altered dendritic spine dynamics we then performed two-photon imaging on *Ift88* cHET+Ket and cKO+Ket *Thy1-GFPM* animals and compared spine density and turnover in the motor cortex. We also utilized human induced pluripotent stem cells (hiPSCs) to examine the impact of identified *de novo* CHD mutations (CHD7, WDR5, and KDM5B) on cilia length/expression and caspase-3 activation in response to ketamine in both neural progenitor cells (NPCs) and differentiated neurons. Our findings indicate that primary cilia deficiency, due to a common genetic predisposition with CHD, exacerbates the toxicity of neonatal anesthesia, suggesting a novel therapeutic treatment strategy for the prevention of neurobehavioral abnormalities in this population.

Abstract: Immunometabolism in septic encephalopathy: a novel therapeutic target
Introduction: Metabolic encephalopathy affects one in three intensive care unit (ICU) patients, with the most serious subtype occurring in the context of sepsis [septic encephalopathy (SE)], which is associated with up to 70% mortality. The cerebellum is particularly sensitive to injury early in the SE process. Here we utilized mesenchymal stem cell-derived extracellular vesicles (MSC EVs) to target immunometabolic dysfunction in metabolic encephalopathy using a murine model of SE.
Methods: We administered cecal contents by an intraperitoneal injection to 7-10-week-old, C57BL/6J mice to induce sepsis/SE. Encephalopathic and control mice received either MSC EVs or EV-depleted media intravenously 6 hours post-sepsis induction. Mice were scored every 2 hours until euthanasia (score ≥15) using a sepsis scoring system that also evaluates neurological status. We obtained cerebellar samples (n=8/group) for Hematoxylin-Eosin (H&E) staining. Total RNA was isolated from cerebellar samples (n=3/group) and was sequenced to identify differentially expressed genes (DEGs).
Results: Average scores at sacrifice were lower in the EV-treated group compared to non-treated mice with SE, indicating improved disease severity. H&E staining on septic cerebella revealed significant neuropathological alterations compared to controls, including shrunken Purkinje and granule cells with irregular nucleus and absent nucleolus, acidophilic (pink) cytoplasm, apoptotic profiles, and disrupted neuropil. Additionally, when comparing the DEGs in RNA seq, 103 downregulated and 119 upregulated genes were identified in the cerebella of EV-treated mice with SE, as compared to the non-treated group. Using the Ingenuity Pathway Analysis software, we showed that neuroinflammatory pathways remained activated in treated mice, while the IL-6 signaling pathway was inhibited. In addition to immune pathways, metabolic signaling pathways that promote ATP generation including PI3K/AKT, IGF-1, AMPK and PPARa were also activated, suggesting an SE-related decreased intracellular energy production.
Conclusions: We demonstrate that EVs alter cerebellar immune and metabolic pathways that may be responsible for the SE-induced neuropathological changes and poor outcomes. Targeting specific immunometabolic signaling pathways that promote energy generation and alleviating immune dysregulation present an opportunity to successfully treat septic and other metabolic encephalopathies.

Title: Global analysis of RNA-protein interactions and RNA structure alterations in response to excitotoxicity in primary cortical neurons

Authors: *E. ALVAREZ-PERIEL[1], M. C. KRAMER[2], D. P. JACKSON[1], Ç. AKAY-ESPINOZA[1], J. TASCA[3], B. A. GARCIA[3], B. D. GREGORY[2], K. L. JORDAN-SCIUTTO[1];
[1]Dept. of Basic & Translational Sci., [2]Dept. of Biol., [3]Dept. of Biochem. and Biophysics, Epigenetics Inst., Univ. of Pennsylvania, Philadelphia, PA

Abstract: A number of mechanisms have been implicated in neurodegeneration associated with Alzheimer's disease (AD), Parkinson's disease (PD), amyotrophic lateral sclerosis (ALS), frontotemporal dementia (FTD), and HIV-associated neurocognitive disorders (HAND) including protein aggregation, oxidative stress, inflammation, excitotoxicity, and disruption of RNA-binding protein function. For this reason, association between some of these processes has been examined and is partially understood. However, to our knowledge, the effect of excitotoxicity on RNA-protein binding alterations has not been thoroughly analyzed. To this end, we aimed to identify global changes in RNA-protein interactions and RNA secondary structure in an excitotoxicity *in vitro* model using rat primary cortical neurons. We have applied the novel protein interaction profile sequencing (PIP-seq) method to identify sites within an RNA molecule that are bound by an RNA-binding protein (RBP), termed protein protected sites (PPS). Our data show relevant shifts in RNA secondary structure between untreated- and NMDA-treated neurons near the start and stop codons of protein coding genes. Additionally, we identify sets of genes that have PPSs specifically in the control condition, after NMDA treatment or in both conditions but at different intragenic regions. Interestingly, GO analysis of these gene sets shows that transcripts that are protein-bound specifically in NMDA-treated samples are associated with several neurodegenerative disorders. Finally, we also detect sequence motifs enriched in NMDA-specific PPSs and use them to identify NMDA-dependent RBPs, which might shed light on RBPs post-transcriptional role in excitotoxic stress. In sum, we have globally examined RNA secondary structure and the RBP-ome of primary cortical neurons in a simple excitotoxic model, providing insights into the potential role RBPs and secondary structure changes in neurological diseases associated with excitotoxicity.

Title: Impact of endocrine disruptors on myelination and remyelination

Authors: *B. ZALC[1], P. JUBIN[2], E. M. MARTIN[3], M.-S. AIGROT[3], B. DEMENEIX[4], S. REMAUD[4]; [1]Sorbonne Université; Inserm, CNRS, AP-HP, ICM, Paris Cedex 13, France; [2]Sorbonne Université, Paris, France ; Inst. du Cerveau- Paris Brain Inst. – ICM, Paris, France ; Inserm, Paris, France ; CNRS, Paris, France ; AP-HP, Hôpital de la Pitié-Salpêtrière, Paris, France, paris, France; [3]Sorbonne University; Inst. du Cerveau- Paris Brain Inst. – ICM; Inserm; CNRS; AP-HP, Hôpital de la Pitié-Salpêtrière, Paris, France, Paris, France; [4]Muséum Natl. d'Histoire Naturelle (MNHN), Lab. PhyMa.2 CNRS UMR 7221, 75005 Paris, France, Paris, France

Abstract: Over the past 30 years an unexplained increased incidence in multiple sclerosis (MS) is observed in developed countries, suspected to be exacerbated by environmental factors. We questioned whether exposure to endocrine disrupting chemicals (EDC) may interfere with the process of myelin formation and remyelination after a demyelination insult. We analysed consequences of some EDC exposure notably flame retardant or fluorosurfactant such as Perfluorooctanoic acid and Perfluorooctane Sulfonate (PFOS) (at dose ranging between 10^{-5} to 10^{-11} M) on myelination and remyelination. To this end, we combined *ex vivo* and *in vivo* approaches to study cellular and behavioral effects of EDC using two models, mouse cerebellar explants and the optic nerve of *Xenopus laevis.* First, we exposed cerebellar slices derived from P4 *plp:GFP* transgenic mouse (before the onset of myelination) to PFOA and PFOS. At P8, we observed that exposure to PFOS (10^{-8} M) significantly delayed myelination. Second, we analyzed consequences of EDC exposure on remyelination using the transgenic *Xenopus laevis* model (*MBP-GFP-NTR*) of conditional demyelination that allow us to monitor behavioural effects. In this model, introduction of metronidazole (MTZ) leads to mature oligodendrocyte cell death and robust demyelination and withdrawal of MTZ leads to spontaneous remyelination. Extend of demyelination and remyelination was assayed by counting the number of GFP+ oligodendrocytes per optic nerve. We reasoned that demyelination should translate into loss of sensori-motor functions. To challenge this hypothesis, we measured speed and distance traveled before and after demyelination and during the ongoing spontaneous remyelination. In addition, to test the functional consequence of demyelination and repair of the optic tract of *MBP-GFP-NTR* transgenic *Xenopus* tadpole we adapted a visual avoidance paradigm, based on a virtual collision test. We evaluated how all these parameters are perturbated when tadpoles are exposed to EDC. Addition of PFOS in the swimming water during the recovery period was one of the strongest inhibitor of remyelination. The dose-response of PFOS toxicity to inhibit remyelination showed an inverted bell-shaped curve with a maximum effect at concentrations in the nanomolar range, typical of some EDC toxic effects reported in the literature. Our data illustrate the toxicity of some EDC on myelination and myelin regeneration evaluated histologically in two models of vertebrates and their behavioural consequences. Our finding questions a possible correlation between the dramatic increase in the number of EDC in our daily life, with the reported increase in the incidence of MS

Title: Cholinergic neurons of the basal forebrain are lost through a $p75^{NTR}$-mediated process in an animal model of HIV-associated neurocognitive disorder.

Authors: *A. SPEIDELL, I. MOCCHETTI;
Neurosci., Georgetown Univ. Med. Ctr., Washington, DC

Abstract: Human immunodeficiency virus type 1 (HIV) positive individuals exhibit an array of neurological and neuropsychiatric symptoms, termed HIV-associated neurocognitive disorders (HAND). These symptoms continue to affect nearly one in two people living with HIV (PLH) even in the post-combined antiretroviral therapy era. HAND may be partially explained by the persistent neurotoxic effects of viral proteins on neural cells. Our lab previously demonstrated that the HIV-1 gp120 envelope protein alters neuronal proconvertase expression to increase proneurotrophin abundance in an age-dependent manner. This neurotoxic outcome is transduced through the pro-apoptotic proneurotrophin receptor $p75^{NTR}$. We hypothesized that basal forebrain cholinergic neurons (BFCNs), which highly express $p75^{NTR}$, are uniquely susceptible to gp120-driven neuronal apoptosis through this receptor. To examine the selective vulnerability of BFCNs to gp120 in vivo, we crossbred gp120 transgenic (tg) and $p75^{NTR-/-}$ mouse colonies to obtain wild type (wt), gp120tg, $p75^{NTR+/-}$ and $p75^{NTR+/-}$gp120tg mice. We then assessed behavioral and histological endpoints in separate 3- and 12-month old (mo) cohorts. Our data suggest that only 12mo gp120tg mice are impaired on a task of extinction of conditioned fear, a complex cognitive behavior subserved by BFCN innervation of the hippocampus and prefrontal cortex. Representative images of BFCNs from our experimental groups also indicate a reduction of neurite complexity and suggest a decrease in the population of choline acetyltransferase-positive cells in the forebrain of 12mo gp120tg. Our results show that loss of BFCNs in HAND individuals may underpin the observed collection of neurological impairments in PLH. Targeting $p75^{NTR}$ through emerging small molecule inhibitors may therefore serve as a viable strategy within adjunct therapies for HAND individuals.

Title: Surface modification of flow diverting stents for improved cerebral aneurysm repair

Authors: *J. W. THOMPSON, D. SHEINBERG, G. CORSALETTI, R. M. STARKE;
Univ. of Miami Miller Sch. of Med., Miami, FL

Abstract: Cerebral aneurysm (CA) rupture produces a devastating form of stroke resulting in high rates of mortality and morbidity. As a result, a large number of CA patients are treated prior to rupturing by either open surgical or endovascular techniques. Detachable coils have been the mainstay of endovascular CA intervention. However, the use of flow diverting stents in endovascular CA treatment has become an increasing popular treatment modality since their introduction in the mid-2000s. Flow diverting stents (a braided cylindrical mesh) work by restoring the original, natural path of blood flow in the vessel, across the aneurysm neck, while providing permeant long-term occlusion of the aneurysm. However, this process requires stent endothelialization across the aneurysm neck, which can take months, resulting in increased risk of aneurysm rupture and treatment failure. The main objective of this study was to determine if a surface modification of flow diverting stents could increase endothelial cell (EC) attachment, proliferation, and stent coverage. In this study Pipeline Flex Embolization flow diverting stents were incubated overnight with either PBS or gelatin and then exposed to isolated human microvessel EC for three hours. EC attachment and proliferation were determined at various time points. Immediately following cell incubation, we found a significant increase ($p< 0.05$, fold increase) in EC attachment on gelatin (6.3 ± 2.1) surface modified stents compared to unmodified control stents. This increase in EC was maintained 5 days (gelatin 9.3 ± 2.5, fold of control) following cell incubation but gradually decreased becoming non-significant by day 17. We also observed a significant increase ($p < 0.05$, fold of control) in EC migration onto (1.8 ± 0.2) and from (1.5 ± 0.033) gelatin surface modified stents compared to unmodified controls. Since CA healing requires complete stent endothelization, we next determined the temporal rate of endothelial stent coverage. Following cell incubation, we found that 20% of surface modified stents were coated by EC at day 5 compared to just 2% in unmodified stents. This difference in cell coverage remained significant ($p<0.05$) with surface modified stents being completely covered by 2 weeks while unmodified stents were only 50% covered. There was no significant difference in cell death on modified versus unmodified stents in any of our studies. This study demonstrates that gelatin, a biocompatible and non-thrombogenic FDA approved product can enhance endothelialization of flow diverting stents which may lead to increased rates of aneurysm occlusion thereby reducing the risk of posttreatment rupture and treatment failure.

Title: The Impact of Intranasal Administration of BDNF on Functional Recovery in aNeonatal Mouse Model of Hypoxic Ischemia

Authors: *S.-K. SIMS[1], C. ROBINSON[1], T. LOWRY[1], L. MCGONEGAL[2], M. SADDOW[2];
[1]Med. Univ. of South Carolina, Goose Creek, SC; [2]Col. of Charleston, Charleston, SC

Abstract: A neonatal stroke is a medical condition that occurs when an infant's blood supply is disturbed within the first 28 days of life. One of the causes of neonatal stroke is hypoxia, an event when oxygen deprivation causes the brain to panic. While treatments for adult and aging ischemic strokes include anticoagulants, and motor and cognitive rehabilitation, neonatal ischemic treatment is limited to more supportive care such as hyperthermia and hyperbaric oxygen therapy. Previous studies in adult stroke have reported that administering brain derived neurotrophic factor (BDNF) in the acute post-ischemic period reduces cell death and infarct volume. Furthermore, pharmacologically enhancing downstream BDNF signaling pathways/targets such as cAMP response-element-binding protein facilitates cortical reorganization and functional recovery after focal ischemia in rats. Hence, while BDNF may be a useful therapeutic target for adult ischemic strokes, BDNF as a potential therapy following neonatal stroke has not been explored. Our overall hypothesis is that intranasal BDNF will improve functional recovery including overall brain health and development following neonatal stroke. We explored the benefit of intranasal BDNF treatment on functional recovery in a neonatal P7 hypoxic mouse model. For our model of hypoxic ischemic, a ligation of the right carotid artery was induced which is followed by a two-hour exposure to an 8% oxygen/ 92% nitrogen in an enclosed chamber. Pups were subjected to a 2 h hypothermia in a temperature-controlled chamber as a standard of care. Mice received BDNF intranasal infusions while awake. A solution of recombinant human BDNF (Harlan Laboratories .1uM in saline) was administered with a Gilson pipette, 3uL at the same time each day for 7 days into each nasal cavity. The objective of these studies is to address these gaps in knowledge and evaluate the role and therapeutic potential of BDNF in neonatal stroke recovery. Preliminary results suggest a differential impact of intranasal BDNF on pro and mature BDNF in cortical and hippocampal brain regions, which correlate with cognitive and motor outcomes. Our results suggest that higher levels of mature BDNF are predictive of better improvements at day 28 on cognitive and motor assessments.

Title: Protecting against experimental ischemic stroke with pro-homeostatic docosanoids

Authors: *N. BAZAN[1], M. M. REID[1], A. OBENAUS[2], P. K. MUKHERJEE[1], L. KHOUTOROVA[1], C. R. ROQUE[3], N. N. DEASI[1], T. SIMONS[1], J. JI[1], N. PETASIS[4], R. B. ORIA[3], L. BELAYEV[1]; [1]Neurosci. Ctr. of Excellence, Louisiana State Univ. Hlth. Sci. Ctr., New Orleans, LA; [2]Univ. of California Irvine, Irvine, CA; [3]Morphology, Federal Univ. of Ceara, Fortaleza, Brazil; [4]Chem., USC, Los Angeles, CA

Abstract: Ischemic stroke triggers lipid peroxidation, uncompensated oxidative stress, and neuronal injury. This study focuses on the neuroprotective bioactivity of docosanoid (DOC) mediators: Neuroprotectin D1 (NPD1), Resolvin D1 (RvD1), and their combination (NPD1+RvD1) against experimental ischemic stroke. These lipid mediators are biosynthesized "on-demand" in response to stroke onset to resolve neuroinflammation and restore homeostasis. This study investigated the dose-response and therapeutic window in a model of focal cerebral ischemia. Physiologically-controlled male Sprague-Dawley rats received 2h of middle cerebral artery occlusion (MCAo) by intraluminal suture. The behavior was evaluated on days 1, 2, 3, and 7, followed by an *ex vivo* MRI of the brains on day 7. In dose-response study, rats were treated with NPD1 (111, 222, and 333µg/kg), RvD1 (111, 222, and 333µg/kg), NPD1 + RvD1 or vehicle (n=4-5 per group). All treatments were administered IV at 3h after the onset of MCAo. In the therapeutic window study, vehicle, NPD1 (222 µg/kg), RvD1 (222 µg/kg), NPD1+RvD1 were administered IV at 3, 4, 5, and 6 h after onset of MCAo. Physiological variables were stable and showed no significant differences among groups. Treatments with NPD1 (111, 222, and 333µg/kg) alone greatly improved neurological scores (by 32, 28, 35%) and RvD1 (111, 222, and 333µg/kg) alone (by 35, 44, 31%) compared to the vehicle group. The neuroprotective effect was enhanced using the NPD1+ RvD1, which improved total neurological scores on days 1, 2, 3, and 7 by 25, 28, 28, 40% compared to the vehicle group. Ischemic core, penumbra, and total lesion volumes (computed from T2WI) were reduced with NPD1+RvD1 by 69, 70, and 67% compared to the vehicle. Therapeutic window: treatments with NPD1 and RvD1 alone when administered at 3h improved behavior on day 7 by 35%. Combinatory NPD1+RvD1 treatment improved behavior when administered at 3, 4, 5, and 6 h by 56%, 23%, 26%, and 28%, respectively, compared to vehicle. We have shown that treatment with NPD1, RvD1 alone provides high-grade neuroprotection in the MCAo model. Combination therapy with NPD1 and RvD1 is more effective than the single therapy, when administered up to 6 h focal cerebral ischemia in rats. These treatments might provide the basis for future therapeutics for patients suffering from ischemic stroke. This study was supported by NIH, NINDS grant R01NS104117, R01109221 (NGB and LB), and Brazilian CAPES (88881.311939/2018-01) (CRR)

Title: Focal stimulation of movement related cortical potentials in mice using a novel TMS circuit design

Authors: *H. N. STRONG[1], D. SENDA[2], R. BAKER[2], D. J. HINES[1];
[1]Psychology, [2]Electrical and Computer Engin., Univ. of Nevada Las Vegas, Las Vegas, NV

Abstract: Activity patterns exist at several levels in the brain and exhibit distinct temporal and spatial characteristics. Circuit level perturbations to rhythmic patterns are characteristics of altered arousal states and behaviors. Using pulsed electromagnetic fields, transcranial magnetic stimulation (TMS) alters states of cortical excitability and motor output. The changes in brain activity caused by TMS can be measured and quantified using electroencephalography (EEG). Developing a focally stimulating TMS model in mice is a multivariate problem requiring proper consideration of both circuit design and coil construction. A high voltage, fast switching, insulated-gate bipolar transistor (IGBT) pulse generator delivering large current pulses was developed for the generation of focal electromagnetic fields. To compare the validity of the presented design with current methods, stimulating pulses were delivered to mice using a butterfly coil attached to a standard TMS system compared to a compact coil attached to the novel circuit. Changes in cortical electrical potentials were recorded at two cortical surface electrode sites using electroencephalography (EEG). Butterfly coil stimulation resulted in movement related cortical potentials (MRCPs) at both EEG recording sites while stimulation with the compact coil elicited MRCPs at a single recording site. Furthermore, the compact coil evoked MRCPs similar in amplitude to MRCPs evoked by the butterfly coil. This novel circuit design enables exemplar stimulation of focal and robust MRCPs. The potential for focal stimulation in murine models will provide valuable insight into other neurological disorders including stroke.

Title: Systematic assessment of PAMAM dendrimer-conjugated N-acetyl cysteine (D-NAC) on long-term outcomes in both male and female mice after severe hypoxia-ischemic encephalopathy (HIE).

Authors: *V. TURNBILL[1], E. S. KHOURY[2], D. ASAFU-ADJAYE[1], B. SOLLINGER[1], T. TREINEN[1], N. RASTOGI[1], D. FLOCK[1], A. SHARMA[3], R. M. KANNAN[3], S. KANNAN[2], F. J. NORTHINGTON[1];

[1]Pediatrics, [2]Anesthesiol. and Critical Care Med., [3]Ctr. for Nanomedicine, Wilmer Eye Inst., Johns Hopkins Univ. Sch. of Med., Baltimore, MD

Abstract: Neonatal hypoxia-ischemic encephalopathy (HIE) causes lifelong disability often in the form of cerebral palsy (CP); including motor, memory, and executive functioning deficits; and is difficult to treat even with therapeutic hypothermia. Challenges to effective treatment include (1) sex-related variations in disease mechanism and outcome and (2) a lack of antioxidants and anti-inflammatory drugs with adequate bioavailability and brain penetration. Previous studies in a rabbit model of CP have shown that dendrimer-conjugated n-acetyl cysteine (D-NAC), which uses PAMAM dendrimers as a drug delivery device, can penetrate the blood-brain barrier and selectively target the activated microglia and mitigate neuroinflammation and subsequently reduce neural injury and neurobehavioral deficits. Here we investigate the impact of D-NAC on a murine model of HIE with the goal of further elucidating long-term effects of D-NAC on phenotype and neuropathology in both sexes. At p10, HI was induced in C57BL6 mice in vehicle and D-NAC treatment groups using the Rice-Vannucci model adapted for mice; sham mice were given only anesthesia. D-NAC (10 mg/kg on a NAC basis) or vehicle was administered intraperitoneally on p10 after HI and then twice weekly from p14 to p46. Reflex testing occurred from p11 to p21; behavior tests began at p30 and included y-maze, open field, social interaction, and fear learning, memory, and extinction. Mice were perfused at p50 with 4% paraformaldehyde, postfixed overnight, and frozen. Striatal, hippocampal, and cortical regions were measured in 50μm, cresyl violet stained tissue sections. Our results demonstrate positive long-term effects of D-NAC treatment in this model of HI. Mortality was minimal; however, sex differences in mortality distribution were observed. D-NAC eliminated mortality only in female HI mice. Reflex testing revealed retention of cliff aversion and negative geotaxis reflexes in females after HI, which D-NAC remediated in the case of cliff aversion. Only D-NAC-treated males showed negative geotaxis reflex retention. Open field testing indicated no profound deficits in locomotion or exploratory behavior as a consequence of HI at p31. Y-maze testing revealed short-term memory deficits in both male and female HI mice that is remediated with D-NAC. In long-term memory testing after fear conditioning, female HI mice showed decreased memory of the cue which is rescued with D-NAC treatment. Taken together, these data indicate that, in addition to sex differences in pathology, response to treatment may vary by sex. Future work will continue to understand and optimize treatment strategies for HIE in both males and females.

Title: Intranasal delivery of novel lipid mediator precursors provides neuroprotection after experimental ischemic stroke

Authors: *M. M. REID[1], L. KHOUTOROVA[1], B. K. PARK[1], N. N. DESAI[1], P. K. MUKHERJEE[1], K. SHELVIN[1], B. JUN[1], A. OBENAUS[2], L. BELAYEV[1], N. G. BAZAN[1];
[1]Louisiana State Univ. Hlth. Sci. Ctr., New Orleans, LA; [2]Univ. of California Irvine, Irvine, CA

Abstract: Stroke is the sixth leading cause of death and permanent disability in the United States. Following ischemic stroke, disruptions in neuroinflammatory signaling, the neurovascular unit, synaptic activity, and subsequent cell death and tissue damage occur. Current therapeutic options are limited and do not address the associated immune response and acute inflammation that occur at the site of cerebral ischemia. ELOVL4 (elongation of very long-chain fatty acids-4), an enzyme selectively located in neurons, catalyzes the biosynthesis of VLC-PUFAs (≥C28) from 26:6 fatty acids derived from docosahexaenoic acid (DHA,22:6,n-3) or eicosapentaenoic acid (EPA,20:5,n-3). We have previously shown that lipoxygenation of these VLC-PUFAs leads to the synthesis of a class of novel lipid mediators, termed elovanoids (ELVs). ELVs, when administered IV, reduce infarct volume and promote cell survival after 2h of MCAo in rats. This study aimed to investigate the neuroprotective efficacy of VLC-PUFA ELV precursors when administered intranasally. Male Sprague-Dawley rats received 2h of the middle cerebral artery occlusion (MCAo). Treatment with C-32:6, C-34:6 (1µg/µl, 20 µg per rat) or vehicle (saline + ethanol) was administered at 1, 24, and 48h after onset of MCAo. Behavior was evaluated using a composite neurological battery; a grading scale of 0-12 was employed (normal score=0, maximal deficit=12). Behavior testing was performed on days 1, 2, 3, and 7 followed by *ex vivo* MRI for lesion volumes and edema (T2WI). Immunohistochemistry was performed on day 7. No adverse physiologic effects were observed in any treatment groups. C-32:6 and C-34:6 improved behavioral function on days 3 by (41% and 20%) and 7 (45% and 24%), respectively. Total, cortical and subcortical infarct areas and volumes were dramatically reduced by treatments with C-32:6 (by 73% and 74%, 84%) and C-34:6 (by 85%, 58%, and 61%) compared to vehicle. Total lesion volumes computed from T2WI were reduced with C-32:6, C-34:6 (by 87% and 61%), respectively, compared to the vehicle group on day 7. We conclude that intranasal administration of VLC-PUFA precursors offers superior neuroprotection improving behavior and histopathological outcomes and reducing infarct areas and volumes. This provides a rationale to explore further ELVs and their precursors as a potential therapeutic for experimental ischemic stroke.

Title: Novel protein inhibitors of nuclear factor kappa B as therapeutics for neuroinflammation following ischemic stroke

Authors: *J. A. HOWELL[1], E. PERKINS[2], G. L. BIDWELL, III[3];
[1]Program in Neurosci., [2]Neurosurg., [3]Neurol., Univ. of Mississippi Med. Ctr., Jackson, MS

Abstract: Strokes are the 5th leading cause of death in the U.S., and ~87% of strokes are ischemic, meaning that they are caused by occlusion of a cerebral artery or its branches. This results in tissue infarction at regions supplied by the occluded vessel, and it also activates inflammatory cascades that worsen damage by affecting infarct size and behavioral outcome. Therefore, drugs targeting the inflammatory response following ischemic stroke may be highly beneficial in reducing infarct size and improving neurological outcomes. We have designed a novel inhibitor of the nuclear factor kappa B cascade, a central pathway of inflammation that is activated by many cytokines and signals that are elevated following ischemic stroke. Our inhibitor is bound to protein drug carrier elastin like polypeptide (ELP), which is based on a sequence from human elastin and can increase plasma half-life. We hypothesize that ELPs can be used to deliver our inhibitory peptide SynB1-ELP-p50i to the damaged region after ischemic stroke, reduce inflammation, and spare brain tissue. To begin, BV2 microglia were treated with 10 μM of rhodamine labeled SynB1-ELP-p50i for 24 hours and imaged with confocal microscopy to determine if the protein was able to enter the cells. We found that SynB1-ELP-p50i enters the cells and is primarily localized to the cytoplasm. To assess efficacy of SynB1-ELP-p50i *in vitro*, we treated BV2 microglia and cortical organotypic slices from Brainbow mouse pups with 50 μM of SynB1-ELP-p50i before exposing them to oxygen and glucose deprivation (OGD). After OGD, media was collected and run on a cytokine array to assess any reduction in production of inflammatory signals during OGD. Preliminary data shows that treatment with SynB1-ELP-p50i resulted in a reduction of inflammatory signals following OGD exposure, with specific reductions in TNF-α, IL-1α, IL-1β, among others. Next, biodistribution of SynB1-ELP-p50i within the brain was assessed using the middle cerebral artery occlusion (MCAO) model of ischemic stroke in Wistar rats. Two routes of administration (intravenous (IV, femoral vein) and intraarterial (IA, carotid catheter)) were compared using a dose of 50 mg/kg rhodamine labeled SynB1-ELP-p50i. SynB1-ELP-p50i accumulated in the ischemic hemisphere at levels 3 fold higher than in the contralateral hemisphere following MCAO (two-way ANOVA $F(1,12) = 15.58$; Sidak's $p < 0.05$). However, there was no difference in intrabrain deposition between IV and IA routes. Future studies will assess effects of SynB1-ELP-p50i treatment on infarct size, inflammatory cytokine production *in vivo*, and neurological deficits following MCAO in Wistar and spontaneously hypertensive rats.

Title: Ascorbate Mediates Epigenetic Reprogramming of Neuroprotective Genes and Prevents Brain Damage After Stroke

Authors: *K. C. MORRIS-BLANCO[1], A. CHOKKALLA[2], T. KIM[3], S. BHATULA[4], M. J. BERTOGLIAT[4], A. B. GAILLARD[4], R. VEMUGANTI[5];

Abstract: Vitamin C is an antioxidant that has recently been identified as an epigenetic regulator by activating ten eleven translocases (TETs), enzymes that produce the DNA hydroxymethylcytosine (5hmC) mark associated with increased gene expression. In the current study we investigated 1) whether Vitamin C may be involved in promoting neuroprotection through epigenetic modulation of 5hmC, 2) sex-specific differences in outcome following ascorbate treatment and 3) the therapeutic potential of Vitamin C treatment in stroke-related comorbidities in adult mice. Post-stroke treatment with ascorbate (reduced form of Vitamin C), but not dehydroascorbate (oxidized form of Vitamin C), increased TET3 activity, 5hmC levels and reduced infarct following focal ischemia. Hydroxymethylation DNA immunoprecipitation sequencing (hMeDIP-seq) showed that ascorbate increased 5hmC across the genome and in several stroke pathophysiology-related genes. Further analysis showed that ascorbate enhanced the expression of protective genes and prevented oxidative stress, mitochondrial dysfunction, apoptosis, and inflammation up to 3 days of reperfusion in neurons of the peri-infarct cortex. Ascorbate further promoted motor function recovery up to 7 days of reperfusion, and enhanced cognitive function up to 25 days of reperfusion in a TET3-dependent manner. Post-stroke ascorbate treatment also reduced infarct and improved motor function recovery in aged, hypertensive and diabetic male and female mice. Delayed ascorbate treatment at 6h of reperfusion was less effective, but still reduced secondary brain damage and motor impairments up to 7 days of reperfusion. Collectively, this study shows that post-stroke treatment of Vitamin C protects the brain through epigenetic reprogramming and may function as a robust therapeutic against stroke injury.

Title: Treadmill exercise concurrent with pharmacological inhibition of alpha5-$GABA_A$ receptor improves motor function and enhances spinal cord plasticity after intracerebral hemorrhage in rats

Authors: *T. INOUE[1,3], Y. TAKAMATSU[2], T. NISHIO[1], K. SOMA[1], M. OKAMURA[1], H. TOHYAMA[2], H. MAEJIMA[2];
[1]Grad. Sch. of Hlth. Sci., [2]Dept. of Rehabil. Science, Fac. of Hlth. Sci., Hokkaido Univ., Sapporo, Japan; [3]Japan Society for the Promotion of Sci., Tokyo, Japan

Abstract: Intracerebral hemorrhage (ICH) is a subtype of stroke that causes severe motor deficits. Rehabilitation, including therapeutic exercise, is an effective approach for improving motor deficits after stroke. Accumulating evidence indicates that excessive GABA-mediated tonic inhibition, which is primarily induced by extrasynaptic α5 subunit-containing $GABA_A$ receptors (α5$GABA_A$R), is an obstruction in post-stroke recovery. Although it has been shown that α5$GABA_A$R inhibitor promotes motor function recovery after ischemic stroke, no study has tested it in an ICH model. Interestingly, recent findings show that rehabilitation combined with pharmacotherapy enhances post-stroke recovery more effectively than individual treatments. Therefore, we examined the synergistic effect of treadmill exercise and pharmacotherapy to specifically inhibit α5$GABA_A$R on motor function recovery after ICH. Nine-week-old male Wistar rats were divided into five groups (n = 8 per group): 1) a sham group, 2) an ICH group, 3) an ICH treated with exercise group, 4) an ICH treated with α5$GABA_A$R inhibitor group, and 5) an ICH co-treated with exercise and α5$GABA_A$R inhibitor group. ICH was induced by the injection of collagenase in the left striatum near the internal capsule (AP: -2.0 mm, ML: 3.7 mm, DV: -6.0 mm). Intraperitoneal administration of α5$GABA_A$R inhibitor (0.5 mg/kg, L-655,708) and treadmill exercise (11 m/min for 30 min/day) were initiated 1 week after the ICH surgery and were performed for 3 weeks. Forelimb motor function was evaluated by the tape removal task. All study procedures were approved by the ethics committee for animal research of Hokkaido University in Japan and conducted according to the guidelines. While partial recovery was induced by each individual treatment of treadmill exercise or L-655,708 administration, combined treatment of these significantly promoted motor function recovery after ICH. L-655,708 administration increased brain-derived neurotrophic factor expression in the cortex and GAP-43 expression as an axonal growth marker in the spinal cord. Furthermore, combined treatment enhanced following expressions in the spinal cord: synaptophysin as a synaptic marker and Nogo-A as an axonal growth inhibitor. The present study is the first to provide a rationale that combined treatment of therapeutic exercise and α5$GABA_A$R inhibitor promotes motor recovery after ICH more effectively than individual treatments. This underlying mechanism could involve both growth and inhibitory modification in remote areas from lesion sites.

Title: Intraperitoneal IGF1 treatment modulates the impact of ischemic stroke in reproductively senescent female rats by repairing the gut

Authors: *Y. EL-HAKIM[1], K. MANI[1], S. PANDEY[2], A. ELDOUH[1], F. SOHRABJI[3];
[1]Texas A&M Hlth. Sci. Ctr., Bryan, TX; [2]Texas A&M, Bryan, TX; [3]Neurosci. and Exp Therapeut., Texas A and M Univ. Syst., Bryan, TX

Abstract: Our previous studies have shown that reproductively senescent (RS) female rats, who have lower circulating levels of the peptide hormone Insulin-like Growth Factor (IGF-1), display worse outcomes after a stroke event than young adult female rats. ICV administration of IGF-1, decreases infarct volume, improves sensory motor performance, and reduces cytokine levels in the ischemic hemisphere of RS females as compared to vehicle-treated controls. Yet, icv IGF1 administration failed to attenuate cognitive decline and depressive behaviors in long-term stroke outcomes. In view of the evidence that stroke induces gut dysbiosis, and that gut dysfunction is implicated in depressive and cognitive behaviors, we hypothesize that unlike icv administration of IGF-1, which is restricted to the brain, systemic i.p. administration of IGF1 would repair the gut, attenuate peripheral cytokine levels and improve long-term behavior outcomes. To test this, acyclic middle-aged Sprague Dawley female rats (9-11 mos) were subjected to endothelin-1 induced middle cerebral artery occlusion (MCAo) or sham operation. Animals received IGF1 via i.p. injections 4h post MCAo and 24 h post MCAo, or icv infusions, while controls received vehicle. Sensory motor tests, blood and gut samples were acquired pre and post MCAo. Animals were terminated either in the acute phase (2d) or chronic phase (20d). The latter group was also subject to tests of cognition and depressive-like behavior.In contrast to icv treatment, i.p.-IGF-1 did not reduce infarct volume or acute sensory motor impairment but significantly attenuated circulating levels of TNFα and IL12p70. IP-IGF-1 significantly attenuated post stroke gut dysmorphology, by preserving villus:crypt ratio and expression of tight junction proteins ZO1 and claudin-2. In addition, i.p. IGF1 treatment attenuated the reduction of social interaction and novel object preference post MCAo. Since long term disability after stroke is correlated with elevated levels of peripheral cytokines, our data suggest that systemic IGF1 may be a better therapeutic option for long term cognitive and depressive behaviors after stroke.

Title: Tenascin-c inhibition prevents post-stroke neuroinflammation

Authors: *B. CHELLUBOINA, A. CHOKKALLA, S. L. MEHTA, S. BATHULA, J. PARK, R. VEMUGANTI;
Univ. of Wisconsin, Madison, WI

Abstract: The role of tenascin-C (TNC) in post-ischemic inflammation is not known despite its pathological role in CNS diseases. TNC upregulated as early as 3h of reperfusion after 1h of transient middle cerebral artery occlusion (MCAO). We presently investigated the effect of TNC knockdown on post-stroke brain damage and its putative mechanism of action in adult mice of both sexes. Male and female C57BL/6 mice were subjected to transient MCAO and injected (i.v.) with either TNC siRNA or a negative (non-targeting) siRNA at 5 min after reperfusion. Motor function (beam walk and rotarod tests) was assessed between days 1 and 14 of reperfusion. Infarct volume (T2-MRI), BBB damage (T1-MRI with contrast), and inflammatory markers were measured at 3 days of reperfusion. The TNC siRNA treated cohort showed significantly curtailed post-stroke TNC protein expression, motor dysfunction, infarction, BBB damage, and inflammation compared to the sex-matched negative siRNA treated cohort. TNC inhibition significantly curtailed neutrophil infiltration, post-stroke neuroinflammation and reduced the post-stroke mRNA expression of the inflammatory molecules such as IL-1β, IL-6, MCP-1, TNF-α, and TNF-related apoptosis-inducing ligand. These results demonstrate that the induction of TNC during the acute period after stroke mediates post-ischemic inflammation and secondary brain damage independent of sex.

Title: The effects of NLY01, a GLP1R agonist, on neuroinflammation, infarct size, and functional recovery in mouse models of ischemic stroke

Authors: *K. PRESCOTT, J. T. HOLSTEN, R. L. BRIMBERRY, T. C. PETERSON;
Univ. of North Carolina Wilmington, Wilmington, NC

Abstract: In the United States, 2.7% of all adults have had a stroke. Using recombinant tissue plasminogen activator to break up the blood clot is the most common treatment for ischemic stroke, but it can only be used within 4 hours of stroke onset, so it is only effective in less than 3% of the population. Recent research into stroke outcomes has examined the beneficial effects of reducing neuroinflammation, which could potentially be accomplished by reducing maladaptive astrocyte reactivity. One way to reduce neurotoxic reactive astrocytes is by reducing the pro-inflammatory cytokines TNF, IL-1α, and C1q released by microglia after stroke. NLY01 is a glycogen-like peptide-1 receptor (GLP1R) agonist that has been shown to cross the blood-brain barrier and is capable of inhibiting microglia from releasing these

cytokines which reduces neurotoxic astrocytes. We hypothesize that NLY01 will reduce microglial activation, astrocyte activation, and infarct volume, as well as decrease behavioral deficits after an ischemic stroke. To examine how NLY01 would affect the neuroinflammatory response and reduce neurotoxic astrocytes following ischemic stroke, a distal medial cerebral artery occlusion (dMCAO) was performed on female C57BL/6J mice. NLY01 was administered 4 hours after surgery using retro orbital (RO) injection and every 48 hours for 7 days using an intraparietal (IP) injection. They were administered with either 0 mg/kg (n=12), 1 mg/kg (n=11), 3 mg/kg (n=11), or 15 mg/kg (n=7) of NLY01 following stroke, and the brain was perfused/extracted 7 days after injury. To examine behavioral deficits after NLY01, a photothrombotic stroke was induced over the motor cortex in female C57BL/6J mice and they were administered with either 0 mg/kg (n=11), 1 mg/kg (n=11), 3 mg/kg (n=11), or 15 mg/kg (n=12) of NLY01. Behavior tasks included grid walk, cylinder task, rotating beam, tapered beam, and grip strength. Brain extraction occurred 30 days after stroke. Infarct size, astrogliosis, and microgliosis are assessed for 7 days and 30 days after stroke. Immunohistochemistry was performed to examine microgliosis (CD68), astrogliosis (GFAP), and infarct size (NeuN). A one-way ANOVA was used for statistical analysis of astrogliosis (p=0.23) and infarct size (p=0.16), with no statistical differences found 7 days after dMCAO surgery. Macrophage differences are still being examined, as are the behavioral tasks. Although the preliminary results indicate that NLY01 does not reduce secondary neuroinflammation, data is still being collected and analyzed to measure its beneficial impact following stroke.

Title: Intestinal organoids transplantation: Potential Therapy To Improve Stroke Outcomes

Authors: *K. MANI;
Neurosci. and Exptl. Therapeut., Texas A & M Univ., Bryan, TX

Abstract: Stroke is ranked as the second leading cause of death worldwide, with about 50% of all stroke patients experiencing a leaky gut, gut hemorrhage and gut epithelium damage. Gut leakiness may increase circulating inflammatory cytokines and other gut products such as endotoxins, which can impair stroke recovery. Here we tested the hypothesis that repairing gut function may improve stroke outcomes. Specifically, we tested whether transplantation of intestinal epithelial stem cells (IESC) after stroke may stimulate repair of gut structures and improve recovery after stroke. Acyclic (reproductive senescent) middle-aged Sprague-Dawley female rats were used for this study and assigned to the following groups: Control (sham), stroke with sham transplant (vehicle), or stroke with IESC transplantation. Rats were

subjected to stereotaxic middle cerebral artery occlusion (MCAo) using Endothelin-1, a chemical vasoconstrictor. Primary IESCs were isolated from young female rats to prepare organoid cultures. Dispersed organoid cells were labeled with PKH67 and injected iv at 4h/24h/48h after stroke. In animals that received PKH67-labelled IESC transplants, transplanted cells were seen in the basal part of the crypt. Behavioral assays and saphenous blood draws were performed pre-stroke and at 2d and 4d after stroke. Trunk blood, brain tissue, and a segment of the small intestine were collected at termination. TTC staining was used to quantify infarct volume. Intestine samples were processed for the histomorphometric analyses and immunohistochemistry to analyze specific markers of gut function (Lgr5+, Wnt3a, ZO-1, Ki67, and Villin). The blood-gut barrier was assessed by measuring serum levels of iFABP, LPS, and Muc-2, which are commonly used surrogate markers of gut permeability. MCAo-induced mortality and infarct volume were significantly reduced in reproductively senescent female rats that received young female IESCs compared to the vehicle group. Sensory-motor performance was similar in sham and transplanted groups but was significantly worse at 2d and 4d after stroke in the vehicle-treated group. Significant deterioration of the gut architecture (blunted or absent villi and irregular crypts) were observed in the non-transplantation group, while transplanted animals displayed improved gut architecture and gut repair, and a reduction of intestinal permeability compared to the vehicle group. Overall, these data show that a novel stem cell population derived from the gut can significantly improve stroke outcomes.

Title: Neuropeptide role of α-Melanocyte-stimulating hormone against cerebral ischemia/reperfusion injury in type 1 diabetes

Authors: *R. GOIT[1], A. TAYLOR[2], A. LO[1];
[1]The Univ. of Hong Kong, Hong Kong, Hong Kong; [2]Boston Univ. Sch. of Med., Boston, MA

Abstract: Type 1 diabetic patients have higher risk of stroke than the general population. α-Melanocyte stimulating hormone (α-MSH) is a peptide derived from a precursor polypeptide, proopiomelanocortin. Several studies showed that α-MSH has protective effects against ischemia/reperfusion (I/R) induced organ damages. Therefore, we aimed to find the neuroprotective role of this peptide on I/R induced cerebral damage after experimental stroke associated with hyperglycemia using C57BL/6J $Ins2^{Akita/+}$ mice. I/R injury was induced by blocking the right middle cerebral artery for 2 hours with reperfusion for 2 hours and 22 hours, respectively using the intraluminal method. Animals were treated intraperitoneally with either vehicle or α-MSH at 1 hour after ischemia and 1 hour after reperfusion. α-MSH treated animals has significantly higher survival rate with lower neurological scores. α-MSH significantly decreased relative infarct area, hemorrhage, glial cells activation as well as oxidative and nitrosative stress. Relative intensities of matrix metallopeptidases 9, cyclooxygenase 2 and nuclear factor-κB were

significantly decreased while intensities of protein kinase b (also known as Akt), heme oxygenase (HO) 1, HO-2 and B-cell lymphoma 2 were significantly increased after α-MSH treatment. In addition, gene expressions of monocarboxylate transporter (MCT) 1, MCT-2 and activity-regulated cytoskeleton-associated protein were significantly higher in brain samples treated with α-MSH. Finally, % TUNEL was significantly lower in α-MSH treated brain slices. In conclusion, α-MSH is neuroprotective under hyperglycemic condition against I/R induced brain damage by its anti-inflammatory, anti-oxidative and anti-apoptotic properties. The α-MSH analogues may be potential therapeutic agents against stroke under hyperglycemic condition.

Title: Lower-limb stroke rehab for chronic patients utilizing brain-computer interface

Authors: W. CHO[1], M. SEBASTIAN-ROMAGOSA[2], F. CAO[3], K. MAYR[1], *C. GUGER[1,2,3]; [1]g.tec medical engineering GmbH, Schiedlberg, Austria; [2]g.tec medical engineering Spain S.L., Barcelona, Spain; [3]g.tec neurotechnology USA, Inc., Albany, NY

Abstract: Conventional rehabilitation regimes have proven to have limited success for chronic stroke patients with severe hemiparesis, however, studies have shown positive rehabilitation effects when neurorehabilitation based on Brain-Computer Interfaces (BCIs) has been applied.
Ten chronic stroke patients with lower-limb hemiparesis were recruited to complete a total of 25 BCI sessions over the course of 2 months (about 3 sessions per week). The patient had to perform a Motor Imagery (MI) task with either the paretic ankle dorsiflexion or the healthy wrist dorsiflexion to receive feedback in the form of an avatar as well as Functional Electrical Stimulation (FES). In order to objectively observe changes in the motor functions, various assessments were conducted before, after and during the 2-month period of BCI training. The main tests were the Timed Up and Go (TUG), the 10-meters walking test (10MWT) and the Range of Motion (ROM) of the ankle dorsiflexion.
The test results show a significant increase in the speed of the TUG by 0.06 m/s, P = 0.002. One out of ten patients could only perform the TUG after all 25 BCI sessions were completed and needed 92.2 seconds to do so. Also, the gait speed of the 10MWT fast velocity was increased by 0.16 m/s (SD = 0.14), which is above the minimally clinically important difference (MCID). Both active and passive ROM assessments increased after rehabilitation training, P =.008 by 8.61° (SD = 6.54), P = 0.002 respectively 8.50° (SD = 7.23).
These results support the proposal to use MI and FES-based non-invasive BCIs as a rehabilitation technique for severely impaired patients with limited mobility to improve their gait even in the chronic

stage after stroke. In order to develop this kind of therapy approach into a new rehab paradigm for stroke patients, the outcomes should be confirmed and validated by bigger studies including more patients.

Title: Visualization of multivariate behavioral data in stroke subjects during robotic rehabilitation therapy for fingers.

Authors: *S. RUEDA[1], J. C. PERRY[2], E. T. WOLBRECHT[2], D. GUPTA[3,4];
[1]Electrical Engin., [2]Mechanical Engin., Univ. of Idaho, Moscow, ID; [3]Natl. Ctr. for Adaptive Neurotechnologies, Stratton VA Med. Ctr., Albany, NY; [4]Electrical and Computed Engin., Univ. of Albany, State Univ. of NY, Albany, NY

Abstract: Interpreting multivariate data from impaired subjects presents a challenge in clinical evaluation. In this work, we seek to find common patterns in subjects for stratifying groups with respect to: a) overall impairment and b) response to therapy, in an effort to understand baseline features that can be related to greater gains in specific domains as a result of therapeutic protocols. Multidomain behavioral data from 27 patients with chronic stroke who underwent a month of therapy with the FINGER robot was obtained before and after rehabilitation. With up to 30 descriptors for each subject, the high dimensionality and low number of samples makes trends challenging to see. Observed values were normalized and scale-inverted when necessary, with values near 0 for poor outcomes and near 1 for good outcomes. We propose a data-driven approach that projects the distance structure of the multidimensional points representing each of the patients to a 2D plane, using: a) t-distributed stochastic neighbor embedding (t-SNE) with principal component analysis (PCA), followed by b) clustering with the affinity propagation algorithm which defines the number of clusters from the similarity matrix of the input data. Group averages on metrics are presented as a radar chart. Tests were performed by running the algorithm several times for baseline and inter-session difference (delta) sets with the same parameters and reducing the dimensionality of the input sets by selecting subgroups of similar metrics. Results reveal groups in datasets that share similar behavioral features. The groups found are robust to changes in parameters related to t-SNE and PCA, with the exception of a few subjects that get assigned to nearby clusters for different runs. In single-domain analyses where similar metrics are given to the model, groups are formed based on domain-specific metrics in ascending order. For multidomain analyses, the algorithm shows high sensitivity to groups with meaningful differences for different domains even though there are

important similarities in other domains. The algorithm described here aids the process of visualizing multidomain data from behavioral tests in stroke patients. Baseline data shows groups with shared features in sensorimotor domains that can be related to motor impairment; it also shows that some of the subjects in these groups are more affected by spasticity or depression (which can harm the gains from therapy). When applied to the delta set, groups of subjects emerge with specific gains in domains such as force, finger dexterity, or coordination, and may allow new insights on subject stratification for therapeutic approaches.

Title: Wearable myoelectric interface for neurorehabilitation training in chronic stroke

Authors: V. PAUL[1], N.-T. HUNG[1], P. PRAKASH[1], T. KOVACH[1], ***M. SLUTZKY**[2];
[2]Neurol., [1]Northwestern Univ., Chicago, IL

Abstract: Abnormal co-activation (also called abnormal synergies) is a significant cause of impaired arm movement after stroke. However, few stroke therapies aim to reduce this co-activation. We designed a myoelectric computer interface (MyoCI) to provide feedback to stroke survivors to reduce abnormal co-activation and associated arm impairment. Here, we describe a novel, wearable version of the MyoCI to control custom-designed computer games as a home-based therapy for chronic stroke survivors. This therapy, called the myoelectric interface for neurorehabilitation training (MINT), enables high-intensity, high-dose training using an inexpensive device at home. The MINT device records surface EMGs from 2-3 arm muscles and wirelessly controls games on a laptop or tablet. By mapping the muscle activities to orthogonal directions of cursor movements, the games operantly condition the participants to learn to reduce abnormal co-activation between the muscles. We are currently investigating home-based MINT therapy in a randomized controlled trial of severely impaired stroke survivors (Fugl-Meyer score <30). Participants were asked to train 90 min per day, 6 days a week, for a total of 6 weeks, with different variants of the paradigm (2 or 3 muscles at a time) vs. a sham control group that trained on one muscle. We surveyed participants about their engagement with the game using a modified Intrinsic Motivation Inventory. Thirty participants have completed the 6-week training to date. They averaged 85±18 min of daily training out of the 90 that were asked. Overall, 89% of participants surveyed found the training enjoyable and motivating. A few participants had significant difficulty with the laptops due to inexperience with computers. Participants' performance on the game, measured by weighted time-to-target, improved steadily overall in the experimental group, while the sham control group stayed at high performance throughout. Functional outcomes were measured using the Wolf Motor Function Test

(WMFT, timed portion). At 6 weeks, WMFT showed a trend of greater improvement relative to baseline in experimental groups than in sham controls (combined mean -3.6 vs -1.5 s, p=0.26, t-test). The group training 3 muscles at a time improved significantly more than sham (-7.3 s, p=0.03) at 6 weeks. Improvement continued 4 weeks after the training ended (-16.9 s in 3-muscle group, p=0.03; -9.4 s overall groups compared to -2.6 s for sham, p=0.14). MINT is a motivating way to provide home-based, high-intensity therapy to stroke survivors with a new mechanism of action. Early results suggest that it improves arm function and is not just overcoming learned non-use.

Title: Retrieve: an automated stereognosis system for brain injury patients with chronic tactile deficits

Authors: *R. HUDSON, J. EPPERSON, J. WRIGHT, Y. DUONG, D. PRUITT, S. HAYS, M. KILGARD;
Univ. of Texas At Dallas, Richardson, TX

Abstract: We have endeavored to test the usability of a novel stereognosis-based system for automated somatosensory training designed for use in clinic or at home. Fourteen participants with chronic brain injury were recruited for this study. Three were excluded as they could not retrieve one object 3 times in 2 minutes. A total of 9 participants (5 male, 4 female, age 55+/-15, years since injury 8+/-8) completed 1 hour of system use in clinic. A total of 3 participants (1 male, 2 female, age 45+/-22, years since injury 4+/-1) completed 5 days of system use at home for 1 hour per day. When using the ReTrieve system, participants are asked to differentiate textures, shapes, weights, or lengths of objects. Harder versions of tasks use more similar objects. The system instructs the participant on the task, and records performance data. Participants averaged 175+/-135 retrievals per hour in clinic. Participants averaged 397+/-102 retrievals per day at home. Participants' percent correct was significantly better than chance ($p < .001$). When participants were presented with "hard" tasks rather than "easy" tasks, retrieval rate decreased for weight and length objects ($p < .05$) and percent correct decreased for weight objects ($p < .05$). Participants distinguish objects at rates above chance and perform worse on more similar objects, indicating that this task could be modified to serve a range of ability levels. The expected decrease in task performance with increase in difficulty for two of our four object types indicates a successful difficulty scaling paradigm for these objects. Repetitions per hour are more than ten times the average of 13 somatosensory repetitions in clinic and could significantly assist in recovery if used at home for an extended period. An ongoing randomized study is investigating whether this fully automated stereognosis improves sensory function as measured with the Erasmus modified Nottingham Sensory Assessment when used at home for 6 weeks.

Title: Operant conditioning of RF H-reflex for treatment of spasticity

Authors: *K. KIM[1], K. MANELLA[2], R. LEE[3], J. S. SULZER[1];
[1]Mechanical Engin., Univ. of Texas at Austin, Austin, TX; [2]Col. of Rehabilitative Sci., Univ. of St. Augustine, Austin, TX; [3]St. David's Med. Ctr., Austin, TX

Abstract: Spasticity, or more specifically hyperreflexia, is a common impairment following neurological injury such as stroke. Clinical interventions aimed at reducing RF hyperreflexia have shown modest results but with side effects and limited clinical evidence. Our previous research has shown that hyperreflexia of the rectus femoris (RF) during pre-swing is closely associated with reduced knee flexion in post-stroke with Stiff-Knee gait (SKG). Thus, reduction of RF hyperreflexia should improve walking function following SKG after stroke. Our recently developed procedure can non-pharmacologically target hyperreflexia using operant conditioning. Operant H-reflex conditioning allows the patient to self-modulate one's own monosynaptic spinal reflex activity, elicited via electrical stimulation on peripheral nerve. At present, operant H-reflex conditioning has shown that individuals with spinal cord injury can learn to self-modulate soleus reflex excitability with improvements in clinical function. Our study is a proof-of-concept study to examine the feasibility of this procedure on the RF muscle. Total of 7 subjects (5 healthy 2 stroke) participated in this study, where we measured surface EMG of RF and provided surface stimulation on femoral nerve. Subjects were asked to regulate visual feedback of their RF H-reflex activity. The protocol consisted of 6 Baseline/24 Training sessions over a 12-week (2-3 time/wk). Sessions consisted of three runs of 75 trials in a standing posture, where no feedback of RF H-reflex was provided during Baseline sessions. Training began with an additional 20 Baseline trials to establish a within-session baseline. Participants were asked to reduce the height of the RF H-reflex bar while maintaining background RF EMG within inactive zone. A successful trial (i.e. below threshold) resulted in a color change of the bar on the screen and an increased success rate. We compared averaged RF H-reflex amplitude of the six Baseline sessions and last six training sessions. We assessed gait speed, spasticity, reflex modulation, and joint kinematics during gait pre-/post- training in stroke. In five healthy individuals, we found an overall decrease in average RF H-reflex magnitude (33% drop, $p<0.001$, paired t-test), and stronger decrease in post-stroke individuals (49% drop, $p<0.001$). Post-stroke individuals also exhibited improvements in peak knee-flexion velocity, reflex excitability during 4 gait-phases, and in spasticity (32° to 43° in 1st swing excursion on the quadriceps pendulum test). These outcome provide promising initial results that operant RF H-reflex conditioning is feasible both in healthy and post-stroke individuals.

