Abstract: The substrate materials used for intracortical electrode devices are most commonly traditional semiconductor, predominantly silicon due to its mature microfabrication technology. When considering additional optical functions, opaque silicon requires integration of transparent structures such as glass or polymers. However, the wide bandgap materials possess both properties and thus have been introduced for neural applications with possible optical advantages. Recently, new advances in materials research are bringing to light more possibilities for substrate materials. In this study, we investigated the viability of a new optically transparent, electrically conductive substrate, single crystal monoclinic beta-gallium oxide (beta-Ga_2O_3), for the application of neural recording devices. The study showed that gallium oxide did not significantly degrade physically in artificial cerebrospinal fluid for a 14-week period at a temperature of 57 ^{O}C (equivalent to 56 weeks in body temperature). The impedance amplitude at 1 kHz fell within a range of 100 - 250 kΩ (vs. platinum wire counter electrode) for devices with an exposed area of 1960 μm^2. There were no changes in impedance spectra or 1 kHz impedance amplitudes indicative of degradation in the surface electrical properties of the substrate after a period of 45 days submerged in phosphate buffered saline at a temperature of 57 ^{O}C (equivalent to 180 days at body temperature). The devices were capable of clean recordings of a simulated action potential. These findings show that gallium oxide is an attractive candidate as a new substrate for intracortical electrode devices, namely for optical neural stimulation and imaging, as well as many other implantable devices.

Title: Synchrony filtering by electrical synapses in developing thalamus

Authors: *R. A. TIKIDJI-HAMBURYAN[1], G. I. GOVINDAIAH[2], W. GUIDO[2], M. T. COLONNESE[1];
[1]Pharmacol. and Physiol., The George Washington Univ. Sch. of Med., Washington, DC; [2]Dept. of Anatom. Sci. and Neurobio., Univ. of Louisville, Louisville, KY

Abstract: Before vision the retina produces spontaneous activity waves that help establish receptive field properties throughout the visual neuraxis. The circuit mechanisms and learning rules for this development are poorly understood. Retinal-waves correlate nearby ganglion cells on the order of 100ms, which is theoretically sufficient to drive topographic refinement through burst-time-dependent plasticity, but unlikely to be sufficient for further receptive field properties such as orientation selectivity. Recently Colonnese et al 2017 showed that despite poor retinal synchronization, nearby neurons in the dorsal lateral geniculate nucleus (dLGN) are synchronized on order of 10ms, which is critical to induce synaptic potentiation in the cortex. Here we use detailed cellular and network modeling to examine the potential role of electrical coupling between dLGN neurons (known to occur transiently during development) as a mechanism for this fast synchronization. Neuron intrinsic dynamics are critical for electrical coupling. Therefore, we used multiobjective optimization methods to obtain conductance-based biophysical models of dLGN relay neurons, and then distribute them into a heterogeneous population. Driving this population with RGC spikes recorded ex-vivo, showed that even 30% coupling probability induces short-latency synchronization of firing between dLGN neurons and improves localization of the wave propagations. Using a simplified model of two coupled neurons, we find that this synchronization is a result of NMDA-dominated synaptic currents, typical for development and sensitive to depolarization through electrical coupling, which induces a requirement for firing within ~100 - 200ms for a coupled postsynaptic neuron. However, this window increases presynaptic burst duration, suggesting synchrony filteringering in dLGN circuit. We explain this phenomenon using the analysis of the simplified model dynamics. Overall our model suggests that electrical coupling between thalamic relay neurons transforms low-temporally correlated firing of RGC into tightly synchronized thalamic activity necessary to refine visual sub-circuits for on/off responses and orientation selectivity.

Title: Non-canonical dopaminergic neurons drive intraretinal vascular development

Authors: *J. H. LIANG, D. JIANG, M. A. SAMUEL;
Baylor Col. of Med., Houston, TX

Abstract: Retinal neuron function instructs and depends on the correct targeting of each of its three laminar-restricted vascular layers, in which defects in vascular organization are associated with a range of visual diseases. These vascular layers begin to emerge in the first postnatal week. The superficial layer forms first, then vessels abruptly grow outward to form the deepest vascular plexus, followed by inward growth to generate the intermediate layer. The neuronal cues that halt superficial layer growth and temporally and spatially instruct the transition to deep vessel growth remain unclear. Through previous findings, we posit that the neuron-derived signaling molecule, dopamine (DA), may be a critical player in the intraretinal vessel development pathway. Using pharmacological manipulation and tyrosine hydroxylase (TH) overexpression, we show that high levels of dopamine inhibit inner retina vessel development, with significant decrease in vessel branching. To identify the cellular source of dopamine responsible for vascular regulation, we employed transgenic mouse models with conditional deletion of TH from select subtypes of retinal neurons. We discovered that removing TH from canonical dopamine-synthesizing amacrine cells did not impact vessel patterning nor alter retina dopamine levels. In parallel, we have observed that tyrosine hydroxylase expression was unexpectedly present in retinal ganglion cell (RGC) layer neurons during the first postnatal week. Removing TH from RGCs or increasing the numbers of TH expressing RGC layer neurons markedly altered deep layer vessel emergence. These are pivotal findings that suggest there is another non-canonical cellular source of dopamine in the retina, other than dopaminergic amacrine cells, critical for intraretinal vasculature formation. From these results, we hypothesize that dopamine synthesis from the RGC layer initiates the proper vessel development of the superficial layer, allowing for subsequent transition and patterning of the deep retinal vessels.

Title: Subsynaptic refinement of neurotransmission machinery underlies activity-dependent eye-specific competition

Authors: *C. ZHANG[1], C. M. SPEER[2];
[1]Univ. of Maryland, Col. Park, College Park, MD; [2]Biol., Univ. of Maryland, College Park, MD

Abstract: The development of eye-specific retinogeniculate connections is a classic model for studying activity-dependent synaptic competition and refinement. In the mouse, axons from the left and right eyes overlap in the dorsal lateral geniculate nucleus (dLGN) and undergo activity-dependent competition during the first postnatal week. Investigating the synaptic basis of such refinement is challenging due to the limited resolution of conventional optical microscopy and difficulties in identifying immature retinogeniculate synapses with electron microscopy. Here we used volumetric STochastic Optical Reconstruction Microscopy (STORM), a single-molecule localization super-resolution imaging technique, together with eye-specific anterograde tracing and synaptic immunolabeling to measure the nanoscale structural and molecular refinement of eye-specific retinogeniculate synapses from P2-P8 in the mouse. By measuring synaptic densities across development, we found that eye-specific synaptic competition is delayed until after P2, reflecting the late arrival of ipsilateral axons relative to contralateral inputs. Eye-specific synapses show a developmental increase in presynaptic active zone (AZ) and vesicle protein abundance with no change in postsynaptic density (PSD) protein expression. These changes are further reflected in a development increase in the total number and spatial compaction of subsynaptic domains of presynaptic AZ and vesicular proteins with no change in PSD organization. To examine the role of neural activity in eye-specific competition, we analyzed synaptic refinement in a transgenic mutant model with disrupted cholinergic retinal waves and arrested eye-specific segregation. Abnormal retinal wave activity blocked retinogeniculate synaptogenesis and reduced presynaptic protein abundance with no impact on PSD protein expression in individual synapses. Activity-mutant presynaptic terminals had fewer subsynaptic domains (SSDs) and showed no spatial refinement compared to controls. Concurrently, the presynaptic readily releasable pool showed developmental and activity-dependent increases during normal eye-specific refinement. These results highlight a role for spontaneous retinal activity in regulating presynaptic refinement during eye-specific competition. Disruption of retinal waves prevents synaptogenesis and causes axon elaboration consistent with a synaptotropic hypothesis of axon branch stabilization. These data highlight the power of super-resolution microscopy for investigating subsynaptic molecular organization and plasticity in developing circuits.

Title: Dominant negative mutations in the small GTPase Arl3 lead to rod nuclear migration defects

Authors: *A. M. TRAVIS, S. MANOCHA, J. R. WILLER, J. N. PEARRING;
Univ. of Michigan, Ann Arbor, Ann Arbor, MI

Abstract: Human mutations in the small GTPase Arl3 cause a variety of inherited retinal dystrophies, including rod-cone dystrophy and retinitis pigmentosa, where blindness is caused by the degeneration of specialized neurons in the retina. These mutations are generally believed to destabilize Arl3 or impair its interactions with binding partners; however, the underlying pathobiology has yet to be studied *in vivo*. Here, we use *in vivo* mouse models as well as *in vitro* biochemistry and cell-based experiments to understand the cellular consequences dominant Arl3 mutations have in rod photoreceptors. We exogenously expressed FLAG-tagged Arl3 constructs representing either characterized GTPase-cycle mutants or retinal degeneration-causing mutants in wild type mouse rod photoreceptors via *in vivo* electroporation. Visualization of Arl3-FLAG in immunostained retinal cross-sections revealed that dominant mutations in Arl3 cause rod photoreceptor nuclei to be abnormally distributed within their nuclear layer and even sometimes mislocalized to an incorrect nuclear layer, a phenotype previously linked to retinal degeneration. *In vitro* biochemistry and cell-based assays were performed in transfected AD293 cells to characterize GTP- and effector-binding of these Arl3 mutants. We show that the dominant human Y90C mutation results in increased binding to the guanine exchange factor, Arl13B, as well as aberrant Arl3 activity in cells. We further determine that the Arl13B sequestration by Arl3-Y90C rather than the aberrant activation of the Arl3-Y90C causes the *in vivo* nuclear migration defect. These findings both expand our understanding of how small GTPases function normally and abnormally in cells and provide a model to study the nuclear component of neuronal migration.

Title: Early and late stages in the development of the avian visual tecto-isthmo-fugal pathway

Authors: *R. REYES-PINTO[1], T. VEGA-ZUNIGA[2], H. LUKSCH[2], G. J. MARÍN[1], *J. MPODOZIS[1];
[1]Facultad de Ciencias, Univ. de Chile, Santiago, Chile; [2]Tech. Univ. of Munich, Freising, Germany

Abstract: The tectofugal pathway, a highly conserved retino-midbrain-fugal visual system, is the main visual pathway in birds and many mammals. In amniotes the tecto-fugal projection arises from the tectal ganglion cells (TGCs) which possesses a broad and large dendritic field and specialized “bottle brush" dendritic endings (BBE) that distribute in specific superficial tectal layers. In birds these endings receive synaptic contact from retinal fibers of the contralateral eye and from columnar, "paintbrush"-like axons terminals from the nucleus isthmi parvocellularis (Ipc). The Ipc nucleus, part of the highly conserved isthmo-tectal network, exerts a strong control on the propagation of visual activity from the TGCs to higher visual areas. TGCs axons projects bilaterally to the nucleus rotundus (Rt), which in turn, project to the visual dorsal ventricular ridge (DVR) in the pallium. This pallial region is made up of 3 layers interconnected in a columnar/recurrent arrangement: entopallium (E), in receipt of afferents from the Rt, intermediate nidopallium, and mesopallium. In this work we sought to describe the ontogenetic establishment and consolidation of the avian tecto-isthmo-fugal pathway. Neurotracing “ex-vivo” experiments revealed a highly organized Rt-E projection as early as E8, and columnarly organized axons, reciprocally and homotopically connected through the DVR layers, from E12 onwards. Immunohistochemical assays suggest that both system of projection probably emerges in conjunction at earlier stages, between E6 and E8. On the contrary, Ipc axons exhibit a mature paintbrush morphology late in development, only at about E18. Since dendrites of TGCs reach the retinorecipient layers around E16, and mature endings are detected only at E18, a stage when an essentially mature pattern of retinotectal connectivity is described, the development of the avian tectofugal pathway seems to have two main phases. During the first phase, the tecto-thalamo-pallial circuitry and the intrapallial arrangement is established, and subsequently, during a second phase, a mature retino-istmo-tectal projection is attained. This suggests that the development of the thalamic and pallial stages of the tectofugal pathway largely proceeds independently of retinal inputs, and that transmission of retinal activity through this pathway, being spontaneous or visually-elicited, would only be possible from E16-E18 onwards.

Abstract: In the developing auditory system, spontaneous activity generated in the cochleae propagates into the central nervous system to promote circuit formation. The effects of peripheral firing patterns on spontaneous activity in the central auditory system are not well understood. Here, we describe wide-spread bilateral coupling of spontaneous activity that coincides with the period of transient efferent modulation of inner hair cells from the brainstem medial olivocochlear system. Knocking out α9/α10 nicotinic acetylcholine receptors, a requisite part of the efferent pathway, profoundly reduces bilateral correlations. Pharmacological and chemogenetic experiments confirm that the efferent system is necessary for normal bilateral coupling. Moreover, auditory sensitivity at hearing onset is reduced in the absence of pre-hearing efferent modulation. Together, these results demonstrate how afferent and efferent pathways collectively shape spontaneous activity patterns and reveal the important role of efferents in coordinating bilateral spontaneous activity and the emergence of functional responses during the prehearing period.

Title: Oncomodulin Alters Spontaneous Calcium Activity in Outer Hair Cells via Purinergic Signaling During Development

Authors: Y. YANG, K. MURTHA, L. CLIMER, A. HORNAK, *D. D. SIMMONS;
Biol., Baylor Univ., Waco, TX

Abstract: In the mammalian cochlea, the role of spontaneous Ca^{2+} activity in the outer hair cells (OHCs) is critical to postnatal development and can be modulated by ATP-dependent activation of purinergic receptors. The tight regulation of Ca^{2+} in OHCs is also essential for both development and mechanotransduction. A plethora of Ca^{2+}-binding proteins (CaBPs) are involved in maintaining Ca^{2+} homeostasis. Oncomodulin (OCM, β-parvalbumin), an EF-hand CaBP, is expressed preferentially in OHCs, and is the only CaBP known to cause progressive hearing loss after genetic deletion. We hypothesize, during the critical period of development, the absence of OCM alters the spontaneous Ca^{2+} activity in OHCs before the onset of hearing.Using *Ocm* wild-type (WT) and *Ocm* knockout (KO) mice at postnatal day 2 (P2) expressing a genetically encoded tissue-specific Ca^{2+} sensor (*Atoh1*-GCaMP6s), we observed both *Ocm*-WT and *Ocm*-KO OHCs exhibited spontaneous Ca^{2+} activity. The fractional changes of fluorescence intensity ($\Delta F/F_0$) of activated Deiters' cells (DCs) and all OHCs in a single field of view were calculated. We found Ca^{2+} activity initiated from the greater epithelium region (GER), temporally synchronized Ca^{2+} activity in both DCs and OHCs. The average correlation coefficient of DCs and OHCs showed a positive relationship with the longitudinal extension of Ca^{2+} activity. This correlation had a linear regression coefficient significantly different from zero ($P < 0.0001$, *f*-test) in both *Ocm*-WT and *Ocm*-KO mice. Additionally, *Ocm*-KO OHCs exhibited greater synchronization when the lontidudinal extension of Ca^{2+} activity in the GER increased (slope rate, 3.70×10^{-3} μm^{-1}) compared to *Ocm*-WT OHCs (slope rate, 3.00×10^{-3} μm^{-1}). In *Ocm*-WT spirals, all Ca^{2+} wave extensions over 53 μm showed significantly synchronized Ca^{2+} signals with OHCs (25 waves analyzed) compared to the background. In *Ocm*-KO OHCs, this extension threshold is decreased to 33 μm. *Ocm*-KO OHCs showed significantly increased average maximum $\Delta F/F_0$ compared to *Ocm*-WT OHCs during Ca^{2+} events in the GER ($P<0.01$, t-test). The spontaneous Ca^{2+} activities were abolished in either Ca^{2+} - free solution or the medium applied with 250 μM nifedipine. The purinergic receptor subtype P2X2 is proposed to mediate spontaneous Ca^{2+} waves in the cochlea. Using qRT-PCR and immunocytochemistry, the P2X2 expression was upregulated in *Ocm*-KO spirals. These data indicate that *Ocm*-KO spirals exhibit a high degree of spontaneous Ca^{2+} signaling at early stages of development, and this activity may be due to purinergic receptor expression. Whether this higher activity leads to deleterious consequences in developing OHCs is not known at present.

Title: Conditional deletion of ISLET1 affects the formation of the spiral ganglion, auditory neurons projections and auditory information processing

Authors: *K. PYSANENKO[1], I. FILOVA[2], M. TAVAKOLI[2], M. DVORAKOVA[2], S. VOCHYANOVA[2], R. BOHUSLAVOVA[2], B. FRITZSCH[3], G. PAVLINKOVA[2], J. SYKA[1]; [1]Inst. of Exptl. Med. CAS, Prague, Czech Republic; [2]Inst. of Biotech. CAS, Vestec, Czech Republic; [3]Dept. of Otolaryngology, Univ. of Iowa, Iowa City, IA

Abstract: The development of inner ear sensory neurons is governed by a number of transcription factors including *ISLET1* (*Isl1*), a LIM homeodomain (LIM-HD) transcription factor. We have developed a novel conditional deletion model of *Isl1* (*Isl1cKO*). Using Neurod1Cre, we specifically eliminated *Isl1* in spiral ganglion neurons without affecting the development of sensory epithelium. The morphological analyses showed that primary auditory neurons, deprived of the transcription factor *Isl1*, form disorganized peripheral projections and dramatically reduced central projections. Since *Isl1cKO* mice are viable, we evaluated how morphological changes in the cochlea affect the properties of auditory processing. With the aim to evaluate physiological functions, we measured the distortion product otoacoustic emissions (DPOAE) and auditory brainstem responses (ABRs). In addition, we evaluated the responses to acoustical stimuli by recording single and multiple unit activity in the inferior colliculus and studied the strength of the auditory startle responses, (ASRs) as well as the efficiency of the prepulse inhibition of ASR. The morphological changes were associated with significant hearing impairment in adult mice. In comparison with controls, the DPOAEs in *Isl1cKO* were absent or significantly decreased for low and middle frequencies but remained unchanged at the high frequency band. ABR thresholds were increased in a similar manner. Responses of inferior colliculus neurons in the *Isl1cKO* mice were characterized by a reduced tonotopic range and increased excitatory thresholds. There were various shapes of tuning curves present, from the simple control-like to wide or multi-peaked, reflecting the tuning impairment of *Isl1cKO* mutants. Acoustic behavioural tests confirmed altered responsiveness to suprathreshold acoustic stimuli especially in the low frequency band. These findings demonstrate that genetically altered properties of neurons in the cochlea may have complex consequences for acoustic signal processing and auditory behavioral performances underlying the *Isl1* deletion.

Title: Intrinsic and training-dependent gradients of timescales of neural dynamics within the primate prefrontal cortex

Authors: *E. TREPKA[1], M. SPITMAAN[1], X.-L. QI[2], C. CONSTANTINIDIS[3], A. SOLTANI[1]; [1]Dept. of Psychological & Brain Sci., Dartmouth Col., Hanover, NH; [2]Dept. of Neurobio. and Anat., Wake Forest Univ. Sch. of Med., Winston Salem, NC; [3]Dept. of Biomed. Engin., Vanderbilt Univ., Nashville, TN

Abstract: Cortical neurons exhibit multiple timescales related to dynamics of spontaneous fluctuations (intrinsic timescales), response to task events (seasonal timescales), and temporal integration of task-relevant signals such as choice and reward outcome. These timescales are uncorrelated within individual neurons but increase systematically across the cortical hierarchy, e.g., from parietal to prefrontal and cingulate cortex. It is currently unknown whether these timescales depend on extensive training in a specific task and/or are an inherent property of cortical computations and whether more fine-grained hierarchies of timescales exist within specific cortical areas. To address these questions, we analyzed single-cell neural recordings within subregions of the prefrontal cortex (PFC) of macaques before and after training on a working-memory (spatial match/nonmatch) task (N = 6 animals, 2,975 neurons). We found that after training, seasonal timescales increased across the prefrontal hierarchy from posterior to anterior subregions, within both dorsal and ventral PFC. This effect appeared to be the result of task training; no such hierarchy was present in the same areas, prior to training. On the other hand, intrinsic timescales decreased along the posterior-anterior axis and this effect was present even before training. Training was accompanied by an increase in the fractions of neurons selective to visual stimuli in more anterior regions. Interestingly, these changes in overall selectivity were accompanied by a decrease in the percentage of neurons that exhibited timescales tied to the timing of the appearance of the visual stimuli in the trial and increased percentages of neurons that exhibited intrinsic timescales, most significantly in anterior regions. Consistent with results from prior studies, in other tasks, timescale hierarchies in PFC were

uncorrelated within individual neurons and independent of selectivity to task-relevant signals.Together, our results provide evidence that neuronal firing is governed by both inherent and learning-shaped, fine-grained hierarchies of timescales within the PFC that can be further shaped by training in a task, pointing to flexibility of canonical computations within the cortex.

Title: Differential axon initial segment morphology and physiology between type A and type B layer 5 pyramidal neurons

Authors: *A. HARRIS, S. D. BENUSA, J. L. DUPREE, K. M. JACOBS;
Virginia Commonwealth Univ., Richmond, VA

Abstract: Within neocortical layer 5, pyramidal neurons can be differentiated into at least two major subclasses on the basis of their projections to the brainstem and thalamus (type A), or to the contralateral cortex and basal ganglia (type B). These two types can be discerned on the basis of surrogate measures of physiology and morphology; in particular, type A manifests a prominent I_h and possesses a wider apical dendrite compared to type B. Because the axon initial segment (AIS) is a crucial locus for control of neuronal excitability, we hypothesized that there may exist functional and/or morphological differences between type A and type B pyramidal neurons.
To investigate this hypothesis, acute brain slices were prepared from male and female C57BL/6NHsd mice, and high-resolution action potentials (AP) and standard IVs were recorded from randomly selected layer 5 pyramidal neurons, which were filled with biocytin and stained post hoc for the AIS scaffolding protein ankyrinG. Layer 5 pyramidal neurons separated into two non-overlapping clusters on the basis of the sum of their sag and their depolarizing afterpotential, calculated as previously described. These two groups were considered type A and type B for further analysis (*N = 42 type A cells; N = 24 type B cells*). Results are reported as mean ±SEM; t-tests were used to compare between neuronal types, with $p<0.05$ considered significant.
Type A neurons manifested a significantly higher AIS- and soma-regional voltage acceleration during the AP upstroke as measured by the second derivative of the AP (*in $mV^2/msec^2$ for type A vs B: AIS peak 2051 ±78 vs 1512 ±102; soma peak 2601 ±102 vs 1855 ±124*). In addition, type A

neurons had a higher frequency-current slope (*165.8 ±8.1 vs 139.4 ± 10.2 Hz/nA*), lower rheobase (*38.8 ±5.5 vs 60.8 ±7.4 pA*), a more hyperpolarized AP threshold (*-48.5 ±0.5 vs -44.8 ±0.6 mV*), and a higher maximum firing frequency (*58.0 ±2.4 vs 41.4 ±3.0 Hz*). Morphologically, type A neurons had a wider apical dendrite (*3.4 ±0.2 vs 2.5 ±0.3 µm*). Intriguingly, the AIS start position as measured by ankyrinG and $Na_V1.6$ immunostaining was located more proximally in type A neurons compared to type B (*1.9 ±0.4 vs 4.2 ±1.1 µm from soma, ankyrinG; 3.6 ±0.4 vs 5.5 ±1.0 µm from soma, $Na_V1.6$).* Taken together, these results suggest that type A neurons are more intrinsically excitable and may possess a higher density of sodium channels at the AIS and soma compared to type B neurons. This functional specialization may exist to support the fidelity of AP transmission to the comparatively longer projection distances type A neurons must cover.

Title: Slow-fast molecular dynamics explain tunable correlations between homeostatically regulated maximal conductances

Authors: *M. ORDORICA[1], J. P. GOLOWASCH[2], A. FRANCI[3];
[1]Univ. Nacional Autónoma de México, Mexico City, Mexico; [2]Dept Biol. Sci., NJIT, Newark, NJ; [3]Dep. Matematicas, Facultad De Ciencias, UNAM, Ciudad DE Mexico, Mexico

Abstract: Neural systems are able to maintain their functions despite the constant changes in tasks and activities and the external disturbances they are subjected to. Recent computational models ([2, 1]) explain this resilience using integral controllers to monitor the intracellular calcium concentration with the premise that, if intracellular calcium is kept at a target value, the neuron will preserve its electrical properties despite disturbances and changes. While these computational models explain the stability of neuronal activity, they impose unrealistically strong correlations between all pairs of regulated conductances. Research conducted in the mouse hippocampal granule cells shows that only specific conductances are strongly correlated. In contrast, other pairs show a low or null correlation coefficient [3]. To explain these observations, we present a mathematical model that includes a molecular homeostatic regulation network with a fast and a slow dynamical component. We show that by suitably designing the slow dynamics of the homeostatic regulation network, it is possible to flexibly tune the

correlation strength between all conductance pairs. In other words, by allowing rich dynamical interactions between molecular regulatory variables, it is possible to capture the flexible degree of correlation observed in experiments. Our results reveal the importance of including sufficiently structured homeostatic regulation networks in neural homeostasis models.

Title: Restoring prefrontal hypoexcitability rescues social behavior deficits in a mouse model of late-stage frontotemporal dementia

Authors: *H. PHILLIPS[1], H. DAI[1], S. CHOI[2], L. DALY[2], L. PETRUCELLI[3], F.-B. GAO[2], W.-D. YAO[1];
[1]Psychiatry and Neurosci., SUNY Upstate Med. Univ., Syracuse, NY; [2]Univ. of Massachussetts Med. Sch., Worcester, MA; [3]Dept. of Neurosci., Mayo Clin., Jacksonville, FL

Abstract: Frontotemporal dementia (FTD) is associated with progressive atrophy of the frontal and temporal lobes. It is the second most common type of dementia after Alzheimer's Disease, and there is no cure. The major subtype of FTD is behavioral variant FTD (bvFTD), characterized by changes in personality, inappropriate social conduct, loss of empathy, anxiety, compulsive behaviors, overeating and disinhibition. The underlying neural mechanisms are largely unknown. A GGGGCC (G_4C_2) hexanucleotide repeat expansion (HRE) in the *C9ORF72* gene is the most common genetic risk for FTD and amyotrophic lateral sclerosis. We have developed an AAV-based somatic transgenic mouse model that expresses 66-G_4C_2 HREs

throughout their central nervous system and recapitulates all major behavioral deficits of FTD. AAV-$(G_4C_2)_{66}$ mice develop impaired sociability, increased anxiety, risk taking-like behavior and increased food intake at approximately 12 months of age. *Ex vivo* whole-cell patch-clamp electrophysiology on layer V pyramidal neurons of medial prefrontal cortex (mPFC) slices showed a significant decrease in neuronal excitability characterized by a profound loss of action potential firing, increased rheobase, and reduced membrane input resistance. Significantly, restoring membrane excitability in the mPFC by *in vivo* chemogenetics effectively rescued social behavior deficits in aged mutant mice. These results demonstrate that prefrontal hypoexcitability mediates FTD-associated sociability impairments, which importantly are rescuable even at a late disease stage when significant neural degeneration has occurred. Thus, targeted restoration of prefrontal cortex excitability could serve as a promising therapy for treating late-stage *C9ORF72*-associated FTD.

Title: Hypoactivity of the infralimbic cortex-nucleus accumbens circuit underlies cocaine conditioned place preference

Authors: *A. M. KOBEISSI, H. L. PHILLIPS, X. WU, W. YAO;
SUNY Upstate Med. Univ., Syracuse, NY

Abstract: Drug addiction is characterized by chronic and compulsive drug use and relapse despite negative consequences. A hallmark of addiction is loss of impulse control, and treatments seeking to restore this cognitive function may promote recovery. The prefrontal cortex (PFC) exerts top-down inhibitory control of subcortical nucleus accumbens (NAc) functions and goal-directed behaviors such as motivation, choice, and reward. In a current view, addictive drugs impair the PFC, leading to hypofrontality and consequential loss of inhibitory control over drug seeking behavior as well as the ability to extinct drug use memories. However, the underlying neural mechanisms remain poorly understood. Combining cocaine conditioned place preference

(CPP) behavior, retrograde circuit tracing, slice patch-clamp electrophysiology, and in vivo chemogenetics in mice, we examined changes in neuronal intrinsic excitability of layer V (LV) prelimbic cortex (PrL) and infralimbic (IL) pyramidal neurons in the PFC that project to the NAc core (NAcC) and shell (NAcSh), respectively, following chronic cocaine administration during CPP. We found that cocaine CPP induced a profound decrease of neuronal excitability of IL-NAcSh projection neurons, characterized by significantly reduced action potential firing frequency, decreased membrane input resistance, increased rheobase, and enhanced afterhyperpolarizations. This cocaine-induced IL-NAcSh circuit hypoactivity lasted for at least two weeks following cocaine withdrawal. In contrast, the intrinsic excitability of PrL-NAcC projection neurons also became significantly decreased after 1-day withdrawal from cocaine CPP but recovered after 15 days of cocaine withdrawal. To test if restoration of neuronal excitability attenuates cocaine CPP behavior, we delivered bilateral microinjections of AAV2-hSyn-DIO-hm3dq-mCherry into the IL and rAAV2-EF1a-mCherry-IRES-wga-cre into the NAcSh to selectively enhance the activity of IL-NAcSh pathway following intraperitoneal administration of clozapine N-oxide (CNO). Mice administered with CNO did not spend more time in the drug paired environment compared to time spent in the saline paired environment on both withdrawal day 1 and 15, suggesting that restoration of the activity of IL-NAcSh circuit is involved in place preference induced by cocaine. Our results demonstrate that the prefrontal IL-NAcSh pathway is more preferentially and sustainably impaired by chronic cocaine administration and this top-down PFC pathway exerts profound control on cocaine reward behavior.

Title: Electrophysiological characterization of VTA-projecting BNST neurons in mice

Authors: *Y. MIURA[1,2], M. SHANLEY[1,2], R. KARIM[1], A. K. FRIEDMAN[1];
[1]Hunter College, City Univ. of New York, New York, NY; [2]Biology, Neurosci., The Grad. Center, CUNY, New York, NY

Abstract: The Bed Nucleus of Stria Terminalis (BNST) is involved in the regulation of a diverse range of behavioral states, including anxiety, reward processing, and appetite control. This diversity is achieved by a distinct mix of opposing neurons within the BNST, both excitatory (glutamatergic) and inhibitory (GABAergic) cell types which have multiple projecting

substrates. Recent mouse studies have utilized cell-type or projection-specific manipulations to identify these neurons' important role in behavioral modulation. Specifically, these studies demonstrate that optogenetic or chemogenic activation or inhibition of individual subpopulations frequently function to induce opposing behavioral outputs. However, the role of the functional electrophysiological diversity within these projections remains understudied.
The goal of the study is to characterize and explore the deeper role of the functional heterogeneity within the BNST's GABAergic subpopulation that projects to the Ventral Tegmental Area (VTA). This limbic connection between the BNST and VTA serves a critical role in integrating information regarding anxiety, modulated in part by corticotropin-releasing factor and reward signaling modulated by dopamine. Revealing the functional differences in electrophysiological properties in this projection will provide insight into circuit mechanisms of stress resilience.
This GABAergic subpopulation has been divided into type I, type II, and type III cells based on the individual electrophysiological properties in rats. However, electrophysiological properties of the VTA-projecting BNST neurons and their functional role are not fully characterized in mice. To this end, we used a combination of a retrograding adeno-associated virus with an EYFP tag (rAAV-hSyn-EYFP) injected into the VTA of 8-week-old C57Bl6/J male mice to identify and perform projection-specific electrophysiological characterization. Following recovery, we performed ex vivo whole-cell patch-clamp recordings to evaluate intrinsic and extrinsic differences which include: 1) resting membrane potential, 2) excitability, 3) voltage sag, 4) inter-spike interval, 5) latency to first spike, 6) Ih current, and 7) maximum firing rate. Utilizing an unbiased analysis of the individual parameters we have identified three functionally distinct VTA-projecting BNST neurons in mice, replicating rat studies. To further explore the functional heterogeneity with this subpopulation we will be exploring the differing inputs of these individual cell-types.

Title: The properties of neurons in the lateral septum: physiology, morphology and pharmacology

Authors: *B. GURUNG[1], A. D. RANDALL[2], J. T. BROWN[1];
[2]Inst. of Biomed. and Clin. Sci., [1]Univ. of Exeter, Exeter, United Kingdom

Abstract: Glucagon-like peptide-1 receptor (GLP-1R) is an important G-protein coupled receptor in the periphery, which when activated stimulates the glucose-dependent release of insulin by the pancreatic β-cells to lower blood glucose. As such drugs that are agonists of this receptor are an approved class of drugs used for Type 2 diabetes mellitus (T2DM). T2DM and the neurodegenerative disease Alzheimer's disease (AD) share common pathophysiological characteristics such as insulin resistance and decreased glucose metabolism. The GLP-R agonist liraglutide is under a Phase IIb clinical trial (NCT01843075) in patients with mild AD dementia to examine the drug's effect on the hallmarks of the progression of the disease. Other agonists of this receptor have also shown improved spatial learning and memory in animal models of AD. GLP-1R activation in the brain is also associated with cell survival, inhibition of apoptosis, cell growth, synapse growth, repair and regeneration. However, to date the details of the effects this receptor system has at a neural circuit level in the brain is not well known. GLP-1R is expressed in many brain structures but it is most highly expressed in the lateral septum. Thus, our research will be based on this subcortical brain structure involved in a wide variety of functional roles such as food intake, stress and anxiety, reward and addiction, contextual memory and locomotion. Therefore, we aim to explore the effects of GLP-1R activation on neuronal activity in the lateral septum. However, in order to study the effects of GLP-1R activation, it is important to first characterise the baseline properties of the neurons in the lateral septum. To this, we have used a multi-electrode array approach combined with computational analysis to identify different potential sub-populations of neurons within the lateral septum. Our data also suggests that the anatomical distribution of these neuronal sub-populations based on physiology is heterogeneous. We also used whole patch clamp method to characterise the morphological and intrinsic properties of individual lateral septal neurons. We will then aim to explore whether different sub-populations respond differently to GLP-1R agonists. Consequently, our work will provide a basis for future works to study whether the effects of GLP-1R activation on neuronal activity is a result of direct or modulatory mechanism, and also how the regulation of neural circuits by this receptor system guides behaviour.

Title: Intrinsic Properties of Basal Ganglia Projecting Neurons Reflect Specific Learned Features of Zebra Finch Song

Authors: *N. MEDINA, D. MARGOLIASH;
The Univ. of Chicago, Chicago, IL

Abstract: The study of plasticity in the intrinsic properties (IPs) of neurons is unveiling new mechanisms beyond synaptic plasticity that relates cellular plasticity, network activity, and learning. Previous results from adult zebra finches established a relationship between the IPs of forebrain neurons and learned singing behavior. Within the song control nucleus HVC, prior studies have reported the IPs of HVC basal-ganglia-projecting neurons (HVCx) are similar within individual zebra finches and different across birds. Those differences were predictive of the overall differences of the birds' songs. Additionally, HVCx IPs are developmentally regulated, such that IPs may become increasingly homogeneous during developmental song learning. Given these prior results, we are directly examining the role of song learning in regulating HVCx IPs. Our approach uses a counterbalanced design to raise sibling or unrelated birds to sing natural or modified songs, using both live tutors and instrumental learning. We assess the IPs of HVCx neurons in slice once birds reach adulthood, evaluating IPs in relation to the tutored song and the song eventually acquired. Preliminary results indicate that the song, not relatedness to the tutor, has the stronger effect on the IPs HVCx will express in adulthood. Examining the correlation between IPs and song features, we have also observed a relationship between timing features of song and the rebound excitation of HVCx neurons. HVCx neurons from birds who sing longer songs, which tend to include longer harmonic stacks, also tend to have a combination of IPs that reflect increased rebound excitation. This demonstrates an explicit link between neuronal IPs and specific features of singing behavior, implicates specific membrane channels (gh, gSK, gCa-T), and given that harmonic stacks are relatively static vocalizations, suggests a mechanism underlying HVCx neurons' ability to integrate over relatively long periods of song. These results constrain models of HVC and implicate the importance of including neuronal IPs in developing realistic network-level descriptions of neural circuits. They also provide further evidence that HVCx activity is not independent of song structure.

Title: The reticular nucleus of the thalamus modulates the onset of the absence seizures on the myelin mutant taiep rat

Authors: *J. M. IBARRA-HERNÁNDEZ[1], C. CORTES[1], J. R. EGUIBAR[2];
[1]Lab. of Neurophysiol. of Behavior and Motor Control, Inst. of Physiology. Benemérita Univ. Autónoma de Puebla., Puebla, Mexico; [2]Res. Office, VIEP. Benemérita Univ. Autónoma de Puebla, Puebla, Mexico

Abstract: The absence seizures are one type of epilepsy which is characterized by a sudden loss of consciousness and with characteristic spike-wave discharges (SWD) in the electroencephalogram. Absence seizures are due to a dysregulation in the activity of the gamma-aminobutyric acid receptor type A ($GABA_A$) in the thalamo-cortical network which are modulate by the reticular nucleus of the thalamus (RNT). The aim of this study was to analyze the role of $GABA_A$ receptors in the RNT on the SWD on adult male *taiep* rats. We used 6 months old *taiep* rats which were implanted with electrodes in the RNT, cerebral cortex, neck muscles and in the right eye orbit for simultaneous recordings. Gaboxadol was infuse at 7.5, 15 y 30 µg/µL and bicuculline 50, 100 and 200 ng/µL in to rostral RNT through guide cannulas at 0800. We did four video-EEG recordings of 8 h, the first one is control, and three additional recordings using an increasing doses scheme every 72 h. Off-line we analyzed the frequency and mean duration of the SWD. We followed the NIH rules for the care and use of experimental animals and the protocol was approved by the University committee. The administration of gaboxadol in the RNT abolished the absence seizures during the first 6 h of EEG recordings with the infusion of 15 and 30 µg ($P<0.001$) with respect to control group. On the other hand, the administration of 100 and 200 ng of bicuculline increased the number of absence seizures for 2 hours ($P<0.05$), with significant reduction on their mean duration ($P<0.001$). The decrease in frequency and duration of absence seizures due to gaboxadol and the corresponding increased induced by bicuculline support the role of rostral RNT in the onset of absence seizures on rat *taiep*, an animal model of the leukodystrophy H-ABC.

Title: The surprising role of the thalamus and corpus callosum during focal to bilateral seizures

Authors: *A. BRODOVSKAYA[1], T. BATABYAL[2], J. KAPUR[3];
[2]Neurol., [1]Univ. of Virginia, Charlottesville, VA; [3]Dept Neurol., Univ. Virginai Hlth. Sci. Ctr., Charlottesvle, VA

Abstract: Previous studies indicate that the thalamus is essential for seizure maintenance and generalization. Famous models show that focal to bilateral seizures engage commissural connections between two thalamic nuclei to spread contralaterally. However, seizure spread from the seizure focus to the contralateral cortex has not been previously traced. We propose that seizures spread from the ipsilateral thalamus to the contralateral by engaging the corpus callosum. To initiate frontal lobe focal to bilateral seizures, we implanted 1.7 mg of cobalt wire in the right (ipsilateral) premotor cortex. We recorded local field potentials from the bilateral premotor cortex and bilateral ventrolateral thalamic nucleus (VL) simultaneously to determine seizure onset latencies. We injected AAV9 GFP at the seizure focus or in the ipsilateral thalamus in activity reporter TRAP2 mice to label anatomical projections and seizure activated cells at the same time. We also performed callosotomy and used chemogenetics and optogenetics to investigate the role of the corpus callosum and thalamus in the spread of frontal lobe focal to bilateral seizures. Surprisingly, we found that seizures spread faster to the contralateral cortex than to the contralateral thalamus. 53% of all seizures required less than 200 ms to arrive at the contralateral thalamic nucleus VL (59.36 ± 5.61 ms), whereas 47% of seizures required several seconds to arrive there (4.47 ± 0.65 s, 30 seizures, n=11). However, 100% of all seizures required less than 200 ms to arrive at the contralateral cortex (25.49 ± 3.00 ms, 64 seizures, n=16), supporting the role of the corpus callosum in seizure generalization. We injected AAV9 GFP at the seizure focus in TRAP2 mice and found extensive GFP and tdTomato expression in the corpus callosum. We injected AAV9 GFP in the ipsilateral thalamus but did not find anatomical projections to the contralateral thalamus from the ipsilateral, explaining onset delay in the contralateral thalamus. TRAP2 mice also did not express tdTomato in the contralateral thalamus because seizures that arrived there were shorter due to the onset delay. Anterior callosotomy stopped the contralateral spread of initial seizures. However, as a mouse experienced more seizures, plasticity and new network formation allowed faster, genu-independent, seizure onset in the contralateral cortex. We also inhibited ipsilateral VL using chemogenetics and optogenetics. Surprisingly, inhibition of the ipsilateral thalamus did not stop the contralateral spread of seizures. We show that frontal lobe seizures use the corpus callosum for focal to bilateral spread rather than commissural connections between two thalami.

Title: Hemodynamics- and electrophysiology-derived connectome dynamics show spatial co-occurrences at frequency-specific, temporally-sparse, and asynchronous times

Authors: *P. MOSTAME[1], J. WIRSICH[2], T. ALDERSON[3], B. RIDLEY[4], S. VULLIEMOZ[2], M. GUYE[4], L. LEMIEUX[5], S. SADAGHIANI[6];
[1]Univ. of Illinois At Urbana-Champaign, Champaign, IL; [2]Univ. of Geneva, Geneva, Switzerland; [3]Univ. of Illinois at Urbana-Champaign, Champaign, IL; [4]Aix Marseille Univ., Marseille, France; [5]UCL Queen Square Inst. of Neurol., London, United Kingdom; [6]Psychology, Univ. of Illinois, Urbana-Champaign, Urbana, IL

Abstract: To maintain the malleable nature of cognition, functional connectivity (FC) spatial organization recurrently reconfigures over time between distinct spatial patterns called "Connectome states". Dynamic spatial reconfigurations of hemodynamics- (fMRI) and electrophysiology-derived (MEG/EEG/iEEG) FC are - independently- shown to be informative to understand the brain. Because of a focus on methodological cross-validation of each data modality, prior multi-modal work has been largely biased towards providing evidence for an association between hemodynamics- and electrophysiology-derived FC over time and/or space. However, beyond a certain level of robust convergence, there is also a considerable divergence between hemodynamics- and electrophysiology-derived FC. Here, we asked to what degree fMRI and electrophysiology capture overlapping connectivity processes by comparing their connectome dynamics. We used rare concurrent fMRI-intracranial EEG (iEEG) resting state recordings of 9 subjects undergoing presurgical evaluations for epilepsy treatment [1]. Importantly, we generalized our findings to whole-brain connectomes of healthy subjects using a secondary concurrent fMRI and source-localized EEG data [2]. Amplitude coupling (AmpC) and phase coupling (PhC) (collectively, iEEG-derived FC) were measured for each canonical frequency band at every 100ms. fMRI-derived FC was calculated using spontaneous multiplication of z-scored ROI signals [3], and up-sampled to the temporal resolution of iEEG-derived FC. Over all frequencies, fMRI-derived FC was spatially similar to iEEG-derived FC in only ~20% of times, with temporally-sparse frequency-specific occurrences. Importantly, such cross-modal co-occurrences of the connectome states were also observed with the same prevalence when looking at all possible pairs of
asynchronous times in fMRI and iEEG. This observation indicates that fMRI and iEEG connectome dynamics are driven by distinct neurobiological connectivity processes that exhibits similar connectome states at different times (i.e. asynchronously linked). However using clustering analysis, we found that the spatial co-occurrences of fMRI and iEEG FC arise at sparse times at which the brain connectome reconfigure into a specific set of discrete connectome states. Altogether, we found that fMRI and (i)EEG FC show spatial co-occurrences at frequency-specific, temporally-sparse, and asynchronous times. We conclude that hemodynamic- and electrophysiology-derived connectivity may be envisaged as capturing distinct aspects of brain function, rather than intermodal measurements of the same phenomenon.

Title: Higher order thalamic nuclei factilitate the cortical generalisation of Spike and Wave Discharges

Authors: *Z. ATHERTON[1], P. SERE[2], G. KOZÁK[2], T. FÖLDI[2], A. BERÉNYI[2], V. CRUNELLI[1], M. LÖRINCZ[2];
[1]Cardiff Univ., Cardiff, United Kingdom; [2]Univ. of Szeged, Szeged, Hungary

Abstract: Spike and wave discharges (SWD), generated by the cortico-thalamo-cortical (CTC) network, are pathological oscillations and the hallmark of absence seizures. SWD begin in cortical initiation networks in both humans and animal models, including the Genetic Absence Epilepsy Rats from Strasbourg (GAERS), where they initiate in the primary Somatosensory cortex (S1). The mechanisms of how SWD rapidly spread across the brain has not been explored in detail and it remains unknown how trans-thalamic corico-cortical communication contributes to this process. We have now investigated the role of higher order thalamic (HO) nulcei in the generalisation of SWD in freely moving GAERS. The diffuse connectivity of HO nuclei, their known anatomical interactions with S1 and their altered synaptic anatomy in GAERS make these nuclei potential candidates for the rapid cortical spreading of SWD. Local field potential recordings of different HO nuclei and different cortical regions revealed a novel feature of SWD: the synchrony in cortical regions located far from S1 (such as primary Visual cortex, V1) transiently disappeared, i.e. there are short breaks in SWD (names SWD-breaks). Additionally, relatively brief SWD would occur only in S1 or in S1 and the neighbouring primary Motor cortex (M1), but not elsewhere. These spontaneous events provded a unique mechanistic insight since they represent unsuccessful maintenance and generalisation of SWD.
Local inhibition of different HO nuclei with muscimol increased the delay of SWD propogation and the occurance and duration of SWD-breaks. Moreover, HO nuclei single unit recordings revealed heterogeneity of burst firing dynamics during SWD of putative excitatory neurons. Noteably, all neurons exhibited a switch from tonic to burst firing before the generalisation of SWD, but responded differently during ictal periods, V1 SWD-breaks and non-generalised SWD events. These results support the view that trans-thalamic cortical communication is utilised in the initial propogation of SWD and has an active role in maintaining cortical sychrony throughout the paroxsysmal activity.