Title: Comparison between the effect of unihemispheric and bihemispheric transcranial direct current stimulation on spasticity, and motor outcome in subacute ischemic stroke patients

Authors: *H. YOUSSEF[1,2], M. ZEINELDIN[3], N. ABDELHAMED[4], M. HAMDY[5];
[1]Neurosci. & Biotech., Alexandria Univ., Alexandria, Egypt; [2]Physical Therapy & Rehabil., Marmara Univ., Istanbul, Turkey; [3]Clin. Abstract: Background Despite the central origin of stroke affecting the primary motor cortex M1, most of the rehabilitative approaches rely on peripheral techniques to regain motor capabilities. The goal of this study was to compare the effects of unihemispheric and bihemispheric transcranial direct current stimulation tDCS on motor outcomes, and spasticity in patients with subacute ischemic stroke. The trial registration in the clinical trial ID is NCT04770363. **Methods** Thirty-six sub-acute ischemic stroke survivors participated in the study, randomly assigned to one of three groups receiving (tDCS), bihemispheric (Anodal over affected M1, and cathodal over healthy M1) or unihemispheric (Anodal over affected M1, and cathodal stimulation over the supraorbital bone of the healthy side) or sham group (electrode placement as Unihemispheric but no current delivered). ActivaDose tDCS (USA) used, to deliver noninvasive brain stimulation, consisted of 20 minutes of 2 mA anodal and cathodal applications according to different groups in each session for 12 sessions three sessions per week. All participants received physiotherapy directly following the tDCS session for 45 minutes/day. Participants assessed by Fugl-Meyer assessment (FMA), and Modified Ashworth scale (MAS) for muscle tone, all measured at baseline, and after four weeks of the treatment. Both of the participants, and the external examiner, was blinded for which interventional groups they had joined. **Sample size calculation** Assuming that the effect size of tDCS on "Subacute ischemic stroke patients" was 0.30, the number of groups= 3, and repetition = 2. The minimum required sample size is 24 patients' alpha error = 5% and study power of 80%. Calculated using G. Power software. **Results** A repeated measures ANOVA yielded a significant effect of tDCS regarding UE (F = 9.857, P = .001), and LE (F = 3.861, P = .034). Post-hoc analyses revealed that unihemispheric stimulation improved performance significantly more than sham stimulation (P = .001) for UE and (P = .029) for LE, and bihemispheric stimulation improved performance significantly more than sham stimulation (P = .008) for UE and (P = .023) for LE. Revealing no additives effects of bihemispheric over unihemispheric cerebral stimulation. (P = .939). Data analysis revealed a significant effect between groups tested by the Kruskal Wallis test for muscle spasticity of biceps (P = .036), and wrist flexors (P = .025). **Conclusion** Adding tDCS to the neuro-rehabilitation plan would promote the advantageous effect of neurorehabilitation of motor measures, and normalizing muscle tone of the stroke survivors.

Title: Effects of repetitive transcranial magnetic stimulation of contralesional dorsal premotor cortex on interhemispheric functional connectivity in severe chronic stroke

Authors: *X. LI[1], D. A. CUNNINGHAM[2], K. SAKAIE[3], M. LOWE[3], Y.-L. LIN[4], S. L. WOLF[5], A. CONFORTO[6], A. G. MACHADO[7], A. MOHAN[1], K. O'LAUGHLIN[1], X. WANG[8], M. WIDINA[1], E. B. PLOW[1];

Abstract: Introduction: Up to 50% of stroke survivors experience persistent, severe upper limb paresis despite intensive rehabilitation. Treatment options for severely impaired survivors are often limited and ineffective. Brain stimulation has received widespread attention for its potential to augment effects of rehabilitation through neuroplasticity. Repetitive transcranial magnetic stimulation (rTMS) is a well-known technique used to promote motor improvement through facilitating excitability of ipsilesional primary motor cortex (iM1). Despite promising early evidence, this approach has failed to produce motor gains in severely impaired survivors. Recent evidence indicates the dorsal premotor cortex in the undamaged, contralesional hemisphere (cPMd) may be a more suitable target due to alternate, viable, bi-hemispheric and ipsilateral contributions. A single session of rTMS delivered to facilitate cPMd increased paretic limb reaching speed in association with heightened interhemispheric connectivity in more severely impaired survivors who otherwise showed little gain with conventional iM1 rTMS. Multiple sessions of cPMd rTMS coupled with rehabilitation may generate longer lasting, clinically meaningful gains. Thus, this ongoing study seeks to investigate whether multiple sessions of cPMd rTMS coupled with rehabilitation produce greater motor improvement than conventional iM1 rTMS coupled with rehabilitation based on recruitment of available neural substrates in severely impaired survivors. We hypothesize that cPMd rTMS coupled with rehabilitation will produce greater motor functional gains along with enhanced interhemispheric functional connectivity quantified using resting state functional magnetic resonance imaging (rs-fMRI). **Methods**: In this pilot randomized, blinded clinical trial, 12 participants with severe chronic stroke have been randomized to receive cPMd or iM1 rTMS both in conjunction with upper limb rehabilitation (2x/wk, 6 wks). Assessments of motor function, neurophysiology, and rs-fMRI are made at baseline and at end of treatment. Interhemispheric connectivity between bilateral motor areas is evaluated as correlation in low frequency blood oxygen level dependent

activity. **Results**: Case series analysis suggests severely impaired survivors who receive cPMd rTMS show gains in functional connectivity between cPMd and iM1 with functional improvement compared to counterparts who receive iM1 rTMS. **Discussion**: Addition of the remaining 12 participants is expected to give insight on mechanisms of a novel brain stimulation approach developed for severely impaired stroke survivors.

Title: An interactive activity assistant to facilitate motor and cognitive rehabilitation following acquired brain injury

Authors: *C. DUNLAP, I. BAUMGART, D. MORALES, L. WENGERD, S. COLACHIS, IV; Battelle Mem. Inst., Columbus, OH

Abstract: Acquired brain injuries (ABI), including traumatic brain injury (TBI) and stroke, affect over a million Americans a year and can cause long-term motor and cognitive disability. The current state of the art for ABI rehabilitation is occupational therapist (OT)-guided exercises. Constraints such as time limitations and insurance reimbursement restrict the number of therapy sessions a patient receives, potentially hindering recovery potential. Furthermore, it is challenging for therapists to track quantitative performance metrics while simultaneously leading therapy sessions. We have developed the Battelle Activity Assistant™, a portable computer-vision based assistive device, to aid both cognitive and motor function, as well as quantify longitudinal functional gains during rehabilitation. Using a video camera, machine learning algorithms, and an optional functional electrical stimulation device to enhance grasp function, the Activity Assistant guides the user through a broad range of tasks including activities of daily living and clinical assessments. The Activity Assistant leverages artificial intelligence methods to understand the kinematics, task performance, and cognitive function of the patient and provides real time biofeedback and task performance information. In an IRB-approved feasibility study, we tested the Activity Assistant with participants with both cognitive and motor impairments due to ABI. We demonstrate feasibility of the Activity Assistant to enhance rehabilitation, autonomously supplement motor function with context-aware functional electrical stimulation, and to quantify performance in the nine-hole peg clinical assessment. We present our successes and challenges in using artificial intelligence to aid occupational therapy for ABI. Lastly, we discuss future opportunities for machine learning interventions to facilitate motor and cognitive rehabilitation. Disclaimer: This is an investigational device,

it is not commercially available, and it has not been cleared or approved by the FDA. Results discussed are from research studies performed.© 2021 Battelle Memorial Institute. All rights reserved.

Title: Upper extremity flexion synergy torque patterns are not exacerbated following ischemic conditioning post stroke.

Authors: E. KLEVENOW[1], P. BALASUBRAMANIAN[2], T. RUOPP[2], B. SCHMIT[2], *A. HYNGSTROM[1];
[1]Physical Therapy, [2]Biomed. Engin., Marquette Univ., Milwaukee, WI

Abstract: Ischemic conditioning (IC) is an emerging intervention that may improve motor function in individuals with chronic stroke. IC is a vascular stimulus that induces transient tissue ischemia through five-minute intervals of blood flow occlusion and reperfusion by inflation and deflation of a blood pressure cuff around a limb. The mechanisms of IC's motor benefits are not completely known but likely involve excitation of afferents sensitive to ischemia which then engage the autonomic nervous system resulting in a release of neuromodulators such as norepinephrine. As these neuromodulators may also be involved in the expression of upper limb synergy patterns post stroke, we aimed to determine if IC affects the expression of the upper extremity flexion synergy torque patterns which could potentially hamper motor performance. Eleven participants >6 months post stroke (4 Male, 50.8 ± 14.5 yrs) completed two study sessions of IC (cuff inflation 225 mmHg) or IC sham (10 mmHg). Isometric shoulder abduction maximal voluntary contraction (SABD MVC) and secondary elbow flexion torques were measured before and after a single session of either IC or IC sham in a randomized order. On average, after IC, SABD MVC increased (mean +8.79% ± 23) versus a smaller +0.64% ± 13.95 change after IC sham. While SABD MVC values increased, involuntary secondary elbow flexion torque measured during SABD MVC did not consistently increase or decrease with torque at the shoulder after IC (+3.63% ± 46.55) or IC sham (+19.84% ± 54.73). These data suggest that IC does not exacerbate secondary elbow flexion torques associated with upper extremity flexion synergy presentation.

Title: Spinal cord injury induced neuropathic pain associates with plasticity in peripheral cutaneous sensory encoding and increased spinal sensory circuit excitability

Authors: *M. BRYSON, H. KLOEFKORN-ADAMS, S. GARRAWAY, S. HOCHMAN;
Emory Univ., Atlanta, GA

Abstract: Spinal cord injury (SCI) commonly leads to neuropathic pain, which manifests largely as tactile allodynia (pain from non-painful stimuli). Spontaneous firing in nociceptor dorsal root ganglia (DRG) due to changes in ion channel expression has been implicated in the emergence of neuropathic pain. Similar changes are seen in 2nd and 3rd order CNS neurons, at least in part due to alterations in Na^+ channel expression. Here, in the thoracic contusion SCI neuropathic pain mouse model, we used *ex vivo* isolated truncal skin-nerve and isolated whole spinal cord preparations to assess the changes in excitability of primary afferents and dorsal horn circuitry, independent of DRG. We performed electrophysiology experiments in parallel in naïve (n = 1), sham (n = 1), and T12 contusion SCI (n = 5) adult mice several months after surgery. Initial analysis of skin-nerve data identified the following possible changes after SCI; (a) reduced frequency of spontaneous events with emergent activity in high-amplitude, fast-rising spiking units. (b) Temperature reduction from 32ºC to 22º recruited unique spontaneous bursting in 2/4 SCI mice. (c) Mechanical activation of truncal hairy skin with air pressure pulses at various forces led to unique amplification of recruited units at lower temperature. In spinal cord, recordings were made at the dorsal root (DR) entry zone of multiple roots bilaterally above and below the lesion and DRs were stimulated at Aβ, Aδ and C fiber intensities to characterize evoked changes in afferent fiber excitability, measured as dorsal root potentials (DRPs) or dorsal root reflexes (DRRs). Compared to sham (n=2) and naïve (n=1) mice, initial analyses suggest that SCI mice (n=4) have increased circuit excitability. (a) Spontaneous afferent activity was increased and synchronized events were able to cross nearby ipsilateral roots, indicating interneuron involvement. (2) High threshold afferent stimulation evoked stronger multi-segmental responses. (3) 4-AP, thought to preferentially recruit superficial dorsal horn pain circuits, induced paroxysmal bursting that included synchronous bilateral activity. A role for recruitment of commissural interneurons was further supported by the fact that DR stimulation evoked contralateral DRRs in SCI mice. More generally, as 4-AP induced bursting was strongly depressed with bicuculline, while CNQX/APV had much less effect, the observed plasticity appears to be primarily driven by GABAergic inhibitory interneurons that may become functionally excitatory. Together, these data support the hypothesis that somatosensory circuits change at multiple levels after SCI, leading to injury-induced neuropathic pain.

Title: High-resolution 3D visualization of neural fibers in spinal cord with BDA tracing and tissue-clearing

Authors: *M. SHINOZAKI, K. NAKANISHI, N. NAGOSHI, M. NAKAMURA, H. OKANO; Keio Univ. Sch. of Med., Tokyo, Japan

Abstract: [Background] Neural circuits constitute a complicated three-dimensional network, and histological aspects such as direction, branching, and branching angle of neural fibers cannot be sufficiently evaluated in sliced sections. In this decade, various techniques to make neural tissue transparent have emerged, and the targeted neural circuit can be visualized in three dimensional ways with fluorescent materials. On the other hand, many clearing-methods are complicated, and various conditions of the protocols are needed to be tested in order to obtain an image that can withstand the evaluation of each neural fiber. Therefore, we developed a method of clearing a spinal cord transparent and of observing it three-dimensionally by using BDA tracer, which was traditional but enabled high-resolution visualization of neural fibers. [Methods] Thoracic spinal cord injury model-mouse was used. A total of 1.2 ul of 10% BDA was injected into four sensorimotor sites of lower limb-area to trace corticospinal tracts. Ten days later, the harvested spinal cord was first immersed in 4% PFA, and then immersed in alexa-conjugated streptavidin solution for one week. After that, clearing method PACT was modified as follows. The tissue was immersed in an acrylamide hydrogel solution at 4 °C for 3 days. Then the gelation was performed at 37 ° C for 3 hours in a water bath. After removing the gel from the tissue surface, the tissue was moved to thermostat chamber at 47 °C in a clearing solution. When the tissue got semitransparent (3 days for spinal cords of mice), it was immersed in observation-solution in room temperature to be completely transparent in half a day. Observation was performed using a Zeiss lightsheet microscope. The obtained sequential images were reconstructed with ImageJ software. [Results] During the staining process, the labeled area expanded from the surface to the center of the tissue block over time, and the whole staining was completely performed in seven days. In the clearing process, transparency was gradually increased. After the tissue was transferred to the observation solution, a completely transparent tissue was obtained. Sequential images were captured with Lightsheet microscope, and the stitching was made in ZEN software, and 3D reconstruction was made with ImageJ. We output 2D images from the reconstructed 3D data, and confirmed that the resolution of images was comparable with that of usual slice sections. It was possible to demonstrate the corticospinal tract fibers and varicosity sprouted in the gray matter. [Conclusion] We have established a tissue clearing method for high-resolution and three-dimensional evaluation of anterograde tracing.

Title: The role of TLR4 in the secondary pathogenesis of spinal cord injury

Authors: *R. D. FESSLER[1], N. BOLES[1], Q. SHEN[1], Y. LOPEZ-RAMIREZ[1], D. TUCKER[1], B. T. DAVID[1], R. G. FESSLER[1], K. DHANDIAPANI[2];
[1]Neurosurg., Rush Univ. Med. Ctr., Chicago, IL; [2]Med. Col. of Georgia, Augusta, GA

Abstract: Introduction: Spinal cord injury (SCI) is a leading cause of paralysis worldwide, however no treatments have been developed partly due to poor understanding of SCI pathophysiology. Toll-like receptor 4 (TLR4), a pro-inflammatory receptor, has been implicated in initiating the sterile inflammatory response to neurologic injury, and presents a potential therapeutic target. VGX-1027, a TLR4 inhibitor, has shown promise as a neuroprotective agent after injury. Objectives: This study established a model of compression SCI in mice for investigation of the role of TLR4 in the secondary pathogenesis of SCI, and evaluation of TLR4 inhibition as a potential therapeutic target. Methods: TLR4 expression was quantified by western blot and cell-type specific expression was evaluated using both immunohistochemistry and flow cytometry. Functional analysis (BMS and mTarlov) was performed comparing wild type vs TLR4 mutants, and in mice treated with the TLR4 inhibitor VGX-1027. Results: TLR4 expression was biphasically upregulated on western blot analysis at 6 and 48hrs after SCI. Immunohistochemistry showed TLR4 colocalization with neurons, but not with astrocytes or macrophages. Flow cytometry showed significant up regulation of TLR4 in neurons, astrocytes, and macrophages, with the greatest upregulation in neurons. TLR4 mutants showed diminished functional deficits compared to the wild type, as well as diminished lesion size and number of Fluoro-Jade B positive cells. Pretreatment with VGX-1027 also showed diminished functional deficit, however delayed treatment showed no significant difference. Conclusion: TLR4 shows biphasic upregulation primarily in neurons following SCI. Both genetic and pharmacologic inhibition of TLR4 appear to diminish injury severity. However, when VGX-1027 treatment is delayed until after the 6hr peak of TLR4 expression, the effect is lost, suggesting that the initial upregulation is associated with increased functional deficit. These data suggest that TLR4 signaling plays a significant role in the pathogenesis of SCI and further investigation of TLR4 inhibition as a potential therapy for acute SCI is warranted.

Abstract: The phrenic motor network is directly compromised by cervical SCI, resulting in diaphragm paralysis and impaired breathing. Despite these consequences, some limited plasticity typically occurs weeks post-injury resulting in increased interneuronal integration with the damaged phrenic network and modest improvement of diaphragm recovery. In an effort to harness and enhance this plasticity, we have engineered stem-cell derived spinal interneurons that can be transplanted directly into the injured spinal cord. We recently found that transplanting neural precursor cells (NPCs) rich with phrenic spinal interneuron precursors promotes phrenic recovery post-SCI. Building on these initial results, the present work tests the hypothesis that enriching neuronal and glial lineage restricted progenitor cells, with stem cell derived V2a and V0 spinal interneuronal (SpIN) precursors, will further enhance diaphragm recovery. Sub-acutely (1week) following a lateralized, mid-cervical contusion injury in the adult female rat (Sprague Dawley), SpIN-enriched NPCs were transplanted into the lesion epicenter. Donor SpINs also express the hM4Di receptor, allowing inhibition of these donor cells during subsequent functional assessments. Clozapine application during diaphragm electromyography is used to assess the functional contribution of donor SpINs. Initial patch-clamp and multi-electrode array recordings are used to confirm silencing *in vitro*. Pseudorabies virus tracing of the injured phrenic network has shown synaptic integration of donor NPC and V2a cells with host neurons. Ongoing analysis of functional data will provide insight into the relative contribution of these integrated cells with phrenic motor recovery. This research provides the first in depth assessment of how these donor spinal interneuron populations contribute to phrenic recovery.

Sci., The City Univ. of New York Sch. of Med., New York, NY

Abstract: Repairing the damaged corticospinal tract (CST) after spinal cord injury (SCI) is a challenge. Neuron-intrinsic and -extrinsic barriers prevent CST neurons from mounting an effective regenerative repair process. Spared CST axons also fail to achieve substantial collateral branching on their own. Augmenting neuronal activity has been shown to coax CST axons into extensive sprouting, to reestablish connectivity and restore function in pyramidotomy (PTx) and SCI models. We previously described that chronic electrical stimulation of the motor cortex (MCX) in intact rats activated mTOR and Jak/Stat signaling (Zareen et al 2018). mTOR and Jak/Stat are necessary for promoting activity-dependent axonal outgrowth and synapse formation, respectively. Importantly, we found that neuromodulation does not alter the expression levels of PTEN protein, a negative regulator of mTOR and a major target for genetic manipulation to promote axon regeneration. Instead, stimulation increases the expression levels of phosphorylated PTEN (pPTEN). This post-translational modification of endogenous PTEN at Ser380 residue suppress PTEN activity in tumor studies (Vazquez et. al 2000; Das et. al 2003). CST sprouting after neuromodulation is remarkably similar to that following PTEN gene deletion. Our laboratory has identified that after PTx and SCI, CST sprouting is promoted following electrical stimulation protocols: high frequency multipulse stimulation (MPS), intermittent theta burst stimulation (iTBS) and cathodal trans-spinal direct current stimulation (c-tsDCS). In this study we ask if pPTEN protein, the deactivated form of PTEN, and mTOR activation are common to these three neuromodulation protocols. Additionally, to understand when this growth-promoting program switches on, we examined their expression levels and extent of CST sprouting at various time points. We find that short-term MPS activates mTOR, does not deactivate PTEN, and does not result in CST sprouting. This indicates a dissociation between PTEN and mTOR and that insufficient pPTEN levels do not lead to sprouting. In contrast, long-term MPS and c-tsDCS activate mTOR signaling, deactivate PTEN, and produce concurrent CST sprouting. Both short- and long-term iTBS result in mTOR activation, PTEN deactivation and CST sprouting. Finally, there is long-term persistence of PTEN deactivation following MPS and iTBS. Thus, PTEN deactivation via phosphorylation is a key mechanism for activity-dependent CST sprouting, can potentially serve as its biomarker and its persistence can help define the length of therapeutic neuromodulation a patient needs to undergo in clinical settings.

Title: Astrocytic Rac1 Contributes toFibroticScarFormation after SCI: ALongitudinal IntravitalImaging Study

Authors: M. L. REIMER[1], C. BENSON[2], S. G. WAXMAN[3], ***A. TAN**[4];
[1]Neurol., Yale University/Dept of VA, West Haven, CT; [2]Neurol., Yale Univ., New Haven, CT; [3]Neurol., Yale University, Neurosci. and Regeneration Res. Ctr., West Haven, CT; [4]Yale University/VA Connecticut Healthcare Syst., West Haven, CT

Abstract: A major challenge in SCI research is identifying biological factors that underlie dysfunction and developing mechanism-based treatments to restore function. Our prior work has shown that astrocytes contribute to fibrotic scar formation at the spinal injury site. However, these published studies were performed in vitro or in a post-mortem setting, only, which prevented a direct physiological analysis of astrocytic scar development. Here, we leveraged our whole-animal, spinal intravital imaging platform to measure the impact of Rac1 activity in astrocytic scar formation within live spinal cord tissue with a spinal injury.

We hypothesized that Rac1 activity is required for rapid fibrotic scar development after SCI and may contribute to inhibiting axonal regrowth. This work is an opportunity for advancing our effort in the search for novel interventions and more effective clinical treatment strategies for SCI and its related complications.

In transgenic mice with astrocytes expressing a fluorescent reporter, and a normal Rac1 or conditional Rac1 knockout (Rac1 KO) phenotype, we implanted a “glass window” over a spinal cord stab injury. Image series over a two week period were analyzed for the proliferation and migration of astrocytes into the injury site. These in-depth longitudinal analyses of the fibrotic scar in vivo revealed both linear and volumetric changes of the scar tissue. Behavioral studies were also performed to assess functional recovery after SCI.

Our in vivo morphological observations demonstrate that the lack of Rac1 in astrocytes reduced the speed of fibrotic scar formation; suggesting that astrocytes decrease migration or proliferation into the injured region, as compared with controls.

Taken together, our study provides a specific and physiologically relevant understanding of the temporal dynamics of astrocyte behavior in fibrotic scar formation after SCI. This work complements and extends our preclinical SCI research space, which seeks to identify and validate novel treatments for SCI/D.

Title: Characterizing chromatin accessibility changes identifies CTCF as transcriptional repressor of CNS regeneration

Authors: *Y. CHENG[1], F. TIAN[2], Z. HE[2], D. H. GESCHWIND[1];
[1]UCLA, Los Angeles, CA; [2]Children's Hosp Boston, Boston, MA

Abstract: The inability of adult neurons to regenerate long axons within the CNS is a major impediment to improving outcome after spinal cord injury, stroke, and other CNS insults. How CNS neurons can acquire a growth-permissive state after being damaged is a central question in the field of neural repair. A specific cell state ultimately represents the readout of a specific gene expression program, driven by epigenetic regulatory events including transcription factor (TF) binding and chromatin remodeling. We hypothesize that chromatin regulations of growth-associated gene programs play a major role in setting the permissive or non-permissive growth state between the regenerating and non-regenerating neurons. Here, we leveraged chromatin accessibility and transcriptomic analysis of CNS-injured neurons, predicting CTCF as negative regulator of chromatin state associated with growth-associated gene transcription. Coupling with *in vivo* CRISPR/Cas9 perturbations, we experimentally validated the bio-informatic predictions, showing that mature mice bearing cell type-specific deletions of CTCF displayed improved optic nerve regeneration. As part of the insulator protein complex that organizes chromatin into sub-domains to control enhancer-promoter interactions, CTCF could act on growth-associated transcription through modeling the chromatin structure. This prediction is supported by chromatin accessibility measurement of CNS-injured neurons with or without CTCF deletion, where we observed a number of peaks differentially accessibility when CTCF is ablated. The core chromatin regulatory mechanisms of CTCF on regenerative gene programs will be further investigated via integrating chromatin structure and transcriptomic analysis.

Title: The role of GABA presynaptic inhibition in hyperreflexia in forelimb and hindlimb muscles after acute and chronic unilateral corticospinal injury in rats

Authors: *T. BETHEA[1,2], J. MARTIN[1,2];
[1]Dept. of Molecular, Cellular, and Biomed. Sci., Ctr. For Discovery and Innovation,City Univ. of New York Sch. of Med., New York, NY; [2]CUNY Neurosci. Collaborative(CNC) Program, Grad. Ctr. of the City Univ. of New York, New york, NY

Abstract: Hyperreflexia is a consequence of spinal cord injury (SCI). A better understanding of the mechanisms driving hyperreflexia is essential for the optimization of rehabilitative therapies that can restore quality of life to SCI patients. Excitatory proprioceptive afferent (PA) sprouting is one of several mechanisms underlying hyperreflexia. We previously demonstrated activity-dependent competition between PAs and the corticospinal tract(CST), whereby muscle electrical stimulation produced PA sprouting, increased PA connections, and reduced CST connections. Following a pyramidal tract lesion (PTX), and the associated loss of CST projections, we observed PA sprouting and an increase in excitatory PA terminals on motoneurons. Another potential mechanism for hyperreflexia is reduced GABAergic presynaptic inhibition (GABApre) of PA terminals on motoneurons. GABApre are involved in the normal regulation of PA afferent terminal excitability. There is evidence of changes in presynaptic inhibition after ischemic stroke in mice, as well as following bilateral pyramidal lesion in rats.In this study we examine these two mechanisms to understand whether a reduction in GABApre regulation further augments excitability in addition to PA sprouting, or if GABApre appropriately regulates newly sprouted afferent terminals after CST injury. Further, we expect persistent hyperreflexia to accompany reduced GABApre regulation in chronically injured animals. We compared naïve, and PTX animals. Injury was followed by weekly H-reflex assessments of rate dependent depression (RDD). At the end of the experiment, animals were injected with cholera toxin subunit b (CTB) to trace PA fibers and identify motoneurons. PA terminals were labeled with Vglut1, and GABApre with GAD65. Motoneurons were individually imaged, reconstructed, and analyzed using Imaris 3D Software. Morphological results acquired 10 days post-PTX show similar and significant increases in excitatory PA terminals on motoneurons in both the cervical and lumbar spinal cord of PTX compared to naïve animals. This indicates PA sprouting after loss of CST. Comparison of the ratio of GAD65 to Vglut1, which indicates the proportion of PA terminals receiving GABApre, revealed a significant reduction in GABApre in the cervical, but not lumbar cord. This suggests impaired GABApre regulation of PA terminals in the cervical, but maintained regulation in the lumbar spinal cord, despite PA sprouting at both levels. H-reflex experiments are ongoing to test the hypothesis that hyperreflexia will be stronger in the cervical than the lumbar cord.

Title: Single-cell RNA-seq analysis of axoplasm transcriptomes from growing, static and retracting axon tips in the lamprey spinal cord

Authors: *L.-Q. JIN[1], Y. ZHOU[3], Y.-S. LI[4], G. ZHANG[1], J. HU[1], M. E. SELZER[1,2];
[1]Shriners Hosp. Pediatric Res. Ctr., [2]Dept. of Neurol., Lewis Katz Sch. of Med. at Temple Univ., Philadelphia, PA; [3]Bioinformatics and Biostatistics Facility, Fox Chase Cancer Ctr., Philadelphia, PA; [4]DNA Sequencing and Genomics Core Facility, NHLBI, Bethesda, MD

Abstract: Local protein synthesis in axon tips plays an important role in axon regeneration. Microarray or next-generation technologies studies in mammals have shown that axon growth cones contain hundreds to thousands of mRNAs. Most of these studies were performed on cultured embryonic or early postnatal peripheral neurons. To confirm that local protein synthesis is involved in CNS axon regeneration after spinal cord injury *in situ*, and to identify key proteins responsible for axon growth or retraction, we micro-aspirated axoplasm from 10 growing, 9 static and 5 retracting tips belonging to large reticulospinal neurons of lamprey larvae approximately 4 years old, and performed 2x100 bp paired end read sequencing on Illumina Novaseq 6000 System. Three lists of genes that were differentially expressed between growing tips and retracting tips (group A=1488 genes), growing tips and static tips (group B = 151), and static tips and retracting tips (group C = 1067) were identified (FC >= 1.5, FDR <= 20). Gene ontology enrichment analysis using DAVID (v. 6.8) for Group A genes revealed that they are involved in ribosome biogenesis, mitochondrion function, endocytosis, RNA degradation or splicing, axon guidance, and multiple pathways such as the PI3K-Akt, mTOR, MAPK, AMPK signaling pathways. Analysis of the Group B genes revealed that they are involved in ribosome biogenesis, RNA transport, amino acid metabolism, nucleotide metabolism and multiple signaling pathways including the PI3K-Akt, MAPK, ErbB, Ras, Wnt pathways. Analysis for the Group C genes indicated that they have very similar functions to Group A genes in participating ribosome biogenesis, amino acid metabolism, nucleotide metabolism, endocytosis, axon guidance, RNA degradation and splicing, and multiple signaling pathways. These results indicate: A) more genes are expressed in growing tips or static tips than in retracting tips, except genes for c-terminus binding proteins, which are more highly expressed in retracting tips than in growing tips. The significance of this is unknown. B) Genes found in growing tips are functionally similar to those found in static tips. C) Multiple signaling pathways that are known to be involved in axon regeneration are present in the axoplasm of growing and static tips, but are missing or incomplete in retracting tips.

Title: Clearing through the lesion site after spinal cord injury using iDISCO+

Authors: *F. L. JALUFKA[1], S. W. MIN[1], M. E. PLATT[1], D. A. MCCREEDY[1,2];
[1]Biol., [2]Texas A&M Inst. for Neurosci., Texas A&M Univ., College Station, TX

Abstract: Spinal cord injury (SCI) triggers a diverse array of processes including cell death, inflammation, and scarring. In contusion injuries in mice, the SCI site typically forms into a dense lesion filled with fibroblasts, macrophages, and extracellular matrix (ECM) components that is surrounded by layers of reactive astrocytes and other cell types, which are collectively referred to as the glial scar. While the glial scar limits expansion of the spinal cord lesion and prevents further damage to the cord by the lesion, it may also inhibit axon regeneration and functional recovery. Optical tissue clearing techniques can allow for the close study of whole tissues and the use of 3D imaging for analysis can enable the up-close study of glial scarring and lesion formation after SCI. Optical tissue clearing works by removing lipids and proteins that scatter light, either through the use of detergents such as sodium dodecyl sulfate or organic solvents such as dichloromethane, and then equilibrating the refractive indices of the tissue to match with the imaging medium thus rendering the sample optically transparent. These cleared samples can then be imaged using a lightsheet microscope and the resulting images can be rendered in 3D through computer software such as Imaris. One issue that arises with using optical tissue clearing techniques is that efficient clearing of the sub-acute and chronically injured spinal cord using aqueous-based clearing protocols, such as CLARITY and the passive CLARITY technique (PACT), has proven to be problematic due to the dense ECM deposition within the lesion site by 10-14 days post-SCI. Organic-based clearing methods such as iDISCO+ have been previously shown to clear ECM-rich tissues and may be suitable for clearing the sub-acute and chronic SCI lesion. In this study, the organic optical clearing technique iDISCO+ was tested for its ability to clear the sub-acute lesion site following a contusion SCI. Injured spinal cord tissue was collected 14 days post-SCI and cleared with a modified iDISCO+ protocol, utilizing ethyl cinnamate (ECI) instead of dibenzyl ether (DBE) for the final refractive index matching step. The modified iDISCO+ protocol successfully cleared the spinal cord lesion site and enabled 3D lightsheet imaging of immunofluorescent labeling for the entire spinal cord tissue and specifically the site of injury. Further optimization of the iDISCO+ protocol will enable the robust interrogation of the glial scar and lesion formation after SCI using 3D lightsheet imaging.

Title: Interaction between autophagy initiator ULK1 and SARM1 in axonal degeneration

Authors: *H. M. C. CHOI, Y. LI, J. WU, M. M. LIPINSKI;
Univ. of Maryland Sch. of Med., Baltimore, MD

Abstract: Autophagy is a cellular catabolic pathway involving the formation of double-membrane vesicles called autophagosomes which sequester cell contents including proteins and organelles and deliver these cargoes to lysosomes for degradation. Autophagy is generally thought to be neuroprotective. However, previous studies found that inhibition of autophagy can delay axonal degeneration in primary dorsal root ganglion neurons and optic nerve injury models. The underlying molecular mechanisms remain unclear. We thereby examined the role of autophagy in axonal degeneration using mouse traumatic spinal cord injury (SCI) model. Consistent with the potential involvement of autophagy in axonal degeneration after SCI, we observed accumulation of the autophagosome marker LC3 and the autophagy initiator ULK1 in the axonal bulbs and injured axons after contusive SCI in mice. Phospho-ATG13, a marker of ULK1 kinase activity, also increased in the $LC3^{+}$ axonal bulbs, indicating that ULK1 is activated. This suggests activation of autophagy in the injured axons and potential relationships between autophagy pathway, ULK1 activity and axonal degeneration after SCI. Interestingly, SARM1, a TIR domain protein with pivotal role in axonal degeneration, was also found to colocalize with ULK1 in axonal bulbs and axons, suggesting potential interaction between autophagy and SARM1-mediated axonal degeneration. Consistent with this notion, in our *in vitro* experiments, ULK1 inhibitor SBI0206965 attenuated neurite fragmentation and reduced SARM1 puncta formation in neurites of primary cortical neurons upon glutamate excitotoxicity. Furthermore, our immunoprecipitation data demonstrated that ULK1 can physically interact with SARM1 in HEK293T cells. These findings suggest a crosstalk between autophagy and axonal degeneration pathways by ULK1-SARM1 interaction. Supporting the hypothesis of autophagy regulating SARM1 in axonal degeneration, we found that axonal accumulation of SARM1 was decreased after SCI in *Becn1*$^{+/-}$ autophagy hypomorph mice as compared to WT controls. Further study will be required to directly manipulate ULK1 *in vivo* to examine the effects on ULK1-SARM1 interaction and axonal degeneration after SCI.

Title: Aav-mediated overexpression of mir-26a stimulates regeneration in the central nervous system in vitro

Authors: *C. R. O. CYRINO[1], C. G. FERREIRA[2], R. A. A. COSTA[2], V. U. S. MATOS[2], L. CALDI-GOMES[4], U. MICHEL[5], V. T. RIBAS[3];
[2]Morphology, [3]Dept. of Morphology, [1]Federal Univ. of Minas Gerais, Belo Horizonte, Brazil; [4]Tech. Univ. of Munich, Munich, Germany; [5]Univ. of Göttingen, Göttingen, Germany

Abstract: The central nervous system (CNS) neurons have low capacity for functional axon regeneration in part due to an imbalance in gene expression. Thus, investigating the role of molecules that control gene expression, such as microRNAs, may lead to the identification of novel targets to treat neurodegenerative disorders. MicroRNAs are small non-coding RNA molecules involved in the post-transcriptional regulation of gene expression. Recent studies highlighted the importance of microRNAs, such as miR-26a, in axonal regeneration control. The miR-26a promotes neurite outgrowth and axonal regeneration in the peripheral nervous system, by targeting mRNAs that encode proteins directly related to regeneration pathways, such as PTEN and GSK3β. However, the role of miR-26a in axon regeneration in the CNS is still not completely known. In the present study, we tested whether the overexpression of miR-26a promotes regeneration of CNS neurons in vitro. We produced recombinant adeno-associated viral (rAAV) vectors expressing miR-26a (rAAV.miR-26a) or EGFP (rAAV.EGFP), as control. Both vectors express EGFP fluorescent protein for identification of transduced neurons. All animal experiments were approved by the ethics committee for animal experiments of the Federal University of Minas Gerais. We used primary cortical neuron culture of Wistar rats at embryonic age 18 days to evaluate AAV transduction efficiency, neurite regeneration after scratch lesion and using a microfluidic device. Quantifications were done in a blinded fashion. We also did an in silico analysis to evaluate the mRNA targets of miR-26a. Both viral vectors showed proper and efficient transduction of primary cortical neurons, showed by positive expression of the reporter gene EGFP. In the neurite regeneration analysis, we found a significant increase in neurite length in the group transduced with rAAV.miR-26a compared to the control rAAV.EGFP. We also found that rAAV.miR-26a significantly increased the number of neurites at a distance of 200μm from the lesion border. Finally, in the in silico evaluation, we found 164 predicted and 33 validated mRNA targets of the miR-26a. Gene ontology analysis showed that some of these targets are involved in biological process and molecular function related to axon growth. These results suggest that miR-26a might control the regeneration of CNS neurons in vitro, however, further experiments are required to confirm this pro-regenerative effect in vivo. Therefore, this study points to the miR-26a as an interesting therapeutic target to promote regeneration in the CNS.

Title: Role of Hedgehog signaling in the differentiation of motor and sensory neurons during spinal cord regeneration

Authors: M. R. KRUEGER, A. M. HAMILTON, *L. BORODINSKY;
Univ. of California Davis, Sacramento, CA

Abstract: Spinal cord injuries often result in loss of spinal cord neurons and atrophy of denervated muscle, causing devastating consequences to sensorimotor function and quality of life. Functional recovery depends on successful regeneration of the injured spinal cord and muscle. However, the signaling mechanisms that promote regeneration are unclear. Our previous studies have shown that Hedgehog (Hh) signaling is necessary for spinal cord and muscle regeneration in the tail of amputated larvae by enabling replenishment of neural stem cells and overall spinal cord outgrowth. Whether replenishing of motor and sensory neurons in the regenerating spinal cord is dependent on Hh signaling remains unknown. Here we investigate the signaling pathways that regulate the regeneration of motor and sensory neurons in *Xenopus laevis* larvae. Two-day old larvae were tail-amputated, allowed to regenerate for 2-4 days in the presence or absence of modulators of Hh signaling and processed for immunostaining for Sox2 (neural stem cell nuclei), HNK1 (sensory neuron axons), 3A10 (motor neuron axons), and HB9 (motor neuron transcription factor). The samples were then imaged and analyzed for sensory and motor neuron axonal density, and motor neuron number and localization. Preliminary data show that there is a decrease in the density of HNK1-labeled processes in the tail between 2 and 3/4 days post amputation (dpa), suggesting an initial overgrowth followed by pruning of sensory axons innervating the regenerated tail. Inhibiting Hh signaling by incubating larvae for 3 dpa with 10 μM cyclopamine, antagonist of Hh signaling effector Smoothened, increases sensory neuron axonal density by nearly 2-fold compared to larvae with enhanced Hh signaling by incubation with 1 μM SAG, Smoothened agonist. Motor neuron axon staining reveals that they are present in the regenerating tail as early as 3 dpa and run along the longitudinal axis of the larvae, but do not align with the dorsoventral axis of muscle chevrons, as observed in the stump, which may correlate with the lack of muscle chevrons in the regenerate. Motor neuron somas were detected in the regenerated spinal cord up to 300 μm from the amputation plane at a similar density as in the spinal cord of the stump. Current efforts are investigating the dependence of motor neuron regeneration on Hh signaling. These results suggest that sensory innervation of the regenerating skin remodels with the progression of regeneration in a Hh signaling-dependent manner. The presence and organization of motor neurons and their axons in the regenerating spinal cord alludes that by 3 days post injury, the spinal cord is resuming motor function in the regenerating tail.

Res. Inst., Calgary, AB, Canada

Abstract: Rationale: Impairment of baroreflex is linked with numerous diseases including autonomic dysreflexia (AD), a condition that emerges after spinal cord injury (SCI) at or above the T6 spinal segment involving dysregulation of the autonomic control. Specifically, the absence of autonomic regulation in response to somatic or visceral stimulation below the SCI results in unmodulated reflexive sympathetic activation leading to episodic hypertensive peaks that may lead to life-threatening medical emergencies such as stroke, cardiac arrest, seizure, and even death. Although approximately >50% of patients with SCI experience AD, there is no effective permanent treatment for this disorder. The impaired reflexive sympathetic activation observed below the SCI suggests independent cardiovascular responsiveness originating from the spinal cord itself, which may be contributing to the hypertensive peaks. Previous data from the Wilson lab demonstrated that thoracic sympathetic preganglionic neurons (SPNs) located at the intermediolateral column (IML) are oxygen sensitive. As vasomotor control is tightly associated with the partial pressure of gases, it is likely that the SPNs may also have a pressure sensoring capability. **Aim:** To investigate the potential sensitivity and cellular mechanisms of SPNs acting as pressure sensors in the spinal cord, independent of regulation from peripheral baroreceptors and brainstem sites. **Methods:** Male Sprague Dawley rats were used in this study (50-150 g, n=6/ group). An *in-situ* artificially-perfused thoracic spinal cord preparation combined with electrophysiology recordings from the splanchnic nerve was performed to determine if sympathetic activity could be modulated by hypotensive events (40 mmHg) independent of descending baroreceptor inputs. Further, we investigated if ENaC and TRPM4/5 receptors might play a role in mediating pressure sensitivity in the IML. **Results:** Our results showed that hypotension stimulates the SPNs and increases sympathetic nerve activity in the absence of known baroreflexes. This response was significantly inhibited by selective ENaC and TRPM4/5 antagonists. Additionally, expression of TRPM4/5 in SPNs was confirmed using immunohistochemistry and RNAscope. **Conclusions:** These results demonstrate the potential role of thoracic SPNs as independent spinal pressure sensors, likely being regulated by the activation of TRPM4/5 and ENaC receptors present in the spinal cord. Further investigations on the pressure sensing mechanisms using *in vivo* models may reveal more effective treatment strategies to improve blood pressure control in spinal cord injured patients suffering from AD.

Title: Microrna-22 promotes neurite regeneration of central nervous system neurons in vitro

Authors: *C. G. FERREIRA[1], C. R. O. CYRINO[1], R. A. DE ALMEIDA[1], V. U. S. MATOS[1], U. MICHEL[2], L. CALDI-GOMES[3], V. T. RIBAS[1];
[1]Federal Univ. of Minas Gerais, Belo Horizonte, Brazil; [2]Univ. Med. Ctr. Göttingen, Göttingen, Germany; [3]Tech. Univ. of Munich, Munich, Germany

Abstract: The neurons that compose the central nervous system (CNS) of adult mammals have reduced axonal regeneration capacity due to intrinsic and extrinsic neuronal properties. Thus, damage to this system, including neurodegenerative diseases and traumatic injuries, can lead to permanent neurological deficits. In this sense, the search for a strategy that provides both neuroprotection and axon regeneration is crucial. The regulation of gene expression by gene transfer mediated by viral vector using microRNAs appears as a promising technique to promote the repair of CNS. The microRNAs are important in the regulatory pathways of gene expression. However, the available knowledge about their role in regeneration is still scarce. The aim of this work is to verify the role of microRNA-22 (miR-22), which has been shown to be an important regulator of neuronal survival, in neurite regeneration in the CNS in vitro. Experiments involving animals were performed with the approval of Ethics Committee for Animal Experiments of UFMG. First, we produced recombinant adeno-associated virus vectors (rAAV) expressing miR-22 (rAAV.miR-22). This rAAV vector also express mCherry fluorescent protein, allowing the identification of transduced neurons. As control, we produced a rAAV vector expressing only mCherry (rAAV.mCherry). We tested the transduction efficiency of rAAV.miR-22 and rAAV.mCherry *in vitro* using primary cortical neurons and *in vivo*, by intravitreal injection in Wistar rats to transduce retinal ganglion cells (RGCs). Then, we verified if rAAV-mediated overexpression of miR-22 promotes neurite regeneration in an *in vitro* model of scratch lesion of primary cortical neurons. Finally, we performed an *in silico* analysis to identify predicted and validated mRNA targets of miR-22 and also functional analysis for those targets. We observed that rAAV.miR-22 and rAAV.mCherry were, both, able to efficiently transduce primary cortical neurons *in vitro* and RGCs *in vivo*. *In vitro* neurite regeneration assay showed that rAAV.miR-22 increases neurite length and also the number of long distance regenerative neurites. According to the bioinformatics analysis, the miR-22 presents 178 predicted and 28 already validated mRNA targets. Functional analysis showed that these targets are related, for instance, to gene expression control, signaling pathways, anabolism and cell morphogenesis, important processes for axon regeneration. In conclusion, we showed a pro-regenerative effect of miR-22 in the CNS in vitro. Thus, this work provides a better understanding of the role of miR-22 in regeneration following CNS damage and points to miR-22 as an attractive target to promote CNS repair.

Title: Sex differences in cortical thickness and subcortical volume in knee osteoarthritis pain

Authors: *S. MONTESINO-GOICOLEA, P. A. VALDES-HERNANDEZ, A. JOHNSON, C. LAFFITTE NODARSE, J. A. PERAZA, R. B. FILLINGIM, Y. CRUZ-ALMEIDA;
Univ. of Florida, Gainesville, FL

Abstract: Osteoarthritis (OA) affects 32.5+ million adults in the US (62% women). The neurobiology underlying sex differences in OA prevalence, as well as in experimental pain sensitivity, are poorly understood. In particular, studies on sex differences in brain structure in OA are virtually inexistent. This study aimed to compare brain morphological measures (BMM) among sexes. Our sample included 145 individuals 45-85 years with knee OA from the *Understanding Pain and Limitations in Osteoarthritic Disease-2* (*UPLOAD-2*) study at the University of Florida and the University of Alabama, Birmingham. Participants completed demographic, psychological, and self-reported and experimental pain assessments. T1-weighted anatomical images were acquired with a Phillips 3T scanner. Using FreeSurfer (v.7.1.0), cortical volume and thickness (CT) and subcortical volumes were calculated in selected areas of the Destrieux atlas known to be related to pain processing (subcentral, frontal, occipitotemporal, postcentral, insulae, cingulate, hippocampi and basal ganglia). Using SPSS v26, we tested BMM differences among sexes controlling for age, race, BMI, study site, and estimated total intracranial volume. In addition, for each sex, we calculated partial correlations (Pcorr), adjusted for same covariates, between BMM and each of several clinical and experimental pain, and psycological measures. Z tests were used to compare Pcorrs between sexes. Two tailed significance was set at alpha=0.05, corrected with False Discovery Rate. CT was significantly higher in females (Fs) than in males (Ms) in the: 1) left superior segment of the circular sulcus of the insula (CSI); 2) left anterior part of the cingulate gyrus and sulcus; and, 3) right middle-anterior part of the cingulate gyrus and sulcus. The Multidimensional Scale of Perceived Social Support (MSPSS) was negatively correlated with CT of left inferior segment of CSI in Fs. Pcorr between pain duration and 1) CT of left central operculum and middle frontal gyrus, and 2) volume of left hippocampus and amygdalae were lower in Ms than Fs. Pcorr between endogenous pain modulation and 1) CT of right middle frontal gyrus, and 2) volume of hippocampi were also lower in Ms than in Fs. Pcorr between CSQ-Passive coping and 1) CT of right parahippocampal gyrus, and 2) CT of right anterior segment of CSI were also lower in Ms than in Fs. Pcorr between endogenous pain modulation and volume of right amygdala, and between MSPSS and CT of left inferior segment of CIS were higher in Fs than in Ms. We provide initial evidence for a mediating role of brain structure in sex differences in clinical and experimental pain, and associated psychological factors.

Title: Long-term imaging of spinal cord neural activity in awake, behaving mice

Authors: B. AHANONU[1], A. CROWTHER[1], M. ROSA CASILLAS[2], A. BASBAUM[1];
[1]Dept. of Anat., [2]Neurosci. Grad. Program, Univ. of California San Francisco, San Francisco, CA

Abstract: Pain and itch are complex, multidimensional percepts that require integration of incoming sensory information from the spinal cord with ongoing brain states to produce appropriate protective behaviors. It follows that studying this sensorimotor integration requires experiments in behaving animals. To date, however, unlike widely adopted techniques for imaging neuronal activity in the brain, the dorsal horn of the spinal cord presents major technical limitations for activity monitoring in awake animals. Thus, with very few exceptions, spinal imaging studies have been performed in anesthetized animals. That limitation precludes faithful study of stimulus-evoked activity in the awake preparation and cannot correlate activity changes over time in the same, genetically-defined neurons with behavioral endpoints of chronic pain or itch nor assess novel pain or itch treatments. A breakthrough, therefore, could result from the development of a durable spinal imaging method that permits longitudinal analysis of single neurons in awake, behaving animals. Building upon earlier methods to image the spinal cord *in vivo* (1,2,3), we have devised a microsurgical protocol to implant a custom-made metal chamber adjacent to vertebrae that, following laminectomy and glass window placement, provides stable optical access to superficial lamina of the lumbosacral spinal cord. Additional material components provided a critical feature, namely, long-term fibrosis inhibition. Our preparation achieved long-term optical clarity, for over three months postoperatively, and proved conducive to daily imaging via widefield and multiphoton time-lapse microscopy in awake, behaving mice. We demonstrate that this method allows long-term tracking of fine axonal structure in Thy1-GFP mice and repeated GCaMP-based calcium imaging of single-cell neural activity. Further, we observed neural responses to different somatic stimuli (noxious mechanical and thermal) that are somatotopically organized over the millimeter field-of-view. Importantly, using physiological measures, sensory and locomotor behavioral assays, and post-mortem histology, we verified spinal cord and animal health post-surgery. Our cost-effective method can empower future studies that aim to address outstanding questions about the processing of pain and itch messages, the longstanding labeled line vs. patterning controversy, referred pain and visceral organ cross-sensitization mechanisms, and spinal action of traditional and novel analgesics. 1. Title: Large scale momentary brain network behavior mediates action of insular excitatory-inhibitory neurotransmitter imbalance on chronic pain hypersensitivity

Authors: I. MAWLA[1], Z. HUANG[1], S. E. HARTE[1], D. J. CLAUW[1], G. A. MASHOUR[1], V. NAPADOW[2], R. E. HARRIS[1];
[1]Anesthesiol., Univ. of Michigan, Ann Arbor, MI; [2]Martinos Ctr. for Biomed. Imaging, Massachusetts Gen. Hosp., Charlestown, MA

Abstract: Background: Chronic nociplastic pain conditions such as Fibromyalgia (FM) are characterized by focal insular neurotransmitter imbalances (excitatory - inhibitory imbalance; E-I) as well as global brain network dysfunction. It is unknown if regional E-I imbalances impact large scale brain networks resulting in pain hypersensitivity.

Methods: Brain imaging was done on 64 females with Fibromyalgia (FM) and 19 healthy controls (HC). Proton magnetic resonance spectroscopy was collected in the right anterior insula (aINS) to calculate E-I balance using ratios of Glutamate+Glutamine to gamma-aminobutyric acid. Functional MRI was collected at task-free (REST) and tonic cuff pressure pain (PAIN) over the left lower leg. Temporal *k*-means clustering was conducted on REST across subjects to capture whole-brain momentary coactivation patterns (CAPs) at single timepoints. A supervised learning approach using REST CAPs was then applied to PAIN. Occurrence rates were computed as the presence of any particular CAP relative to total timepoints per subject. In addition, conventional whole-brain functional connectivity of the aINS was computed.

Results: FM patients required lower cuff pressure (p=0.0002) to evoke comparable painful experience to HC. Lower cuff pressures were associated with greater aINS E-I imbalance (r=-0.34) and pain interference (r=-0.32) in FM. Clustering produced eight distinct CAPs; support vector classification on pain-induced CAP occurrence rate changes (PAIN-REST: ΔP) distinguished FM from HC with 76% accuracy. In FM, ΔP decreased (p<0.0001) in a CAP with positive Salience/negative Default Mode (SLN+/DMN-), and ΔP increased (p=0.0004) in a CAP with positive sensorimotor/negative limbic (SMN+/Limbic-). Larger ΔP decrease in SLN+/DMN- was associated with greater pain interference (r=-0.29) and larger aINS E-I imbalance (r=-0.35). Larger ΔP increase in SMN+/Limbic- was related to greater pain interference (r=0.36) and lower cuff pressure (r=-0.36). The effect of cuff pressure on pain interference in FM was mediated by SMN+/Limbic- ΔP (indirect effect, BootCI=[-.0090,-.0007]). Whole-brain regression showed lower SLN+/DMN- ΔP was related to greater aINS-posterior cingulate (r=-0.51) and aINS-medial prefrontal (r=-0.50) connectivity. The effect of aINS E-I imbalance on aINS-posterior

cingulate connectivity in FM was mediated by SLN+/DMN- ΔP (indirect effect, BootCI=[.032,1.093]).

Conclusions: Hypersensitivity in chronic pain is mediated by a disruption of large scale dynamic brain patterns. In part this is initiated by increased excitability of the aINS leading to increased communication between SLN and DMN networks.

Sch., Boston, MA; [6]Dept. of Anesthesiol., Perioperative and Pain Medicine, Brigham and Women's Hosp., Boston, MA

Abstract: Background & Aims: Migraine, a highly prevalent chronic pain disorder, involves sensitization of the trigeminal nerve system. Neuroimaging technologies offer a non-invasive, in-vivo approach to study the trigeminal nerve properties in humans. Notably, diffusion tensor imaging (DTI) studies have demonstrated microstructural alterations at the trigeminal nerve root in chronic pain conditions such as trigeminal neuralgia and temporomandibular disorder. However, the trigeminal nerve microstructure in migraine has not yet been adequately explored. We used ultra-high field (7 Tesla) DTI, allowing for improved spatial resolution, to evaluate the association between trigeminal nerve microstructural properties and clinical characteristics in episodic migraine. Methods: We enrolled 16 patients with episodic migraine in an ongoing treatment study (15F, mean age +/- SD: 38.1 +/- 13.5 yrs). All patients underwent a 7 Tesla DTI scan (64 directions, b=1,000, 1mm isotropic voxels) and self-reported clinical characteristics of their condition, including migraine disease duration (yrs), number of headache days/month, average headache duration (hrs), average headache pain intensity (0-10), and interictal phase (0-100; timing of DTI assessment relative to preceding (0) versus subsequent (100) attacks). DTI metrics of fractional anisotropy, axial, radial, and mean diffusivity were manually extracted from the root entry

zone of both trigeminal nerves. Spearman's rank-order correlations were performed to determine the association between each DTI metric and clinical measure. Results: High spatial resolution imaging successfully delineated the small-scale structure of the trigeminal nerve roots. There was a significant, negative correlation between axial diffusivity (AD) and disease duration (r=-0.55, p=0.029), and interictal phase (r=-0.53, p=0.043), such that AD was reduced with greater time since diagnosis and as patients approached their next attack. There was also a significant, positive correlation between AD and the number of headache days/month (r=0.57, p=0.022), such that AD was greater with more headaches experienced. No other significant correlations were observed. Conclusions: Trigeminal nerve root AD, a metric of axonal integrity, was correlated with disease duration, interictal phase, and the number of headache days per month. These preliminary results suggest both trait-like (i.e., disease duration, severity) and state-like (i.e., interictal phase) links to trigeminal nerve microstructure. Trigeminal nerve root remodeling may be an important aspect of the dynamics underlying migraine pathophysiology.

Title: Dynamics of theta oscillations in the mouse primary somatosensory cortex represent the ongoing status of pain sensation

Authors: *M. TAMURA[1], S. IWAMOTO[2], A. SASAKI[2];
[1]NeuroDiscovery Lab., Mitsubishi Tanabe Pharma Holdings America, Cambridge, MA; [2]Mitsubishi Tanabe Pharma Corp., Yokohama, Japan

Abstract: Pain, one of the most unpleasant sensations, is caused by tissue injury, inflammatory disease, pathogen invasion, and neuropathy. While several features of brain activity can represent the painful perception, predicting pain variability within a given individual and across individuals is difficult. Here, we examined oscillation dynamics of local field potentials to assess neuronal activity in the mouse primary somatosensory cortex, which is responsible for processing bodily pain, pressure, heat, cold, and vibration sensations. We found that the peak of theta-range oscillations (4-12 Hz) was shifted toward a slower frequency in response to a pain-induced stimulus following a peripheral formalin injection, which usually shows a bimodal behavioral response interposed between pain free periods. Importantly, the instantaneous theta-peak frequency inversely correlated with ongoing pain sensation. Instantaneous oscillatory analysis also revealed that the probability of slow theta oscillations increased during nociceptive phases associated with augmented slow theta power. Finally, phase-power cross-frequency coupling between theta and gamma oscillations demonstrated that the coupling peak frequency of theta oscillations was also shifted toward slower oscillations without affecting coupling strength or gamma

power. Together, these findings indicate that the dynamic changes in theta oscillations in the primary somatosensory cortex represent the ongoing status of pain sensation.