Title: Classifying interictal epileptiform spikes and sharp-wave ripples in SEEG recordings in the hippocampus of patients with temporal lobe epilepsy

Authors: *N. MORTAZAVI, M. KHAKI, G. GILMORE, J. BURNEO, D. STEVEN, J. MARTINEZ-TRUJILLO, A. SULER-MARTI;
Univ. of Western Ontario, London, ON, Canada

Abstract: *Nasim Mortazavi, Milad Khaki, Greydon Gilmore, Jorge G Burneo, David A Steven, Julio Martinez-Trujillo, Ana Suller Marti.* **Purpose:**Interictal epileptiform spikes (IISs) and Sharp Wave ripples (SWRs) are pathological and physiological events in patients with epilepsy. Although these two events may display similar temporal frequency patterns, they carry different energy in different frequency bands. We study a group of epilepsy patients implanted with SEEG depth electrodes to identify interictal abnormalities IISs and differentiate them from SWRs using a new algorithm. Our algorithm uses these frequency-specific IISs and SWR waveforms to detect and discriminate between them. **Method:**We analyzed the SEEG recordings obtained from patients with medically-resistant epilepsy implanted with depth electrodes at the Western University Hospital in Epilepsy Unit. The data were cleaned, denoised, montaged and finally segmented as sleep intervals and observed Ictals. The signal waveform and its power were extracted symmetrically in non-overlapping intervals of 500 ms for event detection. Each waveform's power across all detected spikes was computed and clustered based on their energy distributions. **Results:**We examined the efficiency of an automatic SWRs detection algorithm using 320 hours of data from temporal lobe epilepsy patients implanted with depth electrodes. Our finding shows that the rate of the putative IISs and SWRs were anticorrelated per day. Also, IISs class was mostly expected to happen between seizures. However, the putative SWR class in the hippocampus was most likely to occur in the awake state. Furthermore, the correlation between the frequency bands indicates that putative SWRs and putative IISs have the most overlap around [65-70] Hz centre frequency. Moreover, the temporal extent of IISs and SWR waveform distributions indicate that IEDs are less temporally localized (temporal heterogeneity). However, SWRs appeared localized and, as a result, as one single distribution**Conclusion:**Our algorithm detected and successfully distinguished IISs from SWRs based on their spectro-temporal characteristics. Our results indicate that the two neural events are prone to appear at

different time intervals. Moreover, the clustering shows that the statistical approach can define these events using their temporal extension (peak width), frequency, and energy patterns. This ratio is subject to change in different sessions and is affected by the number of seizures per day. The finding elaborates that putative SWRs are less heterogeneous compared to IISs.

Title: Functional network analysis of high frequency oscillations to identify location of seizure onset zone

Authors: *J. LIN;
Univ. of Michigan, Ann Arbor, MI

Abstract: Since their discovery, pathological high frequency oscillations (HFO) has been implicated to be a promising biomarker for seizure focuses known as the seizure onset zone (SOZ). A number of studies have shown the rate at which these small amplitude, fast (80-500 Hz) waveforms occur in epileptic patients tend to correlate with epileptic tissue. However, HFO research has been primarily focused on examining features from single channels, such as identifying which have the highest HFO rates. On the other hand, epilepsy has always been described as a network disorder, which would require the understanding of the relationships between the HFOs detected on different channels in order for clinicians to make substantial clinical decisions. Therefore, we strive to expand the understanding of the relationship between HFOs and epilepsy through an identification and characterization of functional HFO networks in epileptic patients. We hypothesize that the characterization of HFO networks will yield complementary information in identifying the epileptic seizure onset zone. To do so, we first evaluate the pairwise relationships between channels during HFO detections in order to generate a set of functional connectivity networks, focusing on the relative lead/lag patterns of co-occurring HFO events. Then, we characterize the functional role of each node within the network with a suite of centrality and ranking algorithms, allowing us to pinpoint the nodes that may play a causal role in generating HFO activity. Our results show that nodes with the highest centrality tend to correlate with clinically defined seizure onset zones. Finally, we compared our analysis with the surgical outcomes of patients and found that it was able to identify patients that went on

to have unsuccessful surgeries, based solely on interictal HFO data that were not available to the treating clinicians. These results provide a new perspective on evaluating the role of HFOs in epilepsy which could prove to be useful in future clinical planning.

Title: Interictal activity modulates large-scale cortical networks in children with epilepsy

Authors: *W. KIM[1], **H. YU**[2], D. K. PARK[3], F. A. PROVENZANO[1], D. KHODAGHOLY[2], J. N. GELINAS[1];

Abstract: OBJECTIVE: Intercortical communication is disrupted in patients with focal epilepsy, affecting the functions of anatomically remote brain areas. In the adult brain, pathologic oscillatory coupling between interictal epileptiform discharges (IEDs) and sleep spindles occurs across large-scale networks. Here, we investigate such oscillatory coupling in the developing brain. METHODS: Invasive subdural electroencephalogram (iEEG), presurgical magnetic resonance imaging (MRI) and postsurgical computed tomography (CT) of pediatric patients who underwent investigation due to refractory focal epilepsy were collected and analyzed. IEDs, high frequency oscillations (HFOs) and spindles were detected and cross-correlated to elucidate spatiotemporal relationships. Electrode localization was obtained through co-registration of imaging studies to a standard template. RESULTS: Total of twenty-nine patients (13 males and 16 females) were recruited for analysis. The mean age of iEEG study was 12.7 years old (range 3-21). Mean cortical area of coverage was 58cm2 (range 40-114). 52% (n=15) were temporal lobe exploration and 48% (n=14) were extratemporal lobe exploration. Prominent HFOs were observed in 48% (n=14). IEDs and HFOs demonstrated coupling across local and large-scale networks, with patient specific patterns. In addition, IEDs and HFOs could be phase-locked to physiologic-appearing spindles in distant brain regions. CONCLUSIONS: Pathologic oscillatory coupling is prevalent in immature epileptic networks, but with a diversity of patterns. Our findings suggest that IED-spindle coupling may shape development of interictal global network dysfunction in pediatric epilepsy patients.

Title: Complement-dependent neuron-glia interactions mediate the loss of perisomatic inhibitory synapses in Toxoplasma gondii infection

Authors: *G. CARRILLO[1], V. BALLARD[1], T. GLAUSEN[2], Z. BOONE[1], J. TEAMER[1], C. HINKSON[3], E. WOHLFERT[2], I. J. BLADER[2], M. A. FOX[1,3];

Abstract: Prolonged infection and inflammation within the brain can alter the connectivity and function of neuronal circuits. The intracellular parasite, *Toxoplasma gondii*, is one pathogen that can chronically infect the brain and lead to encephalitis and seizures. Currently, 1 in 3 humans are infected with *Toxoplasma gondii* worldwide, and these infections have been identified as a considerable risk factor for developing complex neurological and psychiatric disorders that arise from alterations in assembly and maintenance of synapses, such as schizophrenia. To directly assess changes in inhibitory synapses, we employed Serial Block Face Scanning Electron Microcopy and quantified perisomatic synapses in neocortex and hippocampus following parasitic infection. Ultrastructural analyses, in combination with genetic and immunohistochemical tools, revealed that persistent infection not only led to a significant loss of inhibitory perisomatic synapses, it also induced the ensheathment of neuronal somata and perisomatic nerve terminals by activated myeloid-derived cells (including microglia), suggesting they may displace or phagocytose synaptic elements in long-term infection. How might microglia contribute to inhibitory synapse loss in parasitic infection? Based on the well-established role of the innate complement cascade contributing to synaptic refinement in the developing brain and synapse loss in the diseased brain, we assessed complement components in parasitic infection. Indeed, C1q and C3 are highly upregulated in neocortex and hippocampus following persistent *Toxoplasma gondii* infection. Therefore, we hypothesized that these components may be required for microglia-induced synapse loss during long-term infection. Using transgenic and knockout mouse models, our current studies demonstrate that C3 is, in part, required for phagocytic microglia to ensheath neurons in long-term infection, likely leading to the loss of inhibitory perisomatic synapses. Together, these studies highlight novel ways in which immune

molecules regulate neuron-glia interactions to alter mature inhibitory circuits in parasitic brain infection.

Title: Astrocyte-secreted chordin-like 1 regulates spine density after ischemic stroke in mice

Authors: *E. BLANCO-SUAREZ[1,2], N. J. ALLEN[2];
[1]Thomas Jefferson Univ., Philadelphia, PA; [2]Salk Inst. for Biol. Studies, La Jolla, CA

Abstract: Focal ischemic stroke is a condition characterized by the interruption of the blood flow to a specific region of the brain. Ischemic stroke causes alterations in the peri-infarct area, the surroundings of the core of the injury, including acute loss and morphological changes of dendritic spines. This drives modifications in the synaptic plasticity that can determine the degree of recovery from ischemic stroke. Astrocytes are known to play detrimental and neuroprotective roles at different stages post-stroke, yet we lack a clear understanding of the mechanisms by which they exert those functions. Recently, we identified Chordin-like 1 (Chrdl1) as the astrocyte-secreted factor that promotes synaptic maturation in the mouse visual cortex, limiting plasticity. Chrdl1 KO mice exhibit enhanced experience-dependent plasticity in a paradigm of visual deprivation, and it has been previously shown that blocking plasticity-limiting molecules lead to better recovery from ischemic stroke. Using a photothrombotic *in vivo* model of focal ischemic stroke in the visual cortex, I analyzed the effects of Chrdl1 absence on structural plasticity (spine density and morphology), astrocyte and microglia reactivity, and injury volume progression. The results from this study suggest that Chrdl1 plays a role in regulating synaptic plasticity in response to acute injury, such as focal brain ischemia. Astrocyte-secreted factors like Chrdl1 represent a new target to prevent detrimental effects of acute injury and to enhance endogenous plasticity to compensate at later stages for the damage caused at early phases after focal ischemic stroke.

Title: Interrogating microglial engulfment of synaptic terminals using FEAST

Authors: *L. DISSING-OLESEN, A. J. WALKER, Q. FANG, D. K. WILTON, I. DAS, L. BENOWITZ, B. STEVENS;
Boston Children's Hosp., Boston, MA

Abstract: Engulfment of synaptic material is a key microglia function in health and disease, however, thoroughly validated tools that facilitate rapid, high-throughput, and unbiased quantification of this process in different paradigms are lacking. We therefore developed FEAST *(Flow cytometric Engulfment Assay for Synaptic Terminals)* to facilitate rapid analysis of *in vivo* engulfment of synaptic material by thousands of microglia at single cell resolution. We optimized FEAST for two different analyses of *in vivo* engulfment: quantification of fluorescent neuronal material inside live microglia and of engulfed endogenous synaptic proteins within fixed microglia. We conducted multiple control experiments to verify that the majority of neuronal material quantified within each microglial cell was engulfed *in vivo* and that *ex vivo* engulfment and technical artifacts have been substantially reduced. We confirmed the specificity of FEAST by interrogating engulfment of eye-specific inputs after optic nerve crush. Additionally, we applied FEAST to discover that depletion of the microbiome leads to increased engulfment by microglia, underscoring the applicability of this technique to novel questions in the field of neuro-immunology. Conceptually, FEAST is not restricted to microglial engulfment of synaptic terminals in the central nervous system and can be expanded to allow quantification of engulfment of any protein by any cell type across different tissues and model organisms. FEAST can also be combined with emerging -omics analyses, providing a functional readout that complements our understanding of the phenotypic heterogeneity of myeloid cells across different paradigms. Ultimately, FEAST has the potential to provide critical insights into neuro-immune interactions that shape development, homeostasis, and disease.

Title: Glial engulfment of synapses is enhanced in a mouse model of Fragile X Syndrome

Authors: *M. LEE[1], L. CHEADLE[5], A. VO[1], A. YADAV[2], M. WEISENHAUS[1], V. MENON[2], M. E. GREENBERG[6], M. M. SHIRASU-HIZA[3], C. MASON[4];

Abstract: Fragile X Syndrome (FXS) is the most common single-gene cause of both autism and intellectual disability and is caused by the transcriptional silencing of *Fmr1*, resulting in loss of FMRP. While neuronal mechanisms underlying aspects of FXS have been identified, therapeutic strategies targeting these mechanisms have been largely unsuccessful, suggesting that our current focus is missing an essential piece of the puzzle. One such missing piece may be glia, or the non-neuronal cells of the brain, which express FMRP and which our lab and others have recently identified as involved in FXS-associated phenotypes. We have leveraged the unique advantages of the developing visual (retinogeniculate) system, a classic model for studying synapse growth and refinement, to test the hypothesis that loss of FMRP alters glia-dependent mechanisms of synapse refinement. Retinal ganglion cells (RGCs) extend from the retina and synapse onto the dorsal lateral geniculate nucleus (dLGN) of the brain, initially forming an excess of synaptic connections that are subsequently eliminated in a stereotyped manner to segregate inputs from each eye. This refinement process requires astrocytic and microglial engulfment of synapses. We found that RGC segregation is enhanced in the *Fmr1* KO dLGN at P7, a time of peak refinement. Additionally, excitatory RGC synapses in the dLGN appear reduced in size at this age. To identify the molecular mechanisms underlying this phenotype, we performed differential single-nucleus RNA sequencing (snSeq) of the P7 *Fmr1* KO and WT dLGN and identified

differentially expressed genes in KO vs WT within different dLGN cell types. Unsupervised analysis of these data indicated that *Fmr1* KO microglia and astrocytes show an upregulation of genes associated with glial phagocytosis. Finally, we found that both microglial and astrocytic engulfment of RGC synapses is upregulated *in vivo* in the developing *Fmr1* KO dLGN. Altogether, these data indicate that loss of FMRP results in aberrantly enhanced glial engulfment of synapses during neural circuit development, demonstrating a novel potential therapeutic target for the treatment of FXS.

Br., Galveston, TX; [5]Dept. of Anesthesiol., Stony Brook Univ., Stony Brook, NY

Abstract: Synaptic loss is implicated in the pathogenesis of HIV-associated neurological disorders (HAND) such as pain and dementia. We previously reported that synaptic degeneration in the spinal dorsal horn is associated with the development of chronic pain in HIV patients. This pathology is also recapitulated in mouse models of HIV-associated pain generated by the HIV envelope glycoprotein, gp120. Glial activation is a common feature in HIV patients and animal models of HIV-associated pain. A recent study from our lab detailed a crucial signaling pathway required for gp120 to induce microglial synapse degeneration. However, the underlying synapse elimination mechanism remains elusive. Recent studies and our preliminary data have revealed a critical role for glia in synapse pruning, therefore we hypothesize that reactive microglia and astrocytes play crucial roles in HIV-associated synapse loss. In this study, we aim to investigate

synapse pruning as a mechanism by which glial cells contribute directly to synapse loss in an HIV animal model. To do so, we compared glial synapse engulfment between wild type and gp120 transgenic mice (gp120tg) in the cortex and spinal dorsal horn. The gp120tg mice express HIV LAV gp120 under the GFAP promoter resulting in expression and secretion of gp120 from astrocytes, a reservoir for HIV in the CNS. GP120tg and age-matched WT mice were euthanized at 5 months of age (n=3 per group). Sex differences were not assessed. Brain and spine tissue were collected for immunofluorescent staining. Tissue sections were stained for pre-synaptic Vglut1, post-synaptic Shank1, lysosome marker LAMP1, and microglia marker iba-1 or astrocyte marker GFAP. Three sections were analyzed per animal and all glial cells within each section analyzed. 3D reconstruction of confocal z-stack images showed increased glial volume and cell body count suggesting activation of microglia and astrocytes in both tissues studied. In the cortex, astrocyte engulfment of both Shank1 and vGlut1 increased from WT to gp120tg ($p=.002$, $p=1.8e-7$), and microglia engulfment of the same markers also appeared to increase from WT to gp120tg ($p=.09$, $p=.08$). In the spinal dorsal horn, compared to WT, gp120tg, astrocyte engulfment of Shank1 appeared to increase ($p=.05$), vGlut1 engulfment increased ($p=.0049$), and microglia engulfment of Shank1 increased ($p=.008$). However, engulfment of vGlut1 by microglia did not appear to increase. A two sample t-test was performed for statistical analysis between groups. These results suggest that synaptic pruning by glial cells is a vital contributor to synapse loss in HAND.

Title: An astrocytic role in regulating dendritic spine maturation in UBE3A-dependent autism spectrum disorder

Authors: *Z. GARDNER, O. HOLBROOK, H.-Y. MAN;
Boston Univ., Boston, MA

Abstract: An astrocytic role in regulating dendritic spine maturation in *UBE3A*-dependent autism spectrum disorder
Zachary Gardner, Otto Holbrook, Heng-Ye Man
Autism spectrum disorders (ASDs) are a diverse class of neurodevelopmental disorders with various aberrant cellular phenotypes such as dysfunctional neurotransmission and irregular neuronal morphology. ASDs have a broad underlying genetic background with many genes

linked to their etiology. *UBE3A* has been identified as a top gene candidate to ASD, and overexpression of *UBE3A* via copy-number variation confers hallmark ASD behaviors in humans and transgenic mice. Our previous work revealed that in the *Ube3A*-ASD mouse model (*Ube3A* 2X Tg, or simply "2X Tg"), synapse formation was negatively affected. However, the cellular and molecular mechanisms underlying the synaptic dysregulation remain unknown. We found that selective overexpression of *Ube3A* in neurons failed to induce changes in synapse development. In contrast, overexpression of *Ube3A* in glia resulted in alterations in spines and synapses. Further, we identified thrombospondin-2 (TSP2), a secreted glial molecule involved in synaptogenesis, which we implicate in the defective synapse formation. *Ube3A* overexpression confers a loss of transcriptional down-regulation of TSP2 in astrocytes, and the medium of glia cultures with *Ube3A* overexpression was sufficient to trigger synaptic changes similar to that observed in mixed cultures from 2X Tg brains. Importantly, supplement of TSP2 to the 2X Tg cultures was able to rescue the synaptic defects. These findings indicate that an increase in *Ube3A* dosage in astrocytes contributes to the synaptic abnormalities in neurons.

Title: Adolescent binge ethanol exposure induces changes in astrocyte morphology and synaptic colocalization disrupting neuronal-astrocyte communication that persists into early adulthood

Authors: *C. D. WALKER[1], H. G. SEXTON[2], B. J. HENDERSON[3], M.-L. RISHER[4]; [1]Biomed. Res., [2]Joan C. Edwards Sch. of Medicine, Marshall Univ., Huntington, WV; [3]Biomed. Sci., Joan C Edwards Sch. of Med. at Marshall Univ., Huntington, WV; [4]Biomed. Sci., Joan C. Edwards Sch. of Med., Huntington, WV

Abstract: Adolescence, a critical time of neuronal development, is characterized as a transitional period between childhood and adulthood that is associated with increased freedom, self-exploration, and participation in novel experiences. Alcohol consumption in the form of binge drinking is highly prevalent among adolescents and emerging adults, increasing the risk of alcohol dependence and cognitive impairment later in life. Animal models have shown disruption of neuronal structure and function as a result of repeated binge-level ethanol (EtOH) exposure. However, the underlying mechanisms that elicit these changes are not well understood.

Furthermore, the contribution of astrocytes on EtOH induced neuronal dysfunction is unknown. Astrocytes have complex morphologies with extensive perisynaptic astrocyte processes (PAPs) that ensheathe pre- and post-synaptic terminals and play an essential role in synaptic maintenance and signal transmission. Here we investigate the consequences of adolescent binge EtOH exposure on astrocyte morphology, PAP-synaptic proximity, and neuronal-to-astrocyte communication in the form of astrocyte Ca^{2+} activity. We hypothesize that adolescent binge EtOH exposure induces changes in astrocyte morphology that results in a loss of PAP-synaptic proximity subsequently impairing astrocyte responsivity to neuronal activation.
Male Sprague Dawley rats received hippocampal intracranial injections of an astrocyte-specific adeno-associated GFP virus or an astrocyte-specific Ca^{2+} indicator GCaMP6f. Beginning at PND30, animals received intermittent EtOH (5g/kg) or water gavage over 16 days followed by a 26-day washout period. On PND70 acute hippocampal slices were prepared for immunohistochemistry (IHC, astrocyte morphology) or electrophysiology (neuronal-astrocyte responsivity). IHC was performed on GFP+ slices using the post synaptic density marker PSD95. GFP+ astrocytes in the CA1 hippocampus were imaged using confocal microscopy and then reconstructed using IMARIS-Bitplane. Astrocyte Ca^{2+} activity was recorded from GCaMP6F+ CA1 hippocampal astrocytes following Schaffer Collateral stimulation.
Our data demonstrate that adolescent intermittent binge EtOH results in a protracted decrease in astrocyte volume and PAP-synaptic colocalization that correlates with decreased astrocyte responsivity to neuronal activation as demonstrated by a reduction in astrocyte Ca^{2+} activity. These findings contribute to our understanding of how adolescent EtOH disrupts neuronal-astrocyte communication, driving astrocytic and synaptic dysfunction that persist into adulthood.

Title: Interleukin 4-induced 1 (IL4i1) modulates the metabolic microenvironment in demyelinated lesions to facilitate remyelination

Authors: *J. HU, H. C. OFT, V. N. SMITH, M. KIM, L. ROSKO, G. S. MELCHOR, M. BAYDYUK, J. K. HUANG;
Georgetown Univ., Washington, DC

Abstract: Multiple sclerosis (MS) is an immune-mediated disease in the central nervous system (CNS) that is characterized by demyelination, axonal injury, and neuronal degeneration. Our previous study found that interleukin 4-induced 1 (IL4i1), an L-amino acid oxidase expressed by microglia/macrophages, is upregulated at the onset of recovery in animal models of MS, promoting inflammation resolution and remyelination. However, it remains unclear what are the downstream targets of IL4i1 and how IL4i1 facilitates the remyelination process. Here, we show that recombinant IL4i1 treatment inhibits the amino acid-dependent mammalian target of rapamycin complex 1 (mTORC1) pathway in immune cells. Deletion of IL4i1 in mice resulted in increased mTORC1 activity in myeloid cells as well as prolonged inflammation in lysolecithin-induced focal demyelination and experimental autoimmune encephalomyelitis (EAE) animal models. Moreover, systemic administration of L-phenylalanine, a major IL4i1 substrate, prolonged inflammation and inhibited remyelination in mice following focal demyelination. Through mass spectrometry analysis of dissected demyelinated tissues, we observed that lesions from IL4i1$^{-/-}$ mice exhibited decreased levels of α-keto acids, corresponding to the failure of amino acid metabolism in the absence of IL4i1. We also found that IL4i1-derived α-keto acids modulate inflammation by activating the aryl hydrocarbon receptor (AHR) pathway in vitro. Moreover, IL4i1$^{-/-}$ mice displayed a reduction of AHR activity in myeloid cells. Our results suggest that IL4i1 modulates inflammation in the demyelinated lesion microenvironment through inhibiting mTOR signaling by oxidizing amino acids, while generating α-keto acids that activate AHR signaling in myeloid cells to facilitate remyelination.

Title: Thyroid receptor beta-selective agonist enhances functional brain delivery and accelerates remyelination in in vitro and in vivo rodent demyelination models.

Authors: M. B. WOERNER[1], J. VIVIAN[1], A. ALAVI[1], M. SHANKARAN[2], E. NYANGAU[2], M. MATTHEWS[2], M. HELLERSTEIN[2], *R. GANDHI[1], C. BEALS[1], B. A. STEARNS[1], D. A. MACKENNA[1];
[1]Autobahn Therapeut., San Diego, CA; [2]Univ. of California at Berkeley, Berkeley, CA

Abstract: Demyelinating diseases are characterized by loss of myelin in the CNS. There are no effective treatments to regenerate damaged myelin, and natural remyelination is often inhibited or impaired. Thyroid hormone (T3) is known to induce oligodendrocyte differentiation and

myelinogenesis *in vivo*. Brain-directed thyromimetics have potential to enhance remyelination in the treatment of demyelinating diseases such as multiple sclerosis.
LL-341070 is a prodrug that delivers a highly potent and selective small molecule agonist for the thyroid hormone receptor beta (TRβ). LL-341070 demonstrates enhanced brain delivery and induction of thyroid-responsive genes *in vivo*. Studies to profile LL-341070 were performed in cellular (OPC differentiation) and rodent demyelination models (cuprizone diet & experimental autoimmune encephalitis (EAE)).
The active metabolite of the LL-341070 prodrug enhanced oligodendrocyte differentiation *in vitro* in an oligodendrocyte progenitor cell assay (EC_{50} = 1.4 nM).
T_3 has been shown to enhance the rate of remyelination in a rat cuprizone model. We assessed the ability of thyromimetics to accelerate the remyelination process *in vivo* by measuring the fractional synthesis of 24-hydroxycholesterol (24-OHC) in the brains of rats following cuprizone-induced demyelination. 24-OHC is a primary metabolite of *de novo* cholesterol synthesis in the CNS, which is required for efficient remyelination, is released into circulation from brain, and may represent a circulating biomarker of brain cholesterol synthesis and remyelination.
At withdrawal from cuprizone diet, rats were provided deuterated water with administration of LL-341070 at 30 or 100 µg/kg for 3 weeks, then 24-OHC deuterium enrichment and labeling pattern were measured in cortex and corpus callosum. LL-341070 induced a dose-dependent increase in deuterated 24-OHC compared to vehicle controls, suggesting an increased rate of myelin synthesis. Additionally, expression of thyroid-responsive genes increased in the brains of treated animals, indicating active engagement with TRβ.
In an EAE mouse model, LL-341070 administered daily from 3 to 300 µg/kg in a prophylactic paradigm dose-dependently improved median day of disease onset and decreased maximum disease severity. Histological analysis of spinal cord 28 days after immunization demonstrated a reduction of inflammatory foci, apoptotic cell count, and reduced area of demyelination by H&E and MBP staining.
In summary, thyromimetic prodrugs demonstrate utility in models of remyelination through enhanced brain delivery *in vivo* and, as such, have potential as valuable therapeutics for demyelination disorders.

Title: Functional changes precede structural changes in the mouse hippocampus following Cuprizone-induced demyelinaition and remyelination

Authors: A. DAS, J. BOROVICKA, D. PATEL, B. D. TRAPP, ***H. DANA**;
Neurosciences, Cleveland Clin. Lerner Res. Inst., Cleveland, OH

Abstract: Damage to the myelin sheath that protects axons in the central nervous system is part of several demyelinating diseases including multiple sclerosis (MS). Many MS patients exhibit repeating episodes of axonal demyelination, which is associated with many of the disease symptoms of motor, visual, and cognitive deficits. In the first stage of the disease, there are also remission periods, where the axons remyelinate and the symptoms are ceased. Current medical treatment focuses on the inflammatory component of MS and unfortunately, is not efficient in

progressive phases of the disease. In this study, we introduce a new method to link the structural demyelination and remyelination processes with functional changes in neuronal activity in the living mouse brain. We used a transgenic mouse line expressing the red genetically encoded calcium indicators jRGECO1a, and induced brain-wide demyelination using the Cuprizone model. We longitudinally recorded the spontaneous activity from thousands of hippocampal neurons using two-photon microscopy for 100 days. In parallel, we monitored longitudinal structural changes in the hippocampal myelin of the same mice using third-harmonic generation. We found that the changes to neuronal activity are relatively rapid and firing rate decreased by ~50% as early as 4 days after the start of the cuprizone diet, whereas the structural changes of the myelin are slower and can be identified only after several weeks. This relationship remained similar upon the termination of cuprizone diet. we identified a partial recovery of the hippocampal activity within several days and slower remyelination process after more than a week. Our study demonstrates an *in vivo* method to detect longitudinal changes during cycles of demyelination and remyelination that can be applied to study the efficacy of new therapeutic treatments to protect the neuronal circuitry.

Title: Myeltracer - a semi-automated software for myeling-ratio quantification

Authors: *T. KAISER[1], H. M. ALLEN[1], O. KWON[1], B. BARAK[2], J. WANG[3], Z. HE[3], M. JIANG[1], G. FENG[1];
[1]MIT, Cambridge, MA; [2]The Sagol Sch. of Neurosci. and The Sch. of Psychological Sci., Tel Aviv University, Israel; [3]Boston Children's Hosp., Boston, MA

Abstract: In the central and peripheral nervous systems, the myelin sheath promotes neuronal signal transduction. The thickness of the myelin sheath changes during development and in disease conditions like multiple sclerosis. Such changes are routinely detected using electron microscopy through *g*-ratio quantification. While *g*-ratio is one of the most critical measurements in myelin studies, a major drawback is that *g*-ratio quantification is extremely laborious and time-consuming. Here, we report the development and validation of MyelTracer, an installable, stand-alone software for semi-automated *g*-ratio quantification based on the Open Computer Vision Library (OpenCV). Compared to manual *g*-ratio quantification, using MyelTracer produces consistent results across multiple tissues and animal ages, as well as in remyelination

after optic nerve crush, and reduces total quantification time by 40-60%. With *g*-ratio measurements via MyelTracer, a known hypomyelination phenotype can be detected in a Williams Syndrome mouse model. MyelTracer is easy to use and freely available for Windows and Mac OS X (https://github.com/HarrisonAllen/MyelTracer).

Title: Rescuing Cholesterol Efflux Transporter 1 Expression Mitigates Visual and Motor-sensory Impairment In Experimental Autoimmune Encephalomyelitis

Authors: *O. W. GRAMLICH, J. J. ANDERS, B. W. ELWOOD, R. H. KARDON;
Dept. of Ophthalmology & Visual Sci., Univ. of Iowa, Iowa City, IA

Abstract: Background: Acute optic neuritis is the initial symptom in 25-45% of newly diagnosed cases of Multiple Sclerosis (MS). The purpose of our study is to determine whether augmentation of cholesterol processing by systemic administration of gentisic acid (GA) rescues the ocular phenotype in an experimental autoimmune encephalomyelitis (EAE) model. Methods: EAE-related optic neuritis was induced in 52 female C57BL6 mice by immunization with MOG33-55, complete Freund's Adjuvant and pertussis toxin. 22 EAE mice received intraperitoneal administration of gentisic acid weekly (EAE+GA) while another 25 naïve mice served as controls. Clinical progression was monitored according to a 5-point EAE scoring scheme. At day 60, visual acuity, pattern electroretinography (PERG) and retinal ganglion cell (RGC) complex thickness were measured. Grades of demyelination (0-3 grading), cell infiltration (0-4 grading) and expression of Cholesterol efflux transporter 1, ABCA1, in optic nerves and spinal cord were determined. Differences were evaluated using Tukey's post-hoc test. Results: EAE+GA animals show significantly lower motor-sensory impairment (area under the curve EAE:122±4 vs. EAE+GA: 78±5; $p<0.0001$). Treatment also preserved visual acuity (EAE:0.23±0.08c/d vs. EAE+GA: 0.34±0.09c/d; $p<0.0001$), improved the PERG amplitude (EAE:16±4 vs. EAE+GA:20±4 µV; $p=0.03$) and slightly diminished RGC complex thinning (EAE:59±4µm vs. EAE+GA:62±3µm; $p=0.2$) when compared to untreated EAE mice. Demyelination in the optic nerve was less severe in GA treated EAE mice (EAE:2.1±0.8 vs.

EAE+GA: 1.1±0.6; p=0.0001) and fewer infiltrating cells were observed (EAE:2.2±1 vs. EAE+GA: 1±0.5; p<0.0001). ABCA1 was significantly less downregulated in spinal cord tissue in GA treated EAE mice. (fold change EAE: -3.9±1.1 vs. EAE+GA: -2.3±1.2; p=0.003). Clinical progression in treated and untreated EAE animals strongly correlate with decline in PERG amplitude (r=0.81), RGC complex thinning (r=0.9) and optic nerve histopathology (r=0.7). Conclusion: Administration of GA, which increases the expression of the Cholesterol efflux transporter, significantly lessens motor-sensory deficits and corelates with rehabilitation of the visual system in an EAE mouse model of MS. The rescue effect may be related to increased clearing of myelin debris and cholesterol recycling by macrophages after optic neuritis. In summary, this study suggests that interventions to improve cholesterol recycling might be a viable approach to promote rehabilitation in MS.

Title: The Effects of Myelin Oligodendrocyte Glycoprotein Antibody-Associated Demyelinating Disease on Regional White Matter Volume and Cognitive Function in Children

Authors: P. THOMAS, C. WILSON, M. HUTCHINSON, *W. I. MATTSON, E. E. NELSON; Nationwide Children's Hosp., Columbus, OH

Abstract: The myelin oligodendrocyte glycoprotein antibody (MOG-Ab) was recently discovered as a contributing factor to some cases of white matter demyelination. MOG mediated demyelination has a much larger prevalence in children than adults. Clinically, the condition manifests as encephalopathy, optic neuritis, acute disseminated encephalomyelitis (ADEM), and neuromyelitis optica spectrum disorder (NMOSD). In MOG-Ab+ individuals, this endogenous antibody binds directly to the myelin oligodendrocyte glycoprotein within the central nervous system, directly affecting both oligodendrocytes and myelinated neurons. Both white matter lesions and clinical symptoms of MOG-Ab+ are successfully managed with immunotherapy including steroids and intravenous immunoglobulin, yet relapses in this disease occur. The underlying cellular mechanisms are being heavily researched, but differentiation in clinical

presentation and relapse-remitting periods are not well defined.
In the present study we examined effects of MOG-Ab+ status on regional white matter volume and neuropsychological profile in a group of pediatric patients recruited from a Neuroimmune clinic at a children's hospital. Multiple MRI scans were obtained from clinical assessments performed on 12 children with demyelinating disease and a matched group of healthy controls. A post-treatment neuropsychological battery was conducted looking at verbal fluency, IQ, attention, executive functioning, and fine motor skills. White matter volumes from T1-weighted MRI scans were calculated with the cortical parcellation function in Freesurfer (v7.1.0). Comparisons were made both within and between subjects at the whole brain and regional lobar levels.
Preliminary evidence indicates regional reductions of up to 6% volume in white matter of frontal lobes are evident in many MOG-Ab+ patients, regardless of lesion location. This regional reduction in white matter volume also tracks with the onset, reduction, and relapsing symptomology of focal lesions. Changes in other lobes are less evident. Post-treatment neuropsychological measures indicate near normal function in MOG-Ab+ patients on nearly all measures. These findings contribute to a narrow pool of literature surrounding this disease presentation, clinical impairments, and cognitive functioning outcomes in pediatric populations. These findings suggest neurological impairment may occur beyond localized lesions, but reasons for this focal volume reduction and long-term functional impact is unclear. Further research is needed to examine neurocognitive and functional outcomes to inform multidisciplinary management to improve recovery.

Title: Studying the role of autophagy in Krabbe disease

Authors: *N. DHIMAL[1,3], N. WEINSTOCK[1,3], E. HURLEY[4], D. SHIN[2], L. WRABETZ[5,3], M. FELTRI[6,3];
[1]Biochem., [2]Dept. of Biotechnical and Clin. Lab. Sci., Univ. at Buffalo, Buffalo, NY; [4]Neurol., [3]Inst. for Myelin and Glia Exploration, Buffalo, NY; [5]Univ. at Buffalo - The State Univ. of New York, Buffalo, NY; [6]Biochem., State Univ. of New York at Buffalo, Buffalo, NY

Abstract: Krabbe disease (KD) is an inherited autosomal recessive, debilitating, lysosomal storage disorder (LSD) caused by mutations in galactosylcerebrosidase (*Galc*) gene. *Galc* deficiency affects both the peripheral nervous system (PNS) and the central nervous system (CNS) and leads to demyelination, neurodegeneration, and death within a couple years. Although therapies that delay the disease exist, there is currently no available cure for KD. Schwann cells-specific deletion of *Galc* (*Galc*-SC-cKO) in mice leads to a PNS pathological phenotype of KD, which includes accumulation of undigested substrates accompanied by demyelination, neurodegeneration, and a neuropathy very similar to the one observed in KD patients (Weinstock et al. 2020, Neuron). Using this validated *Galc*-SC-cKO model, this study aims to investigate autophagy in the PNS to understand how it contributes to development and pathogenesis of KD. Preliminary data indicate that macroautophagy (or autophagy) is defective in Schwann Cells (SC) when GALC is absent. Western blot results suggest that autophagy is increased at the beginning of the disease, but it halts and decreases during disease progression. Autophagosome accumulation in SCs is observed under electron microscopy (EM) during disease progression. Furthermore, using a pH-sensitive fluorescent LC3 autophagy reporter mouse system, we see a significant increase in autophagosome accumulation in SC from *Galc*-SC-cKO *in vivo*, suggesting impaired fusion of autophagosomes with lysosomes in those cells. Thus, we plan to manipulate autophagy in *Galc*-SC-cKO mice in vivo, and this work is currently in progress. Understanding specific mechanistic changes in degradative pathways could help pinpoint the cause and timing of substrate accumulation in KD and other LSDs. Such studies may also be relevant to other more common diseases caused by failure in lysosomes, autophagy, and proteostasis.

Title: The influence of LCGA-17 on behavior and brain elongation factor 2 levels in mice with strong features of dominance and submissiveness

Authors: *A. MALYSHEV[1], E. SHMERKIN[2], A. KLINOV[2], L. VINNIKOVA[2], D. BEGMATOVA[2], D. SUR[2], N. MITKIN[1], I. SUKHANOVA[1], V. GEDZUN[1], V. PAVSHINTSEV[1], I. DORONIN[1], G. BABKIN[1], A. PINHASOV[2];
[1]Lactocore Inc., Plymouth, MI; [2]Dept. of Mol. Biol. and Adelson Sch. of Med., Ariel Univ., Ariel, Israel

Abstract: Background. LCGA-17 is a novel peptide with potent anxiolytic and antidepressant properties that acts through α2δ, with possible synergism by $GABA_A$ receptors. The aim of the current study was to evaluate the effects of LCGA-17 in socially dominant (Dom) and socially submissive (Sub) mice. These two populations had been selectively bred from a background Sabra strain for the behavioral traits of dominance and submissiveness. Dom mice are stress-resilient, exhibiting manic-like behavior and paradoxical effect to the anxiolytic and antidepressant agents. In contrast, Sub mice are stress vulnerable and exhibit depressive-like and impaired social features. **Methods.** LCGA-17 was administered in doses of 0.1, 0.3, and 1 mg/kg intranasally for 10 days. The Three Chamber Test (TChT) was carried out on day 7 and the Hole Board (HB) test was carried out on day 10 of the treatment. Diazepam (Diaz) was used as a reference drug. After the behavioral experiments' prefrontal cortexes (PFC), and hippocampi (Hip) of the mice were dissected. Analysis of elongation factor 2 kinase (EF2K) as well as phosphorylated elongation factor EF2(T56) were carried out with qPCR and WB. **Results.** Dom mice treated with LCGA-17 displayed dose-dependent novelty-seeking behavior with greater sociability in the TChT, a similar but less pronounced effect was also observed in Sub. In the HB, both Diaz and LCGA-17produced an increment of head-dipping in Sub mice, suggesting an anxiolytic-like effect of the peptide in stress-vulnerable population. In Dom mice, Diaz failed to alter this parameter, while LCGA-17 increased head-dipping, which may suggest a potential antipsychotic effect in animals with manic-like phenotype. Chronic LCGA-17 treatment (1mg/kg) increased EF2K protein level as well as EF2(T56) phosphorylation in Dom mice in both PFC and Hip. In Sub mice, we observed an induction of EF2(T56) in Hip only. EF2K inactivates EF2 by phosphorylation on threonine 56 (T56), which results in the inhibition of protein synthesis. **Conclusion.** The results in the TChT suggest a potential implication of LCGA-17 in social phobia treatment. The reduction of protein translation in mouse brains might be implicated in the disruption of the process of traumatic memory consolidation and may diminish PTSD symptoms. This mechanism could underlie LCGA-17 anxiolytic action. Thus, these results suggest a selective anxiolytic/antidepressant-like or mood-stabilizing effect of LCGA-17 in socially submissive and socially dominant populations, respectively.

Title: Long-term Changes in Neuroimaging Markers, Cognitive Function and Psychiatric Symptoms in an Experimental Model of Gulf War Illness

Authors: *X. WU[1], A. K. SHETTY[2], D. S. REDDY[1];
[1]Neurosci. and Exptl. Therapeut., [2]Mol. and Cell. Med., Texas A&M Univ. Hlth. Sci. Ctr., Bryan, TX

Abstract: Gulf War Illness (GWI) is a multi-symptom disease with debilitating cognitive and emotional impairments in veterans. GWI is caused by chemical neurotoxicity and manifests from disturbances in central and peripheral network excitability. However, the mechanisms underlying such devastating neurological and psychiatric symptoms remain unclear. Here we investigated the long-term changes in neurological behavior and brain neuroimaging abnormalities in the GWI-like model of chemical neurotoxicity in rats. GWI is linked to exposure to GWI-related organophosphate chemicals (PB, DEET, and permethrin) during the stressful Gulf war. Experimental GWI was induced in rats by 4 weeks of daily exposure to GWI related chemicals with stress restrain (GWIR-CS). The cohorts were screened in the novel object recognition memory test, open-field test, elevated plus-maze test, and social interaction test. At 5-months and 10-months post-GWIR-CS, rats exhibited significant signs of memory and emotional impairment. Exposure to GWIR-CS produced significant decrease in time spent with the novel object, time spent in the central zone in the open-field, time spent on open arms and entries in the

elevated plus-maze at 5-mon and 10-mon post-GWIR-CS. In forced swimming test, the rats showed significant decreased interests in swimming. These data were confirming strong deficits in emotion and anxiety behaviors. They displayed heightened aggression and reduced social interactive time, indicating stressful anxiety and mood disturbances. In addition, significant changes were evident in learning and memory performances in acquisition and recall of spatial memory in the Morris water-maze test. In the MRI scanning, there were significant increases in lateral ventricle T2 relaxation times and significant differences in the volumes of hippocampus, thalamus, and lateral ventricle at 10 months. These results confirm that chronic GWIR-CS exposure led to striking cognitive and psychiatric deficits along with brain tissue lesions, demonstrating the potential utility of this model for therapeutic interventions for GWI and its comorbidities.

Title: Cofilin knockdown improved behavioral and cognitive functions in ICH aged male and female mice

Authors: *D. ALMARGHALANI, Z. SHAH;
The Univ. of Toledo, Toledo, OH

Abstract: Intracerebral hemorrhage (ICH) represents only 10-15% of total stroke types but carries a high risk of morbidity and mortality, and survivors suffer from long-term disabilities and post-stroke cognitive impairments (PSCI). The overall mortality rate in aged individuals is higher than that of younger individuals. However, the mechanisms involved in secondary injury-induced PSCI after ICH is not clear yet. Our lab reported that inhibiting cofilin with small interfering RNA (siRNA) 72-h prior to induced ICH improved secondary injury-induced neurobehavioral deficits and reduced hemorrhagic volume and microglia activation in mice. In the present study, we investigated if cofilin siRNA treatment immediately after ICH will mitigate the secondary injury and enhance PSCI in aged (18-22 months) male and female mice. The animals were survived for 15 days to observe therapeutic effects. Neurobehavioral deficits and grip strength were performed before (baseline) and after ICH on days 1, 3, 5, 7,10, and 15. Both male and female mice suffered from neurobehavioral deficits after ICH, which was mitigated by

cofilin siRNA treatment. Following the ICH, mice exhibited a sustained functional deficiency of the forelimb strength which was improved with cofilin siRNA treatment. The cognitive function assessed by Y-maze (spatial memory) at 11, 12, 13, and 14 days showed improvement with cofilin siRNA treatment in both male and female mice. These results suggest that siRNA-based gene therapy presents a viable treatment option for ICH.

Title: Raloxifene decreases lumbar intervertebral disc degeneration and increases rewarding corn syrup intake in aged female mice.

Authors: *O. EL JORDI[1], N. BHADOURIA[2], D. L. MCKINZIE[1], N. HOLGUIN[3]; [1]Pharmacol. & Toxicology, Indiana Univ. Sch. of Med., Indianapolis, IN; [2]Sch. of Mechanical Engin., Purdue Univ., West Lafayette, IN; [3]Dept. of Mechanical and Energy Engin., Indiana University-Purdue Univ., Indianapolis, IN

Abstract: Among various bone-related consequences, osteoporosis elevates the risk for vertebral fractures and can promote intervertebral disc (IVD) degeneration that results in chronic back pain and adversely affects activities of daily living. Raloxifene, a selective estrogen receptor modulator, is indicated for osteoporosis in postmenopausal women and has therapeutic benefit in reducing both vertebral fractures and, for unclear reasons, providing symptomatic relief of back pain. Using aged female C57BL/6J mice as an animal model of age-related IVD degeneration, we hypothesized that raloxifene would attenuate IVD pathology and improve physical and psychological measures of health. Mice (n=8/group) were treated for 6 weeks with single daily injections (Monday-Friday dosing) of either raloxifene (0.5 mg/kg) or vehicle. Both prior to and following treatment, mice were evaluated for grip strength, hind-limb clasping, open-field locomotor activity in a light-dark preference test, and consumption of a highly palatable corn syrup solution. Treatment, food and water intake, and wheel running behavior were monitored continuously using home-cage telemetric recording. Following treatment and behavioral assessments, mice were necropsied and spinal degeneration quantified using a computed total IVD degeneration score and section-wise score (nucleus pulposus/annulus fibrosus) of Safranin-O stained motion segments. Additionally, pain biomarker Substance P expression was quantified by immunohistochemistry. Pathology results found a significant reduction in total IVD and

section-wise degeneration scores ($p<0.05$, between-group t-test) in mice treated with raloxifene relative to vehicle treatment. Moreover, raloxifene treatment resulted in significantly reduced Substance P expression levels. Interestingly, the most pronounced behavioral assessment that detected an effect of raloxifene was intake of the highly palatable corn syrup solution. While both groups drank little water when provided with an overnight access to corn syrup, raloxifene-treated mice drank 20% more corn syrup solution than controls. The selective effect of raloxifene treatment on this palatability drinking measure of hedonia suggests potential therapeutic benefit in improving affective domains impacted by IVD degeneration and warrant further investigation.

Title: The neurobehavioral and neurochemical effects of early, chronic methamphetamine exposure in adult and middle-aged mice

Authors: *D. L. DAVIS, P. H. VANN, J. M. WONG, D. B. METZGER, R. A. SHETTY, M. J. FORSTER, N. SUMIEN;
Pharmacol. and Neurosci., Univ. of North Texas Hlth. Sci. Ctr., Fort Worth, TX

Abstract: Prescription stimulant misuse has increased over the last decade, with amphetamine-type stimulants becoming the second most used drug by American college students. Misuse of these psychostimulant drugs can lead to serious health effects linked to their high abuse liability and potential for neurotoxicity. Even at moderate doses, psychostimulants can increase cellular oxidative stress via auto-oxidation or metabolism of dopamine. Heightened levels of oxidative stress have been associated with neurobehavioral impairments and dopaminergic pathways are particularly vulnerable to oxidative insults. We hypothesize that oxidative stress may act as a prominent cellular mechanism in mediating psychostimulant-induced neurotoxicity and associated neurobehavioral deficits. Our study examined the short and long-term consequences of chronic administration of the prototypical psychostimulant, methamphetamine (METH), on motor and cognitive function and markers of oxidative stress, dopaminergic and glial function. Groups of 4 month old young male and female (short-term group, n = 11-12; long-term group, n

= 19-20) C57BL/6J mice received non-contingent intraperitoneal injections of either saline or methamphetamine (1.4 mg/kg) twice daily for 4 weeks (Mon-Fri). The short-term (ST) cohorts were behaviorally tested 2 weeks after the last injection and the long-term (LT) cohorts, were tested every 2 months for motor function and for cognition 4 months after the last injection. Behavioral tests were: the Morris water maze, active avoidance, and fear conditioning, bridge walking coordinated running and gait analyses. After behavioral testing, the mice were euthanized and the brain was further processed to measure oxidative stress, dopaminergic function (tyrosine hydroxylase (TH); Dopamine Transporter (DAT)), and glial function (GFAP). Our behavioral outcomes revealed cognitive deficits in the short-term cohorts, with no long-lasting effect in the long-term cohorts. Longitudinal evaluation of motor function supported motor deficits in gait and coordinated running, while bridge walking and spontaneous activity were not affected. TH and oxidative stress were not greatly affected in both ST and LT groups, while DAT was increased in the ST and marginally in the LT cohort. GFAP, especially the caspase 6-mediated cleavage product, was affected in both ST and LT cohorts. These findings do not support our hypothesis that oxidative stress played a major role in METH-induced impairments of motor and cognitive function. These data indicate that dopaminergic pathway disturbance and astrocytes may play a role in these observed neurobehavioral impairments.

Title: iPSC-derived immune cells have a regenerative effect in mouse models of aging

Authors: *V. A. MOSER, R. M. LIPMAN, M. J. WORKMAN, C. N. SVENDSEN;
Board of Governors Regenerative Med. Inst., Cedars-Sinai Med. Ctr., West Hollywood, CA

Abstract: Previous studies have demonstrated the ability of young blood or plasma to restore cognitive function in aged animals and our lab has shown beneficial effects of young mouse-derived bone marrow transplants into aged mice. However, both of these strategies have significant practical drawbacks that limit their therapeutic value. Induced pluripotent stem cells (iPSCs) offer the ability to generate an autologous therapy. Thus, we sought to identify the cell type responsible for the beneficial effects observed in studies using young plasma and bone

marrow. We generated macrophages from iPSCs (iMACs), which express low levels of the hematopoietic stem cell marker CD34, and high levels of the monocyte/macrophage markers CD11b, CD14, and CD16. iMACs were administered to aged, genetically immunocompromised NOD-scid-gamma (NSG) mice via tail vein injection. Mice received treatments every 3rd day for 22 days and were tested on a number of behavioral assays. We find significant improvements in spatial working memory in the spontaneous alternation test as well as in hippocampal-dependent short-term memory in the novel object placement assay. Treatment with iMACs has significant effects on several key neuronal health indices including the synaptic transporter, VGLUT1, which is decreased in aged mice but restored with treatment. Moreover, the increased numbers of astrocyte and microglia as well as the decrease in microglial branch length seen in aged animals are all reversed by treatment with iMACs. These findings suggest that immune cells, specifically monocytes and macrophages, may be responsible for the regenerative effects previously observed after young plasma transfusions or bone marrow transplants. Importantly, we find that iMACs have significant regenerative potential in aging.

Title: Pharmacokinetics and distribution of AKST4290, a CCR3 antagonist with anti-inflammatory properties in the eye and brain

Authors: *S. RAINA, R. HARISH, Y. LOPEZ, S. REGE, J. MASUMI, A. TEICHERT, O. S. DHANDE, S. S. MINAMI;
Alkahest, San Carlos, CA

Abstract: Age-related macular degeneration (AMD) is an inflammation driven degenerative disease and can lead to severe vision loss. After receiving 6 weeks of orally dosed AKST4290, a potent CCR3 inhibitor, the majority of neovascular AMD (nAMD) patients in phase 2a trials showed stable or improved best-corrected visual acuity. We used the sodium iodate model to investigate the effects of CCR3 inhibition on retinal inflammation. CCR3 inhibition significantly reduced CXCL9 and CCL5, potent immune cell chemoattractants, in the eye. This suggests that inhibition of the CCR3-mediated immune response may reduce ocular inflammation, which in turn may contribute to the efficacy of AKST4290 observed in nAMD patients.
To identify the potential sites of action, pharmacokinetic studies were conducted in the eye, as well as the brain. Autoradiography (ARG) and quantitative whole-body autoradiography

(QWBA) analysis showed preferential retention of orally dosed AKST4290 in the uveal tract in both male and female mice. To localize the retention of AKST4290 in the eye, different retinal compartments were analyzed using liquid chromatography with tandem mass spectrometry (LC-MS/MS) and AKST4290 was found to be retained at higher levels in the retinal pigmental epithelium (RPE)/choroid compared to the retina. QWBA and LC-MS/MS was also used to assess the impact of pigmentation on drug concentration and showed that there were increased levels of the drug in pigmented RPE versus non-pigmented RPE. Additionally, AKST4290 has also been shown to reduce neuroinflammation in the brain. QWBA was used to assess the site of action in the brain and showed no AKST4290 present. LC-MS/MS analysis also showed very low levels in the brain, together demonstrating that it is non-brain penetrant drug. These data suggest that AKST4290 treatment for nAMD can act both systemically as well as centrally in the RPE/choroid, where action may occur through inflammatory pathways.

Title: Zenchi - a VR-based remote patient monitoring system for diagnosis of obstructive sleep apnea in Parkinson's disease patients

Authors: *J. ALZAGATITI, K. AJJARAPU, K. PANDRANGI;
Univ. of California Santa Barbara, Isla Vista, CA

Abstract: Parkinson’s disease (PD) is the second most common neurodegenerative disease. It is characterized by motor and non-motor features, one of which is obstructive sleep apnea (OSA). OSA is reported in 20-60% of PD patients and is diagnosed through polysomnography at a sleep center. However, due to COVID-19 restrictions to in-person care, telehealth monitoring of sleep data to detect OSA is a key alternative. With current telehealth, physicians experience tremendous difficulty accessing patient vitals, such as sleep data, and complex reports, such as CT scans and MRIs. To address this problem, we developed Zenchi, a VR-based remote patient monitoring system. Zenchi enables physicians to view the patient's real-time vitals, e.g. O^2 saturation, heart rate, and sleep data; while also displaying 3D patient reports in an integrated

view, improving the quality of care. Patients are able to use wearables and other devices at home to efficiently send necessary data within Zenchi for physicians to use on demand. Our system can not only identify and monitor OSA within the totality of a patient's medical records, but also help centralize data for physicians for any health issue.

Title: Key Risk Pathways in Aging and Parkinson's Disease Pathogenesis Revealed by Mulitomic Single-nuclei analysis of Human Young, Aged, and PD Midbrain Samples

Authors: *L. ADAMS[1], M. SONG[1], Y. TANAKA[2], Y.-S. KIM[1];
[1]RWJMS Inst. for Neurolog. Therapeut., Piscataway, NJ; [2]Dept. of Med., Univ. of Montreal, Montreal, QC, Canada

Abstract: Parkinson's disease (PD) is the second most common neurodegenerative disease, characterized by the loss of dopamine neurons from the substantia nigra (SN). While many genetic components and environmental risk factors have been identified, aging is the primary risk factor for PD although it remains unclear how aging predisposes an individual to neurodegenerative conditions. In this study, we analyzed 71,106 SN nuclei from 32 individuals to compare young, aged, and PD-diagnosed conditions. We analyzed gene expression and chromatin accessibility simultaneously at the single-nuclei level using paired snRNA-seq and snATAC-seq to identify aging and disease-specific changes in the human midbrain. We identified seven cell types, with oligodendrocytes (OL) making up approximately 75% of the cells in the midbrain. Our data shows widespread, cell type specific changes in chromatin states over aging that influence gene expression. To investigate the contribution of aging to PD pathogenesis, we adapted pseudotime frameworks to combine RNA and ATAC data and established a pseudopathogenesis trajectory between young, old and PD conditions. This analysis allowed us to identify aging and disease relevant cell type populations, their gene expression patterns and chromatin motifs, and compare them with existing GWAS and SNP databases. Astrocytes and oligodendrocyte precursor cells show significant alterations over aging, but no significant differences during PD pathogenesis, suggesting they have little contribution to PD. Interestingly, although dopamine neurons are sparsely myelinated, OL show dramatic changes both over aging and PD. Pseudopathogenesis analysis in OL indicates that genes involved in myelination-related pathways are gradually decreased over aging toward PD, while stress response-related genes are increased. Our multiomic analysis of single-cell transcriptomic and

epigenomic dataset provides an essential resource to further our understanding of how aging affects the midbrain and predisposes this region to degeneration in PD.

Title: Evaluating the Biomarker Potential of c-Abl Pathway Molecules using Serum Derived Exosomes

Authors: *D. BISWAS[1], S. BRAHMACHARI[1], R. SHI[1], W. RANKIN[1], L. ROSENTHAL[2], V. L. DAWSON[1], T. M. DAWSON[1];
[1]Neuroregeneration and Stem Cell Programs, Inst. for Cell Engineering, Johns Hopkins Univ. Sch. of Med., Baltimore, MD; [2]Dept. of Neurology, Johns Hopkins Univ. Sch. of Med., Baltimore, MD

Abstract: The complexities of Parkinson's disease (PD) pathogenesis have made it difficult to produce reliable biomarkers that reflect disease diagnosis. Therefore, discovering molecules that can both be isolated non-invasively and indicate disease severity has significant clinical application. We earlier established that activated c-Abl, a nonreceptor tyrosine kinase (pY245 c-Abl), phosphorylates α-synuclein at tyrosine-39 (pY39 α-synuclein) and both pY245 c-Abl and pY39 α-synuclein levels are profoundly elevated in animal models of PD as well as postmortem PD brains. c-Abl also phosphorylates parkin, an E3 ubiquitin ligase, at tyrosine-143. This inactivates parkin and leads to accumulation of pathogenic parkin substrates such as PARIS (ZNF746) and AIMP2, both of which are also significantly elevated in PD mouse models and postmortem PD brains. As such, we hypothesize that these molecules are elevated in serum-derived exosomes and could serve as blood-based biomarkers for PD. Exosomes are vesicular structures released by all cells and contain proteins and nucleic acids. Particularly, exosomes containing L1CAM, a transmembrane protein preferentially expressed on neurons, was reported as a potential diagnostic tool for neurodegenerative diseases. To determine if L1CAM+ exosomes reflect PD biology, we used a double-blind setup to isolate human serum exosomes from PD patients and age-matched healthy controls in two independent cohorts: Johns Hopkins Parkinson's Disease Biomarkers Program (n=106), and Cleveland Clinic (n=50). L1CAM+ exosomes were obtained with Exoquick™, a nanoparticle-based exosome isolation method,

followed by an enrichment process using L1CAM antibodies. Although L1CAM is preferentially expressed in neurons, it is also found in many other cell types. As a brain-specific window for serum exosomes is not available, we also isolated total serum exosomes from PD patients and age-matched healthy controls from Johns Hopkins Udall Center cohorts (n=66) using a high-throughput size-exclusion-based exosome isolation kit. The levels of pY245 c-Abl, pY39 α-synuclein, α-synuclein, PARIS, and AIMP2 in exosome lysates were determined with immunoblot assays and Meso Scale Discovery (MSD) ELISA assays. The results from immunoblot assays show that pY245 c-Abl, pY39 α-synuclein, PARIS, and AIMP2 levels are significantly elevated in both L1CAM and total serum-derived exosomes among all 3 independent patient cohorts. We further confirm our immunoblot results using quantitative MSD ELISA assays. Taken together, our findings strongly suggest that c-Abl pathway molecules can potentially serve as blood-based diagnostic markers of PD.

Abstract: Proteostasis or protein homeostasis is required by living cells to maintain a functional proteome. Enhanced proteostasis has been related to increased life- and health- span, while proteostasis loss has been described in aging and age-related diseases. In particular, the loss of proteostasis is one of the most common features in neurodegenerative diseases such as Alzheimer's and Parkinson's disease (PD), where different proteins form aggregates that directly affect the progression of the disease and the neuronal survival. Our project focuses on the role

that malfunctioning of a component of the proteostasis network, Chaperone-mediated autophagy (CMA), plays in the pathogenesis of PD. PD is the most common motor disorder in the elderly and it is characterized by severe motor symptoms and dementia. Our group has previously stablished *in vitro* the toxic effect that different PD-related pathogenic proteins such as α-Synuclein or LRRK2 exert on CMA. These CMA alterations in turn could contribute to neurodegeneration and PD progression. In this work, using different mouse models of PD and patient brains, we demonstrate *in vivo* the toxic effect of pathogenic α-Synuclein on CMA activity. We also show how CMA failure can accelerate PD progression and demonstrate the beneficial effect of enhancing CMA activity on PD models. Our results have encouraged us to develop new strategies to overcome the toxic effect of α-Synuclein on CMA. To that effect, we have conducted a genome-wide CRISPR interference screening in cells expressing a pathogenic form of a-Synuclein and a fluorescent reporter for CMA. We anticipate that the newly identified CMA regulators will provide novel targets to modulate CMA with therapeutic purposes in PD.

Title: Imaging and Genetics: Effects of GBA gene on Parkinson's Disease

Authors: *S. GHATTI[1], E. YOON[1], G. LOPEZ[2], D. EHRLICH[1], S. G. HOROVITZ[1]; [1]Natl. Inst. of Neurolog. Dis. and Stroke, Bethesda, MD; [2]Natl. Human Genome Res. Inst., Bethesda, MD

Abstract: Parkinson's Disease (PD) is a common neurodegenerative disorder that is characterized by motor and nonmotor symptoms. A number of genetic variants have been associated with an increased risk for developing PD, such as variants in *GBA*, where specific variants have been associated with faster disease progression. Given these phenotypic changes associated with *GBA* variants, we aimed to explore whether cortical thickness and other markers of neurodegeneration differed in healthy controls and patients with Parkinson's disease with and without *GBA* variants.

Neuroimaging and biospecimen data were obtained from the Parkinson's Progression Markers Initiative (PPMI) database. Using FreeSurfer, we compared T1-weighted MRI images from 47 healthy controls to those of 94 PD patients. The PD cohort included subjects with heterozygousvariants in N370S (N=21), E326K (N=18), T369M variant (N=8) and non-variant carriers (N=47). After an FDR correction of 0.01, we found significant differences between controls and PD patients in ROIs in the following areas: the lateral occipital, superior parietal, and postcentral regions. Within these ROIs, we then compared cortical thickness of each PD group to the control, while accounting for age and ethnicity. Cortical thickness of all PD patients differs fromcontrols in the parieto-occipital areas, where individuals with E326K and T369M variants, aswell as non-variant carriers, showed stronger effects than those with N370S variant. In addition,we compared biospecimen data between the PD groups. There were no significant differences in CSF Abeta, p-tau, and t-tau levels amongst the groups. N370S carriers had significantly higher serum neurofilament light (NfL) levels, a measure of cortical degeneration, among all groups.Our results demonstrate significant cortical thickness changes in PD patients when compared tocontrol group. They also highlight the impact of *GBA* variant on the PD presentation in the parieto-occipital cortex. Finally, they suggest that PD patients with N370S variants have a different disease presentation than PD patients with variants on the same *GBA* gene.

Title: Subcortical iron accumulation pattern may predict neuropsychological outcomes after STN DBS: a pilot study

Authors: *G. BROWN[1], G. DU[1], E. FARACE[2], M. M. LEWIS[1], P. ESLINGER[1], J. MCINERNEY[2], L. KONG[3], R. LI[4], X. HUANG[1], S. DE JESUS[1];

[1]Dept. of Neurol., [2]Dept. of Neurosurg., [3]Dept. of Statistics, Pennsylvania State Univ., Hershey, PA; [4]Dept. of Statistics, Pennsylvania State Univ., University Park, PA

Abstract: Background: Neuropsychological outcomes after deep brain stimulation (DBS) are variable and may arise from the heterogeneous neuropathological processes in Parkinson's disease (PD).
Objective: To explore if brain iron accumulation patterns and its region-specific alterations relate to neuropsychological outcomes post-DBS.
Methods: Thirty-two PD subjects were identified from our database with susceptibility MRI prior to bilateral subthalamic nucleus (STN) DBS between 2011-2016. Demographic (age, sex, education), clinical information (disease duration, neuropsychological scores), and R2* (susceptibility MRI measure reflecting iron) in 11 subcortical regions of interest were obtained. Neuropsychological outcomes were defined as changes in psychomotor speed, executive function, attention, memory, and depression by subtracting pre- and post-DBS scores. A penalized logistic analysis was used to identify the best pre-DBS clinical and R2* predictors for each neuropsychological domain. Pearson's partial correlations explored R2* associations with neuropsychological outcomes.
Results: Combined clinical and MRI metrics were associated better with neuropsychological outcomes ($R^2 \geq 0.373$, p-value≤ 0.008) than either alone. Adding R2* metrics increased prediction of executive function ($R^2=0.455$, $p=0.008$) and attention ($R^2=0.182$, $p=0.018$) outcomes over clinical metrics alone. Specifically, R2* in the substantia nigra, caudate, STN, and hippocampus improved prediction of executive function, and in the putamen for attention. Interestingly, higher caudate R2* correlated with better executive function ($p=0.043$), whereas higher putamen R2* associated with worsening attention ($p=0.018$).
Conclusions: Brain iron accumulation patterns, captured by susceptibility MRI, may add value to clinical evaluation in predicting neuropsychological outcomes post-DBS in PD. Further studies are warranted to validate these findings and understand the region-specific relationships between iron and DBS outcomes.

Abstract: Ketamine has been shown to produce analgesia in various acute and chronic pain states; however, abuse liability concerns have limited its utility. The ketamine metabolite (2R,6R)-hydroxynorketamine ((2R,6R)-HNK) produces antidepressant-like effects similar to ketamine without the abuse liability concerns. (2R,6R)-HNK produces sustained analgesia in models of chronic pain but has yet to be evaluated in models of acute pain. The present study evaluated the efficacy of (2R,6R)-HNK in assays of pain-stimulated (hot plate test and acetic acid writhing) and pain-depressed behavior (locomotor activity and rearing). In assays of pain-stimulated behaviors, (2R,6R)-HNK (1-32 mg/kg) failed to produce antinociception in the hot plate (52- and 56-degree) and acetic acid writhing assays. In assays of pain-depressed behaviors, 0.56% acetic acid produced a robust depression of locomotor activity and rearing that was not blocked by pretreatment of (2R,6R)-HNK (3.2-32 mg/kg). The positive controls morphine (hot plate test) and ketoprofen (acetic acid writhing, locomotor activity, and rearing) blocked pain-stimulated and pain-depressed behaviors. These results suggest that (2R,6R)-HNK is unlikely to have efficacy in treating acute pain; however, the efficacy of (2R,6R)-HNK in chronic pain states should continue to be evaluated.

Health, Adams Sch. of Dent., Univ. of North Carolina, Chapel Hill, Chapel Hill, NC; [6]Alan Edwards Ctr. for Res. on Pain; Fac. of Dentistry; Dept. of Anesthesia, Fac. of, McGill Univ., Montréal, QC, Canada

Abstract: MicroRNAs (miRNAs) are of growing importance to the understanding of pain neurobiology. To identify miRNAs contributing to pain, our group evaluated expression of miRNAs and respective mRNA targets in cohorts with chronic and first-onset pain: one with chronic temporomandibular disorder (TMD) (N= 488) and one with acute pain following a motor vehicle collision (MVC) (N= 167). We found that miR-374a-5p was downregulated in both male and female patients with TMD and MVC-related pain compared to controls. Further, miR-374a-5p was downregulated in our pre-clinical mouse model of acute stress and pain (N= 31). This work provided the first link between miR-374a-5p and pain. What remains unknown is the tissue-specific regulatory effects of circulating miR-374a-5p on its mRNA targets. Thus, the purpose of the present study was to measure expression of miR-374a-5p's mRNA targets associated with clinical pain in tissues collected from mice undergoing stress and pain. Of the 350 mRNA targets upregulated in patients with TMD, we selected 10 (ATXN7, CBL, CRK, CRKL, EP300, HIF1A, KIDINS220, NUMB, PTPN11, TGFBR2) to measure in our mouse model based on: strength of association with miR-374a-5p, magnitude of fold-change in TMD cases compared to controls, and gene function implications. Wildtype male and female C57BL6 mice ~8-12 weeks old were exposed to forced swim stress or sham swim for 3 consecutive days and then, on day 3 following swim, they received an i.p. injection of the COMT inhibitor OR486 or vehicle (N= 4M+4F x 4 groups = 32 mice). Tissues (leukocytes, intrascapular brown adipose, visceral white adipose, subcutaneous white adipose, dorsal root ganglion, and spinal cord) were collected 1 hour following OR486 administration. Relative mRNA expression across conditions was determined by qPCR and 2-ΔΔCt analysis. Differential expression of targets was observed across multiple tissues. Notably, mice with swim stress and COMT inhibition showed increased levels of HIF1A (Hypoxia Inducible Factor 1 Subunit Alpha; stress response), NUMB (NUMB Endocytic Adaptor Protein; neurogenesis), and PTPN11 (Protein Tyrosine Phosphatase Non-Receptor Type 11; cell signaling) in adipose and spinal tissues, with higher levels in females compared to males. This set of correlations provides a novel framework for future experiments to confirm miRNA-mRNA interactions and determine the causal role of miR-374a-5p in the onset and maintenance of pain. Additionally, this work provides rationale for examining specific tissues and sex differences in pain neurobiology.

Title: Rage and tlr5 receptors contribute to nociception in a rat model of fibromyalgia

Authors: *L. E. VILLANUEVA-SOLIS, V. GRANADOS-SOTO;
Pharmacobiology, CINVESTAV, Tlalpan, Mexico

Abstract: Fibromyalgia is characterized by the presence of widespread musculoskeletal pain for which there is no defined cause. Hypersensitivity to pain produced in patients with fibromyalgia could be derived from a dysfunction of the immune system. Evidence suggest that an imbalance of pro- and anti-inflammatory cytokines could lead to the development of hypersensitivity and other co-morbidities in this syndrome. Higher levels of interleucine-8 (IL-8), tumoral necrosis factor (TNF) and high mobility group box-1 (HMGB1) has been found in serum and cerebrospinal fluid of these patients. HMGB1, through the activation of spinal and peripheric Toll-like receptors (TLRs) and advanced glycosylation end products receptor (RAGE) facilitates transmission of pain in models of inflammatory and neuropathic pain. However, the role of TLR5 and RAGE receptors in functional pain is unknown. The purpose of this study was to determine the involvement of TLR5 and RAGE receptors in a reserpine-induced model of fibromyalgia in rats. Subcutaneous administration of reserpine (1 mg/kg, 3 days) in female Wistar rats produced generalized tactile allodynia and muscle hyperalgesia at 5 and 7 days after the last injection, respectively. Von Frey filaments were used to determine tactile allodynia and the Randall-Selitto test was used to assess muscle hyperalgesia. Reserpine-treated rats were intrathecally injected with the TLR5 selective inhibitor TH1020 (30-300 nmol) or the RAGE selective antagonist FPS-ZM1 (1-100 nmol). Intrathecal injection of TH1020 partially reversed tactile allodynia produced by reserpine in a dose-dependent manner. However, this drug had no effect on muscle hyperalgesia produced in this model. Treatment with FPS-ZM1 dose-dependently reduced tactile allodynia induced by reserpine. Nonetheless, administration of the RAGE receptor antagonist had no effect on muscle hyperalgesia produced in this model. In contrast, administration of both drug vehicles had no effect on allodynia or hyperalgesia in this model. Moreover, intrathecal injection of TH1020 or FPS-ZM1 (100 nmol, each) had no effect in pain-like behavior in naïve female rats. These data suggest that activation of TLR5 and RAGE receptors have pronociceptive effects in fibromyalgia-like nociception, with a major role of the RAGE receptor. Results suggest that TLR5 and RAGE receptors contribute to the development of reserpine-induced hypersensitivity, specifically tactile allodynia, in this model of functional pain.

Title: Inhibition of Nociceptor Endocytosis Attenuates Pain Behavior and Disease Progression in MIA-Induced Osteoarthritis.

Authors: J. TABMAN, ***R. RODRIGUEZ**, A. BHATTACHARJEE;
Univ. at Buffalo - The State Univ. of New York, Buffalo, NY

Abstract: Providing safe and effective pain management for osteoarthritis (OA) has become a critical national problem. Injection of corticosteroids into synovial joints is one of the mainstay therapeutic approaches to treat arthritic pain, however, recent studies have put into question their efficacy and point to potential long-term deleterious effects of steroid therapy. Our previous studies have shown that inhibition of the nociceptor endocytotic adaptor protein complex 2 (AP2) reduces neuronal hyperexcitability suggesting that targeting nociceptor endocytosis provides analgesia. Here we demonstrate that pain behavior in arthritis can be reduced by local pharmacological inhibition of the nociceptor AP2 complex using a AP2 cell-penetrating peptide inhibitor. Monoiodoacetate (MIA) was used to induce knee joint OA in Sprague-Dawley rats, and 4 days later after verification of pain, animals were administered a one-time intra-articular injection of either the AP2 inhibitor peptide or a scrambled peptide control into the arthritic knee. Joint pain was assessed by Dynamic Weight Bearing (DWB) and pain behavior was monitored over the course of 28 days post MIA-induced OA. DWB analyses showed the typical decrease in weight bearing on the arthritic knee injected with the scrambled peptide, however an increase in weight bearing was observed, persisting for up to 24 days in the AP2 peptide injected group, indicating an attenuation of pain behavior. Furthermore, micro-computed tomography and histological analyses were performed on arthritic knees as well as the contralateral healthy knee at end of 28 days to evaluate the effects of scrambled peptide vs the AP2 inhibitor peptide on disease progression. Pathological analyses indicated a reduction of subchondral bone content and cartilage formation in scrambled peptide-injected OA knee joints, but intra-articular AP2 inhibitor peptide injection showed a significant retention of bone content and cartilage, suggesting that blocking nociceptor endocytosis decreases OA pathology. Altogether, this study suggests that nociceptor endocytosis plays an important during OA pain, as well as in the pathophysiological process involved in knee joint degeneration.

Title: The pronociceptive role of the mineralocorticoid receptor in inflammatory low back pain in mice

Authors: *K. A. QUALLS, W. XIE, J.-T. ZHANG, J. A. STRONG, S. DAVIDSON, J.-M. ZHANG;
Anesthesiol., Univ. of Cincinnati, Cincinnati, OH

Abstract: Inflammatory low back pain is a common and costly condition in the U.S. that is often treated using corticosteroid injections. These treatments can activate the glucocorticoid receptor (GR), and the mineralocorticoid receptor (MR) with similar potency. While steroids are given to bind the GR to relieve inflammation at the dorsal root ganglion (DRG), the MR has been shown to play a pronociceptive role at the DRG in rat models. **The objective of this work is to characterize the impact of conditional MR knockout in mouse sensory neurons on pain behaviors and neuronal excitability during a model of inflammatory low back pain.** In this study, we first characterized and compared expression profiles of the steroid receptors in mouse and human DRGs using RNAscope to perform in-situ hybridization. We then examined the pronociceptive role of the MR in inflammatory back pain in MR KO mice by crossing MR fl/fl mice with Pirt Cre mice, or by hindpaw injection of AAV9 hSyn-eGFP-Cre. MR fl/fl mice served as controls, and all experiments included both sexes and tested for sex differences before combining results. The local inflammation of the DRG (LID) model was implemented to induce long-lasting inflammatory low back pain. Intracellular sharp-electrode recording was done on whole DRG preparations. RNAscope of human and mouse DRG confirmed that both species exhibit widespread expression of GR and MR mRNAs, lending support for using mice as a model organism, and underlining the importance of these receptors at the DRG. During the LID model, MR KO mice showed a reduction in spontaneous and reflexive mechanical pain measures. Electrophysiology analysis of MR KO mice during this pain model revealed divergent effects on A and C cells. MR KO A cells were less likely to fire multiple action potentials at a suprathreshold stimulus, indicating lower excitability, whereas MR KO C cells had a lower rheobase, indicating higher excitability. We can conclude from these data that MR KO in mouse sensory neurons is therapeutic for mechanical pain behaviors during a model of inflammatory

low back pain. MR KO has opposing effects on neuronal excitability in A and C fibers, suggesting that MR plays a distinct role in these different cell types. This work used a targeted genetic approach to confirm that sensory neuronal MR can exacerbate inflammatory pain in a rodent model and supports that MR could have different mechanisms of action in A and C fibers.

Title: Autonomic regulation of nociceptive and immunologic changes in a model of complex regional pain syndrome

Authors: *P. SAHBAIE[1,2], W.-W. LI[1,2], T.-Z. GUO[2,3], X.-Y. SHI[1,2], W. S. KINGERY[3], J. CLARK[1,2];

Abstract: Chronic pain frequently develops after limb injuries, and its pathogenesis is poorly understood. We explored the hypothesis that the autonomic nervous system regulates adaptive immune system activation and nociceptive sensitization in a mouse model of chronic post-traumatic pain with features of complex regional pain syndrome (CRPS). In studies sympathetic signaling was reduced using 6- hydroxydopamine (6-OHDA) or lofexidine, while parasympathetic signaling was augmented by nicotine administration. Hindpaw allodynia, unweighting, skin temperature, and edema were measured at 3 and 7 weeks after fracture. Hypertrophy of regional lymph nodes and IgM deposition in the skin of injured limbs were followed as indices of adaptive immune system activation. Passive transfer of serum from fracture mice to recipient B cell deficient (muMT) mice was used to assess the formation of pain-related autoantibodies. We observed that 6-OHDA or lofexidine reduced fracture-induced hindpaw nociceptive sensitization and unweighting. Nicotine had similar effects. These treatments also prevented IgM deposition, hypertrophy of popliteal lymph nodes, and the development of pronociceptive serum transfer effects. We conclude that inhibiting sympathetic or augmenting parasympathetic signaling inhibits pro-nociceptive immunological changes

accompanying limb fracture. These translational results support the use of similar approaches in trials potentially alleviating persistent post-traumatic pain and, possibly, CRPS.

Title: Spontaneous activity in long-term organotypic cultures of the adult human spinal cord

Authors: *V. JEEVAKUMAR, T. INDERSMITTEN, T. COTTA, T. WONG, Y. MIRON, N. ABI-GERGES, A. GHETTI;
AnaBios, San Diego, CA

Abstract: Neurons of the spinal cord (SC) form a pattern generator of spontaneous rhythmic bursting activity and oscillations. SC research typically relies on studies conducted with CNS tissue derived from animal models. However, CNS clinical attrition is in part a consequence of the inability of these animal models to generate data predictive of human responses. The ideal test system would utilize human primary tissue, afford reasonable throughput and be highly correlated with clinical outcomes. With our well-established human tissue recovery model from organ donors, we are in an ideal position to perform assays directly on human CNS tissue. To this end, we developed an organotypic slice culture system of adult hSC slices. SCs obtained from organ donors were transported to our laboratory in a protective solution, sliced into 400 µm sections on a vibratome, and cultured in a medium to support neuronal viability up to 27 days in-vitro. We performed Ca^{2+} imaging on the slices to quantify spontaneous activity (SA), focusing on the dorsal horn which receives synaptic inputs from nociceptors in the dorsal root ganglia. Slices were loaded with Fluo-8 AM and imaged on an Olympus IX71 inverted scope at 2 Hz for 10 min of vehicle baseline, followed by 5 min of drug perfusion, and 10 min of acquisition, repeated for each drug / concentration. Neurons were identified as those responding to the application of 1 µM TTX. The persistence of SA was observed on days-in-vitro 20 and 27. Bath application of the AMPAR antagonist CNQX (10 µM) reduced SA, which was subsequently abolished by co-application of the NMDAR antagonist APV (100 µM). Next, we tested Carbamazepine (Tegretol), a Na^{+} channel blocker. Although Carbamazepine is used for the treatment of epilepsy, peripheral neuropathy, and trigeminal neuralgia, it can cause CNS side effects, like dizziness, nausea, mood swings and depression. Therefore, we tested the effects of Carbamazepine on SA at therapeutic exposure (3 µM) and 3- and 10-fold above the therapeutic concentration. SA in the hSC slices was reduced by Carbamazepine in a dose-dependent manner

with an IC_{50} value of 9.2 µM. TTX abolished any remaining SA. Our data shows for the first time that: 1. SA can be reliably measured in adult human CNS tissue up to 4 weeks *in vitro*, which will allow long-term studies of synchronicity, network dynamics and perturbations in the diseased CNS state; 2. Organotypic hSC slice cultures can provide a valuable translational tool for the evaluation of the efficacy and safety of novel CNS drug candidates.

Title: Modulation of ASIC1b/3 by endogenous molecular zinc

Authors: Q. JIANG, M. WILLIAM, X. ZHA, ***X. CHU**;
Univ. of Missouri Kansas City, Kansas City, MO

Abstract: Acid-sensing ion channels (ASICs) are proton-gated ion channels and highly expressed in nervous system. Two subunits, ASIC1b and 3, are highly expressed in peripheral sensory neurons. They are sensitive to endogenous biomolecule zinc at micromolar concentrations and plays a critical role in physiological and pathophysiological conditions, especially in pain sensation. Our previous studies have shown that both homomeric ASIC1b and ASIC3 are not sensitive to zinc by co-application. However, pretreatment with zinc dose-dependently inhibits homomeric ASIC1b currents with an IC_{50} of 26 µM and cysteine 149 in the extracellular domain is responsible for this inhibition. While, pretreatment with zinc also inhibits homomeric ASIC3 currents with an IC_{50} of 61 µM in a sharp range. Here, we found that ASIC1b and ASIC3 were co-expressed in CHO cells. Further, the currents recorded from heterologous expressed ASIC1b/3 channels by whole-cell patch-clamp, were modulated by zinc. Co-application of zinc did not affect both peak amplitude and sustained component of heteromeric ASIC1b/3 currents. While pretreatment with zinc induced a significant inhibition of peak amplitude and potentiated the sustained component of heteromeric ASIC1b/3 channels when zinc concentrations were over 300 µM. These findings suggest that endogenously biomolecule zinc is a modulator of heteromeric ASIC1b/3 channels.

Title: Cgrp signaling in the left versus right central amygdala has differential effects on bladder pain modulation in female mice

Authors: *H. N. ALLEN[1,2,3,4,5], B. J. KOLBER[4,5];
[1]Biol. Sci., [2]Chronic Pain Res. Consortium, Duquesne Univ., Pittsburgh, PA; [3]Pittsburgh Ctr. for Pain Res., Univ. of Pittsburgh, Pittsburgh, PA; [4]Behavioral and Brain Sci., [5]Ctr. for Advanced Pain Studies, Univ. of Texas at Dallas, Dallas, TX

Abstract: The central amygdala (CeA) is a bilateral, mid-brain limbic region that is involved in the processing of pain and emotion. Specifically, the CeA is involved in the processing and modulation of urologic chronic pelvic pain syndromes. Interestingly, the left and right CeA are functionally lateralized and manipulation of left versus right CeA cells has opposing effects on bladder pain. However, the specific mechanisms driving these divergent functions are unknown. Nociceptive signals from the bladder are relayed to the CeA via projection neurons from the parabrachial nucleus (PBN) that express high levels of calcitonin gene-related peptide (CGRP). The aim of this study was to investigate the influence of parabrachial (PBN) CGRP signaling in the left and right CeA on the lateralized modulation of bladder pain. Both optogenetic and pharmacological manipulation of left and right PBN-to-CeA CGRP terminals resulted in opposing effects on bladder pain-like behaviors. Optogenetic activation of CGRP terminals in the left CeA decreased bladder pain-like behaviors while activation of CGRP terminals in the right CeA increased bladder pain-like behaviors. Similarly, pharmacological activation of CGRP receptor cells via CGRP agonist decreased bladder pain when infused in the left CeA but increased bladder pain when infused in the right CeA. Both optogenetic inhibition of CGRP terminals from the PBN in the left CeA and pharmacological inhibition of CGRP receptor cells in the left CeA increased bladder pain-like responses, suggesting that there is ongoing, anti-hyperalgesic CGRP signaling in the left CeA. In a similar but contrasting manner, both optogenetic inhibition of right PBN-to-CeA CGRP terminals and pharmacological inhibition of right CeA CGRP receptor cells decreased bladder pain-like responses, indicating that CGRP signaling in the right CeA is pro-nociceptive. Effects of optogenetic activation of CGRP were able to be blocked by co-infusion with a CGRP antagonist but not a cocktail of AMPA and NMDA receptor antagonists. Similarly, CGRP knock out animals showed no effects of optogenetic manipulation of PBN-to-CeA CGRP terminals, suggesting that CGRP signaling is the driving force of CeA lateralization in the context of bladder pain.

Title: Identification of fungal secondary metabolites with anti-nociceptive activity using a zebrafish model

Authors: *J. A. STROTHER, S. K. ESTES, M. DEADMOND, E. M. MARSHALL, S. LOESGEN;
Univ. of Florida, Saint Augustine, FL

Abstract: Chronic pain is a leading cause of disability and disease and there is an urgent need to develop new therapeutic approaches. Natural products, or compounds isolated from biological sources, have been a reliable source for drug leads and account for a large fraction of clinically approved drugs. However, identifying novel compounds with novel pain-relieving, or anti-nociceptive, activity has been hindered by available testing methods and the difficulty of determining the mechanistic basis of active compounds. To address these challenges, we developed a novel zebrafish-based behavioral assay for anti-nociceptive activity and then surveyed a library of fungal secondary metabolites. We identified several fungal metabolites with previously undescribed anti-nociceptive activity. To determine the mode of action of these compounds, we then used *in vivo* cellular-resolution, whole-brain calcium imaging to locate the neuronal populations affected by active compounds. These results suggest that fungal secondary metabolites are a promising source for anti-nociceptive compounds, and indicate that whole-brain calcium imaging mapping is a valuable tool for understanding the mode of action of active compounds.

Title: Brain networks underlying disability in adolescents with chronic pain

Authors: *R. JABAKHANJI[1,2], M. N. BALIKI[4,3,2], D. AMSTUTZ[4,3], G. REVIVO[4,3];
[1]Physiol., [2]Ctr. for Translational Pain Res., [3]Physical Med. and Rihabilitation, Northwestern Univ. Feinberg Sch. of Med., Chicago, IL; [4]Shirley Ryan AbilityLab, Chicago, IL

Abstract: Chronic pain is a serious problem within the pediatric population and is multi-factorial in nature. Here we investigate the behavioral and brain properties associated with various disability measures in adolescents with chronic pain. Nine adolescents with chronic pain (Females, 14-17yo) were recruited from the pain rehabilitation program at the Shirley Ryan Ability Lab. All participants completed the Bath Adolescents Pain Questionnaire (BAPQ), the Tampa Scale for Kinesiophobia (TSK), the Canadian Occupational Performance Measure (COPM), a 6 Minute Walk Test (6MWT), and rated their pain (0-10). Parents completed the Bath Adolescent Pain Parental Impact Questionnaire (BAP-PIQ). We also collected one anatomical (T1-weighted), and two resting state MRI scans per subject.Unique disability measures were identified using PCA analysis. All disability measures loaded on 3 orthogonal factors mainly 1) functional disability (FD) that included BAPQ - Daily Function, TSK, and 6MWT, 2) Occupational disability (OD) that included BAPQ-Development and COPM and 3) emotional disability that included BAPQ-Emotional Functioning. Pain intensity was only associated to FD ($r=-0.59$, $p=0.096$), while pain duration was correlated to ED ($r = 0.56$, $p=0.12$). Finally, OD was associated with the parent catastrophizing subscale ($r =0.53$, $p=0.13$). Resting state data was analyzed using standard methods. Following image preprocessing and registration, we utilized a standard parcellation schema to determine the correlation between defined brain networks. Association between network connectivity and disability measures were then identified using Pearson correlation ($p<0.05$). FD was mainly associated with decreased cingulo-opercular (CO) - memory retrieval (MR) networks connectivity as well as decreased and Dorsal attention (DA)- salience (Sal) networks connectivity. In contrast, OD was related to increased DA - somatosensory (SS) networks connectivity, and negatively correlated with the frontoparietal (FP) - subcortical networks connectivity. Finally, ES was related to decreased DMN – subcortical network connectivity and increased DMN connectivity to somamatosensory regions.Overall, our results show that pain related disability in adolescents exhibit unique behavioral and brain mechanisms that may aid clinics in optimizing pain rehabilitation protocols.

Title: Learning the temporal statistics of pain states: computational mechanisms and neural correlates

Authors: *F. MANCINI[1], S. ZHANG[2], B. SEYMOUR[3];
[1]Dept. of Engin., Univ. of Cambridge, Cambridge, United Kingdom; [3]NDCN, [2]Univ. of Oxford, Oxford, United Kingdom

Abstract: Pain invariably changes over time, and these temporal fluctuations are riddled with uncertainty about body safety. In theory, statistical regularities of pain through time contain useful information that can be learned, allowing the brain to generate expectations and inform behaviour. To investigate this, we exposed healthy participants to long probabilistic sequences of low and high pain stimuli (electrical pain to the left hand), containing sudden changes in background statistics (frequencies). We demonstrate that humans can learn to extract these regularities, and explicitly predict the likelihood of forthcoming pain intensities in a manner consistent with optimal Bayesian models. We studied brain activity using fMRI whilst subjects performed the task, which allowed us to dissect the underlying neural correlates of these statistical inferences from its statistical surprise. We found that the inferred frequency (posterior probability) of high intensity pain correlated with activity in bilateral sensorimotor cortex and caudate, right secondary somatosensory cortex and nucleus accumbens. This activity therefore tracks the background frequency of high pain states, over and above the encoding of stimulus intensity. An intrinsic part of this hierarchical Bayesian model is the way that unexpected changes in frequency lead to re-learning, and this is reflected by a type of prediction error (KL divergence between consecutive posterior distributions). This was associated with brain responses in the premotor cortex (green clusters in fig), adjacent to the regions inferring the frequency of high pain states (yellow clusters in fig). In conclusion, we show that humans can infer the background temporal statistics of pain in a Bayesian manner, and that distinct sensorimotor and premotor subregions dynamically encode temporal inferences and their prediction error.

Overlaying Bayesian prediction error with temporal inference of high pain (posterior mean).
FDR corrected p<0.001, colorbar shows Z scores, thresholded at Z>3.3.

Title: Neurofunctional connections supporting mindfulness-based pain relief

Authors: *G. RIEGNER[1], G. POSEY[2], V. OLIVA[1], L. KHATIB[1], J. BAUMGARTNER[1], R. KRAFT[2], Y. JUNG[3], F. ZEIDAN[1];
[1]Anesthesiol., UCSD, La Jolla, CA; [2]Wake Forest Sch. of Med., Winston-Salem, NC;
[3]Radiology, Univ. of California, Davis, Davis, CA

Abstract: Mindfulness meditation reduces pain through multiple brain mechanisms. Yet, those involved explicitly during meditation and a painful stimulus are poorly characterized. The proposed pre-registered study (NCT03414138) employed multiple neuroimaging analytical methods to determine a) if mindfulness reduces the *neurologic pain signature* (NPS), a multivariate pattern of voxel weights predictive of pain intensity and, b) the neurofunctional connections supporting mindfulness-based pain relief during a noxious stimulus.

After a baseline testing session, 40 pain-free participants (mean age = 30 years, 20 females) were randomized to four, 20-minute sessions of mindfulness training or book listening. Following completion of the interventions, fMRI scans were acquired during noxious heat stimulation of the right calf (ten, 12-second 49°C trials; Medoc Inc). All subjects rested pre-manipulation and then meditated (mindfulness group) or continued to rest (control group). After each scan, visual analog scale (VAS) ratings of pain intensity (0 = "no pain" to 10 = "worst pain imaginable") were collected. A 2 (group) X 2 (pre- vs post-manipulation) RM ANOVA determined if mindfulness significantly reduced pain. A paralleling whole-brain RM ANOVA was conducted (FSL 6.0.4). For each fMRI scan, a vector of regression coefficients corresponding to voxel activations was compared to the NPS by the dot-product, returning a scalar value representing pattern similarity. Additionally, within-group ventromedial PFC (vmPFC) (derived from a large meta-analysis) to whole-brain functional connectivity was performed. Cluster-level inference was defined by a threshold of $p < .001$ and family-wise error rate of $p < .05$.
The interaction on VAS pain ratings, $p < .001$, $\eta p^2 = .41$, was driven by the reduction in pain during mindfulness (-32%) when compared to controls (+20%). The NPS interaction, $p = .002$, $\eta p^2 = .23$, was associated with a response reduction in the meditation group ($p = .006$) but not the controls ($p = .10$). The whole-brain GLM demonstrated that mindfulness-based pain relief was associated with greater vmPFC deactivation. Functional connectivity analyses revealed that weaker vmPFC connectivity with the contralateral anterior insula and fronto-parietal operculum predicted greater analgesia.
These preliminary findings demonstrate that mindfulness reliably reduces direct behavioral and neural mechanisms of pain. We also reveal that mindfulness-induced pain relief is associated with greater decoupling between the vmPFC, a brain mechanism critical for self-related appraisals of the sensory environment, and brain regions supporting sensory pain discrimination.