Title: Mapping neuronal activity provoked by general anesthesia-induced analgesia

Authors: *C. D. LIU[1], J. A. P. WEINRICH[2], M. E. JEWELL[2], C. R. ANDOLINA[2], J. M. BRAZ[2], A. I. BASBSAUM[2];
[1]Neurosci. Grad. Program, [2]Anat., Univ. of California San Francisco, San Francisco, CA

Abstract: Nitrous oxide (N_2O) is a fast-acting, weak general anesthetic that produces analgesia without loss of consciousness. Previous studies suggest that N_2O induces analgesia by engaging periaqueductal gray (PAG)-mediated descending inhibitory controls. Importantly, as N_2O is increasingly used for treatment-resistant major depressive disorder, N_2O anesthesia presents a unique opportunity to concurrently study the sensory-discriminative and the affective components of the pain experience. Based on its analgesic properties and on previous literature, we predicted that N_2O would decrease neuronal activity in the anterior cingulate cortex (ACC), which is implicated in pain's affective component. Surprisingly, however, N_2O exposure results in rapid, robust activation of ACC neurons (see Weinrich et al. poster). As the ACC provides excitatory input to the PAG, we hypothesized that N_2O-mediated analgesia involves cortically-mediated activation of PAG-derived descending controls. In adult male and female double transgenic TRAP2-Ai14 mice, we captured and compared brain-wide activity patterns in response to subanesthetic doses of N_2O and isoflurane, a sedating general anesthetic that induces unconsciousness. To permanently label neurons that were transiently activated during anesthesia, mice were injected with 4-hydroxytamoxifen and exposed to one hour of N_2O or isoflurane. Two weeks later, mice were exposed to one hour of a different gas and perfused one hour later for Fos immunostaining. We collected confocal images and used Imaris for cell counting and quantification. In both anesthesia experiences, we observed robust Fos+ labeling throughout the brain compared to control conditions, including in the ACC. This dose-dependent effect of anesthesia-induced activity is consistent with our calcium imaging data. We also observed Fos+ labeling in several pain-associated areas downstream of the ACC (e.g. PAG), but not in others (e.g. mediodorsal nucleus of the thalamus (MD)). Downstream regions

with higher N_2O-Fos+ labeling included the somatosensory cortex; regions with higher isoflurane-Fos+ labeling included the bed nucleus of the stria terminalis. Our findings suggest that the canonical understanding of ACC encoding of pain aversion ignores a differential contribution of cell type, layer specificity, and most importantly, projection target of the ACC neurons (e.g. PAG but not MD). Ongoing work includes identifying the cell types and projection targets of Fos+ neurons in the ACC and characterizing the extent to which N_2O and isoflurane activate distinct, non-overlapping, populations of neurons in the same regions.

Title: The multisensory integration between nociception and vision in the rubber hand illusion

Authors: *S. COPPI, H. EHRSSON;
Neurosci., Karolinska Inst., Solna, Sweden

Abstract: Body ownership refers to the subjective perception of the body as one's own. The classic way to study body ownership in healthy individuals is to use a perceptual bodily illusion known as the rubber hand illusion (RHI). In the RHI, a rubber hand in the participant's view is synchronously stroked with the real hand hidden behind a screen. After ~20s of such stimulation, most participants start to experience the touches as originating directly from the rubber hand and that they own the rubber hand. Previous studies have demonstrated that this illusory percept arises from the integration of vision, tactile and proprioceptive signals. However, little is known about the role of nociceptive input to body ownership and the rubber hand illusion. Here we investigate the contribution of nociceptive signaling to body ownership by a "visuo-nociceptive RHI". To selectively activate nociceptors in the skin, we used Nd:YAP laser stimulator (Stimul 1340, Deka, 1.34 μm wavelength, 7 ms pulse) that specifically targets C and Aδ fibers. We recruited 90 naïve healthy participants over three separate experiments. In Experiment 1 we investigated the subjective experience of the visuo-nociceptive RHI with an 8 items questionnaire. We compared a condition with synchronous visual (a brief red light shining on the fake hand) and nociceptive stimulation on the rubber hand with a control asynchronous condition (the nociceptive input had 1000 ms delay compared to the red light). Experiment 2 used the same two conditions but quantified the illusion objectively with a proprioceptive drift task that registers the changes in hand position sense towards the rubber hand that occurs during the illusion and that is probed by asking the participants to close their eyes and point towards the location of their index finger. Finally, in experiment 3 we manipulated the spatial congruence of the orientations of the rubber and real hands. In the illusion condition, the rubber hand was placed in the same position as the real hand (0°) whereas in the control

condition the rubber hand was rotated 180°; we used the proprioceptive drift task. The results of Experiment 1 showed that people rated illusion-related items significantly higher in the synchronous condition than in the asynchronous condition ($p < .01$). In Experiment 2, the proprioceptive drift was significantly higher in the synchronous compared to the asynchronous condition ($p = .01$). Finally, in Experiment 3, the proprioceptive drift was significantly larger in the 0° condition compared to the 180° ($p = .001$). In conclusion, our results suggest that the RHI can be triggered by congruent nociceptive and visual signals and have a bearing on models of body ownership.

Title: The role of anterior cingulate cortex for active defensive response in pain processing

Authors: *J.-Y. LEE, T. YOU, G. IM, H. SEO, C.-H. LEE, S.-G. KIM;
CENTER FOR NEUROSCIENCE IMAGING RESEARCH, Suwon, Korea, Republic of

Abstract: Pain is an unpleasant experience that triggers defensive avoidance responses. The anterior cingulate cortex (ACC) is a critical brain region for signaling the unpleasantness of pain. However, the role of ACC in defense circuits is not well understood. Here, we use optogenetic fMRI (ofMRI) which is a combination of optogenetic modulation and fMRI to explore downstream neural circuits of ACC. Optogenetic silencing of ACC decreased BOLD activity in divergent brain regions including defense circuits such as superior colliculus (SC) and periaqueductal gray (PAG). Noxious electrical stimulation caused a positive BOLD response at both the somatosensory circuits (S1, S2) and defense circuits (SC, PAG). However, optogenetic silencing of ACC reduced the positive BOLD response of SC and PAG but did not affect S1 and S2. Anterograde tracers showed dense projections from ACC to SC and PAG. Especially, the projection from ACC to PAG is limited to dl/l PAG associated with an active defensive response. We also demonstrate that ACC-PAG circuit contributes to pain and defensive behaviors. Optogenetic activation of ACC-PAG projections induced pain hypersensitivity without anxiety behavior and enhanced active avoidance behavior, rather than caused analgesia and freezing response (passive defensive behavior). Taken together, our results indicate that ACC is anatomically and functionally connected with PAG, which contributes to pain and defense circuits.

Title: Investigating the Effects of Flotation Restricted Environment Stimulation Therapy on Neural Networks in Chronic Pain Patients via Functional Magnetic Resonance Imaging

Authors: *T. A. MCGAUGHEY, V. S. FINOMORE, Jr;
West Virginia Univ., Morgantown, WV

Abstract: Investigating the Effects of Flotation Restricted Environment Stimulation Therapy on Neural Networks in Chronic Pain Patients via Functional Magnetic Resonance Imaging
Authors: Finomore V.S. and McGaughey T.A.
According to the CDC, there are 50 million Americans living with chronic pain from which the majority suffer from chronic lower back pain. Current clinical approaches primarily focus on analgesia via strong opioids or invasive surgical interventions; however, these management strategies fail to consider patient suffering in its entirety while mitigating other key factors of the chronic pain experience, such as higher chronic stress levels, which profoundly affect somatosensory, default mode, and other vital neural networks. Flotation Restricted Environment Stimulation Therapy (REST) is a promising intervention for stress reduction, as it has altered key brain networks of interest in healthy participants. REST flotation requires individuals to fully relax in a sensory deprivation tank specifically designed to reduce auditory, visual, thermal, and tactile stimulation. In the present study evaluating the effects of flotation REST on neural networks impacted by chronic lower back pain, participants underwent resting state and task-based functional magnetic resonance imaging (fMRI) both before and after six flotation REST sessions and compared with control participants' identical fMRI scans conducted both before and after six sessions in a zero-gravity chair, located in a warm, quiet, dimly-lit room as to mimic float tank conditions. All scans were taken on a 3T PRISMA MAGNETOM (Siemens Munich, Germany). Resting state fMRI scans were analyzed via independent component analysis through the CONN toolbox (www.nitrc.org/projects/conn), while general liner modeling through AFNI (R.W. Cox NIH) was used to analyze task-based fMRI scans. The results found significant differences in resting state connectivity in the somatosensory and default mode networks across conditions. Additionally, the experimental group, but not the control group, showed significant differences in the prefrontal cortex over time. These neural changes, coupled with subjective alterations in pain, provide promising support for flotation REST as a supplemental treatment option for chronic lower back pain, demonstrating the importance of stress management in chronic pain treatment.

Title: Analytic consistency and neural correlates of peak alpha frequency in the study of pain

Authors: *N. J. MCLAIN, M. S. YANI, J. J. KUTCH;
Div. of Biokinesiology and Physical Therapy, USC, Los Angeles, CA

Abstract: There is long-standing interest in resting-state peak alpha frequency (PAF) as a summary marker of neural activity. Several studies have found evidence of slowed resting-state peak PAF in chronic pain populations and individuals with high sensitivity to experimentally induced pain. There is some disagreement about how PAF relates to the physiology and experience of pain, and comparison across different types of pain populations is necessary. However, the stability of PAF from different analytic pipelines used in the pain literature has not been determined and underlying neural correlates of PAF have not been sufficiently substantiated in humans. Here we examine a range of analytic pipelines and the relationship of PAF to activity in the thalamus, a hypothesized generator of PAF. We collected resting-state functional magnetic resonance imaging (rs-fMRI) data and subsequently 64 channel resting-state electroencephalographic (EEG) from 48 healthy men. We identified important variations in EEG preprocessing pipelines for PAF from a review of 17 papers investigating the relationship between chronic pain and PAF. We tested three progressively more complex pipelines: Pipeline 1) notch filtering only, 2) Pipeline 1 and data re-referencing, and 3) Pipeline 2 and automatic artifact removal. Data for all three pipelines were then processed by the center-of-gravity (COG) method to determine peak frequency at each electrode. For all pipelines, a single principal component, well-represented by the average PAF across all electrodes (global PAF), explained >95% of the variance across participants. We also found that the global PAF was highly correlated among the analytic pipelines (>0.95). We additionally found interindividual differences in global PAF were significantly correlated with differences in fMRI-estimated activity in the thalamus. These results suggest that PAF is a stable marker with respect to analysis method and reflects interindividual differences in brain function.

Title: Neurophysiological improvements in speech in noise task after short-term choir training in older adults

Authors: *S. HENNESSY[1], R. WILCOX[2], A. WOOD[1], A. HABIBI[1];
[1]Brain and Creativity Inst., [2]Dept. of Psychology, USC, Los Angeles, CA

Abstract: Perceiving speech in noise (SIN) is important for health and well-being and decreases with age. Musicians show improved speech in noise abilities and reduced age related auditory decline, yet it is unclear whether short term music engagement has similar effects. In this randomized control trial we used a pre-post design to investigate whether a 12 week music intervention in adults aged 50-65 without prior music training and with subjective hearing loss improves well-being, speech-in-noise abilities, and auditory encoding and voluntary attention as indexed by auditory evoked potentials (AEPs) in a syllable in noise task, and later AEPs in an oddball task. Age and gender matched adults were randomized to a choir or control group. Choir participants sang in a 2 hr ensemble with 1 hr home vocal training weekly; controls listened to a 3 hr playlist weekly, attended concerts, and socialized online with fellow participants. From pre to post intervention, no differences between groups were observed on quantitative measures of wellbeing or behavioral speech in noise abilities. In the choir group, but not the control group, changes in the N1 component were observed for the syllable in noise task, with increased N1 amplitude in the passive condition and decreased N1 latency in the active condition. During the oddball task, larger N1 amplitudes to the frequent standard stimuli were also observed in the choir but not control group from pre to post intervention. Findings have implications for the potential role of music training to improve sound encoding in individuals who are in the vulnerable age range and at risk of auditory decline.

Title: Distraction during selective attention induces rhythmically synced neural and behavioral responses

Authors: *T.-Y. LUI, J. OBLESER, M. WÖSTMANN;
Univ. of Luebeck, Lübeck, Germany

Abstract: Attentional sampling of task-relevant sensory stimuli operates in a rhythmic manner. However, the temporal trajectory of distraction by task-irrelevant stimuli is less well understood. We have previously shown that the vulnerability of working memory to distracting speech items fluctuates rhythmically. Here, we investigate the underlying neural responses to auditory distraction, as well as the correspondence of pre-distractor neural phase with behavioral indices of distraction. In the present behavioral and electroencephalography (EEG) study, we probed the temporal dynamics of distraction using a pitch discrimination task. Human participants (N = 30) compared the pitch of two target pure tones and were instructed to ignore an intermittent, task-irrelevant distractor tone sequence with a 25 Hz temporal structure. We systematically varied the onset time of the distractor, which was presented in-

between the two target tones. The degree of distraction was measured behaviorally via the ability to discriminate the target tones (perceptual sensitivity), and neurally via the amplitude of the distractor-evoked response at 25 Hz. Linear mixed-effect models with distractor onset phase as predictor (via sine- and cosine-transformed regressors) showed that distractor onset phase in the delta and theta frequency range (~3.5–5 Hz) modulated both perceptual sensitivity and 25 Hz amplitude. Furthermore, distractor onset phase at similar frequencies co-modulated the behavioral and neural measures of distraction. In order to reveal the underlying neural sources of rhythmic distractibility, we related the pre-distractor phase of 5 Hz source-projected neural oscillations to perceptual sensitivity. The phasic modulation of sensitivity was most prominent in the left inferior frontal cortex. These results suggest that ~5 Hz phasic modulation of neural activity acts as a rhythmically fluctuating attention filter, which alternates between states of higher versus lower distractibility at a frequency of ~5 Hz.

Title: Age effects on cortical tracking of word-level features of continuous competing speech

Authors: *J. MESIK, L. RAY, M. WOJTCZAK;
Dept. of Psychology, Univ. of Minnesota, Minneapolis, MN

Abstract: Increased difficulty with speech-in-noise (SIN) comprehension commonly arise with aging, yet this deficit is often undetected by traditional speech perception measures. In recent years, electroencephalographic (EEG) studies on young normal-hearing adults identified robust neural signatures of high-level responses to semantic features and lexical predictability. Here we investigated whether these responses vary as a function of age and self-reported SIN perception difficulties. Additionally, we assessed how these measures are affected by the quantity of recorded data. Younger (18-40 yrs., n = 20) and older (41-70 yrs., n = 21) adults participated in a noninvasive EEG recording from 64 surface electrodes, while attending to one of two diotically presented audiobooks (65 dB SPL each). After each ~60 sec block, participants responded to several comprehension questions about the target story. Additionally, participants completed a modified speech, spatial and qualities of hearing (SSQ_m) scale to assess their subjective SIN perception difficulties. Transcripts of the audiobooks were separately used to generate time-resolved four-feature regressors, with each word characterized by its: 1) onset, 2) "semantic" dissimilarity from the preceding context, 3) lexical surprisal, and 4) overall audibility, reflecting the average signal-to-noise ratio. These features were regressed against the EEG signal to estimate the strength of cortical tracking of each feature, and the corresponding temporal response functions (TRF), for both attended and ignored speech. We found robust tracking of all features for attended speech, with surprisal and word audibility showing stronger contributions to neural activity than

dissimilarity. Importantly, older adults showed significantly stronger feature tracking than younger adults, especially at frontal electrode sites, potentially reflecting increased listening effort. Similar trends were observed with TRFs, albeit to a weaker degree. Moreover, we found trends of a negative relationship between SSQ_m and the overall model fit for attended speech, and a positive relationship between task performance and the overall model fit, indicating behavioral relevance of these measures. Finally, while word-level responses were detectable with just minutes of data, both the model fit and TRF estimates monotonically improved with more data up to 40+ minutes (full dataset), indicating that session duration is a critical parameter in multi-feature studies of speech processing. Our results demonstrate the potential for the use of complex, word-level features to study changes in speech processing due to aging and hearing loss.

Title: Relationship between Temporal Fluctuations in Visual and Auditory Attention and Medial Olivocochlear Reflex

Authors: *M. SUZUKI, Y. ISHIZAKA, S. OTSUKA, S. NAKAGAWA;
Chiba Univ., Chiba, Japan

Abstract: The olivocochlear bundle (MOCB) is an efferent neural pathway originating from the brainstem and terminating inside the inner ear. MOCB is activated by sounds and suppresses the amplification of outer hair cells, which is called the medial olivocochlear reflex (MOCR). MOCR is thought to play a role in improving listening in noise and protecting the inner ear from loud sounds. Several studies reported that MOCR is modulated by performing auditory and visual attentional tasks, which was revealed by comparing MOCR strength averaged across time points during each task. However, attention fluctuates from moment-to-moment during sustained performance.
In this study, we quantitatively evaluated the fluctuations in attention by measuring the reaction time to the auditory and visual discrimination task. In the auditory discrimination task, a low- (1-3 kHz) or a high-frequency (3-5 kHz) noise was presented in random order, and listeners were instructed to respond to the low-frequency noise (go signal) as quickly as possible but not to the high-frequency noise (no-go signal). In the visual discrimination task, the go and no-go signal were a cross and a circle displayed on an LCD monitor, respectively. The white noise inducing MOCR was presented simultaneously with the circles and crosses. In both tasks, the probability of appearance of the go and no-go signal was 90 and 10%, respectively. All noises were presented to the left ear at a sound pressure level (SPL) of 60 dB. MOCR was evaluated noninvasively by measuring otoacoustic emission (OAE), which are sounds physiologically emitted from the inner ear. We measured OAEs evoked by clicks presented to the right ear at the rate of 40 clicks per second and at a peak equivalent SPL of 55 dB. The OAE suppression induced by the low-frequency noise (in the auditory task) and the white noise (in the visual task) was

measured. The OAE suppression is reported to reflect MOCR strength.
The reaction time and the MOCR strength (OAE suppression) fluctuated with time on a scale of several minutes. The MOCR strength was negatively correlated with the temporal fluctuations of the reaction time for the auditory task but not with those for the visual task. The results suggest that MOCB activity decreases due to temporary insufficient attention to auditory domain, which would lead to longer response time, but is not affected by visual attention. This suggests that the higher the level of attention to hearing, the stronger the MOCR. In other words, the lack of attention to hearing suggests that MOCR may weaken the inner ear protection and increase the risk for noise-induced hearing loss.

Title: Neural representations of acoustic and spatial features interact during auditory object formation.

Authors: *K. VAN DER HEIJDEN[1], P. M. PATEL[2], S. BICKEL[4], J. L. HERRERO[5], A. D. MEHTA[6], N. MESGARANI[3];
[1]Donders Ctr. for Brain, Cognition and Behavior, Maastricht, Netherlands; [2]EE, Columbia Univ., Ahmedabad, India; [3]Columbia Univ., New York, NY; [4]Neurosurg. / Neurol., Hofstra Northwell Sch. of Med., Manhasset, NY; [5]Neurosurg., The Feinstein Inst. For Med. Res., Manhasset, NY; [6]Neurosurg., Hofstra North Shore LIJ Sch. of Med., Great Neck, NY

Abstract: In everyday life, human listeners readily extract relevant auditory objects from complex, multi-source auditory scenes. Yet, it is presently unclear how neuronal representations of acoustic and spatial features interact during auditory object formation as prior research typically required listeners to attend to a single sound feature only. Here, we address two central questions about the neuronal transformation of an acoustic-based representation into perceived auditory objects by analyzing invasive intracranial neuronal responses in neurosurgical patients measured with stereotactic electroencephalography. First, when and where in the cortical auditory hierarchy do neuronal representations of spatial and acoustic sound features interact during auditory object formation? Second, how is the transient emergence and decay of - multi-dimensional - feature and object representations affected by attention and by moment-by-moment fluctuations in energetic masking? Participants (N = 7) listened to mixtures of two concurrent, spatially separated speakers (-45° and +45°). Participants were instructed to attend to either the male or female speaker and to report the spatial location of the attended speaker at random moments in between trials to ensure simultaneous attention to spatial and acoustic features. To reveal the transient emergence of neuronal representations of acoustic features (speaker spectral profile), spatial features (location) and auditory objects (speech), we extracted the envelope of the high-gamma band (70-150Hz) and analyzed the time course of neuronal activity in primary and secondary cortical auditory regions. Our findings

show that spatial and acoustic feature representations are transformed from an acoustic-based into an attention-dependent, acoustic-invariant representation at different stages of the cortical auditory hierarchy and come together as an object representation in the superior temporal gyrus. Classifiers trained to identify either location or speaker from distributed neuronal activity patterns, revealed a transient emergence and decay of spatial and acoustic feature representations. The emergence of such representations was affected by the moment-by-moment strength of energetic masking in distinct ways for spatial and acoustic features. Taken together, these findings emphasize the multi-dimensional character of auditory object encoding in the cortical auditory hierarchy and shed new light on the interaction between the ventral and dorsal auditory stream.

Title: Brain oscillations during degraded speech perception based on prior and acoustic information

Authors: *S. SAIKAN, S. OTSUKA, S. NAKAGAWA;
Chiba University, Chiba, Japan

Abstract: Neural mechanisms underlying speech understanding have been investigated by seeking the brain areas whose activity covaries with the intelligibility of acoustically degraded speech stimuli. Typically, the intelligibility of a stimulus was modulated by giving prior information about the stimulus, e.g., presenting the original clear speech, or by manipulating acoustic information contained in the stimulus. We investigated neural mechanisms underlying the changes in the intelligibility attributed to those two types of information by measuring gamma-band electroencephalogram (EEG) oscillations. Two types of activity in gamma-band can be differentiated: evoked and induced. Whereas the evoked-gamma response is phase-locked to the stimulus onset, the induced gamma response appears with jitter in latency and is reported to be associated with high-level cognitive processes (e.g., short-term memory). Degraded speech stimuli were generated from original phrases in the form of “Ready bear go to (color) (number) now”, with the inclusion of five colors (red, blue, white, peach, rainbow) and nine numbers (0, 1, 3, 4, 6, 7, 8, 9, 10). In total, 45 original phrases were used. The intelligibility of the degraded speech stimuli was manipulated by changing the bandwidth of their formants from 20 to 200 Hz; the narrower the bandwidth of the formants, the lower their intelligibility. Listeners heard the degraded speech stimuli before and after the exposure to the original phrases. In the pre-exposure condition, listeners were required to answer color and number contained in the degraded speech stimulus, and identification performance was assessed as the correct answer rate. The percentage of correct answers was significantly increased as the formant bandwidth increased. No significant changes associated with the formant bandwidth were observed in the evoked- and induced-gamma response. In contrast, the magnitude of the induced-gamma response tended to increase after the original speech presentations regardless of the bandwidth of the formants. The

magnitude of EEG oscillations at slightly higher than gamma band (70-100 Hz) also increased after the original speech presentations. Given oscillations at the frequency range were reported to be associated with short-term memory, the results imply that processes related to short-term memory are prominent during degraded speech perception based on prior information.

Title: Reduced auditory cortical gamma-Aminobutyric acid (GABA) affects gamma-band oscillations and contributes to speech-in-noise (SIN) loss in older age

Authors: *S. DOBRI[1,2], B. ROSS[1,2];
[1]Rotman Res. Inst., Toronto, ON, Canada; [2]Med. Biophysics, Univ. of Toronto, Toronto, ON, Canada

Abstract: Difficulties in understanding speech in the presence of background noise are a significant concern for aging people. The causes of speech-in-noise (SIN) loss involve aging-related changes at all levels of auditory processing. At the level of perception, deficits in separating the speech sound from noise prevent the older listener from perceiving the target speech as a distinct auditory object and extracting meaningful information from it. The brain uses gamma frequency oscillations to organize acoustical information into auditory objects. Cortical gamma oscillations are generated through reciprocal interconnections between inhibitory interneurons and pyramidal cells, and depend on a fine balance between excitatory and inhibitory connections. Thus, the inhibitory neurotransmitter gamma-Aminobutyric acid (GABA) plays a major role in the generation of gamma oscillations.
This study investigated the associations between healthy aging, behavioural performance in SIN understanding, auditory evoked gamma oscillations, and the concentration of GABA in the auditory cortex. Gamma oscillations were recorded with magnetoencephalography (MEG) in 19 young and 19 older human adults. The level of GABA in their left and right auditory cortices was estimated using MEGA-PRESS magnetic resonance spectroscopy (MRS).
We found bilateral decreases in auditory cortical GABA levels in aging. Decreased GABA in the right auditory cortex was correlated with more severe SIN loss as assessed with QuickSIN. A MEG response suppression paradigm with fast stimulus repetition showed decreased response suppression in aging, indicating reduced ability for response inhibition. Reduced response inhibition was correlated with age but not with SIN loss. However, simultaneously elicited transient gamma-band responses increased in aging and were correlated with SIN loss. In addition, 40-Hz auditory steady-state responses (ASSR) were recorded with and without concurrent multi-talker babble noise. The 40-Hz ASSR amplitude was reduced in the noise condition compared to the no-noise condition. The amount of response reduction was smaller

in aging, and was correlated with SIN loss. The results suggest that an aging-related reduction in auditory cortical GABA impacts functionally relevant gamma band activity, contributing to SIN loss in older age.

Title: Neural tracking of target speech in multitalker speech perception reflects speaker's intelligibility

Authors: *X. HE, V. S. RAGHAVAN, N. MESGARANI;
Columbia Univ., New York, NY

Abstract: Neural responses in the auditory cortex track the acoustic envelope of speech, and this tracking is enhanced by attention to a speaker in multi-talker speech. Recent research has shown that neural speech tracking can be used to predict speech intelligibility and is closely linked to intelligibility through a range of influences, such as SNR, speech rate, visual cues, and prior knowledge. However, our current understanding of neural speech tracking is limited either by a narrow set of experimental conditions or a lack of behavioral data. Further, neural speech tracking can be leveraged for auditory attention decoding, a system used in neurally-assisted hearing devices to improve speech understanding in challenging multi-talker acoustic environments. Therefore, it is important to characterize neural speech tracking in a variety of multi-talker experimental conditions and compare it with behavioral intelligibility data.
Here, we recruited 15 native English speakers for a 1.5h EEG experiment. Subjects were presented with 160 trials of 35s stories from 2 speakers spatially separated at ±45° azimuth with background noise. First, word-level speech intelligibility is measured for each subject as a function of SNR. Then, subjects were instructed to focus on a specific speaker in different types and volumes of noise based on their intelligibility-SNR curves. Decoders were then trained to reconstruct the acoustic envelopes of the attended and unattended speakers from 64-channel EEG using regularized linear regression and were tested using leave-one-trial-out cross-validation. Neural speech tracking for both attended and unattended speakers was assessed by computing the correlation between the predicted and true envelopes under each experimental setting.
We identified a minimum threshold of intelligibility for each subject above which the neural tracking of the attended speaker exceeded that of the unattended speaker, and this threshold was consistent across noise types. Below this level, the prediction correlations were similar between speakers due to the competition of top-down attention on the target speech and bottom-up speech saliency of the surroundings. These results support the idea that there is a threshold of intelligibility for successful neural speech tracking and this threshold is not dependent on the type of background noise. These findings deepen our understanding of the relationship between intelligibility and speech tracking and crucially constrain the implementation of auditory attention decoding systems.

Title: The electrophysiological representations of hierarchical speech features vary as a function of background noise

Authors: *S. R. SYNIGAL[1], A. J. ANDERSON[2,3], E. C. LALOR[1,2,3];
[1]Biomed. Engin., [2]Neurosci., [3]Del Monte Inst. for Neurosci., Univ. of Rochester, Rochester, NY

Abstract: Speech is a hierarchically organized form of communication that consists of features that are differentially processed in distinct brain areas, at various timescales. The brain's ability to track each feature, however, may change when background noise is introduced. For example, it has been shown that the cortex continues to track the speech envelope until there is more than twice the amount of noise masking it. Meanwhile, other work has shown that blood oxygen level-dependent (BOLD) activations to syllables decrease in dorsolateral temporal cortex, and BOLD responses to semantically coherent sentences first increase and then decrease in left inferior frontal regions as speech gets noisier. Each of these studies, however, uses different tasks, maskers, and signal-to-noise ratios which can all affect brain activation patterns. Testing each feature in one experiment will show how the encoding of each representation varies across different listening conditions. Although studies have examined how individual speech features are affected by noise, these features are not independent of one another. In fact, it has been hypothesized that higher-level representations can bias perception when incoming stimuli are noisy. The top-down influence of semantic context has been used to bias listeners to hear a specific word even when the critical phoneme of that word is replaced with noise. Recent work also found that semantic context can affect the processing of a word's acoustic and phonetic features. Yet, it is unclear how this bias varies at different hierarchical levels of speech and across different noise levels. Thus, the first goal of this study is to determine how the encoding of various speech features covary across different listening conditions. The second goal is to explore how top-down influences change as speech intelligibility decreases. In this experiment, electroencephalography data was collected while participants listened to a narrative in five different levels of background noise. Subjects also answered comprehension questions and rated speech intelligibility after each trial. Using linear modeling, we find that the encoding of acoustic and linguistic features weakens differentially with increasing levels of noise. Additionally, a second stage regression analysis shows that predictions based on higher-level speech features positively impact the encoding of acoustic-phonetic features for certain noise levels. With this study we seek to extend our understanding of the hierarchical processing of continuous speech under a range of realistic listening conditions.

Title: Distinct neural encoding of glimpsed and masked phonetic features in multitalker speech perception

Authors: *V. S. RAGHAVAN[1], J. A. O'SULLIVAN[1], S. BICKEL[2], A. D. MEHTA[2], N. MESGARANI[1]; [1]Electrical Engin., Columbia Univ., New York, NY; [2]Hofstra Northwell Sch. of Med., Manhasset, NY

Abstract: Speech perception in multitalker acoustic environments is a challenging task requiring a listener to extract and group the phonetic features of a target talker from those of non-target talkers. Because speech is a structured sound composed of sparsely distributed regions of energy with redundant information, it is hypothesized that listeners rely on glimpses of spectrotemporal regions in which one talker contains more energy than the others. The glimpsing hypothesis has been tested with computational and behavioral models to show that glimpses contain sufficient information to support speech recognition. While the glimpsing model makes no claims regarding the processing of masked phonemes, one possibility, supported by the phoneme restoration effect, is that masked phonemes may be restored at the acoustic-phonetic level using glimpsed information. Despite the computational and behavioral evidence, the neuroscientific evidence for the glimpsing model is lacking. Specifically, we do not know if glimpsed and masked phonemes of target and nontarget talkers are encoded differently in the human auditory cortical areas. It is also unclear how attention to a talker changes the processing of glimpsed and masked phonemes of that talker. Here, we obtained intracranial EEG recordings in primary and nonprimary auditory cortex, including Heschel's gyrus (HG) and superior temporal gyrus (STG) respectively, while subjects attended to one talker in a co-located two-talker mixture. We used linear encoding models to predict the high-gamma band envelope of neural responses using acoustic, phonetic, and phonotactic features of the target and non-target talkers. We confirmed that linguistic processing beyond phonetic features is only present for the target talker. In processing phonetic features, neural responses were more accurately predicted using separate glimpsed and masked phonetic representations. In particular, we found a robust encoding of glimpsed phonetic features of both target and non-target talkers in HG; however, masked phonemes of either talker were not encoded in HG. We also found that STG represents both masked and glimpsed phonetic features but only for the target talker, with masked phonetics encoded with an additional 100ms delay. Together, these findings provide neural evidence for the glimpsing model, suggesting that the auditory cortex selectively uses glimpses of the target talker to restore masked speech at the acoustic-phonetic level, leading to a complete and invariant representation of target talker phonetic features in the STG that can simplify noise-invariant lexical and semantic processing in downstream auditory cortical areas.

Title: Cortical Processing of Arithmetic and Simple Sentences, in an Auditory Attention Task

Authors: *J. P. KULASINGHAM, N. H. JOSHI, M. REZAEIZADEH, J. Z. SIMON;
Electrical and Computer Engin., Unviversity of Maryland, College Park, MD

Abstract: The neural basis of arithmetic and language processing may rely on distinct cortical networks which must also be disentangled from mechanisms underlying the sensory modality of presentation. Here we use spoken equations and sentences to investigate neural processing of arithmetic, compared to general language processing, in an attention-modulated cocktail party paradigm. Magnetoencephalography (MEG) data was recorded from 22 participants listening to simple sentences and arithmetic equations which were presented diotically at distinct word, symbol, sentence and equation rates. This allowed for analysis of neural responses to words and symbols to be largely dissociated from responses to sentences and equations. The sentences and equations were presented either alone, or simultaneously in a competing speaker paradigm and participants were told to attend to only one of the speech streams. Neural responses at the word and symbol rates (which also correspond to repetitive acoustic features), were seen for both speech streams, indicating pre-attentive auditory processing. In contrast, neural responses at the sentence and equation rates (which do not correspond to stimulus acoustics), were present only for the attended stream. Source localized responses in the frequency domain revealed both shared and distinct cortical networks underlying equation and sentence processing. Responses to both sentences and equations were found in temporal lobe, with a left-hemispheric dominance. However, equation responses additionally localized to bilateral parietal areas, possibly indicating distinct networks involved in arithmetic processing. Critically, these higher-level neural responses were significantly correlated with behavioral performance in a deviant detection task. Additionally, the spatiotemporal dynamics of these responses were investigated using Temporal Response Functions. Cortical activity peaked towards the end of the sentence/equation in temporal/parietal areas, possibly indicating processing of sentence/equation completion. Finally, linear decoders trained to classify attention to sentences vs. equations based on MEG responses revealed further differences in these neural responses, with decoding accuracy being highest in superior parietal areas. These results indicate that the cortical networks underlying arithmetic and language processing are well segregated during a competing speaker paradigm, and that these neural responses are linked to comprehension or correct calculations.

Title: The role of Purkinje neuron bistability in cerebellar output and motor behaviour in larval zebrafish

Authors: *V. AGARWAL, S. NARAYANAN, S. CHINTA, V. THIRUMALAI;
Natl. Ctr. For Biol. Sci., Bangalore, India

Abstract: The cerebellum is a brain structure involved in motor control and coordination and its circuitry is well conserved among vertebrates. A lot is known about inputs to the cerebellum, but not much is known about cerebellar output and its effect on motor activity. We looked at 2 neuronal types in the cerebellum - Purkinje neurons (PNs), first place of convergence of multiple inputs to the cerebellum and eurydendroid cells (ECs), which are output neurons of the zebrafish cerebellum and are homologs of the mammalian deep cerebellar nuclear cells. PNs exhibit membrane potential bistability and their activity patterns are distinct in these two states. In the ‘up’ state PNs generate tonic spiking while in the ‘down’ state, they produce burst firing. Multiple PNs converge onto single ECs and inhibit them. We recorded the activity of ECs simultaneously with motor bouts and found that most ECs show correlated spiking during motor bouts. To understand how PN membrane potential bistability and spiking patterns affect EC activity, we used optogenetics to modulate both. While long duration light pulses stably reset PNs to the depolarized ‘up’ state, short pulses triggered synchronized spiking. We used these to modulate the output of PNs while simultaneously monitoring motor output and EC activity during the closed loop optomotor paradigm. We will discuss the results from these experiments.

Title: Modulation of synaptic inhibition in Purkinje cells during sensorimotor integration in vitro and in vivo

Authors: *M. R. HOLLA, S. T. BROWN, I. M. RAMAN;
Neurobio., Northwestern Univ., Evanston, IL

Abstract: In awake mice, suppression of crus I/II cerebellar Purkinje (Pkj) cell firing is the first response to somatosensory input (air puffs) to the whisker pad. This inhibition of Pkj cells briefly disinhibits cerebellar nuclear (CbN) cell targets, increasing cerebellar output and augmenting whisker movement. Sensory-evoked inhibition of Pkj cells is interesting, since trigeminal nuclei mossy fibers excite granule cells whose parallel fiber (pf) axons directly excite Pkj cells and indirectly inhibit Pkj cells via molecular layer interneurons (MLIs). This circuitry raises the questions of how the effect of disynaptic inhibition precedes that of monosynaptic excitation, as well as whether this dominantly inhibitory response is subject to modulation. To investigate these issues, we made whole cell voltage clamp recordings of Pkj cells in cerebellar slices of 4- to 6-week-old mice. Stimulating pf 5x at 50 Hz evoked excitatory and inhibitory postsynaptic currents (EPSCs and IPSCs). Pf-EPSCs were strongly facilitating, whereas pf-MLI-IPSCs were stable (non-facilitating), resulting in a changing E/I ratio over the train of stimuli. Cell-attached recordings of action potentials showed that, with the same pf stimuli, suppression of firing rates was more effective early in the train, suggesting that inhibition strength may depend on pf facilitation status. Since synaptic currents are sensitive to neuromodulators like norepinephrine (NE), we tested the effect of bath application of isoproterenol. With this beta-adrenergic agonist, pf-MLI-IPSC amplitudes nearly doubled, with no changes in short term plasticity; Pkj cell baseline firing rate was reduced; and the frequency of spontaneous IPSCs in Pkj cells increased, consistent with increased firing of MLIs. Also, the mean amplitude and decay rate of spontaneous IPSCs increased, suggesting that activation of beta-adrenergic receptors may differentially recruit basket and stellate cells. Isoproterenol also increased the magnitude of pf-evoked suppression of Pkj firing. The data suggest that neuromodulatory changes in the E/I ratio in Pkj cells in vivo may affect sensorimotor integration. To begin to test if/how different E/I ratios may affect movement, air puffs were applied at different frequencies (5x at 5-40 Hz) to the whiskers of awake head-fixed mice during Pkj cell recordings. The magnitude of suppression of Pkj cells changed with stimulus number and interval and correlated with similar changes in whisker movement. The data illustrate how E/I ratios that dictate Pkj cell output can change with stimulus parameters, context, and/or neuromodulatory state, thereby modulating cerebellar control of movement.

Title: Circuit-level computations in the cerebellar flocculus: transforming inputs to outputs

Authors: *D. J. HERZFELD, N. J. HALL, S. G. LISBERGER;
Duke Univ., Durham, NC

Abstract: The floccular complex of the cerebellum is crucial for the performance of smooth pursuit eye movements. Leveraging the well-characterized anatomy of the cerebellar circuit, we can begin to investigate the computations performed by the circuit in support of this motor behavior. Here, we recorded from the floccular complex of rhesus macaques using multi-contact silicon probes. Using a combination of waveform, firing rate characteristics, and cerebellar layer, we assigned a putative cell type label to each well-isolated unit. These data allow us to begin to answer how the flocculus performs intrinsic computations.
Mossy fibers (MFs) are the primary excitatory input to the flocculus. In agreement with previous data, our MFs demonstrate diverse pursuit-related responses including modulation due to eye position, velocity, and visual (retinal-slip) signals. MFs synapse onto granule cells, whose axons form the excitatory input to Purkinje cells (PCs), the primary output of the cerebellar cortex. Beyond this feedforward excitatory pathway, the cerebellar circuit features feedback; recurrent and feedforward inhibitory processing elements that may substantially alter the flow of information from MFs to PCs. A crucial first question is whether feedforward excitation from MFs through granule cells to PCs is sufficient to explain PC firing. We constructed an artificial population of 10,000 granule cells with responses during pursuit based on input from our recorded MFs. Each simulated granule cell received four randomly chosen MF inputs with a random positive weight. We then asked whether this simulated population of granule cells was capable of predicting the pursuit-related firing responses of recorded PCs. That is, we asked whether granule cell inputs derived from MFs form a sufficient basis set to explain PC firing during pursuit. Using non-negative linear regression, we found the optimal weights between these simulated granule cells and our recorded PCs. Across the PC population, the feedforward excitatory pathway from MFs to granule cells to PCs was able to explain 55% of the PC response variance. Crucially, this result was largely independent of the number of simulated granule cells.We next asked whether the addition of feedforward inhibition from molecular layer interneurons provided an enhanced basis set to explain PC firing. It did: addition of feedforward inhibition explained 72% of the PC response variance. Taken together, our results demonstrate that processing in the feedforward and recurrent circuitry of the floccular complex is likely to involve significant processing beyond the simple feedforward excitation pathway.

Title: Stimulus and response encoding in a population of Purkinje cells in Crus I and Crus II of the cerebellum during an arbitrary visuomotor association task.

Authors: *A. IPATA[1,2,3], V. FASCIANELLI[3,4], N. SENDHILNATHAN[1,2,5,3], M. E. GOLDBERG[1,2,3,6,7], S. FUSI[1,4,3,6];

Abstract: We previously showed that when monkeys perform a reinforcement learning arbitrary visuomotor association task, Purkinje cells (PCs) in Crus I and II exhibit an error signal which approaches zero as the monkeys learn the correct associations (Sendhilnathan, 2020). In our previous analysis we showed that the average firing rate of these neurons reflects neither the kinematics of the movements nor the identity of the stimuli. Here we asked if information about the nature of the stimulus or the choice of the movement could be decoded from the activity in the ensemble of PCs. We recorded neural activity of single PCs in the mid-lateral cerebellum while monkeys performed an arbitrary visuomotor association task. Each trial started when monkeys grabbed two bars, after which one of a pair of stimuli appeared at the center of the screen. The identity of each stimulus instructed which bar to release. In the familiar task, their performance was close to 100% in every session. In the novel task we presented a pair of stimuli that the monkeys had never seen, and they had to learn the correct associations between the stimuli and the hand movements through trial and error. Using a linear decoder on the population ensemble, we identified which hand the monkey would release on every trial. In the familiar task and during the later learning trials, the decoder identified the hand 380 ms before the movement. In correct early learning trials, the decoder identified the hand 200 ms before the movement. In early error trials the decoder identified the hand only 100 ms before the movement. Because the hand and stimulus were tied together, we could not dissociate the identities of the stimulus and the movement. To dissociate them, we reversed the associations after the monkeys had learned the novel task. Now the monkeys had to learn the new associations of the same symbols. By combining both novel and reversal trials, where the same symbols evoked opposite movements, we found that the decoder identified movement and symbol at 400 ms after stimulus onset in the early learning trials. In the late learning trials the decoder identified the stimulus at 200 ms after stimulus onset, and the movement at 300 ms after stimulus onset. These results show that the cerebellum has independent access to the movement that the monkey will make, and the identity of the stimulus evoking the movement in a arbitrary visuomotor association task. The cerebellum identifies the stimulus only when the monkey learns the association, and as the monkey learns the association the decoder identifies the movement at a time closer to the stimulus appearance.

Title: Cerebellar Purkinje cell responses to regular and irregular trains of somatosensory stimuli in awake mice

Authors: *S. A. GOLDSTEIN, S. T. BROWN, I. M. RAMAN;
Neurobio., Northwestern Univ., Evanston, IL

Abstract: The cerebellum is involved in tasks that require tracking intervals briefer than one second, raising the question of how absolute and/or relative timing is represented in the activity of cerebellar neurons. Recently, we found that with repetitive air puff stimulation (300 ms intervals) of the whiskers in awake mice, Purkinje cell (Pkj) complex spike and simple spike responses changed throughout the course of stimulation. When air puffs were unexpectedly omitted, complex spikes were suppressed during the omission interval. Whether the observed changes in Pkj activity result from the number of repetitive stimuli applied, the duration between stimuli, or the regularity of the stimuli remains an open question, however. We therefore recorded from Pkj cells in awake, head-fixed mice while applying a regular or irregular series of air puffs to the whiskers, interrupted by infrequent and unpredictable stimulus omissions. Each protocol consisted of 1800 stimuli, with intervals of 300 ms for regular stimulation or 100-500 ms (mean, 300 ms) for irregular stimulation, with 120 omissions; the protocol that was run first was varied across cells. As seen before, Pkj cells responded to the air puff with a short-latency, transient, well-timed decrease in simple spike firing (N=8/11) and a longer-latency increase followed by a decrease in complex spike firing (N=9/11). Puff-evoked responses to regular and irregular stimuli were indistinguishable. With repetitive stimulation, the mean simple spike rate as well as the peak puff-evoked complex spike rate decreased, independent of the regularity of the stimuli. These changes therefore appear to be related to the quantity rather than the timing of stimuli. After omissions during regular stimulation, complex spike probability fell below baseline. During irregular stimulation, this omission-associated suppression was absent, indicating that the drop in complex spike probability during the omission interval is not a long-latency response to the preceding puff. Instead, Pkj cell complex spike omission responses appear to be related to the regularity of the stimuli, consistent with participation of the cerebellum in relative (beat-based) timing.

Title: Context-dependent conditioned responses and Purkinje cell activity in cerebellum-dependent associative learning

Authors: *M. KISLIN[1], S. BERGELER[2], G. J. BROUSSARD[1], Y. CHEN[1], J. W. SHAEVITZ[2], S. S.-H. WANG[1];
[1]Princeton Neurosci. Inst., Princeton, NJ; [2]Dept. of Physics and Lewis-Sigler Institute, Princeton Univ., Princeton, NJ

Abstract: We studied the context-dependence of delay tactile startle conditioning (DTSC), in which mice learn to withdraw from a conditional stimulus (CS; tone) that predicts an impending unconditional stimulus (US; nosetap). When head-fixed, mice produced progressively more CS-evoked responses (CR) over 6 daily sessions and plateaued with a CR probability of 0.63 ± 0.16 (mean ± sd). In subsequent CS-only experiments, extinction of the response was incomplete: CR probability declined to 0.27 ± 0.09 after 200 trials and remained at that level, higher than the pre-training CR probability (0.07 ± 0.02). Reacquisition of the CR during a second round of CS+nosetap training occurred within 100 trials, resulting in a CR probability of 0.49 ± 0.22 and reaching 0.73 ± 0.18 after 300 trials.
Nosetap-trained mice responded differently when placed in an open arena. We investigated CS-evoked responses in freely-moving mice, monitoring and classifying movements by tracking the pose of the animal over time using SLEAP[1]. CS-alone presentation during locomotion initially led to a rapid deviation in trajectory, but this response disappeared after fewer than seven trials. When subsequently placed in the head-fixed apparatus, the CR returned almost immediately, producing a response within the first few trials of 0.52 ± 0.26 CR probability.
Cerebellar lobule IV/V has a crucial role in acquisition during DTSC[2]. As a second type of US, we expressed the optogenetic probe channelrhodopsin-2 in Ai27 mice and targeted light at central vermal lobule IV/V. Pairing of CSs with direct short-pulse optogenetic stimuli (15 ms) in head-fixed mice led to the acquisition of conditioned startle responses. Continued CS+opto training in the open arena led to ongoing production of CS-triggered startle responses even after many trials.
Finally, we tracked climbing-fiber-driven complex-spike activity using fast-GCaMPs in lobule IV/V Purkinje cell dendrites during learning, extinction, and relearning. We found that CS+nosetap pairing caused a gradual acquisition of CS-triggered calcium transients that appeared with initial learning, diminished with extinction, and re-emerged with reacquisition. We are now testing the hypothesis that calcium signals undergo rapid modulation under changes in behavioral context.

Title: Synchronous spiking and encoding of eye movements by cerebellar Purkinje cells

Authors: *E. SEDAGHAT NEJAD, J. PI, P. HAGE, M. FAKHARIAN, R. SHADMEHR;
Biomed. Engin., Johns Hopkins Univ. Sch. of Med., Baltimore, MD

Abstract: The information that the brain transmits from one region to another is often viewed through the lens of firing rates. However, if the output neurons could vary the timing of their spikes, then they might encode information beyond that which is present in their average rates. A special form of temporal coding is synchronization of spikes among a population of neurons. Indeed, it has been hypothesized that during control of movements, information transfer from the cerebellar cortex to the nucleus might rely on synchronization, as well as modulation of firing rates. Is synchrony among the output neurons a means of transmitting information from one region of the brain to another?

To approach this question, we focused on Purkinje cells (P-cells) because they are the sole output channel from the cerebellar cortex, and because they can be definitively identified via their simple and complex spikes. P-cells are GABAergic, and thus their activity inhibits the downstream nucleus neurons. However, if the spikes produced by P-cells are synchronous, then the P-cells can entrain the nucleus neurons, transforming inhibition into production of spikes. Do P-cells transfer information through synchronization of their spikes?

Here, we recorded from n=143 Purkinje cells (P-cells) while marmosets performed saccadic eye movements. The simple spike firing rates of individual cells exhibited a bewildering assortment of responses, often with modulations that lasted long after saccade end. However, when we organized the cells into populations based on their complex spike response to visual events, the population firing rates of simple spikes varied precisely with saccade direction, velocity, and duration, reproducing our earlier observations in macaques. We analyzed spike patterns in pairs of simultaneously recorded P-cells (n=40 pairs) and found that before saccade initiation, firing rates increased as a function of future saccade velocity, thus inhibiting the nucleus. As the saccade initiated, rates declined below baseline and reached a minimum precisely at the onset of saccade deceleration. Remarkably, during the deceleration period the P-cell spikes became synchronized.

This suggests that the cerebellum controls movements through a combination of rate and temporal codes: nucleus cells are initially inhibited, then released from inhibition precisely at a time when the few remaining spikes from P-cells become synchronized. The fact that this synchrony occurs only during deceleration implies that through entrainment of the nucleus cells, the P-cells are predicting when the movement should be stopped.

Title: Saccade related neurons in the fastigial nucleus of the marmoset cerebellum

Authors: *P. HAGE, E. SEDAGHAT-NEJAD, J. PI, M. A. FAKHARIAN, K. POE, R. SHADMEHR; Biomed. Engin., Johns Hopkins Univ. Sch. of Med., Baltimore, MD

Abstract: The cerebellum plays a critical role in control of movements, illustrated by the fact that a hallmark of cerebellar damage is dysmetria. For example, during saccadic eye movements, the ability of the brain to stop the eyes accurately at the target comes about because of the activity of caudal fastigial nucleus (cFN) neurons. The behavioral deficits that follow cerebellar damage imply that firing rates of cFN neurons should encode saccade parameters, particularly the timing of saccade termination. Yet, the firing rate of individual cFN neurons, at least in macaques, is modulated long after the movement comes to an end. How can the cerebellum control saccades if the activity of cFN neurons appear to poorly encode movement parameters? This problem of encoding is not unique to the cerebellar nucleus. In the cerebellar cortex, P-cells in the oculomotor vermis (OMV) also exhibit simple spike (SS) firing patterns that show no obvious relationship to saccade direction, velocity, and duration. Yet, when the P-cells are organized based on their complex spike (CS) response to visual error, the SSs of the population show exquisite modulation with all three parameters. Thus, a key to understanding the cerebellum may be to organize cells based on their response to error. Does this idea generalize to the cerebellar nucleus? To test this, we recorded from the cFN of marmosets. We chose this species because like macaques, they are highly visual animals that rely on saccades to explore their environment. However, being a fraction of the size of macaques, it is possible to accurately target the cerebellum and its deep nuclei with relatively short, high-density probes. These advantages have made it possible to simultaneously record from multiple neurons in the cFN as the animal performs a visually guided saccade task. We recorded the activity of 77 well-isolated cFN neurons, including 138 simultaneous pairs, using multi-contact probes during visually guided saccades. We observed a wide range of spiking patterns during saccades: some neurons produced a burst, some produced a pause, and some did both, with response durations that consistently exceeded saccade duration. Intriguingly, a subset of neurons produced a spiking response at 60-70 ms following onset of visual error, similar to the timing of the CS response in P-cells of the OMV. The cFN response to visual error was tuned to the contralateral direction, which is remarkably similar to

P-cells. We speculate that this tuning may allow for grouping of cFN cells into populations, wherein the combined firing characteristics reflect the encoding of specific saccade kinematic parameters.

Title: Encoding of sensory but not motor events via complex spikes of Purkinje cells

Authors: *J. PI, E. SEDAGHAT-NEJAD, P. HAGE, A. FAKHARIAN, R. SHADMEHR;
Johns Hopkins Univ., Baltimore, MD

Abstract: Input from the inferior olive plays a major role in organizing the cerebellum, carving anatomical modules that bring together groups of Purkinje cells (P-cells) and their downstream nucleus neurons. This input produces complex spikes in P-cells with near 100% probability, yet despite their significance, the question of what is signaled by the complex spikes is strongly debated. On the one hand, unexpected sensory events can modulate the probability of complex spikes, which has led to the theory that complex spikes signal sensory prediction errors, and thus promote learning. On the other hand, complex spikes often precede production of movements, which has led to the theory that they play a role in timing well-learned movements. Disentangling these two possibilities is difficult because a salient sensory event is often followed by a movement. Here, we designed a novel task to separate sensory events from movements. We trained marmosets to fixate a central location and make saccades to a primary visual target (presented randomly in one of 8 locations). During this saccade we displaced the target to a random secondary location, thereby promoting a sensory prediction error. Critically, this secondary target was available only briefly (80 – 250 ms), after which it returned to the primary target location. As a result, following the completion of the primary saccade there was always a sensory prediction error, but only occasionally the animal responded via a movement. At other times, the sensory event was present but did not result in a movement. Finally, we considered a third case in which the animal made spontaneous saccades without externally driven visual cues: movements that were not in response to sensory prediction errors. We recorded from vermis lobules VI and VII in two marmoset monkeys (Callithrix jacchus) and isolated 90 P-cells. Each P-cell exhibited a preference for a particular direction of sensory error. When the sensory event was in the preferred direction of the P-cell, it responded with a complex spike at around 110 ms following the onset of the sensory event. Remarkably, the complex spike response was present even when the sensory event was not followed by a movement. Furthermore, the complex spike response was absent for spontaneous movements that were not driven by the visual cues. Thus, the olivary input to

the cerebellum appeared to signal the onset of a sensory event regardless of whether that event was followed by a movement or not. Indeed, complex spikes were missing from saccades that were not driven by the onset of visual events. These results appear consistent with the idea that complex spikes signal unexpected sensory events to the cerebellum.

Title: Neck muscle activity during active head movements reflects the level of sensory prediction error introduced by unexpected velocity-dependent loads in non-human primates

Authors: *R. L. MILDREN[1], O. ZOBEIRI[1], K. E. CULLEN[2];
[1]Biomed. Engin., [2]Dept. of Biomed. Engin., The Johns Hopkins Univ., Baltimore, MD

Abstract: Passive vestibular and neck proprioceptive stimulation generates reflex responses in neck muscles that function to stabilize the head. However, during voluntary active movements, it is critical that reflexes are suppressed since they would be counterproductive to the intended movement goal. Previous work has shown that vestibular primary afferent input is suppressed during active head movements at the level of the vestibular and deep cerebellar nuclei when the brain's internal model can accurately predict the sensory consequences of motor commands [1]. However, when a perturbation introduces sensory prediction error, these nuclei encode the motion as if it were passive. Importantly, the vestibular and deep cerebellar nuclei provide output to the spinal cord and are well situated to produce reflexes that ensure postural control. Thus, it might be expected that neck muscle activity could reflect errors in the internal model's prediction of the sensory consequences of motor commands.
Here we characterized vestibulo- and cervico-collic reflexes in the splenius capitis muscle with motion in the yaw plane, and then examined muscle responses to sensory prediction error induced by velocity-dependent torques applied unexpectedly while alert rhesus macaques made active head movements. To examine vestibulo- and cervico-collic reflexes, we applied passive yaw movements to the whole body (vestibular stimulation), body under the head (neck proprioceptive stimulation), and head on body (combined vestibular and proprioceptive stimulation) while we recorded indwelling EMG from the right splenius capitis muscle. Vestibulo- and cervico-collic reflexes were observed in rectified EMG and single motor unit activity during whole body and body under head motion, while head on body motion evoked muscle activity that reflected the summation of these reflexes. Next, while the monkey performed active head movements, we applied four levels of velocity-dependent torque that either assisted or resisted the intended movement. While the muscle was acting as an agonist, resistive torque evoked graded excitatory responses in rectified EMG amplitude and increased gain; conversely, assistive torque evoked graded

inhibitory responses in EMG amplitude and decreased gain.
These modulations in neck muscle activity reflect perturbation induced errors in sensory prediction, which would cause a lack of vestibular reafference suppression as well as neck muscle stretch reflexes. Thus, neck muscle activity can provide insight into the functioning of the brain's internal model of the sensory consequences of voluntary motor commands.

Title: Rapid decision-making during human-human sensorimotor interactions

Authors: *R. LOKESH[1], J. CALALO[1], A. ROTH[1], S. SULLIVAN[1], M. J. CARTER[2], J. G. A. CASHABACK[1];
[1]Univ. of Delaware, Newark, DE; [2]Univ. of Mcmaster, Hamilton, ON, Canada

Abstract: Whether driving a car or playing a sport, humans often make rapid decisions based on the actions of others. Cognitive decision-making is often studied in a single human or animal, where researchers often manipulate the uncertainty of visual information that provides evidence to select the correct action. Despite its relevance, to our knowledge using visual information of another person's actions to perform rapid decision-making remains unstudied. Here we test the idea that humans accumulate evidence about the intended action of others when making a rapid decision. We designed an interactive two-player sensorimotor version of the matching pennies game. Each participant, of a human pair, moved a robotic manipulandum to control a cursor from a start position to one of two potential targets (left or right). Both participants had vision of their opponent's cursor. The two players were assigned as either 'predator' or 'prey'. The predator won the trial by reaching to the same target as the prey. Conversely, the prey won the trial by reaching to a different target from the predator. In Experiment 1, participants performed a symmetric reward condition, where the winner of a trial received 1 point and the loser received 0 points. We manipulated the available time to reach to a target (500ms, 850ms, and 1500ms). In Experiment 2, participants performed both a symmetric and an asymmetrical reward condition. The symmetrical (described above) and symmetrical reward conditions were similar, except in the asymmetrical reward condition the predator received 3 points when both players selected the right target. For each reward condition, participants performed two different timing conditions (500ms and 1500ms). Both experiments used a within subject design, condition order was counterbalanced, and there were 150 trials per condition. Across experiments, participants exploited the additional time in the longer trials. Only near the end of a trial was a participant's hand path predictive of target selection and related to the actions of their opponent. Successful participants delayed their final change in cursor movement direction, suggesting they relied on accumulated evidence of their opponent's intended action to make a rapid decision. Participants proportionally selected targets in a manner that approached an optimal

solution (i.e., Nash equilibrium). Preliminary work shows that a drift-diffusion model does well to capture decision-making during human competition. Taken together, these results suggest that successful participants exploited time to accumulate evidence about their opponent's intended action, and then relied on rapid decision-making to select a target.

Abstract: Sight-reading music highlights the impressive ability for individuals to simultaneously perceive notes on the page, prepare motor actions, and contact keys at the proper time. This task of perceiving, deciding, and acting in parallel becomes particularly challenging as the speed of the performance increases and reaches a capacity limit. Two hypotheses are commonly put forward to explain these limits in capacity: a structural bottleneck model, where processes interfere when they queue to use a particular neural circuit; and a shared resource model, where processes interfere when they compete for resources in a central pool. Here we explore limits in rapid sensorimotor performance to understand which processes are at risk of interference and under which conditions.
We studied the interference of perceptual, decision-making, and motor control processes during behavioural tasks where subjects must rapidly generate upper-limb movements to achieve time-constrained goals. Healthy human subjects (N=487, 212 male, 432 right-handed, age range 18-93) performed Object-Hit (OH) and Object-Hit-and-Avoid (OHA), two related motor decision tasks, in the Kinarm Exoskeleton lab. The goal of each task is to hit as many targets as possible during an ~2.5-minute trial, with OHA adding the requirement to avoid distractor objects that are distinguished by shape. Subjects' performance was measured using their steady-state target hit rate, which represented their peak, sustained level of performance.
We found that subjects with the highest steady-state rates in the OH task are the most affected by the

increased task difficulty in the OHA task, demonstrating that the additional task demands were multiplicative in nature. We also found that the subjects with the poorest performance often demonstrated equal performance between the OH and OHA tasks, seemingly unaffected by the additional task demands. These results are consistent with the shared resource model for process interference and suggests that processes compete for shared resources, such as attention, to mitigate the impact of bottlenecks and maximize task performance. We believe that this shared resource model may be useful when interpreting changes in performance during motor skill learning and physical rehabilitation.

Title: Long-latency feedback responses reflect explicit sensory priors

Authors: *J. A. MICHAELS[1], J. ZHENG[1], O. CODOL[1], J. WEILER[1], A. PRUSZYNSKI[1,2];
[1]The Brain and Mind Inst., [2]Physiol. and Pharmacol., Western Univ., London, ON, Canada

Abstract: As we move through the world, the brain must constantly integrate sensory information with prior expectations to select the most appropriate actions. Reaching experiments have demonstrated that contextual information can modulate the magnitude of long-latency feedback responses (EMG 50-100ms after perturbation onset) in arm muscles following unexpected mechanical perturbations and that cortical processing plays a key role in these responses. However, it's not known if immediate changes in sensory priors can be integrated into long-latency feedback responses. To answer this, we performed an experiment in which human participants (N = 20) sat in a planar robotic exoskeleton and reached to a target after elbow perturbations that pushed their hand towards or away from the target. For each trial, differently sized arrows randomly cued the relative directional probability (0/25/50/75/100%) of the upcoming perturbation. The trajectory of the hand following perturbations was modulated by the perturbation direction probability, showing the fastest movements for more likely directional perturbations and the slowest responses for unlikely directional perturbations. Crucially, we found that long-latency feedback responses in stretched arm muscles following perturbations that moved the hand away from the target linearly scaled with the cued probability within ~70ms of the perturbation. These results could not be explained by anticipatory muscle contractions before the perturbation nor by participants guessing on individual trials. Training neural networks to control biomechanical models of

the arm with realistic muscles, delays, and noise to perform similar tasks revealed that two key ingredients are necessary to observe scaling of long-latency feedback responses by sensory priors: a penalty on metabolic cost in the muscles and an input signaling the occurrence of a perturbation that precedes perturbation direction specific information. The sensory prior inputs provided to the networks shifted the neural population state along the same axis that differentiated perturbation direction during movement, increasing or decreasing the latency of the muscle response proportional to the probability of the perturbation direction. These findings show that long-latency feedback responses flexibly reflect immediate sensory priors, and suggest that the motor system prepares a single control policy that incorporates these expectations, which is deployed as soon as a perturbation is detected.

Title: Dynamical adjustments of goal-directed feedback control in human reaching movements

Authors: *A. DE COMITE, F. CREVECOEUR, P. LEFEVRE;
Univ. Catholique de Louvain, Louvain-la-Neuve, Belgium

Abstract: Humans execute movements using a goal-directed feedback control policy tuned to the task goal and to the environmental context. For example, the structure of the goal target is considered while planning and executing movements: humans do not reach to a wide target the same way as they reach to a narrow one. Recently, we showed that these goal-directed control policies can be adjusted online in response to an unexpected change in the target structure or in the task environment. However, it is still unknown whether these online adjustments are tuned to dynamical changes such as time-varying changes in target structure. To we investigate this question, we varied the rate of changes in target width to probe whether it evoked gradual adjustments in control policies. Participants (N = 14) had to reach to a rectangular goal target (30 x 2.5 cm) whose structure could unexpectedly change during movement. Three types of changes in target structure were investigated. The first condition was an abrupt switch, where the rectangular target instantaneously turned into a narrow square (2.5 x 2.5 cm). The two remaining conditions were gradual changes whereby the target width decreased continuously during movement at slow or fast rate (respectively 33 and 45 cm/sec). In addition to these changes in target structure, we introduced unexpected mechanical perturbation loads to the hand, orthogonally to the main reaching direction, in order to assess change in control policy associated with the change in target structure. We analysed kinematics of the hand during trial and EMG correlates from the shoulder flexor and extensor muscles to determine whether and how fast the feedback responses to mechanical perturbations reflected

the dynamical changes in target width. We found that the final hand position was dependent on the target change condition, such that more eccentric positions were associated with slower decrease in target width. The analyses of the EMG activities revealed a modulation of long-latency and voluntary responses to the perturbation load with the target condition. Moreover, we observed between trials adjustments of the responses in the dynamical conditions, which could characterize some form of learning. These adjustments were such that the responses to the mechanical perturbations in the dynamical trials were less jerky in the late trials compared to the earlier ones. Altogether, our results demonstrate that the factors that contribute to updates in control consider time-varying changes, suggesting a continuous monitoring of task-related variables allowing dynamic and time varying adjustments in goal-directed reaching control.

Title: Sport expertise-dependent movement adjustments impact Go/No-go decision in rapid hitting task

Authors: *A. KOBAYASHI, T. KIMURA;
NTT Communication Sci. Labs., Atsugi city, Japan

Abstract: In order for an athlete to achieve high performance, such as hitting a ball on baseball or tennis, both appropriate decision-making and precise motor control are required under tough time constraints. Although recent studies have proposed that motor and decision-making processes interact, often referred to as embodied decision-making, it is still unclear how the embodied decision processes behave under short time constraints and how they depend on sport expertise. We conducted a baseball batting-like Go/No-go hitting task experiment in which Go/No-go judgment and movement execution behavior are assessed simultaneously by collecting movement profiles. Eighteen elite university players with different sport skills (baseball and gymnastics) are required to reach-to-hit a moving target in a strike zone (Go) and not to hit it outside the area (No-go) with different values of time-to-contact (TTC): 400, 500, and 600 ms. We found that the hitting variability was significantly smaller for baseball players at TTC500 and above, but the difference disappeared at TTC400. On the other hand, as TTC decreased, decision success rate (d') decreased, most markedly for the gymnasts, indicating that decision accuracy is more sensitive to sport expertise. Moreover, hierarchical Bayesian estimation based on the Drift-Diffusion Model revealed differences in the decision parameters. Interestingly, movement adjustment for the No-go decision was also distinctive, that is, the participants tended not to move their hand in TTC600, while they started and then stopped their movement in TTC400. We found that the baseball players had a shorter stopping time than gymnasts, and the baseball players had a higher rate of successful cancellation of hitting than gymnasts in TTC400, indicating that the cancellation strategy is effective in maintaining decision success under severe time constraints depending on sport expertise. Our results suggest that motor inhibition, rather than activation, determines rapid embodied decision-making performance.

Title: Arm configuration variance accounts for endpoint jerk in circular arm motion.

Authors: M. MRAVCSIK[1,2], L. BOTZHEIM[1,2], D. PIOVESAN[3], ***J. LACZKO**[2,1,4,5];
[1]Dept. of Information Technol. and Biorobotics, Univ. of Pecs, Pecs, Hungary; [2]Neurorehabilitation and Motor Control Res. Group, Wigner Res. Ctr. for Physics, Budapest, Hungary; [3]Gannon Univ., Erie, PA; [4]Information Technol. and Bionics, Pazmany Peter Catholic Univ., Budapest, Hungary; [5]Feinberg Sch. of Medicine, Dept. of Physiol., Northwestern Univ., Chicago, IL

Abstract: We investigated the magnitude of endpoint (hand) jerk as function of crank direction during arm cranking movements. The profile of jerk magnitude during a uniform circular motion is theoretically constant. During human arm cranking the neural control tries to approach this motion. It was found that the endpoint jerk performed by the participants is the smallest in two extreme positions: when the hand is closest to the body and when the hand is furthest away from the body. Furthermore between these positions the magnitude of the jerk increased and after reaching a plateau it did not change much until the hand approached the next extreme position. In the vicinity of this hand position the jerk dropped to reach a local minimum. These were found for both of the left arm and right arm for bimanual and unimanual cycling against 3 resistance levels. Participants performed arm cranking movements on an arm cycle ergometer (MEYRA, Kalletal, Germany) with a cadence of 60 revolutions per minute. The crank of the ergometer was 10 cm long. When the handle of the ergometer was at the most distant position (the crank was directed horizontally forward) with respect to the participant, the external angle of the elbow was approximately 10-15 degrees. The cycling task was performed against 3 levels of crank resistance bimanually and unimanually by 15 participants (aged 24 ± 4 years). Arm configuration was defined by the intersegmental joint angles in the shoulder, elbow and wrist. We previously demonstrated that the variance (across cycles) of joint angles as the function of crank direction is the highest when the crank is directed horizontally away from the body (the hand is furthest away from the body) and has two smaller local maxima in each cycle, one during the forward and one durig the backward stroke of the cycling movement. The finding that the jerk is minimal in the positions where the arm configuration variance is the highest, suggests that the central nervous system successfully uses the redundancy of the multi-joint human arm to ensure smooth hand movements in this position (when the hand turns from forward to backward movement). In this hand position the arm is near to singular configuration (the Jacobian of the 3-joint arm is almost singular) but must avoid this configuration to implement a smooth hand movement.

To do this the central control employs more available arm configurations. Our experiment indicates that during the forward and backward phases of the cycles, the arm configuration variance increased and reached local maxima to keep the endpoint jerk magnitude steady as prescribed by the theoretical kinematics of this constrained uniform circular motion.

Title: A physiological metabolic energetic cost to reaching explains preferred durations and trajectories

Authors: *J. D. WONG, A. D. KUO;
Univ. of Calgary, Calgary, AB, Canada

Abstract: Humans perform upper extremity reaching movements with stereotypical hand trajectories and stereotypical durations. The hand trajectories can be explained by optimal control for kinematic accuracy, for example minimizing error variance for a given duration (Harris & Wolpert, 1998). In contrast, reaching durations are explained by energetics, namely the metabolic cost for moving a given distance traded off against a movement reward (Shadmehr et al. 2016). It seems unlikely that aspects of the same human motion should be governed by such disparate objectives. But the kinematic theory for trajectories is presently incompatible with the energetic theory for durations. Here we show that one objective is sufficient to explain both trajectories and durations simultaneously. We use an energetic cost model informed by recent physiological experiments to resolve the incompatibility of the two models. It includes mechanical work performed by muscle, and a separate "force-rate" term associated with activating muscle to produce rapid changes in force, attributable to calcium transport. The overall minimization also includes a cost for time, equivalent to a reward for briefer reaching durations. Optimal control with this model predicts stereotypical, bell-shaped hand velocity trajectories and reaching durations, which increase approximately linearly with movement distance similar to empirical data (Reppert et al. 2018). The energy cost model also agrees well with empirical metabolic cost of cyclic reaching (Wong et al., 2020, bioRxiv 2020.12.28.424067). The model is also compatible with the previous kinematic theory, because both force-rate and accuracy favor similar bell-shaped velocities under most conditions. We propose that general reaching movements may be governed by energetic cost, accuracy, and a penalty or reward associated with duration.

Title: Effort cost of reaching biases reward responsiveness towards reacting faster over moving faster

Authors: *R. COURTER, E. SUMMERSIDE, A. AHMED;
Univ. of Colorado Boulder, Boulder, CO

Abstract: Why is healthy aging linked with a reduction in movement speeds? Older adults tend to walk, reach, and make saccades more slowly, yet the mechanisms underlying this slowing remain unclear. If we approach this question from a neuroeconomics perspective - where choice of movement speed is a consideration of both the effort required and the reward gained - then slower speeds could be due to higher effort costs or lower reward valuation. Indeed, in previous experiments, we found that with greater reward at stake, older adults rely on reacting faster rather than moving faster to acquire it sooner, whereas young adults will both react and reach faster. Faster movements incur a greater energetic cost, and even more so in older adults; perhaps older adults prefer reacting faster as a less costly strategy to obtaining reward sooner.

We asked whether older adults' altered strategy for reward reflected increased movement effort, or reduced reward valuation. Young adults ($n = 20$; 23 ± 4 yrs) performed 10-cm radial, out-and-back reaches to rewarded and non-rewarded quadrants, under high and low effort. In the high effort condition - to simulate the higher effort costs of older adults - reaches were performed with 8 lbs mass affixed to the robotic arm; no mass was added in low effort.

In both effort conditions, rewarded trials exhibited faster reaction times and greater peak speeds ($p < 0.0001$). Higher effort resulted in slowing of these kinematic measures ($p < 0.0001$) and modified the strategy in which this reward was obtained. With low effort, peak speed increased by 2.50 ± 0.184 cm/s towards a rewarded target compared to nonrewarded; when high effort was required, the increase in peak speed was smaller, at 1.21 ± 0.184 cm/s ($p < 0.0001$). Thus, the increase in speed when responding to reward was mitigated by effort. Conversely, subjects reduced reaction time by 5.94 ± 1.413 ms for reward in the low effort condition, compared to 8.22 ± 1.413 ms in the high effort condition. In the high effort condition, rather than react slower, subjects reacted at least as fast, if not faster, to reward ($p > 0.05$). These results were further supported by a computational model, which demonstrated that increased changes in reaction time and reduced changes in movement time for reward are the result of increased effort, not reduced reward valuation.

Effort costs led people to acquire reward sooner by prioritizing reacting earlier more than moving faster. These results suggest that older adults move more slowly largely because of increased effort costs, not because they value reward less. Further, reward-mediated changes in reaction time and movement speed may offer a novel metric to dissociate effort from reward valuation.

Title: The influence of reward prediction error on reach vigor

Authors: *D. APUAN, G. BRUENING, A. A. AHMED;
Univ. of Colorado Boulder, Boulder, CO

Abstract: Dopamine cells increase their activity in response to a reward prediction error (RPE). Increased dopaminergic activity has also been linked to greater ensuing movement vigor, indicating that RPE is modulating movement vigor via its influence on reward related dopamine firing. Indeed, saccade reaction times are faster in the instant immediately following a positive RPE, compared to a negative RPE. Here we investigate the vigor of reaching movements and ask whether it is modulated by the magnitude (low vs. high) of the RPE and if this effect is symmetric about the sign of the RPE (+RPE vs -RPE). Subjects (n=42) made 10 cm reaches to one of four cued targets arranged equidistantly on the perimeter of a visible circle. The experiment consisted of four blocks of 180 trials, where each target was cued 45 times in pseudorandom order. Subjects were informed that in each block, every target was associated with a different probability of being rewarded (100%, 66%, 33% and 0%). Reward consisted of a target flash and pleasing tone after reach completion. The probabilistic reward allowed us to categorize reaches in terms of reward prediction error (RPE). Rewarded reaches to the 66% and 33% targets led to a positive RPE, whereas unrewarded reaches led to a negative RPE. Further, rewarded reaches to the 33% target led to a greater positive RPE (high +RPE) than rewarded reaches to the 66% target (low +RPE), and vice versa for the unrewarded reaches. Reaches to the 100% and 0% targets are categorized as having no RPE. We asked whether reach vigor after an RPE event, was influenced by its sign and magnitude. Relative to the previous trial, subjects increased their peak velocity when they experienced a high +RPE ($p = 2.79e-5$) and decreased their peak velocity when they experienced a high -RPE ($p = 9.12e-3$). Interestingly, the magnitudes of these changes in peak velocity were asymmetric ($p = 5.41e-3$), as they increased their velocity more in response to a +RPE than they decreased their velocity following a -RPE. In contrast, subjects did not change their velocity when they experienced no RPE or a low RPE, regardless of it's sign ($p's > 0.05$). Additionally, we observed an effect of the expected value of the reward, i.e. the probability of the reward for each target. Average peak velocity increased with increasing expected value of the reward ($p = 3.00e-7$). Our findings demonstrate that the vigor of movement is modulated by reward prediction errors. Therefore, vigor reflects not only the immediate expectation of reward, but our recent surprise in predicting that reward, providing evidence for an intriguing link between the unpredictability of the outcome of our actions and the vigor of the movements that follow.

Title: The effects of repetition and reward on the vigor of movements

Authors: *C. KORBISCH[1], S. SUKUMAR[2], A. A. AHMED[3];
[1]Univ. of Colorado, Boulder, Boulder, CO; [2]Univ. of Colorado Boulder, Boulder, CO; [3]Mechanical Engin., Univ. of Colorado, Boulder, CO

Abstract: In tasks emulating foraging, laboratory experiments on humans and animals have shown a consistent tendency to overstay and harvest reward from patches/reward sites long after it is optimal to do so. Similarly, repeating specific actions biases future action to be more similar and have also been accompanied with a reduction in reaction time (RT). (Mawase et al., 2018; Verstynen & Sabes, 2011; Yu & Cohen, 2009). These use-dependent effects could be related to overstaying behavior in foraging and reluctance to switch action, to the extent that harvesting is realized through repeated action. Therefore, to understand the mechanism behind this repetition bias, we seek to first thoroughly understand how the vigor of a movement changes with repetition and how this change is further modulated by the value of action outcomes. We hypothesize that repetition will reduce RT and that this reduction further increases with higher repetition count. Further, while it has been shown that RT reduces with added reward, it is unclear how this phenomenon interacts with repetition count (Reuter et al., 2018). We also expect that an increase in reward will enhance reduction in RT. We believe that these RT reductions afford an improvement in average rate of reward from an environment, thereby rendering bias towards repeating previous behaviors optimal.

We designed an arm reaching study to test these hypotheses. In this study we had subjects perform a series of arm reaching movements towards a cued target (one of two possibilities) under duration constraints. We measured the RT to movement initiation as subjects made either a repeated or alternate movement. The number of repetitions and reward value of successful movements were randomly varied across the subject pool (n=5).

Our preliminary findings show that RT is modulated by both repetition count and reward. We find that after 5 repetitions to a given direction for an added reward of 1 point per accurate reach, subjects on average do not decrease their RT (RT normalized to the first trial in repetition is 1.003). However, after 20 repetitions in the same reward conditions, RT decreased to 88.7% of their RT on the first trial. Further with reward of 5 points per reach, we find that after 5 reaches RT decreases to 93% of that in trial 1 and to 89% of trial 1 RT after 20 reaches. To note, RT towards the initial higher value target was slightly faster than towards the lower value target (0.248 s compared to 0.256 s). Future work involves continued data collection, more detailed analysis of behavioral metrics to determine the effect of repetition. We expect our findings to shed light on the prevalence of repetitive behavior observed in healthy and pathological populations.

Title: A generative model to assess the behavior of humans and monkeys in a virtual balancing task

Authors: *M. SADEGHI[1], R. SHARIF RAZAVIAN[1], S. BAZZI[1], R. CHOWDHURY[2], P. LOUGHLIN[2], A. BATISTA[2], D. STERNAD[1];
[1]Northeastern Univ., Boston, MA; [2]Univ. of Pittsburgh, Pittsburgh, PA

Abstract: A large body of behavioral and neurophysiological studies on primates have attempted to address the computations needed for the control of voluntary movements. Despite numerous insights, these studies mostly relied on simple reaching movements that tended to be short and stereotypic in their kinematic profiles. Much remains unknown about the control mechanisms that govern movements involving continuous interactions with the world. An example of such interactions is balancing a beam, which requires integration of continuous feedback and leads to unique behavior at each attempt. To explore such interactive control, we introduced the Critical Stability Task (CST), where monkeys were trained to balance a linear unstable system in the virtual environment, akin to balancing a beam. Previous analysis of CST behavioral data revealed that despite large trial-by-trial variations, monkeys exhibited consistent features in behavior. For example, as task demands became more difficult, the success rate dropped, and the control response showed shorter lag and lower feedback gains. However, these observations alone could not fully capture the behavioral richness of the task to provide insight into the monkeys' control strategies. To gain more insight, this study adopted a normative approach based on stochastic optimal control theory to develop a generative model. This model produced strikingly similar behavior to the monkeys, both at the aggregate and at the single-trial level of behavior. On average, the model successfully captured how success rate, lag of control response, and magnitude of feedback gains changed as a function of task difficulty. In addition, analysis of single trials provided further insight into different control strategies that the monkey employed for different task demands. Specifically, the model suggested that the behavior in easier trials resembled that of position-based control, while the behavior in more difficult trials exhibited features of a velocity-based control strategy. The proposed model also makes new predictions about the role of different sensory information in task success, which can be later tested in behavioral experiments with both humans and monkeys. Importantly, with available neural recordings from monkeys, this model may inform the analysis of neural data and hence add to the understanding of the neural basis of sensorimotor integration during continuous interactive behavior.

Title: Catch me if you can: task occlusion effects on football catching skills performed in a virtual reality environment

Authors: *K. BURGER[1], M. AUBANEL[2], N. KUZNETSOV[1], M. DALECKI[1];
[1]Sch. of Kinesiology, Louisiana State Univ., Baton Rouge, LA; [2]Digital Media Arts & Engin., Lousiana State Univ., Baton Rouge, LA

Abstract: Virtual reality (VR) is used to train various interceptive tasks as they relate to sports performance. Most research has shown positive learning effects in these environments and has supported VR as a valuable tool for training. A long-used method in motor learning, occlusion training, has been adapted to VR to overload the visual system in a controlled way to understand and improve the learning process. This study aimed to test the learning process of football catching skills in VR and explore if occlusion training in VR affects skill improvement and retention. We hypothesized that the group receiving occlusion training in VR would have lower catching scores through the training session vs. catching without occlusion due to the increased difficulty. However, we also expected that VR occlusion training would lead to higher retention scores due to the increased load on the visual system during practice. Twenty-six healthy young adults (M = 21.2 yrs, 4 males) were placed in a virtual football stadium via a head-mounted display (HTC Vive ProEye) and wore trackers on their wrists that rendered hand motion in VR. A quarterback in the VR environment threw a football and the participant had to catch the ball virtually with both hands. Following a baseline session of 10 catches, the control group practiced catching in VR with 30 throws at 43 mph each. The intervention group also practiced catching with 30 throws at 43 mph for their training session, but the ball disappeared for the middle 40% of its flight trajectory, forcing the participants to react to the ball's reappearance shortly before arrival. 24 hours after the training session, participants returned to test absolute retention consisting of another 10 throws with full visibility of the ball's trajectory.Catching performance at baseline, during the training session, and retention was measured by the percentage of successful catches. The control group significantly improved their catching percentages from baseline to the end of practice (+30% [SD = 17%]) ($p<0.05$), while the intervention group did not (+18% [SD =25%]) ($p>0.05$). Scores recorded 24 hours after the end of training showed good levels of retention in the intervention group (52% [SD = 20%]) ($p>0.05$), and the control group (70%, [SD = 23%]) ($p>0.05$). The results suggest that virtual catching skills can be improved with training, but that partial occlusion, in contrast to our expectation, did not induce any additional benefits to performance. Future studies will explore other intervention settings and the extent to which catching skills learned in VR positively transfer to real world catching skills, which may be useful to improve sport performance.

Title: Slow firing single units are essential for optimal decoding of silent speech.

Authors: A. GANESH[1], A. J. CERVANTES[2], ***P. KENNEDY**[1];
[1]Neural Signals Inc, Duluth, GA; [2]4760 Univ. Heights, West Landivar,, Belize Intl. Inst. of Neurosci. (BIIN),, Belize City, Belize

Abstract: *Introduction:* The development of a speech prosthetic for those who are locked-in (paralyzed and mute) requires decoding patterns of individual single units during *silent* speech[1,2]. The aim of this abstract is to provide evidence that fast *and* slow single units recorded from the speech motor cortex of locked-in and intact subjects *speaking silently* are both important in decoding. Slow firing units are essential for *optimal decoding accuracy. Materials, Methods and Results:* The speech motor cortices in two human subjects were implanted with Neurotrophic Electrodes. In both subjects, single units were decoded during audible and silent speaking of phones. The decoding was performed using a Classification paradigm (Matlab). The results indicate that even though fast firing units are important to maintain accuracy (because when fast firing units are excluded, the accuracy drops to 64% as shown), slow firing units contribute to decoding accuracy because when they are removed from the analysis, the accuracy drops from **96.7% to 80%.** *Legend: The accuracy of phone identification during silent speech in subject 6 is 96.7% when ALL UNITS are included (left bar ALL). Excluding each unit (1-23) in sequence may change the accuracy. When the non-firing units (NO) are excluded the accuracy remains the same. When FAST firing units are excluded the accuracy drops to 64%. When slow firing units are excluded the accuracy drops to 80%. The results are similar in the locked-in subject.Discussion:* The slow firing units are important, though not as important as the fast firing units as can be evidenced from the decreases in accuracy shown in the figure. The data is essentially the same for the locked-in subject. The figure above is derived from 23 single units recorded from one electrode in subject 6. Histological analysis after implantation for 13 years in locked-in subject 5 indicates copious numbers of myelinated axons, and no scarring[3] with no loss of functionality[2]. These findings are unique to this electrode. *Significance:* Slow firing units cannot be omitted from analysis as evidenced by these data.

Title: Decoding confidence from pre-response EEG enables an augmentative brain-computer interface

Authors: *N. SADRAS[1], O. G. SANI[1], D. VALERIANI[2], C. CINEL[2], R. POLI[2], M. M. SHANECHI[1]; [1]Electrical Engin., USC, Los Angeles, CA; [2]Sch. of Computer Sci. and Electronic Engin., Univ. of Essex, Colchester, United Kingdom

Abstract: Confidence is a cognitive state that reflects a subject's belief in the correctness of a decision. If confidence can be reliably decoded from a subject's brain signals *before* they make a decision (pre-decision), it would then be possible to develop a brain-computer interface (BCI) that could increase a user's decision accuracy. Although prior studies have shown that decision confidence is indeed represented in human brain signals, it remains unclear whether this representation is stimulus-locked (pre-decision) or response-locked (post-decision), and whether pre-decision decoding accuracy is high enough

to enable an augmentative BCI to improve a user's performance. In this work, we investigate the neural representation of decision confidence by collecting electroencephalography (EEG) activity while subjects perform a stimulus discrimination task with realistic stimuli. We use event-related potential (ERP), source-localization, and decoding analyses to characterize the neural correlates of confidence and investigate whether these correlates can be used to reliably decode confidence from single-trial EEG prior to response time. We then develop a simulated BCI to investigate if, and under what conditions, a confidence-based BCI can be used to improve a user's performance. Our ERP and source localization analyses show that the neural representation of confidence is stimulus-locked (pre-decision) in the presence of a post-stimulus gap, and that the absence of this gap can cause the representation to appear as if it is response-locked. This suggests the feasibility of decoding confidence before a decision is made. We then show that decision confidence can be accurately decoded from single-trial, stimulus-locked, pre-decision EEG signals using a nonlinear support vector machine (SVM) classifier. Lastly, our BCI simulation shows that the confidence decoded by the SVM can be used in a BCI to improve a user's performance, specifically when the task is difficult and has a high error cost. These results serve as a proof-of-concept for a non-invasive, confidence-based BCI that can augment human performance.

Title: Identifying distinct neural features between the initial and corrective phases of precise reaching using autoLFADS

Authors: *W. LEE[1], B. M. KARPOWICZ[3], C. PANDARINATH[3,4], A. G. ROUSE[2,1];
[1]Bioengineering Dept., [2]Dept. of Neurosurg., Univ. of Kansas Med. Ctr., Kansas City, KS; [3]Wallace H. Coulter Dept. of Biomed. Engin., Emory Univ. / Georgia Technol., Atlanta, GA; [4]Dept. of Neurosurg., Emory Univ., Atlanta, GA

Abstract: Reaches to small targets often consist of an initial reach followed by corrective submovements. Thus, when monkeys perform a precision center-out task with small targets and are allowed to make as many corrective submovements as needed, there can be diverse behavior and neural activity on individual trials. We trained two monkeys to perform such a task and used floating microelectrode arrays to record

from primary motor cortex (M1) across multiple sessions. Since the difficulty of the task induces self-generated errors and corrections, each corrective submovement was idiosyncratic and there were a limited number in each session, precluding traditional analyses that use trial-averaging. We used latent factor analysis via dynamical systems (LFADS) to analyze the neural population activity with a non-linear dynamical system, which enabled inference of underlying latent factors and 'denoised' single-trial firing rates. We used automated hyperparameter tuning (autoLFADS) to optimize model fitting and selection. Additionally, we used "stitching" to infer a latent factor space that was common to all sessions, enabling comparison of latent factors across sessions despite changes in the recorded neural population. LFADS improved our ability to predict velocities via linear regression for both initial and corrective movements compared to smoothed firing rates. However, for both LFADS and smoothing, prediction of corrective movements was worse than initial, and the linear mapping that best predicted initial movements did not generalize to corrective movements. When visualized with t-SNE, the neural population state space showed clear clusters for initial movements based on their velocity profiles. In contrast, corrective submovements did not overlap with the clusters of the initial movements, contrary to our expectation if corrective submovements evoked neural activity patterns that were comparable to small initial movements. Instead, corrective submovements formed a separate grouping of neural activity patterns more related to each other than initial movements. Within this separate cluster, the neural factors formed a continuum depending on both velocity and position. Our results highlight how latent neural factors improve the ability to interpret individual trials with variable behavior and design less constrained and more naturalistic tasks. Additionally, it appears that unique differences in neural activity occur during corrective movements making it difficult to decode from a model built from initial movement data alone with a variety of neural patterns encoding the different submovements.

Title: Deep learning-based decoding of sensorimotor information from superior parietal lobule of macaque

Authors: *M. FILIPPINI[1], D. BORRA[2], M. URSINO[2,3], E. MAGOSSO[2,3], P. FATTORI[1,3];
[1]Dept. of Biomed. and Neuromotor Sci., Univ. of Bologna, Bologna, Italy; [2]Dept. of Electrical, Electronic and Information Engin. "Guglielmo Marconi", Univ. of Bologna, Cesena, Italy; [3]Alma Mater Res. Inst. for Human-Centered Artificial Intelligence, Bologna, Italy

Abstract: To successfully guide our actions, several brain computations are needed. Given the dynamism that the system requires and the inherent delay in collecting sensory feedback, our brain must implement an internal model of our surroundings and body to predict the outcome of our actions in a timely manner.

This feedforward model was proposed running in the posterior parietal cortex (PPC). PPC is implicated in the processing of sensory information coming from surrounding environment and proprioception to guide actions. Yet, little is known about how this integration of different signals can occur and how it is distributed across PPC areas. We investigated how the information is processed in the superior parietal lobule (areas V6A, PEc and PE), belonging to the dorso-medial visual stream that is specialized in planning and guiding reaching movements. We trained two macaque monkeys to perform a delayed reaching task towards 9 positions (distributed on 3 different depths and direction levels) in the 3D peripersonal space. The activity of single cells was recorded from V6A, PEc, PE and fed to convolutional neural networks (CNNs) that exploited the temporal structure of neuronal activation patterns to reconstruct the target positions reached by the monkey. In addition to discrete positions in space (classification problem), we used the same CNN architecture to decode *x,y,z* positions of monkey's index finger during reaching (regression problem). Then, we introduced a positive or negative delay between neural activity (network inputs) and kinematics (network target) to check whether the neural activity was more linked to somatosensory feedbacks (negative delays) or processing of the motor plan (positive delays). CNNs using signals from the most caudal V6A and PEc areas outperformed those using signals from area PE in the reached target and movement trajectories decoding. In all areas, decoding accuracies started to increase when the information about the target to reach was provided, and reached a plateau at movement onset. Results support a dynamic encoding of the different phases and properties of the reaching movement differentially distributed over a network of interconnected areas. Furthermore, decoding accuracies did not change significantly by introducing positive or negative offsets between neuron activity and kinematics, pointing towards a simultaneous presence of feedback and planning signals. This supports the view of an internal feedforward model dealing with in these PPC areas. This study may have implications in the perspective of novel neuroprosthetic devices based on the decoding of these rich signals for reliably carrying out patient's intentions.

AbstractWith the development in the field of neural networks (NN), *Explainable AI* (XAI), is being studied to ensure that AI models can be explained. There are some attempts to apply NN to neuroscientific studies to explain neurophysiological information with high machine learning performances. However, most of those studies have simply visualized features extracted from XAI and seem to lack an active neuroscientific interpretation of those features. In this study, we have tried to actively explain the high-dimensional learning features contained in the neurophysiological information extracted from XAI, compared with the previously reported neuroscientific results. We designed a deep neural network classifier using 3D information (3D DNN) and a 3D class activation map (3D CAM) to visualize high-dimensional classification features. We used those tools to classify monkey electrocorticogram (ECoG) data obtained from the unimanual and bimanual movement experiment. The 3D DNN showed better classification accuracy than other machine learning techniques, such as 2D DNN. Unexpectedly, the activation weight in the 3D CAM analysis was high in the ipsilateral motor and somatosensory cortex regions, whereas the gamma-band power was activated in the contralateral areas during unimanual movement, which suggests that the brain signal acquired from the motor cortex contains information about both contralateral movement and ipsilateral movement. Moreover, the hand-movement classification system used critical temporal information at movement onset and offset when classifying bimanual movements. As far as we know, this is the first study to use high-dimensional neurophysiological information (spatial, spectral, and temporal) with the deep learning method, reconstruct those features, and explain how the NN works. We expect that our methods can be widely applied and used in neuroscience and electrophysiology research from the point of view of the explainability of XAI as well as its performance.

Title: Fenet feature extraction neural network for brain machine interfaces

Authors: *B. HAGHI[1], T. AFLALO[2], S. KELLIS[2], K. KADLEC[1], N. POURATIAN[3], R. A. ANDERSEN[4], A. EMAMI[1];

Abstract: Clinical neural prosthetic systems decode brain signals recorded from implanted electrode arrays to enable paralyzed human participants to control external devices. This process occurs in two basic steps. First, electrical signals that convey information about the activity of neurons around the electrode tip are transformed into "neural features". Second, the relationship between neural features and the participant's intent is learned, and subsequently decoded to control external devices. Here, we present FENet, a compact (F)eature (E)xtraction (Net)work that learns an optimized mapping between electrical signals and neural features, which significantly improves decoding performance compare to the classic feature construction methods. FENet is parameterized using a novel architecture that jointly optimizes the feature extraction and feature decoding stages of the neural decoding process, while constraining the feature extraction algorithm to use the same parameterization for all the electrodes used in our training set. This approach is based on the understanding that while the activity of different neurons will contribute to the decoding of the participants' intentions in different ways, the underlying process by which neural activity is translated into electrical fluctuations detected by an electrode is conserved across different electrodes, recording times, and brain regions.
In this work, we validate the FENet architecture by predicting the kinematics of a computer cursor movements using neural data recorded from electrode arrays implanted in human cortex. We compared performance of neural features computed from FENet against two current gold standards: 1) the rate of neural spike events computed by counting threshold crossings of the broadband neural signal; and 2) a wavelet decomposition of the broad band neural data. We found that FENet based features outperformed these two methods by 50 and 47 percent decrease in mean square error, and 51 and 28 percent increase in R2, respectively. We further present an evaluation of the effect of hyperparameter choice on FENet performance, including the amount and quality of training data as well as the choice of parameter initialization. Our results demonstrate that the trained FENet can be used for novel datasets, without modification, and leads to improved performance, generalization, and efficiency of training. Moreover, our approach demonstrates how machine learning techniques constrained by domain specific knowledge can significantly improve generalization performance.

Title: Adaptive Brain-Computer Interfaces allow credit assignment learning and formation of sparse control strategies

Authors: *P. RAJESWARAN[1], J. M. CARMENA[2], A. L. ORSBORN[1,3,4];
[1]Dept. of Bioengineering, Univ. of Washington, Seattle, Seattle, WA; [2]Dept. of Electrical Engin. and Computer Science, Helen Wills Neurosci. Inst., UC Berkeley, Berkeley, CA; [3]Dept. of Electrical & Computer Engin., [4]Washington Natl. Primate Res. Ctr., Univ. of Washington, Seattle, WA

Abstract: Introduction: In a Brain Computer Interface (BCI), select neurons (readouts) control an external device. There are two key elements to successful BCI control. First, users must produce reliable firing patterns in readout neurons. Second, a decoder translates that neural pattern into a command to achieve the desired movement. Closed-Loop Decoder Adaptation (CLDA) updates the decoder to map learned activity patterns to intended movements to improve performance. However, CLDA still requires the brain to generate reliable activity in readout neurons. Understanding how the brain solves this computation in the presence of adaptive decoders will shed light on learning mechanisms in BCI and inform training protocols to shape user learning. Studies using fixed decoders show that learning produces differential modulation of readout populations compared to non-readout populations, reflecting a credit assignment process. CLDA introduces a moving target for the brain and reduces overall task error, both of which may impact credit assignment learning. Here, we investigate credit assignment in the presence of intermittent CLDA and changes to the readout populations. **Methods:** We analyzed neural activity as a monkey learned to control a 2D BCI cursor with CLDA intermittently performed across 16 days (Orsborn et al, Neuron 2014). 78 motor cortex multi-units were recorded, from which 20 readout units were used in a Kalman Filter decoder. We used a multiclass logistic regression model to quantify how task information is distributed across neural populations over days. **Results**: Consistent with credit assignment learning, readout units became more predictive of task performance than non-readout units over training (*Prediction accuracy on Day 16 (readout, non-readout) : 89.34 ± 3.6%, 52.22 ± 9.8 %; Day 2: 56.69 ± 3.9%, 52.99± 9.4 %*). Model coefficients converged with learning, though changing readout units impacted stability. Within the readout population, neural representations were more sparse after learning, with fewer neurons required to explain 80% of variance (Day 16: 5.5 (mean across targets), Day 2: 7.9). **Conclusion:** Despite reduced task error and decoder instability with CLDA, the brain learns stable representations specific to readout ensembles. Our results further suggest learning may lead to sparse representations within the readout ensemble. This could reflect optimization for low-dimensional tasks or may be incomplete credit assignment. Insights into how and why sparse BCI control strategies emerge will shed light on the neural mechanisms that facilitate and constrain learning BCI.

Title: Closed loop simulation of neural feature selection to accelerate initial brain computer interface decoder training

Authors: *S. LI[1], A. L. ORSBORN[2,1,3];
[1]Bioengineering, [2]Electrical & Computer Engin., [3]Washington Natl. Primate Res. Ctr. (WaNPRC), Univ. of Washington, Seattle, WA

Abstract: Advances in neural recording have drastically increased the number of simultaneous neural measurements. This trend could be beneficial for brain-computer interfaces (BCIs) which extract features from neural measurements to decode user intentions. However, increased measurements also introduce new considerations for training closed-loop BCI decoders. Decoders can be trained offline on pre-collected data or online in "closed loop" as the user controls the BCI in real-time. Linear algorithms trained via closed-loop decoder adaptation (CLDA) currently provide the best performance for continuous motor BCIs, and are particularly useful for rapidly calibrating a decoder without requiring initial training data. Increases in the number of parameters to estimate may impact CLDA algorithm convergence for calibration. For instance, inclusion of "noisy" features can reduce performance and slow parameter convergence. Current CLDA methods couple feature selection with decoder parameter estimation. We hypothesize that starting training on a subset of reliable features will accelerate initial decoder training and propose a framework for adaptive feature selection separate from parameter estimation. As an initial test of our hypothesis, we simulated a BCI user with a fixed encoding model relating movement intention to firing rates of neurons. The decoder was a Kalman Filter initialized with random parameters and then trained using SmoothBatch CLDA. To test the role of initial feature selection, we ran simulations with neural populations of varying signal-to-noise ratios (SNR). In a population of neurons, we set 25% as a high SNR feature subset with twice the encoding weights and 40% less noise compared to other neurons. Training on the high SNR subset followed by iterative addition of other neurons allows the user to finish 10% more center-out reaching trials in the same training time compared to a decoder trained with the full set of features from the start. The mean decoder weight of high-SNR neurons also converged faster to the simulated user's encoding model. Future directions include 1) understanding how feature selection scales with the number of neural features, 2) adaptively estimating feature SNRs for closed-loop feature selection, and 3) exploring decoder-encoder interactions using an adaptive encoding model. Our simulations demonstrate the potential utility of initial feature selection for decoder calibration in closed-loop, where user-decoder interactions influence the quality of training data to estimate decoder parameters. Strategic selection of neural features may facilitate initial BCI decoder training and shaping user learning.

Title: Long-term pattern recognition control using Regenerative Peripheral Nerve Interfaces (RPNIs) in humans with upper-limb amputations

Authors: P. P. VU[1], A. K. VASKOV[1], T. A. KUNG[2], C. A. CHESTEK[1], P. S. CEDERNA[2], S. W. KEMP[2];
[1]Biomed. Engin., [2]Plastic Surgery Section, Univ. of Michigan, Ann Arbor, MI

Abstract: Introduction: State-of-the-art control systems can provide upper-extremity prosthetic users greater control, but rely on recording methods limited by low signal-to-noise ratios (SNRs). Consequently, these control systems require frequent recalibration, leading to user frustration and prosthesis abandonment. We developed the Regenerative Peripheral Nerve Interface (RPNI) as a more reliable recording interface for prosthetic control. An RPNI consists of a free muscle graft reinnervated by a transected peripheral nerve and produces SNRs that can be 12x greater than other methods. In this study, we hypothesized that RPNI signal quality can remain stable over time and allow control systems to maintain prediction performance without recalibration. **Materials and Methods**: Two participants with transradial amputations (P1 and P2) underwent surgery to place RPNIs on each of their median and ulnar nerves in 2015 and 2017, respectively. In 2018, intramuscular bipolar electrodes were placed into their RPNIs. Participants were then instructed to volitionally move their phantom limb to mirror 2 finger movements (thumb flexion, small finger flexion). These tasks were repeated in 11 sessions over 276 days in P1 and 14 sessions over 422 days in P2 to track SNRs over time. Additionally, we trained a multi-grip (fist, pinch, point) classifier and tested prediction accuracy in several different arm postures (arm at side, arm raised, arm in front, and arm across body) without recalibration up to 478 days in P2.**Results**: In both participants, SNRs remained consistently high, ranging from 15-250 across sessions, and showed no significant decreasing trend over time ($p = 0.92$). However, signals did vary substantially from session to session. Specifically, P1's median RPNI SNRs ranged between 65-250 across days for thumb flexion, whereas the ulnar RPNI SNRs ranged between 15-55 for small finger flexion. P2's SNRs ranged between 20-40 for the median RPNI and 15-80 for the ulnar RPNIs. The multi-grip classifier predicted greater than 94% accuracy across all arm postures with no significant decrease in performance across sessions ($p = 0.26$). Of the 1,179 trials performed, 85% of trials had prediction speeds of less than 250 ms, which is well below the 300 ms threshold of perceived delay between muscle activation and prosthetic hand movement.**Conclusions**: RPNIs provide high signal quality and stability (SNRs > 15), allowing them to be used as prosthetic control systems to maintain prediction performance without recalibration for up to 478 days. As a result, RPNIs have the potential to increase prosthetic use satisfaction and decrease prosthetic abandonment.

Title: Investigation of the most informative electrocorticography features for speech decoding

Authors: *A. SCHIPPERS, Z. V. FREUDENBURG, M. J. VANSTEENSEL, N. F. RAMSEY;
Univ. Med. Center, Utrecht, Utrecht, Netherlands

Abstract: Brain-computer Interfaces (BCI) can provide new means of communication for those who lost the ability to vocalize speech due to severe paralysis, caused by e.g. amyotrophic lateral sclerosis. The most intuitive way to control a BCI would be by attempting or silently producing speech, with words being decoded in real-time from the sensorimotor cortex (SMC). We have previously shown we are able to detect four different individually spoken phonemes from SMC electrocorticography (ECoG) recordings (Ramsey et al. 2018). However, to decode phonemes that are spoken within a word and are thus subject to coarticulation, it is crucial to know which ECoG features are most informative. Here, we conducted an investigation of ECoG features that may be used for speech decoding. In specific, we aimed to assess which time window around phoneme pronunciation contains the most information for decoding.
We recorded ECoG data from subdural high-density (HD) electrode grids over the SMC in three patients with epilepsy who were chronically implanted for presurgical diagnostic purposes. Patients performed overt speech tasks, producing isolated phonemes. We analyzed their high frequency band (HFB) power change in a window of 2s centered on phoneme onset time, which was determined manually by the experimenter as the time the phoneme could be acoustically detected. For each phoneme, the mean HFB response over trials was calculated for all electrodes and for all timepoints in the 2s time window, creating a spatiotemporal template per phoneme. This template was divided in non-overlapping sub-templates of equal time window sizes. Each of these sub-templates of a specific phoneme was tested for correlation to the full spatiotemporal templates of all phonemes, to determine how informative each phoneme specific sub-template was for decoding that phoneme.
Using this method, we identified a sub-template that is most informative about the full spatiotemporal template of its own phoneme compared to the other three phoneme templates. However, this sub-template differed per phoneme. For some phonemes the highest correlating sub-template was found prior to phoneme onset time, while for other phonemes this was found after phoneme onset time.
These results suggest that for accurate detection of phonemes from ECoG signals, there is a need for phoneme specific spatiotemporal templates. The method proposed in this study is able to identify the most informative ECoG features and may thus be applied to increase phoneme decoding accuracies. We hypothesize that the most informative time period for each individual phoneme can also be used to decode words, since every word is a unique combination of phonemes.

Title: A biophysical counting mechanism for keeping time

Authors: *K. ZEMLIANOVA[1], A. BOSE[2], J. M. RINZEL[3];
[1]New York Univ., New York, NY; [2]Dept. of Mathematics, New Jersey Inst. of Technol., Newark, NJ;

Abstract: The ability to estimate and produce appropriately timed responses is central to many behaviors including speaking, dancing, and playing a musical instrument. A classical framework for estimating or producing a time interval is the pacemaker-accumulator model in which pulses of a pacemaker are counted and compared to a stored representation. However, the neural mechanisms for how these pulses are counted remains an open question. We present a biophysical model of how to keep count of a pacemaker using a system of bistable Wilson-Cowan units asymmetrically connected in a one-dimensional array; all units receive the same input pulses from a central clock but only one unit is active at any point in time. With each pulse from the clock, the position of the activated unit changes thereby encoding the total number of pulses emitted. This neural architecture maps the counting problem into the spatial domain, which in turn translates count to a time estimate thus allowing our mechanism to be used in time interval production and estimation. We show that our mechanism allows encoding of count that is robust to two sources of stochasticity: noise internal to the neural units themselves and variability that arises from using a stochastic oscillator as the pacemaker. Finally, we extend the model to a hierarchical structure to be able to robustly achieve higher counts.

Title: The persistence of time cell sequences during delay intervals does not depend on ongoing theta oscillations

Authors: *L. YUAN[1], J. FIGUEROA[1], A. KHAN[1], C. HSU[1], G. NARAYAN[1], J. K. LEUTGEB[1], S. LEUTGEB[1,2];

Abstract: Working memory (WM) retention over periods of seconds is essential for cognitive tasks. Many studies have reported sequential firing of hippocampal cells which represent intervals of time (time cells) in WM tasks as a possible mechanism for memory maintenance. The sequential firing patterns of time cells are thought to be internally generated, and time compression during theta oscillations is a potential mechanism to generate time cell sequences on the behavioral time scale. Consistent with this notion, hippocampal sequential firing patterns were abolished when theta was reduced by inactivating the medial septal area. However, time cells have also been reported in tasks in which there was no sustained theta during WM retention. We therefore asked whether the emergence or stability of time cells during a delay interval in a WM task depends on ongoing theta oscillations. While recording hippocampal CA1 ensembles in rats (n=4) that performed a delayed spatial alternation task with delay intervals of 10 s and 30 s, differences in the occurrence of theta oscillations during the delay period were generated by taking advantage of the link between movement and the emergence of hippocampal theta. The task included blocks of trials when rats were either forced to run on a treadmill or were allowed to rest during the delay interval, and theta power was significantly lower during resting compared to running. Despite the substantial differences in theta power, the proportion of time cells in CA1 did not differ between running or resting during delay intervals [running: n=138 of 280 cells (49.3 %), resting: n = 125 of 280 cells (44.6 %)]. In both running and resting trials, reliable time cells with a short time field were limited to the first few seconds of the delay regardless of its duration (10 s or 30 s). In addition, a second population of late-firing cells were observed in 30 s delays, which were silent during the first few seconds, but then constitutively active across the remainder of the delay period. Taken together, our results show that consistent theta oscillations are not required for the emergence or stability of hippocampal time cells. These results support the hypothesis that other mechanisms, such as network activity that can temporally organize firing patterns over several seconds, are required for supporting time cell sequences. In addition, with WM lasting 30 s in our experiment (percent correct trials: 84.0 % for running, 86.7 % for resting) and time cell sequences only lasting for the initial seconds of the delay, WM retention likely requires mechanisms other than the sustained activity of hippocampal time cells.

Title: Propofol differentially modulates early consolidation of ego- and allocentric spatial navigation

Authors: *D. IGGENA[1], P. M. MAIER[1], S. HÄUßLER[2], M. MENK[3], H. OLZE[2], C. FINKE[1], C. J. PLONER[1];

Abstract: Successful navigation in familiar environments can be achieved by reproducing previously travelled path sequences and by using the remembered positions of environmental landmarks. It is currently unclear, whether the substrates supporting the corresponding egocentric and allocentric memory representations can be dissociated at the neural level and regarding the temporal dynamics of their consolidation. Here, we investigated possible differential contributions of hippocampus-dependent networks to early consolidation of egocentric and allocentric spatial memory by using a neuropharmacological approach in neurologically normal human subjects. We used the $GABA_A$-ergic anesthetic propofol to transiently modulate hippocampal neural activity during the early stage of spatial memory consolidation. A total of 52 patients undergoing minor ear-nose-throat surgery learned to navigate to a target in a five-armed maze derived from animal experiments immediately prior to injection of propofol (early group) or more than 60 minutes before injection (late group). Two hundred and forty minutes after anesthesia, subjects were tested for egocentric and allocentric memory-guided navigation. Our results show a selective impairment of memory-guided navigation in the early group and near-normal performance in the late group. Both egocentric and allocentric navigation were affected, albeit with distinct error patterns. In the egocentric condition, early group patients navigated significantly more often to a wrong alley but showed otherwise efficient navigation, suggesting a deficit for path sequence memory. By contrast, in the allocentric condition, early group patients mostly navigated to the correct alley but showed a significant increase in detours and prolonged navigation times, thus suggesting a weakened representation of the relationship between landmarks. We conclude that hippocampus-dependent networks contribute to early consolidation of representations underlying both egocentric and allocentric memory-guided navigation. Distinct aspects of these representations are susceptible to $GABA_A$-ergic modulation within a brief time window of less than 60 minutes, indicating an early redistribution and reconfiguration of hippocampus-dependent memory networks.

Title: Tracking elapsed time: contrasting striatal vs. hippocampal neural activity

Authors: F. ROLANDO[1], T. W. KONONOWICZ[2,1], J.-R. DUHAMEL[1], V. DOYERE[2], *S. WIRTH[1]; [1]Inst. des Sci. Cognitives, CNRS-UMR 5229, Bron, France; [2]Univ. Paris Saclay, CNRS-UMR 9197 Neuro-Psi, Saclay, France

Abstract: Processing time gives a sense of continuity and allows to order events throughout days to years. Yet, at a smaller scale, during daily events, we can also tell when a blank in a conversation is too long, or that the metro door is going to close shortly. Here we asked how neural regions previously

involved in timing represent different durations scaling from sub second to supra second range. We focused on the striatum (caudate and putamen) and the hippocampus, as time cells were discovered in both regions. We designed an ongoing 3 intervals discrimination task, where the durations to be timed changed from 0.25s to 8s. Cross-species comparison showed that humans performed better at durations above the second range, whereas rhesus macaques were accurate at both, sub-second and supra-second timing. Time related activity was found in all 3 neural regions. To further characterize the nature of time representation in each region, we performed a decoding analysis using the activity of the population of neurons through time. We asked how any individual point in time differed significantly from any other time points of the interval. This analysis allowed for each region to determine the evolution of the discrimination through time and its temporal resolution. Below 2s, the decoding analysis based on the population of caudate neurons suggests that this region discriminates time accurately in a continuous manner with a fine time resolution. This contrasted with putamen-based decoding, for which specific intervals corresponding to expected events were represented. Finally, despite the presence of time cells, decoding based on hippocampus activity performed poorly compared to the other two striatal regions. The results highlight strong differences across neural structures, despite the presence of time cells in all 3 regions. We attempt to interpret these differences in light of the different role of each regions in motivation, motor planning and memory.