Title: Structural brain connectivity predetermines early acute pain in mild traumatic brain injury

Authors: *P. BRANCO[1], N. BOSAK[2], O. CONG[1], J. BIELEFELD[1], Y. GRANOVSKY[2], D. YARNITSKY[2], A. APKARIAN[1];
[1]Ctr. for Translational Pain Res., Northwestern Univ., Chicago, IL; [2]Rappaport Fac. of Medicine, Technion – Israel Inst. of Technology, Haifa, Israel, Haifa, Israel

Abstract: Acute pain is one of the most debilitating symptoms of mild traumatic brain injury (mTBI). It can last for days-to-weeks, and, for many patients, it can persist for years; and its magnitude is a strong predictor of chronic pain post mTBI. There is a poor relationship between pain reports, tissue injury, and imaging findings of the injured tissue. Here we test the hypothesis that mTBI acute pain (within 48 hours of car accident) is in part predicted by brain structural and resting state connectivity. Resting state fMRI (rsfMRI), anatomical (T1) and white matter (DTI) brain scans were collected in 155 mTBI patients immediately after a car accident (within 48 hours). All participants also underwent pain psychophysical testing, and clinical and demographic measures were also collected. We used a robust machine-learning pipeline to map acute pain to DTI and rsfMRI connectivity properties. Brain predictors of acute pain were then related to clinical and pain related measures. We show that white-matter brain properties - but not functional properties - explain a quarter of the variance in pain ratings after injury; this finding replicated in two additional independent samples of 38 and 13 patients with and without whiplash-like symptoms, respectively. These findings were not dependent on injury-related clinical or demographic characteristics. Instead, white matter properties mapped to conditioned pain modulation and pain sensitivity scores. Together, these parameters could explain a third of the pain variability irrespective of tissue damage. White matter connectivity showed strong within-subject reliability because it did not change up to a year after the injury; and connectivity metrics collected at baseline, as well as at six months, were able to predict subjects' pain up to six months after the initial injury. The study is the first evidence that brain structural connectivity properties can determine a large portion of the variance of acute pain for mTBI. As these properties were invariant over months from the injury and could still be related to mTBI pain, we conclude that they are preexisting properties. We speculate that resting state fMRI could not be related to the acute mTBI pain as it may be perturbed by multiple negative emotional states during acute mTBI.

Abstract: Patients with chronic back pain (CBP) and disability represent a formidable challenge to scientists and health professionals. A better understanding of the behavioral and neural factors affecting disability can provide a conceptual framework for the evaluation and treatment of CBP patients. In this study we determine the demographic, pain, and psychological properties associated with disability and then identify the unique brain networks mediating their effects using resting state fMRI (rs-fMRI).
We recruited 2 groups of CBP patients for this study. Group 1 (n=143) was used to investigate the behavioral correlates of pain disability, while group 2 (n= 130) was used for validation . Disability was assessed using the Oswestery disability index (ODI). In addition, patients completed various questionnaires including numerical pain rating (NRS), pain duration, exercise and smoking frequency, pain anxiety symptom scale (PASS), pain catastrophizing scale (PCS), Becks depression index (BDI), Positive and negative affect schedule (PANAS). Finally, rs-fMRI and anatomical images were collected for all patients in Group2.
The relationship between ODI and behavior was determined using multiple linear regression with cross-validation in group 1. Only NRS and PASS-avoidance showed significant regression across all folds ($R^2 = 0.48$, $p<0.01$). This relationship was validated in group 2 ($R^2=0.44$, $p<0.001$). rs-FMRI dawas analyzed using standard methods. Following image preprocessing, we utilized a standard parcellation schema to determine the correlation between 260 ROIs across 12 defined brain networks. Functional connectivity associated with ODI was determined using robust regression ($p<0.05$, FDR corrected). ODI was associated with 72 pair-wise connections mainly localized to somatosensory, default-mode and salience networks. In order to determine whether this connectivity patter mediated the effect of pain and PASS-avoidance on disability, we first used a PCA analysis to decompose the 72 “betas” into 20 orthogonal components that accounted to 80% of the variance. The components were submitted to mediation analysis. Only component 1 significantly mediated the effect of pain intensity (a, b, ab paths $p<0.001$) as well as PASS-avoidance (a, b, ab paths $p<0.05$). Finally we validated our mediation results in 20 patients with high-impact pain.
Overall our results show that disability in chronic pain patients is primary mediated by pain intensity and avoidance. Therefore therapeutic approaches specific targeting these clinical properties may be successful in managing disability in chronic pain patients.

Title: Constituent dimensions of chronic pain domains and their relationship to psychology and brain connectivity.

Authors: *C. BONIN PINTO[1,2], J. BIELEFELD[2,1], J. BARROSO[2,1], B. YIP[3], L. HUANG[1,2], M. N. BALIKI[4,2], T. SCHNITZER[3,2], V. APKARIAN[1,2];

Abstract: Chronic pain is a multidimensional pathological state. Evidence suggests that specific brain properties and patients' psychological and performance ability traits are modified in chronic pain patients. However, the relationship between these alterations and pain dimensions remains poorly understood.In this cross-sectional analysis, we evaluated multiple dimensions of chronic pain and its relationship with brain connectivity and measures of personality, social interaction, psychological and ability traits (bio-psycho-social traits). By assessing a broad battery of pain-related outcomes questionnaires of 107 chronic low back pain patients we show that chronic pain is characterized by three distinct domains - pain magnitude, pain affect & disability and pain quality. Next, we modeled the relationship between each of these domains and the bio-psycho-social traits. Pain magnitude (OOS $r^2 = 0.33$) and pain affect & disability (OOS $r^2 = 0.79$) were significantly associated with different patterns of patients' bio-psycho-social traits. Pain quality did not relate significantly to these variables. Interestingly, while mindfulness and awareness were major contributors of pain magnitude, social relationship dysfunction seem to be the major contributor for higher pain affect & disability scores.Lastly, we investigated whether specific patterns of brain activity were related to each of the chronic pain domains. Pain magnitude was associated with the sensorimotor and the cingulo-opercular task control networks (OOS $r^2=0.41$). Pain affect & disability related to the functional connectivity within the frontoparietal task control and default mode networks (OOS $r^2 = 0.35$). Finally, pain quality integrated the sensorimotor, auditory, and cingulo-opercular task control networks (OOS $r^2 = 0.43$). By using Neurosynth to provide a meta-analytic summary of terms related to these brain networks, we show that pain magnitude relates mostly to motor and sensory terms, pain affect & disability relates to brain regions associated with memory terms, and the pain quality domain to both memory and motor and sensory terms. Finally, a mediation analysis showed that

the relationship between the bio-psycho-social traits and the pain domains is only partially mediated by the brain functional connectivity networks.Our results show the high-level dimensionality of chronic pain and how distinct facets of the pain experience have different bio-psycho-social correlates and can be determined by unique brain network signatures.

Title: A Novel White Matter Predictor of Resilience to Pain Chronification

Authors: N. LEE[1], Z. ZHANG[2], K. MURRAY[3], ***P. GEHA**[4];
[1]Dept. of Psychiatry in Univ. of Rochester, Rochester, NY; [2]Univ. of North Carolina at Chapel Hill, North Carolina, NC; [3]Universiyt of Rochester, Rochester, NY; [4]Univ. of Rochester, NY, NY

Abstract: Early identification of the likelihood of pain "chronification" is a pre-requisite step for the efficient implementation of preventive treatment. However, validated quantitative prognostic biomarkers that can predict disease trajectory of acute or chronic pain have yet to be identified. Here we identify a brain white matter biomarker of resilience to chronic pain in our data set and validate it on 2 data sets originating at a different site. 27 patients suffering from new onset sub-acute low-back pain (duration 6-12 weeks) were studied at baseline and at 1-year follow-up. 15 patients recovered (SBPr) at follow-up as their pain dropped by > 30% and 12 patients persisted in having pain (SBPp). All patients underwent structural brain imaging to obtain an anatomical and diffusion weighted images (DWI) both at baseline and at follow-up. We compared white matter properties (fractional anisotropy, FA) between SBPr and SBPp patients using tract based spatial statistics (Smith *et al.*, 2006) and using a novel population based structural connectome (SC) (Zhang *et al.*, 2018). T1 and DWI data was also obtained from www.openpain.org from 15 SBPr and 25 SBPr patients both at baseline and at one year follow-up. This data was used to validate our results. Unpaired t-test comparison between SBPr and SBPp patients at baseline revealed increased FA in the right superior longitudinal fasciculus (RSLF) of SBPr patients ($p < 0.05$, whole brain corrected against 5000 permutations) (**Figure 1A**). FA values extracted from the RSLF in the validation data collected at a different site accurately classified SBPr and SBPp patients with an area under the receiver operating

characteristic curve of > 0.75 both at baseline and at follow-up (**Figure 1B-C**). Preliminary study of the SC revealed decreased white matter fiber count ($p < 0.05$, corrected) in SBPr patients between brain areas falling within the right parietal lobe. We conclude therefore that the local properties of the RSLF and its structural connectivity are potential biomarkers for resilience to pain chronification, a result validated across sites.

Title: Sex-related differences in brain morphology in chronic musculoskeletal pain in older adults

Authors: *P. VALDES-HERNANDEZ[1], S. MONTESINO-GOICOLEA[1], A. JOHNSON[1], C. LAFFITTE-NODARSE[1], J. PERAZA-GOICOLEA[1], R. FILLINGIM[1], Y. CRUZ-ALMEIDA[2]; [2]Inst. on Aging, [1]Univ. of Florida, Gainesville, FL

Abstract: Musculoskeletal pain (**MSK**) affects millions of US adults, especially older populations. The neuroanatomical underpinnings of reported differences in prevalence of MSK between females (**Fs**) and males (**Ms**), as well as in experimental and clinical pain measures remain understudied, especially in older adults. This study aimed to compare brain morphological measures (**BMM**) among sexes. Our sample had 77 individuals 61-94 years with and without MSK (**P and NP groups**) from the *Neuromodulatory Examination of Pain and Mobility Across the Lifespan* (*NEPAL*) study at the University of Florida. Participants completed demographic, psychological, and clinincal/experimental pain assessments (**Vars**). T1-weighted anatomical images were acquired with a 3T scanner. Using FreeSurfer (v.7.1.0), cortical volume, areas (**CA**) and thickness (**CT**) and subcortical volumes were calculated in selected areas of the Destrieux atlas known to be related to pain processing (subcentral, frontal, occipitotemporal, postcentral, insulae, cingulate, hippocampi and basal ganglia). Statistical tests were corrected for multiple comparisons using False Discovery Rate ($p<0.05$). We investigated the extent of BMM sex differences on P and NP (sex-by-pain interaction), controlling for age, race and total intracranial volume. This interaction was significant in CA of the left inferior segment of the circular sulcus of the insula (**ICIns-L**). This solely owed to a greater CA in Ms than Fs (significant simple effect of sex) in P, since no significant difference among sexes (no significant simple effect of sex) were found in NP. The interaction was also significant on CT of the middle-anterior part of the cingulate gyrus and sulcus, solely owing to a smaller CT in Ms in P (i.e., there was a significant simple effect of sex in P, no significant simple effect of sex in NP, and no significant simple effect of pain in Fs, but only in Ms). Post-hoc analysis evaluated the moderation of Vars on the sex differences in BMMs in P. The number of anatomical pain sites (**APSites**) and positive scale of the Positive and Negative Affect Schedule (**PANAS-pos**) significantly moderated the sex difference in CA of ICIns-L. Johnson-Neyman (**JN**) analyses showed that this sex difference was significant for APSites equal 3 or higher, where CA in Ms was significantly greater for lower APSites, while did not significantly change across APSites values in Fs. JN also showed that the sex difference in CA of ICIns-L was significant for PANAS-pos higher than 33, being greater for Ms and smaller for Fs for higher PANAS-pos. We provide initial evidence for sex differences in brain structure in MSK in older adults, which may be related to psychological processes.

Title: Poor spatial representation in visual cortex in the absence of visual input

Authors: *C. WILHITE[1], Y. SENZAI[2], M. SCANZIANI[2];
[1]UCSF, SAN FRANCISCO, CA; [2]Univ. of California, San Francisco, San Francisco, CA

Abstract: Recent studies using virtual reality environments in mice have demonstrated that neuronal responses in primary visual cortex (V1) are modulated by spatial location[1,2]. It is unknown, however, whether these signals reflect a higher-order spatial code that can be maintained by self-motion or other sensory cues in the absence of visual input. To explore this question, we record V1 units in freely moving mice on a linear track in various levels of ambient luminance, including pitch darkness. Prior to recording, mice were adequately familiarized on the track in both light-on and pitch-dark conditions. Many cells in V1 maintain consistent spatial modulation across a wide range of luminance levels. In pitch darkness, however, overall spatial information in V1 is strongly reduced and the locations of peak firing fields remap across the entire length of the track. Furthermore, units in V1 that are significantly modulated by spatial location in pitch darkness tend to have peak firing fields at the edges of the track, resulting in reduced spatial coverage compared to light-on conditions. These data indicate that even in familiar environments, spatial representation in V1 cannot be maintained by self-motion or other sensory cues in the absence of visual input.

Title: Direction selectivity is scrambled in visual cortex during saccades

Authors: *S. K. MIURA[1], M. SCANZIANI[2];
[1]Univ. of California San Francisco, San Francisco, CA; [2]Univ. of California, San Francisco, San Francisco, CA

Abstract: Sensory stimuli are often evoked by the animal's own actions. In both vertebrates and invertebrates, nervous systems distinguish these self-generated stimuli from stimuli evoked by changes in the environment. How this distinction is achieved has been the subject of much investigation, especially in the context of saccades. Saccades are rapid eye movements performed by many animals across phyla, and they induce a quick motion of the visual scene on the retina. While behavioral studies indicate that this saccade-induced motion is distinguished from motion that occurs in the environment, the neural mechanisms by which visual systems differentiate the two types of motion are not fully understood. We addressed this issue in mouse primary visual cortex (V1). We report that saccade-induced motion and motion in the environment evoke distinct patterns of activity in V1, even when the resulting visual stimuli on the retina are identical. This is because during saccades, neurons in V1 linearly integrate the visual input with a strong, non-visual input arriving from the pulvinar nucleus of the thalamus. This non-visual input arrives in V1 prior to the initiation of saccades and encodes the direction of the eye movement. Silencing the pulvinar prevented the non-visual input from reaching V1, such that the pattern of activity in V1 was now similar no matter whether the motion was generated by saccades or by changes in the environment. Thus, our work reveals the mechanisms through which the non-visual input ensures differential responses to self-generated motion and external motion in V1.

Title: Inter- and intra-hemispheric sources of vestibular signals to the primary visual cortex

Authors: *G. BOUVIER[1], A. SANZENI[2], N. BRUNEL[2], M. SCANZIANI[1];
[1]Univ. of California, San Francsico, San Francisco, CA; [2]Neurobio., Duke Univ., Durham, NC

Abstract: Sensations often trigger movements, but one's movements also generates sensory experience. Vestibular organs monitor head movements and contribute to the brain's ability to distinguish between self- and externally-generated sensory stimuli. Signals from the vestibular organs are broadcasted throughout the brain, including primary sensory regions like the primary visual cortex (V1). However, what type of signals relative to head movements reach V1 and what the upstream sources of these signals are, remain poorly understood. Here we show that, in the absence of visual input, V1 neurons encode the direction of head rotation as well as the angular velocity and acceleration in a layer specific manner. We also discovered that the ipsilateral latero-posterior/centro-lateral thalamus (LP/CL) and the contralateral visual cortex are key source of vestibular input to V1. The ipsilateral LP/CL provides the main head movement signal and this signal is biased toward contraversive head movements (i.e. clockwise head movements when recording from left V1). Instead, the contralateral visual cortex provides head-movement signals during ipsiversive head movements. Thus, this study reveals a direction specific recruitment of intra- and interhemispheric sources of vestibular signals to V1.

Title: Functional and anatomical map of a visual cortex for the superior colliculus

Authors: *J. BRENNER[1], R. BELTRAMO[2], M. SCANZIANI[3];
[1]Univ. of California San Francisco, San Francisco, CA; [2]Physiology, Develop. and Neurosci., Univ. of Cambridge, Cambridge, United Kingdom; [3]Univ. of California, San Francisco, San Francisco, CA

Abstract: Studies of cortical visual processing in mammals have traditionally focused on the visual pathway that ascends from the retina to primary visual cortex (V1) via the lateral geniculate nucleus of the thalamus, the so-called geniculate pathway. However, visual information can also reach cortex through an alternate "extrageniculate" visual pathway in which retinal projections to the superior colliculus (SC) are relayed through the pulvinar nucleus of the thalamus (PN) before radiating to various regions of the visual cortex. Recent experiments in the mouse (Beltramo 2019) have demonstrated that this extrageniculate pathway is the principal driver of visually evoked activity in one higher-order visual area of the mouse called postrhinal

cortex (POR). However, the extent to which the extrageniculate pathway drives visually evoked activity in other higher visual areas remains uncertain. We used widefield calcium imaging to map the functional impact of the mouse SC on higher visual cortices. Tetrodotoxin injections in SC revealed that, in addition to POR, visual responses in several higher visual areas depend on SC. These include the laterointermediate area (LI), the posterior area, and, partially, the lateromedial area. Blocking synaptic transmission in widefield SC neurons (tagged by the NTSR1-209 line) via the conditional expression of tetanus toxin light chain strongly attenuated visual responses in POR and LI, establishing SC widefield neurons as a main source for SC mediated visual responses in higher visual areas. Using a transsynaptic anterograde tracing approach, we delineated the disynaptic projections from SC through PN to visual cortex and found that the extent of these projection within each higher visual area matched our functional mapping. Finally, we compared the responses for each higher visual area to self versus externally generated motion of visual stimuli. For this experiment, we presented stimuli moving horizontally in the nasotemporal direction such that the speed of the stimulus was either coupled or uncoupled to the running speed of the mouse on a circular treadmill. POR responded preferentially to exogenously generated motion as compared to V1, specifically when the stimuli moved faster than expected from the running speed of the animal. This work thus delineates a map of higher visual areas in mouse visual cortex whose visual responses depend on the SC and identifies the SC neurons that mediate those responses. At least one of these higher visual areas, POR, shows higher selectivity than V1 to external as compared to self- generated visual motion.

Title: Corticotectal Neurons and Putative Fast Spike Interneurons: Distinct Properties of Two Types of Complex Cells in Layer 5 of Primary Visual Cortex

Authors: *C. SU[1], Y. BERESHPOLOVA[1], R. F. MENDES-PLATT[1], S. E. KIM[1], J.-M. ALONSO[2], H. A. SWADLOW[1];
[1]Dept. of Psychological Sci., Univ. of Connecticut, Storrs, CT; [2]Biol. and Visual Sci., SUNY Optometry, New York, NY

Abstract: The receptive fields (RFs) of most neurons of primary visual cortex can be classified as simple or complex, either using the classical criteria of Hubel and Wiesel (1962) or by linearity of their responses to drifting gratings (F1/F0 ratios) (Skottun et al., 1991). Here, we investigate two types of complex cells found in visual cortical layer 5 of awake rabbits: (1) corticotectal (CTect) neurons, and (2) putative fast-spike inhibitory interneurons (suspected inhibitory interneurons, SINs). The CTect neurons were identified by antidromic responses following electrical stimulation of the superior colliculus, and the SINs by their high-frequency response to electrical stimulation of the thalamus and by short-duration spikes (3+ spikes at >600 Hz). All of the CTect neurons (n = 29) and all of the SINs (n = 16) had complex RFs, as defined by nonlinear responses to a drifting grating (F1/F0 ratios of <1) presented at near-optimal orientation, spatial frequency, temporal frequency and contrast. CTect neurons and SINs were very similar in their (1) response nonlinearity (0.39 ± 0.05 vs. 0.28 ± 0.06, $P = 0.15$, Wilcoxon test for all comparisons), (2) median response latency to stationary visual stimuli (32.2 ms vs. 31.5 ms, $P = 0.83$), (3) evoked responses to optimal drifting gratings (25.06 ± 3.03 spks/s vs. 41.23 ± 9.96 spks/s, $P = 0.21$), (4) spatial tuning properties (peak spatial frequency: 0.31 ± 0.07 cpd vs. 0.43 ± 0.08 cpd, $P = 0.12$.; spatial frequency bandwidth: 0.56 ± 0.10 oct vs. 0.61 ± 0.07 oct, $P = 0.4$), and the contrast generating half-maximum response (C50) (14.82 ± 2.54 % vs. 14.18 ± 2.0 %, $P = 0.57$). However, they were distinct in a number of ways: (1) Whereas all SINs had complex RFs as defined by low F1/F0 ratios, and had highly overlapping ON and OFF subfields, the spatial RFs of CTect neurons were more diverse, with ~50% showing some significant separation of ON and OFF subregions. (2) CTect neurons had much lower spontaneous activity than L5 SINs (5.86 ± 0.62 spks/s vs. 14.98 ± 2.36 spks/s, $P < 0.001$). (3) CTect neurons showed higher response reliability (lower Fano factor) than L5 SINs (1.00 ± 0.14 vs. 1.76 ± 0.27, $P = 0.005$). (4) Most CTect neurons were selective for stimulus orientation and many of these were directionally selective. However, L5 SINs were broadly tuned to stimulus orientation and direction (orientation selective index: 0.55 ± 0.04 vs. 0.28 ± 0.05, $P = 0.001$; direction selective index: 0.43 ± 0.06 vs. 0.12 ± 0.03, $P = 0.002$). We conclude that layer 5 complex cells are heterogeneous in their RF properties, and that this heterogeneity is related to morphologically and physiologically distinct cell types found in this layer.

Title: Pronounced differences in retinotopic scatter between putative inhibitory and excitatory neurons in rabbit visual cortex

Authors: *Y. BERESHPOLOVA[1], C. SU[1], R. F. MENDES-PLATT[1], S. E. KIM[1], J.-M. ALONSO[2], H. A. SWADLOW[1];
[1]Dept. of Psychological Sci., Univ. of Connecticut, Storrs, CT; [2]Biol. and Visual Sci., SUNY Optometry, New York, NY

Abstract: Neighboring neurons in primary visual cortex respond to similar stimulus positions in the retina and their retinotopic scatter is very limited in cats and primates. Here we show that, in rabbits, the retinotopic scatter is strongly dependent of cell type. It is 2-4 times larger for layer 4 (L4) simple cells and layer 5 (L5) corticotectal cells (CTect) than for fast-spike suspected inhibitory interneurons (SINs) in both layers. To estimate the retinotopic scatter, we simultaneously measured the receptive fields (RF) of single cortical cell and neighboring multiunit activity (MUA) using reverse correlation from sparse noise stimuli (light and dark squares of 1-2 deg2). Then, we compared the RF positions of MUA and neighboring single neuron by calculating the distance between their RF centers. We classified the RFs as either simple or complex based on the linearity of spatial summation to near-optimal drifting grating stimuli (F1/F0 ratios, complex: <1.0, simple: > 1.0). In L4, the complex cells studied were SINs, identified by high-frequency burst of spikes (> 600 Hz) elicited by thalamic electrical stimulation and very short duration spikes (Swadlow, 2003). In L5, we also studied SINs, as well as antidromically identified Ctect neurons (all of which had F1/F0 ratios of <1, see accompanying poster by C.Su et al). The ON and OFF subregions of the MUA RF were very closely aligned in the two layers (ON-OFF difference in RF center position: 0.95 ± 0.1 deg, n= 29 in L4 vs 0.86 ± 0.08 deg, n = 35 in L5, P = 0.243, Wilcoxon test for all comparisons). The RF centers of SINs were also closely aligned with the center of the MUA RF in both layers, with the alignment being slightly more precise in L4 (MUA-SIN difference in center position: 0.72 ± 0.11 deg, n = 11 in L4 vs 1.02 ± 0.11 deg, n = 17 in L5, P = 0.034). When compared with the SINs, the RF centers of L5 Ctect cells and L4 simple cells were 2-4 times more scattered and frequently found at the edges of the MUA RF (difference in center position: 1.77 ± 0.24 deg, n = 18 L5 Ctect vs. 2.7 ± 0.43 deg, n= 18 L4 Simple, P = 0.243). The differences in RF scatter between SINs and non-SIN neurons were very pronounced and highly significant (P < 0.001 for L4, P = 0.005 for L5). Since the average RF size of a geniculate input at the same eccentricity is 3.9 degrees (n = 57), the average retinotopic scatter of non-SIN neurons spanned from 0.4 (L5) to 1 (L4) geniculate RF centers. We conclude that non-SIN neurons display greater retinotopic scatter than SIN neurons consistently with their more limited thalamocortical convergence (Bereshpolova et al., 2020). The pronounced retinotopic scatter of non-SIN neurons may explain the absence of orientation columns in rabbit visual cortex.

Title: Functional interlaminar connectivity in mouse primary visual cortex

Authors: *M. ROSSA, E. M. CALLAWAY;
Salk Inst., La Jolla, CA

Abstract: One of the defining characteristics of the cerebral cortex is its organization into 6 layers, each distinguishable by a unique composition of cell types and together representing a fundamental component of sensory information-processing. Most of what we know about functional interlaminar connectivity is from paired recordings in slice preparations which, due to cut axons, dramatically underestimate the rate of interlaminar connections. This leaves us with an incomplete understanding of how cortical circuits transform sensory information across layers. In this study, we use an optogenetic approach to bypass the issue of cut axons and comprehensively characterize functional excitatory interlaminar connections originating from cortical layers 2/3, 4, 5, and 6 onto both excitatory neurons and 3 inhibitory cell classes in layers 2/3, 4, 5, and 6. We are using transgenic mouse lines and conditional AAV vectors to restrict Channelrhodopsin-2 expression to excitatory cell populations within a single layer and to selectively label inhibitory cells of a particular class in mouse primary visual cortex. We then pair optogenetic stimulation of axon terminals with *ex vivo* intracellular recordings in excitatory neurons and somatostatin-, parvalbumin-, or vasoactive intestinal polypeptide-expressing inhibitory cells across cortical layers and measure the monosynaptic input strength from the stimulated cell population to the recorded cell. This enables us to compare postsynaptic responses between excitatory and inhibitory subtypes and cells recorded in different layers. We can thereby quantify the proportion of excitatory input from each cortical layer to each neuron subpopulation within and between layers. L4 provides most of its input to L2/3, and L2/3 provides strong input both within L2/3 and to L5. While extratelencephalic (ET) neurons in L5 primarily provide input to other cells in L5, L5 intratelencephalic neurons provide the majority of their input to L2/3. Inputs from L6 ET neurons are evenly distributed between L4, L5, and L6. Preliminary suggest input strength from a given layer to a particular inhibitory cell type depends strongly on both the input layer, the laminar location and the inhibitory subtype of the recipient cell. We also expect functional input strength to differ between excitatory cells and inhibitory cells and are further examining how each layer-specific population provides input to excitatory versus inhibitory cells across layers. Together, our results provide a more complete picture of the

relative distribution of excitatory synaptic input from each layer to distinct cell subpopulations across layers within a single cortical region.

Title: Correlation of brain-state related acetylcholine fluctuations and dendritic activity in mouse cortex.

Authors: *M. A. GALDAMEZ, E. NEYHART, C. L. SMITH, J. REIMER;
Dept. of Neurosci., Baylor Col. of Med., Houston, TX

Abstract: The integration of sensory feedforward and contextual feedback information is long thought to be key to adaptive cortical processing in varying environmental contexts. Within Layer 1 of the cortex, recipient apical dendrites of pyramidal cells integrate information from feedback projections with somatic activity. In addition, Layer 1 apical dendrites receive projections from interneuron subclasses and from subcortical neuromodulatory nuclei, including cholinergic axons from the basal forebrain. Previous *in vitro* studies have shown that acetylcholine modulates the excitability of Layer 1 dendritic tufts, and recent *in vivo* studies have demonstrated strong correlations between acetylcholine and brain states. However, the relationship between natural fluctuations in acetylcholine levels and dendritic activity *in vivo* remains unknown. Here we employed two-photon random access mesoscope (2P-RAM) imaging to simultaneously record acetylcholine levels and Layer 1-5 cortical activity using the fluorescent acetylcholine sensor, GACh4.3, and a genetically encoded calcium indicator, GCaMP7f, in awake mice. Our initial results suggest that acetylcholine levels are more correlated with dendritic excitation than somatic activity. We will perform acetylcholine and calcium imaging in Layer 5 Cre-dependent mouse lines to further characterize the natural spatiotemporal dynamics between local acetylcholine levels and dendritic activity. Our preliminary results are consistent with the idea that acetylcholine fluctuations gate feedback integration with implications for cortical plasticity and processing.

Title: A multiplexed gradient in human cerebellum of macromolecules, function, and development

Authors: *J. GOMEZ[1], X. LIU[2], F. D'OLEIRE UQUILLAS[1], Z. ZHEN[2];
[1]Princeton Neurosci. Inst., Princeton, NJ; [2]Beijing Normal Univ., Beijing, China

Abstract: Despite its role in mediating a wide range of cognitive functions, and its implication in disorders such as autism, how the basic tissue and functional properties of the cerebellum are organized across development is unknown. Combining multiple large datasets, we demonstrate in the human cerebellum multiple gradients across the cerebellum with coordinated structural, functional, and developmental properties. First, in a large group of adults from the Human Connectome Project (HCP, n=1026), we find a static U-shaped tissue gradient in adults whereby dorsal cerebellar lobules (the most distant from the brainstem) show the least myelination compared to ventral lobules. We hypothesized that this adulthood myelin gradient should predict a developmental gradient across childhood, under a model in which the cerebellum follows a similar rule to cortex whereby highly myelinated structures (e.g., sensory cortex) myelinate early in development. Employing the developmental HCP dataset, we validate this prediction in n=625 individuals between the ages of 8 and 20. We find that dorsal cerebellar lobules undergo the most dramatic tissue growth across childhood, resulting in a smooth U-shaped gradient of tissue growth rates around the cerebellum ($F(24,5449) = 7.21$, $p < 0.001$). To investigate if these structural changes have any bearing on function, we ask if potential myelin growth sculpts the intrinsic functional properties of the cerebellum, with the strong a priori hypothesis that functional development should also follow a similar U-shaped gradient. Using resting-state data in the same individuals, we find that those lobules that undergo the most tissue growth demonstrated the most dramatic decrease in low-frequency fluctuations from a frequency analysis of the resting-state time series ($F(24, 5367) = 6.36$, $p < 0.001$), suggesting the structural development may serve to dampen random fluctuations. Importantly, the rate of functional development in different lobules forms a U-shaped gradient across the cerebellum that mirrors the tissue development gradient. Applying quantitative MRI in the cerebellum for the first time, we show the observed tissue gradient may have a unique macromolecular source compared to neocortex. Overall, across multiple datasets, we provide evidence for the existence of a coordinated multilayer gradient in the human cerebellum. These findings significantly advance our understanding of how the human cerebellum develops both structurally and functionally from childhood to adulthood. The existence of this multiplexed gradient provides a useful biomarker for future research to classify atypical development of the cerebellum.

Title: Myogenic evoked responses to cerebellar dentate nucleus deep brain stimulation in human subjects

Authors: *F. PUCCI[1], M. SCHROEDEL[1], S. SAHOO[2], A. G. MACHADO[3], K. B. BAKER[4]; [1]Cleveland Clin. Fndn., Cleveland, OH; [2]Cleveland Clin. Lerner Col. of Med., Cleveland, OH; [3]Ctr. Neurolog. Restoration, [4]Dept. of Neurosci., Cleveland Clin., Cleveland, OH

Abstract: We report here evidence for myogenic evoked potentials (EPs) in response to electrical stimulation of the cerebellar dentate nucleus (DN) in a limited cohort of human subjects. Deep brain stimulation (DBS) of the deep cerebellar nuclei is under active investigation as a potential therapy for stroke recovery, TBI, and psychiatric conditions. Patients with a history of cerebral stroke affecting upper extremity (UE) motor function were enrolled in the *Electrical stimulation of the dentate nucleus* (EDEN) trial and underwent surgical implantation of a DBS system in the DN ipsilateral to the affected extremity. Data from two adult human subjects are reported here. The dentate nucleus was stimulated at a low frequency (3-6 Hz) with either single pulses or a train of three (pulse width 90 μs, amplitude 2-6 mA) in an EP paradigm. Electromyography (EMG) was recorded from muscle groups in the UE. The EMG signal was filtered from 10-1000 Hz, rectified, and a moving root mean square was taken. Segments of data time-locked to DN stimulation were excerpted and averaged to generate an EP. The experiment was performed with the affected UE both at rest and during a motor block-tracking task. Robust EPs could be elicited by DN stimulation in UE muscles ipsilateral to DN stimulation during the motor task. In a smaller subset of trials, evoked potentials could be elicited at rest. The waveform was composed of multiple peaks: a short latency (mean 32.5 ms) increase in EMG power indicating muscle activation, a subsequent inhibition of EMG activity below baseline (58.2 ms), and a second increase in power (106.4 ms). DN stimulation therefore can produce bidirectional modulation of muscle activity. EPs elicited during the motor task were then re-generated by subsampling the data and sorting it by baseline EMG power. In this way, one can compare the EP waveform stratified during active contraction and relaxation of the muscle belly according to EMG. The normalized positive going peaks were 2.8 and 1.3 times larger, respectively, during periods of relatively greater electrophysiological muscle activity. The short latency of these peaks in EMG power suggest an alternative path to the dentatothalamocortical tracts. One

hypothesis may be DN output to the reticulospinal pathway seen in animal models. Our data furthermore show that motor output from the DN to the UE muscle is somehow gated by the baseline motor state of the muscle, with evoked potentials being greatest during putative muscle contraction. This is an early demonstration of DN stimulation evoked myogenic potentials in humans, and further experiments are needed to determine the mechanism and physiological or clinical relevance of this EP paradigm.

Title: Movement-related Cortico-cerebellar Interactions In Chronic Post-stroke Patients

Authors: *R. GOPALAKRISHNAN[1], D. A. CUNNINGHAM[5], M. SCHROEDEL[2], B. CAMPBELL[2], E. B. PLOW[3], K. B. BAKER[4], A. G. MACHADO[1];

Abstract: Novel therapies aimed at promoting post-stroke rehabilitation are in great need. Our group is investigating deep brain stimulation (DBS) of the dentatothalamocortical pathway as a method to modulate cerebral cortical activity and promote long-term motor recovery. Given the anticipated lack of acute behavioral effect(s) associated with the intervention, a key component of our strategy is to understand the connectivity dynamics between the surgically-targeted cerebellar dentate nucleus (DN) and the contralateral perilesional cerebral cortex. This is an essential first step to develop biomarkers that could facilitate therapeutic programming. Here, we present electrophysiological data collected during a motor control task. Ten patients undergoing DN DBS for post-stroke rehabilitation underwent scalp electroencephalography (EEG), local field potentials (LFP) from the externalized, 8-contact DN DBS lead, and surface electromyography (EMG) during a visuo-motor grip block tracking task. An average of 76 block tracking trials were collected with effort set to 20% maximal voluntary contraction. Each trial had a movement onset (grip squeeze), isometric grip hold and movement offset (grip relax). Movement related oscillations in the cerebellar DN were highly correlated with perilesional cortex oscillations during movement onset especially in the low beta band, with classic Event-related Desynchronization and Synchronization (ERD/ERS) phenomena representing motor

facilitation and inhibition, respectively. Less impaired subjects show greater ERD in both DN and perilesional cortex (low beta band), compared to high impaired subjects. During the isometric hold period of the tracking task, we observed significant coherence in the low beta band between the DN and the perilesional cortex. This cortico-cerebellar coherence was significantly positively correlated with task accuracy. The results show first ever in-human electrophysiological evidence for communication between the cerebellar DN and perilesional cortex in the low beta band during motor control. Future work will focus on how these metrics could facilitate therapeutic programming and evaluate DN DBS therapy.

Title: Leveraging temporally-specific reinforcement to train a sequential movement in cerebellar ataxia

Authors: *R. A. MOONEY[1], D. CAO[1], P. A. CELNIK[1], A. J. BASTIAN[2,1];
[1]Johns Hopkins Univ., Baltimore, MD; [2]Kennedy Krieger Inst., Baltimore, MD

Abstract: Damage to the cerebellum causes ataxia, a movement disorder characterized by impaired motor coordination. People living with ataxia exhibit dysmetria and prolonged trajectory paths when making upper limb movements, which can lead to difficulty in performing activities of daily living. Previous studies have shown that reinforcement mechanisms, driven by simple binary signals (e.g., success or failure), can be leveraged to reduce elements of ataxia during discrete point-to-point reaching. Yet, many activities of daily living require sequential movements, such as reaching for, drinking from and then replacing a glass of water. Binary feedback after a sequential movement can be difficult to interpret - it does not tell the individual which segments of the sequence are faulty. Here we examined whether people with ataxia could use segment-specific binary feedback to learn a sequential movement. Participants learned a 3-dimensional sequential arm movement in virtual reality over four consecutive days. They were asked to make a continuous arm movement that traversed four invisible segments marked by a starting point, three via points and an end point. Their hand position was represented by a virtual ball. For each trial, we calculated the average distance error between their hand position and the invisible segments. Reinforcement was given via binary feedback based on whether each segment's error was above or below the average error of the previous five trials. On each day, five trials with no binary feedback were performed before and after 60 trials of reinforcement training. In a first experiment, we compared learning with binary feedback delivered immediately after each segment (temporally-specific) or after the entire sequence was complete (terminal) in healthy young subjects ($n = 12$ per group). Both groups improved performance on the whole movement by the end of day four (both $p < 0.001$). However, the temporally-specific group learned significantly more than the terminal group, reducing error by ~75% versus ~50%, respectively ($p < 0.001$). Next, we determined whether temporally-specific reinforcement could be used to train the same sequential movement in a group ($n = 10$) of people with ataxia. We found that the ataxia group was able to reduce error by ~50% by the end of day four ($p = 0.001$). These findings indicate that segment-specific reinforcement, provided in close temporal proximity to execution, can be leveraged to train a sequential upper limb movement in people with ataxia. Our results have important implications for designing effective reinforcement paradigms to optimize motor learning in the context of clinical rehabilitation.

Title: Topographically organised frontal cortex maps in the human cerebellar cortex.

Authors: *M. LONGLEY, M. DANVERS, N. RAMNANI;
Psychology, Royal Holloway, Univ. of London, Egham, United Kingdom

Abstract: The cortico-cerebellar system is one of the largest in the primate brain and connectivity with the frontal cortex is particularly well-understood. Prefrontal area 46 in anterior parts of the frontal lobe is connected with cerebellar cortical lobule HVIIA. However, some cerebral cortical areas have discontinuous representations in the cerebellar cortex. Primary motor cortex (area 4) is interconnected with lobules HIV-HVI and lobules HVIIB-HVIII, either side of lobule HVIIA (Kelly and Strick, 2003). Previous human resting state fMRI (rsfMRI) studies also show that spatially distinct cerebellar cortical areas form networks with the same areas in the cerebral cortex (Buckner et al, 2011; Guell et al., 2018; Xue et al. 2021).
The frontal lobe is functionally organised along an anterior-to-posterior axis (Ramnani and Owen, 2007; Badre and D'Esposito, 2009), and projections from the frontal lobe to subcortical structures are topographically ordered (Ramnani et al., 2006; Marquand et al., 2017). We tested the hypothesis that similarly, adjacent anterior-to-posterior segments of the frontal cortex are represented in adjacent areas of the cerebellar cortex.
We performed seed-based resting-state analysis (CamCAN dataset; N=80, 43 female; CONN Toolbox / SPM12 / Matlab) using a frontal cortex mask divided into 10 contiguous anterior-to-posterior sections (fig. 1a, AP1-AP10).
Consistent with previous work, we report evidence for three maps in the cerebellar cortex (fig 1b, c; cerebellar cortical flatmaps; SUIT). First, an area between lobule HIII and Crus I HVIIA (fig 1c). Second, an area from Crus II HVIIA to lobule HVIIIB. Third, within lobule HIX. We also report these to be topographically organised (fig 1b): anterior parts of the frontal cortex are represented immediately adjacent to and either side of HF, and within lobule HIX. More posterior segments of the frontal cortex are represented at increasingly distant areas from the HF in the first two maps. Our future work will investigate the ways in which each map interacts with the frontal cortex to support movement and cognitive control.

Title: Fatigue perception: The role of the cerebellum

Authors: *A. CASAMENTO MORAN[1], R. A. MOONEY[1], V. S. CHIB[3], A. J. BASTIAN[4], P. A. CELNIK[2];
[1]Physical Med. and Rehabil., [2]Physical Med. & Rehab, Neurol, Johns Hopkins Univ., Baltimore, MD; [3]Biomed. Engin., Johns Hopkins Sch. of Med., Baltimore, MD; [4]KKI & Johns Hopkins, Baltimore, MD

Abstract: Fatigue is the subjective sensation of weariness, increased sense of effort, or exhaustion and is common in neurological illness. Despite its prevalence, we have a limited understanding of the neurophysiological mechanisms underlying fatigue because previous studies have investigated factors that impair motor function (e.g., reduced force capacity, also

known as fatigability) without addressing fatigue itself (i.e., the percept). Growing evidence suggests that the cerebellum, known for its role in motor control and learning, is a key structure involved in perceptual processing. However, the relationship between cerebellar activity and the perception of fatigue remains largely unexplored. Here, we perform two experiments to examine how cerebellar excitability is modulated after a fatiguing task and its association with both fatigue and fatigability. In 21 participants, we used a cross-over design to assess corticomotor excitability, cerebellar inhibition (CBI), and the participant's perception of fatigue before and after a fatiguing or a control protocol. Participants performed five trials of an isometric pinch between their thumb and index finger at 80% maximum voluntary capacity (MVC) until failure (force lower than 40% MVC; fatigue) or at 5% of maximum capacity for 30 s (control). We found reduced CBI after the fatigue protocol, indicating a reduction in cerebellar excitability. Interestingly, lower CBI correlated with a milder perception of fatigue but did not correlate with the time to task failure (i.e., fatigability). Furthermore, we found reduced M1 excitability after both protocols, with a greater reduction in the fatigue condition, a finding consistent with prior reports. These results suggest that cerebellar excitability after a fatiguing task may reflect a compensatory mechanism to minimize the perception of fatigue. To investigate the behavioral consequences of reduced cerebellar excitability after fatigue, we performed a follow-up experiment to examine the interaction between fatigue, CBI changes, and motor control. We recruited another 20 participants and measured CBI, perception of fatigue, and performance during a ballistic goal-directed task before and after the same fatigue and control protocols. Again, we found reduced CBI after fatigue and replicated our observation that lower CBI correlated with a milder perception of fatigue. In terms of performance, we found greater endpoint error and variability which correlated with reduced CBI after fatigue. Together, these results suggest that changes in cerebellar excitability after fatigue may modulate the perception of fatigue at the expense of motor control.

Title: Exercise duration differentially effects age-related neuroinflammation and hippocampal neurogenesis

Authors: M. G. CONNOLLY[1], S. R. BRUCE[2], *R. A. KOHMAN[2];
[1]Neurosci., Univ. of Illinois Ubrana-Champaign, Champaign, IL; [2]Psychology, Univ. of North Carolina Wilmington, Wilmington, NC

Abstract: Regular exercise has many health benefits and may be particularly important with aging as exercise attenuates cognitive decline, neuroplasticity deficits, and immune dysregulation. The response to exercise varies as a function of frequency and length. However, research on the duration-dependent effects of exercise has focused primarily on young adults and less is known about the influence of exercise duration in the aged. The current study compared the effects of short-term and long-term running wheel access on hippocampal neurogenesis and neuroimmune markers in aged (19-23 months) male C57BL/6J mice. Aged mice were given 24-hour access to a running wheel for 14 days (short-term) or 51 days (long-term). Groups of non-running aged and young (5 months) mice served as comparison groups to detect age-related differences and effects of exercise. Long-term, but not short-term, exercise increased hippocampal neurogenesis as assessed by number of doublecortin-positive cells in the granular cell layer. Assessment of cytokines, receptors, and glial-activation markers showed the expected age-related increase compared to young controls. In the aged, exercise as a function of duration regulated select aspects of the neuroimmune profile. For instance, hippocampal expression of interleukin (IL)-33 was reduced and IL-10 increased only following long-term exercise. Whereas brain levels of IL-6 were reduced by both short- and long-term exercise. Additional findings showed that exercise does not modulate all aspects of age-related neuroinflammation and/or may have differential effects in hippocampal compared to brain samples. Overall, the data indicates that increasing exercise duration produces more robust effects on immune modulation and hippocampal neurogenesis.