Title: Hedonic and semantic modulation of subjective temporal duration in healthy ageing

Authors: *M.-C. REQUENA-KOMURO[1], J. JIANG[1], C. J. D. HARDY[1], F. N. BADER[2], M. WIENER[2], J. D. WARREN[1];
[1]Univ. Col. London, London, United Kingdom; [2]George Mason Univ., Fairfax, VA

Abstract: Our ability to perceive time supports our everyday living. Our brain should therefore keep track of the physical time in an accurate and precise way in order to guide us in our interactions with the external world. However, our common experience tells us that our perception of time is highly subjective and constantly modulated by our internal states. Previous research suggests that the important role of hedonic valence in modulating the perceived duration of external events and stimuli may reflect both attentional and arousal effects on internal clock mechanisms. However, to our knowledge, the influence

of the semantic identity of perceived objects has not been investigated. Moreover, some evidence suggests that ageing itself modulates our awareness of time passing. How the interaction between affective and semantic stimulus characteristics impacts subjective time perception is not well understood however, and how healthy ageing affects this interaction is not clear. Here we addressed this issue using an online auditory temporal bisection paradigm in which we manipulated the pleasantness of natural sounds of several seconds duration as well as their semantic category (human versus environmental sounds). Healthy young adults (n=106, 57 female; aged 18 to 30) and healthy older adults (n=83, 44 female; aged 50-75) were recruited through a third-party recruitment platform known as Prolific. They were first asked to rate the pleasantness of the sounds before completing the time experiment on a different day. Psychometric curves were fitted to participants' responses to extract time perception parameters (temporal bisection task and weber's ratio) which were then statistically compared using repeated measures ANOVA. Choice and reaction time data were further analysed using a hierarchical drift-diffusion model. We found no evidence of an ageing effect on the bisection point, while older adults showed a higher discrimination sensitivity for environmental unpleasant sounds compared to younger adults. Both groups perceived the human pleasant and unpleasant sounds as shorter in duration than the environmental pleasant sounds, which were in turn perceived as shorter than the environmental unpleasant sounds; both groups also showed lower discrimination sensitivity for human unpleasant sounds compared to other sounds. Those differences were further reflected in the decision-making parameters. The findings further our understanding of subjective temporal experience in everyday life and how it may change in healthy ageing.

Title: Pharmacological inactivation of the rat mediodorsal thalamus but not lateral cerebellar nucleus impairs supra-second timing performance

Authors: *J. PURNELL[1], B. J. DECORTE[2], K. HESLIN[1], K. L. PARKER[3];
[1]Psychiatry, [2]Neurosci., [3]Dept. of Neurol., Univ. of Iowa, Iowa City, IA

Abstract: While cortical regions like the prefrontal cortex have long been associated with cognitive function, less is known about how subcortical structures like the cerebellum and thalamus contribute to cognitive processing. Supra-second interval timing relies on cognitive functions such as attention and working memory, mediated by the frontal cortex. However, the extended neural circuit necessary for successful supra-second timing has not been fully defined. We used a supra-second interval timing task to probe whether two subcortical structures, the mediodorsal thalamus (MD) and the lateral cerebellar nuclei (LCN), are necessary for temporal processing in rats. Male Long Evans rats learned to time 4- and 12-second intervals in an operant dual-interval peak procedure. In Experiment 1, we used a disconnection

design to determine whether the MD and LCN work together to influence timing performance. We used focal pharmacology to inactivate either half the LCN-MD circuit, or the full LCN-MD circuit during the timing task. In Experiment 2, we assessed the contribution of the MD and LCN independently in our task, with respective bilateral pharmacological inactivations. Preliminary results of these experiments suggest that inactivating the MD impacts the ability to respond in the correct response location for a given cue-duration pairing, but not timing precision or accuracy. LCN inactivations appear to have no effect on timing performance measures nor response location accuracy. Future directions will include performing analyses of inter-trial intervals to examine if the incorrect responding is exploratory in nature or tied cue onset. Additionally single-trial analyses may provide insights into when incorrect responding is occurring during a given trial.

Title: The role of movement in optimal multimodal timing

Authors: *R. DE KOCK[1], P. DATTA[1], W. ZHOU[1], K. A. GLADHILL[2], W. M. JOINER[1], M. WIENER[2];
[1]Univ. of California, Davis, Davis, CA; [2]Dept. of Psychology, George Mason Univ., George Mason Univ., Fairfax, VA

Abstract: Time perception research spans a variety of paradigms to understand how we perceive and time sensory events. However, a gap exists between our understanding of sensory timing and motor timing, as these processes can robustly influence each other. We previously found that motor activity enhanced timing precision of auditory intervals when participants manipulated a robotic arm, compared to participants held in place. We propose that this improvement is achieved via optimal cue combination, whereby movement introduces a new channel of sensory information that is more precise than auditory information, and as such, the combination of the two produces an estimate that is more precise than either alone. In the current experiment, participants timed durations of isolated arm movements, isolated auditory tones, and a combination of both. We hypothesized that precision would be highest for the combined estimates (in line with optimal integration), and that movement estimates would be similar or more precise than auditory estimates. We administered a temporal reproduction task in which participants encoded one of seven durations (1000-4000 ms, linearly spaced). Participants performed the task using a robotic arm manipulandum with a flat workspace. There were three trial types: “movement”, “auditory”, and “auditory-movement”. In “movement” trials, participants began in a randomized location and were cued to begin moving freely until they were interrupted by a “brake” to signify duration offset. In

"auditory" trials, participants were held in place in a randomized location while passively listening to an auditory tone. In "auditory-movement" trials, they simultaneously timed a movement and auditory interval, with aligned onsets and offsets (i.e., the brake aligned with the tone offset). After encoding, in all conditions the duration was reproduced by holding and releasing a button attached to the handle. We analyzed timing accuracy for each condition via estimation means, and to test our hypothesis, we examined the coefficient of variation for each condition (standard deviation/mean). Results demonstrated that subjects exhibited similar accuracy between conditions in reproducing durations. Additionally, the variability for movement and auditory-only conditions were equivalent, with the combined auditory-movement condition exhibiting superior precision over both conditions. These preliminary results suggest that movement can provide a timing signal that is at least as good as auditory timing, and that the combination of these signals leads to improved timing performance, in line with cue combination predictions.

Title: Cerebellar interactions with the cerebral cortex in healthy and ataxic mice

Authors: *B. L. CORREIA[1], M. DHAMALA[2], R. V. SILLITOE[3], Y. LIU[1], D. H. HECK[1];
[1]Univ. of Tennessee Hlth. Sci. Ctr., Memphis, TN; [2]Physics & Astronomy, Georgia State Univ., Atlanta, GA; [3]Pathology and Immunol., Baylor Col. of Med., Houston, TX

Abstract: Long known for its role in motor control, it is increasingly clear that the cerebellum is also involved in numerous cognitive behaviors. Though the neuronal mechanism for the role of the cerebellum in cognition is still unclear, there is a consensus that it involves cerebellar interactions with the cerebral cortex. Recent studies from us and other groups suggest that the cerebellum monitors, and possibly coordinates, the precise phase alignment or coherence of neuronal oscillations in cerebral cortical areas. Specifically, we previously showed that Purkinje cells in right lobulus simplex (LS) and Crus I of healthy mice represent the instantaneous phase and phase differences of local field potential (LFP) oscillations in the medial prefrontal cortex (mPFC) and the dorsal hippocampus (dHC). Here, we asked how loss of cerebellar function affects the coherence of oscillations between the cerebellum and the mPFC or dHC and between the mPFC and dHC. We used multisite *in vivo* extracellular recordings in freely moving mice to measure neuronal oscillations in the LFPs of the cerebellar LS, mPFC, and dHC in a home cage environment. We compared a mouse model of cerebellar ataxia and their littermate controls. The ataxic mice were designed to have a genetically induced loss of Purkinje cell neurotransmission, resulting in an expected repertoire of cerebellar motor deficits. The question we asked here is whether these mice also

have neurophysiological defects that are indicative of cognitive circuit dysfunction. We quantified power spectra of LFP oscillations in each structure and the magnitudes of coherence of oscillations and Granger causality (GC) between each pair of structures using a nonparametric spectral method. Resting-state coherence of gamma oscillations between LS and mPFC was increased in ataxic mice relative to their control littermates and trended towards significance. GC analysis revealed direction and frequency band specific differences between ataxic and control animals. For example, ataxic animals showed significantly larger GC from the mPFC to cerebellar LS in the high gamma band compared to littermate controls. Loss of Purkinje cell neurotransmission also affected GC between the dHC and mPFC where ataxic mice showed significantly lower GC from the dHC to mPFC than control mice in the low gamma frequency range. Our findings reveal that Purkinje cell neurotransmission is required for normal functional interactions between the cerebellum and cerebral cortex and between cerebral cortical areas involved in cognitive functions, suggesting an involvement of the cerebellum in the modulation or coordination of functional communication between brain areas.

Title: Mice Rapidly Update Timed Behaviors in a Serial Fixed Interval Task

Authors: N. AGGADI, R. K. VAN DER MERWE, R. I. ALBERT-LYONS, O. LU, G. MALAKI, C. J. MADDOX, M. GHANEM, J. R. SCOTT, C. R. MOREHOUSE, P. SIMEN, C. D. HOWARD; Oberlin Col., Oberlin, OH

Abstract: Almost all cognitive functions rely on temporal information and perception, though brain circuits encoding timing processes have remained elusive. Much work has investigated how animals time fixed interval durations, but far less work has investigated how animals learn to update behavior to mirror new time intervals, and very little is known about brain circuits contributing to this process. The aim of this study is to investigate whether mice can rapidly update responding in a serial Fixed Interval (sFI) task. In this task, mice are rewarded for presses made after a fixed duration ranging from 12 and 60 seconds, and this fixed interval is updated after a randomly chosen number of trials (ranging from 13-21 trials). Updating of timed behaviors was inferred through three metrics: 1. the time when mice first press the lever in each trial, 2. the time of the first bout of presses in each trial (3 presses, each separated by <0.5 sec), and 3. the time when mice reach 63% of their maximum press rate in each trial. We found that mice are capable of rapidly updating their responding in new blocks, and the average time of first press, time of first bout, and time reaching 63% maximum press rate are all linearly related to fixed interval duration. This updating is often rapid and can take place in only a few trials after the start of a new block. Now, pilot studies are underway to determine how manipulation of secondary motor cortex (M2) using optogenetics in GAD-Cre and CAMKII-Cre mice modifies the speed of updating in this task, and the

performance within fixed interval blocks. Our findings provide a platform for investigating the updating of temporal behavioral patterns in a dynamic timing task and will provide new insights into brain circuits involved in this process.

Title: Wireless EEG recordings in freely behaving marmosets reveal potential neuronal correlates of temporal expectation.

Authors: *T. DRAGOI[1], H. SUGIHARA[1], J. SHARMA[1], G. FENG[2], R. DESIMONE[2], M. SUR[1]; [1]Picower Inst. for Learning and Memory, [2]McGovern Inst. for Brain Res., MIT, Cambridge, MA

Abstract: Environments constantly undergo change and the brain often needs to dynamically adjust stimulus-response-reward associations due to varying contexts and stimuli. Amongst changing environments, the prioritization of relevant incoming information helps animals generate optimal internal models of their environment to help predict future outcomes. Previous studies have implicated fronto-parietal circuits as playing a key role in generating predictions. The predictive coding hypothesis posits a progressively increasing fronto-parietal influence as an animal utilizes an internal model of prediction. To test whether neural responses in marmosets follow predictive coding models, we designed a simple timing task in which freely behaving marmosets were required to make a timed response prompted by a visual stimulus change with a uniform distribution of stimulus durations. We implanted a wireless EEG system in one marmoset to simultaneously record from occipital, parietal, and frontal cortices while he learned the simple timing task. We found that once the animal had learned the task, there was a clear ramping up of EEG signal, consistent with the animal using an internal prediction model of stimulus offset timing that qualitatively followed similar changes in its behavioral performance. An analysis of oscillatory dynamics during learning revealed that in general, low frequency oscillations increased in power across cortical regions but especially in occipital cortex, and high frequency oscillations broadly decreased in power for sessions when the marmoset had learned the task. These findings are consistent with a model in which low frequency oscillations carry top-down predictions which inhibit high frequency oscillations in sensory areas. Altogether, our preliminary results demonstrate distinct changes in brain activity as the

animal learns and uses an internal model of prediction. Our data also suggests that temporal prediction may be facilitated by top-down effects mediated by fronto-parietal circuits.

Title: Temporal reversibility of neural dynamics as a signature of consciousness

Authors: *L. DE LA FUENTE[1], F. ZAMBERLAND[2], H. BOCACCIO[3], E. TAGLIAZUCCHI[4]; [1]Facultad De Ciencias Exactas y Naturales, UBA, CABA, Argentina; [2]COCUCO/DF-IFIBA/UBA, CABA, Argentina; [3]DF-IFIBA-UBA, CABA, Argentina; [4]Univ. of Buenos Aires, Buenos Aires, Argentina

Abstract: The brain is capable of constructing representations of the physical world, which might include the temporal asymmetry manifest due the preferred direction of time (thermodynamic arrow of time). In this work, we investigated whether the direction of time can be decoded from electrocorticography (ECoG) recordings in non-human primates in different states of consciousness (awake, sleep and under ketamine), and how the accuracy of this decoding relates to the level of consciousness. Time courses of the 3 first principal components (PC) of ECoG data were epoched and transformed to frequency and phase spectrograms. This information was used as the input of a convolutional (1, 3 and 5 blocks) network trained to distinguish original vs. time reversed epochs. In total, 16,200 models were fitted for 81 conditions (3 levels of model complexity, 3 types of data, 3 PCs, in 3 states of consciousness) with 100 iterations each. This was repeated after randomizing data labels to construct a null model. Unshuffled models yielded a significantly higher performance ($p < 0.001$). For wakefulness, the AUC in the validation set was always above .75. In the case of sleep, the best performance was observed for the models that included the phase information of the 2nd PC. For the ketamine condition, significant performance was only observed for the most complex models and/or those that included frequency information of at least 2 PCs. The probabilities for each data sample were consistent among models ($p < 0.001$), this consistency was especially high for the awake condition. To analyze which characteristics of the data were most relevant, gradient images were calculated. In the frequency domain, a greater relative importance was observed for high frequencies, most marked in the 2nd PC. Particularly in sleep, the importance was highest for the phase data of the 2nd PC. In summary, deep convolutional network models were able to predict the direction of time from ECoG data during wakefulness, but this prediction was hindered in states of reduced awareness such as deep sleep or under ketamine anesthesia. This suggests that conscious representations of information encode the arrow of time. Thus, this may indicate that in active states the ordering of events is given by external information and/or is an intrinsic property of neural activity, being present mostly in high and low frequencies. Finally, the possibility of decoding the direction of time from

sleep using phase domain information is consistent with the presence of cortical waves travelling between pairs of cortical regions, as shown by experiments in sleeping human and non-human primates.

Ltd., Singapore, Singapore

Abstract: Optogenetics enables precise interrogation of brain circuits by combining genetically specific cell-type targeting with deterministic neuron actuation. Despite the cellular precision of the technique, most light delivery systems used in optogenetic experiments, such as fibers and light-emitting diodes, do not offer control on the directionality or pattern of the light beam. Patterned light can precisely target a tissue region with micron-scale resolution, thereby addressing highly specific populations of neurons. To deliver patterned light in brain tissue at depth, we are developing implantable nanophotonic neural probes with specially designed gratings that emit light beams. Our probes are fabricated in a semiconductor foundry on 200mm diameter silicon wafers to ensure the technology can be broadly disseminated to the scientific community in the future.

In this work, we report the characterization of silicon neural probes that integrate together electrophysiology electrodes and nanophotonic waveguides. Each probe contains up to 72 titanium nitride (TiN) electrodes with 16 optical emitters distributed across 1 to 4 shanks each about 100 to 154 um wide. The electrodes are chemically treated post-fabrication to reach the impedance for electrophysiology recording. A custom optical scanning system and multicore fiber are used to couple laser light into the neural probe and to address the light emission sites. We have realized a variety of emission patterns including beams that are low-divergence, planar sheets, or steerable. Each probe is packaged onto a custom printed circuit board compatible with the Intan recording headstage. These probes show how silicon nanophotonic and microelectronic technologies can create new disseminable tools for precision brain activity mapping.

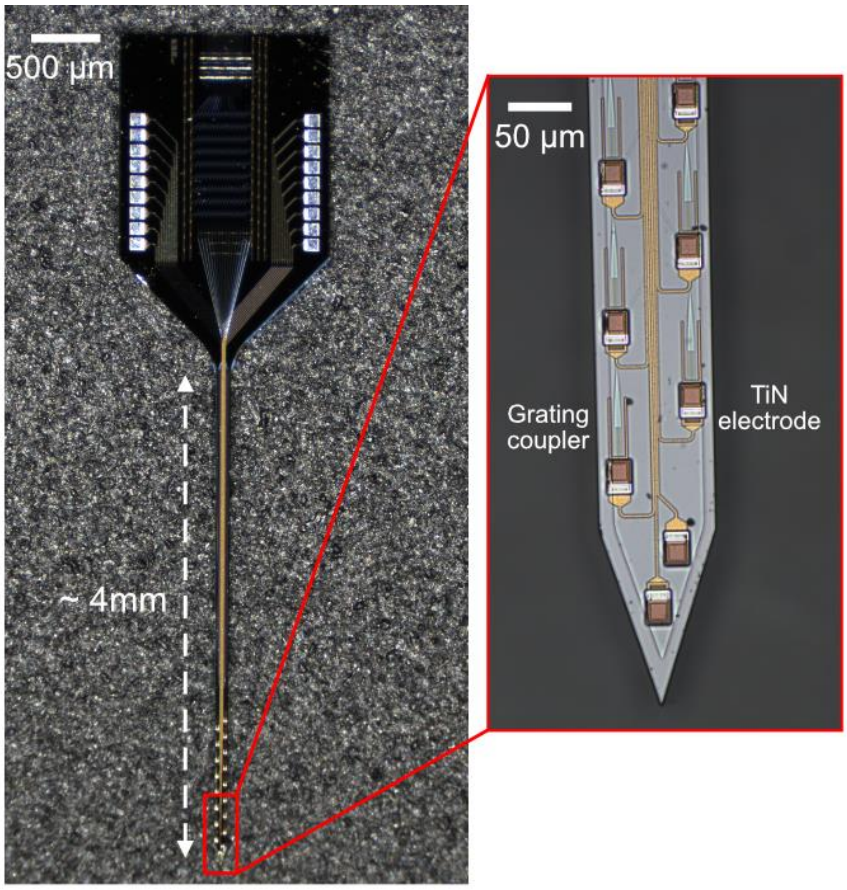

Figure 1. Top-down microscope images of an example implantable probe with integrated waveguides and recording electrodes. The probe contains 18 TiN electrodes and 16 grating couplers that emit low-divergence light beams.

Title: Implantable nanophotonic neural probe system with compact scanning optics and custom visible light multicore fiber

Authors: H. WAHN[1], F.-D. CHEN[1,2], S. S. AZADEH[1], A. STALMASHONAK[1], W. D. SACHER[1], *J. K. S. POON[1,2];

Abstract: To overcome the optical scattering limitation to light penetration in brain tissue for optogenetics and functional optical imaging, implantable photonic neural probes are an emerging technology that delivers patterned illumination at depth in brain tissue. We have been developing neural probes that are manufactured in a semiconductor foundry on 200mm diameter silicon wafers to ensure scalable production. The neural probes integrate nanophotonic waveguides onto long (3-6mm) thin (50-100µm) implantable shanks. The probes are passive to reduce heating, and the light emission sites on the probes are addressed spatially using a multicore fiber connected to the on-chip waveguides. Though several prototypes have been demonstrated for light-sheet imaging and beam-steering optogenetic stimulation, for the wide deployment of this technology as a practical system for neuroscience laboratories, the peripheral optics must be reduced in size and optimized.
Here, we combine our neural probes with a newly developed multicore fiber and a compact scanning optical unit. The optical unit has a portable footprint of 300mm x 300mm, including the laser, a fiber alignment stage and other components. The first-of-its-kind multicore fiber is specially designed to be single-mode over the visible spectrum. It has an outer diameter of 300µm and a linear array of 16 cores of 3µm diameter at a 16µm pitch. The custom scanning optics transfer a collimated laser beam of 0.7mm diameter via a micro-electromechanical system (MEMS) mirror to a steerable focused spot addressing the cores of the fiber. Currently, 50% of the optical power at a wavelength of 488nm is coupled from the scanning system to the fiber. To improve the power stability of the optical emission from the probe, the scanning optics and the neural probes have been co-designed such that the emission is independent of polarization fluctuations in the fiber. The progress described in this work is important for the deployment of implantable nanophotonic neural probes. Our future work includes the simultaneous operation at several laser wavelengths.

Title: Integration of microprism and micro-electrode array for long-term in vivo two-photon imaging of the intracortical neural interface

Authors: *Q. YANG, B. WU, E. CASTAGNOLA, A. L. VAZQUEZ, T. X. CUI;
Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Intracortical electrodes have long been used for communicating with neural tissue in both clinical therapies and research studies, but exactly how the brain cells interact with the electrodes has not been fully elucidated, especially for chronic implants. Two-photon microscopy (TPM) has been a

valuable tool for monitoring cellular activities at high resolutions *in vivo*. However, in chronic setups, conventional TPM maintains the best imaging quality only in the superficial brain regions (up to ~150μm) due to skull bone regrowth, meningeal thickening, and foreign body responses. Microprism implants bypass the above issues at the superficial regions by reflecting lights at 90 degrees and directly presenting a vertical view of the brain-implant interface (down to ~1mm deep). Here we integrate optical microprisms with microelectrode arrays (MEA) in order to chronically visualize the brain cell activities in all cortical layers near the intracortical neural electrode. The flexible and mostly transparent 4x4 MEA is fabricated by patterning Pt onto an ultrathin SU8 substrate using a standard photolithography process. To further improve the electrochemical properties of the electrodes, we electrically deposit nanostructured Pt or PEDOT onto each site. The MEA is then adhered to the microprism and coverglass using optical glue. In vivo electrochemical characterizations of the MEAs show an initial drop in the performance but then stabilize in one week. By implanting the microprism/MEA assembly into the cortex of Thy1-GCaMP6s mice, we achieve reliable electrophysiological recordings and calcium imaging of neuronal activities in all cortical layers on the same animal for more than 10 weeks. Additionally, by implanting the microprism/MEA assembly into CX3CR1-GFP mice, the inflammatory cell responses to different electrode regions and materials can be tracked over time. This microprism/MEA assembly technology enables longitudinal TPM imaging and electrophysiological studies of the neural interface across all cortical depths.

Abstract: Microendoscopy, the use of miniature optical probes to access and image deep brain areas, in combination with optogenetics is a popular technique for studying neuronal activity *in-vivo*. In recent years, there has been a push to apply this type of technology to the operating room to quickly evaluate the diagnostic viability of tissue samples, visualize blood vessels and other morphology, and potentially aid in surgical navigation. For example, Deep Brain Stimulation (DBS) surgery is an FDA approved

treatment for the motor symptoms of Parkinson's Disease (PD). The success of this surgery largely depends on the accurate localization of implanted electrodes at deep brain targets of interest like the subthalamic nucleus (STN). In the United States, a combination of stereotactic surgical techniques and microelectrode recordings (MER) are typically utilized to ensure accurate placement of the electrode(s). Even with these methods, the rate of electrode revision or removal in North America is between 15% and 34%. Furthermore, the use of sharp needles, microelectrodes, requires specialized training and increases the cost, duration, and risk of intracranial hemorrhage during the procedure. Therefore, there is a need to reduce or eliminate the use of MER during DBS and not forfeit the targeting accuracy of deep brain nuclei. Our group proposes to use two-photon microendoscopy to access and image deep brain locations in real time along the surgical trajectory. In this work, we present the initial design and testing of a long endoscopic probe composed of gradient refractive index (GRIN) lenses and perform some preliminary *in-vitro* tissue imaging as a proof of concept.

Title: Electrophysiological setup for simultaneous microscale BOLD response and multi-unit activity recording at 14.1 Tesla

Authors: *A. VON RAVEN[1], A. OELTERMANN[2], M. BEYERLEIN[2], K. SCHEFFLER[1];
[1]High Field Magnetic Resonance, [2]Physiol. of Cognitive Processes, Max Planck Inst. for biological cybernetics, Tuebingen, Germany

Abstract: Introduction. Performing fMRI and electrophysiological measurements simultaneously offer a better understanding of the hemodynamic response function due to the high temporal and spatial resolution of the combination of these methods. In 2020 we introduced a monolithically integrated NMR chip on a needle for local in vivo measurements (Handwerker et al., 2020). As the NMR needle achieved a similar spatiotemporal resolution as electrophysiology while offering the specificity and versatility of NMR, an electrophysiology setup has been developed to detect multi-unit activity (MUA) as well as local field potential (LFP) simultaneously to the NMR needle measurements, potentially closing the gap between these complementary modalities. **Methods**. The electrophysiological electrode was based on carbon monofilament, causing low susceptibility distortions in a 14 Tesla MR scanner close to the NMR needle. Furthermore, it was electroplated with PEDOT:pTS to be able to record MUA additional to LFP

activity (Chuapoco et al., 2019). In order to prevent SNR loss, the non-magnetic, custom-made preamplifier was placed inside the magnet close to the recording electrode. We used a custom-designed galvanically separated main amplifier. We added several shielding applications to work under high magnetic-field conditions and to minimize interferences between the transmission pulse of the NMR needle and the microelectrode inside the tissue. (Image 1) **Results**. The electrophysiological electrode including magnetic field proof electronics was designed and constructed to detect stimulus-evoked neuronal signals with simultaneous NMR needle recordings. First experiments outside the magnet have shown its ability to detect multi-unit activity. **Conclusion**. This combined experimental setup will allow capturing localized BOLD activity within distinct cortical layers. It will enable to observe neurovascular coupling directly at high temporal and spatial resolution. We aim to detect the hemodynamic response of different non-evoked neuronal activities at distinct locations with this setup.

Title: Manipulation of network activity in the spinal cord by single cell stimulation via nanoscale photodiodes

Authors: *M. FONTANINI[1], A. THALHAMMER[1], B. TIAN[2], D. SCAINI[1,3], L. BALLERINI[1]; [1]SISSA, Trieste, Italy; [2]Univ. of Chicago, Chicago, IL; [3]ELETTRA, Trieste, Italy

Abstract: The aim of this project is to exploit nanoscale photodiodes (nPDs) to achieve selective and minimally-invasive manipulation of neural activity with high spatial and temporal resolution. Upon light stimulation a charge separation is induced on nPD surfaces that is able to depolarize cell membranes. We used near-infrared (NIR) light activation of nPDs at the single cell level in organotypic slice cultures (OSCs) of the spinal cord, where the 3D structure of neuronal networks is preserved while allowing easy access for molecular, pharmacological and optical manipulation. In order to record activity at a network level, we made use of neuronally expressed genetically encoded Ca^{2+} indicator GCaMP7f.We found that stimulating nPDs (1hr incubation) attached to the cell body of a visually identified neuron in the dorsal horn (DH) area of 2-3 weeks old OSCs, with a temporal pattern of illumination of 100 stimuli at 25Hz, induced a long lasting (>20min) increase (35%) in spontaneous network activity. Conversely illumination of the ventral area was not effective in inducing long term changes of spinal networks, nor was illuminating DH in absence of nPDs. This suggests that selective stimulation of a single excitatory DH neuron can cause potentiation of network activity. Light stimulation of single excitatory neurons live labelled for transient receptor potential cation channel subfamily V member 1 (TRPV1) receptors confirmed that the increase in network firing observed occured mainly via capsaicin-sensitive pathways. These findings are reminiscent of 'Central Sensitisation' in chronic pain signaling, the molecular mechanism underlying pain hypersensitivity.In summary, our nanoscale photo-activatable material allows for non-genetic and minimally-invasive stimulation of single neurons, resulting in diverse changes of activity in intact neuronal networks depending on type and location of neuron stimulated. Considering that aelective stimulation of the spinal cord has been in use for decades as treatment for chronic pain, future experiments will be critical to reveal if activation of inhibitory interneurons of the DH can dampen the effect of nociceptive fiber input, paving the way for potential therapeutic application of nPDs *in vivo*.

Title: Ultra-compact Magnetoelectric Antennas for Sub-mm Brain Implants to Record and Stimulate the Activity of Neurons

Authors: *M. NASROLLAHPOUR[1], A. KHALIFA[2], I. MARTOS-REPATH[1], M. ZAEIMBASHI[1], X. LIANG[1], H. CHEN[1], H. LIN[1], Z. XU[1], D. DAS[1], A. MITTAL[1], M. ONABAJO[1], A. SHRIVASTAVA[1], S.

CASH[2], N.-X. SUN[1];
[1]Northeastern Univ., Boston, MA; [2]MGH, Boston, MA

Abstract: Emerging healthcare applications require the contribution of wireless implantable devices to manage the neural recording and brain stimulation. The current technologies with the micro-coils provide low power transfer efficiency, which often implies the need for transmitted power in excess of the requirements defined by the Federal Communications Commission (FCC), especially for deep brain stimulation where the tissue loss and field attenuation is significant. Recent brain implant technologies operate based on voltage and current sensing, which brings two major issues: 1) direct contact of the electrode and the tissue degrades over time due to the electrochemical fouling, and 2) the differential recording across space. Two different ultra-compact non-electrochemical magnetoelectric (ME) antennas, Film Bulk Acoustic Resonator (FBAR) and Solid Mounted Resonator (SMR), were designed for wirelessly powered implants to stimulate the neurons while providing small magnetic field measurements for neural activities. The proposed FBAR antenna resonates at 2.51 GHz with the size of 0.0435 mm^2 and the SMR antenna resonates at 2.61GHz with the size of 0.04 mm^2, both showing power transfer efficiency of 1~2 orders of magnitude higher than the conventional micro-coils. This allows to operate within the FCC's specific absorption rate (SAR) limit. The proposed hybrid FBAR antenna provides the lower frequency resonance of 63 MHz that provides the magnetic sensing capability within the nano-Tesla range at frequencies more than 100 Hz, allowing the implant's neural recording without differential recording. The results demonstrate that the ME antenna provides efficient energy harvesting in case of transmitter coil misalignment or a rotated structure. Energy harvesting integrated circuits (ICs) were designed and fabricated in 180nm XFAB SOI technology. The first version of the energy harvesting circuit is considered for an ME antenna providing 50Ω matching, and the other design is considered for an ME antenna having an input resistance of more than 50Ω to improve the power transfer efficiency during energy harvesting. The recorded field potentials from a rat hippocampus slice in response to a 200 µs monopolar stimulus are shown while a stimulating stereotrode was connected to the rectifier output while a recording glass micropipette was connected to an external amplifier and data acquisition system (DAQ) to display the field response.

Abstract: Methods for the detection of neural signals involve a trade-off between invasiveness, spatial resolution, temporal resolution, and the number of neurons or brain regions recorded. Electrode-based probes offer excellent spatial and temporal resolution but usually require transcranial wiring and capture small portions of the brain. Noninvasive methods such as electroencephalography (EEG) and magnetoencephalography (MEG) offer fast readouts of field potentials or biomagnetic signals, respectively, but have spatial constraints that prohibit recording from single neurons. A device that can enhance neural magnetic fields can be used as an *in situ* sensor for MEG and increase the ability to detect signals from deeper brain regions. We have designed a device capable of forming a tight electrical connection with a neuron, and of using changes in cellular potential to drive current through an inductor, which transduces neuronal electrical activity into magnetic signals. Here, we present detailed quantification of the device performance using realistic finite element simulations with signals and geometries taken from patch-clamped neurons *in vitro,* and demonstrate the device's capability to produce magnetic signals readable via existing modalities from a single neuron. We compare the magnetic output of this device to that of a single neuron, and show that the transduced magnetic signal is not only higher at its peak (1.70 nT vs 0.39 nT), but importantly, is spread over a larger volume, making the transduced magnetic field output within a carefully chosen voxel (40x40x10 microns) over 250 times higher than the native signal (0.64 nT vs 2.5 pT).

Abstract: Precisely timed activation of genetically targeted cells is a powerful tool for investigating neural circuits and controlling cell-based therapies. Magnetic control of cell activity or "magnetogenetics" using magnetic heating of nanoparticles to activate temperature-sensitive ion channels enables remote, non-invasive activation of neurons for deep-tissue applications and studies of freely behaving animals. However, the *in vivo* response time of thermal magnetogenetics is currently tens of seconds, which prevents the precise temporal modulation of neural activity achieved by light-based optogenetics. Moreover, magnetogenetics has not provided a means to selectively activate multiple channels to drive behavior. Here we demonstrate that by combining magnetic nanoparticles with a rate-sensitive thermoreceptor (TRPA1-A) it is possible to achieve sub-second behavioral responses in *Drosophila melanogaster*. Additionally, we have identified novel TRPA1 channels that show promise of translating this work to mammalian systems. Furthermore, by tuning the properties of magnetic nanoparticles to respond to different magnetic field strengths and frequencies, we can achieve fast, multi-channel stimulation, analogous to optogenetic stimulation with different wavelengths of light. These results bring magnetogenetics closer to the temporal resolution and multiplexed stimulation possible with optogenetics while maintaining the minimal invasiveness and deep-tissue stimulation enabled by magnetic activation.

Title: Cellular resolution, volumetric recording of neuronal activity over a large cortical area in freely-moving mice

Authors: *A. DAS[1], S. HOLDEN[2], J. BOROVICKA[1], D. PATEL[1], J. RABER[2,3], H. DANA[1];
[1]Dept. of Neurosciences, Lerner Res. Inst., Cleveland, OH; [2]Dept. of Behavioral Neurosci., Oregon Hlth. and Sci. Univ., Portland, OR; [3]Departments of Neurology, Psychiatry, and Radiation Medicine, Div. of Neurosci., ONPRC, Oregon Hlth. and Sci. Univ., Portland, OR

Abstract: Genetically-encoded calcium indicators (GECIs) are widely used to record neuronal activity *in vivo*. GECIs are mostly used in one of two configurations: 1) Fixing the animal's head under a microscope, or 2) Implanting a recording device onto the animal's skull. Both options have limitations. Head fixation imposes unnatural posture and behavioral performance and the implanted device puts a

relatively heavy weight on the head of the animal, especially for mice, that also restricts natural behaviors. To address these limitations, we show that Calcium-Modulated Photoactivatable Ratiometric Integrator (CaMPARI) can be used to record single-neuron, cortical activity in freely-moving animals without any implanted device or head fixation during the experiment. The fluorescence signal of CaMPARI undergoes an irreversible change from green to red when the increased intracellular calcium concentration coincides with light illumination at 400nm. We show that this activity-dependent photoconversion can be used in freely-moving mice to detect large-scale activity as deep as Layer V of the cortex during behavioral tests. Moreover, we show that the red signal decays within 7 days and therefore allows recording multiple times from the same mice. Thus, CaMPARI-based recording expands the capabilities of "traditional" GECIs and can be used to selectively detect cortical neuronal activity under minimally-restricted experimental conditions.

Title: Long-term, cortex-wide neural interfacing in single-cell resolution via SomaGCaMP8f and 3D-printed transparent skull combined with polymer electrodes.

Authors: *Y. WANG[1,2], Y. ZHENG[3], K. D. PIATKEVICH[1];
[1]Westlake Univ., Hangzhou, China; [2]Xi'an Jiaotong Univ., Xi'an, China; [3]Dept. of NanoEngineering, Univ. of California San Diego, La Jolla, CA

Abstract: Imaging neuronal activities at single-cell resolution at mesoscopic levels in multiple brain regions are critical for studying how neural activity in specific cortical regions contributes to behavior. Progress has been made in developing transparent "See-Shells", that allows for optical access to a larger area of the dorsal cerebral cortex in the mouse. However, this "See-Shell" is lacking the long-term ability to perturbing and recording neural activities. In addition, one-photon methods used in mesoscopic imaging with this "see-shell" usually suffer from higher levels of crosstalk among neuropils, resulting in a decreased signal-to-noise ratio and artifactual correlations of neural activity. To address these problems, we engineered a new version of soma-target GCaMP8f, with improved signal-to-noise ratio and increased brightness, combined with 3D-printed, digitally designed, biocompatible, and stable polymer electrodes on the See-Shell, to achieve long-term cortex-wide neural interfacing in single cell resolution.

Title: The use of DEL (DNA-encoded library) drug discovery platform for neurodegenerative diseases

Authors: Y. K. SUNKARI, V. K. SIRIPURAM, T.-L. NGUYEN-MEDRIHAN, W. WANG, ***M. FLAJOLET**;
rockefeller university, new york, NY

Abstract: The DNA-encoded library (DEL) technology, conceptualized by Drs. Brenner and Lerner in an article published in PNAS in 1992, started to emerge in 2005 and has been considerably developed and optimized over the last 10 years. While relatively rare in the academia, this technology is particularly suited for academic research due to its extremely compact nature. Indeed, the screening activity is totally lab compatible and does not require any specific large equipment, handling robots, large storage spaces, etc. For several reasons it is especially suited for Neuroscience and neurodegenerative diseases. Briefly, the methodology implies that drug-like compounds are made in a combinatorial way and barcoded with unique and specific DNA sequences. Because each compound is barcoded with a unique and specific DNA sequence all tagged compounds can co-exist in a single tube. Due to the combinatorial nature of the process, very large number of compounds are being made following this approach; we will introduce one of our DEL libraries that combines over 100 millions compounds and several applications directed toward Alzheimer's disease dysfunctions. The protein target of interest is expressed, purified and immobilized onto a solid support using a classical tagging system. Because very little of the protein target is required for 1 tube/1 screening campaign, it allows for the target to be purified from other sources than *E. coli*, from more physiological sources, such as mammalian cells or even brain tissue. This methodology will open up new screening avenues, especially when the protein target has a complex post-translational modification pattern and that it is often not fully identified (e.g., tau phosphorylation). Furthermore, several screens can be performed in parallel, for example comparing WT versus mutants, or comparing the same target protein expressed in stimulated and non-stimulated conditions. We will further detail some of these concepts and present specific examples of screening campaign results, focusing on Alzheimer's disease, and especially in the context of sTREM2 and tau.

Title: Design and development of Heterobifunctional peptide molecule against neurodegenerative proteins

Authors: *K. BHAVSAR[1], S. GUPTA[2];
[2]Biol. engineering, [1]Indian Inst. of Technology, Gandhinagar, Gandhinagar, India

Abstract: Neurodegenerative disorders (ND) are increasingly recognized as the major cause of disability and deaths, currently affecting 47.5 million people globally with dementia in people aging 60 or above. One common feature linked to mostly all ND is the misfolding and aggregation of certain proteins, which generates the cascade of pathological events leading to failure to protein homeostasis in the physiological state. TAR DNA binding protein 43 (TDP-43), is one such protein responsible for Amyotrophic Lateral Sclerosis (ALS) and Frontotemporal lobar degeneration (FTLD). Physiologically TDP-43 is a regulator of gene expression, RNA processing, etc. However, the mutation in TDP-43, leads to the excess deposition and formation of misfolded toxic protein aggregates in the cytoplasm of the cell, leading to disease. The aggregation-prone proteins are pharmacologically difficult to target because of their misfolded and disordered structure. To tackle this stumbling block, we contemplated Targeted Protein Degradation approach and developed a peptide-based Proteolysis Targeting Chimera (PROTAC) against aggregated TDP-43 degradation. PROTAC is a heterobifunctional molecule, composed of two different binding domains connected by a linker. One is for engaging an E3 ubiquitin ligase and other for the binding to targeted protein. E3 ligase recruitment leads to the ubiquitination of targeted protein, and recognition by the Ubiquitin proteasome system for the degradation. As a protein quality control system, the UPS plays a key role in the degradation of misfolded or aggregated proteins and maintaining protein homeostasis. Our objective is to study the degradation potential of cytoplasmic mutated TDP-43 utilizing synthesised peptide-PROTAC Synthesis of the peptide-PROTACs was done via Fmoc-base solid phase peptide synthesis methodology. Purity and characterization of the molecule was checked using RP-HPLC and MALDI mass spectrometer. TDP-43 recombination protein expressed and purified in *E.Coli* bacterial culture was performed. The Cell penetration study of the synthesized PROTAC was performed in SH-SY5Y neuroblastoma cell line using confocal microscopy. Further the cell viability assay was done using MTT Assay and analysed. Further experiments including the protein expression in SH-SY5Y cell lines are currently in process. The preliminary studies performed on peptide-PROTAC was seen to be promising and further evaluation needs to be done. Conclusion: We believe that the synthesized novel PROTAC will regulate the aggregated cytosolic TDP-43 towards the selective degradation, utilizing inherent cellular UPS.

Title: Identification of the cellular origin of brain-derived exosomes by combined reflectance and fluorescence microscopy

Authors: C. BAGCI, N. BELDER, M. SEVER-BAHÇEKAPILI, **S. ERDENER**, *T. DALKARA; Hacettepe Univ. Inst. For Neurolog. Sci. and Psychiatry, Ankara, Turkey

Abstract: Exosomes are endosomal membrane vesicles commonly found in tissues and biological fluids. They have a diameter of ~40–150 nm and are produced by nearly every cell. Exosomes carry a variety of cargo from the cell that they are released, including RNAs, DNAs, proteins, and lipids. Exosomes are taken up by local and distant cells, hence, play a role in intercellular communication. Their content varies during pathological and physiological processes; therefore, exosomes may be used as reporters of intracellular milieu of the cell of origin.There are several methods available for efficient exosome isolation, but no standardized techniques for quick characterization of their cellular origin following their extraction from the brain tissue except complex sorting approaches. Exosomes originate from a number of different CNS cells in vivo. This heterogeneity together with their small size makes their characterization challenging. Exosomes can be fluorescently labelled by using antibodies against their surface markers or payloads. Fluorescent emission from them can be detected by confocal microscopy despite their actual size being below the optical resolution (approximately 200 nm at 532 nm wavelength; Van Der Pol et al., 2010). However, fluorescent speckles corresponding to single or aggregated exosomes is confounded with non-specific particulate-like emissions from the tissue or in vitro medium. We found that confocal reflectance microscopy, which is readily available in almost all commercial equipment, enabled detection of exosomes and their clusters owing to high refractive index mismatch with the medium, provided by their lipid content (Ter-Ovanesyan et al., 2017). In the present study, we describe a reproducible and practical method combining fluorescence and reflectance modalities to overcome the above imaging limitations. For this, exosomes isolated from the mouse brain tissue were immuno-labelled with antibodies against the cell-specific intracellular and surface proteins such as ALDH1L1 and s100β (astrocyte markers), CD171 (neuronal marker) and Iba1 (microglia marker) to determine their cellular origins. Combining fluorescent and reflectance signals correctly identified the exosomes and eliminated the false fluorescent speckles. With double or triple immunofluorescence staining and reflectance microscopy, we were able to determine payloads of exosomes along with their cellular origins (i.e., neuronal, astrocytic, etc.). The combined reflectance and fluorescent microscopy can therefore be employed to identify the cellular origin of isolated exosomes and their payloads as a practical method.

Title: Lysolecithin (LPC) induced demyelination of the optic chiasm as a model to evaluate remyelinating agents

Authors: *G. EDU, A. LORENZANA, M. POON, D. LORRAIN;
Pipeline Therapeut., San Diego, CA

Abstract: Myelination of axons is necessary for faithful, long-distance conductance of electrical impulses. Multiple sclerosis (MS) is characterized by immune mediated myelin injury and progressive axonal loss. Many patients with MS exhibit myelin-dependent slowing of neuronal transmission in the optic nerve which can be measured through visual evoked potentials (VEP). VEP is a clinically translatable endpoint used to quantify myelin damage in MS patients and in animal models of MS. Demyelination is characterized by a significant latency shift in the VEP waveform signal (Toussaint et al., 1983, Green et al., 2017). While current MS therapies primarily address the immune mediated component of the disease, there has been recent interest in mechanisms that promote remyelination. To evaluate mechanisms that directly impact remyelination, mouse models using acute demyelinating agents, such as, lysolecithin injection into the spinal cord or corpus callosum are used with a histological endpoint to assess the cellular and structural aspects of remyelination. Because of its focal nature, however, attempts at a reliable functional endpoint, such as a behavioral score is difficult to evaluate. While other MS models, like MOG-EAE provide the benefit of both a histological and functional endpoint - the model evaluates compounds that could impact the immune component, oligodendrocyte differentiation, or both. Moreover, the model can at times vary with respect to onset and severity of the demyelination. This model evaluates the myelination component specifically. Recently, a group described a model whereby lysolecithin was directly injected into the optic chiasm (Mozafari et al., 2010). Here we validate this model, show a progression from demyelination to remyelination, and importantly, show a correlation between VEP latency and histology across time points. Peak latency delays were seen by 7 days post-lysolecithin suggesting an optimal timepoint to evaluate remyelinating compounds. We further show that the VEP delay and recovery are not caused by differences in inflammation. Because both histological and VEP endpoints can be measured, acute, focal lysolecithin induced demyelination in the optic chiasm provides a rapid, comprehensive method for evaluating remyelinating agents.

Title: Characterization of M1-Selective and Brain-Penetrant [11C]-PIPE-307 PET Radiotracer in Cynomolgus Monkeys

Authors: A. CHEN[1], A. L. AMENTA[2], C. BACCEI[1], G. BOSCUTTI[3], B. P. BURKE[3], C. PLISSON[3], C. SANDIEGO[3], L. WELLS[3], *D. LORRAIN[1];
[1]Pipeline Therapeut., San Diego, CA; [2]Invicro, New Haven, CT; [3]Invicro, London, United Kingdom

Abstract: Recent preclinical and clinical research have suggested that the selective antagonism of M1 in the CNS should facilitate the remyelination of denuded axons by effectively promoting the differentiation of oligodendrocyte precursor cells (OPCs) into oligodendrocytes. In this regard, we have identified PIPE-307, a novel, potent and selective M1-antagonist, as a potential treatment of demyelinating diseases such as multiple sclerosis (MS), that is complementary to currently known immunotherapies. To support the clinical development of PIPE-307, a carbon-11 labelled PIPE-307 ([^{11}C]-PIPE-307) radiotracer suitable for imaging M1 receptors using positron emission tomography (PET) was synthesized and characterized. [^{11}C]-PIPE-307 was prepared using [^{11}C]-CH_3OTf after 34 ± 3 min of synthesis, with isolated radiochemical yield of 10 ± 2 %, radiochemical purity greater than 99%, and molar activity of 253 ± 85 GBq·µmol^{-1}The CNS pharmacokinetics of [^{11}C]-PIPE-307, its binding to the M1 receptors, and its displacement *in vivo* by cold PIPE-307 as a function of dose and plasma exposure, was assessed in non-human primate (NHP) brain. Two cynomolgus NHPs underwent dynamic PET imaging, acquired over 90 min post-injection of [^{11}C]-PIPE-307, at baseline and after I.V. administration of cold PIPE-307 (0.01 to 2 mg/kg) 5 min prior to radiotracer injection. [^{11}C]-PIPE307 demonstrated excellent brain uptake, reversible kinetics, and regional distribution consistent with M1 expression. Specific binding (BP_{ND}) in brain regions were estimated using Logan graphical analysis, with the cerebellum as the reference region. At baseline, BP_{ND} range was 1.30 ~ 1.49 in caudate and putamen, and 0.56 ~ 0.90 in amygdala, hippocampus, frontal, occipital, and temporal cortices. Unlabeled PIPE-307 decreased BP_{ND} dose-dependently from baseline levels, and the resulting change in regional BP_{ND} was used to estimate occupancy. An Emax model was used to derive the relationship between occupancy with dose (ED_{50} = 0.032 mg/kg) plasma concentration (EC_{50} = 7.14 nM). BP_{ND} test-retest variability was 2 ± 8%, averaged across regions and animals.These favorable results support the translation of the novel radiotracer [^{11}C]-PIPE-307 to clinical imaging studies for the assessments of human M1 dose-occupancy in the CNS.

Title: [^{125}I]ippi: a novel tau radioligand for assessing neurofibrillary tangles in human hippocampus of postmortem alzheimer's disease subjects

Authors: R. MONDAL, R. M. LADWA, C. LIANG, *J. MUKHERJEE;
Radiological Sci., Univ. of California, Irvine, Irvine, CA

Abstract: Title: [^{125}I]IPPI: Novel Tau Radioligand for Assessing Neurofibrillary Tangles in Human Hippocampus of Postmortem Alzheimer's Disease Subjects
Objective: Alzheimer's disease (AD) is a neurodegenerative disease characterized by aggregation of Tau protein into paired helical filaments causing neurofibrillary tangles (NFT) in the brain. We have developed a Tau selective radioligand, [^{125}I]IPPI which is suitable for autoradiographic studies of NFT accumulation in AD brains. Here we report binding of [^{125}I]IPPI in hippocampus (HP) in postmortem AD (n=29) and compared to cognitively normal (CN, n=32) brains.
Methods: Hippocampus from well-characterized subjects were used in the study. All brain sections were obtained from Banner Health Research Institute, Sun City, Arizona. Brain slices with [^{125}I]IPPI in 10% ethanol PBS buffer pH 7.4 (60 mL; 0.1 μCi/mL) were incubated at 25 oC for 1.25 hr. The slices were then washed with cold PBS buffer, 50% ethanolic PBS buffer twice, PBS buffer and cold water. The brain sections were air dried and extent of binding of [^{125}I]IPPI was measured in DLU/mm2. Adjacent slices were immunostained with DAKO polyclonal antibody to total Tau which detects all 6 six isoforms of Tau. QuPath was used for analysis of the IHC images. The pixel thresholder and pixel classifier functions were used to detect percent and area of Tau, based on DAB staining intensity.
Results: All AD subjects exhibited high [^{125}I]IPPI binding in the HP grey matter (GM) regions. In comparison CN subjects had significantly lower binding as expected. Ratio of average GM [^{125}I]IPPI in AD versus CN was found to be 7.31. All AD subjects IHC were positively stained for the presence of NFT. A more detailed correlative analysis of [^{125}I]IPPI with IHC intensity using coregistered images is currently being carried out using Qupath as shown in Figure 1.
Conclusion: [^{125}I]IPPI is a novel radioligand well suited for autoradiographic studies of NFT in AD. The autoradiography binding profile of IPPI to Tau matches the QuPath generated profile from 2D coregistered IHC and IPPI images.

Title: Development of a selective ELISA for pre-formed alpha-synuclein fibrils over alpha-synuclein monomers

Authors: J. T. WONG, *R. S. AKHTAR;
Northwestern Univ., Chicago, IL

Abstract: Fibrillar α-synuclein (α-syn) is hypothesized to be central in the pathogenesis of Parkinson disease (PD). However, there are no clinical assays or biomarkers capable of tracking fibrillar α-syn in patient samples. Such biomarkers are necessary to evaluate putative disease-modifying treatments designed to interrupt α-syn fibrillization. Adequate biomarkers for α-syn fibrils are particularly challenging to develop since the assays must exclude the normally folded, non-fibrillar monomeric form of the protein. Here, we developed and optimized an enzyme-linked immunosorbent assay (ELISA) to detect recombinant human α-syn monomer and distinguish it from pre-formed α-syn fibrils (PFFs). We selected a 96-well ELISA platform for its ability to perform simultaneous assays on many samples. Recombinant human α-syn was prepared as PFFs by templated recruitment reaction. Fibrillar nature of α-syn was confirmed using thioflavin T assay and sedimentation assay. ELISA plates were coated with commercially available antibodies for α-syn. We systematically tested multiple blocking agents to optimize sensitivity and reduce nonspecific background signal. The plates were then incubated sequentially with either α-syn monomer or PFFs, a secondary α-syn antibody of differing host species, and an HRP-antibody conjugate. We systematically tested antibody concentrations, diluents, incubation times and temperatures, pH, and chromogen parameters to enhance fibril detection over monomer. We found that a combination of rabbit monoclonal antibody MJRF1 (Abcam) and mouse monoclonal antibody S5566 (Sigma) adequately detected α-syn PFFs while excluding α-syn monomer. Of several blocking agents, Blockace (Bio-Rad) allowed adequate sensitivity while reducing nonspecific background signals. Varying diluent composition minimally affected sensitivity of PFFs over monomer. Lower pH and increased incubation times resulted in higher sensitivity for both species but no change in selectivity of PFFs. We developed an ELISA using commercially available α-syn antibodies to detect both α-syn monomers and PFFs. Selectivity for the fibrillar form can be achieved using optimized assay conditions and antibody concentrations. Our next step is to leverage this assay to detect fibrillar α-syn in patient samples, coupled with high quality clinical data. These analytic measures have potential as diagnostic and / or prognostic biomarkers for PD.

Title: Continual Cerebrospinal Fluid Sampling in the Neonatal Domestic Piglet for Biomarker and Discovery Studies

Authors: *M. PINO[1], R. GANGULY[2], K. RICH[1], A. FOX[1], L. MATTOX[3], E. KECKLEY[3], M. JOSEPH[4], R. MALBRUE[3], V. KRISHNA[2], B. YOUNGBLOOD[3], S. KOLB[1,5];

Abstract: Background: Continual access to cerebrospinal fluid (CSF) is useful when studying neurological disorders or diseases affecting CSF composition. For longitudinal studies, there is a need for reliable and safe permanent intrathecal access. Large animal models provide opportunities to discover and characterize CSF contents. In this study, we tested a new method for insertion of a permanent intrathecal catheter, facilitating longitudinal collection of CSF.
Methods: Postnatal day (PND) 4 domestic piglets received broad-spectrum antibiotics, steroids, and isoflurane-induced anesthesia prior to surgery. Piglets were placed in prone position over a towel roll with the hips flexed. Following sterile surgical preparation, an incision was made over the lumbosacral area. Soft tissue was dissected and a laminectomy made at the L5 spinal level. The dura was exposed, a micro-incision was made, and CSF egress was visualized. A barium-impregnated, fenestrated catheter was inserted into the thecal sac under direct visualization, then advanced superiorly under fluoroscopic x-ray guidance until the tip reached the cisterna magna. Iohexol contrast dye was injected in the catheter and visualized in the cisterna magna under fluoroscopy. The catheter and access port were flushed with sterile saline and sutured in place subcutaneously. Immediately after surgery, CSF flow through the catheter and port was assessed via needle aspiration. Beginning three days post-surgery, CSF samples were drawn from the port at regular intervals (every 2-4 days) under light anesthesia and analyzed for neurofilament light chain, a biomarker of axonal injury.
Results: Frequent, longitudinal sampling of CSF was achievable in PND 4-60 pigs. CSF was readily accessible through the catheter and port multiple times per week during the two-month study period. Post-mortem dissections confirmed proper catheter placement. Catheterized pigs demonstrated slowed, but normal, weight gain compared to control pigs. Post-procedural complications included elevated white blood cell count and limb weakness but were manageable with medications. Levels of CSF neurofilament light chain at multiple time points will be presented.
Conclusion: We have developed a reliable and minimally invasive method for repeated CSF collection in the piglet that is both safe and effective for long-term, intrathecal use. Our methodology enables the biomarker, pharmacodynamic, and discovery studies of central and peripheral nervous system conditions where continual access to CSF is desired.