Title: The immune cell profile of the developing rat brain

Authors: *E. L. REINL, A. C. BLANCHARD, E. L. GRAHAM, M. M. MCCARTHY;
Univ. of Maryland Sch. of Med., Baltimore, MD

Abstract: Peripheral immune cells (PICs) populate the brain and its surrounding meninges, contributing to the function and development of the CNS. In recent years, flow cytometric and single cell sequencing studies have described the immune cell composition of the adult rodent brain in healthy, diseased, and injured states, whereas studies of the developing brain have been vastly limited. Knowledge of the immune system within the developing brain is essential for understanding how these cells may contribute to normal developmental processes, and the induction of developmental disorders rooted in immune disruption. Our objective was to delineate the immune cell repertoire of specific brain regions including the hippocampus, hypothalamus, and cerebellum from developing rats of both sexes starting from embryonic day 20 (E20) to postnatal day 0 (PN0), PN7, and PN16. We used 11-color flow cytometric analysis to identify 10 unique cell types including microglia, T cells, B cells, NK cells, mast cells, neutrophils, and monocytes. We report four main findings. FIRST: immune cell counts within brain regions increased with age, this increase was primarily driven by microglia, and the percent of total immune cells that are peripherally derived decreased with age. At their peak at E20, PICs were most abundant in the cerebellum (40%), followed by hippocampus (20%) and hypothalamus (10%). SECOND: within the PIC compartment, monocytes dominated in all brain regions and at all ages, composing ~60% of PICs at E20 and decreasing to ~40% by PN7. Their subtype makeup changed with age. CD43hi (non-classical) monocytes made up an increasing proportion of the monocyte pool as animals developed, and HIS48hi (classical) monocytes decreased over the same period. Additionally, a novel monocytic cell type was discovered that decreased with age in all brain regions. These cells were negative for CD43 and HIS48, but like other myeloid cells, were CD45hi, CD11b+, CD172+, and, surprisingly, B220+. These cells may represent monocyte progenitors infiltrating from the bone marrow niches as was recently described in PMID 34083447. THIRD: T cell populations increased with age in all brain regions. Both CD4+ (helper) and CD8+ (killer) populations increased, but helper T cells increased at a greater rate, such that the CD4/CD8 ratio flipped by PN7. FOURTH: mast cells were more populous early in development, with numbers peaking at PN7 and dropping to near zero by PN16, and they were much more numerous in the hippocampus, followed by the hypothalamus, and were sparse in the cerebellum. Our findings implore investigators to look beyond microglia and toward PICs as a source of immunomodulation in the developing brain.

Title: Adrenergic Attenuation of Immune Activity is Associated with Anhedonia in Adolescents

Authors: *T. N. B. NGUYEN[1], B. A. ELY[1], D. PICK[1], S. KIM-SCHULZE[2], C. ALONSO[1], V. GABBAY[1,3];
[1]Psychiatry and Behavioral Sci., Albert Einstein Col. of Med., Bronx, NY; [2]Human Immune Monitoring Ctr., Icahn Sch. of Med. at Mount Sinai, New York, NY; [3]Nathan S. Kline Inst. for Psychiatric Res., Orangeburg, NY

Abstract: ***Background***: While the link between peripheral inflammation and psychiatric symptoms has been supported, the role of immune-modulating processes by the adrenergic nervous system in psychopathology remains unclear. Here, we sought to investigate the β_2-agonist clenbuterol (CBL) as a promising agent to model adrenergic-driven immune attenuation following *ex vivo* immune activation with lipopolysaccharide (LPS). Further, we explored the relationships between CBL-modulated cytokine levels and psychiatric measures in our adolescent participants. ***Methods***: We conducted semi-structured interviews to evaluate 130 participants. Depression, anxiety, and anhedonia levels were measured with the BDI, MASC, and TEPS questionnaires. Fasting whole-blood samples were acquired and stimulated with LPS (0.1 μg/mL) in the presence and absence of CBL (10^{-6} M) for 6 hours. Supernatants were collected and subjected to Luminex multiplex assay for 41 cytokines. Cytokine levels were compared between 3 conditions: Control, LPS, and LPS+CBL. Then, we utilized an exploratory factor analysis (EFA) to dimensionally reduce cytokine data from the 3 experimental conditions. Spearman correlations between each immune factor and psychiatric symptoms were examined, controlling for age, sex, and BMI. The statistical significance of all associations was assessed after Bonferroni correction for multiple comparisons. ***Results***: Levels of 9 cytokines were significantly attenuated by CBL treatment compared to LPS alone. Across 3 conditions, EFA reduced 41 cytokines into 5 orthogonal factors, and a similar factor was identified to be significantly correlated with anticipatory anhedonia after Bonferroni correction. Specifically, correlations were found between anticipatory anhedonia and a) Control Factor (F) 4 (rho = -0.35, $p = 3.6 \times 10^{-4}$), b) LPS F3 (rho = -0.36, $p = 2.6 \times 10^{-4}$), and c) LPS+CBL F3 (rho = -0.39, $p = 7.4 \times 10^{-5}$). In addition, LPS+CBL F3 significantly correlated with consummatory anhedonia (rho = -0.36, $p = 3.3 \times 10^{-4}$). No significant correlation was found between any immune factor and depression or anxiety. Post-hoc analysis contrasting cytokine relationships between LPS+CBL and LPS conditions revealed differences in inter-cytokine correlation structures, possibly explaining CBL's effects on the relationships between peripheral immune response and anhedonia sub-components. ***Conclusions***: Findings support our hypothesis that CBL attenuates inflammatory effects thought to underlie psychiatric conditions in youth. Following data-driven analyses, distinctive associations between adrenergic-modulated immune activity and dimensional anhedonia were identified.

Title: A cell atlas and live imaging tools to study the choroid plexus blood-CSF barrier

Authors: *N. DANI[1], R. H. HERBST[3], F. B. SHIPLEY[2], C. MCCABE[3], H. XU[2], G. S. GREEN[4], K. KAISER[5], J. P. HEAD[2], D. DIONNE[3], V. BRYJA[5], O. ROZENBLATT-ROSEN[3], C. I. MOORE[6], N. HABIB[4], M. L. ANDERMANN[7], A. REGEV[3], M. K. LEHTINEN[2]; [1]Boston Children's Hosp., Quincy, MA; [2]Boston Children's Hosp., Boston, MA; [3]Broad Inst., Cambridge, MA; [4]Hebrew Univ. of Jerusalem, Jerusalem, Israel; [5]Masaryk Univ., Brno, Czech Republic; [6]Brown Univ., Providence, RI; [7]Beth Israel Deaconess Med. Ctr., Boston, MA

Abstract: The choroid plexus (ChP) is found in each of the four brain ventricles and functions as a distributed blood-CSF barrier system. Cells of the choroid plexus produce CSF and secrete age-specific factors that support brain development and health across lifespan. The ChP also functions in host-defense as a neuroimmune barrier that gates the entry of immune cells into the brain. More recently, the SARS-CoV-2 virus is reported to show neurotropism for the ChP, which potentially contributes to neurological symptoms associated with the disease. Now more than ever, there is a pressing need to understand this vital brain barrier. However, there have been historical setbacks presented by an incomplete characterization of the ChP and the lack of tools to study the system *in vivo* using genetically tractable models. Recently, we applied single-cell and single-nucleus transcriptomics to generate a cell atlas of the choroid plexus in the developing (embryonic day (E)16.5), adult (4 months) and aging (20 months) mouse brain. We find stable, ventricle- and age-specific gene expression patterns in ChP cells including epithelial, endothelial, mesenchymal, neuronal, glial and immune cell types. Using trajectory analysis and lineage tracing approaches, we identify and map the location of a common progenitor pool that gives rise to choroid plexus epithelial cells and neurons in the developing mouse brain. Further,

mapping ligand and receptor gene expression across brain ventricles and ages, we identify extensive cellular crosstalk within the ChP, with mesenchymal cells functioning as a signaling hub that communicates with all cell types. Guided by transcriptional insights from the cell atlas, we can now genetically target ChP cells (CRISPR) and use recently innovated live imaging strategies to visualize their activity in explants, *ex vivo* and *in vivo*. For example, by two-photon calcium imaging (GCaMP6f) in awake behaving adult mice, we visualize apocrine secretion into the CSF evoked by 5-HT2C serotonin receptor agonists. Similarly, by tracking *Cx3cr1-GFP* expression in choroid plexus macrophages, we identify homeostatic, inflammation and tissue-damage evoked responses *in vivo*. Overall, by combining transcriptional insights from the cell atlas and the live imaging technologies, we can investigate cellular and molecular mechanisms of ChP cell types during brain development, host-defense, aging and in neurologic disease models.

Title: Sex differences in stroke dysbiosis in a rodent model of focal cortical ischemia

Authors: *E. DANIELE[1], N. SACHEWSKY[1], J. COPELAND[3], E. Y. SCOTT[2], L. UMBRIO[1], M. FAIZ[1];
[1]Dept. of Surgery, [2]Dept. of Chem., Univ. of Toronto, Toronto, ON, Canada; [3]Dept. of Cell & Systems Biol., Univ. of Toronto, CAGEF (Centre for the Analysis of Genome Evolution and Function), Toronto, ON, Canada

Abstract: Stroke is a devastating neurological disease which effects males and females differently across the lifespan (Haast *et al.,* 2012). Stroke related changes in gut microbiota, stroke dysbiosis, have been shown to play important role in stroke outcomes (Singh *et al.,* 2016). Given that there are sex differences in gut microbial composition throughout the lifespan (Kim *et al.,* 2020), there has been little study of stroke dysbiosis in males and females in rodent models. The aim of this study was to characterize whether there are sex differences in the trajectory of stroke dysbiosis in the acute and chronic phase of stroke injury using a rodent model of focal cortical ischemia. We collected feces from 8-week-old male and female C56 BL6/J mice prior to (D0) and at acute (D4) and chronic timepoints (D10, D20, D60) following ET-1 stroke injury. Fecal gDNA was extracted and subjected to 16s V4 hypervariable region sequencing. We

observed that females exhibit a significant increase in alpha species diversity (Shannon Entropy) at post-stroke D60 compared to D4 (Kruskal Wallis, $p<0.05$), whereas males did not exhibit such change (Kruskal Wallis, > 0.05). When comparing beta species diversity (Bray Curtis Dissimilarity), we observed that both males and females exhibit stroke dysbiosis at D4 (PERMANOVA, $p < 0.05$), however males and females differed in stroke dysbiosis in the chronic phase of injury. Strikingly, females exhibited a return to D0 composition at D20 (PERMANOVA, $P > 0.05$), whereas males remained significantly different from their D0 composition at D20 and D60 (PERMANOVA $p < 0.05$). Next, we studied differentially abundant bacteria in the gut microbiota in males and females following ischemic stroke injury using a linear discriminant effect size (LEFSE) analysis on the relative abundance of operational taxonomic units (OTUs). Interestingly, we did not observe LEFSE hits when examining the relative abundance of OTUs in female animals, however we observed that males exhibited an increased abundance of *Lactobacillaceae* OTUs at D0, *Verrucomicrobiaceae* OTUs at D4 and *Dehalobacteriaceae* OTUs at D10 (Kruskal Wallis, $p < 0.05$). To our knowledge, this study is the first to characterize stroke dysbiosis in the acute and chronic phase of injury in both males and females. These findings will support future studies of how sex differences in the gut-microbiota-brain-axis contribute to stroke outcomes.

Title: Quantification of unmyelinated nerve fibers in electron microscopy images using deep learning

Authors: V. MANNAM[1], V. TOTH[2], *E. H. CHANG[2,3], T. ZANOS[2,3];
[1]Dept. of Electrical Engin., Univ. of Notre Dame, Notre Dame, IN; [2]Inst. for Bioelectronic Med., Feinstein Inst. For Med. Res., Manhasset, NY; [3]Zucker Sch. of Med. at Hofstra/Northwell, Hempstead, NY

Abstract: The vagus nerve is a mixed nerve containing sensory and motor fibers that carry signals between the brain and body. Selective targeting of different fiber subsets is a major goal of neuromodulation strategies, including vagus nerve stimulation (VNS). Improved methods for identifying and quantifying specific fiber types within the vagus nerve (such as A, B, and C-fibers) would provide important insights for selective neuromodulation at the ultrastructural level and enable more realistic in-silico testing of different VNS parameters. While larger myelinated

A- and B-fibers are straightforward to identify, most of the fibers in the vagus nerve are unmyelinated sensory C-fibers that are difficult to identify due to their small size and poor contrast in most imaging modalities. Traditional methods have failed to provide quantitative information about unmyelinated fibers, which number in the thousands, to tens of thousands, depending on the species studied. In this study, we trained a deep learning (DL) based convolutional neural network (CNN) to identify and quantify unmyelinated C-fibers in the mouse cervical vagus nerve. Cross-sections from wildtype C57BL6 mice were processed with glutaraldehyde-paraformaldehyde fixation, followed by 1% osmium tetroxide, then stained in uranyl acetate. Ultra-thin sections were imaged with a transmission electron microscope (FEI) and UltraScan 4000 imaging system (GATAN). These TEM images were used as input images for training the model. Our trained DL model has instance segmentation architecture that can provide the spatial distribution (mask) and count of type-C unmyelinated fibers simultaneously for a given test image. We validated the fine-tuning of the DL model with various hyper-parameters (learning rate, batch size, number of iterations) for accurate type-C fiber detection. Generation of the target images requires intensive manual annotations; therefore, we limited our training dataset to a subset of our dataset. We incorporated a rapid inference-based image denoising network on the input images that enhanced the contrast information during the pre-processing step. Our trained model detects more than 50% type-C fibers for a given test image. By adding additional target images, we expect our model will identify more than 75% type-C fibers, in addition to providing quantitative measurements such as average area, the radius of fibers, and their spatial distribution within the nerve based on segmentation results. The demonstrated novel method implements an automated pipeline to quantify unmyelinated fibers from mouse vagus nerve TEM images, but it may also be applied to other nerves and species of interest.

Title: Cerebral Malaria Induced Neuronal Hyper-Excitability Rescued via TNF signalling modulation:Potential for New Therapeutics

Authors: N. M. DVORAK[1], N. D. DOMINGO[2], C. M. TAPIA[1], ***R. STEPHENS**[3], F. LAEZZA[1];
[1]Pharmacol. and Toxicology, [2]Intrnl. Medicine, Div. of Infectious Dis. and Microbiology and Immunol., Univ. of Texas Med. Br., Galveston, TX; [3]Intrnl. Medicine, Div. of Infectious Dis. and Microbiology and Immunol., Univ. of Texas Med. Branch, 301 Univ. Blvd., Galveston, TX

Abstract: Cerebral malaria (CM), caused by infection *with Plasmodium spp.* parasites, kills an estimated 425,000 people per year. While seizures increase the likelihood of death from CM, mechanisms driving seizures and the neuroinflammation seen in malaria are poorly understood. In this hyperinflammation driven model of CM, systemic erythrocyte-tropic *P. chabaudi* infection in IL-10 deficient animals, an excess of tumor necrosis factor (TNF) driven by absence of regulatory cytokine, IL-10, reproduces many symptoms of CM. In CM rodent models, TNF drives excess coagulation, blood brain barrier disruption, gliosis and epileptiform-like activity in the hippocampal CA1 region. As the voltage-gated Na+ (Nav) channel Nav1.6 is the primary molecular determinant of CA1 pyramidal neuron excitability, we postulated that molecular mechanisms underlying TNF-induced neuroinflammation in CM could be mediated via signaling pathways targeting the Nav1.6 channel. Using a high-throughput screening of kinase inhibitors, we previously showed that Janus kinase-2 (JAK2) signaling downstream of TNF leads to phosphorylation of fibroblast growth factor 14 (FGF14), a regulatory accessory protein of Nav1.6. Building on these results, we sought to determine the contribution of the JAK2 pathway to systemic infection-driven hippocampal alterations in CM. Using whole-cell patch-clamp electrophysiology, we now show that TNF, induced during CM, leads to an increase in intrinsic firing of CA1 pyramidal neurons, which is in line with previously reported epileptiform-like activity in CM. We also show that this increase in basal firing of CA1 hippocampal neurons can be prevented via *in vivo* genetic silencing of FGF14. Furthermore, small molecules targeting either JAK2 or the downstream FGF14:Nav1.6 channel complex can reverse the increased excitability of CA1 hippocampal neurons induced by TNF. Thus, pharmacologically targeting the TNF/JAK2 downstream FGF14:Nav1.6 channel complex may prove a viable therapeutic strategy to reduce epileptic seizures and decrease risk of death from hyperinflammatory CM.

Title: Microbe-immune crosstalk: evidence that T cells influence the brain metabolome

Authors: *M. GREEN[1], G. CASPANI[3], J. SWANN[3], J. A. FOSTER[2];
[2]Psychiatry & Behav Neurosci, [1]McMaster Univ., Hamilton, ON, Canada; [3]Imperial Col. London, London, United Kingdom

Abstract: The gut-brain axis describes a unique paradigm in which the intestinal microbiome acts as an important determinant of brain development, neurobiology, and behaviour. However, the mechanistic links connecting commensal microbes to neurological outcomes remain incompletely understood. T-lymphocytes, a key cellular component of the adaptive immune system, have recently emerged as an important mediator of this microbiota-brain communication, given their ability to interface with both the intestinal lumen and brain parenchyma at distinct lymphatic barriers. This study aimed to determine the impact of T cell deficiency on various “nodes” in the microbiota-brain axis, including compositional and functional microbiota characteristics as well as brain metabolites. We collected fecal and cecal samples from male and female T cell receptor (TCR) deficient (*TCRβ-/-δ-/-*) and C57Bl/6 wild type (WT) mice at postnatal day 17, 24, 28 and 84. Brain tissue samples including hippocampus, hypothalamus, and cortex were also collected. DNA extracts from feces and cecum were sequenced to obtain a microbiome profile based on 16S ribosomal rRNA. Additionally, we implemented 1H-NMR spectroscopy to extract a complete profile of metabolites within tissue, cecal and fecal samples. By examining both the microbiota (cecal and fecal) and the metabolome (cecal, fecal, gut and brain), we have identified key T-cell-related taxa and their metabolites that are integral to microbe-immune-brain signaling in the postnatal period. *TCRβ-/-δ-/-* mice display reduced microbial diversity, a unique microbiome composition and a distinct metabolic signature in both gut and brain compared to WT controls. Multiomic analysis also revealed that taxa of the family *Muribaculaceae* are strongly impacted by T cell deficiency and associated with specific metabolites, including the short-chain fatty acids butyrate and valerate in the gut. These were in turn associated with various neuroactive molecules, such as GABA and glycine, in the brain. Together, our findings demonstrate that T-cell related changes to the microbiome can directly affect levels of neuroactive metabolites in the CNS, with potential implications for host behaviour and neurodevelopment. Furthermore, these results align with previously observed behavioural deficits in *TCRβ-/-δ-/-* mice, suggesting a molecular basis for an altered neurodevelopmental trajectory in absence of adaptive immune signaling. These novel findings offer insight into the role of T cells in mediating microbe-brain crosstalk, in a dialogue that is essential for maturation of a normal brain and gut metabolome throughout postnatal life.

Title: The beneficial impact of IRF7 in human immunodeficiency virus-1 transgenic rats

Authors: *N. KOTA[1], M. VIGORITO[2], V. KRISHNAN[3], S. CHANG[3];
[2]Psychology, [3]Biol. Sci., [1]Seton Hall Univ., South Orange, NJ

Abstract: Interferon regulatory factors (IRFs) are a family of transcription factors that drive anti-viral responses. One member of this family, IRF7, is elevated in the brains of human immunodeficiency virus-1 transgenic (HIV-1Tg) rats. The purpose of this study is to investigate how IRF7 beneficial activity in response to HIV by comparing the differential expression of IRF7's associated molecules between HIV-1Tg and F344 (control) rats in the prefrontal cortex, striatum, and the hippocampus. This study utilized the CLC Genomic Workbench and the Ingenuity Pathway Analysis (IPA) from QIAGEN to analyze the differential expression between HIV-1Tg and F344 rats. The RNA sequencing data from GSE47474 was analyzed using CLC. Using the research findings from the QIAGEN Knowledge Base (QKB), 514 molecules associated with IRF7 were identified. Of this group, the molecules that overlapped with molecules from the differential expression dataset between HIV-1Tg and F344 rats ($p<0.05$) was identified, giving 29 molecules which include, but are not limited to, IFNG, MAP3K8, PARP14, and TRAF1. The Core Analysis of the molecules with differential expression between HIV1-Tg and F344 rats (with IRF7, $p<0.05$) generated 532 canonical pathways (with $p<0.05$). Of these pathways, 39 were found to with z score > +/- 2, with a z score greater than zero indicating a positive correlation and a z score less than zero indicating a negative correlation. A comparison between these significant pathways and their counterparts in the Core Analysis without IRF7 indicated that IRF7 is engaged in several key immune related pathways, such as the Th2 pathway, which is involved in the formation of the humoral cell response. In the presence of IRF7 and its associated molecules, the z score for the correlation between HIV and cardiac-related pathways significantly decreases, suggesting that IRF7 may play a beneficial role to prevent cardiovascular disease in HIV patients. Most noteworthy, IRF-7 plays its greatest role in epigenetics by modifying the expression of proteins that are necessary for chromatin modification and transcriptional activation. This antiviral epigenetic activity by IRF7 may have implications for decreasing HIV viral replication. Taken together, these findings reveal that IRF7 has a profound beneficial impact on the body's response to HIV by increasing the immune response, decreasing HIV's risk factors for cardiac-related diseases, and decreasing HIV's potential to replicate. Future studies can investigate if IRF7's beneficial activity may have

therapeutic value in developing treatment for HIV patients by investigating the relevant canonical pathways.

Title: Ccr2 monocytes repair cerebrovascular damage caused by chronic social defeat stress

Authors: *M. LEHMANN, J. SAMUELS, S. KIGAR, C. POFFENBERGER, M. HERKENHAM;
NIH, Kensington, MD

Abstract: Immune surveillance of the brain plays an important role in health and disease. Peripheral leukocytes patrol blood-brain barrier (BBB) interfaces and respond to signals to engage appropriate targets during infection and injury. Classical $CCR2^{+}$ monocytes guided by chemoattractant signals respond to these insults and enter target tissue where they follow a temporally scripted pattern of pro- and anti-inflammatory activity leading to repair and return to tissue homeostasis. We have shown that chronic social defeat (CSD) causes blood-brain barrier dysfunction in the form of scattered disruptions of the cerebrovasculature. Here, we tracked monocyte trafficking to the vascular injury sites in *CCR2*$^{wt/rfp}$ reporter mice both during the CSD and following CSD cessation. We found that CSD for 14 days induced behavioral deficits in sociability coupled with microhemorrhages where plasma fibrinogen leaked into perivascular spaces and parenchyma. CSD had no effect on either the anatomical distribution or density of CCR2+ monocytes in the brain. However, if mice were given seven days to recover from CSD stress in the homecage environment, a substantial and selective elevation in numbers of adhered vascular CCR2+ cells was detected. Endothelial cell expression of the CCR2 ligands CCL7 and CCL12, but not CCL2, was found in the CSD recovery group. Adhered CCR2+ cells were mostly the non-classical, anti-inflammatory $Ly6C^{lo}$ type, and they were shown by confocal microscopy to phagocytose fibrinogen in perivascular spaces. In CCR2-deleted *CCR2*$^{rfp/rfp}$ mice, fibrinogen levels remained elevated in recovery. Fibrinogen infused intracerebroventricularly induced CCR2+ cells to adhere to the vasculature in *CCR2*$^{wt/rfp}$ but not *CCR2*$^{rfp/rfp}$ mice. We hypothesize that peripheral CCR2+ monocytes play little role during chronic psychosocial stress but have restorative functions mediating vascular repair in stress recovery.

Title: Distinct stromal niches orchestrate neonatal lymphopoiesis at the borders of the brain

Authors: *A. J. WALKER[1,4,6], T. M. FISHER[2], H. J. BARR[2,5], S. E. MARSH[7,6], V. H. GAZESTANI[6], L. DISSING-OLESEN[1], T. R. HAMMOND[2,5,6], B. A. STEVENS[3,5,6,8]; [1]F.M. Kirby Neurobio. center, [3]Harvard Med. Sch. Neurobio., [2]Boston Children's Hosp., Boston, MA; [4]Immunol., [5]Harvard Med. Sch., Boston, MA; [6]Stanley Ctr. for Psychiatric Research, Broad Inst., Cambridge, MA; [7]Neurobio., Boston Children's Hospital/Harvard Med. Sch., Boston, MA; [8]Howard Hughes Med. Institute, Boston Children’s Hosp., Boston, MA

Abstract: Brain border interfaces including the meninges - and the immune populations that reside there - serve as key intermediaries in neuroimmune communication in the healthy adult and diseased central nervous system (CNS). However, much less is known about how meningeal immune cells develop, the stromal niche that shapes their function, and their crosstalk with the developing brain.We set out to map the development of the meningeal immune and stromal compartment in the postnatal mouse. Surprisingly, we uncovered a wave of B cells that colonize the dural meninges shortly after birth and largely disappear by adulthood. Single cell RNA sequencing (scRNA-seq) demonstrated that early life meningeal B cells recapitulate Pro, Pre, and immature B cell stages and are transcriptionally similar to B cells found in the overlying calvarium bone marrow. Given the intimate anatomical relationship between the calvarium bone marrow and the dura, we next aimed to define the stromal niches that orchestrate lymphopoiesis across this bone-meninges interface. Our scRNA-seq data revealed diverse populations of fibroblasts in the dura that produce canonical hematopoietic niche factors but are largely transcriptionally distinct from stromal populations that support hematopoiesis in the calvarium bone marrow. We found that large clusters of B cells associate with defined populations of fibroblast-like cells lining the dural meningeal sinuses, and that specific ablation of niche factors from meningeal fibroblasts disrupts B cell localization to this peri-sinus niche. Trans-calvarial two-photon imaging of neonatal mice revealed dynamic movement of B cells between the calvarium and the dura after disruption of niche factors, suggesting that these molecularly and

spatially defined niches may coordinately regulate lymphopoiesis in early life.This data provides critical insight into early life B cell development and underscores a general feature of the meninges as a functional B cell niche. Ongoing studies aim to explore the role of this fibroblast niche in B cell driven CNS diseases such as multiple sclerosis and CNS leukemia.

Title: Cervical spinal electrical epidural stimulation (EES) induced phase resetting of respiration

Authors: *Y. ZHOU[1], R. HUANG[2], J. WORRELL[2], E. GARNER[2], S. WANG[2], T. TOMSEY[3], B. XU[2], E. L. GALER[2], S. TAVAKOL[3], M. DANESHVAR[4], T. LE[2], H. V. VINTERS[2], N. SALAMON[1], D. L. MCARTHUR[1], M. R. NUWER[1], I. WU[2], J. C. LEITER[5], D. C. LU[2]; [1]UCLA Chapter, Los Angeles, CA; [2]UCLA, Los Angeles, CA; [3]USC, Los Angeles, CA; [4]Oakland Univ. William Beaumont Sch. of Med., Rochester, MI; [5]Dartmouth, Hanover, NH

Abstract: Phase resetting is the activity of an oscillator that restarts with interruption before it completes a cycle. In the central nervous system (CNS) of humans and other mammals, phase resetting of an oscillator often indicates the change in the firing patterns of neurons that contribute to establishing the time frame of the oscillator. Among the oscillators in the human CNS, the respiratory central pattern generator (CPG) is one of the oscillators that are essential for life. Investigating the phase resetting of respiration not only elucidates the neuronal structure but also helps to develop therapeutic interventions for respiratory dysfunction. In this study, we discovered that electrical epidural stimulation (EES) delivered at the dorsal cervical spinal cord can induce respiratory phase resetting in human subjects. Respiratory phase resetting was analyzed by noting the change in phase (or not) when the onset of EES occurred at different times of the respiratory cycle in the anesthetized human subjects with spontaneous breathing. We measured the respiratory phase shift during the spontaneous respiration and compared phase resetting between the stimulation and sham (no stimulation control) tests at seven different cervical levels. Respiratory cycle phase resetting was more common during 5 or 30 Hz EES than

during sham stimulation. Resetting may advance or delay the respiratory cycle. Therefore, we took the absolute value of the change in phase angles and transformed these absolute values using the Box-Cox transformation since angles are not normally distributed. After transformation, the two-way ANOVA and paired comparisons indicated that the EES-induced phase angle changes observed after the start of 5 Hz EES and 30 Hz EES was significantly greater than the spontaneous variation of phase angles in the sham condition ($p < 0.0001$ for both sham vs. 5 Hz and sham vs 30 Hz). Our finding is consistent with the previous studies reporting respiratory settings after single pulses of dorsal cervical epidural stimulation, but not after ventral after EES. This observation suggests that spinal EES activates elements of the supraspinal respiratory CPG via recruitment of the propriospinal neurons and afferent sensory pathways in the dorsal spine or by activating a local spinal respiratory CPG.

Abstract: The rhythmic neural activity that produces breathing in mammals is generated by specialized neuronal networks - the respiratory central pattern generator (CPG) - located in the brainstem. However, those regions related to the respiratory pattern generation, such as the preBotinger Complex (preBotC) and rostral ventral respiratory group (rVRG), are difficult to access. The respiratory failures due to pathologies of the central nervous system, especially the brainstem, has high mortality and morbidity rate since there is no safe and effective means to

modulate respiration through the brainstem. The stimulation at the cervical spinal cord emerges to be a novel alternative in respiratory facilitation. In the spinal cord injured and non-injured animals, pharmacogenetic stimulation of cervical excitatory interneurons enhances respiratory motor function. Furthermore, epidural electrical stimulation (EES) at cervical spinal cord facilitates the respiratory frequency in non-injured mice and human subjects. Given all these promising discoveries, it is important to investigate if the stimulation at the cervical spinal cord can facilitate respiratory drive when the respiratory circuit in the brainstem is compromised. In this study, we optogenetically suppressed the activity of somatostatin (SST)-expressing neurons in the preBotC and rVRG. This was performed in SST-Cre expressing mice injected with adeno-associated virus (AAV) that harbored Cre-dependent halorhodopsin. EES was delivered between cervical level 3 and 4 at 30 hertz frequency for 30 seconds during the opto-inhibition. The thirty-second EES was sufficient to reverse the respiratory inhibition caused by optogenetics during the stimulation and the respiration perpetuated another 30 second after the EES stopped under the opto-inhibition. Our findings above suggest that the cervical spinal cord could serve as a neuromodulation portal to activate the respiratory CPG.

Title: The role of glutamatergic signaling in central noradrenergic neurons in respiratory control

Authors: *Y. CHANG[1], R. RAY[2];
[1]Mol. Physiol. and Biophysics, [2]Deparment of Neurosci., Baylor Col. of Med., Houston, TX

Abstract: Central noradrenergic (NA) neurons are key constituents of the respiratory homeostatic network. NA dysfunction is implicated in several developmental respiratory disorders such as the fatal Sudden Infant Death Syndrome (SIDS) and Rett Syndrome, in which abnormal chemosensory function is implicated. However, which NA populations modulate respiratory chemoreflexes and the underlying mechanisms are still not fully understood. Histological evidence suggests that glutamate is co-transmitted in subsets of brainstem NA

neurons, some of which may contribute to regulating chemoreflexes. However, the extent of glutamate co-transmission in the central NA system remains uncharacterized. Further, it remains unclear what role NA-based glutamatergic signaling plays in various aspects of respiratory homeostasis. To anatomically map potential glutamate-expressing NA neurons, we characterized the expression profile of all three known of Vesicular Glutamate Transporters (Vglut1, Vglut2 and Vglut3) in NA neurons by intersectional genetic fate mapping. For each Vglut1/2/3 transporter, a corresponding Cre knock-in recombinase line was combined with *DBH-p2a_Flpo* mice. These *Vglut1/2/3_Cre; DBH-p2a_Flpo* compound lines were crossed with the *RC::F_TdTomato_P_GFP* intersectional reporter mice. In each of the three intersectional reporter crosses, NA neurons co-expressing either Vglut1, Vglut2, or Vglut3 are labeled by green fluorescent protein (GFP) while NA neurons without any Vglut1/2/3 expression are labelled by red fluorescent protein (tdTomato). Our preliminary cumulative fate maps found expression of one or more glutamate transporters in every single NA nucleus in adult mice. Importantly, these fate maps reflect the cumulative expression profiles of glutamate markers in NA neurons throughout the development and lifetime of the mouse. To determine what physiological role, if any, Vglut2-based glutamatergic signaling may play in adult respiratory homeostasis, we conditionally ablated Vglut2 in central NA neurons by crossing *DBH-Cre/+* with *Vglut2*$^{flox/flox}$ mice. Mutants and sibling controls (6-8 weeks) were assessed for respiratory function by whole-body barometric plethysmography. Ventilation and VO2 were assessed under room air (21%O_2,79%N_2), hypercapnia (21%O_2, 74%N_2, 5%CO_2) and hypoxia (10% O_2, 90% N_2). Our preliminary data indicates that loss of Vglut2 in NA neurons does not significantly impact breathing under room air, hypercapnia or hypoxia, suggesting that Vglut2-based glutamatergic signaling in the central NA system may be dispensable for several aspects of ventilatory control.

Title: Butyrate supplementation rescues sex-specific deficits in respiratory plasticity and mean arterial pressure in adult offspring exposed to gestational intermittent hypoxia

Authors: *C. R. MICKELSON, E. P. KOBITTER, A. L. MEZA, A. B. RADCLIFF, K. K. HILL, R. SONG, J. S. MISHRA, S. KUMAR, J. J. WATTERS, T. L. BAKER;
Comparative Biosci., Univ. of Wisconsin-Madison, Madison, WI

Abstract: Sleep disordered breathing (SDB) in pregnancy is increasing in parallel with the obesity epidemic, and is linked to adverse perinatal outcomes in the offspring. Consequences of maternal SDB during pregnancy on the adult offspring are not well-understood. Preliminary data indicate that adult male, but not female, offspring of dams exposed to intermittent hypoxia during gestation (GIH - gestational intermittent hypoxia), a rat model of SDB during pregnancy, have elevated mean arterial pressure (MAP), increased neuroinflammation, inflammation-induced impairment of homeostatic plasticity in the respiratory control system, and gut dysbiosis. Specifically, adult male GIH offspring have decreased relative abundance of gut bacteria that produce butyrate, a short-chain fatty acid that has potent anti-inflammatory properties and regulates immune function in the central nervous system. Since literature suggests that gut dysbiosis, neuroinflammation, and hypertension exist in a complicated vicious cycle, we treated male GIH offspring with tributyrin, a butyrate prodrug. Prior to tributyrin treatment, MAP in male GIH offspring was 96±3 mmHg, versus 76±1 mmHg in control rats receiving gestational intermittent normoxia (GNX). Similarly, male GIH offspring exhibited deficits in respiratory plasticity in response to recurrent central apneas (3.6±6.8% plasticity), when compared to GNX offspring (59.3±4.8% plasticity). GIH offspring exhibited evidence of elevated neuroinflammation in brain regions underlying respiratory control (e.g., IL-1β expression 1.6±0.2-fold higher than GNX controls (1.0±0.2)). Following three weeks of tributyrin treatment, MAP had normalized (80±2 mmHg) and the ability to express respiratory neuroplasticity was rescued (78±30%). Studies on whether tributyrin also reduces neuroinflammation are ongoing. These data indicate that gut dysbiosis may contribute to sex-specific impairments induced by maternal exposure to intermittent hypoxia during gestation that can be rescued in adulthood by supplementing with butyrate.

Title: Endomorphin-2 at low concentrations increases respiratory motor burst amplitude in neonatal rat brainstem-spinal cord preparations

Authors: *M. G. GUMNIT, J. J. WATTERS, T. L. BAKER, S. M. JOHNSON;
Univ. of Wisconsin-Madison, Madison, WI

Abstract: Mu-opioid receptors (mOR) and their endogenous ligands are part of an intricate peptidergic neuromodulatory system that regulates respiratory neural activity. The association of opioid use and respiratory depression is well established, but the endogenous role of mOR in respiratory motor control is poorly understood. To explore this question, we tested very low (nanomolar) concentrations of mOR agonists using isolated neonatal rat (P1-P3) brainstem-spinal cord preparations and quantified respiratory-related motor output from spinal C4-C5 ventral rootlets. When DAMGO (synthetic opioid mOR agonist) or endomorphin-2 (endogenous ligand for mOR) were bath-applied for 15 min at 10-100 nM, respiratory-related motor burst frequency decreased, but there was also a large increase in burst amplitude. Burst amplitude facilitated 45 ± 38% and 32 ± 24% (mean ± stdev) above baseline for 50 nM DAMGO (n=8) and 100 nM endomorphin-2 (n=10), respectively ($p<0.001$). When DAMGO or endomorphin-2 were bath-applied at 20 nM, burst amplitude increased by 26-29% ($p<0.05$), burst frequency decreased by 10-20% ($p<0.01$), but the overall minute activity (total motor burst area per min) was unchanged at -8 ± 30% ($p=0.84$) and 1 ± 32% ($p=.84$) of baseline, respectively. These data suggest that mOR activation with low agonist concentrations transforms the respiratory network to produce a different motor pattern without compromising blood-gas homeostasis. We speculate that the endogenous mOR system in the brainstem may play a role in respiratory motor behaviors requiring a large tidal volume and low frequency, such as coughing or gasping.

Title: Activation of leptin receptor positive neurons in dorsomedial hypothalamus stimulates breathing in obese mice

Authors: *M. R. AMORIM[1], X. WANG[2], H. PHO[1], S. BEVANS-FONTI[1], F. ANOKYE-DANSO[1], J. ESCOBAR[2], O. DERGACHEVA[2], L. G. S. BRANCO[3], D. MENDELOWITZ[2], V. Y. POLOTSKY[1];

Abstract: Introduction: Obesity leads to obstructive sleep apnea (OSA), characterized by loss of upper airway muscle tone during sleep leading to carbon dioxide retention and intermittent hypoxemia. OSA leads to high neurocognitive, cardiovascular, and oncologic morbidity and mortality. There is no effective pharmacotherapy for OSA. We have previously shown that an adipose-produce hormone leptin acts in the brain to abolish hypoventilation and upper airway obstruction during sleep, and, therefore may be a promising therapeutic in obese patients with OSA. Our previous data also suggest that leptin stimulates breathing acting on the leptin receptor ($LEPR^b$) positive neurons in the dorsomedial hypothalamus (DMH), but not in the medulla. **Aim:** In this study, we examined the contribution of $LEPR^b$ positive neurons in the DMH to control of breathing and upper airway function during sleep in diet-induced obese mice. **Methods:** We expressed designer receptors exclusively activated by designer drugs (DREADD) selectively in the $LEPR^b$ positive neurons of the DMH of *Lepr^b*-Cre-GFP mice with diet-induced obesity (DIO) and examined the effect of DREADD ligand, J60, on breathing during sleep. **Results:** Chemogenetic activation of $LEPR^b$ positive DMH neurons increased inspiratory flow, respiratory rate, and minute ventilation during REM sleep, without significant changes in sleep architecture. The effect was particularly pronounced during inspiratory flow limitation, which suggest that upper airway obstruction during REM sleep was relieved. Activation of $LEPR^b$ positive DMH neurons with a DREADD ligand J60 increased the hypercapnic ventilatory response (HCVR) and this response was blunted by a serotonin receptor antagonist, methysergide. *In vitro* experiments revealed that DMH $LEPR^b$ neurons project to the serotonergic neurons in the dorsal raphe and that optogenetic stimulation of DMH $LEPR^b$ neurons evoked excitatory post-synaptic currents in ChR2 expressing neurons. **Conclusion:** Leptin up-regulates the hypercapnic ventilatory response and upper airway patency during sleep acting on $LEPR^b$ neurons in the DMH. Respiratory effects of leptin are likely mediated via projections of these neurons to the dorsal raphe.

Title: Glutamatergic preBötzinger Complex neurons as potential targets to alleviate opioid-induced respiratory depression

Authors: *N. PARZEI[1,2], C. SCARPELLINI[1], G. MONTANDON[1,2,3];
[1]Keenan Res. Ctr. for Biomed. Sci., St. Michael's Hosp., Toronto, ON, Canada; [2]Inst. of Med. Sci., [3]Div. of Respirology, Dept. of Med., Univ. of Toronto, Toronto, ON, Canada

Abstract: The current opioid epidemic in North America is staggering and has been exacerbated by the COVID19 pandemic. Opioid drugs are highly addictive, and when abused and overdosed can lead to lethal respiratory depression. The preBötzinger Complex (preBötC) is a small brainstem region generating respiratory rhythm and mediating opioid-induced respiratory depression (OIRD). In the preBötC, a large population of neurons are glutamatergic and co-express μ-opioid receptors (MOR). Blocking MOR in the preBötC reverses OIRD, suggesting that preBötC neurons may be potential targets to selectively prevent respiratory depression. However, it is unknown whether glutamatergic neurons may serve as druggable targets for the development of an antidote for OIRD. To specifically stimulate glutamatergic preBötC neurons, we expressed the Designer Receptors Exclusively Activated by Designer Drugs, hM3Dq (an engineered version of the M3 muscarinic receptor), in neurons with vesicular glutamate transporter 2 (VGLUT2, a marker of glutamatergic neurons) using a cre-lox recombination approach. We unilaterally injected the viral vector (AAV-hM3Dq-mCherry) in the preBötC region of Vglut2-IRES-Cre male mice (Jackson Labs stock # 016963). Four weeks after virus injection, mice were anesthetized, and electrodes were implanted in the diaphragm and genioglossus muscles to measure respiratory activity. OIRD was induced by injection of fentanyl (5 μg/kg) and VGLUT2 cells were activated with the hM3Dq ligand clozapine-N-oxide (CNO, 1 mg/kg). Mouse brains were collected to quantify hM3Dq expression in the brainstem. Preliminary data show that activation of VGLUT2 preBötC neurons with CNO increased respiratory rate. This suggests that it would prevent respiratory rate depression by fentanyl when compared to mice receiving fentanyl alone. Further experiments aim to demonstrate whether hM3Dq-mCherry is specifically expressed in preBötC cells and co-expressed with MORs. OIRD will also be assessed in freely-behaving mice using whole-body plethysmography. Preliminary data suggest that glutamatergic preBötC neurons may be considered as potential targets for the development of preventive drug therapies for respiratory depression during opioid overdose.

Title: Spinal Adenosine 2A receptor inhibition amplifies moderate acute intermittent hypoxia-induced phrenic long-term facilitation in aging male rats

Authors: *A. B. MARCIANTE, G. S. MITCHELL;
Physical Therapy, Univ. of Florida, Gainesville, FL

Abstract: Phrenic long-term facilitation (pLTF) is a form of respiratory plasticity elicited by acute intermittent hypoxia (AIH). AIH activates competing cellular mechanisms of phrenic motor plasticity, initiated by serotonin 2 and adenosine 2A (A_{2A}) receptors on phrenic motor neurons, respectively. With moderate AIH (mAIH), the serotonin-dependent Q pathway to phrenic motor facilitation dominates, with an adenosine constraint. Consequently, spinal A_{2A} receptor inhibition blocks this adenosinergic constraint and enhances mAIH-induced pLTF. With increasing age, pLTF decreases due to progressively declining levels of circulating testosterone and glial-derived estrogen levels in males and post-menopausal females in the CNS. We hypothesize that, in aged male rats, mAIH triggers greater glial adenosine release, increasing the "brake" on the still dominant Q pathway to phrenic motor facilitation, thereby decreasing pLTF. Thus, we predict that blocking spinal A_{2A} receptors in aged male rats will release the age-enhanced adenosine constraint, restoring pLTF to levels equal to or above those observed in young male rats. To test this hypothesis, a selective A_{2A} receptor antagonist (MSX-3; 10 uM, 12 uL) or vehicle (0.9% sterile saline) were delivered intrathecally (C4) in anesthetized, vagotomized, paralyzed and ventilated young (3-6 months) and aged (20-22 months) male Sprague-Dawley rats prior to mAIH (3, 5 min hypoxic episodes; arterial Po_2 = 45-55 mmHg). In young males, mAIH consistently and reproducibly induces pLTF of approximately 60% above baseline at 60 minutes post-hypoxia. As expected, A_{2A} receptor inhibition significantly enhanced mAIH-induced pLTF in young male rats (n = 6; 118.5 $\pm$ 5.4%) versus vehicle controls (n = 6; 55.3 $\pm$ 8.7%; $p < 0.001$) and time controls (n = 6; 11.7 $\pm$ 4.4%; $p < 0.001$). In aged males, A_{2A} receptor inhibition enhanced mAIH-induced pLTF to an even greater extent (n = 6; 180.3 $\pm$ 21.3%) versus vehicle controls (n = 4; 29.4 $\pm$ 19.4%; $p < 0.001$) and time controls (n = 3; 2.3 $\pm$ 6.8%; $p < 0.001$). Preliminary data suggest aged female rats (16-18 months) also have enhanced mAIH-induced pLTF with A_{2A} receptor inhibition (n = 2; 148.8 $\pm$ 1.9%) versus vehicle controls (n = 2; 46.2 $\pm$ 3.7%) and time controls (n = 2; 5.3 $\pm$ 17.2%) in estrus. These findings advance our understanding of age-related sexual dimorphism in intermittent hypoxia induced phrenic motor plasticity. Understanding age and sex effects on AIH-induced respiratory motor plasticity is fundamental as we translate and develop new therapies for severe neuromuscular disorders that compromise breathing and other movements.

Title: Suppression of apneas by dextromethorphan in Sprague Dawley rats

Authors: *M. W. CALIK;
Biobehavioral Nursing Sci., Univ. of Illinois Chicago, Chicago, IL

Abstract: Obstructive sleep apnea (OSA) prevalence in American men and women is estimated at 14% and 5%, respectively, and prevalence rates are increasing. OSA's acute physiological effects (hypoxemia/hypercapnia, fragmented sleep, etc.) can develop into long-term sequelae (diabetes, cardiovascular morbidities, etc.). There are no pharmacological treatments for OSA. Accumulating evidence indicates the potential importance of afferent vagus nerve activity and its central synaptic targets in modifying respiratory control. Recent work has shown that cannabimimetic treatment using dronabinol (Dron) in rats decreased sleep apnea duration/events through activation of cannabinoid receptors on nodose ganglia; similar cannabimimetic decrease in apneas has been shown in humans. However, cannabinoids have also been shown to decrease REM sleep in rats and humans. Though it is the most advanced candidate for a pharmacotherapy for OSA, Dron is a controlled substance with substantial psychogenic effects. Thus, further research is needed to identify better pharmacological treatments. Dextromethorphan (DEX), a safe nonprescription antitussive, has been shown to inhibit serotonin-induced inward current in rat nodose ganglion cells. However, it is unknown if DEX can decrease apnea propensity. Here, we hypothesized that DEX would decrease apneas in rats. Two experiments were conducted. In the first experiment, using an established animal model of reflex apnea, adult male Sprague Dawley rats were anesthetized and instrumented with bilateral electrodes to monitor genioglossi EMG and with a piezoelectric strain gauge to monitor respiratory pattern. Serotonin was IV infused to induce apnea. DEX was injected into each nodose ganglion and IV serotonin infusion was repeated to induce apneas. In the second experiment, using a conscious animal model of sleep, adult male Sprague Dawley rats were individually placed in PiezoSleep cages to noninvasively monitor breathing and sleep. Before placement into the cages, a repeated measures random order crossover design was implemented, such that each rat received each of 4 IP injections exactly one time: vehicle alone (DMSO); Dron alone; DEX alone; or Dron/DEX combination. Our results show that DEX injected into the nodose ganglia decreased reflex apneas and increased upper airway activation compared to controls. In conscious rats, IP DEX showed no effect on sleep efficiency; Dron, however, decreased sleep efficiency as previously. IP DEX and IP Dron decreased apneas, and combination of Dron/DEX had the largest decrease in apneas. Collectively, the results show the feasibility of DEX as a potential pharmacological treatment for OSA.

Title: The optogenetic stimulation of PiCo neurons increases the sympathetic activity during postinspiration in vivo mice

Authors: *M. KARLEN-AMARANTE[1,2], A. D. HUFF[1], N. A. BAERTSCH[1], D. S. A. COLOMBARI[2], J. RAMIREZ[1,3];
[1]Ctr. for Integrative Brain Res., Seattle Children's Res. Inst., Seattle, WA; [2]UNESP Sch. of Dent., Araraquara, Brazil; [3]Neurolog. Surgery, Univ. Washington, Seattle, WA

Abstract: Inspiratory rhythmic activity is generated by the synchronized activity of the preBötzinger complex (preBötC), a well-known heterogenous network consisting of glutamatergic and glycinergic/GABAergic neurons that are essential for breathing. Recent studies identified the so called postinspiratory complex (PiCo), a rhythmogenic network which is critical for generating postinspiratory (post-I) activity in vivo and in vitro. Like the preBötC, PiCo contains inhibitory and excitatory neurons. The excitatory neurons are characterized by a cholinergic/glutamatergic transmitter phenotype. There is increasing evidence that respiratory neurons also interact with presympathetic neurons involved in the generation of sympathetic activity. This interaction has been attributed to the increased sympathetic activity and changes in respiratory-sympathetic coupling following exposure to chronic intermittent hypoxia (CIH). To investigate the contribution of PICo in the respiratory-sympathetic coupling, we used an optogenetic *in vivo* mouse preparation previously exposed to CIH for 3 weeks (5% O_2 - 80 bouts/day). The ventral surface of the brainstem in spontaneously breathing, anaesthetized (Urethane 1.5mg/kg) CHATCre/Ai32 adult and Vglut2cre/Ai32 mice was exposed and an optical fiber positioned bilaterally over the PiCo, while recording the diaphragm muscle (DIA), hypoglossal (HN), cervical vagus (cVN) and cervical sympathetic nerves (cSN). Our data show that CIH exposure increased the respiratory frequency, post-I vagus activity and sympathetic activity during all respiratory phases. The predominance of inspiratory coupled sympathetic activity seen in controls was reduced after CIH exposure due to an increased sympathetic activation during the post-I and late expiratory (E2) activity phase. Random optogenetic

stimulation (200ms) of PiCo Chat or Vglut neurons (~ 9mV, 447nm) in control mice significantly promoted sympathetic activity during post-I activity, thereby blunting the difference between post-I and E2. We conclude that CIH increases baseline respiratory frequency and sympathetic activity *in vivo* and suggests that an increased PICo activation may contribute to increased sympathetic drive during post-I and hypertension in CIH.

Title: Impact of the laryngeal adductor reflex on swallow-breathing relationship during high respiratory drive
Swallow is initiated by oral/pharyngeal afferent feedback, but it must coordinate with breathing. This relationship is critical for maintaining a clear airway and reducing risk of aspiration. Swallow is modulated by afferent input, and numerous other reflexes also act to protect the airway and must coordinate with swallow and breathing. The laryngeal adductor reflex (LAR) is a rapid reflex which closes the glottis and limits the chance of aspiration. We induced LAR and swallowing in anesthetized spontaneously breathing cats by infusing water into the oropharynx under conditions of room air or 10% CO_2. Electromyogram activity was measured using bipolar electrodes inserted into the upper airway, chest wall, and diaphragm muscles. In cats breathing

room air, 90% of swallows occurred during expiration (E), 10% during the transition from inspiration to expiration (I-E), and 0% during inspiration (I). Under hypercapnic conditions of 10% CO2, swallows occurred more frequently during I (31%), 19% during I-E transition, 22% during E-I transition, and 28% during E. On room air, 100% of the LARs occurred during E. During hypercapnia, LARs occurred during I (13%), I-E transition (25%) and E-I transition (63%). Overall, hypercapnia significantly reduced LAR occurrence. These results suggest that the LAR is suppressed during high respiratory drive, which causes swallow to occur more frequently during inspiration. This confluence of factors may increase risk of aspiration during periods of high respiratory drive. Abstract: The intense audiovisual stimuli of modern casinos may promote riskier play - a phenomenon that can be modeled preclinically using the rat gambling task. Rats are given a choice between large, unlikely rewards (risky) and smaller, more certain ones (optimal). When casino-like cues are introduced, the proportion of risk-preferring rats is enriched over time. We theorize that the phasic dopamine release evoked by these cues causes compensatory changes in the dopamine system to promote risk-taking. The neurons supplying acetylcholine to nucleus accumbens core (NAc) are powerful titrators of NAc dopamine release. Via local terminal modulation of dopamine neurons, NAc acetylcholine contributes to the maintenance of tonic NAc dopamine. Motivationally relevant cues halt NAc acetylcholine release, thus stopping the tonic stream of dopamine, giving way to the influence of the cue-evoked phasic dopamine we theorize to potentiate risk-taking. We therefore sought to leverage the NAc acetylcholine system

to manipulate cue-driven risk taking. By depleting NAc acetylcholine and consequently reducing tonic DA release, we hypothesized that the cue-induced phasic DA signal would have a greater impact (i.e., greater signal to noise ratio), thereby enhancing cue-induced risk-taking. Driving NAc acetylcholine release should, conversely, decrease the signal-to-noise ratio of cue-induced tonic DA release and foster an optimal strategy. Using DREADDs in combination with female and male ChAT:cre transgenic rats, we bidirectionally modulated the cholinergic neurons supplying the NAc. In separate cohorts, we performed the manipulation chronically as rats learned the task and acutely in well-trained rats. In rats that underwent chronic inhibition during learning, a longitudinal increase in risk taking was observed, while excitation resulted in a reduction. Interestingly, the inhibition effect was observed only in females and the excitation effect only in males -- this may be due to baseline differences in tonic dopamine levels across the sexes. Acutely inhibiting NAc acetylcholine had a less pronounced effect, supporting our theory of a cue-induced longitudinal emergence of a risk-taking phenotype. These findings furthermore point to biological sex as an important consideration in the development of pharmacotherapies.

Title: Midbrain dopamine neurons are powerful effectors of addiction-like behaviour

Authors: *T. HYNES[1], K. HRELJA[1], C. CHERNOFF[1], M. TSE[3], G. D. BETTS[1], M. LYSENKO-MARTIN[5], B. RUSSELL[1], B. RUSSELL[1], L. CALDERHEAD[1], A. LI[1], S. KAUR[2], S. B. FLORESCO[4], C. A. WINSTANLEY[3];

Abstract: Addiction is a complex affliction, characterized not only by the use of drugs, but also by deficits in cost/benefit decision making. A critical biological factor in the development of addiction is aberrant dopamine (DA) neurotransmission. Biological sex is also an important consideration. Investigating such phenomena is difficult in humans, because of the profound influence the socio-political construct of gender has on behaviour. We therefore sought to longitudinally probe the complex intersection of addiction, decision making, sex, and DA

neurotransmission by combining our cued rat gambling task (crGT; a rodent assay of cost/benefit decision making) with operant intravenous cocaine self-administration and chemogenetic manipulations of DA neurons. We infected the midbrain DA neurons of female and male rats with either excitatory or inhibitory designer receptors, before training them in our crGT. Prior to daily crGT training sessions, we administered clozapine-N-oxide to activate the receptor and modulate the excitability of midbrain DA neurons. Once rats achieved stable crGT performance, we allowed them to self-administer intravenous cocaine. In females, both inhibition and excitation of midbrain DA neurons increased risk-taking. Excitation of midbrain DA neurons also increased impulsivity and psychomotor sensitization to cocaine. In males, risk-taking was reduced by inhibition of midbrain DA neurons and their projections to the accumbens. Inhibition of midbrain DA neurons furthermore decreased impulsivity in males. In both sexes, inhibition or excitation of midbrain DA neurons increased cocaine-taking and psychomotor sensitization to cocaine but prevented cocaine-induced deficits in decision making. Regardless of direction, upsetting the balance of the DA system has generally deleterious effects in females. For males, dopaminergic inhibition is generally protective against addiction-relevant behaviours, while excitation of the system is pro-addictive. Excitation was furthermore associated with sensitized phenotype (i.e., increased phasic activity of DA neurons locomotor reactivity to cocaine). These findings shed light on the still outstanding question as to how both hyper- and hypo-dopaminergic states contribute to addiction vulnerability.

Title: In order to drive risky choice, cues must be predictable and win-paired: a computational modelling analysis

Authors: *D. R. KIM, S. B. A. MALHAS, C. A. WINSTANLEY, B. A. HATHAWAY; Univ. of British Columbia, Vancouver, BC, Canada

Abstract: Win-associated cues can enhance disadvantageous risky choice in both rats and humans, and the impact of cues on risky choice is a major component of many theories of addiction. However, the role of specific elements of such cues in producing this behavioural

effect has not been thoroughly investigated. Accordingly, the present experiments assessed the effect of five different cue administration paradigms on reinforcement learning and risky decision making.
Four cohorts of 32 to 64 male Long-Evans rats were trained on six versions of the rat Gambling Task (rGT), a rodent analogue of the human Iowa Gambling Task. This task was designed such that the optimal strategy for earning sugar pellets over time is to favour options paired with lower per-trial gains, as these are associated with a higher probability of winning and shorter time-out penalties. Consistently selecting the high-risk, high-reward options - which feature larger per-trial gains but longer and more frequent time-out penalties - leads to less reward overall. Audiovisual cues were paired with differing sets of outcomes to create five variants of the rGT. On the standard-cued version of the task, audiovisual cues are delivered only on winning trials, and scale in magnitude and complexity with reward size. For the reverse-cued task, the cues are reversed such that the longest and most complex cue is paired with the smallest reward. For the outcome-cued task, cues are delivered with every outcome - both wins and losses. For the random-cued task, cues are delivered with a 50% probability across both winning and losing trials. Finally, the loss-cued task only delivers cues on losing trials.
As observed in previous experiments, there was a higher proportion of risk-preferring rats on the standard-cued task compared to the uncued task. The outcome-cued and reverse-cued task variants produced a similar risky choice profile to the standard-cued task. Conversely, rats trained on the loss-cued and random-cued variants did not exhibit this cue-induced risk preference. Early computational analyses indicate that win-paired cues reduce the impact of losses on decision making, and the impact of wins is increased when cues track reward size. These results suggest that cues do not increase risky choice by simply elevating arousal, or amplifying the difference between wins and losses. Instead, it is important that the cues are associated with wins, and that they occur on every win. Interestingly, if such conditions are met, presenting the cues on losing outcomes does not diminish their ability to drive risky choice. These results may help us understand how sensory stimulation can increase the addictive nature of gambling products.

Title: The effects of selective activation of the dopamine D2 and D3 receptors on risk preference in male rats

Authors: *B. RUSSELL[1], H. BRODIE[1], K. HRELJA[1], S. ANSARY[1], T. CHANG[1], C. A. WINSTANLEY[2];
[1]Univ. of British Columbia, Vancouver, BC, Canada; [2]Psychology, Univ. British Columbia, Vancouver, BC, Canada

Abstract: Dopamine D2/D3 receptor agonists, like ropinirole, are commonly prescribed to individuals with Parkinson's disease. Although these drugs are effective at alleviating Parkinsonian motor symptoms, they have also been found to induce gambling disorder and other behavioural addictions, as well as impulse control disorders, in a substantial minority of patients. However, the underlying mechanism by which these drugs induce these behaviours has been debated. There are findings to support the role of both the D2 receptor and D3 receptor in the development of iatrogenic gambling disorder, with some studies suggesting that activation of the D3 receptor, and not the D2 receptor, is precipitating these disorders. Previous research has shown that the administration of non-selective dopamine D2/D3 receptor agonists can increase preference for uncertainty and risky decision-making in healthy male rats. Thus, the purpose of the current experiment was to examine whether the D2 receptor and/or the D3 receptor can independently induce risky decision-making in male rats on the cued rat gambling task (cued rGT), an adaptation of the Iowa Gambling Task (IGT). 88 male Long Evans rats were trained on the cued rGT, in which rats choose between four options associated with distinct magnitudes and probabilities of reward (1-4 sugar pellets) or time-out penalties (5-40s). The optimal strategy is to favour options associated with smaller per trial gains, but shorter penalties. Following training to nose-poke for reward, rats received daily injections of the selective D2 agonist sumanirole (n=16 at 0.10 mg/kg and n=16 at 0.65 mg/kg), the selective D3 agonist PD128907 (n=16 at 0.10 mg/kg and n=16 at 0.60 mg/kg), or saline (n=24) prior to testing. These injections were administered throughout the acquisition phase of the cued rGT and until behavioural stability on the task was reached. Next, the rats completed 8 sessions on the cued rGT without any drug being administered prior to testing. Although 0.10 mg/kg of PD128907 increases risky choice when given acutely once rats have acquired the task, chronic administration during acquisition at this dose did not increase risk preference. The results from this experiment will offer insight into the selective contribution of D2 and D3 receptor agonism on decision making and the development of both iatrogenic and idiopathic gambling disorder and other addictive disorders.

Title: Excitation of substantia nigra pars compacta increases motor impulsivity during probabilistic decision making

Authors: *G. D. BETTS, B. A. HATHAWAY, T. J. HYNES, C. A. WINSTANLEY;
Univ. of British Columbia, Vancouver, BC, Canada

Abstract: Dopamine has a significant influence on decision making and impulsivity - two defining phenotypes of many neuropsychiatric disorders. A critical node of DA neurotransmission is the substantia nigra pars compacta (SNc), which makes it a promising target for pharmacotherapy. The necessary experimental manipulations to explore the behavioral role of SNc dopamine in humans, however, is prohibitive. We therefore sought to determine the role of SNc dopamine neurons in the cued rat gambling task (rGT) - a translationally-valid model of impulsivity and decision making. We transfused the SNc of TH::Cre transgenic rats with a DIO viral vector carrying the construct for the DREADD hM3D(Gq), allowing us to gain excitatory control over the DA neurons projecting from the region. Prior to each cued rGT training session, we administered clozapine-N-oxide (1.0 mg/kg for 30 sessions) to actuate the DREADD for the duration of the task. We found that Gq stimulation of SNc dopamine neurons increased impulsivity, while having no effect on decision making. This impulsivity could not be attributed to hyperlocomotion, as Gq stimulation had a small effect of increasing response latencies. Further, this increase of impulsivity and response latency was present only in risk-preferring rats. These findings are unique from Gq stimulation of the ventral tegmental area dopamine neurons, which causes deficits in decision making while leaving impulsivity intact. The SNc preferentially innervates the dorsal striatum, whereas the ventral tegmental area projects more ventrally; albeit a simplified interpretation, it is possible that the present discovery points to dissociable striatal loci that govern dopaminergic control over decision making (ventral tegmental area) as opposed to impulsivity (SNc). Projection-specific manipulations of SNc dopamine neurons will be conducted to further investigate this theory.

Title: The effect of dopamine D2 receptor agonists and antagonists on decision making in a rodent cognitive effort task

Authors: *L. CALDERHEAD, C. WINSTANLEY;
Univ. of British Columbia, Vancouver, BC, Canada

Abstract: Maladaptive decision-making involving effort is common in multiple psychiatric disorders. Animal models of effort-based decision making have implicated mesolimbic dopamine in regulating motivation to engage in effortful tasks to obtain greater rewards. While this effort can be physical or cognitive, these two forms have overlapping but distinct neural circuitry. A rodent cognitive effort task (rCET) has previously been developed to study such decision making in rats. The psychostimulant amphetamine has been shown to influence decision making on the rCET. When administered amphetamine rats who previously preferred low effort options (slackers) to choose high effort options more and those who preferred high effort (workers) to choose the low effort option more. However, the biological mechanism of amphetamines action is unknown. Here we conduct confirmatory research to examine the effect of pharmacological dopamine D2 receptor agonism and antagonism on male Long-Evans rats choice behaviour on the rCET while replicating previous amphetamine results and determining if the effects of amphetamine can be blocked by co-administration of a D2 antagonist. The D2 antagonist L-741,626 showed no effect on choice behaviour while the D2 agonist sumanirole decreased choice of the high effort option for both worker and slacker animals. We replicated previous results of amphetamines ability to cause slackers to choose the high effort option more and workers to choose the high effort option less. Co-administration of amphetamine and L-741,626 did not alter behaviour when compared to administration of amphetamine and drug vehicle. In conclusion, we show that D2 receptor agonism plays a role in guiding effortful decision making however its action is not required for amphetamines effects.

Title: The impact of noradrenaline on cue-driven decision making and impulsivity is dissociable across frontal brain regions

Authors: *C. S. CHERNOFF[1], J. D. SCHUMACHER[2], S. RAMAIAH[1], T. J. HYNES[1], L. CALDERHEAD[1], S. B. FLORESCO[2], C. A. WINSTANLEY[3];

Abstract: The intense audiovisual stimuli of modern casinos are thought to contribute to the development of disorder gambling. Indeed, in both human and rat models of gambling behaviour, such casino-like stimuli can elicit cravings to gamble and promote risky decision making. These cues may act to elicit the maladaptive attentional states associated with problem gambling (e.g., 'dark flow'). Critically, noradrenaline underlies the neurobiology associated with attending to salient environmental stimuli, and moreover, is known to play a role in cognitive elements of gambling (i.e., impulsivity and decision making). Prefrontal brain regions, such as the orbitofrontal cortex (OFC) and the medial prefrontal cortex (mPFC) are highly implicated in such cognitive processes and receive dense noradrenergic innervation. We recently demonstrated that systemic delivery of atomoxetine, a noradrenaline transporter inhibitor, and guanfacine, an α_2-adrenergic receptor agonist, reduce risk preference and motor impulsivity in the cued rat gambling task (crGT, a rodent cost/benefit decision making paradigm). We now seek to determine which frontal regions mediate the effects of these noradrenergic drugs. Guide cannulae were implanted in the lateral OFC (lOFC, n=15) or prelimbic cortex (PrL; n=16) of male rats trained on the crGT. Each rat received a high and low dose of both guanfacine and atomoxetine. Only atomoxetine improved decision making on the crGT when infused into the lOFC. Neither drug influenced motor impulsivity when delivered into the lOFC, yet intra-PrL administration of both atomoxetine and guanfacine reduced impulsive premature responses. Our findings here substantiate the role of prefrontal noradrenaline in cue-mediated decision making and impulsivity, and highlight the different brain regions that may guide these separate but related behaviours.

Title: Modulating dopaminergic nigrostriatal activity can accelerate or delay the development of risky choice patterns driven by reward-paired cues in female rats

Authors: *B. A. HATHAWAY, A. C. LI, H. G. BRODIE, C. A. WINSTANLEY;
Univ. of British Columbia, Vancouver, BC, Canada

Abstract: It is well-established that risky decision making can play a critical role in the development and maintenance of addiction. Reward-concurrent cues may mediate this relationship, as previous results have indicated that such stimuli enhance risk preference and may potentiate cocaine intake in rats. Despite extensive addiction research implicating the dorsal striatum in compulsive drug seeking, the role that dorsal striatal dopaminergic activity plays in the development of risk preference driven by reward-paired cues remains unclear.
Accordingly, the present studies examined the effects of chronic inhibition or activation of the dopaminergic nigrostriatal pathway during the learning phase of a risky decision-making task in rats. Female TH:Cre rats (n = 32) and transgene negative litter mates (n = 32) were trained on the cued version of the rat gambling task, a rodent analogue of the human Iowa Gambling Task, to assess cue-enhanced risky decision making. This task was designed such that the optimal strategy for earning sugar pellets over time is to favor options paired with lower per-trial gains, as these are associated with a higher probability of winning and shorter time-out penalties. Consistently selecting the high-risk, high-reward options ultimately results in longer and more frequent time-out penalties, and therefore less reward overall. Adding reward-paired audiovisual cues to the task results in a higher proportion of rats that prefer the disadvantageous, risky options at baseline.
To assess nigrostriatal involvement in the development of choice preferences on the cued rGT (cRGT), Cre-dependent inhibitory hM4D(Gi) DREADD or excitatory hM3D(Gq) DREADD was infused into the substantia nigra. Rats received 1 mg/kg injections of Clozapine-N-Oxide prior to task training for the first 30 sessions of the cRGT. Risk-preferring rats were uniquely affected by these manipulations. Chronic activation of this pathway during task learning delayed the establishment of a risky decision-making profile in risk-preferring rats, whereas inhibition accelerated the development of their preference for the risky options. Motor impulsivity was bidirectionally modulated in all rats, indicated by an increase in premature responding with nigrostriatal activation and decreased premature responding with inhibition. These results provide evidence for the involvement of the dopaminergic nigrostriatal pathway in the development of cue-driven risk preference and impulsive action, therefore shedding light on its role in risky decision making associated with addiction in humans.

Title: Examining the interaction between gambling, drug-taking, and decision-making using a novel behavioural task in female rats

Authors: *K. HRELJA[1], S. ANSARY[1], E. CHONG[1], B. RUSSELL[1], C. A. WINSTANLEY[2]; [1]Univ. of British Columbia, Vancouver, BC, Canada; [2]Psychology, Univ. British Columbia, Vancouver, BC, Canada

Abstract: Impaired decision-making is recognized as a diagnostic criterion for many psychiatric disorders including depression, gambling disorder, and substance use disorders. The cued rat gambling task (rGT) is translationally valuable, as it incorporates salient audiovisual cues and complex schedules of reinforcement to closely model human gambling, and accounts for factors like cost-benefit calculations and uncertainty of outcomes. In this experiment, we use a novel behavioural task to gain insight into the individual differences that exist in complex decision-making, and how volitional drug-taking impacts these cognitive processes. Female Long Evans rats (N=32) were first trained to nose-poke and lever press for reward (sugar pellet). Animals were then taught rGT contingencies and to associate one lever with the cued rGT, and the other with the uncued rGT, by enforcing forced-choice before rats could proceed to the free-choice version of the choice rGT. On the choice rGT, rats can choose which task and probabilistic outcome they want to engage with on a trial-by-trial basis. Once stable responding was achieved, animals were implanted with jugular vein catheters and allowed evening self-administration of cocaine to determine to what extent these animals engage in drug-taking, as well as how drug-taking influences decision making on morning choice rGT sessions. In the choice rGT, we found that the presence of cues was sufficient to induce decision-making biases, and that a subset of animals were naturally risk preferring. Contrary to our hypotheses, we found that risky rats made less total cocaine infusions than optimal rats. We also found that while risky rats had a greater preference for the cued task at baseline, this preference was diminished after acquisition of cocaine-taking behaviour. This change in task preference was not observed in optimal rats, or in saline self-administering controls. This demonstrates a potential trade-off between two forms of dopamine-evoking tasks: cued gambling and cocaine-taking. Optimal rats may thus consume more cocaine as a result of not receiving adequate dopamine increases through the rGT. In future experiments, the use of this novel behavioural task will allow us to more realistically model the multifaceted impairments seen in human psychiatric disorders.

Title: Investigating patterns of complex decision-making using a novel behavioural task in male rats

Authors: K. M. HRELJA, ***E. CHONG**, S. ANSARY, B. RUSSELL, C. A. WINSTANLEY; Univ. of British Columbia, Vancouver, BC, Canada

Abstract: The rat gambling task (rGT) closely models human gambling, and accounts for factors like cost-benefit calculations and uncertainty of outcomes. While a majority of animals adopt an optimal decision-making profile in order to maximize reward, a subset of animals trained on the rGT exhibit risky decision-making. Moreover, when trained on a cued variation of the rGT, in which rewards are accompanied with flashy lights and jingles akin to those at casinos, the subset of risk-preferring rats is larger than on the classic rGT. However, experiments to date have never used task variation (i.e. cued or uncued rGT) as a within-subjects variable. It was thus unknown whether or not rats were driven by cued-induced excitement to take more risks, or if they were somehow responding out of stress. We therefore trained the same rats on both versions of these tasks to determine differences on within- and between-subjects variables, as well as task preference. Male Long Evans rats (N=32) were first trained to make nose-poke responses and lever press for (sugar pellet) reward. They were then taught rGT contingencies and to associate one lever with the cued rGT, and the other with the uncued rGT by enforcing forced-choice, before rats could proceed to the free-choice version of the choice rGT. On the free-choice choice rGT rats could freely choose which task and probabilistic outcomes they want to engage with on a trial-by-trial basis. Once stable responding was achieved on this task, animals were implanted with jugular vein catheters and subjected to evening self-administration of cocaine to determine to what extent these animals engage in drug taking, as well as how drug-taking influences their decision making on morning choice rGT sessions. We found the percentage of risk preferring animals on the choice rGT was larger than in experiments where animals were only exposed to the classic rGT, but smaller than cued rGT. Furthermore, the majority of rats preferred to engage with the cued version of the task. We also found that rats took longer to initiate cued trials but were faster to collect reward when compared to uncued trials in the same session. These findings indicate that the presence of salient audiovisual cues is preferred to their absence, and that cues are sufficient to induce decision-making biases on the same rats within the same sessions, underscoring the risk to human gamblers since audiovisual cues often accompany gambling environments.

Title: The link between conditioned reinforcers and rodent decision-making on a cued gambling task

Authors: *S. ANSARY, B. RUSSELL, C. A. WINSTANLEY;
Univ. of British Columbia, Vancouver, BC, Canada

Abstract: The salient audiovisual stimuli that are omnipresent in casinos may sustain or exacerbate gambling behaviours in the same way drug-paired stimuli play an important role in maintaining addiction. Cues that predict reward increase the release of dopamine in the brain, and this efflux is maximal when the reward is probabilistic. It has therefore been suggested that both repeated choice of uncertain options, and repeated exposure to cues that predict reward with maximal uncertainty, may predispose individuals to developing an addictive disorder, like gambling disorder, by sensitizing the dopamine system. Previous studies have shown that the addition of reward-concurrent audiovisual cues that increase in complexity with the size of the reward can increase the choice of disadvantageous “high-risk, high-reward” options on the rat gambling task (cued rGT), a rat model of the Iowa Gambling Task (IGT). We therefore hypothesize that 1) increased risky choice on the cued rGT reflects greater sensitivity at baseline to conditioned reinforcement (CRf; i.e., the degree to which a reward-paired cue comes to act as a reinforcer that the rat will work for), and 2) repeated choice of the risky options may itself precipitate a greater ability for reward-paired cued to act as conditioned reinforcers. Subjects were 32 male Long Evans rats. Responding for CRf was tested either before (n = 16) or after (n = 16) acquisition of the cued rGT. In the cued rGT, rats chose between four options associated with distinct magnitudes and probabilities of reward (1-4 sugar pellets) or time-out penalties (5-40s). The optimal strategy was to favour options associated with smaller per trial gains, but shorter penalties. We expect that most rats performing the cued rGT develop a preference for the risky options. We have previously found that higher rates of responding for CRf prior to training on the cued rGT was associated with a better choice strategy, less motor impulsivity, and more trials completed in female rats. We also found that cued rGT training did not increase motivation to respond for CRf. Thus, the results from this study will help elucidate any sex differences in cue-driven behaviour and inform our understanding of how cues influence more complex decision-making in male rats.

Title: Chronic Cannabis Sativa and Indica Exposure Impairs Decision-Making Strategies in Adult Rodents

Authors: *M. LYSENKO-MARTIN[1], C. P. HUTTON[2], H. BRODIE[1], C. A. WINSTANLEY[3]; [1]Neurosci., Univ. of British Columbia, Vancouver, BC, Canada; [2]Univ. of Victoria, Victoria, BC, Canada; [3]Psychology, Univ. British Columbia, Vancouver, BC, Canada

Abstract: Cannabis is becoming increasingly prevalent in society, with legalization occurring globally at rapid rates. Cannabis impairs decision making and can lead to addiction, particularly when exposure occurs chronically. This impairment can be quantified using a rodent assay of cost-benefit decision making called the cued rat Gambling Task, in which exposure to cue-paired probabilistic rewards triggers neural adaptations that lead to a pro-addiction phenotype. To evaluate the decision-making strategies used by adult rats chronically exposed to *cannabis sativa* and *cannabis indica*, Long Evans male rats were orally dosed daily with 3mg/kg of THC prior to performing the cued rat Gambling Task. Once choice preferences were established, animals underwent a washout period and experimental groups were crossed over and evaluated anew on their decision-making strategies, to account for any impairments THC may have had on learning the task. Animals exposed to *cannabis sativa* were more impulsive and chose riskier strategies early on in daily dosing, after which they slowly learned the optimal choices and aligned with the strategies used by control animals. Animals exposed to *cannabis indica* learned the optimal strategy quicker than *sativa*-exposed animals, but slower than controls. Importantly, both within-subject and between-subject choices were considered. A mixed-effects model was used to evaluate choice preferences, as individual experiences with cost-benefit tasks can vary widely based on whether the prior choice was a win or a loss, and no 2 animals in the same group had an identical decision-making pattern throughout 100+ choices a day for 40+ days of testing. These results suggest that chronic exposure to *cannabis sativa* versus *cannabis indica* can have differential effects on impulsivity, motivation, and decision making behaviors that are indicative of a pro-addiction phenotype.

Title: Investigating the effects of selective D3 agonist on risk preference in male rats.

Authors: *H. BRODIE, B. RUSSELL, C. WINSTANLEY;
Univ. of British Columbia, Vancouver, BC, Canada

Abstract: Dopamine agonist drugs such as ropinirole are often prescribed to patients with Parkinson's disease to alleviate motor symptoms. However, these drugs often have adverse side effects, and a significant minority of patients go on to develop gambling disorder or other impulse control disorders. Previous research using rodent models established that in healthy male rats, chronic administration of ropinirole can increase risky decision making. This effect is thought to be driven by activation of dopamine receptors. Ropinirole is a D2/D3 agonist and there is evidence of both D2 and D3 receptor involvement in the development of iatrogenic gambling disorders. Accordingly, the purpose of the current experiment was to determine the effects of a selective D3 agonist on risky decision making in male rats using the rodent gambling task (rGT). A cohort of 24 male Long-Evans rats were trained on the cued version of the rGT, a rodent adaptation of the Iowa gambling task commonly used to study risky decision making in humans. Optimal decision making in this task is achieved by preferentially selecting the low risk, low reward options over the high risk, high reward options. Selection of the low risk, low reward options results in fewer timeout penalties and more sugar pellets awarded over time. Audiovisual cues were paired with rewards and have been shown to increase risk preference. Rats were dosed with saline(n=12) or 0.1 mg/kg of D3 selective agonist PD128907(n=12) ten minutes before completing the task. Rat were dosed throughout acquisition of the task and until they reached a stable behavioural baseline (32 sessions). Rats then completed an additional 8 sessions in washout. Results showed that although the D3 agonist significantly increased the number of omitted trials and latency to choose an option while decreasing the number premature responses, risk preference was not significantly affected. The effects on omissions, choice latency and premature responses disappeared immediately in washout. These findings offer new insights into the effects of ropinirole on risky decision making and suggest that D3 receptor activation alone may not be responsible for the development of iatrogenic gambling disorder.

Title: Autophagy induction and accumulation of phosphorylated tau in the hippocampus and prefrontal cortex of adult male C57BL/6 mice exposed to adolescent fluoxetine treatment

Authors: *M. RODRIGUEZ, O. LIRA, F. J. FLORES RAMIREZ, S. D. IÑIGUEZ; Psychology, The Univ. of Texas at El Paso, El Paso, TX

Abstract: Fluoxetine (FLX) represents the antidepressant of choice for the management of pediatric mood-related illnesses. Accumulating preclinical evidence suggests that ontogenic FLX exposure leads to deregulated affect-related phenotypes in adulthood. Mood-related symptomatology constitutes a risk factor for various neurological disorders, including Alzheimer's disease (AD), making it possible for juvenile FLX history to exacerbate the development of neurodegenerative diseases. Because AD is characterized by the pathological accumulation of hyperphosphorylated Tau - which can result from impaired function of protein degradation pathways, such as autophagy and the ubiquitin-proteasome system (UPS), we evaluated the long-term effects of adolescent FLX exposure on these pathways, using mice as a model system. To do this, we subjected C57BL/6 adolescent male mice to FLX (20 mg/kg) during the adolescence stage of development (postnatal days [PD] 35-49). After a 21-day washout period, mice were euthanized (PD70) and, using immunoblotting analysis, we evaluated protein markers of autophagy (Beclin-1, LC3-II, p62) and the UPS (K48-pUb), as well as AD-associated forms of phosphorylated Tau, within the hippocampus and prefrontal cortex. We found that juvenile FLX mediated a long-term increase in the expression of autophagy protein markers (LC3-II and p62) in a manner that is consistent with autophagy activation, particularly in the prefrontal cortex. Furthermore, FLX history induced persistent accumulation of AD-associated variants of Tau in both the hippocampus and prefrontal cortex. Overall, our data suggest that adolescent FLX treatment may have enduring effects in the neuronal protein degradation machinery, which could adversely influence the clearance of abnormal proteins, potentially predisposing individuals to develop AD in later life.

Title: Female rats display greater nicotine withdrawal-induced cellular activation of a central portion of the interpeduncular nucleus versus males

Authors: *V. E. ESPINOZA[1], F. MATOS[1], P. CORREA[1], A. M. KHAN[2], L. E. O'DELL[1]; [1]Dept. of Psychology, [2]Dept. of Biol. Sci. and Border Biomed. Res. Ctr., The Univ. of Texas at El Paso, El Paso, TX

Abstract: *Background:* The *interpeduncular nucleus (>1840)* (IPN) has been shown to modulate the behavioral effects of nicotine withdrawal in male rodents. To date, the contribution of this brain structure to sex differences in withdrawal is largely unexplored. *Methods:* This study compared neuronal activation, as reported by observable Fos expression in the IPN of nicotine-dependent female and male rats experiencing withdrawal. We provisionally localized the Fos-expressing cells to certain IPN subnuclei within Swanson's standardized brain atlas (2018). Adult female and male rats were prepared with a pump that delivered nicotine (3.2 mg/kg/day; base) continuously. Controls received a sham surgery. Fourteen days later, the rats received administration of saline or the nicotinic receptor antagonist, mecamylamine (3.0 mg/kg; salt), and physical signs and anxiety-like behavior were assessed. The rats were then euthanized and brain sections containing the IPN were processed for Fos immunofluorescence to infer the possible IPN subnuclei displaying differential activation between sexes. *Results:* Both female and male rats displayed withdrawal-induced Fos expression within the IPN. Compared to males, female rats displayed greater numbers of withdrawal-induced Fos-positive cells within a circumscribed portion of the IPN that may fall within the cytoarchitectural boundaries of the *central subnucleus (>1840)* (IPNc). The withdrawal-induced activation of the IPN was correlated with negative affective states in females, but not males. *Conclusion:* These data suggest that that a centrally located group of IPN cells, presumably situated partly or completely within the IPNc, play a role in modulating sex differences in negative affective states produced by withdrawal.

Title: Alprazolam exposure during adolescence induces life-long dysregulation of reward sensitivity and second messenger signaling within the nucleus accumbens (NAc).

Authors: *A. CARDONA-ACOSTA[1], O. K. SIAL[2], T. GNECCO[1], G. ENRIQUEZ MARTI[1], D. HERNANDEZ-GUZMAN[1], C. A. BOLANOS-GUZMAN[2];
[2]Psychological and Brain Sci., [1]Texas A&M Univ., College Station, TX

Abstract: Benzodiazepines are prescribed widely as anxiolytics, hypnotics, muscle relaxants, and anticonvulsants. However, their utility is limited by unwanted side effects such as abuse liability and the potential for dependence. Benzodiazepine-related emergency room visits have increased in the US within the past two decades, and despite concerns surrounding their use, there has been a substantial increase in their prescription rates. Benzodiazepines are commonly abused concurrently with opioids, resulting in greater psychopathology and complex comorbidities. There is evidence of increased use and abuse of alprazolam (Xanax; ALP) during adolescence, yet most available neurobiological evidence has been derived from studies using adult organisms. This study was designed to investigate the behavioral and molecular consequences of ALP exposure during adolescence. Adolescent C57BL/6J male mice (postnatal day [PD] 35) were pretreated with ALP (0, 0.5, 1.0 mg/kg) once daily from PD35-49. Changes in behavioral responsiveness to morphine (2.5 and 5.0 mg/kg), using the conditioned place preference paradigm (CPP) were assessed 24 h (short-term) and one-month (long-term) after the end of ALP treatment. In a separate experiment, male mice were treated with ALP (0.0, 0.5 mg/kg) from PD35-49 and then sacrificed 24 h (short term) or 1-month (long-term) after the last injection to assess levels of extracellular signal regulated kinase1/2 (ERK1/2) protein phosphorylation within the nucleus accumbens (NAc). Our results show that ALP-pretreated mice developed a strong preference to the CPP compartment paired with a subthreshold dose (2.5 mg/kg) of morphine (short-term), and this effect was also present in the long-term group (a month after ALP exposure). In addition, we report an increase (short-term) followed by a decrease in ERK1/2 protein phosphorylation (long-term) within the NAc. Ongoing studies are assessing protein phosphorylation of ERK's downstream targets such as the cAMP Response Element-Binding Protein (CREB) and Protein Kinase B (AKT). Overall, these findings indicate that exposure to ALP during periods prior to adulthood potentiates the rewarding effects of drugs of abuse such as morphine, and that ALP exposure during this period results in persistent changes in ERK-signaling within the NAc, a brain region implicated in regulation of both drug reward and mood-related disorders.

Title: Adolescent fluoxetine exposure induces persistent gene expression changes in the hippocampus of adult male C57BL/6 mice

Authors: *A. THEMANN, O. LIRA, F. J. FLORES RAMIREZ, S. D. IÑIGUEZ;
Psychology, The Univ. of Texas at El Paso, El Paso, TX

Abstract: Fluoxetine (FLX), a selective serotonin reuptake inhibitor, is the first line of pharmacological intervention in pediatric patients suffering from affect-related illnesses, such as anxiety and depression. Although the use of this antidepressant treatment has been deemed efficacious in the adolescent population, the enduring neurobiological consequences of juvenile FLX exposure are not well understood. Thus, we explored for persistent molecular adaptations in the adult hippocampus, as a function of adolescent FLX pretreatment. To do this, we administered daily peritoneal injections of FLX (20 mg/kg/day) to male C57BL/6 mice during adolescence (postnatal day [PD] 35-49). After a 21-day washout period (PD70), whole hippocampal tissue was dissected, and subsequent qPCR analysis was ran to assess changes in the expression of genes associated with neuronal survival. Specifically, we evaluated major intracellular signal transduction pathways, including the Ras-mitogen-activated protein kinase (MAPK), phosphatidylinositide-3-kinase (PI3K)/AKT pathway, as well as several transcription factors. Our results indicate that adolescent FLX treatment results in a long-term upregulation of mRNA levels across numerous genes from the ERK, and PI3K/AKT pathways, along with increases of the transcription factors CREB, ΔFosB, and zif268. Additionally, adolescent FLX treatment resulted in persistent increases of transcripts associated with cytoskeletal integrity (β-actin) and caspase activation (DIABLO), while decreasing genes associated with metabolism (fucose kinase) and overall neuronal activation (c-Fos). Collectively, these data indicate that adolescent FLX exposure mediates persistent alterations in hippocampal gene expression in adulthood, thus, questioning the safety of early-life exposure to this antidepressant medication.

Title: Adolescent and adult rats exhibit context-dependent methamphetamine sensitization while preweanling rats fail to exhibit sensitization using a one-trial procedure.

Authors: *F. S. OMERJEE, G. C. VERDUZCO, B. SORTMAN, C. MORENO-BARRIGA, E. NUÑEZ-LARIOS, D. FRANCO, A. R. ZAVALA;
California State University, Long Beach, Long Beach, CA

Abstract: Behavioral sensitization is a phenomenon in which previous administration of a psychostimulant drug elicits a heightened behavioral response in subsequent exposures. Even one previous pairing is enough to elicit sensitization, known as a one-trial or two-shot design. In this paradigm, adult rats exhibit a sensitized response only evident in the area in which they previously received the psychostimulant. This is known as context-dependent sensitization. Preweanling rats (postnatal day [PD] 24 or younger), however, exhibit context-independent sensitization, which is a heightened response regardless of what environment the drug was associated. Interestingly, adolescent rats (PD 25-50) do not exhibit a sensitized response when exposed to methamphetamine (METH). Prior studies examining the preweanling and adolescent stage have used a wide range of doses, but doses lower than 1 mg/kg METH have not been used. Thus, the present study examined one-trial sensitization in preweanling, adolescent, and adult rats using 0.1 and 0.3 mg/kg of METH as well as an additional 1.0 mg/kg dose of METH for adult rats. The study also sought to determine the role of context in moderating a sensitized response across development. During the two-day study, PD 18, 28, 38, or 68 male and female rats were pretreated with saline or 3 mg/kg METH and placed in a novel activity chamber where their locomotor activity (distance traveled in m) was assessed for 60 min. Rats were then taken to their home cage and, based on the assigned groups, injected with saline or 3 mg/kg METH 45 min later and placed back in their home cage. During the challenge test, PD 19, 29, 39, or 69 male and female rats were injected with saline or either 0.1 or 0.3 mg/kg METH (also 1.0 mg/kg for PD 69) before being placed in the activity chamber, during which distance traveled was assessed for 90 min. The study results found that adolescent rats (PD 29 and PD 39) and adult rats (PD 69) exhibited context-dependent sensitization. However, preweanling rats did not exhibit behavioral sensitization at any dose. Interestingly, sex-related differences were observed as PD 29 and PD 39 female rats exhibited behavioral sensitization with both challenge doses of METH. In contrast, male rats exhibited behavioral sensitization only at 0.1 mg/kg METH. Contrary to prior studies, both groups of adolescent rats exhibited context-dependent

sensitization using low doses of METH. These findings highlight the need to examine a wide range of doses and different age periods to understand the development of sensitization in rats.

Title: Enduring effects of juvenile ketamine exposure for the rewarding properties of cocaine and sucrose in mice

Authors: *I. GARCIA CARACHURE[1], O. LIRA[1], S. A. CASTILLO[1], A. R. ZAVALA[2], S. D. IÑIGUEZ[1];
[1]Psychology, The Univ. of Texas At El Paso, El Paso, TX; [2]Psychology, California State Univ., Long Beach, CA

Abstract: Ketamine, a non-competitive N-methyl-D-aspartate (NMDA) receptor antagonist, has shown rapid antidepressant efficacy in adolescent treatment-resistant depressed patients. However, the potential enduring side effects of ketamine exposure during early development have not been explored. Thus, using male and female C57BL/6 mice, we examined whether exposure to ketamine during adolescence, alone (Experiment 1) or in combination with stress (Experiment 2), results in long-lasting changes in sensitivity to the rewarding properties of cocaine and sucrose in adulthood. Specifically, in Experiment 1, mice received either ketamine (20 mg/kg) or saline (VEH) for 15 consecutive days during adolescence (Postnatal Day [PD] 35-49). Twenty-one days after ketamine exposure, once mice reached adulthood (PD70), we assessed their behavioral responsivity to a two-bottle choice sucrose (1%) test or cocaine (0, 5, 10 mg/kg) place preference (CPP) experiment. Our results showed that adult mice pre-treated with ketamine during adolescence displayed an enhanced preference for sucrose and environments paired with cocaine in male, but not female, mice. Thus, in Experiment 2, using male mice only, we evaluated whether adolescent ketamine exposure (PD35-44), in combination with social defeat or the vicarious defeat stress paradigms, would influence responses to sucrose or cocaine preference later in life (PD70). Here, no long-term differences in sucrose or cocaine preference were evident as a function of juvenile stress-and-ketamine pretreatment, in male mice. Together, our findings suggest that in the absence of social stressors, juvenile exposure to

ketamine alters sensitivity to the rewarding properties of non-drug (sucrose) and drug (cocaine) reward-related stimuli, in a sex-dependent manner, later in life.