Title: PET compatible opsins for translational optogenetics

Authors: *M. A. BOEHM[1,2], J. BONAVENTURA[3], H. P. JEDEMA[1], O. SOLÍS[1], E. A. STEIN[1], C. W. BRADBERRY[1], M. MICHAELIDES[1,4];
[1]Intramural Res. Program, NIH - Natl. Inst. on Drug Abuse, Baltimore, MD; [2]Dept. of Neurosci., Brown Univ., Providence, RI; [3]Univ. of Barcelona, Barcelona, Spain; [4]Dept. of Psychiatry and Behavioral Sci., Johns Hopkins, Baltimore, MD

Abstract: Optogenetic technologies enable the manipulation of target neuronal populations and circuits with precise spatiotemporal control. This capability offers preclinical and therapeutic utility, but a major translational obstacle is the need to monitor the location and function of opsins without invasive procedures. Positron emission tomography (PET) is a versatile molecular imaging technique that can be used to visualize transgenic constructs with compatible radiotracers (e.g. chemogenetic receptors). To adapt this approach for optogenetics, we developed the first PET compatible opsin - ChRERα - by attaching the ligand binding domain (LBD) of the estrogen receptor alpha (ERα) to the excitatory channelrhodopsin-2 (ChR2). In vitro validation experiments in HEK-293 cells show ChRERα retains the original ERα-LBD affinity for binding estradiol and fluoroestradiol. In addition, blue light stimulation (473 nm) of cells transfected with ChRERα elicited photocurrents indistinguishable from cells transfected with ChR2, thus ChRERα retains the functional properties of the original excitatory opsin. To test whether ChRERα expression can be visualized with PET in vivo, we performed scans with the FDA approved radiotracer [^{18}F]-fluoroestradiol (FES) before and after intracranial injections of a ChRERα adeno-associated viral vector (AAV2/5-hSyn-ChR2-V5-ERαLBD) in the motor cortex (M1) of rats (Sprague Dawley, n=8) and squirrel monkeys (*Saimiri sciureus*, n=2). FES-PET scans in rats post-AAV (3-5 weeks following surgery) and monkeys (5-7 weeks following surgery) showed localized increases in FES-PET signal (measured as standard uptake value (SUV) and SUV ratios) near the M1 injection site (~2x SUV ratio of baseline) as well as in established motor cortical projection areas. Interestingly, these localized increases were still observed in monkey FES-PET scans performed 1-1.5 years after the AAV injection, although to a lesser extent than observed 5-7 weeks post-AAV. Immunofluorescence microscopy (with anti-ChR2 primary antibody) was used as post-mortem confirmation of ChRERα expression and coincided with brain areas showing localized increases in FES-PET signal post-AAV. This project demonstrates the application of the first transgenic opsin designed for compatibility with a PET radiotracer. Importantly, FES-PET was capable of localizing ChRERα in rodents and nonhuman

primates, and repeated within subject scans revealed longitudinal changes in opsin expression. This approach may be adaptable for visualizing a variety of opsins (and other transgenic constructs) to advance the translational potential of optogenetics and related technologies.

Title: Epifluorescent assessment of viral mediated gene expression is unreliable compared to immunostaining in neuronal populations of the primate model: implications for neuronal actuator use

Authors: *T. DAW[1], H. G. EL-NAHAL[2], M. A. BASSO[3], E. J. JUN[3], A. R. BAUTISTA[3], R. J. SAMULSKI[4], M. A. SOMMER[2], M. O. BOHLEN[2];
[1]Neurobio., [2]Biomed. Engin., Duke Univ., Durham, NC; [3]Psychiatry and Biobehavioral Sci. and Neurobio., UCLA, Los Angeles, CA; [4]UNC Gene Therapy Ctr., Univ. of North Carolina, Chapel Hill, NC

Abstract: Neuronal actuator technologies are increasingly used in rodent research, but their utility in non-human primates (NHP) remains limited. The lack of robust physiological and behavioral results in NHP suggests a fundamental issue with translating these techniques from rodents to primates. In the present study, following viral injections in the brain, epifluorescent assessment of transduction and expression patterns consistently failed to reveal adequate transgene labeling, whereas immunofluorescence and immunohistochemical assessment reliably provided visualization of robust transgene expression. Using epifluorescent assessment, viral gene expression was typically restricted to neuronal cell bodies and large processes, such as apical dendrites. In contrast, following immunostaining, viral mediated labeling was visualized in cell bodies, apical dendrites, and small neuronal processes, including dendritic and axonal terminal fields. Thus, it is likely that, although many viral constructs successfully transduce neurons in NHP, the transgene is not necessarily being expressed in targeted cells. Epifluorescence is therefore inadequate for assessment of viral mediated expression in NHP, and immunostaining is necessary to avoid false negative conclusions about transduction. Furthermore, the findings suggest a need for reagent optimization specifically in the NHP model. Reagent optimization in the primate for the primate will drastically improve the efficacy of neuronal actuator techniques in NHP behavioral studies.

Title: A Novel Device for Spatiotemporally Precise Large-Scale Optogenetic Stimulation of Deep Cortical Layers in Non-Human Primates

Authors: *A. ANGELUCCI[1], A. INGOLD[1], D. CUNDY III[1], C. REICHE[2], J. L. BALSOR[1], F. FEDERER[1], N. MCALINDEN[4], J. ROLSTON[3], L. RIETH[5], K. MATHIESON[4], S. BLAIR[2], **A. M. CLARK**[1];
[1]Ophthalmology and Visual Sci., [2]Electrical and Computer Engin., [3]Neurosurg., Univ. of Utah, Salt Lake City, UT; [4]SUPA, Inst. of Photonics, Dept. of Physics, Univ. of Strathclyde, Glasgow, United Kingdom; [5]Feinstein Inst. of Med. Res., Manhasset, NY

Abstract: Optogenetics is a powerful tool for studying neural circuit function. While widely applied in rodents, a significant obstacle to applying optogenetics in non-human primates is spatially precise stimulation of deep cortical layers across large volumes. Here, we describe a novel device, the Utah Optrode Array (UOA), that meets this critical need. The UOA is a 10x10 array of glass needle shanks tiling a 4 x 4mm area. For photostimulation, a custom µLED array is integrated to the device, with an individual, electrically addressable, 80µm^2 µLED delivering light through each individual shank. A pinhole layer at the µLED/array interface and an optically opaque interposer on the backplane eliminates surface illumination. Shank length and tip profile are customizable, in order to target different layers and vary the spatial profile of light spread, respectively. The UOA is capable of delivering irradiances far exceeding activation threshold across a range of opsins. We used *in vivo* linear electrode array (LEA) recordings to assess the utility of UOAs for precise modulation of neural activity in deep layers of monkey cortex expressing the excitatory opsin *Channelrhodopsin-2* (ChR2). We also employed *ex vivo* imaging of immediate early gene (cFos) expression to determine the downstream consequences of focal deep layer optogenetic activation. Comparison of surface and UOA stimulation revealed a sharp difference in laminar activity patterns. Surface stimulation of ChR2-expressing regions via a laser-coupled collimated optical fiber evoked responses spanning layers 2-4. Conversely, ChR2 activation via a UOA inserted so shank tips terminated in layer 4 evoked responses across layers 4-6. At lower intensities, UOA-evoked neural responses were localized to the layer nearby the UOA tips. Varying the pattern of

UOA stimulation revealed a preference on each LEA contact for stimulation at particular sites (optrode receptive fields - ORFs). ORF centers varied smoothly across contacts and generally increased in size with stimulation intensity. Differences in response latencies across layers were consistent with localized optogenetic activation followed by synaptic spread. cFos imaging revealed downstream consequences of this deep layer optogenetic activation at the scale of inter-connected cortical regions. These results demonstrate the capacity to utilize the UOA, in tandem with new vectors for targeting opsin expression, to isolate the role of deep cortical layers in complex intracortical and corticocortical circuits. We recently integrated a second µLED array to the device, capable of delivering light between UOA shanks for photostimulation of superficial layers.

Title: Network-level modelling of stimulation-induced functional connectivity change: An optogenetic study in non-human primate cortex

Authors: *J. BLOCH, A. GREAVES-TUNNELL, E. SHEA-BROWN, Z. HARCHAOUI, A. SHOJAIE, A. YAZDAN-SHAHMORAD;
Univ. of Washington, Seattle, WA

Abstract: The ability to shape network-level inter-area synchronization of the brain would be a profound accomplishment for developing treatments for neural disorders. Large-scale inter-area synchronization, termed “functional connectivity,” has been repeatedly shown to underlie healthy brain function. Brain stimulation has been established as a promising method for modifying large-scale functional connectivity, but the mapping from stimulation to the resulting modification remains unclear.
The prevalent framework for inducing targeted connectivity change is neural stimulation informed by Spike-Timing Dependent Plasticity (STDP), a mechanism which relates a change in synaptic strength to the delay between the spiking times of pre- and post-synaptic neurons. Although STDP governs neural connectivity change at the single-synapse level, translation from its original controlled in vitro setting to

more challenging and clinically relevant in vivo settings required targeting multi-synapse level connectivity. While researchers could adapt to this change such as by measuring functional connectivity instead of individual synapse connection strength, the use of STDP-informed stimulation in its non-native context yielded inconsistent results. First, studies reported that the stimulation often failed to induce desired connectivity changes. Second, although STDP only predicts connectivity changes between stimulated sites, studies reported widespread connectivity changes between unstimulated sites. Taken together, these results highlight the need for an updated framework for modeling widespread stimulation-induced functional connectivity change in vivo.
Here, we successfully develop a model which accurately predicts stimulation-induced functional connectivity changes over a large-scale (~1cm2) network of non-human primate sensorimotor cortex. We arrive at this model through a large-scale optogenetic brain interface for simultaneous stimulation and recording, graph theory tools for network-level analysis, and an interpretable machine learning model for accurate prediction and inference. Our model is accurate over multiple days of stimulation, subjects, and for both stimulated-state functional connectivity changes and resting-state functional connectivity changes. From our model we observe that STDP-informed protocol features alone poorly predict stimulation induced functional connectivity changes, whereas the structure of the pre-existing functional connectivity network is an accurate predictor. Our model and insights represent a promising new framework for targeted network-level functional connectivity change.

Title: Remapping of Adult-Born Neuron Activity during Fear Memory Consolidation in Mice

Authors: P. VERGARA, D. KUMAR, S. SRINIVASAN, I. KOYANAGI, T. NAOI, S. SINGH, *M. SAKAGUCHI;
Univ. Tsukuba WPI-IIIS, Tsukuba, Japan

Abstract: Adult-born neurons (ABNs) in the dentate gyrus (DG) are constantly being integrated into the hippocampal circuit. These ABNs undergo a process of maturation that ultimately leads to synaptic and electric properties that are equivalent to those of developmentally born granule cells. However, when ABNs are still immature, they display properties that largely differ from their mature counterparts, such as increased synaptic plasticity and excitability, and weaker inhibitory inputs. These properties may bestow ABNs with unique roles during memory processing; indeed, several studies indicate that ABNs contribute to each of the three main stages of memory: encoding, consolidation, and retrieval. However, the exact mechanism by which ABNs contribute to each of these stages is unknown. One possibility is that ABNs operate as engram cells. If this is the case, ABNs activity dynamics should satisfy at least two conditions: 1) A specific population of ABNs should be activated during learning, and 2) this same population should be reactivated when animals remember the encoded memory. Nonetheless, the activity dynamics during memory encoding, consolidation, and retrieval are unknown. To address this issue, we imaged ABNs calcium activity across a 6-hour-long contextual fear conditioning memory paradigm. This revealed two fundamental notions about how ABNs operate during memory processing: First, ABNs active during memory encoding do not overlap with the cells active during memory retrieval. Indicating that, at least at the population level, ABNs do not behave as putative engram cells. Second, ABNs underwent a constant process of activity remapping through time, in such a way that at different time points, different populations of ABNs were predominantly active. These results suggest that ABNs support the establishment of a fear memory trace in a different manner to directly holding the memory. Moreover, this activity remapping process in ABNs may support the segregation of memories formed at different times. These results provide new insight into the role of adult neurogenesis in the mammalian memory system.

Title: Whole-brain imaging at synaptic-scale resolution with axially swept light-sheet microscopy.

Authors: R. FIOLKA, ***K. M. DEAN**;
Lyda Hill Dept. of Bioinformatics, Univ. of Texas Southwestern Med. Ctr., Dallas, TX

Abstract: Large-scale interdisciplinary efforts aim to comprehensively map the functional architecture of neuronal cells and circuits. To date, this has largely been performed with serial sectioning-based approaches such as Focused Ion Beam Scanning Electron Microscopy (FIB-SEM). Nonetheless, while

such efforts provide incredible detail, imaging a select brain region is prohibitively expensive and takes months to years, thereby limiting the acquisition of important biological replicates. Furthermore, unlike fluorescence, FIB-SEM fails to provide molecular specificity. To circumvent these limitations, we developed a scalable imaging platform that delivers isotropic sub-cellular resolution throughout intact volumes of chemically cleared tissues. The system, referred to as cleared-tissue Axially Swept Light-Sheet Microscopy (ctASLM), combines high-speed aberration-free remote focusing and residual aberration correction to achieve an isotropic imaging resolution of 360 and 310 nm laterally and axially after deconvolution, in aqueous and BABB-cleared samples, respectively, throughout a ~330 micron field of view. Owing to ctASLM's performance, we can resolve and automatically detect synaptic spines in any spatial dimension while also evaluating long-range projections with trans-synaptic tracers throughout centimeters of tissue. Furthermore, when combined with expansion and iterative expansion microscopy, ctASLM provides ~80 and ~20 nm isotropic resolution, respectively. ctASLM is affordable, easy to assemble, has a better axial resolution than Lattice Light-Sheet Microscopy, and is orders of magnitude faster than leading confocal microscopes. Thus, ctASLM serves as an ideal imaging system for next-generation connectomic studies in both health and disease.

Title: Mammalian Directed Evolution of Allosteric Optobodies

Authors: C. WOODS[1], A. ZAHM[2], ***J. ENGLISH**[2];
[1]Biochem., [2]Univ. of Utah, Salt Lake City, UT

Abstract: Found in every cell, G-protein coupled receptors (GPCRs) mediate neurotransmission and are the functional targets of most drugs of abuse and psychiatric therapeutics. The past one-hundred years of biochemical research on GPCRs has produced over 500 structural determinations, >100,000 confirmed ligands, and a wealth of signaling assay platforms. Absent from this impressive roster are any tools for the discrete, cell-type specific tuning of endogenous receptor activity. Without such tools, we lack the ability to directly connect discrete GPCR signaling events to cell-type specific physiological outputs. Such tools are essential if we are to understand how GPCRs dictate human health and disease.
I have previously developed a platform for the directed evolution of protein sequences in mammalian cells (VEGAS). My lab has advanced this platform to enable the evolution of optogenetic tools in mammalian cell contexts. We are now using this platform to engineer optogenetically activated, GPCR allosteric intrabodies to directly engage with and control GPCR signaling events in the brain. I will share these advances, including improvements on the VEGAS platform and our strategy for developing these optogenetic intrabodies.

Title: Holographic imaging and stimulation of deviance detection ensembles in auditory cortex

Authors: *Y. SHYMKIV, R. YUSTE;
Biol. Sci., Columbia Univ., New York, NY

Abstract: Perception of sensory information by the brain is highly dependent on context, where responses to the most informative, or deviant (novel), stimuli are selectively amplified. Deficits of deviance detection appear in patients with schizophrenia, suggesting its importance for normal information processing and cognitive function.Here we use a holographic two-photon microscope with a spatial light modulator (SLM) integrated on both imaging and stimulation paths, to do aberration-free simultaneous volumetric imaging and stimulation. We imaged awake mice in the auditory cortex (AC) undergoing passive auditory oddball paradigm. We found novelty detection cells across all imaged areas of auditory cortex, in both primary (A1 and AAF) and secondary (A2 and UF) areas, with higher density and selectivity than cells responding in neutral (control) context. To analyze multineuronal activity, we developed a NMF-based pipeline to 1) compute data dimensionality, 2) extract neuronal ensembles and 3)

evaluate ensemble quality with a cross-validation prediction model. The analysis of ensemble dynamics suggests that the stimulus-evoked single trial activity is higher dimensional than expected, with more dimensions than the number of unique stimuli presented. That is, for seemingly identical trials, including deviant trials of oddball, there are often multiple distinct stimulus-tuned ensembles responding individually, but not at the same time. In addition, 30% of extracted ensembles were not tuned to any presented stimuli or locomotion, corresponding to ongoing cortical activity. We hypothesize that ensembles are context-coding units and to test this we are using our holographic setup to imprint (optically train) enhanced evoked responses to deviant stimuli, by stimulating deviance detection ensembles. A method to improve perception of deviance may be important for rescuing the deficits associated with schizophrenia.

Title: Optimized, large-scale optogenetic interface for non-human primates

Authors: *D. GRIGGS, W. K. S. OJEMANN, J. BLOCH, S. FISHER, A. YAZDAN-SHAHMORAD; Univ. of Washington, Seattle, WA

Abstract: High spatial and temporal precision and cell type specificity make optogenetics a powerful tool for studying fundamental neural mechanisms and developing neurorehabilitation techniques. To these ends, we introduced an optimized large-scale optogenetic interface for non-human primates (NHPs) [1] and we acutely validated our novel, semi-transparent electrode array [2].
This interface consists of a flexible, semitransparent recording and stimulating miniature-electrocorticography (ECoG) array called a multi-modal artificial dura (MMAD) which we have integrated into a transparent silicone artificial dura for chronic use. We have surgically implanted the MMAD which provides both optical access to about 2.7 cm^2 of the brain and ECoG recording capability to about 1 cm^2 of the brain which collectively enable large-scale cortical optogenetic experimentation.

This interface improves upon the stability and scale of our previous interface iterations [3]. Previously, optical access to the brain was limited to 2-3 weeks due to the optical window being clouded with opaque tissue growth which required resection before continued use, μECoG recording hardware was prone to corrosion, and the setup was limited to 2-3 simultaneous optical stimulation channels. Here, we will validate our optimized design allows for months of optical access, is corrosion resistant, and supports up to 15 LEDs for simultaneous optical stimulation, thus improving the stability and scale of the interface. We have performed convection enhanced delivery (CED), an efficient pressure-based viral delivery approach, to genetically modify cortical neurons of the NHP with uniform, widespread viral delivery [3-4]. After optogenetic expression, various optical and electrical stimulation protocols will be employed to modulate neural activity and the results will be recorded by the MMAD.
If successful, our experiments will validate the stability and scale of the interface design by (1) increasing the length of time of optical access to neural tissue from a few weeks to several months, (2) demonstrating no significant corrosion to electrical recording hardware, and (3) demonstrating neural modulation via various optogenetic and electrical stimulation protocols as measured by ECoG recordings. This work will set the stage for the development of stable, large-scale, multi-modal neural modulation protocols for the purpose of studying cortical organization and plasticity, and developing neurorehabilitation techniques.

Abstract: Translational control of a specific gene by light-induced liquid-liquid phase separation
Hyeonjeong Jeong, Hyungseok Moon, Min Lee, Yongdae Shin, Hyeyoon Park
Biological asymmetry originates from differential orchestration of gene expression. One of the ways to introduce cellular asymmetry is precise spatiotemporal control of translation. For example, mRNA

localization with regulated translation is known to be essential for long-term plasticity in neurons. However, there lacks a tool which recapitulates this nature's ability to precisely control the translation of a specific gene. Here, we implemented a technique to control translation by light using a recently developed OptoDroplet system. We demonstrate that the OptoDroplet system can be applied to control translation of β-actin mRNA in neurons. Analysis of structural long-term potentiation (s-LTP) of dendritic spines during chemical long-term potentiation (c-LTP) revealed the role of newly synthesized β-actin in sculpting synaptic strengths in neurons.

Title: A comparison of DREADDs agonists using fear conditioning in a rodent model

Authors: *T. B. WISE, D. L. POETA, J. G. LEE, M. M. MAZUMDER, R. D. BURWELL;
Brown Univ., Providence, RI

Abstract: Designer receptors exclusively activated by designer drugs (DREADDs) is an increasingly popular chemogenetic technique used in neuroscience to temporarily and selectively modify neuronal activity. Currently, clozapine-*N*-oxide (CNO) is the most widely used DREADDs agonist, but due to concerns regarding off-target effects of CNO, deschloroclozapine (DCZ) has been proposed as a possible alternative. In vitro studies indicate that DCZ has a high affinity for common muscarinic-based DREADDs that may be comparable or greater than that of CNO. Evidence from these studies also suggest that DCZ may be faster acting and permeable at lower doses than CNO, therefore providing an argument for broader use of DCZ as an alternative to CNO (Nagai et al 2020). Studies investigating the potential of DCZ, however, remain limited in scope. To our knowledge, the effectiveness and possible behavioral impact of DCZ have not yet been examined in rats.
In this study, we compared the effectiveness of DCZ to CNO using DREADDs manipulation of the basolateral amygdala (BLA) in rats. Utilizing a standard signaled contextual fear conditioning paradigm, we measured the behavioral effects of silencing the BLA during training using either DCZ or CNO. Freezing behavior was also measured during both context extinction and tone extinction phases as well as during reactivation of fear conditioning. Rats were euthanized and brains were taken immediately after the reactivation procedure. We verified DREADDs virus placement using fluorescent microscopy, and we analyzed c-fos expression in the BLA. This examination for differences between DCZ and CNO may provide support for or against using DCZ as a CNO alternative, guiding future research and potentially motivating the transition to a more accessible and targeted DREADDS agonist.

Title: Chronic behavioral manipulation via orally delivered chemogenetic actuator in macaque monkeys

Authors: *K. OYAMA[1], Y. HORI[1], Y. NAGAI[1], N. MIYAKAWA[1], K. MIMURA[1], T. HIRABAYASHI[1], K.-I. INOUE[2], M. TAKADA[2], M. HIGUCHI[1], T. MINAMIMOTO[1];
[1]Natl. Inst. for Quantum and Radiological Sci. and Technol., Chiba, Japan; [2]Primate Res. Institute, Kyoto Univ., Inuyama, Japan

Abstract: The chemogenetic technology referred to as designer receptors exclusively activated by designer drugs (DREADDs) offers reversible and less invasive means to control neuronal activity for investigating its functional correlation with behavioral action. Deschloroclozapine (DCZ), a recently-developed highly potent and selective DREADDs actuator, displays a capacity to expand the utility of DREADDs for chronic manipulation without side-effects in non-human primates, which has not yet been validated. Here we investigated the pharmacokinetics and behavioral effects of orally administered DCZ in macaque monkeys. Pharmacokinetic analysis and positron emission tomography (PET) occupancy examination demonstrated that oral administration of DCZ yielded a slower and prolonged kinetics, and that its bioavailability was 10-20% of that in the case of systemic injection. We then examined the chemogenetic effect of oral DCZ administration on behavior in two monkeys that expressed hM4Di in the bilateral dorsolateral prefrontal cortex (dlPFC) around the principal sulcus (Brodmann's area 46), a brain region known to be responsible for spatial working memory. Orally administered DCZ (300-1000 μg/kg, 3-10 times higher doses than systemic injection) induced significant working memory deficits for at least 4 h. The oral DCZ doses did not cause any detectable behavioral changes in control monkeys without vector injection. We also found that repeated daily oral doses of DCZ consistently caused similar deficits over two weeks without discernible desensitization. Our results indicate that orally delivered DCZ affords a less invasive strategy for chronic but reversible chemogenetic manipulation of neuronal activity in non-human primates, which has potential for clinical application.

Title: The effect of Deschloroclozapine on fMRI functional-connectivity.

Authors: *A. FUJIMOTO[1], C. ELORETTE[1], S. H. FUJIMOTO[1], L. FLEYSHER[2], P. H. RUDEBECK[1], B. E. RUSS[3,4,1];
[1]Neurosci., [2]BioMedical Engin. and Imaging Inst., Icahn Sch. of Med. at Mount Sinai, New York, NY; [3]Nathan S. Kline Inst. For Psychiatric Res., Orangeburg, NY; [4]Psychiatry, New York Univ. at Langone, New York, NY

Abstract: Chemogenetic techniques such as Designer Receptors Exclusively Activated by Designer Drugs (DREADDs) enable transient, reversible, and minimally invasive manipulation of neural activity *in vivo*. Their development in non-human primates is essential for uncovering how specific cell types, neural circuits, and areas contribute to behavior as well as potentially enabling their translation to humans. Recently, deschloroclozapine (DCZ) has been shown to be a selective, high affinity ligand that reliably activates DREADD receptors at dosing levels that do not cause behavioral alterations in normal controls. However, it is unknown whether low dose DCZ causes subtle changes in brain activity. To address this issue, we acquired resting-state fMRI scans from lightly anesthetized macaque monkeys (N = 8) that were administered with either 0.1, 0.3 mg/kg of DCZ, or vehicle systemically (i.v.) halfway through an imaging session. As 0.1 mg/kg DCZ does not impair performance of control monkeys in a working-memory task (Nagai et al., *Nat Neurosci*, 2020), we hypothesized that fMRI functional-connectivity patterns will be similar between pre and post DCZ injections, whereas 0.3 mg/kg DCZ will cause significant changes in connectivity. Whole brain functional images were acquired on a Siemens MAGNETOM Skyra 3T scanner (TR/TE 2100/16ms, voxel size 1.6x1.6x1.6mm) while animals were lightly anesthetized. We found that 0.1 mg/kg DCZ, as predicted, did not lead to any consistent or specific changes in whole-brain functional connectivity. Notably, a higher dose of DCZ (0.3 mg/kg) known to cause behavioral impairments (Upright and Baxter, *Neuropsychopharm*, 2020) was associated with changes in whole brain functional connectivity patterns. Our findings show that at dose levels that are not associated with behavioral effects, DCZ does not alter whole-brain resting-state functional connectivity. Because fMRI is non-invasive and has higher spatial/temporal resolution than other whole-brain measures such as FDG-PET, it is a powerful tool for a drug-screening of individual animals especially for chemogenetic experiments in non-human primates.

Title: Assessing differing DREADD construct effectiveness in prelimbic cortex-projecting neurons.

Authors: *A. GLORIUS, P. MAHBOD, B. PACKARD, D. BUESING, Y. M. ULRICH-LAI, J. P. HERMAN;
Univ. of Cincinnati, Reading, OH

Abstract: Chronic stress is associated with the development of affective disorders. Prior work from our group indicates that performing pleasurable behaviors can ameliorate the negative effects of stress on behavior. This study was designed to identify neural circuitry underlying the beneficial effects of palatable food intake, focusing on connection between the basolateral amygdala (BLA) and the prelimbic (PL) division of the medial prefrontal cortex. In these exploratory experiments, we used differing constructs of Designer Receptor Exclusively Activated by Designer Drugs (DREADDs) to specifically target chemogenetic activation/inhibition of this connection and assess the optimal construct to conduct large-scale experimentation. Male rats underwent stereotaxic surgical procedures to receive an ipsilateral dual region-injection (no sex differences were assessed). In the initial study rats received a unilateral stereotactic injection of a retrograde AAV (adeno-associated virus) construct expressing Cre recombinase (rgAAV2-Cre) in the BLA and ipsilateral injection of Cre-dependent mCherry-tagged excitatory (AAV8 or AAV2 Gq-DREADD) or mCherry-tagged inhibitory (AAV8 or AAV2 Gi-DREADD) constructs into the PL in the same surgical session. CNO was used to actuate DREADD constructs, either alone (Gq-DREADD) or in combination with restraint stress (Gi-DREADD)(a manipulation known to activate PL neurons). The ability of the Cre-inducible DREADD to modulate PL◊BLA activation was measured by cell counts of Fos activated cells bodies expressing mCherry and/or Cre recombinase. Our results indicate that Fos was highly expressed in mCherry/Cre labeled neurons following CNO in Gq-DREADD animals, and the % Fos colocalization was significantly higher than that observed in mCherry negative, Cre positive neurons. In contrast, activation of Gi-DREADD almost entirely prevented restraint-induced Fos activation in mCherry/Cre positive cells. Broader analysis of mCherry expression revealed occasional mCherry/Cre-expressing in regions outside the PL, including the paraventricular thalamus and BLA, suggesting retrograde trans-neuronal spread of AAV8 virus. In contrast, we did not observe spread of mCherry, Cre outside the PL in AAV2 treated animals. These results suggest we have sufficient control of the PL◊BLA projections, via DREADDs, to examine the role of these connections in stress resilience. More so, these results suggest that use of AAV2 vectors may be preferable to avoid retrograde transmission of viral DREADD constructs.

Title: Development and Validation of Photo-caged Oxytocin Analogs

Authors: *I. A. AHMED[1], J. LIU[2], C. J. BAIR-MARSHALL[1], B. E. HETZLER[3], A. ADEEWAKUN[1], C. ARP[3], D. TRAUNER[3], R. TSIEN[2], R. C. FROEMKE[1];
[1]Skirball Institute, NYU Neurosci. Inst., [2]NYU Neurosci. Inst., New York Univ. Sch. of Med., New York, NY; [3]Dept. of Chem., New York Univ., New York, NY

Abstract: Oxytocin is an evolutionarily conserved neurohormone that regulates fundamental physiological processes involving reproduction, childbirth, and milk ejection[1,2]. More recently, oxytocin has been shown to play a key role in social behavior such as pair-bonding and maternal behavior[3,4]. Deficiencies in oxytocin signaling have been linked with several neuropsychiatric disorders affecting social interaction, such as autism spectrum disorder and postpartum depression[5]. At the molecular level, oxytocin activates its respective G-protein-coupled receptor (OXTR), which is expressed in various regions of the brain and throughout the rest of the body. For example, in the brain, oxytocin modulates neuronal excitability and synaptic transmission. However, methods to precisely deliver and activate neuropeptides like oxytocin within specific anatomical regions of the brain and periphery with spatiotemporal specificity are lacking. To achieve spatiotemporal activation of oxytocin in mammalian tissue, we developed photocaged analogs of oxytocin. These caged-oxytocin peptides are functionally inert prior to photolysis, and irradiation with ultraviolet (UV) light causes the release of native oxytocin. We validated the caged compounds in vitro using a fluorescent calcium flux assay and calcium imaging in cell culture. We further demonstrated its utility in brain tissue by performing whole-cell electrophysiological recordings in acute brain slices of mouse auditory cortex. We demonstrated that photorelease of the caged-oxytocin cause significant ($p = 0.0299$, unpaired t-test) membrane depolarization of OXTR+ neurons (n= 9) but not OXTR- neurons (n=5). The effect of photolyzed caged-oxytocin compares well with the pharmacological application of oxytocin peptide, which produces significant ($p = 0.0014$, unpaired t-test) membrane depolarization of OXTR+ neurons (n= 13) but not OXTR- neurons (n=9). Furthermore, we show that caged-oxytocin is relatively inert in brain slices. We show both caged-oxytocin (n= 10) and artificial cerebrospinal fluid (n= 7) show no significant (unpaired t-test) change in the cell resting potential of OXTR+ hippocampal CA2 neurons. Conversely, uncaging of the caged-oxytocin (n= 10) induces membrane depolarization of OXTR+ hippocampal CA2 neurons to a similar extent (n.s., unpaired t-test) of pharmacologically applied oxytocin (n=7). Together, these results demonstrate that photo-caged peptides are useful tools for spatiotemporal control of the release of neuropeptides like oxytocin in the mammalian brain.

Title: Effect of near infrared-laser stimulation in single neurons and electrically coupled cells

Authors: A. GARRIDO-PEÑA[1], P. SÁNCHEZ-MARTÍN[1], R. LEVI[1], J. CASTILLA[2], J. TORNERO[2], *P. VARONA[1];

Abstract: Near-infrared lasers can be used as a non-invasive stimulation technique for studying neural dynamics. Such optical stimulus elicits changes in single neuron dynamics with little or no cell damage and have a potential use for medical purposes. However, the detailed biophysical basis of the effect of this stimulation is not yet known. In this work, we quantified the outcome of infrared laser stimulation both on single cells and on electrically coupled neurons. To explain the effect of the stimulation we employed a combined experimental and modeling approach in the nervous system of Lymnaea stagnalis. We first characterized the activity recorded with intracellular electrodes comparing the amplitude, duration, depolarization and repolarization slopes of individual spikes before, during and after the infrared-laser stimulation. In these experiments, the laser beam was focused on one of the neurons being recorded. Spike duration was reduced under the laser stimulation, along with a change in the repolarization slope. The effect was reversible after termination of the stimulation. The analysis was repeated on well-known electrically-coupled cells of the right parietal and visceral ganglia of Lymnaea. For electrically coupled cells, the activity was simultaneously recorded in both neurons while the laser was illuminating only one of them. The experimental protocols were reproduced in a conductance-based model that considered multiple explanations for the observed effect of the laser stimulation, and we tested which ones best reproduced all observations. Our study unveiled several factors underlying the source of the infrared-laser effect and supports the use of this stimulation in multiple experimental protocols.

Title: Using LITE-1 for X-genetic control of behavior in C. elegans

Authors: K. E. CANNON[1], M. RANASINGHE[2], L. DOBRUNZ[1], J. ANKER[2], *M. BOLDING[1];
[1]Univ. of Alabama at Birmingham, Birmingham, AL; [2]Clemson Univ., Clemson, SC

Abstract: “X-genetics” proposes to replace visible light stimulation used in optogenetics with X-radiation, which penetrates bone with higher efficiency, avoiding the need for surgical implantation of optic fibers. Finding a receptor protein sensitive to X-rays or the biochemical products of X-radiation is crucial for the development of the X-genetics technique. Here we report that LITE-1, an unusual UV-sensitive photoreceptor protein found in C. elegans, functions as an X-ray receptor, mediating X-ray induced behavioral responses in wild type and transgenic worms. Videos were obtained of behavioral avoidance responses of adult hermaphrodite wild type and LITE-1 mutant nematodes exposed to focused X-ray stimulation. Nematode activity was quantified using WormLab tracking software. Videos were obtained of paralysis responses of swimming wild type and pmyo-3::lite-1 transgenic nematodes exposed to unfocused X-ray stimulation. Body bend frequency was tallied manually by an individual blinded to the experimental condition and worm strain. Wild type and LITE-1 intact nematodes were found to respond to focused 0.5, 0.7, and 1 Gy/s X-radiation with a short-latency avoidance response (within ~2 s), seen as a robust increase in activity, that was absent in strains deficient for LITE-1 (N = 20, 10, 10, 10, and 17 for wild type at 0, 0.2, 0.5, 0.7, and 1 Gy/s; N = 10 for each mutant strain at 0 and 1 Gy/s). Additionally, transgenic expression of LITE-1 in C. elegans myocytes was found to elicit a paralysis response, seen as a increase decrease in body bend frequency, and egg ejection to unfocused X-radiation administered at dose rates of 0.56 and 0.74 Gy/s (N = 10, 9, 11, 11, and 12 for pmyo-3::lite-1 strain at 0, 0.19, 0.38, 0.56, and 0.74 Gy/s; N = 12 for wild type at 0 and 0.74 Gy/s). The paralysis experiments were replicated in two labs using different X-ray sources. Together, these results suggest that LITE-1 can function as an X-ray sensitive receptor, playing a critical role in the transduction of X-ray signals into neural activity to produce behavioral responses. As such, LITE-1 shows strong potential for use in X-genetics to transduce transcranial X-ray signals for precise minimally invasive manipulation of neural activity in mammals.

Title: Resistance heating can selectively block small-diameter axons similar to IR inhibition

Authors: *J. ZHUO[1], C. E. WEIDRICK[2], Y. LIU[1], M. A. MOFFITT[1], E. D. JANSEN[3], H. J. CHIEL[4], M. W. JENKINS[1];

Abstract: Small-diameter nerve fibers carry various sensory signals (e.g., pain, heat/cold, pressure) and play an important role in the autonomic regulation of normal biological processes. An implantable device for the selective block of small-diameter nerve fibers is an unmet medical need. Our group has shown that Infrared (IR) neural inhibition can selectively inhibit the small-diameter nerve fibers by IR-induced heating. Furthermore, the power threshold for IR inhibition can be lowered by isotonic extracellular ion replacement or by varying the IR application length. Based on our previous modeling and experimental work, we hypothesize that resistance heating via a heating cuff can induce the selective heat block of the small-diameter nerve fibers, similar to the IR inhibition effect. We tested our hypothesis on the pleural-abdominal connective nerve of *Aplysia californica* in vitro. The nerve was placed in a chamber filled with *Aplysia* saline, in which both the heating cuff and the IR optical fiber were immersed to mimic an in vivo thermal condition. The resistance heating and the IR light were applied on the same segment of the nerve where the temperature increase (ΔT) at the nerve surface was measured by a 200 μm thermocouple. For each nerve, both heating modalities were applied with a range of power levels that covered a similar range of ΔT. Suction electrodes were used to electrically stimulate and record compound action potentials (CAPs) at 2 Hz with a 2 ms pulse width and 0.3 - 0.5 mA current range to ensure full recruitment of all CAP components. The rectified area under the curve (RAUC) of the CAP or its subcomponents were used to characterize the inhibition strength. The latency of different subcomponents in the CAP corresponded to the different nerve diameters and conduction velocities, which permitted the analysis of the response from different nerve subgroups (large *vs.* small). The dose-response curve of the RAUC versus ΔT for both IR and resistance heating showed a similar trend. When looking at the response on different nerve size subgroups, resistance heating showed a selective block on the small-diameter nerve fibers that was similar to IR inhibition. The results demonstrated that other heating modalities, such as resistance heating via a heating cuff, can be used as a selective neural inhibition modality. In addition, the resistance heating system's energy efficiency is high enough to allow further development of a battery-powered, implantable, selective, nerve-block device.

Abstract: A common outcome after chronic stroke is long term loss of arm function. Vagus Nerve Stimulation (VNS) paired with intense rehabilitation is a promising intervention that may reduce arm impairment after chronic stroke. The VNS-Rehab trial was a randomized, triple-blinded, sham controlled study. In total, 108 participants across 19 sites were implanted at the start of the study and randomized to Active-VNS (n=53; VNS group) and Sham-VNS (n=55; Control group) in conjunction with rehabilitation. During the randomized phase, participants received 6 weeks of in-clinic therapy followed by 3 months of home therapy paired with Active or Sham-VNS. After the completion of home therapy, participants in the VNS group showed a significant and clinically meaningful improvement in arm impairment (Upper Extremity Fugl-Meyer Assessment: FMA-UE $\geq$ 6 points) compared to the Control group. Participants, therapists, and assessors were unblinded at the end of the randomized phase and the Control group then crossed over to receive 6 weeks of in-clinic Active-VNS followed by a 3 month Active-VNS home exercise program. Here we report the results from the cross-over phase of the study, where 49 participants who were initially randomized to the Control group crossed over to receive Active-VNS with rehabilitation.
No adverse or serious adverse events were attributed to the Sham or Active-VNS paired with rehabilitation. FMA-UE outcomes were determined at baseline, after the Sham-VNS phase, after in-clinic Active-VNS and after the 3 month Active-VNS home exercise program. Following 3 months of home-based therapy during the Sham-VNS phase, FMA-UE score increased by 3.06 (SE 0.76) points from 35.65 to 38.71 (n=49, $p<0.0002$). FMA-UE score increased by an additional 2.82 (SE 0.46) points from 38.71 to 41.53 after in-clinic Active-VNS (n=49, $p<0.0001$), and 2.42 (SE 0.73) points from 38.71 to 41.13 after the 3-month active-VNS home exercise program (n=43, $p<0.002$). 24% of participants showed a clinically meaningful response after the control therapy which increased to 44% after receiving Active-VNS in the cross-over phase.
Participants initially receiving Sham-VNS with rehabilitation demonstrated further improvement in arm impairment after receiving Active-VNS. Moreover, an additional 20% of participants achieved a clinically meaningful improvement after completing the Active-VNS cross-over phase. In summary, VNS may be a promising novel intervention to help mitigate arm impairment after chronic stroke.

Title: Fuzzing the connectome: sampling the input space for peripheral nerve stimulation

Authors: *C. CONNOLLY[1], J. CORNWELL[3], P. D. LINCOLN[2], N. TRIANTOS[3];
[2]Computer Sci. Lab., [1]SRI Intl., Menlo Park, CA; [3]Neurome, Inc., Menlo Park, CA

Abstract: Peripheral nerve stimulation is a potentially valuable therapeutic tool. Proper selection of stimulus parameters for optimal benefit must be balanced with the need to minimize off-target effects. This problem is compounded by the size of the stimulus signal space: infinite. An analogous problem is seen in software vulnerability research. In that domain, a surprisingly simple technique—fuzzing—has found critical vulnerabilities in many different software systems, despite the magnitude of the input space. By sampling the input space, either randomly or progressively, fuzzers have accelerated the discovery of "interesting" inputs to many different software systems. Here, we suggest that parameter sampling methods borrowed from computer science and engineering can be applied to help accelerate the experimental design process. Using an inexpensive experimental apparatus, parameter surveys that employ fuzzing—randomized search of the stimulus parameter space—or chirping of the parameter space can be collected in a relatively short time span using consumer off-the-shelf equipment. By averaging multiple time-aligned recordings using the same stimulus, we can identify stimulus parameter regimes as candidates for closer and more rigorous experimental scrutiny. As with fuzzing in the software setting, these surveys are not meant to be definitive experimental results, but rather indicators of interesting ("corner") cases: regimes of frequency, power, waveform shape, and waveform sequence that can shed light on effective parameters to optimize physiological effects.We present examples of parameter surveys performed with unilateral and bilateral acoustic stimuli, using high-quality headphones, a Polar H10 ECG chest strap, and a Macbook laptop. Certain acoustic parameter regimes appear to be effective at affecting heart rate, suppressing heart rate variability, and perhaps increasing or decreasing power in the gastric smooth muscle frequency band. We caution that, as is the case in computer science, physiological fuzzing is akin to assay development, and strong conclusions cannot be drawn from these surveys alone. However, data obtained from surveys provide a relatively fast, inexpensive approach to parameter discovery for rigorous experimental design.

Title: Getting ahead in animal welfare practices: An analysis of the longevity of head restraint implants in rhesus macaques (Macaca mulatta)

Authors: *C. J. LONG, M. S. PUJARA, E. A. MURRAY;
Natl. Inst. of Mental Hlth., Bethesda, MD

Abstract: Nonhuman primates, including rhesus macaques, contribute to biomedical research in a variety of fields, from cellular and molecular mechanisms of infectious disease to the neural underpinnings of cognition. Research employing neurophysiological recording, pupillometry, and eye-tracking typically requires the monkey's head to be in a stable, fixed position. This can be accomplished by using cranial implants—a post mounted on the skull that allows the head to be stabilized for short durations of experimental study. However, cranial implants, like other medical devices, can fail, affecting both study objectives and the well-being of the animal. In this study, we analyzed records from 124 macaques to identify which variables, if any, decreased the longevity of the implant in the 25% of subjects that had experienced an event (where an "event" involved either the repair or removal of an implant). We developed three main hypotheses: (1) Because infections of dental implants in humans can cause an implant to fail, we predicted that, as the number of infections increased in our sample, the likelihood of an event would also increase; (2) Titanium and fiberglass implants have been shown to produce similar results regarding stability; therefore, we predicted that material type would not contribute to the likelihood of an event; (3) Lastly, literature in humans suggests that males would be more likely to experience implant failure, whereas conflicting evidence suggests that females would have more failures; therefore, we predicted that there would be sex differences in implant failures but did not have a prediction with respect to directionality of the effect. We tested the effects of infection and implant type on the probability of an event using a multivariate binomial logistic regression. Both number of infections (OR = 2.77, p = 0.007) and fiberglass implants (OR = 0.279, p = 0.012) predicted the likelihood of an event. A chi-square test indicated no significant differences between males and females in experiencing an event (df = 1, $x;^2$=0.9877, p = 0.3203). To increase the longevity of implants, we propose implementing routine implant cleaning and incorporating head caps to decrease the chance of infection. Although systematic, longitudinal follow up studies are necessary to determine causality, we believe this study is the first step in identifying ways to improve the time available for data acquisition and the well-being of our animals.

Title: Acentrosomal microtubule assembly in the primary protrusion of quiescent neural stem cells

Authors: Q. DENG[1], Y. TAN[1], L. CHEW[2], ***H. WANG**[3];
[1]Duke-NUS Med. Sch., Singapore, Singapore; [2]Temasek Life Sci. Lab., Singapore, Singapore; [3]Duke-NUS Med. Sch., Singapore, Singapore

Abstract: The ability of stem cells to switch between quiescence and proliferation is crucial for tissue homeostasis and regeneration. *Drosophila* quiescent neural stem cells (NSCs) extend a primary cellular protrusion from the cell body prior to their reactivation. However, the structure and function of this protrusion are not well established. Here, we show that in quiescent NSCs, microtubules are predominantly acentrosomal and oriented plus-end-out toward the tip of the primary protrusion. We have identified Mini Spindles (Msps)/XMAP215 as a key microtubule regulator in quiescent NSCs that governs NSC reactivation via regulating acentrosomal microtubule growth and orientation. We show that quiescent NSCs form membrane contact with the neuropil and E-cadherin, a cell adhesion molecule, localizes to these NSC-neuropil junctions. Msps and a plus-end directed motor protein Kinesin-2 promote NSC cell cycle re-entry and target E-cadherin to NSC-neuropil contact during NSC reactivation. Together, this work establishes acentrosomal microtubule organization in the primary protrusion of quiescent NSCs and the Msps-Kinesin-2 pathway that governs NSC reactivation, in part, by targeting E-cad to NSC-neuropil contact sites.

Title: Investigation of molecular mechanisms underlying the expansion and gyrification of the cerebral cortex using ferrets

Authors: N. MATSUMOTO, S. TANAKA, T. HAMABE-HORIIKE, Y. SHINMYO, ***H. KAWASAKI**; Sch. of Med, Kanazawa Univ., Ishikawa, Japan

Abstract: The cerebral cortex has changed during evolution, and there are many differences among the cerebral cortices of various mammals. The cerebral cortex has become larger, and gyri were formed on the surface of the cerebral cortex. Although these changes in the cerebral cortex are considered to be important for the development of the brain functions, the mechanisms underlying the expansion and folding of the cerebral cortex remain unclear. Therefore, we utilized ferrets, which have relatively large and gyrencephalic cerebral cortex and established in utero electroporation techniques for ferrets in order to manipulate gene expressions in the ferret cerebral cortex. Furthermore, we found that gene knockout in the ferret cerebral cortex can be achieved by combining in utero electroporation and the CRISPR/Cas9 system. Using our techniques, here we show the role of sonic hedgehog (Shh) signaling in the development of the ferret cerebral cortex. We found that activation of Shh signaling resulted in additional

folding in the ferret cerebral cortex. Consistently, suppression of Shh signaling by expressing Hhip-DeltaC22 inhibited cortical folding. Interestingly, we found that Shh signaling was more activated in the developing cerebral cortex of ferrets than that of mice, suggesting that Shh signaling is involved in the evolution of the cerebral cortex. Our techniques for the ferret cerebral cortex should be useful for investigating the mechanisms underlying the development and evolution of the cerebral cortex.

Title: Transcriptional regulation of neural progenitor proliferation and cortical development by the macrocephaly related gene ZBTB7A

Authors: *N. K. TIWARI[1], P. KC[1], B. L. MEYERINK[1,3], C. EVANS[2], **L.-J. PILAZ**[1,3];
[1]Pediatrics and Rare Dis., [2]Histology Core, Sanford Res., Sioux Falls, SD; [3]Basic Biomed. Sci., Univ. of South Dakota, Vermillion, SD

Abstract: The cerebral cortex regulates complex cognitive tasks through intricate networks of neurons. The number of neurons is largely controlled through proliferation and differentiation of neural progenitor cells (NPCs) in a tightly regulated process. Deviation from these normal NPC divisions can give rise to lower or higher neuronal number and eventually lead to different neurodevelopment conditions such as microcephaly, macrocephaly, and autism. Many molecular pathways are known to control the balance between proliferation and differentiation in NPCs. Epigenetic regulation by chromatin accessibility factors is critical in NPCs, the constituents and timing of these signaling events remain to be fully discovered. Here, we investigate the role of one such chromatin accessibility factor *ZBTB7A* which when deleted in 19p13.3 deletion syndrome leads to macrocephaly, intellectual disability, sleep apnea and speech delay. While the role of ZBTB7A has been studied in many cell lineages, the molecular mechanisms through which it regulates cortical development are still not known. In mouse embryonic cortices, we discovered that ZBTB7A is specifically expressed in the nucleus of cells in the germinal zone which points to a role in NPCs. ZBTB7a's known dependence on other cis-acting factors suggests its impact may depend on the TF content of the cells, thus we expected that it may differentially influence proliferation and differentiation decisions in NPCs and thus play critical role in proper cortical development. We found that *in vivo* conditional deletion of *Zbtb7a* in cortex disrupts the proliferation of NPCs with lower progenitor numbers at E13.5 and higher progenitor numbers at E15.5. This ultimately leads to altered neuron numbers in different cortical layers and increased cortical thickness postnatally. RNA sequencing in cHet and cKO at 12.5, when the cortex is mostly composed of NPs, was performed to gain insight into the transcriptomic changes that could lead to altered proliferation. This experiment

revealed that *Zbtb7a* knockdown leads to misexpression of NPC proliferation and differentiation genes, including targets of Notch signaling: *Hes1* and *Hes5*., We tested if ZBTB7A binds to Hes genes promoters to mediate their expression, and thus impact NPC proliferation. Chip-PCR and luciferase assays confirmed that ZBTB7A binds to the *Hes5* promoter to repress its expression. This suggests that *Zbtb7a* regulates proliferation of NPCs in part by repressing *Hes5*. Altogether, this study will help us understand novel transcriptional mechanisms orchestrating cortical development and how their dysregulation leads to neurodevelopmental diseases.

Title: Setd1a hypofunction associated with poor cognition impacts neurodevelopment and cell cycle regulation

Authors: *R. LEASE, R. T. OSHONE, M. CORTES-GUTIERREZ, H. SAADI, S. A. AMENT;
Inst. for Genome Sci., Univ. of Maryland Sch. of Med., Baltimore, MD

Abstract: Exome sequencing in large case-control cohorts has revealed that loss-of-function or hypofunction of the gene SET Domain containing 1A (*SETD1A*) is associated with cognitive impairments and up to 20-fold increased risk for schizophrenia. In mice, *Setd1a* is first required in neural stem cells during prenatal development, but effects of *SETD1A* mutations on human neurodevelopment are unknown. Here, we characterized neurodevelopmental consequences of *SETD1A* hypofunction using induced pluripotent stem cells (iPSCs) derived from carriers of a hypofunctional SETD1A missense variant associated with clinical deficits in cognition. Our findings show *SETD1A* was expressed in pluripotent cells and throughout neural induction, with ~2-fold higher expression at the neural rosette stage, modeling early radial glia-like cells in the neural tube. During neural induction, SETD1A iPSCs displayed reduced cellular proliferation with G1 pileup, deficits in neural rosette formation, abnormal patterns of embryoid body expansion and spreading, and a 3-fold decrease in neurite extensions from iPSC-derived neural progenitor cells. Several assays suggest accelerated maturation of neural progenitors, including senescent cell morphology, strong expression of β-galactosidase, and accelerated induction of gene expression signatures for late-stage progenitor populations. These results suggest a critical role for *SETD1A* in regulating cell cycle progression and proliferation during early brain development, potentially relevant to clinical deficits in cognition and risk for schizophrenia.

Title: Linking mitochondria to experience-dependent cell proliferation in the developing brain

Authors: *J. E. BESTMAN[1], M. FENG[2], A. RAMAKRISHNAN[2];
[1]Dept of Biol. & Neurosci. Program, [2]Neurosci. Program, William & Mary, Williamsburg, VA

Abstract: Radial glial neural progenitor cells (NPCs) are the heterogeneous proliferating stem cell population that gives rise to all cells in the brain. Early on, NPCs are largely symmetrically dividing, progenitor pool-expanding cells, but as development continues the NPCs begin to asymmetrically divide to produce neurons. Intrinsic and extrinsic cues guide this irreversible and critical fate switch. If regulated inappropriately, a premature shift to neurogenesis limits brain development and contributes to the etiology of neurodevelopmental disorders. Although proliferating cells do not rely on mitochondria for ATP, mitochondria are abundant in these cells. The diverse cellular functions of the semi-autonomous, motile mitochondria place them at the intersection of the intrinsic and extrinsic cues that guide the fate of NPCs. We use time-lapse confocal imaging to image eGFP-labelled mitochondria in the NPCs and their cellular progeny in the intact optic tectum of albino *Xenopus laevis* tadpoles. This approach preserves the surrounding neural circuitry of the developing visual system and allows us to monitor and track the NPCs over days. Quantifying the labelled mitochondria throughout the slender radial process of the NPCs revealed that the mitochondria distribution is biased toward the site of cytokinesis before NPCs undergo a symmetric cell division, suggesting that the position of the mitochondria may forecast neurogenic cell divisions. Our data show that interfering with mitochondria through the delivery of the antisense morpholino against metabolic regulator peroxisome proliferator-activated receptor Gamma co-activator 1a (PGC-1a), a transcription factor that regulates mitochondrial biogenesis, limits neurogenesis. Together our data suggest that mitochondria within NPCs contribute to their fate.

Title: Nmda receptor-mediated transmission is required for brain-region-specific regulation of neurogenesis

Authors: *A. J. NAPOLI, J. D. ZOODSMA, B. BIJU, O. MUCOLLARI, S. SCHUBEL, A. SAYED, L. P. WOLLMUTH, H. I. SIROTKIN;
State Univ. of New York At Stony Brook, Stony Brook, NY

Abstract: Development of normal brain cytoarchitecture is dependent upon precise spatiotemporal regulation of neural stem cells (NSC) and neural progenitor cells (NPC) to ensure that the appropriate numbers of neurons populate each brain region. NMDA receptors (NMDAR) are glutamate-gated ion channels that mediate a calcium signal. They play essential yet complex roles in early neurodevelopmental events, not all of which are fully understood. The role of NMDARs in neurogenesis is controversial. Some studies indicate that suppression of NMDAR-mediated signaling promotes neurogenesis, while other studies support the opposite view. We have created a mutant zebrafish line that lacks NMDAR-mediated signaling (*grin1* double mutants). These fish survive to 10 days post fertilization, far beyond the comparable age of rodent models, thereby providing an opportunity to examine the role of NMDARs in early brain development, including neurogenesis. To address the role of NMDAR-mediated signaling in early neurogenesis, we quantified the number of cells within specific cell populations across the entire larval brain. We find that relative to wild type fish, *grin1* double mutant fish show dysregulation of neurogenesis but that the nature of the change depends on the specific brain region: In the forebrain and anterior hindbrain there is an overpopulation of cells whereas in the midbrain of the very same animals there is a reduced population. Both phenomena are observed without any gross morphological alterations to the brain. We next assessed changes in population size and proliferative activity of NSCs (radial glial cells and neuroepithelial cells) and NPCs (neuroblasts, type3 cells) to determine where the neurogenic process becomes dysregulated. Our preliminary forebrain evidence suggests that there are changes to the type3a progenitor cell population and proliferative rates, which could imply a maturational delay in these immature neuroblasts. Our results demonstrate that, within an individual organism, NMDAR perturbation causes diametrically opposed results in different brain regions. Furthermore, these disparate results may be due to changes in neuroblast maturation and the differential trajectory of this process in distinct regions of the developing zebrafish brain. This work helps resolve conflicting prior studies and establishes a framework to elucidate the mechanisms of NMDAR regulation of neurogenesis that unify these findings.

Title: "Lead (Pb) poisoning impairs thyroid hormone-dependent mechanisms of brain development"

Authors: *L. DAHORA[1], A. ROBINSON[2], C. K. THOMPSON[2];
[1]Dept. of Biol. Sci., [2]Sch. of Neurosci., Virginia Tech., Blacksburg, VA

Abstract: Lead (Pb) poisoning during early development is associated with behavioral and cogntive deficits. The specific mechanisms by which Pb impairs brain development are still not fully understood, however. One potential mechanism is that Pb poisoning may impair thyroid hormone (TH)-mediated changes in brain development. To address this issue, we performed two experiments to assess the effects of Pb poisoning on (TH)-dependent changes in cellular and molecular mechanisms in the developing *Xenopus laevis* tadpole brain. We treated stage 47 tadpoles to combinations of 1000 ppb Pb bath for seven days and added one of three different concentrations of thyroxine (T_4) for the final two days of treatment. We found that lead exposure decreased body length, including in T_4-treated tadpoles. We also performed immuno-staining for proliferative marker pH3 and found that Pb disrupts T_4-induced increase in neuronal proliferation. Finally, we used syGlass VR data visualization software to measure volume of the forebrain, midbrain, and hindbrain in 3D. We found that Pb exposure impaired T_4- mediated changes in brain volume. Last, we found that Pb poisoning reduced T_4-mediated increases of some TH-sensitive genes. These results illustrate that Pb poisoning impairs TH-dependent changes in the developing brain. Second, we have performed a series of experiments to assess Pb poisoning impairs the degree to which TH is distributed throughout the developing brain. TH is carried throughout the body via TH distributor proteins (THDPs), and transthyretin (TTR) and lipocalin-like prostaglandin D_2 synthase (L-PTGDS) are critical THDPs, primarily passing through the choroid plexus. We found that Pb-poisoning decreased expression of TTR in the liver and L-PTGDS in the brain. These changes suggest Pb may diminish the degree to which TH is distributed throughout the brain via these THDPs. Ongoing experiments are assessing the effects of knocking down TTR and L-PTGDS via morpholinos to determine if they are necessary for TH-mediated changes in brain development. Additional experiments are assessing if overexpression of TTR and/or L-PTGDS in the choroid plexus can rescue the developing brain from the harmful effects of Pb poisoning.