Title: Sex- and dose-dependent differences in preference for ethanol in preadolescent and adolescent rats

Authors: *T. M. NELSON[1], T. A. GONZALEZ[1], A. K. GARCIA[1], D. Q. PHAM[1], D. FRANCO[1], E. A. BATES[1], U. M. RICOY[2], S. D. IÑIGUEZ[3], A. R. ZAVALA[1];
[1]California State Univ. Long Beach, Long Beach, CA; [2]Univ. of Arizona, Tucson, AZ; [3]Univ. of Texas at El Paso, El Paso, TX

Abstract: Ethanol is the drug of choice among adolescents in the United States. Adolescence is a pivotal period in brain development making young people specifically at risk for a variety of different consequences as a result of ethanol use. Previous literature using the conditioned place preference (CPP) paradigm, a validated animal model of drug reward, has revealed the difficulty of reliably demonstrating ethanol preference in adolescent rats, potentially due to sex and dose-related differences. Therefore, we hypothesized that male and female adolescent rats would exhibit dose-dependent differences in ethanol preference. Rats underwent a 10-day CPP procedure to assess ethanol preference during preadolescence (experiment 1) and adolescence (experiments 2 and 3). On day 1, initial preference for a two-chamber CPP apparatus was assessed during 15 min (experiments 1 and 2) or 20 min (experiment 3) sessions. On days 2-9, rats were conditioned with saline in their initially preferred chamber or ethanol in their initially non-preferred chamber on alternating days for 15 min. On day 10, the preference for the ethanol-paired chamber was assessed using identical procedures to the first day of the experiment. In experiments 1 and 2, rats were randomly assigned to receive an injection of ethanol (0.0, 0.5, 1.0, or 2.0 g/kg, IP) before being placed in the ethanol-paired chamber. In experiment 3, rats were

randomly assigned to receive an injection of ethanol (0.0, 0.0156, 0.0313, 0.0625, 0.125, 0.5, or 2.0 g/kg, IP) before being placed in the ethanol-paired chamber. In experiment 1, both male and female rats demonstrated ethanol-induced CPP when administered the highest dose of ethanol (2.0 g/kg). In experiment 2, sex differences emerged as female rats continued to prefer a high dose of ethanol (2.0 g/kg) and male rats demonstrated a preference for the ethanol-paired chamber with the lowest ethanol dose (0.5 g/kg). In experiment 3, male rats demonstrated a robust preference for ethanol when administered low ethanol doses (0.0625, 0.125 g/kg). Overall, sex differences did not emerge in preadolescence because rats exhibited a similar preference for ethanol, regardless of sex. However, during adolescence, a shift in preference was seen in male rats that demonstrated ethanol-induced CPP at low doses of ethanol. In conclusion, ethanol-induced CPP can be reliably demonstrated in adolescent rats, which can aid in a better understanding of the underlying brain mechanisms involved in adolescent ethanol use.

Title: Reciprocal cross-sensitization between cocaine and RU 24969

Authors: *J. A. M. ROBINSON, D. C. GLEASON, L. L. COTTER, S. A. MCDOUGALL; Dept. of Psychology, California State Univ., San Bernardino, CA

Abstract: Cross-sensitization occurs when a drug causes an enhanced behavioral response after a pretreatment regimen with a different drug. The ability of drugs to cross-sensitize is often used as evidence that a common neural substrate underlies the sensitization process. Cocaine, amphetamine, and methamphetamine are the psychostimulant compounds most typically used to induce behavioral sensitization, but indirect and direct serotonin (5-HT) agonists can also produce locomotor sensitization. The goal of the present study was to use the cross-sensitization paradigm to determine whether repeated treatment with the nonselective 5-$HT_{1A/1B}$ receptor agonist RU 24969 produces the neuronal changes necessary for behavioral sensitization. The preweanling rat model was used, because it has proven useful for elucidating drug action in a variety of behavioral and physiological assays. In a series of experiments, preweanling rats were pretreated with RU 24949 for four consecutive days and then tested with a psychostimulant drug

(cocaine or methamphetamine). Reciprocal cross-sensitization was also assessed (i.e., rats were pretreated for four days with a psychostimulant drug and challenged with RU 24969). In addition to the multi-trial procedure, reciprocal cross-sensitization was examined using a one-trial sensitization procedure (i.e., rats were pretreated with a psychostimulant on a single day and then challenged with RU 24969 two days later). Using the multi-trial procedure, reciprocal cross-sensitization between cocaine and RU 24969 was evident, whereas methamphetamine and RU 24969 did not cross-sensitize. When a one-trial pretreatment regimen was used, cross-sensitization was only detected when preweanling rats were pretreated with RU 24969 and tested with cocaine, but not the reverse. In sum, the present results show that the nonselective 5-$HT_{1A/1B}$ receptor agonist RU 24969 cross-sensitizes with cocaine, but not methamphetamine, in the preweanling rat. This dichotomy may be a function of cocaine having a greater affinity for the serotonin transporter than methamphetamine. Nonetheless, the present evidence suggests that the behavioral sensitization produced by repeated cocaine and RU 24969 administration shares a common neural substrate.

Title: Importance of the serotonin 5-HT_{1B} receptor for the locomotor activity of preweanling and adult male and female rats

Authors: *L. L. COTTER, M. J. ROE, J. A. M. ROBINSON, D. C. GLEASON, D. J. GONZALEZ, S. A. MCDOUGALL;
Dept. of Psychology, California State Univ., San Bernardino, CA

Abstract: 5-$HT_{1A/1B}$ receptor agonists (e.g., RU 24969), as well as 5-HT_{1A} receptor agonists (e.g., 8-OH-DPAT), increase the locomotor activity of both preweanling and adult rodents. Sex differences, are apparent, as adult female mice are more sensitive to the locomotor activating properties of RU 24969 than adult male mice. The role played by the 5-HT_{1B} receptor in locomotion is less certain, and preliminary evidence suggests that the actions of 5-HT_{1B} receptor agonists are not uniform across ontogeny. To more fully examine the ontogeny of the 5-HT_{1B} receptor system, the locomotor activity and axillary temperatures of preweanling and adult male and female rats were assessed in two experiments. In the first experiment, preweanling (PD 10

and PD 15) and adult (PD 70) male and female rats were injected with a broad dose range of the 5-HT_{1B} agonist CP 94253 (2.5-10 mg/kg) immediately before locomotor activity testing (axillary body temperatures were also recorded). In the second experiment, specificity of drug action was determined in preweanling rats (PD 10) by administering saline, WAY 100635 (a selective 5-HT_{1A} antagonist), or GR 127935 (a 5-HT_{1B} antagonist) 15 min before CP 94253 (10 mg/kg) treatment. Results showed that all doses of CP 94253 significantly increased the locomotor activity of preweanling rats on PD 10, but CP 94253 did not increase the locomotor activity of older preweanling rats (PD 15). CP 94253 significantly decreased the locomotor activity of both male and female adult rats. The ability of CP 94253 to increase the locomotion of PD 10 rats was due to actions at the 5-HT_{1B} receptor, because GR 127935 (a 5-HT_{1B} antagonist), but not WAY 100635, fully attenuated the CP 94253-induced locomotor activity. Regardless of age, CP 94253 (2.5-10 mg/kg) significantly reduced the axillary temperatures of preweanling and adult male and female rats. When considered together with past results, this study shows that the 5-HT_{1B} receptor system mediates the locomotor activity of male and female preweanling rats during early ontogeny; however, the 5-HT_{1B} receptor plays a significantly reduced role with increasing age. The serotonin neurotransmitter system in general, as well as the 5-HT_{1B} receptor system, shows substantial maturational changes across early ontogeny, adolescence, and into adulthood. It is likely that one or more of these ontogenetic changes is responsible for the age-dependent differences in locomotor responsiveness to CP 94253.

Abstract: Repeated treatment with serotonin (5-HT) and dopamine (DA) agonists can cause a progressive augmentation of locomotor activity called behavioral sensitization. On the other hand, repeated treatment with the selective 5-$HT_{1A/1B}$ receptor agonist RU 24969 causes a pronounced tolerance response. Specifically, acute administration of RU 24969 produces

locomotion, motoric disturbances, and hypothermia in preweanling and adult rats: effects that weaken or are eliminated with repeated daily treatment. Because tolerance could potentially mask expression of behavioral sensitization, it is uncertain whether repeated stimulation of 5-$HT_{1A/1B}$ receptors produces the neurobiological changes necessary for sensitized responding. To further examine the role of 5-HT_{1A} and 5-HT_{1B} receptors in the development of tolerance and behavioral sensitization, preweanling rats were repeatedly treated with the selective 5-HT_{1A} receptor agonist 8-OH-DPAT and/or the selective 5-HT_{1B} receptor agonist CP 94253. Locomotor activity and axillary temperatures were measured. In a series of three experiments, male and female preweanling rats were injected with saline or the selective 5-HT_{1A} agonist 8-OH-DPAT (0.1-8 mg/kg) on PD 20. On PD 22, rats previously administered saline were injected with 8-OH-DPAT (0.1-8 mg/kg), whereas rats initially given 8-OH-DPAT were injected with the same dose of 8-OH-DPAT again. Identical experiments were conducted using the selective 5-HT_{1B} agonist CP 94253 (2.5-20 mg/kg) or combined treatment with 8-OH-DPAT (4 mg/kg) + CP 94253 (5 mg/kg). Immediately after drug injections, rats were placed in activity chambers and distance traveled was measured for 45 min (axillary temperatures were also recorded). On the pretreatment day, 8-OH-DPAT, CP 94253, and DPAT+CP increased locomotor activity and caused hypothermia. Repeated treatment with 8-OH-DPAT (2 or 8 mg/kg) or DPAT+CP caused locomotor sensitization in preweanling rats, because rats pretreated and tested with these compounds exhibited more locomotor activity on the test day than rats given the same drugs on only the test day. In contrast, tolerance to the hypothermic effects of 8-OH-DPAT (8 mg/kg), CP 94253 (5-20 mg/kg), and DPAT+CP was evident after repeated drug treatment. These results show that repeated treatment with 8-OH-DPAT causes both tolerance (hypothermia) and sensitization-like effects (augmented locomotor activity) in preweanling rats. Although CP 94253 increased locomotor activity and produced hypothermia in preweanling rats, repeated treatment with CP 94253 only produced a tolerance response (axillary temperatures) and not behavioral sensitization.

Title: Activation of dopamine D2 receptors in the medial shell region of the nucleus accumbens increases Per1 expression to enhance alcohol consumption

Authors: *V. MISHRA, M. PARIKH, A. SONI, R. SHARMA, P. SAHOTA, M. THAKKAR; Neurol., Univ. of Missouri, Columbia, MO

Abstract: Circadian genes, including Per1, in the medial shell region of nucleus accumbens (mNAcSh), regulate binge alcohol consumption. However, the upstream mechanism regulating circadian genes-induced alcohol consumption is not known. Since activation of dopamine D2 receptors (D2R) increases Per1 gene expression, we hypothesized that local infusion of quinpirole, a D2R agonist, by increasing Per1 gene expression in the mNAcSh, will increase binge alcohol consumption in mice. We performed two experiments on male C57BL/6J mice, instrumented with bilateral guide cannulas above the mNAcSh, and exposed to a four-day drinking-in-dark (DID) paradigm. The first experiment determined the effects of bilateral infusion of quinpirole (100 ng/300 nl/site) or DMSO (Vehicle group) in the mNAcSh on Per1 gene expression and alcohol consumption. The second experiment determined the effect of antisense-induced downregulation of Per1 in the mNAcSh on the quinpirole-induced increase in alcohol consumption. Control experiments were performed by exposing the animals to sucrose (10% w/v). After the experiment, animals were euthanized, brains removed, and processed for localization of injection sites and analysis of Per1 gene expression in the mNAcSh. As compared to the DMSO, local bilateral infusion of quinpirole significantly increased the expression of Per1 in the mNAcSh along with an increase in the amount of alcohol consumed in mice exposed to DID paradigm. In addition, local antisense-induced downregulation of Per1 significantly attenuated the effects of intro-accumbal infusion of quinpirole on alcohol consumption. Our results suggest that Per1 in the mNAcSh mediates D2R activation-induced increase in alcohol consumption.

Title: Antisense-induced downregulation of circadian genes in the medial shell region of the nucleus accumbens reduces alcohol consumption, in mice, exposed to chronic excessive alcohol consumption

Authors: *R. SHARMA, V. MISHRA, M. PARIKH, A. SONI, P. SAHOTA, M. THAKKAR; Research, Neurol., Truman VA Med. Center/University of Missouri, Columbia, MO

Abstract: Background: Circadian genes, present in the nucleus accumbens, are implicated in a variety of psychiatric disorders including anxiety, stress, reward and substance abuse, however, their role in chronic alcohol abuse has not been investigated. We hypothesized that antisense-induced knockdown of major circadian genes (Per1, Per2 and NPAS2) in the mNAcSh will reduce alcohol consumption and preference in mice exposed to intermittent access 2-bottle choice (IA2BC) paradigm, a model for alcohol use disorders. **Methods:** Adult male C57BL/6J mice (N = 14), surgically implanted with bilateral guide cannulas above the mNAcSh, were exposed to alcohol (20% v/v) or saccharin (0.03%). In the fourth week, after alcohol consumption was stabilized, a mixture of antisense (AS-ODNs; Antisense; N = 7) or nonsense oligodeoxynucleotides (NS-ODNs; Nonsense; N = 7) against circadian genes, were bilaterally infused into the mNAcSh. Subsequently, alcohol/saccharin consumption and preference were monitored for 18 h. On completion, animals were euthanized and brains removed. Localization of injection sites and verification of circadian gene downregulation was performed by selecting sections containing microinjection sites. Tissue punches were obtained and processed for RT-PCR to verify antisense-induced gene knockdown in the mNAcSh. **Results**: Histological and/or visual verification of injection sites suggested that all infusion sites were localized in the mNAcSh. As compared to NS-ODNs, AS-ODNs infusion significantly reduced the expression of all three circadian genes along with the reduction in alcohol consumption and preference without affecting saccharin consumption and preference. **Conclusions:** Our results suggest that circadian genes in the mNAcSh may have a causal role in alcohol consumption.

Title: D1-msn ensembles in the dorsomedial striatum positively regulate alcohol-seeking and relapse

Authors: T. TAN[1], J. LU[1], X. XIE[1], W. WANG[1], W. PURVINES[2], K. WOODSON[1], J. BONIFACIO[1], K. BEGO[1], X. WANG[1], J. WANG[1];
[1]Dept. of Neurosci. and Exptl. Therapeut., Texas A&M Hlth. Sci. Ctr., Bryan, TX; [2]NEXT, Texas A&M Univ., Bryan, TX

Abstract: The dorsomedial striatum (DMS) is essential for the reinforcement of addictive behaviors. The involvement of dopamine D1 receptor-expressing medium spiny neurons (D1-MSNs) in the DMS is increasingly being appreciated for mediating reinforcement behavior in addiction, and enhanced excitatory synaptic transmission has been found in D1-MSNs after chronic alcohol drinking. In this study, we found excessive ethanol intake strengthened cortico-striatal glutamatergic transmission selectively in DMS D1-MSNs. Using triple transgenic FosTRAP; D1-tdTomato; Snap25-EGFP mice in which D1-MSNs expressed tdTomato and activated neurons expressed EGFP after tamoxifen-induced Cre recombination, we discovered more striatal D1-MSNs were activated in ethanol-drinking mice than their water control under the two-bottle choice (2BC) procedure. Additionally, we observed a greater cortico-striatal transmission in alcohol-activated D1-MSN ensembles than non-activated D1-MSNs. Notably, another experiment using ArcTRAP animals found more alcohol-activated neuronal ensembles in the DMS than in other striatal regions. Consistent with these physiological and histological results, behavioral studies found that chemogentic inhibition of trapped D1MSN-2BC ensembles suppressed the alcohol consumption during the 2BC test even in the presence of quinine, suggesting alcohol-activated neurons also contribute to the compulsive alcohol consumption. Similar results were found in ArcTRAP mice trained with operant alcohol self-administration (SA): chemogenetic inhibition of the trapped D1-MSN-SA ensembles decreased both alcohol-seeking and relapse. Interestingly, chemogenetic inhibition D1-MSN-SA ensembles also decreased alcohol consumption under the 2BC test in the presence or absence of quinine. Conversely, chemogenetic inhibition of D1-MSN-2BC ensembles suppressed the subsequent SA seeking and relapse. These findings indicate that *ad libitum* alcohol experience during the 2BC may share at least part of neuronal ensembles with the SA addictive behaviors. In summary, our results demonstrate that DMS D1-MSNs are activated by alcohol consumption (both *ad libitum* and SA) and contribute to compulsive drinking, alcohol-seeking, and relapse. This study also suggests that targeting inhibition of the D1-MSN ensembles may help to alleviate alcohol use disorders.

Title: Genetic ablation of cholinergic interneurons in the medial shell region of the nucleus accumbens reduces binge drinking in C57BL/6J mice

Authors: *A. SONI, R. SHARMA, V. MISHRA, M. PARIKH, P. SAHOTA, *M. THAKKAR; Truman VA Med. Center/University of Missouri, Columbia, MO, Columbia, MO

Abstract: Background: Alcohol use disorder (AUD) is a chronic relapsing brain disorder responsible for serious health and economic consequences in the U.S. Apart from genetic predisposition, binge drinking or heavy alcohol consumption is a leading cause of AUD, hence it is important that we understand the mechanism of alcohol consumption to treat AUD. Cholinergic interneurons (CIN) present in the nucleus accumbens NAc have been strongly implicated in substance abuse including cocaine, however, their role in alcohol abuse has not been investigated. We hypothesized that genetic ablation of CIN in the medial shell region of the NAc (mNAcSh) will reduce alcohol consumption in mice exposed to alcohol via the drinking-in-dark (DID) paradigm. **Methods:** To test our hypothesis. ChAT-cre mice (C57BL/6J transgenic mice expressing Cre-recombinase in the cholinergic neurons) were used in this study. Mice were bilaterally infused either with taCasp3-encoding AAV (serotype 8) containing EF1a for cre-dependent, bicicstronic expression of designer pro-taCasp3 and TEVp (**AAV-flex-taCasp3-TEVp; taCasp3 group)** or control virus (Ns, **AAV-EF1a-DIO**; 500nL/side; **Control group**) in mNAcSh and left them undisturbed for two weeks to allow for the expression of taCasp3 in the CIN. Next, mice were subjected to binge alcohol consumption using the 4-day DID paradigm. Alcohol consumption was measured for 2 h (Days1-3) and 4 h (Day 4). Blood alcohol concentration was measured after alcohol consumption on Day 4. Separate groups of mice were used to examine the effects of CIN ablation on sucrose (10% w/v; control for calorie and taste) consumption using the same paradigm. Microinfusion sites and the loss of cholinergic neurons were verified using choline acetyltransferase (ChAT) immunohistochemistry (IHC). **Results:** Infusion of taCasp3 caused a significant reduction (~50%) in the number of CIN in the mNAcSh as revealed by ChAT IHC. In addition, as compared to the Controls, mice in the taCasp3 group displayed a significant reduction in the amount of alcohol consumed during four hours of binge drinking on day 4 of the DID paradigm. No differences were found in sucrose consumption. **Conclusions:** Our results strongly suggest that CIN neurons in the mNAcSh are responsible for binge drinking in mice.

Title: Adenosine A2a receptor in accumbal shell region of nucleus accumbens modulate per 1 expression to alter the alcohol consumption in mice

Authors: *M. PARIKH, R. SHARMA, V. MISHRA, A. SONI, M. THAKKAR, P. SAHOTA; Truman V.A. Med. Center/University of Missouri, Columbia, MO

Abstract: INTRODUCTION: Adenosine via its receptors (A1R and/or A2R) mediates most of the behavioral effects of alcohol such as sleep promotion via A1R in the basal forebrain, motor incoordination via A2aR in the cerebellum etc. Evidence from studies using systemic pharmacological interventions or global knockout animals suggests that adenosine via adenosine A2 receptors (A2a) attenuates the rewarding and reinforcing effects of alcohol. However, the underlying neuroanatomical mechanism is not clear. Circadian genes including Per1 gene in the medial shell region of nucleus accumbens (mNAcSh) play a key role in alcohol consumption, hence we hypothesized that local A2a activation in the mNAcSh will reduce Per1 gene expression in the mNAcSh resulting in a reduction in the alcohol consumption.**METHODS:** To test our hypothesis, we surgically implanted bilateral guide cannulas above the mNAcSh in male C57BL/6J mice. After surgical recovery, mice were exposed to four-days Drinking-in-the-dark (DID) paradigm. On day, one hour prior to alcohol consumption, mice were infused with either A2a agonist, CGS 21680 (50 ng/site) or DMSO (vehicle), bilaterally in the mNAcSh. Subsequently, the amount of alcohol consumed during 4 h of alcohol access was examined. At the end of alcohol consumption, animals were euthanized, brains removed and processed for examination of Per1 gene expression by RT-PCR. Control experiments were performed by exposing the animals to sucrose [10% (w/v taste and calorie].
RESULTS: Compared to controls, mice administered with CGS 21680 displayed a significant reduction in the alcohol consumption without affecting sucrose consumption. In addition, the expression of Per1 genes in the mNAcSh was significantly reduced in mice treated with CGS 21680 compared with the controls. **CONCLUSIONS:** Our results suggest that A2a in the mNAcSh negatively regulates alcohol consumption which is associated with a reduction in the Per1 gene.

Title: Neural dynamics of striatal dopamine projection predict individual alcohol drinking

Authors: *S. MONTGOMERY[1], C. MOREL[1], A. GODINO[2], L. LI[1], S. J. RUSSO[1], E. S. CALIPARI[3], E. J. NESTLER[4], M.-H. HAN[1];

Abstract: Harmful alcohol use is an increasing public health issue, currently resulting in 3 million deaths globally and contributing to more than 200 disease and injury conditions per year. An interesting phenomenon is the variability of alcohol consumption occurring within the population; some individuals drink casually while others drink in an uncontrolled or excessive manner. It is well established that the ventral tegmental area to nucleus accumbens (VTA-NAc) striatal dopamine projection is critical to encoding the primary reinforcing properties of both naturalistic stimuli and drugs. However, the mechanisms underlying how the neural dynamics of this circuit drive harmful alcohol use in some individuals and not others, remain vague. Using cell- and circuit-specific *in vivo* calcium imaging (fiber photometry) and *in vivo* electrophysiology, we investigated neural and behavioral signatures that predict voluntary alcohol drinking in mice and performed longitudinal assessments of how these phenotypes diverge or converge with continued alcohol consumption. We found that innate differences in reward sensitivity and exploratory behavior predict future alcohol phenotype. Conversely, we found that high levels of voluntary alcohol consumption normalize behavioral traits that are present in mice prior to alcohol exposure. In tandem, we show that VTA-NAc neural dynamics at baseline predict the future development of alcohol drinking phenotype, and these dynamics elucidate different mechanisms and consequences during encoding of naturalistic stimuli. Using *in vivo* electrophysiology, we determined that a higher pattern of VTA DA neuronal activity is associated with lower consumption of alcohol in the future, suggesting an innate protective effect of this circuit activity. Lastly, using RNA-sequencing, we investigated how the transcriptional landscape within the VTA and NAc shape distinct alcohol drinking profiles, aiming to identify molecular targets for future therapeutic use. By assessing the neural dynamics of this projection and naturalistic mammalian behaviors prior to and after voluntary alcohol drinking, this project will provide novel insights into the neural and behavioral risk signatures for the future development of alcohol misuse, as well as uncover novel mechanisms harnessed by individuals that are resilient to excessive alcohol drinking.

Title: Peripheral-central signaling involving dopamine 2 receptors affects locomotor activity and dopamine dynamics within the mesolimbic dopamine circuit

Authors: *S. C. STEFFENSEN[1], J. D. OBRAY[2], C. SMALL[1], J. LEBARON[1], E. BALDWIN[1], E. JANG[4], J. T. YORGASON[3];
[1]Dept. of Neurosci. and Psychology, [2]Dept. of Psychology, [3]Brigham Young Univ., Provo, UT; [4]Res. Ctr. for Convergence Toxicology, Korea Inst. of Toxicology, Daejeon, Korea, Republic of

Abstract: Recent research has demonstrated that peripherally administered dopamine (DA) enhances DA levels in the nucleus accumbens (NAc). This enhancement of DA levels is accompanied by changes in locomotor activity and a reduction in negative affect associated ultrasonic vocalizations (USVs) and fear responses. These changes have been posited to occur through a mechanism involving increased firing of VTA DA neurons. Despite this, the mechanism underlying this effect is poorly understood. In this study we demonstrated that administration of domperidone, a peripheral dopamine 2 receptor (D2R) antagonist, prior to administration of peripheral DA attenuated the effects of peripheral DA on DA levels in the NAc. Further, single unit recordings of ventral tegmental area (VTA) DA neurons demonstrated that VTA DA neurons display a biphasic response to peripherally administered DA characterized by a brisk inhibition followed by a longer period of excitation. The excitation portion of the response of VTA DA neurons to peripheral DA was blocked by pretreatment with domperidone. Further, it was found that peripherally administered DA was mildly rewarding in a place conditioning paradigm, an effect which was blocked by domperidone. Many drugs of abuse are known to enhance sympathetic tone, resulting in increased circulating DA resulting from DA spillover at sympathetic nerve terminals. This observation suggests that some effects of drugs of abuse such as ethanol on DA neurotransmission may be mediated in part by activation of peripheral D2Rs. This hypothesis was tested by measuring DA levels in the NAc following ethanol administration in rats pretreated with vehicle or domperidone. It was observed that domperidone reduced ethanol mediated increases in NAc DA levels, consistent with the hypothesis that a portion of the effect of ethanol on DA neurotransmission would be mediated by

peripheral D2Rs. Further effects of pretreatment with domperidone were observed on ethanol induced sedation without any effect on ethanol reward or the amount of dopamine release from DA terminals in the NAc following phasic stimulation. These results are broadly consistent with a role for peripheral D2Rs in ethanol effects on the mesolimbic DA system.

Title: Striatal dopamine system mediates anxiolytic effects of ethanol

Authors: *M. BOCARSLY[1], V. A. ALVAREZ[2];
[1]Rutgers NJMS, Newark, NJ; [2]Lab. on Neurobio. of Compulsive Behaviors, Natl. Inst. on Alcohol Abuse and Alcoholism, Bethesda, MD

Abstract: The literature suggests that anxiety is causally related to alcohol craving, consumption, and the development of alcohol use disorder (AUD). Alcohol has known anxiolytic properties, suggesting that individuals consume alcohol as a way to self-medicate against an aversive state. Animal models are consistent with this clinical observation: rats bred to consume large amounts of alcohol show higher basal anxiety and higher anxiolytic effects of alcohol compared to controls. Despite these behavioral observations, the underlying neural circuitry is unknown. The mesolimbic dopamine system has been implicated in drug abuse, including AUD. In both humans and rodents, alcohol abuse is associated with low levels of striatal dopamine D2 receptors (D2Rs). The current study implements transgenic mice with a targeted deletion of the D2R on striatal medium spiny neurons (MSNs) in order to better understand the neurobiology underlying the anxiolytic effects of alcohol. Mice with a knockout or knockdown of D2Rs on MSNs show enhanced anxiety-like behavior on the elevated zero maze, open field maze and light-dark box compared to littermate controls. They also show physiological indications of anxiety, such as elevated basal serum corticosterone levels. Further, the knockout and knockdown mice also show decreased preference for 1% sucrose compared to littermate controls, indicating anhedonia. When administered ethanol (1.2 g/kg; i.p.) these mice show enhanced anxiolytic effects of alcohol as measured on behavioral tasks. Interestingly, mice with

low levels of D2Rs on MSNs show increased activity of dopamine D1 receptor containing neurons, which leads to enhances anxiolytic effects of ethanol. Taken together, these data begin to describe the neural circuitry underlying and perpetuating the anxiolytic effects of alcohol.

Title: Peripheral mechanoreceptor activation alters chronic ethanol-induced changes to VTA GABA neurons, NAc DA release and measures of withdrawal in rats

Authors: *K. BILLS[1,2], C. SMALL[2], D. OTTESON[2], G. JONES[2], J. BATES[2], S. STEFFENSEN[2];
[1]Noorda Col. of Osteo. Med., Springville, UT; [2]Psychology and Neurosci., Brigham Young Univ., Provo, UT

Abstract: There is growing evidence that mechanical stimulation (MStim) modalities (osteopathic and chiropractic manipulation, acupuncture and physical therapy) modulate substrates in the supraspinal central nervous system (CNS) that are outside the canonical somatosensory circuits. The aim of this study was to evaluate the effects of MStim applied to the cervical spine on neurons and neurotransmitter release in the mesolimbic dopamine (DA) system, an area implicated in reward and motivation. Utilizing electrophysiological, pharmacological and neurochemical techniques, in male Wistar rats, we demonstrate that low frequency (45-80 Hz), but not higher frequency (115 Hz), peripheral MStim to the lower cervical spine depresses firing of ventral tegmental area (VTA) GABA neurons (52.8% baseline; 450 sec) and increases VTA DA firing (248% baseline; 500 sec) and basal (178.43 % peak increase at 60 min) and evoked DA release in the nucleus accumbens (NAc; 135.03 % peak increase at 40 min). Furthermore, MStim-induced DA release was mediated, in part, by endogenous opioid and acetylcholine release in the NAc. Additionally, peripheral MStim, administered concurrently with alcohol, alters alcohol-induced desensitization of VTA GABA neuron firing rate in response to a reinstatement dose of ethanol (2.5mg/kg;IP) from 117.5 % of baseline to 32.3 %. Dopamine release in the NAc at 20 min post-injection was changed from 95.4% of baseline to 144.4 % and at 80 min from 104.1% to 138.2%. Further, behavioral indices of withdrawal (rearing, open-field crosses, tail stiffness and gait) were substantively ameliorated with concurrent MStim treatment.

Title: Low doses of psychostimulant and opiate co-administration augment short-term behavioral activation and acute withdrawal via D1 receptor activation

Authors: *I. WHITE, W. WHITE;
Morehead State Univ., Morehead, KY

Abstract: Previously, we reported that a high dose of either amphetamine (2 mg/kg) or morphine (5 mg/kg) reduces activity 12 to 24 hours after administration, a sign of acute withdrawal. Such reduction was prevented by SCH23390, a D1 antagonist, given 30 minutes after amphetamine or morphine. This study compared the effects of separate administration with co-administration of low doses of amphetamine and morphine on behavioral activation during the first several hours after administration (short-term effect) and on acute withdrawal. Male Wistar rats received a series of tests during which locomotor activity was monitored in an openfield for 24 hours after each treatment. Near light onset of Test Day 1, each animal received saline. On Test Day 4, each animal received amphetamine (0.5 mg or 1 mg/kg), morphine (1.25 mg or 2.5 mg/kg), a combination of amphetamine (0.5 mg/kg) and morphine (1.25 mg/kg), or the same combination followed 15 minutes later by administration of SCH23390 (0.05 mg/kg) to test reversibility by D1 receptor blockade. The combination of amphetamine (0.5 mg) and morphine (1.25 mg) produced dramatically more short-term behavioral activation and more intense and prolonged acute withdrawal, compared to doses given separately. SCH23390 prevented both the short-term activation and the acute withdrawal due to co-administered amphetamine and morphine, suggesting that the augmented effect is dopamine dependent. Recreational drug users self-administer combinations of stimulants and opioid substances (“speedballs”) to produce augmented drug effects, but such combinations may lead to greater health risks, such as increased intensity and duration of acute withdrawal, as well as overdose.

Title: Antagonizing serotonin 2A (5-HT_{2A}) receptors attenuates expression of methamphetamine-induced conditioned place preference in female but not male rats

Authors: *N. C. REYNA, J. T. MADDEN, K. B. COX, N. PENTKOWSKI;
Univ. of New Mexico, Albuquerque, NM

Abstract: Antagonizing serotonin 2A (5-HT_{2A}) receptors attenuates expression of methamphetamine-induced conditioned place preference in female but not male rats
Despite the need, there are currently no FDA-approved pharmacological treatments for methamphetamine abuse disorders. Cue-induced craving during drug withdrawal remains a significant contributor to high relapse rates. Thus, understanding the neurobiological mechanisms of cue-induced drug seeking will aid in the development of effective pharmacotherapies. Previous research has shown that the selective 5-HT_{2A} antagonist M100907 attenuates the acquisition of methamphetamine-induced conditioned place preference (CPP) in male and female adult rats. However, these findings have not been extended to blocking cue-induced drug-seeking behavior. Therefore, the present study examined the effects of M100907 on expression methamphetamine-induced drug-seeking behavior using a biased CPP design in adult male and female Long Evans rats (PND 90-111). During conditioning trials, rats were administered either saline or methamphetamine (1 mg/kg, i.p.) and then were immediately placed into their initially non-preferred chamber for 30 minutes. After four days of conditioning, rats either received vehicle or M100907 (0.0025, 0.025, 0.1 mg/kg i.p.) 15 minutes prior to expression testing. Pretreatment with the high dose of M100907 (0.1 mg/kg) attenuated methamphetamine-induced expression of CPP in females. In contrast, none of the doses affected expression in males. These data suggest that blocking the 5-HT_{2A} receptor can decrease cue-induced methamphetamine-seeking behaviors, and provide a promising target for treating methamphetamine use disorder.

Title: Antagonizing serotonin 2A (5-HT_{2A}) receptors with M100907 attenuates methamphetamine-induced reward in adult male and female rats and blocks methamphetamine-induced anxiety-like behaviors in adult male rats

Authors: *J. T. MADDEN, N. C. REYNA, E. V. GORANSON, N. S. PENTKOWSKI; Psychology, Univ. of New Mexico, Albuquerque, NM

Abstract: Antagonizing serotonin 2A (5-HT_{2A}) receptors with M100907 attenuates methamphetamine-induced reward in adult male and female rats and blocks methamphetamine-induced anxiety-like behaviors in adult male rats
John T. Madden[1], Nicole C. Reyna[1], Emerald V. Goranson[1], Nathan S. Pentkowski[1]
Department of Psychology[1], University of New Mexico, Albuquerque, New Mexico
Methamphetamine is a highly addictive and globally used psychostimulant. Currently, there are no FDA approved pharmacological treatments for methamphetamine use disorders, highlighting the need for research examining the neural mechanisms underlying the rewarding effects of methamphetamine and the factors that perpetuate sustained methamphetamine use. Research indicates that serotonin 2A (5-HT_{2A}) receptors play a key role in the mediation of psychostimulant-induced behaviors, including conditioned place preference (CPP). These findings have yet to be extended to methamphetamine. The present studies investigated the effects of the selective 5-HT_{2A} receptor antagonist M100907 on methamphetamine-induced CPP in adult male and female rats, and methamphetamine-induced anxiety-like behaviors in adult male rats. Adult male and female rats were tested for methamphetamine CPP using an unbiased two-chamber apparatus across eight consecutive days. During each conditioning session rats were pretreated with an assigned dose of M100907 (0, .0025, .025 or .25 mg/kg, i.p.) 15 minutes prior to methamphetamine administration (0 or 1 mg/kg, i.p.). Following methamphetamine administration, rats were immediately confined to their initially non-preferred chamber. After four conditioning sessions, the effects of M100907 on methamphetamine-induced shifts in CPP were assessed. Following the eight days of CPP testing, adult male rats were screened for anxiety-like behaviors in the elevated plus-maze. Pretreatment with M100907 attenuated methamphetamine-induced CPP in both male and female subjects, without producing any rewarding or aversive effects when administered alone. In male subjects, pretreatment with M100907 prevented methamphetamine-induced elevations in anxiety-like behavior. Additionally, M100907 attenuated some behavioral indices of anxiety in methamphetamine-naïve male rats. These findings add to a growing body of evidence suggesting that 5-HT_{2A} receptors may be an effective target for the treatment of methamphetamine use disorders.

Title: Sex, Drugs, and Choline: Interactive effects of biological sex and dietary choline on the locomotor response of rats to amphetamine

Authors: L. AUGUSTIN[1], E. DONIGAN[2], K. WALKER[3], A. SCHULMAN[3], &. ADEOYE-LAWAL[1], J. HERSH[1], *M. GLENN[1];
[1]Psychology, [2]Anthropology; Chem., [3]Biol., Colby Col., Waterville, ME

Abstract: Choline is an essential dietary nutrient integral to the development and proper function of the central nervous system. Among its many biological roles, it is the precursor to acetylcholine, an integral component of cell membranes, and the primary source of methyl groups for methylation reactions. In rats, the availability of choline during developmental sensitive periods exerts profound and persistent impacts on several neural systems. Notably, there are marked enhancements in cell signaling and neural plasticity, particularly in hippocampal-cortical circuits, with prenatal and adolescent choline supplementation and diminished function with choline deficiency. Aligning to these neural changes are a host of alterations to behavior. Adult rats whose mothers consume a choline-rich diet exhibit enhanced learning and memory and reduced stress reactivity and anxiety and these effects are resistant to age- and disease-associated declines. Choline deficient mothers produce offspring that are severely compromised under challenging cognitive conditions, inhibited, and anxious, with worse outcomes with age and disease. The aim of the present study was to extend these findings into the domain of addiction and reward with an initial focus on stimulant drugs that work mainly as dopamine agonists. Given the widespread action of choline in the nervous system and its effects on neural plastic mechanisms, we hypothesized that choline availability during adolescence would alter rats' responsivity to amphetamine and that these effects would vary as a function of biological sex. To test this hypothesis, female and male Sprague Dawley rats were fed synthetic diets (AIN76A) in adolescence: either 0, 1.1 or 5 g/kg of choline chloride (DEF, STD, and SUP, respectively). As adults, rats' locomotor responses to each of three doses of amphetamine (0, 0.5, and 1 mg/kg) was assessed using a modified Latin square design. Consistent with other research, there were marked sex differences in activity: females were more active than males overall and in response to amphetamine. There were also interactive effects of sex and diet: female SUP rats were more active than STD or DEF rats in response to 0.5 mg/kg amphetamine and DEF rats showed a prolonged response to that dose when compared to STD rats; these patterns were not observed in male rats. These findings indicate that adolescent choline supplementation may modify reward circuits to alter the way that stimulant drugs act there and may do so in a sex-specific way. Additional analyses are focused on how choline influences the rewarding properties of these drugs, rats' motivation to seek them out, and the neural bases for these changes.

Title: Rewarding and relapse effects of levamisole and fentanyl as adulterants in methamphetamine.

Authors: *M. I. PAZ RAMOS[1], T. BROWNE, Jr[2], S. L. CRUZ[1];
[1]CINVESTAV, IPN, Mexico City, Mexico; [2]Colombo Plan Secretariat, Drug Advisory Program, Colombo, Sri Lanka

Abstract: Levamisole (LEV) is one of the most prevalent psychostimulant adulterants; nevertheless, its potential to induce relapse, alone or in combination, has not been assessed. Also, fentanyl (FEN) has been recently identified in various drugs, including methamphetamine (METH). Data on the opioid and stimulant combinations are well known, but information about FEN and METH co-administration is scarce. Here, we explored the rewarding effects of these substances, the combination of sub-effective doses, and their potential to produce relapse in the conditioned place preference (CPP) paradigm on its four different phases. We trained 81 adult male Wistar rats (200-250 g) in the CPP apparatus and administered the drugs s.c. First, we standardized the experimental conditions to reproduce previously reported data of the rewarding and relapse effects of METH on CPP. After four 1 mg/kg METH administrations, animals spent more time in the drug-paired chamber than in the initially preferred. Preference returned to basal conditions after extinction training. A challenge dose of 0.5 mg/kg METH reinstated CPP. With 1 mg/kg LEV animals showed drug-induced CPP after four doses, CPP disappeared after extinction training, and a challenge 0.5 mg/kg LVM dose did not reinstate CPP. Animals treated with FEN changed their preference after conditioning with four 30 µg/kg administrations, this preference disappeared after four drug-free sessions, and a challenge 15 µg/kg FEN dose reinstated CPP. These results suggest that LVM has rewarding effects, but to a lower extent than METH and FEN. To our knowledge, fentanyl reinstatement on CPP was not previously reported. Next, we did dose-response curves to determine the sub-effective METH, LEV, and FEN doses: 0.01 mg/kg, 0.1, and 0.3 µg/kg, respectively. These doses were used for co-administration experiments. LEV+MET potentiated the rewarding effects of individual drugs, but FEN+MET did not. Cross-reinstatement experiments showed that 0.01 mg/kg METH did not induce relapse, and 0.1 mg/kg LEV increased the time spent in the drug-paired chamber, but this data did not

reach statistical significance. Present results suggest that LEV might increase METH effects and play a role in relapse.

Title: Intra-accumbal administration of CB1 agonist arachidonyl-2-chloroethylamide (ACEA) modulates the expression of methamphetamine-induced locomotor sensitization through participation of GABAB receptors

Authors: *F. MIRANDA-HERRERA, J. C. JIMENEZ, F. CORTES-SALAZAR, R. I. RUIZ-GARCIA, A. I. BARRIENTOS-NORIEGA;
Univ. Nacional Autonoma De Mexico, Tlanepantla, Edo Mex, Mexico

Abstract: INTRODUCTION: We have previously reported that systemic administration of GABAB receptor agonist baclofen (BCF) blocked the development and expression of AMPH-induced locomotor sensitization (LS) and reduced amphetamine-induced discriminative cue. Although these findings and those of other labs have indicated that GABAB agonists, such as BCF, may be useful in the treatment of drug abuse, at the present, the mechanisms underlying the effects of BCF on psychostimulant-related behaviors are not well known. Saigusa and his colleagues have reported that the administration of delta1-opioid receptor agonist DPDPE into the nucleus accumbens (nAcc) increased the DA efflux in the nAcc, and the activation of the GABAB receptors in the nAcc suppressed the effects of DPDPE on DA efflux into the nAcc. In line with these results, in the present study, we evaluated the effects of intra-accumbal administration of CB1 agonist arachidonyl-2-chloroethylamide (ACEA) on the expression of methamphetamine (METH)-induced LS and if these effects could be modulated by GABAB receptor agonist BCF. METHOD. Male Wistar rats were divided in four groups (n=6) and treated with METH or saline during days 3-7 (development of METH-induced LS). On day 10 (expression of METH sensitization test) rats were treated with drugs. Group S-S was treated with saline, group M-M was treated with METH, group M-AM was treated with ACEA and METH, group M-ABCFM was treated with ACEA, BCF and METH. METH was administered ip and ACEA and BCF were administered into the nAcc shell (AP 1 mm from bregma, ML ± 1.3 mm, DV -6.8 mm).The behavioral activity was recorded for 60 min on open-field cages during development and expression of METH-induced LS. RESULTS. The data showed that

administration of ACEA induced an increase in locomotor activity in rats during the expression phase. However, BCF administration in the expression phase produced a reduction of the effect of ACEA on METH-induced LS. CONCLUSION: These results are in line with previous studies and suggest that BCF could be acting on DAergic nerve endings and plays an inhibitory role in the regulation of DA release into the nAcc, essential for the development and expression of psychostimulant-induced LS.

Title: Effects of Hunger on Drug response in Zebrafish

Authors: *P. BANSAL, D. AGGARWAL, E. E. JUNG;
Univ. of Illinois at Chicago, Chicago, IL

Abstract: Clinical and preclinical studies suggest that physiological state, such as hunger and satiety, can affect behavioral response to abused drugs Here we investigate the relationship between hunger and drug responses (neuronal and behavioral) in zebrafish larvae. To analyze neural activity and behavioral responses to the psychostimulant drugs, we have used 6 days post fertilization (dpf) Zebrafish (*Danio rerio)* larvae as an animal model and administered them D-amphetamine hemisulfate, a scheduled-II psychostimulant drug, to record direct physiological responses such as locomotion (n=18), tail flipping behavior (n=18), heart rate (n=12) and motor neuronal expression (n=8) in the spinal cord of the larvae *in vivo* linked to locomotor behavior. We performed these experiments in starved and satiated groups and responses were recorded pre (control_starved and control_fed) and post drug administration (drug_starved and drug_fed) for 40 minutes in the same subjects to obtain the baseline and observe the change in the activity. We observed that the drug_starved group showed 50% higher activity than control_starved group whereas activity of drug_fed group was 30% lower than control fed. We observed that base lines for control groups decreased, which can cause decreased activity even after the drug exposure in fed groups. Similar trend was observed in tail flipping activity, heart rate and motor neuronal

expression as well. These findings can call for further research to investigate the relationship between drug addiction related neural circuits and hunger mediating neurons.

Title: Striatal spinophilin function and amphetamine sensitization

Authors: *D. S. WATKINS[1], C. W. MORRIS[3], B. MUÑOZ[2], A. J. BAUCUM II[4]; [1]Med. Neurosci., [2]Dept. of Psychiatry, Indiana Univ. Sch. of Med., Indianapolis, IN; [3]Med. Neurosci., Indiana Univ. Purdue Univ. at Indianapolis, Indianapolis, IN; [4]Biol., Indiana University-Purdue Univ. Indianapolis, Indianapolis, IN

Abstract: Proper synaptic transmission is critical for maintaining neuronal communication. There is increasing evidence that in many striatal pathological disease-states such as Obsessive Compulsive Disorder (OCD), Attention Deficit Disorder (ADD/ADHD), drug addiction, and others, synaptic transmission is perturbed. Furthermore, the principle striatal neurons, medium spiny neurons (MSNs), in many striatal-dependent disease-states exhibit differential perturbations in downstream signaling. Signal transduction pathways that are localized to the post-synaptic density (PSD) of MSNs regulate protein phosphorylation in a tightly controlled manner. Aberrant phosphorylation state dynamics within striatal MSNs are observed in myriad striatal pathological disease-states. While serine/threonine kinases obtain substrate specificity, in part, by phosphorylating specific consensus sites, serine/threonine phosphatases such as protein phosphatase 1 (PP1), are much more promiscuous. To obtain substrate selectivity, PP1 associates with targeting proteins. Spinophilin is the major targeting protein that binds PP1 as well as multiple other synaptic proteins within the striatum. Our lab has found that modulation of the striatal dopaminergic milieu, impacts the spinophilin protein interactome. However, spinophilin function under amphetamine-dependent signaling such as those observed following amphetamine-induced behavioral sensitization is less well characterized. Here, we begin to report the functional role of spinophilin in mediating behavioral changes associated with amphetamine-induced locomotor sensitization and delineate changes in spinophilin interactions that may mediate behavioral changes associated with amphetamine sensitization. To more specifically elucidate spinophilin's function, we have generated multiple transgenic animals that allow for cell-specific loss of spinophilin as well as interrogation of spinophilin protein

interactions. Our data suggest that spinophilin interactions are modulated in specific cell types following psychostimulant administration. Mechanisms regulating spinophilin's interactions in specific cell types as well as loss of spinophilin in specific cell types in modulating amphetamine-induced behavioral sensitization responses will be discussed.