Title: Adult neurogenesis and protective effect of Combretum molle methanolic leaf extract on D-galactose induced aging rat model of Sprague Dawley

Authors: *T. M. D. FASEMORE[1,2], P. NKOMOZEPI[2], E. F. MBAJIORGU[1];

Abstract: INTRODUCTION During normal aging, the brain suffers both morphological and functional modifications affecting circulation, metabolism, and neurotransmission. These modifications such as decrease in dendritic trees and decrease sensitivity of catecholaminergic, dopaminergic and cholinergic systems alter sensory and motor systems, sleep, memory, and learning. Chronic subcutaneous injections of D-galactose (D-gal) with doses ranging from 50mg/kg to 200mg/kg in rodents induce cognitive dysfunction and lead to neurological impairments including increased apoptosis, decreased density of synapses and reduction in the migration of the neural progenitor cells in various areas of the mammalian brain. In this study, we sought for potential beneficial effects of *Combretum molle* (*C.molle*) methanolic extract against the D-gal induced aging in the brain of male SD rats. **MATERIALS AND METHODS** Fifty rats grouped into five groups were given daily subcutaneous injections of D-galactose (150mg/kg) and 500mg/kg of *C.molle* intragastrically for a period of 90 days. After treatment the animals underwent behavioural tests such as the Open Field, Novel Object recognition and Object location to investigate effects on memory retention. Five brains in each group were cut at 50 µm thick frozen sagittal sections (1 in 6 series) for immunohistochemistry using Doublecortin (DCX), Ki-67 and Caspase antibodies. **RESULTS** Strong DCX and Ki-67 expression was present in various established neurogenic sites and in the cerebellar white matter for animals that received *C.molle* only compared to the groups that received D-gal only which had high apoptotic cells. For the combination of Dgal and C.molle group DCX and Ki-67 expression was fair. **CONCLUSION** The *C.molle* has beneficial effect in reversing or protecting against the effects of D-gal induced aging in the brain.

Title: Microrna-124 modulates neurogenesis and mesodermal specification

Authors: *K. KONRAD[1], J. L. SONG[1], S. SUAREZ[2];
[1]Univ. of Delaware, Newark, DE; [2]Regeneron, Albany, NY

Abstract: MicroRNA-124 (miR-124) plays a conserved role in regulating parts of neurogenesis; however, its additional function in various developmental processes is less defined. We aim to elucidate the function of miR-124 in early development, using the purple sea urchin (*Strongylocentrotus purpuratus*) as a model. The sea urchin has one of the most well-documented gene regulatory networks (GRN), making it an excellent model to integrate the function of miR-124 into its GRN. To identify the

function of miR-124, we microinjected miR-124 inhibitor into newly fertilized eggs and examined specific cell and tissue phenotypes. We observed that miR-124 inhibition resulted in decreased larval swimming and gut contractions, indicating potential neuronal defects. miR-124 inhibition also led to a decrease in mature neurons and a concurrent increase in neuronal progenitor cells. We find miR-124 to directly suppress *NeuroD1*. Blocking miR-124's suppression of *NeuroD1* with a target protector morpholino (*NeuroD1* TP) resulted in embryos exhibited similar swimming and gut contraction defects as in miR-124 inhibitor injected embryos. In addition, *NeuroD1* TP injected embryos had an increase in neural progenitor markers (*SoxC* and *Brn1/2/4*). These results suggest that NeuroD1 may function to sustain neural progenitor cells. Furthermore, we observed miR-124 has a novel role in regulating the differentiation of mesodermally-derived immune cells. The sea urchin immune cells consist of blastocoelar cells (BCs) and pigment cells (PCs), which are derived from the same progenitor cells that must make a binary fate decision to differentiate into BCs or PCs. We determined that miR-124 modulates mesodermal development by temporally regulating Nodal and then Notch signaling pathways to mediate proper immune cell development. We have systematically identified the function of miR-124 in the specification, differentiation, and maturation of neurons as well as miR-124's novel role in mesodermal development.

Title: Defects in neurogenesis in the retinal ciliary margin alter binocular vision

Authors: *N. SLAVI[1], M. A. LEE[1], M. LIAPIN[1], C. MASON[2];
[1]Zuckerman Inst., [2]Dept. Pathology & Cell Biology, Neuroscience, and Opthalmology, Columbia Univ., New York, NY

Abstract: In animals with frontally positioned eyes, partial decussation of retinal ganglion cell (RGC) axons at the optic chiasm in specific proportions forms the basis of stereopsis. The albino visual system is characterized by a reduction in the number of RGCs expressing Zic2, the transcription factor necessary for ipsilateral specification, and a decrease in the ipsilateral RGC projection to the brain. To uncover the developmental processes important for the establishment of ipsi- and contralateral RGC properties, and ultimately stereo vision, we examined neurogenesis and its regulation by CyclinD2 in the ciliary margin zone (CMZ), a neurogenic niche at the embryonic retina periphery that may be a specialized source of ipsilateral RGCs. We combined genetic inducible fate mapping with birthdating to determine the number and production rate of CMZ-derived $Zic2^+$ RGCs. We performed dual pulse birthdating to monitor the cell cycle progression and exit of CMZ progenitors, and its regulation by CyclinD2 in pigmented, albino,

and CyclinD2-deficient mice. We find that in the albino fewer Zic2^{+} RGCs are generated from CMZ, where there is reduced CyclinD2 expression and delayed cell cycle progression. In addition, deletion of CyclinD2 from the pigmented CMZ leads to a reduced number of progenitors reaching mitotic exit in time to express Zic2 and acquire ipsilateral RGC identity. To examine whether these aberrations in the ipsi/contra RGC output lead to impaired depth perception, we compared the performance of pigmented, albino, and CyclinD2-deficient mice in a binocularly-driven visual cliff behavioral task. Both albino and CyclinD2-deficient mice failed to reliably recognize the "cliff", indicating reduced depth perception. Our study thus links proper RGC neurogenesis with the establishment of the circuit for binocular vision.

Title: Regulation of neural stem cell differentiation and brain development by MGAT5-mediated N-glycosylation

Authors: *A. YALE[1], E. KIM[2], J. L. NOURSE[2], M. SALVATUS[2], R. F. HUNT[2], E. S. MONUKI[3], L. A. FLANAGAN[1];
[1]Neurol., [2]Univ. of California, Irvine, Irvine, CA; [3]Univ. of California, Irvine - Sch. of Med., Irvine, CA

Abstract: Neural stem and progenitor cells (NSPCs) have the potential to treat many neurological diseases and injuries due to their ability to secrete beneficial factors and form the major cell types of the central nervous system. In the brain, undifferentiated NSPCs encounter numerous extracellular signals that bind plasma membrane proteins and impact differentiation into neurons or glia. Plasma membrane proteins are regulated by N-linked glycosylation, making it possible that glycosylation has a significant impact on cell differentiation. However, links between specific glycosylation enzymes and NSPC differentiation have not been described. Our lab found that N-glycosylation patterns correlate with NSPC fate potential *in vitro*; specifically, NSPCs expressing more highly-branched N-glycans generate more astrocytes and fewer neurons. Furthermore, increasing expression of highly-branched N-glycans on NSPCs enhanced astrocyte formation at the expense of neurogenesis. We therefore tested whether enzymes in the N-glycan branching pathway directly affect NSPC differentiation. Disruption of mannosidase enzymes early in the branching pathway altered multiple cell surface N-glycan species and did not affect NSPC differentiation into neurons and astrocytes. However, loss of a later enzyme responsible for generating the most highly-branched N-glycans, N-acetylglucosaminyltransferase V (MGAT5), led to specific changes in NSPC differentiation *in vitro* and *in vivo*. *Mgat5* homozygous null NSPCs in culture formed more neurons and fewer astrocytes compared to wild-type controls. In the brain, loss of MGAT5 caused accelerated neuronal differentiation and expression of mature neuronal markers in

the cerebral cortex. Rapid neuronal differentiation led to a depletion of cells in the NSPC niche, resulting in a decrease in the numbers of neurons formed in *Mgat5* null mice. Thus MGAT5 plays a critical and previously unrecognized role in cell differentiation and early brain development.

Title: Progenitor cell diversity in the developing mouse neocortex

Authors: *X. RUAN, B. KANG, C. QI, W. LIN, J. WANG, X. ZHANG;
Univ. of Chicago, CHICAGO, IL

Abstract: In the mammalian neocortex, projection neuron types are sequentially generated by the same pool of neural progenitors. How neuron type specification is related to developmental timing remains unclear. Our single-cell RNA sequencing (scRNA-Seq) analysis uncovered neuroepithelial cell-enriched genes when compared to radial glia cells (RGCs). RGCs display dynamic gene expression over time. Interestingly, intermediate progenitor cell marker gene *Eomes* coexpresses temporally with known neuronal identity genes at different developmental stages. Our results delineate neural progenitor cell diversity in the developing mouse neocortex and support that neuronal identity genes are transcriptionally evident in *Eomes*-positive cells.

Title: A daily cell atlas of neural differentiation across embryonic and postnatal development by single-cell mass cytometry

Authors: *E. ZUNDER;
Univ. of Virgina, Charlottesville, VA

Abstract: Precisely controlled development of the central and peripheral nervous systems is essential for organismal function and survival. To produce a comprehensive day-by-day analysis of the diversification and maturation of neural cell types, we performed single-cell mass cytometry on brain and dorsal root ganglia from C57/B6 mice at daily time points from embryonic day E11.5 to postnatal day P4. Brain tissues were microdissected into cortex, diencephalon, midbrain, and hindbrain for separate analysis. Additionally, differences between in vivo and in vitro neural differentiation were assessed by monitoring E14TG2a mouse embryonic stem cells over a 12-day embryoid body culture with retinoic acid-induced differentiation. In each of these studies, daily biological replicates were analyzed with a 40+ antibody panel optimized for either brain (25 million cells), dorsal root ganglia (3 million cells), or E14TG2a (2 million cells). The resulting protein-level molecular profiles were used to identify specific progenitor, neuronal, and glial cell types, and track how these cell types changed over the course of development. By comparing these results to previous RNA-based studies, we observed substantial discrepancies between protein and RNA cognate pairs, highlighting the importance of protein-level measurements to identify functional cell states. We also observed dynamic changes in what appear to be cell engulfment events, indicating that this approach may be useful to monitor how phagocytosis regulates nervous system development. Overall, these studies demonstrate the utility of mass cytometry as a high-throughput platform to rapidly phenotype neural tissues by protein-level single-cell molecular profiling.

Title: Essential role for Atoh7 in the proper establishment of the retinotectal topographic map in the visual system

Authors: *I. AL DIRI[1], M. DAGHSNI[2], T. KUWAJIMA[2];
[2]Ophthalmology, [1]Univ. of Pittsburgh, Pittsburgh, PA

Abstract: *Atoh7* is a bHLH transcriptional factor required for retinal ganglion cell (RGC) differentiation. *Atoh7* is transiently expressed in a subset of retinal precursor cells during retinogenesis, but mechanisms that control its own expression remain not well understood. Using single cell ATAC-Seq analysis, we defined cis-regulatory elements coupled with *Atoh7* expression during mouse retinogenesis. We show that activities of the *Atoh7* enhancer landscape is associated with a cluster of cells that demarcates the

transition from retinal proliferation to differentiation. We provide evidence that Atoh7 inhibits the activity of its own enhancer elements, underscoring a potential negative autoregulatory loop that controls Atoh7 expression. We further show that deletion of an *Atoh7* distal enhancer leads to a dramatic reduction in *Atoh7* expression in the developing retina but not in the cerebellum where *Atoh7* is also expressed. While genesis of RGCs proceeds normally upon loss of *Atoh7* enhancer, transcriptome analysis revealed a dysregulation of genes important for axonogenesis. Importantly, deletion of *Atoh7* enhancer disrupts eye-specific targeting of RGC axons in the dorsal lateral geniculate nucleus (dLGN). We propose that high levels of *Atoh7* expression is specifically required for proper circuit organization of the eye-specific targeting of visual system but is dispensable for RGC formation.

Title: Fezf2 specifies glutamatergic projection neuron identity by functioning as a selective repressor.

Authors: *J. TSYPORIN[1], D. TASTAD[2], T. FINN[3], X. MA[4], A. NEHME[5], L. HUEBNER[1], G. LIU[6], D. GALLARDO[1], A. MAKHAMREH[1], J. ROBERTS[1], S. KATZMAN[1], N. SESTAN[7], S. K. MCCONNELL[8], Z. YANG[9], S. QIU[5], S. QIU[5], B. CHEN[10];
[2]Dept. of Molecular, Cell, and Developmental Biol., [3]Molecular, Cell, and Developmental Biol., [1]Univ. of California, Santa Cruz, Santa Cruz, CA; [4]Univ. of Arizona Col. of Med., Phoenix, AZ; [5]Univ. of Arizona Col. of Med., Phoenix, CA; [6]Frontiers Ctr. for Brain Sci., Fudan, China; [7]Yale Sch. of Med., New Haven, CT; [8]Stanford Univ., Palo Alto, CA; [9]Fudan Univ., Fudan, China; [10]Univ. of California Santa Cruz, Santa Cruz, CA

Abstract: Excitatory projection neurons in the mammalian cerebral cortex are specified by genetic programs that confer a glutamatergic identity along with subtype-specific morphology, physiology, and axonal projections. Subtype-specific transcription factors have been identified as critical regulators of the specification and generation of distinct classes of projection neurons. Exactly how these genetic programs work is unclear. In neuroblasts of the Drosophila embryonic central nervous system, temporal transcription factors are sequentially expressed that confer temporal identity. In *C. elegans*, terminal selector genes initiate and maintain the expression of effector genes that define a particular neuronal phenotype. *Fezf2* was reported to be a terminal selector gene for layer 5 subcerebral neurons, yet its ability to directly activate effector gene transcription has not been rigorously tested. To determine how FEZF2 functions, we created a fusion protein consisting of the FEZF2 DNA binding domain and the Engrailed transcription repressor domain that we termed FEZF2-EnR. By utilizing BAC transgenics to express *Fezf2-EnR* in the context of a *Fezf2* knockout mouse, we observed that *Fezf2-EnR* fully rescued

the molecular and axonal projection defects. Therefore, in the context of cell fate specification, FEZF2 functions as a repressor. Furthermore, we conditionally knocked out *Fezf2* in newly born neurons, rather than at the progenitor level, and found that the defects seen when knocking out *Fezf2* in newly born neurons were comparable to the full *Fezf2* knockout. We found that *Fezf2* is also necessary for the proper development of layer 6 corticothalamic projection neurons. Without *Fezf2*, these neurons take on the molecular characteristics of layer 5 subcerebral projection neurons. We showed that *Tle4*, a gene highly specific to corticothalamic projection neurons and necessary for proper corticothalamic neuron physiology, encodes a co-repressor of FEZF2. Indeed, in *Tle4* knockout mice, layer 6 corticothalamic projection neurons take on molecular characteristics of layer 5 subcerebral projection neurons. These findings support a novel model of deep-layer projection neuron specification wherein FEZF2 promotes the acquisition of layer 5 subcerebral identity by directly repressing layer 6 corticothalamic genes; in the context of a newly born corticothalamic projection neuron, FEZF2 and TLE4, together, promote layer 6 identity by directly repressing layer 5 subcerebral genes. Therefore, FEZF2 functions as a selective repressor in a cell-type-specific context to inhibit the acquisition of alternate cell identities.

Title: Thyroid hormone regulates neural stem cell fate from development to ageing

Authors: *S. REMAUD;
CNRS MNHN 7221, PARIS, France

Abstract: <The subventricular zone (SVZ) of the adult mammalian brain harbors neural stem cells (NSCs) that generate neurons and oligodendrocytes throughout life. We have previously demonstrated that thyroid hormones (THs) regulate adult NSC fate in the SVZ: THs favour NSC commitment toward a neuronal fate whereas a transient lack of THs promotes the generation of new NSC-derived oligodendroglial precursors (OPCs), capable of restoring functional nerve conduction after a demyelinating insult. We also showed that intracellular TH availability in NSC and neuronal precursors is modulated by several TH regulators (i.e., TH distributors as TTR and TH-transporters as MCT8, OATP1C1), thus modulating the neuron/glia output: SVZ-oligodendrogenesis is favoured at the expense of SVZ-neurogenesis in *Ttr* KO or *Mct8/Oatp1c1* double-knock out mice. Our main goal is now to determine the action of TH at two other key developmental stages: the early postnatal life when a peak of

circulating THs occurs around postnatal day (P) 15 and later, as a function of ageing. First, re-analysis of single-cell data from the P2 and P20 SVZ data revealed increased expression of TH transporters and TH-(in)activating deiodinases in postnatal SVZ-NSCs, promoting local TH action. Immunostainings showed a concomitant burst in SVZ-neurogenesis between P4 and P21 whereas SVZ-oligodendrogenesis remained stable. Inducing neonatal hypothyroidism reduced NSC proliferation, disrupted expression of genes implicated in NSC determination and TH signaling, and altered neuro/glia outputs in newborns. Interestingly, three-month-old adult mice recovering from developmental hypothyroidism had fewer olfactory interneurons and underperformed on short-memory odor tests, dependent on SVZ-neurogenesis, showing long-term irreversible effects of a transient developmental lack of THs. Second, as a function of ageing, we showed by immunohistochemistry that the SVZ-OPC density in increased whereas neuronal cells derived from old NSC decreased as well as the olfactory memory. Molecular analysis demonstrated that ageing impacted the intrinsic properties of NSCs, favouring a gliogenic profile at the expense of a neurogenic profile. Together, our findings show that SVZ-oligodendrogenesis is maintained throughout life whereas the generation of new neuroblasts is strongly sensitive to any changes in TH levels, thus impacting the supply of newly-formed olfactory interneurons and olfactory behavior. The stable production of new oligodendroglial cells all along development till ageing could be promoted after a demyelination injury to participate to myelin repair and neuronal survival even in older animals.>

Title: Investigating the celltype specific roles of foxp1 in the development of human neocortex using brain organoids

Authors: *S. E. PARK, G. KONOPKA;
Univ. of Texas southwestern medical center, Dallas, TX

Abstract: The molecular mechanisms underlying human cognition remain mostly unknown. Insights into the genes and pathways important for cognition will provide entry points into understanding cognitive disorders such as autism. De novo mutations in the gene encoding the transcription factor FOXP1 lead to a syndromic form of autism characterized by intellectual disability. Studies from our lab using Foxp1 cortical conditional knockout mouse models have shown that cortical lamination is altered and autism-relevant behaviors are affected. Recent findings in the human fetal brain show that FOXP1 expression is high in progenitor cells including the cell types (e.g. basal radial glia and basal intermediate progenitors) that are associated with human cortical expansion. Moreover, when overexpressed, human FOXP1 results in more progenitors than mouse Foxp1. Other genetic manipulation experiments have shown that knocking down Foxp1 at E13.5 affects results in cells unable to exit the intermediate progenitor stage.

Therefore, I hypothesize that FOXP1's role is important in the progenitors for proper generation of cortical projection neurons in the cortical plate. I am testing this hypothesis using stem cell-derived human cerebral organoids as model systems of early human neocortical development. My results indicate that proliferation of neural cells in the ventricular zone and sub-ventricular zone are affected with the loss of FOXP1. Excitatory neurons in the cortical plate also show signs of premature differentiation in the FOXP1 KOs. Overlap between snRNA-seq and Cut and Run chromatin profiling assay show changes in the regulation of genes involved in proliferation, differentiation and axonogenesis in a cell-type specific manner. Taken together, these data will inform our understanding of the role of FOXP1 in human brain development and how such mechanisms might be relevant to autism and human cognition.

Title: Isl1 is Required for the Specification and Maturation of Starburst Amacrine Cells

Authors: *Y. C. SANTANA AGREDA[1], T. STACKHOUSE[1], P. C. KERSTEIN[2], B. SIVYER[3], K. M. WRIGHT[2];
[1]Oregon Hlth. & Sci. Univ. Neurosci. Grad. Program, Portland, OR; [2]Oregon Hlth. & Sci. Univ. Vollum Inst., Portland, OR; [3]Casey Eye Inst., Oregon Hlth. & Sci. Univ., Portland, OR

Abstract: The mammalian nervous system is comprised of hundreds of distinct neuronal subtypes that wire together into functional circuits. During development, neuronal subtype differentiation is regulated by transcription factors (TF's) which control effector genes that define cell fate. TFs can regulate initial neuronal specification, the development of cell features (morphology, neurotransmitter expression, physiology) or both. The mammalian retina consists of 5 classes of retinal neurons with each type containing many subtypes. Specific transcriptional pathways that direct development for each subtype are unknown. The most diverse class of retinal neurons are amacrine cells (ACs), with ~63 distinct neuronal subtypes. Within the AC population, the TF *Isl1* is expressed in a single subtype: starburst amacrine cells (SACs). *Isl1* is also expressed in other retinal neuron classes, and pan-retinal deletion of *Isl1* results in a loss of these retinal neurons, thus confounding conclusions about *Isl1*'s role in SAC development. To examine *Isl1*'s role in SACs, we developed two approaches to selectively delete *Isl1* at distinct stages of development. The first deletes *Isl1* from AC precursors using a $Ptf1a^{Cre};Isl1^{cKO}$ mouse line, allowing us to examine its role in the initial specification of SACs. The second approach uses a $ChAT^{Cre};Isl1^{cKO}$ mouse line to delete *Isl1* after SACs are specified and migrate to their correct target area, but before the completion of dendritic growth. This approach allows us to examine how *Isl1* can regulate SAC-specific features. Preliminary data indicates that deleting *Isl1* in $Ptf1a^{Cre};Isl1^{cKO}$ results in an absence of SACs. If

deleted in *ChAT^{Cre};Isl1^{cKO}*, SACs adopt abnormal dendritic morphology and lamination. Together, these data suggests *Isl1* is required for the initial specification of SACs and the subsequent development of proper morphological maintenance. Detailing the specific roles TFs have in neuronal subtype development is crucial for understanding how morphological properties contribute to overall circuit function.

Title: Thalamocortical axons regulate superficial layer neurogenesis and cell fate in the embryonic and neonatal sensory cortex

Authors: *T. MONKO[1], J. REBERTUS[1], J. STOLLEY[1], S. SALTON[2], Y. NAKAGAWA[1];
[1]Dept Neurosci, Univ. of Minnesota, Minneapolis, MN; [2]Fishberg Dept. of Neurosci., Icahn Sch. of Med. at Mount Sinai, New York, NY

Abstract: The mammalian neocortex is composed of diverse types of neurons that are sequentially generated during embryonic development and are arranged in an orderly manner across layers. In the adult neocortex, the distribution and density of each neuronal type differ across the cortex. In primary sensory cortex—visual, somatosensory, and auditory—neurons that reside in layer 4 are targeted by axons from corresponding principal sensory nuclei of the thalamus. Synaptic activity of these thalamocortical axons are known to shape cellular organization, characteristic morphology, and patterns of gene expression of layer 4 neurons in postnatal sensory cortex. However, whether these axons influence earlier stages of development, including neurogenesis and neuronal fate specification is poorly understood. We first found that thalamocortical axons arrive in the cortex during the early period of superficial layer neurogenesis. Analysis of mutant mice lacking the majority of thalamocortical axons showed a decreased number of superficial layer neurons in primary visual and somatosensory areas, but not in motor areas, at early postnatal stages. During embryonic development, lack of thalamocortical axons decreased the number and division of radial glia and intermediate progenitor cells in a sensory area-specific manner. Cell fate analysis using pulse-labeling of progenitor cells with a thymidine analog revealed that thalamocortical axons are required for proper specification of superficial layer neurons towards layer 4. Further evidence revealed that this role of thalamocortical axons on cell fate is exerted as early as neonatal stages, demonstrating that these axons are required for the proper number of layer 4 neurons to

be generated and specified in primary sensory areas even before mature synaptic input. We found that these area-specific roles are in part played by the thalamus-derived molecule VGF. In summary, our study provides a mechanism by which afferent input to the neocortex from the thalamus complements the intrinsic program of early cortical development, allowing the sequential generation of diverse neuron types in an area-specific manner.

Title: Rcor2, from corepresor to tubulin interactor

Authors: *D. E. VERBEL-VERGARA[1], M. GONZÁLEZ[1], G. MERELLO[1], C. RIVERA[2], M. E. ANDRÉS[1];

Abstract: REST corepressor 2 (RCOR2) belongs to RCOR family proteins, which are mainly characterized as a repressor of neuronal gene expression in non-neuronal cells. RCOR2 is required for cell proliferation and division of embryonic stem cells, neural stem cells, and neural progenitor cells. Although RCOR2 is expressed mainly and to a great extent in neuronal tissues and has a relevant role in regulating the development of the cortex, it is unknown how it is distributed at the cellular level. The present study aimed to characterize the distribution of RCOR2 in neuronal cells and brain tissue. We identified cytoplasmic and nuclear subpopulations of RCOR2 in N2A, PC-12, HT22, and HEK293T cells using high-resolution microscopy. Neuronal cells show large granules within the nucleus and a smaller punctuated pattern in the cytoplasm, whereas kidney cells show a homogeneous small-punctuated pattern. Cells in the striatum show an RCOR2 pattern similar to that of neuronal cell lines. Recently, mass spectrometry studies have reported tubulin as an RCOR2 interactor. We performed an immunofluorescence analysis that confirmed that RCOR2 colocalizes with tubulin in N2A and HEK293 cells. Also, co-immunoprecipitation assays showed an interaction between RCOR2 and tubulin. There are two RCOR2 isoforms, but it is unknown their specific functions or cellular localization. To answer these questions, we expressed RCOR2-FLAG in different cell types. Recombinant RCOR2-FLAG isoform 1 shows a punctate pattern inside the nucleus while isoform 2 surrounds the nucleolus. Both are also localized in the cytoplasm and recapitulated the colocalization with tubulin. In conclusion, RCOR2 shows a conspicuous localization inside the nucleus, suggesting additional functional roles beyond the transcriptional corepression.

Title: Chromatin regulation of subplate neuron identity and wiring of cortical connectivity

Authors: *D. Z. DOYLE[1,2,3], M. M. LAM[1,2], A. QALIEH[1,2], Y. QALIEH[1,2], A. SOREL[1,2], O. H. FUNK[1,2], K. Y. KWAN[1,2,3];

Abstract: Subplate neurons orchestrate multiple developmental processes essential to cortical circuit assembly. Here, we uncover an unexpectedly selective role for chromatin remodeler *Arid1a* in subplate neurons and their circuit wiring functions. We find that pan-cortical deletion of *Arid1a*, but not sparse deletion, leads to non-cell autonomous mistargeting of callosal and thalamocortical axons reminiscent of subplate ablation. These miswiring phenotypes coincide with disruptions in subplate neuron transcriptional identity, and deficits in subplate organization, subplate-thalamocortical axon co-fasciculation ("handshake"), and extracellular matrix, revealing a necessity for *Arid1a* in distinct aspects of subplate circuit wiring functions. To empirically test *Arid1a* sufficiency in subplate, we generate a cortical plate deletion of *Arid1a* that spares subplate neurons. Subplate *Arid1a* is sufficient for subplate-thalamocortical axon co-fasciculation and extracellular matrix, and remarkably, non-cell autonomously supports callosal formation and thalamocortical axon targeting. Thus, in *Arid1a*, we identify a multifunctional regulator of subplate-dependent axon guidance mechanisms indispensable for cortical circuit wiring.

Title: Neural Stem Cells Direct Axon Guidance via their Radial Fiber Scaffold

Authors: *N. KAUR, W. HAN, Z. LI, N. SESTAN;
Neurosci., Yale Univ. Sch. Med., New Haven, CT

Abstract: Neural stem cells are bipolar epithelial-like cells that reside in the ventricular and subventricular zones (VZ and SVZ) and transform into highly elongated radial glial progenitors as the central nervous system (CNS) grows. These cells are responsible for two key processes of the developing CNS. First, they directly or indirectly generate all neurons and macroglial cells. Second, they guide the migration of new-born neurons to their final destinations in the developing parenchyma using their long radial (basal) fibers, which traverse the entire wall of the CNS and form a physical palisade-like scaffold.Here, we describe a critical role for neural stem cells in axon guidance at a distance from their cell bodies. While investigating how corticospinal tract (CST) axons navigate the long distance from the cerebral cortex to the the spinal cord, we identified novel functions of the radial glia/ neural stem cells within the ventricular zone of the ventral forebrain's medial ganglionic eminence (MGE). We show that radial glial cells form an axon guidance scaffold to direct CST axons through a previously unknown choice point at the boundary between the embryonic striatum and globus pallidus (i.e., striatopallidal junction; SPJ). To our surprise, this role was dependent on a previously unknown function of RND3 (RHOE), an atypical member of the RHO GTPase superfamily that lacks GTPase activity but regulates actin cytoskeletal organization, and its binding partner, ARHGAP35 (P190A) a RHO GTPase-activating protein. RND3 and ARHGAP35 expression specifically in radial glia/ neural stem cells, but not in the growing CST axons, is essential for maintaining this radial glial scaffold. Thus, in addition to cell-autonomous roles in axonal and dendritic growth, RND3 and ARHGAP35 regulate axon pathfinding cell non-autonomously by promoting the hitherto unexplored role of the striatopallidal radial glial scaffold as a guidepost structure.

Title: The zinc finger transcription factor SALL1 is required for normal developmental transition of microglia in mouse embryos

Authors: E. P. SCOTT, E. BREYAK, ***Y. NAKAGAWA**;
Univ. Minnesota, Minneapolis, MN

Abstract: Microglia, resident immune cells in the CNS, play many critical roles in early neuraldevelopment ranging from neurogenesis, neuronal migration and axon growth, in addition tolater roles in synapse pruning and cell survival. Although recent single-cell RNA-sequencingstudies have found pronounced temporal and spatial diversity of developing microglia, howmicroglia diversity is generated during development is unknown. Knowledge of the underlyingmechanisms for this process is key to understanding how each subpopulation of microgliainfluences neural development. To address this question, we first characterized the expressionof CD206 as a potential marker of early-stage embryonic microglia in mouse brain sections. At E12.5, a majority of parenchymal Iba1-positive immune cells in most CNS regions that weanalyzed expressed CD206, which overlapped with a microglia-specific marker P2RY12.Between E12.5 and E13.5, there was a sudden reduction in CD206 expression, and thepercentage of CD206-positive parenchymal immune cells remained low throughoutdevelopment except in early postnatal microglia in the white matter. The period of this earlydevelopmental transition of microglia populations from CD206-positive to CD206-negativestatus coincides with the peak of many early neural developmental events in the CNS, and alsowith the onset of the zinc-finger transcription factor *Sall1*, a signature microglia gene in theadult CNS. Therefore, we tested if *Sall1* is required for this early transition of microglia status bydeleting the gene specifically in microglia. When *Sall1* was deleted in most microglia from theonset of its expression in early embryos, many *Sall1*-deficient microglia continued to expressCD206 when it is normally downregulated. In addition, the mutant microglia showed lessramified morphology compared with controls even at postnatal stages. Thus, SALL1 isintrinsically required for an early subpopulation of microglia to transition into a more maturestatus during embryonic development.

Title: Redox-dependent changes in trafficking of the neuronal glutamate transporter, EAAT3

Authors: *S. RADHAKRISHNAN, S. AMARA;
Lab. of Cell. and Mol. Neurobio., Natl. Inst. of Mental Hlth., Bethesda, MD

Abstract: Glutamate transporters are essential for clearing glutamate from the extracellular space and thus limit the actions of glutamate within the brain. The neuronal glutamate transporter EAAT3 has also

been shown to transport cysteine, which serves as a rate-limiting substrate for the synthesis of neuronal glutathione, an essential regulator of oxidative stress in cells. Hence, EAAT3 can contribute to cellular redox by acting as the primary cysteine transporter in neurons. EAAT3 mutations are also involved in several neuropsychiatric disorders such as schizophrenia and obsessive-compulsive disorders. The activity of plasma membrane transporters can be altered by changes in trafficking, expression levels and recycling of the transporters. EAAT3 rapidly cycles to and from the cell surface and through intracellular compartments within a few minutes and this can be regulated through several different intracellular signaling pathways. Previous studies have demonstrated that activation of protein kinase C (PKC) can regulate EAAT3 trafficking and increase the localization of EAAT3 at the membrane surface which is potentially important for regulating neuronal cysteine intake. There is evidence of some redox-triggered mechanisms that can directly or indirectly influence signaling by altering the catalytic properties or influencing subcellular compartmentation of different PKC isoforms. This suggests a mechanism by which EAAT3 trafficking could be modulated by PKC as a response to cellular redox stress as cysteine is essential to the synthesis of the antioxidant glutathione. To study this, we monitored if oxidizing agents such as hydrogen peroxide can stimulate a redox response in the cell and lead to increased membrane localization of EAAT3. We found that application of hydrogen peroxide leads to an increase in EAAT3 membrane localization in Neuro2A cells expressing EAAT3. We used TIRF and biotinylation assays to confirm that EAAT3 localization can be altered by PKC activation and further examined whether this surface expression can be additionally modulated during redox stress. To further study the downstream effects of cysteine and N-acetyl cysteine on cytosolic and mitochondrial stress, we monitored the redox changes in the cytosol and mitochondria with live-cell imaging. This was done using genetically encoded fluorescent sensors that measure cellular redox status which were targeted to specific subcellular compartments. Using this approach, we were able to conduct live-cell imaging with spatio-temporal accuracy and delineate sub-cellular changes in redox dynamics caused by EAAT3 mediated transport of cysteine.

Title: Stimulation of amygdalar-cortical projections induces release of glutamate and enhances synaptic communication

Authors: *A. HERNANDEZ-MATIAS, F. BERMUDEZ-RATTONI, D. OSORIO-GÓMEZ; Neurociencia Cognitiva, Inst. De Fisiologia Celular - UNAM, Mexico City, Mexico

Abstract: The basolateral nucleus of the amygdala (BLA) and the insular cortex (IC) are brain structures anatomically connected that are required for the formation and expression of conditioned aversive

responses. In this regard, the BLA and IC have a crucial role in tasks such as Conditioned Taste Aversion (CTA). However, there is also some evidence pointing at a possible modulation of the IC made by BLA. Nevertheless, more information on the functional role of the amygdalar projections that communicate to the insula in establishing aversive memories is needed. Previously, we obtained experimental evidence indicating that the induction of CTA is possible through activation and reactivation of the BLA-IC pathway at specific times; this behavioral outcome is similar to that observed in CTA protocols pairing a gustative stimulus with gastric malaise. Therefore, we aimed to investigate the neurochemical and plasticity changes by which the reactivation may generate an aversive memory. Male Wistar rats infected with channelrhodopsin-2 (ChR2) or only the EYFP reporter in BLA received a double photostimulation with blue light (473 nm) pulses at 20 Hz in the projections of amygdala that reach IC; we maintained the conditions of the behavioral experiments of reactivation, so that the stimulations lasted 10 minutes each and were separated by 30 minutes. Simultaneously, we carried out microdialysis experiments to identify changes in neurotransmitter release within IC, as well as recordings of excitatory postsynaptic potentials in independent groups of animals. The neurochemical activity monitoring in IC revealed an increase in extracellular levels of glutamate concurrent with both photostimulations and exclusively in the ChR2 group. Moreover, electrophysiological recordings of the BLA-IC projection showed that the double stimulation also leads to the induction of Long-Term Potentiation (LTP). Interestingly, LTP was not induced with two stimulations in the EYFP group nor with one stimulation in animals expressing the opsin; a similar pattern of results was previously observed in our taste avoidance experiments. Taken together, these findings suggest that stimulation of the BLA-IC pathway, a critical neural substrate for long-term aversive memory, is associated with release of glutamate and a sustained improvement in synaptic communication.

Title: Evaluation of the molecular interaction of viral E protein of ZIKA virus and the Alpha 1 and GluN2A subunits of GABA-A and NMDA receptors.

Authors: A. RENGIFO[1], O. TORRES FERNÁNDEZ[3], *Z. DUEÑAS[2], C. CASTRO[3], E. NINO[2]; [1]Doctorado en Ciencias Biomédicas, [2]Grupo de Neurofisiología Comportamental Dept. de Ciencias Fisiológicas, Facultad de Medici, Univ. Nacional de Colombia, Bogota DC, Colombia; [3]Morfología Celular, Inst. Nacional de Salud, Bogotá D.C, Colombia

Abstract: Zika virus (ZIKV) is a neurotropic flavivirus that produces malformations in the cortex and cerebellum with morphological changes associated with neuronal death or degeneration (1). It has been

reported that GABAergic neurons are vulnerable to neurotropic viruses (2) and that neuroinvasion by flavivirus requires the participation of calcium to mediate the entry and exit of the virion into the cell (3), for this reason, it is possible to consider that ionotropic NMDA-type glutamate receptors could also participate as viral targets. In this study, the molecular interaction of the Alpha 1 subunits of the GABA-A receptor and GluN2A of the NMDA receptor with the viral fusion E protein of ZIKV was evaluated using an in silico approach. Working files were obtained from the Protein Data Bank (PDB) or with structures generated from the Swiss model models of the UniProt database. Three-dimensional structures of GABA and glutamate ligands were obtained from the Pubchem database. Molecular docking between GABA-A and NMDA receptor subunits with ZIKV E protein was performed from the tertiary structures obtained from PDB using autodock vina, Haddock 2.2 and CPORT plugin software, using different models for residue interaction. In this study, high protein-protein molecular docking was found when GABA and glutamate binding sites for each evaluated subunit and asparagine residue 154 for ZIKV E protein were used as active residues. The ΔG-energy values found were -155.6±18.3 for the couplings with Alpha1 and -193±21.8 with GluN2A.The results suggest that ZIKV E-protein could be use GABA-A and NMDA receptor subunits as viral targets, with a more favorable value for NMDA subunits.This result could be attributed to the fact that flavivirus furins use calcium as a key signal for infection and perhaps their interaction with NMDA could have a significant contribution to the formation of calcifications observed in different models of ZIKV infection.

Title: Ventral tegmental area mRNA expression changes in delta-9-tetrahydrocannabinol exposed young mice

Authors: C. SMITH, I. CRESS, *J. EDWARDS;
Brigham Young Univ., Provo, UT

Abstract: The ventral tegmental area (VTA) is the reward center of the brain where synaptic plasticity is at the root of many learned behaviors, including maladaptive forms of drug dependence and addiction reinforcement. Used for recreation or for pain modulation purposes, delta-9-tetrahydrocannabinol (THC), the main psychoactive component in marijuana, alters synaptic plasticity in the VTA, and chronic use is associated with cannabis use disorder. The synaptic plasticity that we examined is long term depression (LTD) of glutamate inputs to VTA GABA cells. THC, an exogenous cannabinoid, induces LTD of these inputs via cannabinoid receptor 1 (CB1). While research shows that plasticity in the VTA changes in response to chronic THC exposure, there is little research on what happens to the transcription of genes in the VTA after exposure to THC. To understand the effects of THC in the VTA, we measured gene expression via mRNA levels in various groups of mice. We isolated mRNA from tissue punches of VTA taken from 400 μm thick brain slices. Samples then underwent reverse transcription to create a cDNA library of each. These samples were isolated from juvenile/adolescent mice (P15-32 days) that were either naive (n=8), mice chronically exposed to THC (n=8), THC seven-day withdrawal mice (n=7), or vehicle control mice (n=8). All groups included male and female subjects. We examined transcripts encoding for proteins involved in synaptic glutamate neurotransmission as well as the endocannabinoid system. These included AMPA receptor subunit 1 (GlutA1) and 2, NMDA receptor subunits 1, 2a and 2b, glutamate metabotropic receptor 5, diacylglycerol lipase-alpha (DAGLα), cannabinoid receptor 1 (CB1), Fatty Acid Amide Hydrolase and Tyrosine Hydroxylase.In mice exposed to chronic THC we identified significant increases in GlutA1 ($p<0.01$), DAGLα ($p<0.05$) and CB1 receptor transcripts ($p<0.05$). Surprisingly, after the withdrawal from THC the increase in CB1 receptors decreased to naïve levels, while the GlutA1 receptors did not ($p<0.05$). These results suggest GlutA1, CB1 and DAGLα as targets for further examination regarding the impact of THC on VTA synaptic transmission. Understanding the transcriptional changes in the VTA when exposed to THC helps further our understanding of the mechanisms behind marijuana impact at the molecular level, which may have relevance for cannabis use disorder or THC dependence development.

Title: Application of a novel in silico / ex vivo pipeline to study the effects of glutamate kinetics on fast, excitatory neurotransmission

Authors: *C. CHEN, J. HENNESSEY, I. A. SAVTCHOUK;
Biomed. Sci., Marquette Univ., Milwaukee, WI

Abstract: <The excitatory neurotransmitter glutamate is a key signaling molecule in the brain whose dysregulation is a common feature in pathologies like dementia and drug addiction. Historically, studying

glutamate in the brain has been difficult. Because of glutamate's small diffusion radius and ultrashort timecourse in extracellular space, existing approaches to capture accurate glutamate kinetics have poor spatial and temporal resolution or use indirect measurements. Newer optical glutamate sensors (e.g. iGluSnFR) provide less biased readouts, yet still convolve the true glutamate waveform due to sensor kinetics and buffering properties. As such, computational (in silico) approaches that model molecular diffusion are attractive and have described key aspects of glutamate behavior. However, these have been limited due to lack of precise data on: 1) Extracellular membrane morphology; 2) Molecular expression profiles; and 3) Glutamate-specific kinetic interactions. Here, we exploited open-source reconstructions of 3D electron microscopy data, advances in computer hardware, and the growing body of accurate kinetic models for glutamate receptors and transporters to help resolve these limitations. To model glutamate diffusion and interaction, we used a Monte Carlo-based Mcell / Blender package that supports the use of membrane reconstructions while tracking individual molecules and their interactions. Our model consisted of EM reconstruction data of ~300 μm^3 of somatocortical space, while our glutamate interactions were modeled from previously-published kinetic schemes. The workflow consisted of using a Python-based environment to systematically set up simulations, vary parameters, launch simulations in a batch fashion, and analyze simulation readouts on glutamate's location, timecourse and interactions with transporters and receptors. Specifically, we built upon previous reports detailing the role of excitatory amino acid transporters (EAATs) in clearing glutamate from synaptic and extrasynaptic space. Our data suggests the existence of an EAAT-dependent submicron gradient with "near-field" regions closer to EAAT clusters establishing different concentrations of glutamate compared to "far-field" regions. We have also used the model to predict "true" glutamate activity in hippocampal slices based off SnFR-mediated glutamate transients recorded using two-photon imaging. Future questions include how LTP- and LTD-like stimulation patterns recruit different receptor subtypes and how patterned glutamate release from neurons (e.g., tetanic, theta-burst) and astrocytes (channel-mediated release) may skew plasticity.>

Title: Inhibition of neuro-inflammation through glutamate signalling pathway in valproic acid induced autism spectrum disorder in rats: Neuroprotective role of Granulocyte colony-stimulating factor

Authors: *B. MEDHI, A. MISHRA, R. SINGLA, R. RAJPOOT, R. JOSHI, P. SARMA, A. SHARMA; Post Grad. Inst. of Med. Educ. and Res. (PGIMER), Chandigarh, India

Abstract: Background Granulocyte colony-stimulatingfactor(G-CSF) being a haemopoietic growth factor has been used in treatment of myelosuppression and also found to elicit anti-inflammatory and neuroprotective properties.Chronic neuro-inflammation induced anomalous glutamate receptor activation

has been identified as one of the important factor in pathogenesis of autism spectrum disorder (ASD).Thus, the current study was designed to elucidate the neuro-protective effect of G-CSF and to decipher the underlying mechanism(s) in valproic acid (VPA) induced experimental model of ASD. **Methods** Experimentally, ASDrat model was induced by single dose of VPA (600 mg/kg;i.p) on gestation day (GD) 12.5 to the pregnant female rats. After birth, pups were treated with vehicle i.e Normal saline 0.9% i.p), Risperidone (2.5 mg/kg; i.p) and G-CSF (10, 35, 70 μg/kg; i.p) from Post natal day (PND) 23 to 43. All the groups were subjected to various developmental, and behaviour tests from birth. The rats were sacrificed on PND 55 and their brain were excised and processed for biochemical (oxidative stress, inflammatory markers, BDNF), histological examination (H&E, Nissl staining), NMDA and AMPA receptor expression by immunohistochemistry and RT-PCR evaluation. **Results** In VPA-exposed rats, postnatal treatment of G-CSF rescued the social impairment and alleviated spatial memory and learning impairment in a dose dependent manner. There was increase in BDNF levels, IL-10 and reduction in IL-6,IL-1β and TNF-α levels with G-CSF treatment.The up-regulated expression of NMDA and AMPA both in the prefrontal cortex as well as hippocampus was alleviated by G-CSF thereby validating its anti-inflammatory and excito-protective properties. Additionally, G-CSF in a dose dependent manner improved oxidative stress (GSH, MDA, Catalase, SOD) and displayed neuropreservation of brain of ASD offsprings. **Conclusion** G-CSF demonstrated neuroprotection against the core symptoms of autism in the VPA induced rodent model, making it a potential candidate for treatment of ASD. The glutamate signalling (NMDA and AMPA) may be attributed as the underlying mechanism for its excitoprotective, anti-inflammatory and immunomodulatory effects.

Title: The role of NMDA receptors subunits in the progression of inflammatory breast cancer (IBC).

Authors: *L. MENDEZ-SANTACRUZ, X. S. BITTMAN-SOTO, K. M. RODRIGUEZ-MARTIR, E. PETERSON, C. MALDONADO-VLAAR;
Univ. of Puerto Rico - Rio Piedras Campus, San Juan, Puerto Rico

Abstract: Inflammatory Breast Cancer (IBC) has a 73% incidence of metastasis to the brain as compared to other cancer types like breast, lung, and bone cancer. Previous research showed that tumor cells from different breast cancer subtypes (-HR / -HER2) and (-HR / + HER2) have a high incidence of crossing the blood-brain barrier and inducing increased expression of glutamate receptors NMDA subunits (NMDAR1 and NMDR2) in the brain. IBC is the most aggressive and rare type of breast cancer. The absence of a solid tumor is replaced by swelling, redness, and skin changes, resulting in many cases in misdiagnosis of

an infection in the invasion and migration phase; this type of cancer blocks blood and lymphatic vessels in the breast's skin, causing local inflammation and rapid metastasis. However, little is known of the role that these glutamatergic receptors have in the development and/or progression of IBC. The present work provides a new understanding of the cellular and molecular effects NMDA receptors (NMDAR) have on oncogenic phenotypes in IBC. The detection and quantification of the NMDAR were evaluated by RT-qPCR, Western blot, and immunofluorescence (IF) techniques in deferments breast cancer cell lines (MCF7, MDA-MB-231) and IBC cell lines (SUM149, and SUM190). Also, NMDAR antagonists (memantine and dizocilpine "MK-801") were used in 2D cell cultures to see the pro-oncogenic effects of migration and proliferation in cell models. Results showed a significant increase in the expression of NMDARs in IBC cell lines. In the functional cell culture assays with NMDAR antagonists, a decrease in migration and proliferation in IBC cell lines was found. These findings may be related to the high aggressiveness and the high rate of metastasis by IBC within the brain. Our results have high clinical relevance since having extensive knowledge of the role of NMDARs in IBC progression could complement therapeutic approaches for patients with IBC.

Title: Exposure to H_2O_2 leads to a change in ubiquitination status of the glutamate/cystine exchanger, System x_c-

Authors: C. BUCK[1], A. GIBSON[2], S. MACKENZIE[2], *L. CHASE[2];
[1]Hope Col., Holand, MI; [2]Hope Col., Holland, MI

Abstract: System x_c^- exchanges intracellular glutamate for extracellular cystine across the membrane of many cell types, including astrocytes. Its activity directly regulates the synthesis of the antioxidant glutathione and the extracellular concentration of glutamate in some areas of the brain. We recently demonstrated that oxidants acutely upregulate System x_c^- activity by triggering the rapid redistribution of the transporter from intracellular compartments to the cell surface. However, little is known about the mechanism by which oxidants regulate the cell surface expression of the transporter. Given that the trafficking of many transporters and ion channels are regulated by alterations in their ubiquitination status, we sought to determine if a similar mechanism may be responsible for the oxidant-induced upregulation of System xc-. Specifically, we hypothesized that H_2O_2 exposure may lead to a decrease in ubiquitination of the transporter, thus leading to an increased residence time in the cell membrane. To test this hypothesis, we used site-directed mutagenesis to determine if alteration of lysine residues with xCT

would alter cell surface expression. There are seven highly conserved lysine residues within xCT that are located on the cytoplasmic side of the membrane. These residues are located at positions 4, 37, 41, 43, 422, 472, and 473. Using a radioisotope uptake assay and cell surface biotinylation assay, we found that mutation of three of the N-terminal lysine residues to arginine (K4, K41 and K43) increased transport activity and cell surface expression, while mutation of K37 led to a significant decrease in activity and cell surface expression. Similarly, a triple mutation of the C-terminal lysine residues (KKK422,472,473RRR) also decreased activity or cell surface expression. Collectively, these results suggest that post-translational modification of lysine residues do appear to alter trafficking of System x_c^-, but the regulation is complex. In a follow up experiment, we performed an immunoprecipitation of xCT in the presence and absence of H_2O_2. Surprisingly, we observed that the H_2O_2 led to an increase in transporter mono-ubiquitination with no observable changes in poly-ubiquitination. Therefore, we are currently assessing which lysine residue is likely the site of mono-ubiquitination. Given that the K37R and the C-terminal triple mutant exhibited decreased activity, we are focusing specifically on those residues. However, our initial results suggest that xCT monoubiquitination is associated with an increase in cell surface expression following oxidant exposure.

Title: Sub-sedative allopregnanolone effects on cortical EEG in mice

Authors: *P. M. LAMBERT[1], N. RENSING[2], R. NI[1], S. SALVATORE[1], A. BENZ[1], M. WONG[2], C. ZORUMSKI[1], S. MENNERICK[1];
[1]Psychiatry, [2]Neurol., Washington Univ. In St Louis, Saint Louis, MO

Abstract: Depression is one of the most common mental health disorders. Pharmacologic treatment for depression has relied on monoamine reuptake inhibitors, which have significant drawbacks. Recently the FDA approved Brexanolone, a formulation of the endogenous neurosteroid allopregnanolone (AlloP), as a novel rapid-acting treatment for postpartum depression. The antidepressant effects of AlloP occur at relatively low sub-sedative doses, but the sedative effects of AlloP are an important safety concern for its use as an antidepressant therapy. Unlike monoamine treatments, AlloP is a positive allosteric modulator (PAM) of $GABA_A$ receptors. While there is a rich literature on how AlloP affects neural physiology at the level of $GABA_A$Rs and single neurons, our understanding of how these cellular changes converge to affect network activity such as neural oscillations is lagging. This information can aid in the continued development of safer, more effective therapies. We characterized the acute effects of sub-sedative doses of AlloP in mice on network-wide neural activity recorded with cortical EEG, including comparisons to

pentobarbital and diazepam, $GABA_AR$ PAMs that lack antidepressant effects clinically, and to ketamine, another rapid-acting antidepressant. Five adult mice of both sexes were assigned to each drug treatment, and a control vehicle injection was delivered prior to administration of a sub-sedative dose of the assigned drug. Sub-sedative doses of drugs were selected based on pilot experiments. Acute network effects of AlloP (5 mg/kg) were evident with rapid onset and persisted for thirty minutes. These effects included a decrease in the peak frequency of the theta rhythm in the parietal electrodes and a broad increase in power spectral density between 15-60 Hz in all cortical electrodes. EEG responses in animals treated with pentobarbital (15 mg/kg) or diazepam (1 mg/kg) shared many similarities to the effects of AlloP, including a slowing of theta rhythms, and a mid-frequency power increase. Ketamine (10 mg/kg) mainly showed a reduction in mid-frequency spectral power and an increase in power in faster gamma range frequencies (>40 Hz). Additionally, the three $GABA_AR$ PAMs shift theta-gamma phase-amplitude coupling in the parietal EEG to the slower theta rhythm peak and lower gamma frequencies, and the strength of the modulation decreases significantly, whereas ketamine led to a strengthening of modulatory coupling between the same frequencies observed prior to drug treatment. Overall, the results suggest that in the baseline state, little differentiates allopregnanolone from other $GABA_A$ PAMs to mark its selective antidepressant effects.

Title: Preventing adolescent synaptic pruning in female mouse prelimbic cortex via local knockdown of $\alpha_4\beta\delta$ $GABA_A$ receptors generates anxiety in adulthood.

Authors: *M. R. EVRARD, M. E. LI, S. SMITH;
Physiol. and Pharmacol., SUNY Downstate Med. Ctr., Brooklyn, NY

Abstract: Anxiety is increasingly reported, especially in adolescent females. The etiology is largely unknown, which limits effective treatment. Layer 5 prelimbic cortex (L5PL) generates anxiety but undergoes extensive adolescent synaptic pruning, raising the question of the impact of pruning on anxiety. Here we show that preventing pubertal L5PL pruning increases anxiety in response to an aversive event in adolescent and adult female mice. Spine density of Golgi-stained neurons decreased ~63% from puberty (~PND35, vaginal opening) to post-puberty (PND56, $P<0.0001$). Expression of $\alpha4\beta\delta$ $GABA_A$ receptors (GABARs) transiently increased 10-fold in L5PL at puberty (<0.00001), but decreased post-pubertally. Both global and local knockdown of these receptors during puberty prevented pruning, increasing spine

density post-pubertally (P<0.0001), an effect reversed by blocking NMDA receptors (NMDARs). Pubertal expression of the NMDAR-dependent spine protein kalirin7 decreased (50%, P<0.0001), an effect prevented by α4 knock-out, suggesting that α4βδ-induced reductions in kalirin7 underlie pruning. Increased spine density due to local α4 knockdown at puberty decreased open arm time on the elevated plus maze post-pubertally (62%, P<0.0001) in response to an aversive stimulus, suggesting that increases in L5PL synapses trigger anxiety. These findings suggest that prelimbic synaptic pruning is necessary to limit anxiety in adulthood and may suggest novel therapies.

Title: Sex differences in α4βδ $GABA_A$receptor mediated motor behavior flexibility correlated with selective pruning of mushroom spines in adolescent mice

Authors: *M. TEKIN[1], S. S. SMITH[2];
[1]Dept Physiol Pharmacol MS31, S.U.N.Y. Downstate Med. Ctr., BROOKLYN, NY; [2]Dept Physiol Pharmacol MS31, SUNY Downstate Med. Ctr., Brooklyn, NY

Abstract: Adolescent synaptic pruning is critical for proper neurodevelopment and we have shown this is mediated by α4βδ $GABA_A$ receptors (GABAAR) in the motor cortex. These receptors have high expression in the ventrolateral (VL) thalamic relay nuclei which projects to the primary motor cortex, but synaptic pruning has not been assessed in this area. Thus, for this study, we assessed synaptic pruning in adolescence in the thalamic relay nuclei. To this end, spine density/types were assessed in Golgi-stained brain slices from z-stack projection (0.3 μm) photomicrographs taken with a Nikon DS-U3 camera mounted on a Nikon Eclipse Ci-L microscope using a 100x oil objective. Spine density across the dendrites of multi-polar excitatory neurons in the VL relay nucleus of the thalamus (proximal and distal segments) was compared using pubertal and post-pubertal female mice (~P35, vs. P56). In the multi-polar excitatory neurons of the VL relay nucleus of the thalamus, no general synaptic pruning was observed (P35=0.348 ±0.022 spines per 10 μm, P56=0.404±0.022, P>0.05), but there was selective mushroom spine pruning in the distal region (P35=0.098±0.012 spines per 10 μm, P56=0.064 ±0.0091, P<0.05). We additionally explored whether there were sex differences in motor behavioral flexibility since we have previously shown that hippocampal adolescent mushroom spine pruning is needed for spatial learning flexibility. To this end, we performed a rotarod test with four groups of post-pubertal mice: male wildtype, female wildtype, female α4 knockouts, and male α4 knockouts. During this test, the mice were first trained at 4 RPM for 4 trials. Then to test behavior flexibility we trained them the next day at an accelerated speed of 4 to 40 RPM over 5 minutes for 4 trials. Only female wildtype mice showed improvement (T1 = 87±12 seconds, T4=138±9 seconds, P<0.05). These results suggest that sex

differences in the pruning of mushroom spines in VL thalamus are associated with improved behavioral flexibility on a motor task post-pubertally, an effect prevented by knock-out of α4βδ GABAARs.

Title: Distinct functional alterations and therapeutic options of two pathological de novo variants of the T292 residue of GABRA1 identified in children with epileptic encephalopathy and neurodevelopmental disorders

Authors: *W. CHEN[1], Y. GE[1], J. LV[1], J. MELO[2], R. JUNEJA[2], L. LIU[1], Y. WANG[1];
[1]Univ. of British Columbia, Vancouver, BC, Canada; [2]Neurol. Ctr. of Toronto, Toronto, ON, Canada

Abstract: The $GABA_A$ receptor ($GABA_AR$) is a chloride (Cl^-) channel receptor and the primary mediator of neuronal inhibition, and thereby plays critical roles in controlling excitation-inhibition balance in the mammalian brain. Mutations of $GABA_AR$ have reportedly led to epileptic encephalopathy and neurodevelopmental disorders. In our experiments, we first identified a novel *de novo* T292S (C875G) missense variant from a pediatric patient with developmental delay. This mutation coincidentally occurs at the same residue as that of the previously reported variant T292I (C875T) identified from a pediatric patient with epilepsy. The distinct phenotypes associated with these two patients promoted us to compare the functional alterations of the two mutant receptors and search for suitable therapeutics. To achieve our objectives, we used biochemical techniques, whole-cell patch-clamp recordings, and pharmacological characterizations in HEK293 cells overexpressing the wild-type and mutated human recombinant $GABA_ARs$ containing α1/β2/γ2 subunits. We found that the $\alpha1_{T292S}$ variant significantly increased GABA-evoked whole-cell currents, shifting the dose-responsive curve to the left with an unchanged maximal response. In marked contrast, the $\alpha1_{T292I}$ variant significantly reduced GABA-evoked currents, shifting the dose-responsive curve to the right with a severely diminished maximal response. Neither mutation affected $GABA_AR$ expression in the cell and on the plasma membrane, suggesting the functional alterations are resulted from the changes in channel gating properties. Indeed, $\alpha1_{T292S}$ variant increased and $\alpha1_{T292I}$ variant decreased single-channel open time and open probability. After screening several $GABA_AR$-targeted therapeutics, we found that $GABA_AR$ allosteric inhibitor thiocolchicoside removed the gain of function due to T292S mutation by restoring the mutant receptor's GABA agonist sensitivity. On the other hand, a combination of $GABA_AR$ positive allosteric modulator diazepam and a calcium channel blocker verapamil, which was recently shown to rescue the functional loss caused by several other *de novo* GABRA1 mutations, rescued the loss of function due to T292I mutation. In conclusion, the bidirectional change in receptor function caused by these two *de novo* mutations suggests that $\alpha1_{T292}$ is a critical residue for controlling $GABA_AR$ channel gating. Moreover, we provided differential therapeutic suggestions for managing these two patients, highlighting the importance of precision medicine for pediatric channelopathies.

Title: Lmtk3 deficiency alters steady-state $gaba_a$ receptor-mediated cl^- currents via kcc2 in dentate granule cells

Authors: *N. CHO[1], G. KONTOU[2], J. L. SMALLEY[2], G. GIAMAS[3], P. A. DAVIES[2], S. J. MOSS[2]; [1]Neurosci. Program, Tufts Univ. Grad. Sch. of Biomed. Sci., Boston, MA; [2]Dept. of Neurosci., Tufts Univ. Sch. of Med., Boston, MA; [3]Univ. of Sussex, Falmer, Brighton, United Kingdom

Abstract: In the adult mammalian CNS, fast hyperpolarizing postsynaptic inhibition is mediated by $GABA_A$ receptors. Deficits in GABAergic inhibitory transmission is implicated in the pathophysiology of epilepsy, anxiety, mood disorders, schizophrenia, and autism spectrum disorders. The establishment and maintenance of proper hyperpolarizing GABA signaling is dependent on the expression and activity of KCC2, a neuron-specific K^+/Cl^- cotransporter. KCC2 membrane transport and activity can be modulated via the phosphorylation of individual serine and threonine residues within the intracellular C-terminus. Using affinity purification coupled to LC-MS/MS, our lab has previously identified numerous proteins that comprise the KCC2 proteome on the mouse plasma membrane. Lemur tyrosine kinase 3 (LMTK3), a brain specific transmembrane serine/threonine-protein kinase, was highly enriched within KCC2-containing complexes (Smalley et al., 2020). Given the consequences of KCC2 dysfunction, it is of great interest to identify targets that can modulate KCC2 levels and transporter activity. Our current study focuses on evaluating the role of LMTK3 in regulating KCC2-mediated GABA signaling. Using biochemical experiments, immunocytochemistry, and immunohistochemistry, we have characterized the interaction between KCC2 and LMTK3 in the brain. To investigate the functional impact of LMTK3 and KCC2 in dentate granule neurons, we have utilized a whole-cell patch-clamp Cl^- loading electrophysiological assay to measure the reversal potential of $GABA_AR$-mediated currents (E_{GABA}) that reports KCC2 activity and Cl^- extrusion capacity under specific chloride loads. Our observations show a significant hyperpolarizing shift of E_{GABA} in dentate granule cells of 8-week-old $LMTK3^{-/-}$ mice. Our findings suggest that LMTK3 is a novel kinase regulator of inhibitory neurotransmission and we hope further investigation of the phosphorylation balance among key players that mediate GABAergic inhibition will provide a better understanding of how these are able to be modulated and used for novel therapies.

Title: Benzodiazepine tolerance induced by prolonged treatment is characterized by GABAergic synaptic plasticity

Authors: *C. CHAPMAN[1], J. M. LORENZ-GUERTIN[1], S. DAS[1], N. POVYESHEVA[2], A. COYNE[3], J. LOMBARDI[3], J. PABLO[3], T. JACOB[1];
[1]Pharmacol. and Chem. Biol., Univ. of Pittsburgh Sch. of Med., Pittsburgh, PA; [2]Dept. of Neurosci., [3]Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Benzodiazepines (BZDs), such as Valium or Xanax, are commonly prescribed drugs for seizure, anxiety and pain control. They act as positive allosteric modulators at GABA type A receptors ($GABA_AR$s), which mediate the majority of fast inhibitory neurotransmission in the central nervous system. This results in the sedative, anxiolytic, anticonvulsant, and myorelaxant effects of BZDs. Despite the therapeutic efficacy of BZDs, their clinical use is limited by tolerance, dependence, and cognitive impairment. Our lab is studying the BZD-induced GABAergic neuroadaptations involved in tolerance. $GABA_AR$ inhibitory synaptic strength is determined by the abundance and type of $GABA_AR$s, which is regulated through dynamic trafficking mechanisms, regulatory proteins, and post-translational modifications. We previously showed 24-hour treatment with the BZD diazepam (DZP) increases phosphorylation and destabilization of the inhibitory postsynaptic scaffolding protein gephyrin, decreasing synaptic retention of receptors and enhancing lysosomal-mediated degradation of the $GABA_AR$ γ2 subunit, which is required for BZD binding. We are further investigating GABAergic synaptic plasticity *in vitro* and *in vivo* under conditions of prolonged DZP treatment. Prior data from our 7-day DZP tolerance model found that mice treated with DZP vs vehicle have synaptic alterations in $GABA_AR$ subunit composition and significantly reduced sensitivity to DZP. Ongoing *in vivo* co-immunoprecipitation and *in vitro* FRET experiments are further evaluating $GABA_AR$ subtype changes during BZD treatment. Phosphorylation of the $GABA_AR$ γ2 subunit at serine 327 has been implicated in reduced BZD sensitivity, while an additional phosphorylation site serine 343 remains largely uncharacterized. We have developed single and double $\gamma2^{S327A}$ and $\gamma2^{S343A}$ mutants to elucidate the role of each site in BZD tolerance through surface biotinylation, immunofluorescence, and electrophysiological experiments in primary neurons subjected to 7-day vehicle or DZP treatment. Finally, we are investigating the mechanisms by which Shisa7, a novel $GABA_AR$ auxiliary subunit that increases DZP potentiation, regulates $GABA_AR$ trafficking and how this is modified with DZP treatment. By uncovering DZP-induced GABAergic neuroadaptations that define tolerance we will provide a foundation for approaches to promote the development of safer prescription drugs without long-term risks to patients.

Abstract: **Introduction:** Lorazepam belongs to the benzodiazepine class of pharmacological compounds that have amnestic, anticonvulsant, anxiolytic, hypnotic, myorelaxant, and sedative properties. Benzodiazepines modulate gamma-aminobutyric acid type A ($GABA_A$) receptors in the brain, leading to enhanced inhibition and reduced neuronal excitability. The aims of this study were to i) develop a physiologically-based pharmacokinetic (PBPK) model of lorazepam, ii) predict interstitial unbound brain concentrations of lorazepam over a range of intravenous doses, iii) determine the concentration effects on GABAergic function and neuronal excitability, and iv) correlate the findings to sedation and impaired recall in individuals. **Methods:** The PBPK model was developed with PK-Sim® modeling software (version 9.0, www.open-systems-pharmacology.org). Data from the scientific literature was digitized with WebPlotDigitizer (version 2.0, https://automeris.io/WebPlotDigitizer) for analysis and model development. Sensitivity analysis was performed on all input parameters prior to parameter identification for optimization. Model parameters were optimized using a Monte Carlo algorithm while simultaneously fitting average parent-metabolite plasma concentration-time profiles from a subset of clinical studies. Interstitial unbound brain concentrations were determined after model validation. Graphing, data fitting, and calculations were accomplished with Origin 2021 (www.originlab.com) and Microsoft Excel (2013). **Results:** After single intravenous doses of lorazepam, plasma levels rise within minutes, and decline over 40-60 hours. Peak plasma levels increase linearly with dose. The PBPK model for lorazepam and the metabolite lorazepam glucuronide successfully predicts lorazepam plasma levels not used in model development. Following a 4 mg intravenous dose, peak interstitial unbound brain concentration is 172 nM and declines to 15 nM by 30 minutes. Maximum potentiation of 10 microM GABA-triggered responses from hippocampal cells in culture is 26% at 36 seconds and 13% at 30 minutes. The percentage of spinal cord neurons in culture with sustained repetitive firing at high frequency of action potentials declines to 7% at 36 seconds with 94% recovery by 30 minutes. The time-course of lorazepam brain concentrations parallels the clinical endpoints of sedation and impaired recall seen in individuals who received a 4 mg intravenous dose of lorazepam. **Conclusions:** PBPK modeling can be applied to compounds that target the central nervous system to determine pharmacodynamic effects at clinically relevant levels.

Title: The modulation of inhibitory inputs onto vta gaba neurons

Authors: *B. WU[1], T. M. NUFER[2], J. G. EDWARDS[1];
[1]Brigham Young Univ., Provo, UT; [2]Univ. of Utah, Salt lake city, UT

Abstract: The ventral tegmental area (VTA) is an essential component of the mesolimbic dopamine circuit, processing reward and motivated behaviors. VTA dopamine (DA) cells are crucial in this process as well as GAD67-expressing GABAergic inhibitory cells that regulate DA cell activity. In response to drug exposure, synaptic connections in this circuit can be altered via synaptic plasticity, a phenomenon thought to be responsible for some of the pathological development of addiction. Currently, much less is known regarding VTA GABA cell plasticity. Expanding on the work of Bocklisch et al. (2013; Science), we investigated the plasticity of inhibitory inputs to VTA GABA neurons. Using whole cell physiology in male and female GAD67/GFP mice (14 -30 PND), we observed that these VTA GABA cells not only exhibit significant long-term potentiation (LTP; n=7, $P<0.001$) as demonstrated previously, but also significant long-term depression (LTD; n=8, $P<0.001$) in response to a 5 Hz stimulus. Therefore, we focused on characterizing this novel form of plasticity. Paired pulse ratios suggest a presynaptic mechanism for both LTP and LTD. VTA DA cells also exhibit presynaptic LTP that is mediated by the nitric oxide synthase (NOS) pathway (Nugent & Kauer, 2007; Journal of Physiology), therefore we examined the involvement of the NOS pathway in the plasticity of inhibitory inputs to VTA GABA neurons and noted that neither the NO analog SNAP nor the antagonist L-NAME altered plasticity. Interestingly, the observed LTP was blocked by APV, an NMDA receptor antagonist, demonstrating its dependence on nearby glutamatergic synapses. As many forms of LTD are dependent on cannabinoid-1 receptor (CB1), we tested its potential involvement at this synapse, but determined that neither CB1 antagonism with AM251, physiologic absence in CB1 knockout mice, nor direct antagonism with WIN55 demonstrated robust modulation of the inhibitory inputs to GABA neurons. We also tested the involvement of $GABA_B$, an important presynaptic modulator, and found that application of $GABA_B$ antagonist CGP 54626 blocked LTD. As alcohol is known to modulate the GABAergic circuit and alter plasticity in the dorsal striatum, we also examined alcohol impact on inhibitory inputs to VTA GABA neurons. We determined that chronic exposure to alcohol occluded the observed LTD while leaving LTP intact. In summary, the LTD at the inhibitory synapse onto VTA GABA cells have not been reported previously. We believe such findings will help us better explain not only VTA neural circuitry, but also the neurological and molecular basis on how dependency is developed in the CNS upon alcohol administration.

Abstract: α-Synuclein (α-Syn), whose mutations contribute to Parkinson's Disease (PD), is thought to function presynaptically as a regulator of neurotransmitter vesicular release. Here we utilized mice lacking all three isoforms of synuclein: alpha, beta, and gamma (Synuclein triple-KO, Syn-tKO) and measured basal synaptic transmission and both short and long-term plasticity in the striatum. We found that Syn-tKO results in a loss of both forms of endocannabinoid (eCB)-dependent plasticity - long-term depression (eCB-LTD) and depolarization-induced suppression of inhibition (DSI) - at synapses onto striatal spiny projection neurons (SPNs). Direct presynaptic weakening via pharmacological activation of cannabinoid CB1 receptors (CB1Rs) in Syn-tKO mice is intact, suggesting normal presynaptic CB1R function. Instead, the expression of α-Syn in postsynaptic striatal SPNs was able to fully restore eCB-dependent synaptic plasticity in Syn-tKO mice. Furthermore, we identified α-Syn membrane-interacting domains that are required for normal eCB plasticity. Finally, postsynaptic expression of A30P mutation, one of the mutations that were linked to familial PD, could not rescue eCB-dependent plasticity. Together, our study demonstrates a role for synucleins, traditionally thought to be solely presynaptic proteins, in regulating postsynaptic eCB release and synaptic plasticity in health and PD.

Title: Subcellular segregation of synaptic long-term depression in hippocampus CA1

Authors: *K. M. KEARY, III[1], Z. LI[2];
[1]Brown Univ. NIH Grad. Partnership Program, Bethesda, MD; [2]Natl. Inst. of Mental Hlth., Bethesda, MD

Abstract: Synaptic plasticity is a cellular substrate for learning and memory in the brain, with abnormalities in plasticity associated with many neurological and psychiatric disorders. Synaptic plasticity can vary in duration from seconds (short-term plasticity) to hours or days (long-term plasticity). Long-term plasticity is divided into long-term potentiation, strengthening synapses, and long-term depression (LTD), weakening synapses. The Schaffer Collateral synapse, Hippocampus CA3 to CA1, is a widely studied model long-term plasticity, including NMDAR dependent LTD. NMDAR dependent LTD is required for spatial navigation, behavioral flexibility, and social recognition in mice. Interestingly, this form of LTD is only readily inducible at the Schaffer Collateral synapse in pre-adolescent mice. This developmental shift coincides with an increased number of autophagosomes at the proximal dendrites in CA1, the termination site for the Schaffer Collaterals. Previous work from our lab has shown that inhibiting autophagy is both necessary and sufficient for long-term synaptic depression at the Schaffer Collateral synapse. Knocking out ATG5, autophagy related protein 5, can even rescue LTD inducibility in adult mouse slices. Compared to the proximal dendrites, there are fewer autophagosomes at the CA1 distal dendrites, the termination site for the direct cortical input (DCI) from medial entorhinal cortex. We hypothesized that this existing subcellular difference may allow for the persistence of NMDAR dependent LTD inducibility at the DCI synapse in adult slices. To test this, we utilized field recordings from the distal dendrites of CA1 in adult slices. Here we show that LTD is in fact inducible at the DCI synapse in adult hippocampal slices. This LTD is dependent on NMDA receptor activation, and independent of mGluR activation. Knocking out caspase-3, a protein upstream of autophagy inhibition, abolished LTD. Furthermore, pharmacologically increasing autophagy via rapamycin was able to block LTD as well. This effect was autophagy specific, as rapamycin administration in ATG5 knockout slices had no effect on LTD. Further investigations will revolve on the behavioral relevance of this form of LTD in adult animals, as well as how the existing differences between autophagy and LTD at proximal and distal dendrites affect dendritic spine refinement throughout development.

Title: Glycine-site Occupancy as a Determinant of Synaptic Plasticity Directionality

Authors: *E. V. BARRAGAN[1,2], J. A. GRAY[2,3];
[1]Neurosci. Grad. Group, [2]Ctr. for Neurosci., [3]Dept. of Neurol., Univ. of California, Davis, Davis, CA

Abstract: NMDA receptors (NMDARs) are arguably the most complex subfamily of ionotropic glutamate receptors and master regulators of synaptic plasticity. NMDARs are unique among receptors in that, in addition to glutamate binding, they also require binding of a co-agonist - either glycine or D-serine - to the glycine-site on the GluN1 subunit. However, the fundamental role of this co-agonist requirement remains poorly understood. Recent evidence has shown that NMDAR-mediated LTD may occur during the competitive antagonism of the co-agonist binding site, a phenomenon that has been termed non-ionotropic LTD. Interestingly, blocking the co-agonist site also results in a typically LTP-inducing stimulus to instead lead to LTD. Based on these results, we hypothesized a role for glycine-site occupancy in determining the directionality of synaptic plasticity, specifically that low glycine-site occupancy biases synaptic plasticity towards LTD. To investigate this hypothesis, we manipulated glycine-site occupancy during the induction of synaptic plasticity using pharmacological approaches and enzymatic scavenging. We show that in the third postnatal week, decreasing glycine-site occupancy results in an overall bias towards synaptic depression regardless of the synaptic plasticity induction protocol. In addition, increasing extracellular co-agonist concentration during induction results in synaptic potentiation, supporting an overall shift of the plasticity curve. These results support our hypothesis that a primary role of the NMDAR glycine-site is to influence the direction of synaptic plasticity, highlighting the glycine-site as an attractive target for treatment of the vast range of psychiatric and neurologic disorders that arise due to NMDAR dysfunction.

Title: Differential activation of CB1-dependent long-term depression in ventral tegmental area GABA neurons in adult versus adolescent mice

Authors: *I. OSTLUND, M. VON GUNTEN, J. G. EDWARDS;
Brigham Young Univ., Provo, UT

Abstract: Within the ventral tegmental area (VTA) dopamine (DA) signaling mediates reward prediction, pleasure, and motivation. DA cells are regulated by neighboring inhibitory GABA cells, which express glutamic acid decarboxylase 67 (GAD67). Using whole-cell electrophysiology in juvenile/adolescent and

adult GAD67-GFP knock-in mice we examined glutamatergic plasticity in fluorescent VTA GABA neurons. We previously determined that cannabinoid type 1 receptor (CB1) mediated a novel form of long-term depression (LTD) of GABA neurons in the VTA. This LTD could be evoked via high-frequency stimulus (HFS), was dependent on both metabotropic glutamate receptor 5 (mGluR5) and CB1, and was occluded by injections of chronic Δ9 -tetrahydrocannabinol (THC). We sought to examine the mechanism of THC-induced LTD occlusion and whether THC impact or CB1-dependent plasticity was different between adult (PD70-130) and adolescent (PD15-32) male and female rodents. First, we noted that chronic (7-10 days) THC injections occluded CB1 agonist WIN55-212,2-mediated depression, illustrating chronic THC desensitizes or removes CB1 from this synapse. Many drug-induced plasticity changes are reversible, thus we examined and noted that seven days of THC withdrawal restored LTD and WIN55-212,2-induced depression. Next, as adult animals tend to exhibit reduced drug affect when compared to adolescents we examined if LTD of VTA GABA neurons was present in adults. Surprisingly, adult mice no longer undergo HFS-induced LTD. We then examined what changed in adults to eliminate this LTD by investigating direct mGluR5 and CB1 agonist activation and discovered both still elicit depression. These data illustrate mGluR5/CB1 are still functional in adults. As adults seemed to retain the key components necessary for LTD, but resist HFS-induced LTD, we examined the quantitative nature of this plasticity by doubling the HFS protocol. We determined that HFS doubling was sufficient to induce LTD in adults which suggests the mGluR5/CB1 pathway of LTD is present but requires a greater electrical stimulus to activate. To determine if this was due to changes in AMPA and NMDA receptors, key factors in many forms of plasticity, we examined AMPA/NMDA ratios. We noted that AMPA/NMDA ratios were decreased in adults compared to adolescents, potentially due to a decrease in NMDA receptor levels which would reduce calcium influx and require greater activation to induced LTD in adults. Collectively, our data demonstrate differences in adult and adolescent CB1-mediated plasticity, which illustrates a potential rationale for the increased severity of long-term THC impact in adolescents versus adults.

Title: Investigation of adolescent alcohol exposure interactions with stress on BNST CRF signaling across sex

Authors: *E. B. HOLMGREN, J. M. LACEY, T. A. WILLS;
Cell Biol. and Anat., LSU Hlth. Sci. Ctr. Cell Biol. & Anat., New Orleans, LA

Abstract: Adolescent alcohol exposure and stress are strong predictors of future development of alcohol use disorders. Understanding how adolescent alcohol exposure impacts plasticity in the bed nucleus of the stria terminalis (BNST) is critical as this region mediates negative affect and stress-induced drug relapse. Previous research from our lab finds that adolescent intermittent ethanol vapor exposure (AIE) mediates BNST synaptic plasticity through two distinct mechanisms depending on sex. Adolescent alcohol exposure enhances spontaneous EPSCs (sEPSCs) frequency in both sexes, in conjunction with an increase in NMDA receptor-mediated plasticity in male mice and mGluR1/5-mediated plasticity in female mice. As stress is a strong trigger for relapse, we then explored if AIE-mediated changes persist into adulthood and if stress modulates these changes. When mice with an AIE history receive one hour of restraint stress in adulthood, the adolescent phenotype of sEPSC frequency is uncovered in male but not female mice. Female mice instead have increased sEPSC amplitude, an effect not seen in male mice. Restraint stress also recapitulates sex-dependent AIE-induced changes in BNST plasticity. Corticotropin releasing factor (CRF) signaling through corticotropin-releasing factor type 1 receptors (CRFR1) is known to be critical in alcohol withdrawal, stress-induced relapse, and withdrawal-associated negative affect. Our current work investigates the influence of CRF-CRFR1 signaling on sex dependent plasticity and glutamate release in the BNST. C57Bl/6J male and female mice were exposed to two, 4-day cycles of alcohol vapor exposure (16 hr/day) with a 3-day period of rest between cycles from PND30-41. Whole-cell voltage clamp experiments were performed during acute withdrawal or in adulthood (PND 70+) following one-hour of restraint stress. Preliminary data suggests that antagonism of CRFR1 with 1μM NBI27914 can blunt enhanced frequency sEPSCs in high frequency responding cells in adolescent male but not female mice during acute withdrawal. In adulthood following restraint stress, we find CRFR1 antagonism in adult female mice specifically ameliorates enhanced DHPG-induced LTD in AIE treated mice, potentially suggesting a novel interaction of CRFR1 signaling on mGluR1/5-mediated plasticity in female mice following adolescent alcohol exposure. Future studies will further investigate the role of CRFR1 antagonism on AIE and adulthood stress-induced changes in BNST plasticity.

Title: Mechanisms gating of a rapid disconnection of fast-spiking cell circuits in visual cortex

Authors: *D. SEVERIN, C. MORENO, L. MESIK, S. MENHTA, C. KNIGHT, H.-K. LEE, A. KIRKWOOD;
Johns Hopkins Univ., Baltimore, MD

Abstract: Disinhibition is an obligatory initial step in the remodeling of cortical circuits by sensory experience. Previous investigations on disinhibitory mechanisms in the classical model of ocular dominance plasticity uncovered an unexpected novel form of experience-dependent circuit plasticity. In layer 2/3 of the mouse visual cortex, monocular deprivation (MD) triggers a complete, “all-or-none”, elimination of connections from pyramidal cells onto nearby parvalbumin-positive interneurons (Pyr→PV). This binary form of circuit plasticity is unique as the remaining connections are not affected in strength. We aimed to examine the mechanism underlying the “all-or-none” Pyr→PV disconnection, testing some of the elements described for spike timing LTD induction in PV cells. In PV cells, α1-adrenergic receptors enable spike timing LTD independently of the induction mechanism and depending on mGluR5 receptors. Using a combination of standard slices electrophysiology method, along with optogenetics and whole-cell recordings from PV and pyramidal cells, we evaluated the modifiability of local excitatory inputs originating from layer 2/3. We found that mGluR5 is necessary for the MD-evoked Pyr→PV disconnection. Also, α1-adrenergic receptor activation, in-vivo and in slices, in conjunction with presynaptic activation, enable “all-or-none” elimination of excitatory input onto PV cells. We propose that the α1-adrenergic dependent Pyr→PV disconnection resembles the MD-evoked synapse elimination and mechanistically works according to the pull-push rule.

Title: Disruption of Arc ubiquitination alters calcium-dependent intracellular signaling pathways and protein localization.

Authors: *M. A. GHANE[1], Z. D. ALLEN[1], B. DONG[2], J. YANG[2], N. FANG[2], A. M. MABB[1];
[1]Neurosci. Inst., [2]Chem., Georgia State Univ., Atlanta, GA

Abstract: Arc is an immediate-early gene that is rapidly expressed in response to learning and memory-related behaviors. Arc is rapidly degraded partly through the ubiquitin-proteosome pathway. Disruption of Arc ubiquitination by mutation of the relevant ubiquitinated lysine residues (K268/269R; ArcKR) leads to enhanced metabotropic glutamate receptor (mGluR)-mediated long-term depression (LTD), a process dependent on endoplasmic reticulum-mediated calcium release. Here, we show that aspects of

intracellular calcium signaling are disrupted in ArcKR neurons. This change is coupled to altered activity states as well as changes in co-localization of calcium-dependent molecular regulators of plasticity. Our findings contribute to our understanding of how Arc regulates a key form of plasticity and provides a potential link in how disrupting Arc ubiquitination can lead to changes in learning behaviors.

Title: Characterizing distinct pyramidal cell populations in the ventral hippocampus

Authors: D. J. LODGE[1], H. B. ELAM[1], A. M. BOLEY[1], ***J. J. DONEGAN**[2];
[1]The Univ. of Texas Hlth. Sci. Ctr., San Antonio, TX; [2]Dell Med. Sch. at UT Austin, Austin, TX

Abstract: The ventral hippocampus (vHipp) regulates a diverse set of behaviors associated with motivation and emotion. Hyperactivity in this region has been observed in schizophrenia and we have previously shown that normalizing the activity of specific vHipp projections can alleviate behavioral and physiological deficits in a neurodevelopmental disruption model. Specifically, reducing activity in the vHipp-medial prefrontal cortex (mPFC) pathway improves correlates of negative and cognitive symptoms while inhibition of the vHipp-nucleus accumbens (NAc) pathway improves correlates of positive symptoms. In the current experiments, we aimed to further characterize these distinct projection pathways. We first used retrograde viral tracing to show that vHipp-mPFC and vHipp-NAc projections are distinct and anatomically segregated cell populations. NAc projections made up approximately 43% of labeled cells while mPFC-projections accounted for ~56%. Only ~1% of cells projected to both regions. Next, RNASeq was used to characterize the transcriptional profile of these two cell populations. We identified 99 differentially regulated genes, including Nedd and Grn, involved in synaptic plasticity. RNAScope confirmed the differential expression of these two genes. We have shown previously that unique interneuron subtypes (parvalbumin (PV) or somatostatin (SST)) within the vHipp also differentially regulate behavior. Therefore, the next set of experiments aimed to determine the anatomical connectivity and functional regulation of vHipp projections by local interneuron populations. First, eGRASP was used to map the synaptic connections between pyramidal cell projections and PV or SST interneurons. We found that PV interneurons form a similar number of synaptic connections on pyramidal cells that project to both mPFC and NAc while SST-positive interneurons form far fewer synapses on mPFC projections. Electron microscopy confirmed these results. To determine if these anatomical differences result in functional changes, we used fiber photometry, *in vivo* electrophysiology, and optogenetics to show that inhibiting PV cells increased pyramidal cell acitivty regardless of projection

target while SST cell inhibition has a much smaller effect on the activity of mPFC-projecting cells. Together, these results suggest that vHipp projections are made up of discrete cell populations with unique gene expression and patterns of connectivity. Characterization of these cell populations may lead to the identification of new molecular targets for the treatment of specific symptoms of schizophrenia and other psychiatric disorders associated with vHipp dysfunction.

Title: Investigating cortical readout of temporal codes

Authors: *R. BLAZING[1], K. M. FRANKS[2];
[2]Neurobio., [1]Duke Univ., Durham, NC

Abstract: Many neural circuits exhibit reproducible sequences of activity that correlate with perception, action, or distinct internal states. Neural sequences lasting on the order of tens to hundreds of milliseconds have been proposed to mediate essential cognitive processes including navigation, memory encoding and retrieval, and sensory discrimination. Temporal features of sequence activity, such as the precise response timing and order of activated cells, are thought to encode perceptually or behaviorally relevant information. However, the sensitivity of downstream brain regions to the temporal structure of input sequences is not known. Moreover, while many possible mechanisms for the cortical readout of millisecond-timescale temporal codes have been identified, few have been explicitly tested in-vivo. To address these questions, we implemented a system to perform patterned optogenetic activation of olfactory bulb glomeruli while recording extracellularly from large populations of neurons in mouse piriform cortex (PCx). Odors evoke activity from spatiotemporally-specific sequences of glomeruli, and this information is propagated to downstream PCx where sparse ensembles of neurons encode odor identity. To assess how glomerular sequence timing impacts PCx output, we optogenetically activated sequences of glomeruli and varied the relative onset timing of each glomerulus in the sequence. We found that neurons in PCx exhibit tuning to specific temporal patterns that depend on the identity of activated glomeruli. We hypothesized that the dense recurrent network in PCx coordinates these temporally specific responses. We therefore eliminated recurrent circuits within PCx using tetanus toxin light chain, which blocks synaptic transmission in infected cells, but does not affect responses to feedforward input. Our preliminary experiments suggest that eliminating recurrent circuitry sharply attenuates the temporal specificity of PCx responses. Thus, operations carried out by recurrent circuits may be essential for precise sequence readout in cortical networks.

Title: Proactive and context-dependent motor to sensory cortical feedback regulation of network excitability

Authors: *Z. ZHANG, E. ZAGHA;
UC Riverside, Riverside, CA

Abstract: Cortical feedback, the anatomical pathways from higher-order to lower-order brain regions, are believed to modulate sensory processing according to internal and behavioral context. Current studies on cortical feedback focus primarily on resolving how it shapes post-stimulus activity of lower-order regions, with the assumption that cortical feedback regulation requires a stimulus-triggered bottom-up signal. In this study, we recorded single unit activity in the mouse whisker primary somatosensory cortex (lower-order), while conducting interleaved inhibition in the whisker motor cortex (higher-order) to assess the impacts of cortical feedback under different conditions. We found that cortical feedback strongly influences spontaneous (pre-stimulus) activity. We found that cortical feedback modulates spontaneous network excitability differently under different behavioral contexts, and that these modulations of excitability can, at least in part, account for changes in post-stimulus responses. Overall, our study emphasizes the importance of cortical feedback as proactive regulators of feedforward signal processing.

Title: Transcutaneous auricular vagal nerve stimulation (taVNS) parameters differentially influence neuronal activity in the nucleus of the solitary tract and spinal trigeminal nucleus

Authors: *M. OWENS[1], L. DUGAN[1], C. COOPER[1], *E. HARRIS[1], V. NAPADOW[2,3], E. BEAUMONT[1];
[1]Biomed. Sci., East Tennessee State Univ., Johnson City, TN; [2]Martinos Ctr. for Biomed. Imaging, Massachusetts Gen. Hosp., Charlestown, MA; [3]Radiology, Logan Univ., Chesterfield, MO

Abstract: Transcutaneous auricular vagal nerve stimulation (taVNS) activates axons located in the auricular branch of the vagus nerve, which terminates at the concha of the ear. Currently, taVNS is under investigation to treat a wide range of disorders including gastric motility, cardiac, and migraine disorders. Human fMRI studies have localized taVNS response to the nucleus of the solitary tract (NTS) and spinal trigeminal nucleus (Sp5c), which also receives input from the meningeal layer of the brain, making this pathway relevant for migraines. It is hypothesized that the ability of taVNS to increase or decrease neuronal firing rates in these brain regions can act to counterbalance abnormal function that occurs in these disorders. To identify the optimal taVNS parameters for modulating neuronal activity within NTS and Sp5c, six different taVNS paradigms were administered to chloralose-anesthetized rats (n = 24). The activity of 60 to 70 neurons from rostral NTS (rNTS) and caudal NTS (cNTS) were recorded individually using a high-impedance tungsten electrode. Neuronal firing rates were analyzed for changes in activity during and immediately following stimulation as compared to their individual baseline level. Neurons were then classified as non-responders, negative responders, positive responders, or super responders. We found that the optimal stimulation parameters were dependent on NTS sub-region. Specifically, cNTS showed greater positive activation using low-frequency standard parameters regardless of intensity and bursting parameters at higher intensities. Alternatively, rNTS showed greater levels of positive activation with standard low-frequency stimulation at high intensities. The only parameters producing negative activation in NTS were high-frequency standard patterns regardless of NTS sub-region. Interestingly, NTS is also differentially activated by cervical vagal nerve stimulation (cVNS), potentially allowing for future identification of taVNS parameters that better mimic cVNS effects in chronic disease. Furthermore, it is not known if positive or negative NTS neural activation is beneficial for disease outcomes, particularly for disorders characterized by aberrant NTS activity. Studies are ongoing to contrast Sp5c activation with NTS, using these same taVNS parameters to determine optimal activation for this important trigeminal processing brainstem region. Identification of ideal stimulation parameters will be important for broader applicability of both taVNS and implanted cVNS therapy across a range of disorders.

Title: Concentration-dependent effects of volatile anesthetics on network dynamics in layer 2/3 somatosensory cortex

Authors: *J. NOUEIHED, F. R. FERNANDEZ, J. A. WHITE;
Biomed. Engin., Boston Univ., Boston, MA

Abstract: The effects of volatile anesthetics are generally well understood at the behavioral and molecular levels. However, these effects and how they result in different anesthetized states have not been well-characterized at the mesoscale level (i.e. networks of neurons). We address this gap in the field by simultaneously recording through calcium imaging, the dose-dependent changes in spontaneous activity of excitatory and inhibitory neurons in temperature-controlled animals under isoflurane-induced anesthesia.
Dual color two-photon calcium imaging was used to capture the activity of excitatory neurons and inhibitory interneurons in layer 2/3 of the mouse somatosensory cortex during the induction and emergence from different states of anesthesia (awake, partially anesthetized, and deeply anesthetized). For animal comfort and to control for any confounding effects of changes in body temperature, head-fixed mice were placed on a heated treadmill. The calcium indicator jGCaMP7f was used to track neuronal activity, along with a static fluorophore (tdTomato) to identify specific sub-populations of inhibitory neurons (glutamate decarboxylase (GAD2+), parvalbumin (PV+), or somatostatin (SST+)) in adult mice. In post-hoc analysis, hundreds of cells in layer 2/3 were identified and tracked in multiple sessions by extending the approach used in existing calcium image analysis pipelines to account for long, discontinuous recording sessions with computational efficiency.
Consistent with previous studies, we observed a suppression of activity across all neuron types during the induction into deep states of anesthesia, with activity gradually restored during emergence. We also established the correlation between neurons as a function of anesthesia depth, distance between neurons, and type of neurons. We observed an increase in the pairwise cross-correlation between excitatory neurons as depth of anesthesia increases, and a corresponding decorrelation during the emergence out of anesthesia. Preliminary evidence indicates that inhibitory neurons are more sensitive to isoflurane than excitatory neurons.

Title: Principal Component Analysis for Neuronal Network Analysis Under Isoflurane Sedation in Mice

Authors: *D. CARBONERO, J. NOUEIHED, J. A. WHITE;
Biomed. Engin., Boston Univ., Boston, MA

Abstract: Anesthetics are essential to modern medicine, allowing painless performance of medical procedures that would otherwise be unbearable. Characterization of the mechanisms of anesthesia has focused principally on either receptor-level biophysics or gross, cortical (e.g. field potential) activity levels. The impact on regional network activity at the cellular level remains poorly understood, for two reasons. First, it has until recently been very challenging to collect local-network data with cellular resolution. This has been largely solved by the development of in vivo imaging of calcium transients from identified call types. Second, data sets from such experiments are immense and challenging to interpret. Here, we explore using principal component analysis (PCA) to make such data sets manageable and understandable. PCA and related techniques produce a low-dimensional representation of high-dimensional data while maintaining innate variation necessary for feature extraction. Harnessing PCA to extract, highlight, and analyze latent features of anesthetized neuronal networks can give insight regarding how populations of neuron work as an ensemble to determine an animal's behavioral state. To measure behaviorally salient activity in local cortical networks, we used 2-photon microscopy to image calcium activity of identified neocortical neurons from mice expressing the calcium indicator jGCaMP7f. Layer 2/3 somatosensory cortex was imaged under varying concentrations of anesthesia (0%, 0.7%, and 1.4% isoflurane by volume). Recorded activity was processed to extract neuronal spatial footprints and traces of calcium activity from individual neurons. Recordings from the three states of anesthesia were then stitched together to create one cohesive time series. A PCA model was fit using this extended stitched recording, and the data were reduced to a lower number of dimensions. The PCA model was then used to detect hidden structures of activity in the network under the different levels of anesthesia. Analyzing the activity in the lower dimensional space, activity progressively collapses, becoming more consistent, and distinctly different network behaviors arise as a function of progressively deeper anesthesia. PCA of the data, therefore, suggests a complex structure of activity, with several highly active subnetworks competing to drive the majority of activity during awake conditions. However, while under increasing sedation, the data suggest a shift to a network that is driven by a set of formerly dormant, more cohesive networks.

Title: Circuit and synaptic mechanisms of E-I balance and cell firing as a function of repeated pulses of spatially patterned input

Authors: *A. ASOPA, U. S. BHALLA;
Natl. Ctr. for Biol. Sci., Bengaluru, India

Abstract: Hippocampal CA3-CA1 circuit represents multiple modalities including time, space, and orientation. One feature of this network is its tight and precise balance of inputs between excitation and inhibition (E-I) at CA1 (Bhatia et al 2019). When excitation at CA1 is increased by activating more CA3 cells, the inhibitory inputs also increase proportionately, thus balancing the depolarization. But for CA1 cells to represent information, they must cross the threshold and fire. We study how the precise and tight E-I balance in CA1 pyramidal neurons evolves with changing firing rates in CA3 layer cells, resulting in action potentials.
We performed in vitro whole cell patch clamp recordings from CA1 cells in acute mouse hippocampal sections (male and female, 2-3 months of age). We simultaneously stimulated Channelrhodopsin (ChR2) expressing CA3 pyramidal cells with 13um x 8um spots using a sub-cellular-resolution patterned projection (Mightex Polygon 400). We created 5-spot and 15-spot patterns from a set of 45 spots. These patterns were used to stimulate CA3 cells at multiple frequencies (8 pulses at 20, 30, 40, 50, and 100Hz). Current clamp recordings were made to record suprathreshold responses and voltage clamp recordings were made to record E and I synaptic conductances resulting from these stimuli. Responses to single spots that form the patterns were also recorded to determine the expected subthreshold responses. Gabazine was used for no-inhibition control.
We measured the responses of CA1 cells to these stimuli in CA3 to find which conditions induce spiking and corresponding E-I dynamics. We find that spiking in CA1 is modulated by tight E-I balance, degree of convergence of inputs at interneurons and CA1 cells, and short-term plasticity of E and I synaptic inputs. The combined effect of these factors can allow repeating CA3 activity at certain frequencies to stimulate CA1 cells out of E-I balance, resulting in spikes. We found that the subthreshold responses build up over successive repetitions till about the fourth pulse, and then fall. Spikes occur in earlier pulses for stronger stimuli (15 spots vs 5). Moreover, lower frequency stimuli (20-30 Hz) are more likely to induce spiking in CA1 neurons.
To further understand the role of these parameters we developed a model of CA1 cell activity from the E-I currents obtained from voltage clamp recordings along different stimulation dimensions: stimulating frequency, and pattern size.
We propose that these E-I dynamics resulting in activity gating may be relevant to understand the formation and representation of place and time cell sequences and have implications for understanding diseases that arise from E-I imbalance.

Title: The Corpus Callosum is heterotopic and its heterotopicity directly impacts cortical networks

Authors: *D. SZCZUPAK[1], P. M. IACK[2], D. RAYEE[3], R. LENT[2], F. TOVAR-MOLL[4], A. C. SILVA[1]; [1]Univ. of Pittsburgh, Pittsburgh, PA; [2]Federal Univ. of Rio de Janeiro, Rio de Janeiro, Brazil; [3]Albert Einstein Col. of Med., New York, NY; [4]D Or Inst. For Res. and Educ. / UFRJ, Rio de Janeiro, Brazil

Abstract: The corpus callosum is the most extensive white matter structure of the brain. Previous studies have associated and characterized it as a structure that connects homotopic cortical areas with a small number of heterotopic connections possibly related to plastic adaptations in corpus callosum dysgenesis and sprout/pruning mechanisms in normal callosal development. We hypothesized that callosal heterotopic connections are underestimated given its complex and plastic structure. Using the Allen Brain Institute histology connectivity atlas, we show that heterotopic connections are roughly two thirds of the overall interhemispheric connections in the C57BL6/J wild-type mice (Figure1). Furthermore, based on diffusion-weighted imaging, we show that these heterotopic connections are the major constituents of the corpus callosum in mice, monkeys, and humans and present in distinct topographies. These connections have a significant impact on the cortical network across species and their network properties. This set of results reshape the view of the corpus callosum and its connectivity, directly impacting on multiple neuroscience fields that investigate cortical connectivity and brain development.

Title: Cellular Organization of the Locus Coeruleus in Adult Mice

Authors: *A. MCKINNEY[1,2], X. JIANG[1,2];
[1]Neurosci., Baylor Col. of Med., Houston, TX; [2]Texas Children's Hosp., Houston, TX

Abstract: The Locus Coeruleus (LC) is the source of ~90% of the brain's noradrenergic connections and coordinates behavioral responses that are crucial to survival, yet our understanding of its physiology is largely restricted to its long-range projections and diverse effects on postsynaptic targets. Utilizing an *ex vivo* brain slice preparation that allows simultaneous recording of up to 8 adult LC neurons (targeted by expression of dopamine β-hydroxylase, DBH+), we performed parallel recordings of the connections between LC DBH+ neurons. From these paired recordings, we have evidence that synaptic connectivity between LC neurons is absent in the adult murine locus coeruleus, that gap junctions are the primary means by which LC neurons pool information and coordinate their responses, and that blocking these Cx36-mediated gap junctions decreases synchrony between simultaneously recorded LC neurons. Leveraging our high-throughput patch clamp technique, we have also constructed a systematic survey of the electrophysiological and morphological properties of LC neurons that validates existing morphological classifications and compares the intrinsic properties between LC neuronal classes for the first time. We find that the probability of gap junction connectivity is a function of intersoma distance and morphological class. More experiments are currently underway to uncover how molecular and genetic variation underlies the unique organization of LC microcircuits and what roles these properties play in the construction of putative ensembles in the LC.

De Recherche Du CHU De Quebec, Quebec, QC, Canada

Abstract: The developmental origins of stress-related mental illnesses are well-established, and early-life stress/adversity (ELA) is an important risk factor. However, it is unclear how ELA impacts the maturation of salient brain circuits, provoking enduring vulnerability to stress and stress-related disorders. Here we find that ELA increases the number and function of excitatory synapses onto stress-sensitive hypothalamic corticotropin-releasing hormone (CRH)-expressing neurons, and implicate disrupted synapse pruning by microglia as a key mechanism. Microglial process dynamics on live imaging, and engulfment of synaptic elements by microglia, were both attenuated in ELA mice, associated with deficient signaling of the microglial phagocytic receptor Mer. Accordingly, selective chemogenetic activation of ELA microglia increased microglial process dynamics and reduced excitatory synapse density to control levels. Selective early-life microglial activation also mitigated the adrenal hypertrophy and prolonged stress responses in adult ELA mice, establishing microglial actions during development as powerful contributors to experience-dependent sculpting of stress-related brain circuits.

Title: Microglia morphology is altered by gamma oscillations within the hippocampus

Authors: *M. ELLEY, J. WITTON, J. BROWN;
Univ. of Exeter, Exeter, United Kingdom

Abstract: Microglia are the immune cells of the central nervous system, which are responsible for mediating neuroinflammation in both health and disease. Their activity has been implicated in several neurological diseases such as dementia, and it is currently debated as to whether the inflammatory response observed in neurodegenerative disease is causative or compensatory. A recent series of studies has demonstrated that inducing neuronal network oscillations at the gamma frequency of 40 Hz is capable

of reducing the neuropathology and cognitive deficits associated with dementia, which appears to occur as a result of microglia activation. To investigate this novel neuron-microglia interaction, we have developed an *ex vivo* assay, using hippocampal brain slices prepared from two mouse models (C57BL/6J and CX3CR1-GFP$^{+/-}$, which express GFP exclusively in microglia). This assay involves pharmacologically inducing gamma oscillations in the CA3 region of the hippocampus, fixing the brain tissue and then assessing microglia morphology following staining and mounting using two-photon microscopy. We have demonstrated that microglia morphology is altered in response to gamma oscillations, as microglia that have been exposed to these network oscillations have a significantly more amoeboid morphology than those in a control condition, where no oscillations were induced. These data suggest that sustained gamma oscillations result in the activation of microglia. Therefore, we have developed a new reduced model of gamma oscillation-microglia signalling that can be used to gain mechanistic understanding of this novel neuroimmune interaction.

Title: Microglial Calcium Signaling and It's Role in Phagocytosis

Authors: *A. UMPIERRE[1], L.-J. WU[2];
[1]Neurol., [2]Mayo Clin., Rochester, MN

Abstract: Microglial calcium signaling underlies a number of key physiological and pathological processes in vivo in awake mice. Here, we investigate the role of microglial calcium signaling during epilepsy development, modeled by the systemic administration of kainate. In WT microglia, calcium signaling is exceptionally elevated in the days following status epilepticus (up to 10 days). During this time, calcium transient frequency is greatly heightened, transients are prolonged, and spreading calcium waves can emerge. Mechanistically, we have identified a key contribution of the UDP-sensitive purine receptor, P2Y6, in mediating this calcium rise. In P2Y6 general KO mice, microglial calcium signaling during epileptogenesis is largely attenuated. P2Y6 is identified as a receptor that promotes recognition of stressed neurons in a key first step underlying phagocytosis. We are actively developing a new in vivo assay to promote neuronal cell death through excitotoxicity in order to study P2Y6 and phagocytosis in an isolated, experimental system.

Title: Spinal cord microglia age in a caudal to rostral fashion and preferentially target motor neurons

Authors: *R. CASTRO[1], L. M. DE BIASE[3], G. VALDEZ[2];
[1]Neurosci., [2]Mol. Biology, Cell Biology, and Biochem., Brown Univ., Providence, RI; [3]Physiol., David Geffen Sch. of Med. At UCLA, Los Angeles, CA

Abstract: The impact of aging on spinal cord microglia remains largely unknown, despite the critical role these cells play in innate immunity, tissue homeostasis, and neuronal modulation. In the brain, previous work has revealed that microglia present with regional diversity in their adoption of an immunogenic, pro-inflammatory state during aging. Thus, it is possible that spinal cord microglia also exhibit unique spatiotemporal responses to age-related damages. Using light microscopy, we found spinal cord microglia with a phagocytic and pro-inflammatory phenotype. Our data strongly indicate that microglia age in a caudal to rostral progression within the spinal cord and between the spinal cord and motor cortex. Additional analysis revealed that microglia preferentially aggregate around the somata of motor neurons compared to other neurons in the spinal cord. Using RNA sequencing, we uncovered pathways dysregulated and potentially responsible for the accelerated aging of spinal cord microglia and their preferential association with motor neurons. These comprehensive analyses provide insights critical to reducing the deleterious actions of aging microglia in the spinal cord, and particularly on motor neurons.

Title: Astrocyte Ensheathment of Calyceal Axons Precedes Myelination in the Ventral Brainstem

Authors: *D. HELLER[1], E. AMICK[1], D. KOLSON[3], A. BRANDEBURA[4], J. RAMADAN[3], T. DEERINCK[5], M. H. ELLISMAN[6], P. MATHERS[3], G. A. SPIROU[2];

Abstract: During neurodevelopment, axons are encompassed by growing myelin sheaths to provide an electrically insulating layer, thereby allowing for rapid and temporally precise propagation of action potentials. Myelination is a complex process involving the coordinated orchestration of several myelin-associated proteins, resulting in axonal ensheathment and compaction of the myelin sheath. This process has long been attributed to Schwann cells in the periphery and oligodendrocytes in the central nervous system, but recently the functional role of astrocytes in regulating myelination has come to light. Astrocytes regulate oligodendrocyte proliferation and differentiation and provide lipids for myelin synthesis. Additionally, several studies have shown that astrocytes promote myelination, but the extent of astrocyte-axonal interactions has not been described. The medial nucleus of the trapezoid body (MNTB) has become an attractive model system for studying neuronal-glial cell interactions during neural circuit formation. During the short time-period of nerve terminal competition and growth from postnatal day (P)2-6, astrocyte and oligodendrocyte populations increase in number and begin to exhibit mature morphological features, thus allowing for a detailed study of the synergistic roles of glial cells during myelination. To achieve high structural resolution, a series of serial block-face scanning electron microscopy (SBEM) data sets from the mouse MNTB at P2, P4, P6, P9, and P30 were employed for this study. This allowed for a detailed investigation of individual calyceal axons at various timepoints, which elucidated ultrastructural characteristics of the onset and progression of axonal wrapping and myelin compaction. Glial cells from our electron microscopy volumes were classified using multiple correspondence analysis for discrete data, followed by hierarchical clustering based on ultrastructural criteria from classic EM literature. At P4, a majority of calyceal axons exhibited single glial wraps, with compaction of the myelin sheath beginning at P6, after most MNTB principal neurons are mono-innervated, and becoming widespread by P9. From the analysis of our SBEM volumes, we find early axonal wrapping at P4 by astrocytes, while oligodendrocytes do not begin wrapping until P6. Quantification of the spatial distribution of glial wrapping across calyceal axons, MNTB principal cell axons, and fiber fascicles reveal that astrocytes predominately ensheathe the CH. This study highlights a novel role for astrocytes during developmental myelination.

Title: TDP-43 maximizes nerve conduction velocity by repressing a cryptic exon for paranodal junction assembly and maintenance in Schwann cells

Authors: *K.-J. CHANG[1], *K.-J. CHANG[1], I. AGRAWAL[2], A. VAINSHTEIN[3], W. HO[2], W. XIN[1], G. TUCKER-KELLOGG[2], K. SUSUKI[4], E. PELES[3], S.-C. LING[2], J. R. CHAN[1];
[1]Univ. of California, San Francisco, San Francisco, CA; [2]Natl. Univ. of Singapore, Singapore, Singapore; [3]Weizmann Inst. of Sci., Rehovot, Israel; [4]Wright State Univ., Dayton, OH

Abstract: TDP-43 is extensively studied in neurons in physiological and pathological contexts. However, emerging evidence indicates that glial cells are also reliant on TDP-43 function. We demonstrate that deletion of TDP-43 in Schwann cells results in a dramatic delay in peripheral nerve conduction causing significant motor deficits in mice, which is directly attributed to the absence of paranodal axoglial junctions. By contrast, paranodes in the central nervous system are unaltered in oligodendrocytes lacking TDP-43. Mechanistically, TDP-43 binds directly to *neurofascin* mRNA, encoding the cell adhesion molecule essential for paranode assembly and maintenance. Loss of TDP-43 triggers the retention of a previously unidentified cryptic exon, which targets *neurofascin* mRNA for nonsense-mediated decay. Thus, TDP-43 is required for neurofascin expression, proper assembly and maintenance of paranodal junctions, and rapid saltatory conduction. Our findings provide a framework and mechanism for how Schwann cell-autonomous dysfunction in nerve conduction is directly caused by TDP-43 loss-of-function.

Title: Investigating the mechanism underlying pyridazine-derivatives enhanced functional and structural plasticity of tripartite glutamatergic synapse

Authors: *Z. XU[1], X. WANG[2], J. B. FOSTER[2], C.-L. G. LIN[3];
[2]Neurosci., [1]The Ohio State Univ., Columbus, OH; [3]Dept Neurosci, Ohio State Univ., Columbus, OH

Abstract: Tripartite synapse is formed by a pre-synapse, a post-synapse, and a peri-synaptic astrocytic process (PAP). Exosomes, a type of extracellular vesicles (EVs) carrying molecules such as microRNAs, proteins and lipids, can be released from the PAP to regulate synaptic activity. Changes in the function and structure of tripartite synapses have been found in Alzheimer's disease (AD). We discovered that pyridazine-derivatives can enhance functional and structural plasticity of tripartite glutamatergic synapse. Efficacy studies of one of the pyridazine-derivatives in AD mouse models demonstrated therapeutic potential for clinical use. However, the underlying mechanism of the compound action has not been fully understood. In a previous study, we found that the compound action site is located at the PAP. A set of PAP proteins is rapidly upregulated following compound treatment, and a subset of these PAP proteins is locally synthesized. Recently, we found that a set of proteins immediately localizes to the plasma membrane of the PAP following compound treatment. These proteins include membrane trafficking proteins, endocytic proteins, adhesion proteins, cytoskeletal proteins, signaling proteins, receptors and transporters. Rab35, a small GTPase that regulates exosome secretion, was found to be increased on the plasma membrane. In light of these observations, we hypothesize that the compound activates a signaling pathway which results in localization of a set of proteins to the plasma membrane, and subsequently, a subset of these proteins is released from the PAP via exosomes to regulate synaptic activity. To test this hypothesis, we isolated EVs from mouse brains followed by size fractionation to obtain exosomes. Isolated exosomes were then assessed for concentration and size distribution by nanoparticle tracking analysis. Results showed increased secretion of exosome following compound treatment. Furthermore, exosomes were subjected to proteomic analysis. Ingenuity pathway analysis (IPA) suggested the activation of synaptic signaling pathway, PKA signaling pathway following compound treatment. These results suggest that exosomal release folowing compound treatment may regulate synaptic function. We are investigating the underlying mechanism of immediate compound action at the PAP and the effects of released proteins on the functional and structural plasticity of the synapses.

P221. Cellular and Molecular Mechanisms III

Location: Virtual Only

Time: Thursday, November 11, 2021, 9:30 AM - 10:30 AM

Program #/Poster #: P221.01

Topic: C.05. Tauopathies, Tau-dementias, and Prion Diseases

Support: NIH Grant P30AG013854
NIH Grant R01AG062566
NIH Grant R01NS075075
NACC Grant U01AG016976
NIH Grant R01DC008552
NIH Grant R01AG056258
NIH Grant K08AG065463

Title: Concordance between Neocortical Distribution of Pick's Disease and the Salience of Distinct Dementia Phenotypes

Authors: A. KAWLES[1], R. KESZYCKI[1,2], G. MINOGUE[1], C. SPENCER[1], I. AYALA[1], R. SHEPARD[1], N. GILL[1,3], J. LILEK[1,4], K. AJROUD[1,4], C. COVENTRY[1], E. ROGALSKI[1,2], S. WEINTRAUB[1,2], A. FELDMAN[1,4], Q. MAO[1,4], M. E. FLANAGAN[1,4], H. ZHANG[1,3], M.-. M. MESULAM[1,5], C. GEULA[1,6], ***T. GEFEN**[1,2];