Title: Evaluation of the roles of differential rearing and sex on cue-induced amphetamine-seeking and astrocyte expression

Authors: *T. D. FORT, T. J. MOSER, M. C. AZUMA, M. E. CAIN;
Psychological Sci., Kansas State Univ., Manhattan, KS

Abstract: Previous research demonstrated that environmental enrichment during adolescence engenders lower responding for drug reinforcement during self-administration and cue-induced relapse following drug abstinence. However, few studies examined whether enrichment is able to attenuate escalations in drug intake during extended-access amphetamine (AMP) self-administration (SA). The current study used 6-hr SA procedures to elucidate the effect that differential rearing (DR) may have on overall AMP self-administration, relapse following forced abstinence, and the extent to which relapse can be mitigated by treatment with the therapeutic *N-acetylcysteine* (NAC). Given that DR alters glutamate homeostasis, the impact of DR and NAC treatment on astrocyte expression was evaluated via immunohistochemical (IHC) staining of GFAP+ cells in the mPFC and NAcc. We hypothesized that enrichment would protect against escalation and would result in the greatest GFAP expression. Male and female Sprague-Dawley rats were raised in their respective environmental conditions for 30 days. Enriched (EC) rats were raised communally, given novel arrangements of toys, and handled daily. Isolated (IC) rats were single-housed in hanging cages, lacked novel objects, and were not handled during the rearing period. Standard (SC) rats were pair-housed, lacked novel objects, and were only handled once a week during cage changes. After rearing, all rats were implanted with an indwelling jugular catheter. Upon recovery, rats were placed into the operant chamber to undergo 12, 6-hr FR-1 sessions. Active lever presses resulted in an infusion of AMP (0.1 mg/kg/infusion) which

was followed by a time-out period. After 12 sessions, all animals were given daily treatments of NAC (100 mg/mL; ip) or vehicle during the abstinence period while remaining in their respective environments. After 14 days, all animals were placed back into the operant chambers for a 2-hr long relapse test in the absence of AMP, and brains were extracted immediately after for IHC staining of GFAP. Enrichment significantly lowered overall AMP SA as well as escalations in AMP intake during the 12 SA sessions. During the relapse test, enrichment also significantly attenuated cue-induced AMP seeking. Cue-seeking was significantly greater in females when compared to males. NAC failed to attenuate cue-induced responding during the relapse test in any environmental condition. Our ongoing IHC analyses to date suggest the ability of enrichment to attenuate escalating intake and relapse is not due to enrichment-induced changes in astrocyte expression.

Title: A proposed mechanism for stimulant-induced behavioral sensitization involving the transporter VMAT

Authors: V. GARCIA[1], S. A. COLLINS[2], A. J. TELLEZ[2], B. N. BRITO[2], R. A. PEREZ[2], M. MIRANDA-ARANGO[3], *E. CASTAÑEDA[4];
[1]Psychology, [2]Biol. Sci., Univ. of Texas as El Paso, El Paso, TX; [3]Dept. of Biol. Sci. and Border Biomed. Res. Ctr., [4]Univ. of Texas at El Paso, El Paso, TX

Abstract: Repeated exposure to psychostimulants produces sensitization, an enhanced behavioral and neurochemical sensitivity to both the drug and drug-related cues, that is thought to sustain addictive behavior. It was hypothesized that VMAT, the protein responsible for storage of dopamine (DA) into vesicles, may be functionally altered to redistribute intracellular DA between cytoplasmic vesicular pools based on demands for drug-mediated overflow versus release evoked by depolarizing electrical stimulation. Two behavioral tests of this hypothesis utilized rats that were pretreated with the VMAT blocker tetrabenazine (TBZ) before each daily

treatment of a 7-day sensitizing regimen of amphetamine (AMPH). Aim 1 tested whether TBZ pretreatment blocked sensitization of AMPH evoked rotational behavior in unilateral striatal DA depleted rats, a response primarily mediated through the reversal of DA Transporter function. Aim 2 tested whether TBZ pretreatment blocked sensitization of electrically evoked rotational behavior (ESRB) in rats receiving unilateral electrical stimulation of the medial forebrain bundle, a response mediated through exocytotic-like activation of DA release. After a 7-day incubation period following the sensitization protocol, rats were tested for expression of sensitization or its blockade by measuring AMPH-evoked rotational behavior (Aim 1) or ESRB (Aim 2). Within Subjects comparisons during the induction phase corroborate behavioral sensitization and acute effects of TBZ to block behavioral sensitization (Aim 1). Total turns were found to be an inadequate measure of behavioral sensitization in intact animals (Aim 2). On the challenge day testing for expression of sensitization, Between Subjects comparisons revealed behavioral sensitization of both AMPH-evoked rotational behavior (Aim 1) and ESRB (Aim 2). Most importantly, sensitization was blocked by TBZ pretreatment in both pharmacokinetic driven and exocytotic-like driven behaviors. It is concluded that VMAT may play a critical role in behavioral sensitization to stimulant drugs. This research is significant because a common mechanism (ie, VMAT) may play a role in behaviors evoked by different mechanisms involving drug-related responses and other behaviors mediated by exocytotic processes, such as drug-related discriminative stimuli. Future research must evaluate the effects of VMAT blockade during AMPH exposure upon DA overflow/exocytosis and investigate potential pharmacotherapeutic interventions that target VMAT function.

Title: Distress tolerance and prelimbic activity predict cocaine-seeking in male, but not female rats

Authors: *T. M. MOSCHAK[1], T. J. SLOAND[2], R. M. CARELLI[3];
[1]Univ. of Texas at El Paso, El Paso, TX; [2]Rowan Univ., Glassboro, NJ; [3]Univ. of North Carolina at Chapel Hill, Chapel Hill, NC

Abstract: Distress tolerance (DT) is defined as the ability to persist in challenging goal-directed behavior in the face of stress, and individuals with low DT exhibit heightened drug-seeking behavior. However, no preclinical studies have examined the neurobiology underlying this phenomenon. To assess this, we used in vivo electrophysiology in Long Evans rats (n = 15 female, n = 20 male) during a DT task to record neural activity in the prelimbic cortex (PrL) and nucleus accumbens (NAc) core, two brain regions implicated in drug-seeking. For the DT task, rats were initially trained to press a lever within a brief window of time in order to receive a sucrose pellet. On the DT test day, this brief window of time was progressively shortened so that it became impossible for animals to obtain a correct response, and we assessed how long animals persistently responded in the task as our measure of DT. Following the test day, rats underwent two weeks of self-administration for either water/saline or cocaine (1 mg/kg/inf) for 6 hr/day. Animals then began a 1-month period of experimenter-imposed abstinence to induce heightened drug-seeking behavior (Grimm et al., 2001). On day 28 of abstinence we reassessed DT and neural activity, and on day 30 we assessed cocaine-seeking behavior. Males had significantly higher DT than females ($p = 0.009$). Additionally, male (but not female) rats with low DT after 28 days of abstinence had significantly heightened drug-seeking behavior (male: $p = 0.048$; female: $p = 0.624$). Furthermore, we found that a subset of PrL neurons tracked behavioral persistence during the DT task. Critically, task-induced activity in these neurons (but not those in the NAc core) negatively correlated with subsequent drug-seeking behavior in males ($p = 0.027$). These findings suggest that males that can maintain heightened PrL activity during stressful/challenging contexts are less likely to persistently seek out drug later. Conversely, DT may not play as large of a role in drug-seeking in females. In total, these data demonstrate an important role for the PrL in DT and link this neural activity and behavior to drug seeking.

Title: Cues associated with social defeat stress recruit CRF in the nucleus accumbens and invigorate drug-seeking following abstinence from cocaine

Authors: *M. LEONARD[1], K. A. MICZEK[1,2];
[1]Psychology, Tufts Univ., Medford, MA; [2]Neurosci., Tufts Univ., Boston, MA

Abstract: Cocaine-dependent individuals experience intense drug cravings in anticipation of imminent drug availability. Acute stressors can further exacerbate heightened states of arousal produced by drug-related stimuli and increase propensity to seek and consume drug. The present studies extend ongoing work examining the role of the stress peptide CRF in facilitating maladaptive arousal in the presence of drug-predictive stimuli. In rats, CRF enhances instrumental behavior directed towards gaining access to cocaine, in part through local control of DA transmission in the nucleus accumbens (NAc). Because CRF modulates motivational states in both appetitive and aversive contexts, we explored the extent to which an ecologically relevant stressor (social defeat) augments cocaine self-administration under a chained response sequence (ie seeking-taking), and whether NAc-CRF is recruited. On alternating days, male rats were exposed to acute social defeat in the presence of a compound stimulus (CS^+: peppermint odor+3kHz tone) or an empty cage (CS^-: almond odor+25kHz tone); 4 sessions each. Microdialysis conducted in the presence of the conditioned cues revealed that the stress-CS^+ produced a rapid increase in both CRF and DA in the NAc, which was temporally distinct from a delayed rise in CORT. Separate rats were trained to self-administer cocaine under a chained schedule of reinforcement (FI-FR) in order to dissociate *anticipatory* (drug-seeking) from *consummatory* (drug-taking) behavior. Completion of an FI (5m) produced access to continuous cocaine reinforcement (FR1) on a separate lever (5m). Accelerating responding across the FI was considered an index of arousal in anticipation of impending drug access - ostensibly, when craving is heightened. After a 7d drug-free (ABST) period, rats were reintroduced to the drug context to self-administer cocaine in the presence of either stress-paired (CS^+) or neutral cues (CS^-) in a counterbalanced manner. Compared to pre-ABST, responding during the FI was elevated under both conditions. Critically, CS^+ exposure produced significantly higher anticipatory responding for cocaine than the CS^- ($CS^+ > CS^- >$ pre-ABST), suggesting that stress cues augmented the effects of ABST alone. Cocaine intake was similar across conditions. These data support the idea that environmental stressors can amplify the impact of returning to a drug-context after an abstinence period, such to invigorate putative “drug-seeking” behavior. Anticipation of threat may engage common motivational salience circuits that generate arousal during cocaine expectation, whereas unconditioned aspects of drug-reward are differentially controlled.

Title: Differential plasticity in nucleus accumbens core and shell mGlu5 glutamate receptor following cocaine self-administration is both dose and withdrawal dependent.

Authors: *M. GHASEMZADEH, O. BURGOS, M. AL RUBAYE, D. SHARMA, M. MIRZAEI;
Biomed. Sci., Marquette Univ., Milwaukee, WI

Abstract: Prolonged high level cocaine abuse leads to severe drug addiction in humans. This pattern of drug abuse also leads to gradual increase in drug intake over time and produces exacerbated drug craving during periods of abstinence known as incubation of craving. We can model this pattern of drug abuse by using extended-access cocaine self-administration in rats (LgA, 6hr daily session). A major obstacle in the treatment of addiction has been the propensity to relapse, often mediated by drug-associated cues, even after prolonged period of abstinence from drug use. Recent work suggests that glutamatergic signaling has an important role in cocaine addiction and particularly in drug seeking and relapse. In particular, the group1 metabotropic mGlu1/5 receptors have been shown to be important for both drug taking and drug seeking; and therefore, they have been pursued as promising targets for therapeutic development. Male Sprague-Dawley rats were trained to self-administer cocaine (FR1; 1.0 mg/kg/200 µl/inf) during either 2-hr (ShA) or 6-hr sessions (LgA) for 14 days. Subsequently, animals remained in the home cage for 3, 10, or 60 days. Following abstinence period, rats were tested under context-primed extinction condition for cocaine seeking after systemic administration of either saline or an mGlu1/5 receptor antagonist (JNJ16259685 or MTEP). Following a short abstinence period (3 or 10 days), the systemic blockade of mGlu5 receptor reduced drug seeking only in ShA subjects without affecting the LgA animals, while mGlu1 receptor blockade was effective in reducing drug seeking in both groups. However, after a long abstinence period (60 days), the systemic blockade of either receptor significantly reduced drug seeking in both ShA and LgA rats. It has been demonstrated that intracerebral infusion of MTEP (3µg/side) after 10 days of abstinence into either NAcore or NAshell leads to a decrease in drug seeking in ShA rats, whereas blockade of NAshell mGluR1 does not block drug seeking. However, our results in LgA rats suggest that while blockade of mGluR5 in NAcore reduced drug seeking, its blockade in NAshell was not effective in reducing drug seeking. These results suggest that exposure to cocaine produce a transient intake dependent plasticity in mGluR5, but not in mGluR1, function in the brain. Moreover, our data point to nucleus accumbens shell as the anatomical substrate contributing to the selective modulation of mGluR5 function in LgA rats. Our observations suggest that systemic activation of mGluR5 (CDPPB, 10 mg/kg), during early abstinent period may prevent development of incubation craving. Interestingly, this effect of mGluR5 PAM may emanate from NAshell.

Title: Renewal of cocaine seeking using social and nonsocial contexts

Authors: *B. A. HUMBURG, L. R. HAMMERSLAG, S. G. MALONE, P. S. KELLER, M. T. BARDO;
Univ. of Kentucky, Lexington, KY

Abstract: Individuals with substance use disorders undergo craving when re-exposed to a drug-associated context. It has been shown that social peers throughout abstinence can be protective; however, drug-associated peers can also serve as cues that trigger craving and relapse. To date, a majority of preclinical research assessing the mechanisms of relapse have been restricted to nonsocial cues or contexts (e.g., tones, lights or odors). The purpose of this study was to determine if cocaine seeking is differentially renewed by a social context (peer) vs. a non-social context (house light (HL) illumination). A dual-compartment apparatus was used in which rats could have limited social contact through a wire screen partition. In experiment 1, young adult Sprague-Dawley (7 male and 8 female) rats were trained with a 2-lever procedure to self-administer (SA) cocaine (0.75 mg/kg/inf) for 21 days in a context consisting of both a same-sex, same-age peer (non-self-administering) and illumination of a HL in each compartment (Context A). Half the rats were then extinguished in Context A and the other half in Context B (no peer or HL illumination). Renewal of cocaine seeking was then tested in the presence of Context A stimuli in counterbalanced order as follows: (1) peer alone; (2) HL alone; or (3) peer + HL compound. We also included a control test which involved the same context as extinction for each group. Multi-level modeling was used to analyze differences in responding between AAA and ABA groups. Following acquisition of cocaine SA, the AAA group extinguished at a faster rate than the ABA group. During renewal tests, the ABA group showed significant renewal to the peer alone and peer + HL compound when compared to extinction, whereas the AAA group did not. The HL alone did not renew cocaine seeking in either group, indicating that it was overshadowed completely by the peer. To ensure that the HL alone was salient enough to elicit renewal, Experiment 2 was conducted exactly the same as above (7 male and 8 female Sprague-Dawley rats) except that Context A consisted of only illumination of a HL in each compartment (no peer) and context B had no HL illumination. Again, following acquisition of cocaine SA, rats significantly decreased their responding, with the ABA group having more responding on the active lever than the AAA group. The renewal test showed that the ABA group increased responding to the HL illumination compared to extinction, whereas the AAA group did not. Overall, these results indicate that social peers can serve as powerful stimuli that can overshadow nonsocial stimuli in renewal of drug seeking. Supported by NIH grant R21 DA041755.

Title: The protective effect of operant social reward on cocaine self-administration, choice, and relapse is dependent on delay and effort for the social reward

Authors: *M. VENNIRO[1], L. V. PANLILIO[2], D. H. EPSTEIN[2], Y. SHAHAM[2];
[1]Univ. of Maryland Sch. of Med., Baltimore, MD; [2]NIDA/IRP/NIH, Baltimore, MD

Abstract: Background: Social-reinforcement-based treatments are effective for many, but not all, people with addictions to drugs. We recently developed an operant rat model that mimics features of one such treatment, the community-reinforcement approach. In this model, rats uniformly choose social interaction over methamphetamine or heroin. Abstinence induced by social preference protects against the incubation of drug seeking that would emerge during forced abstinence. Here, we determined whether these findings generalize to cocaine and whether delaying or increasing effort for social interaction could reveal possibly human-relevant individual differences in responsiveness. Methods: We trained male and female rats for social self-administration (6 days) and then for cocaine self-administration, initially for 2-h/day for 4 days, and then for 12-h/day continuously or intermittently for 8 days. We assessed relapse to cocaine seeking after 1 and 15 days. Between tests, the rats underwent either forced abstinence or social-choice-induced abstinence. After establishing stable social preference, we manipulated the delay for both rewards or for social reward alone, or the response requirements (effort) for social reward. Results: Independent of cocaine-access conditions and sex, operant social interaction inhibited cocaine self-administration and prevented incubation of cocaine seeking. Preference for social access was decreased by delay of both rewards or social reward alone, or by increased response requirements for social reward, with notable individual variability. Conclusion: This choice procedure can identify mechanisms of individual differences in an animal model of cocaine use and could thereby help screen medications for people who are relatively unresponsive to treatments based on rewarding social interaction.

Title: Genome-wide association study in outbred heterogeneous stock rats for the conditioned and unconditioned effects of cocaine

Authors: *E. RAKOWSKI[1], C. P. KING[2], A. S. CHITRE[3], O. POLESSKAYA[4], S. B. FLAGEL[5], T. E. ROBINSON[6], L. C. SOLBERG WOODS[7], A. A. PALMER[8], P. MEYER[9]; [1]Psychology, State Univ. of New York, Univ. at Buffalo, Buffalo, NY; [2]Psychology, Univ. at Buffalo, Buffalo, NY; [3]Dept. of Psychiatry, [4]Univ. of California San Diego, La Jolla, CA; [5]Mol. and Behavioral Neurosci. At Buffalo, Buffalo, NY

Abstract: Addiction vulnerability is frequently modelled in rodents using behavioral tasks that measure the conditioned and unconditioned effects of cocaine, both of which are shaped by genetic and environmental factors. To examine these heritable genetic factors, we performed a genome-wide association study (GWAS) to identify genomic regions associated with cocaine sensitivity in two tasks. Specifically, we characterized genotypically and phenotypically diverse heterogeneous stock (HS) rats in two cohorts (total n = 3,228) in cocaine conditioned cue preference (CCP) and contextual conditioning (CCC) tasks, in which tactile floors and contexts were paired with repeated cocaine treatment. We then conducted GWAS on measures of locomotor activity and conditioned responses to the cues and context. Measures of cocaine conditioning showing modest heritability (h^2 = .065-.255), and we found two loci on chromosomes 16 and 19 which were associated with the initial locomotor response to cocaine and approach to the cocaine-paired floor following conditioning, respectively. Each loci contained multiple genes (*e.g. Hmox1, Large1*). In contrast, most genetic loci we found reflected baseline locomotor behaviors and showed larger heritability values (h^2 = .308-.121). For example, locomotor activity during habituation sessions or saline treatments were associated with loci on chromosomes 1, 2, 6, 15, and 18, which included multiple genes (*e.g. Ptpn2, Spire1*). We further examined the 3Mb region surrounding each of these loci with other behavioral measures collected as part of this project using a phenome-wide association study (PheWAS), and found that these regions were also associated with other behaviors reflecting general exploratory behavior and arousal, including responding during light reinforcement and distance traveled in an open field test. These data indicate that the conditioned and unconditioned effects of cocaine, while influenced by genetic and heritability factors, are not largely informed by individual single genetic loci. Additional approaches using gene network analysis may be more useful for disentangling complex multi-gene system interactions underlying heritability. We found that more loci were detected for non-drug measures related to baseline exploratory

behavior and arousal. This study suggests that HS rats are useful for identifying gene systems influencing complex behaviors related to addiction vulnerability, although the utility of identifying individual loci may be dependent on the task.

Title: The experience of control mitigates stress-induced behavioral changes: Implications for cocaine demand and seeking

Authors: *K. A. SILETTI, K. T. BROWN, G. C. KNOPP, M. C. HILLMAN, E. C. WARNOCK, M. V. BARATTA, M. P. SADDORIS;
Psychology & Neurosci., Univ. of Colorado Boulder, Boulder, CO

Abstract: Motivation to obtain natural and drug rewards is sensitive to costs that an animal must endure to obtain them, such as risk and effort. Demand that is highly elastic will decay quickly as costs accrue, while inelastic demand will persist despite escalating costs. Following chronic, voluntary drug administration, drugs often serve as inelastic reinforcers; animals will often persist drug-seeking despite decreasing dose or drug availability. However, this demand can be further modulated by factors such as exposure to stress or drug-associated cues. Specifically, inescapable stress or re-exposure to drug paraphernalia can induce intense drug cravings and promote relapse, even during prolonged abstinence.
Our work explores how prior experience with stress modulates cost sensitivity and motivation to seek sucrose and cocaine reward. While stress is an unavoidable aspect of life, not all stressors are inescapable. Learning to control stress can alternatively have protective benefits against future stressors. Animals that are trained to control stressors do not demonstrate enhanced hypervigilance or neophobia otherwise exhibited by uncontrollable stress-exposed counterparts. In the “Escapable Stress/Inescapable Stress”, or ES/IS, model of stressor controllability, an “ES” rat can turn a wheel to terminate a 1 mA tail-shock. A yoked “IS” rat receives the exact same intensity and duration of shock, without the experience of control. Our work demonstrates that ES-experienced animals are less sensitive to effort costs when the reward is sucrose, as ES-experienced animals will lift weight similar to no stress controls. However, using a behavioral

economics paradigm in which cocaine cost is manipulated by decreasing the dose delivered per infusion, we demonstrate that these same stress experiences may have no effect on cost sensitivity when the outcome is cocaine.
Moreover, we show preliminary data suggesting that stressor controllability training may reduce drug-seeking in comparison to IS-experienced controls, but only during abstinence when the drug is unavailable. Animals that experience ES did not incubate to cocaine-associated cues over 30 days of forced abstinence, while IS-experienced animals exhibited greater drug-seeking on withdrawal day 30 than day 1. Our work suggests that stressor controllability may moderate aspects of cocaine-seeking under abstinent conditions wherein drug is unavailable; alternatively, when drug is available, demand for cocaine is insensitive to benefits of stressor controllability training.

Title: Schedules of reinforcement influence cocaine-seeking patterns that correspond with goal-directed and habitual behavior in rats

Authors: *S. N. HANDEL[1], B. O. JONES[2], R. J. SMITH[3];
[1]Psychological and Brain Sci., [2]Inst. for Neurosci., [3]Psychological and Brain Sciences, Inst. for Neurosci., Texas A&M Univ., College Station, TX

Abstract: Our lab recently developed a novel method to discriminate goal-directed and habitual cocaine seeking in rats using outcome devaluation via satiety. Sensitivity to outcome devaluation indicates the use of a goal-directed strategy, whereas insensitivity indicates the use of a habitual strategy. We found that random ratio (RR) and random interval (RI) schedules of reinforcement bias responding to be goal-directed or habitual, respectively, but that cocaine seeking can be

goal-directed or habitual on both schedules. Here, we wanted to further explore how response strategies and reinforcement schedules interact. We trained male Sprague Dawley rats to self-administer intravenous cocaine on a seeking-taking schedule of reinforcement with RR20 or RI60 requirements on the seeking lever. To assess response strategy, the cocaine outcome was devalued via satiety by administering noncontingent intravenous cocaine prior to a 10-min extinction test. Results thus far indicate that the occurrence of goal-directed or habitual strategies within a schedule corresponds with distinct behavioral patterns that are particular to that schedule. As compared to goal-directed responding, habitual responding is associated with increased inter-infusion variance on the RR schedule but decreased variance on the RI schedule. Further analyses indicate that the schedule also influences strategy-specific patterns of responding on the seeking lever, including number of responses and rate of responding. These behavioral analyses will provide greater insight into how schedule influences response strategy, as well as how response strategy influences patterns of cocaine seeking and taking. Understanding the interactions between schedule and response strategy will be key to developing better animal models of habitual and compulsive drug seeking, and to unraveling the behavioral and neural mechanisms of habits in addiction.

Title: Predator odor stress exposure produces sex-specific effects on cocaine self-administration in rats

Authors: *T. J. TEMPLETON, N. W. GILPIN;
Physiol., LSU Hlth. Sci. Ctr., New Orleans, LA

Abstract: Post traumatic stress disorder (PTSD) and cocaine use disorder (CUD) are highly comorbid and pose serious health consequences. Women are twice as likely to develop PTSD than males; and females with CUD are more likely to have PTSD than males with CUD. Despite these clinical findings, preclinical research investigating the role of stress on cocaine use has been conducted exclusively in males. This project was designed to 1) identify the effects of traumatic stress exposure on operant cocaine self-administration, and 2) identify neurochemical changes following stress-induced cocaine self-administration in males and females. Male and female Wistar rats were trained to self-administer cocaine intravenously for 10 days, then were

exposed to predator odor (i.e., bobcat urine) and tested for avoidance of the odor-paired context. Unstressed controls were not exposed to predator odor. Animals then once again self-administered cocaine for 10 days either 1hr/day (short access [ShA]) or 6hr/day (long access [LgA]) before tissue was collected for analysis. Preliminary results suggest that predator odor exposure promotes escalation of cocaine self-administration in female (but not male) rats with long access but not short access to cocaine. Stressed LgA females exhibited escalation of cocaine intake across 10 days of self-administration following predator odor stress exposure relative to 1) unstressed LgA females, 2) stressed ShA females, and 3) stressed LgA males. Additionally, results suggest that females (but not males) with long access to cocaine gain less weight post-stress than unstressed controls and females with short access to cocaine. These findings suggest that females are at a higher risk of developing cocaine use disorder following stress exposure than stressed males and unstressed females. Our data also suggest that stressed male rats exhibit blunted escalation, or perhaps even reductions, of cocaine intake relative to unstressed male controls. Ongoing work is measuring stress peptide content in the brains of these animals. This work was funded in part by NIH grant AA023305.

Title: Prenatal circadian rhythm disruption induces sex-specific substance use-related phenotypes in mice

Authors: *L. DEPOY[1], C. A. MCCLUNG[2];
[1]Psychiatry, Univ. of Pittsburgh, Pittsburgh, PA; [2]Psychiatry, Univ. of Pittsburgh Med. Sch., Pittsburgh, PA

Abstract: 20% of Americans are at risk for environmental circadian rhythm disruptions (CRD) due to shift work. These individuals experience substantial negative health outcomes, but females are especially affected with greater vulnerability for substance use (SU) and adverse outcomes associated with pregnancy. These outcomes not only occur *during* pregnancy, but offspring are also affected at birth and later in life. Prenatal CRD (pCRD) in mice recapitulates these risks, increasing adverse pregnancy outcomes and altering behavior in adult offspring.

However, it is unknown whether pCRD affects SU in mature offspring. C57Bl/6J dams were sham handled or disrupted, by reversing the light/dark cycle 4 times during gestation. Reward-related behaviors were measured in mature offspring. Cocaine reward was measured using conditioned place preference (5 mg/kg cocaine). Contingency degradation was used to measure decision making. Mice were trained to respond on two levers for food, then the likelihood that one of those levers will be reinforced was degraded. Another cohort was trained to respond for food before jugular catheterization. After recovery, mice were trained to respond on another lever for cocaine. Acquisition, the reinforcing and motivational properties of cocaine, extinction and cue-induced reinstatement were measured. Interestingly, females exposed to pCRD developed an anhedonic-like phenotype with decreased food self-administration, cocaine intake and reinforcing properties of cocaine. On the other hand, males showed a SU-like phenotype with increased cocaine preference, higher order food self-administration and cocaine reinforcement. Furthermore, male pCRD mice maintained goal-directed decision making, responding more on a reinforced aperture, while female pCRD mice did not, indicating habit formation. Together these results suggest that male and female mice exposed to pCRD respond differently for rewarding outcomes. In order to determine whether these divergent behavioral outcomes are unique to reward I then measured anxiety-like behavior. As expected, behavior in the open field test and elevated plus maze paralleled reward-related behavior. Anhedonic-like female pCRD mice showed increased anxiety-like behavior and pCRD males showed decreased anxiety/increased risk-taking behavior. These results suggest that pCRD may predispose individuals to distinct psychiatric disorders based on sex, mood disorders in females and SU disorders in males. By understanding how disrupted rhythms during pregnancy affect behavior in adulthood, we can develop novel therapeutic approaches for SU and mood disorders in adults.

Title: Aversive stimuli that decrease nucleus accumbens dopamine signaling also increase drug preference

Authors: E. M. GRAFELMAN[1], D. S. WHEELER[1], M. GELIN[1], P. LAMBERTON[1], M. C. HEARING[1], J. R. MANTSCH[2], *R. A. WHEELER[1];
[1]Marquette Univ., Milwaukee, WI; [2]Med. Col. of Wisconsin, Milwaukee, WI

Abstract: Aversive stimuli have a complex impact on the neural systems responsible for the pursuit of drug and natural rewards. Aversive stimuli can punish reward-seeking behaviors, but in a different situation, the same stimuli can invigorate drug-seeking behaviors. Physiologically, aversive stimuli can acutely suppress dopamine (DA) release in the nucleus accumbens (NAc) but may simultaneously stimulate dopamine release in other brain areas, such as the prefrontal cortex (PFC). Here we investigated the effect of various aversive stimuli on DA signaling in the NAc and PFC using fiber photometry. Then we examined the effect of an aversive stimulus on the self-administration of freely available drug and natural rewards. Female and male rats underwent surgery in which they received an infusion of AAV5-hSyn-dLight 1.3 into the NAc or medial PFC and implantation of an optic fiber to the same location. Following recovery, the effects of different aversive stimuli on DA signaling in the NAc and PFC were examined. The aversive tastant, quinine, an intense white noise, and electric footshock were each found to reliably reduce DA in the NAc while increasing DA in the PFC. Following this determination, a separate group of rats was implanted with intrajugular catheters and tested in a free choice design. Rats were trained to press a lever for sucrose pellets and trained to press a lever for an intravenous infusion of cocaine followed by a 20s timeout. After training, rats were tested in a free choice design in which responding on one lever provided two sucrose pellets and responding on the other provided an infusion of cocaine. Both levers were available throughout the 120 min session. Following the establishment of stable responding for both the natural and drug rewards in daily sessions, an intense white noise aversive stimulus was presented during the task on alternating days. For both male and female rats, the presence of the white noise stimulus increased cocaine self-administration. Following extinction training on the cocaine lever, white noise reduced responding on both levers. These data show that an aversive stimulus can increase the motivation to seek a drug reward, and that decreased NAc DA signaling is a physiological correlate of this process. Ongoing studies are monitoring DA release in the NAc during the free choice task in the presence of the aversive stimulus.

Title: Effects of punishment on goal-directed and habitual responding for food and cocaine.

Authors: *B. JONES[1], R. J. SMITH[2];
[1]Texas A&M Univ., Bryan, TX; [2]Dept Psychological and Brain Sci., Texas A&M Univ., College Station, TX

Abstract: Addiction is characterized by compulsive drug use that persists even when faced with negativeconsequences. Animals that are resistant to punishment will continuing to self-administer cocaine despite receiving footshock. Our lab is interested in testing the hypothesis that punishment resistance arises from failure to exert goal-directed control over habitual drug seeking for intravenous (IV) cocaine. To directly test the relationship between punishment resistance and habits, our lab developed a novel outcome devaluation procedure for IV cocaine that can be used to discriminate goal-directed (GD) and from habitual (H) response strategies. Previous work from our lab has established a link between response strategy and punishment resistance for IV cocaine and food. We found that being GD or H prior to receiving punishment does not predict how animals will respond to punishment. In contrast, we find that sensitivity to punishment is associated with the response strategy utilized after punishment. Additionally, we find that punishment can cause rapid shifts in response strategy. A habitual rat that is sensitive to punishment can quickly shift to a GD strategy and a GD rat that is resistant to punishment can shift to a habitual strategy. However, we also find that some H rats remain habitual after punishment, and some GD rats will remain GD. Here, we investigate if the way a rat shifts response strategy (i.e. a rat shifting from GD to H) is correlated with punishment sensitivity and recovery from punishment. Male Sprague Dawley rats were trained on a seeking-taking chained schedule of self-administration for either food pellets or intravenous cocaine, in which completion of a random ratio or random interval schedule on the seeking lever gave access to a separate taking lever. Animals were then exposed to 4 days of punishment testing, in which footshock (0.4 mA, 0.3 s) was delivered randomly on one-third of trials, immediately following completion of seeking and prior to extension of the taking lever. Response strategy was assessed 4 days before and after punishment. While being H after punishment was correlated with resistance to punishment, rats that were GD prior to punishment and switched to a H strategy were more resistant to punishment than the H rats that did not switch. Similarly, rats that shifted from H to GD were more sensitive to punishment than rats that remained GD throughout testing. Interestingly, within the group of rats that remained GD, we found no correlation with sensitivity to footshock. Taken together, these data suggest that sensitivity to punishment utilizes GD behavior, however, a rat utilizing GD behavior is not necessarily sensitive to punishment.

Title: Behavioral and neuroactivational correlates of psychosocial stress-induced cocaine seeking in rats

Authors: *N. M. HINDS, I. D. WOJTAS, D. M. PULLEY, S. J. MCDONALD, S. DE GUZMAN, N. E. HUBBARD, C. M. KULICK-SOPER, J. J. DEBSKI, B. PATEL, D. F. MANVICH;
Dept of Cell Biol. and Neurosci., Rowan Univ., Stratford, NJ

Abstract: A major challenge for treating cocaine use disorder is the high risk of relapse that can persist even after prolonged periods of abstinence. Exposure to psychosocial stress induces cocaine craving and is thought to be a major contributor to cocaine relapse, yet the neural circuitry by which it induces drug seeking has not been thoroughly explored. This study aimed to identify brain regions selectively activated during psychosocial stress-induced cocaine seeking in rats. Adult male and female Long-Evans rats were trained to self-administer cocaine (0.5 mg/kg/inf, i.v.) in 2-h daily operant-behavioral sessions for 20 d. On days 11, 14, 17, and 20, a discrete tactile cue was presented in the operant chamber and these sessions were immediately followed by social stress (social defeat, n=16), nonsocial stress (footshock, n=12), or a no-stress control condition (n=12). Beginning on day 21, animals underwent extinction training during which lever-presses were not reinforced. Once responding was extinguished, rats were re-exposed to the tactile cue that signaled their assigned stress/no-stress stimulus and cocaine seeking was measured for 2 h under extinction conditions. Immediately after this reinstatement test, animals were sacrificed, and brains collected and processed for c-Fos expression. When all groups were combined, cocaine-seeking magnitude was found to be positively correlated with neural activity in several brain areas, including the rostral periaqueductal gray (rPAG). Interestingly, activity within different subdomains of the rPAG varied as a function of the stressor employed, as activation of the dorsomedial rPAG correlated with footshock-associated cocaine seeking while activation of the dorsolateral and lateral rPAG correlated with psychosocial stress-associated cocaine seeking. Moreover, activity in these rPAG subdomains were differentially correlated with activation in other brain areas. Finally, ethographic analysis of social defeat episodes revealed that rPAG activity at the time of the cocaine seeking test was positively correlated with prior display of “active-defensive” coping behaviors in response to social threat. Taken together, our results suggest that psychosocial stress may trigger cocaine seeking via a unique neural network that involves the dorsolateral and/or lateral rPAG, and that the rPAG may represent a shared neural substrate mediating active coping responses to social stress as well as social stress-induced drug-seeking behavior. Studies are currently underway to examine the functional role of the rPAG in stress-induced cocaine seeking behavior.

Title: Performance on a visuo-spatial working memory task in adolescent and aged rhesus macaques

Authors: *M. MUNOZ[1], M. L. JUTRAS[1], C. GLAVIS-BLOOM[2], J. H. REYNOLDS[3], C. R. VANDERLIP[3], A. D. GARCIA[1], E. BUFFALO[1];
[1]Univ. of Washington, Lynnwood, WA; [2]Neurosci., Salk Inst. for Biol. Studies, La Jolla, CA; [3]SNL-R, Salk Inst., La Jolla, CA

Abstract: Results from a large and long-standing body of literature demonstrate that aged non-human primates (NHPs) are impaired on short-term visuo-spatial memory tasks compared to younger NHPs (Moss et al., 1997; Amaral & Rapp, 1989). One such task, the Delayed Recognition Span Task (DRST), has been employed in both NHP and human studies (Moss et al, 1989). In this task, the subject is rewarded for identifying a novel stimulus amongst a successively increasing number of familiar stimuli by remembering information about the stimuli's visual features, spatial locations, or a combination of both. Here, we trained adolescent (n=2, mean age=5 yo) and aged (n=3, mean age=20 yo) female rhesus macaques on a touch-screen version of visuo-spatial DRST using tablets mounted to their home cages (Lafayette Instrument Company, Lafayette, IN). To measure individual animal performance on the DRST we assessed memory capacity by calculating, on average, how many correct stimuli the monkey chose on each trial. All macaques, regardless of age, learned to perform this task above chance levels. However, performance differences were noted across age groups. Specifically, there was greater individual variability in maximum DRST performance amongst aged macaques compared to young (SD, young: 0.94; aged: 2.28), and aged macaques had a lower average span length compared to young (span length, young: 7.17; aged: 4.26). Taken together, these findings demonstrate the potential of home-cage automated testing and suggest that performance on the DRST is impaired in some aged macaques. This flexible testing paradigm will enable future studies with larger arrays, multiple delays, and a comparison of visual vs spatial memory. Further, this task could be used in longitudinal studies to identify the progression of age-related memory impairment in NHPs.

Title: Medial temporal lobe network efficiency supports mnemonic discrimination of objects in older adults

Authors: *J. N. ADAMS, J. L. YAROS, S. KIM, L. MCMILLAN, M. A. YASSA; Neurobio. and Behavior, Univ. of California, Irvine, Irvine, CA

Abstract: The medial temporal lobe (MTL) is comprised of anterior and posterior functional networks that process object and spatial information, respectively, which converge in the hippocampus. We tested whether the local efficiency of these networks was related to mnemonic discrimination of object and spatial stimuli in cognitively normal older adults (OA). We hypothesized associations between anterior MTL local efficiency and object memory, posterior MTL local efficiency and spatial memory, and hippocampal local efficiency with both domains. Resting state fMRI was analyzed for 55 OA participants (72 ± 6 yrs; 67% F). Functional connectivity analyses were conducted in CONN across 22 unilateral MTL ROIs. Local efficiency was calculated with the Brain Connectivity Toolbox for each ROI and was averaged for the anterior MTL (perirhinal cortex, anterolateral entorhinal cortex, and amygdala), posterior MTL (parahippocampal cortex, posteromedial entorhinal cortex), and hippocampal (DG/CA3, CA1, subiculum) networks. OAs performed object and spatial versions of a mnemonic discrimination task (n=44), and performance was assessed with the lure discrimination index (LDI). Object mnemonic discrimination was more strongly related to local efficiency of the hippocampal ($r = 0.34$, $p = 0.03$) and anterior MTL ($r = 0.29$, $p = 0.07$) networks than the posterior MTL network ($r = 0.20$, $p = 0.22$; Figure 1A). Spatial mnemonic discrimination was not associated with the local efficiency of any network (ps>0.65; Figure 1B). Our results indicate local efficiency of MTL networks, specifically the hippocampal network, support mnemonic discrimination of object stimuli. As object processing is particularly vulnerable to aging, understanding the functional basis of this deficit is critical to preventing cognitive decline.

Title: Regional white matter hyperintensities are associated with reduced medial temporal lobe subregion volumes in older adults

Authors: *B. RIZVI[1], M. SATHISHKUMAR[1], F. MARQUEZ[1], S. J. GRANGER[1], L. MCMILLAN[1], A. M. BRICKMAN[2], N. J. TUSTISON[1,3], M. A. YASSA[1];
[1]Neurobio. and Behavior, Univ. of California, Irvine, Irvine, CA; [2]Taub Inst., Columbia Univ., New York, NY; [3]Radiology and Med. Imaging, Univ. of Virginia, Charlottesville, VA

Abstract: White matter hyperintensities (WMH) are visualized on a T2-weighted FLAIR image and are a radiological marker of small vessel cerebrovascular disease. WMH are associated with aging and clinical expression of Alzheimer's disease (AD), affecting the onset and progression of the disease. WMH are known to affect memory functioning in older adults, and one proposed mechanism by which they impact memory is via neurodegeneration of structures such as the entorhinal cortex and hippocampus. However, little is known about whether WMH affect specific medial temporal lobe (MTL) subregions that underlie episodic memory functioning, and how the spatial distribution of WMH plays a role in these relationships. We studied how total and lobar (frontal, temporal, parietal, occipital) WMH are associated with MTL subregion volumes. We derived total and lobar WMH volumes by processing T2-weighted FLAIR images using the MICCAI 2017 winning methodology, which was ported to the ANTsX ecosystem; the resulting labeled masks were segmented by a lobar atlas and further manually edited. Using T1 and T2-weighted images, the Automatic Segmentation of Hippocampal Subfields (ASHS) pipeline was used to derive labels and volumes of hippocampal and medial temporal lobe subregions. MTL subregion volumes were adjusted by total intracranial volume (TIV). 136 older individuals were included in these analyses (mean age (SD) = 76.32 (10.06) years; 90 (66%) women). After adjusting for age, sex/gender, and education, we found that total, frontal, parietal, and occipital WMH volumes were associated with reduced total Brodmann area (BA) 36 volume. Furthermore, occipital WMH was associated with lower total CA1, CA2, CA3, dentate gyrus (DG), entorhinal cortex (ERC), subiculum, and parahippocampal cortex TIV-adjusted volumes. These findings highlight the potential role of posterior WMH in promoting neurodegeneration of MTL subregions that have important roles in episodic memory.

Title: Examining the diagnostic utility of the mnemonic discrimination task for classification of cognitive status and amyloid-b positivity

Authors: *S. KIM, M. G. CHAPPEL-FARLEY, D. KEATOR, J. JANECEK, L. MCMILLAN, B. A. MIRANDA, A. MIKHAIL, M. A. YASSA;
Univ. of California, Irvine, Irvine, CA

Abstract: Deposition of beta-amyloid (Aβ) plaques is an early biomarker of Alzheimer's disease (AD), but current methods of measuring Aβ accumulation are invasive or expensive. Therefore, developing a non-invasive platform that can effectively predict Aβ burden is crucial, as this technology could help to identify individuals with increased risk for AD and provide a window for potential treatment or intervention. Mnemonic discrimination tasks (MDT) assess the ability to discriminate highly similar episodic memory representations (e.g., objects or spatial locations), and task performance is reliant on the DG/CA3 subregions of the hippocampus. Prior work has shown age-related impairment in object and spatial discrimination as well as hyperactivity within DG/CA3 subregions. The relationship between the MDT performance and Aβ burden, however, has not yet been directly tested. In this study, we investigated whether MDT performance can successfully classify cognitive status or Aβ load in older adults. A sample of 93 older adults (60-91 yrs old) with normal cognition and 10 older adults with a clinical diagnosis of Mild Cognitive Impairment (MCI) (62 -89 yrs old) underwent either cerebrospinal fluid (CSF) lumbar punctures or ^{18}F-florbetapir-PET imaging. Cognitively normal individuals were stratified into Aβ+ and Aβ- subgroups based on quantitative thresholds for Aβ positivity (SUVR >1.15, CSF $A\beta_{1\text{-}42/1\text{-}40} < 0.062$). Participants performed the object and spatial versions of the MDT. We used logistic regression and random forest algorithms, including MDT performance metrics and demographic factors (age, gender, education) as features to classify cognitive status (normal vs. MCI) and Aβ status (positive vs. negative). We evaluated the area under the receiver operating characteristic curve (AUC) using the classifiers in a 10-fold cross validation design. For classification of cognitive status, the best model performance was achieved by including all the features of object and spatial MDT metrics and demographics (AUC = 0.8). For classification of Aβ status in cognitively normal participants, object MDT metrics combined with demographics were the most effective features (AUC = 0.70). Our findings suggest that the object and spatial MDT may have clinical utility as a diagnostic tool to predict cognitive status and *in vivo* Aβ burden in preclinical older adults.

Title: Understanding the age-related decline in mnemonic lure discrimination performance using a hierarchical Bayesian diffusion model

Authors: *C. CHWIESKO[1], J. JANECEK[1], S. S. DOERING[1], J. VANDEKERCKHOVE[2], M. LEE[2], M. HOLLEARN[1], R. RATCLIFF[3], L. MCMILLAN[1], M. A. YASSA[1];

Abstract: The number of older adults is rapidly rising in the world population. Episodic memory is impacted by age to varying degrees and is dramatically impaired in mild cognitive impairment and Alzheimer's disease. To better understand and distinguish healthy from pathological aging it is important to study normal age-related changes in episodic memory.The Mnemonic Discrimination Task (MDT), a modified object recognition memory task, which uses similar "lure" stimuli (perceptually similar but not identical images) has become a popular cognitive assay to study those changes. Several research groups have confirmed that older adults, in comparison to young adults, tend to identify similar lures more often incorrectly as old (i.e. overgeneralize). It is currently believed that this age-related decline in discrimination is due to a memory deficit, i.e. a reduction in pattern separation due to decreased hippocampal integrity. However, contributions of other cognitive processes to this age-related decline have not been thoroughly investigated. In the current study, we used a custom-designed hierarchical Bayesian diffusion model to investigate which cognitive processes contribute to the age-related decline in lure discrimination performance. The Ratcliff Diffusion model is a mathematical process model that allows us to decompose decision behavior in the MDT into the different underlying cognitive processes. For each of the model parameters (representing specific cognitive processes) we estimated the difference in the group means between older and younger adults across a series of hierarchical models. The best performing model was chosen based on the deviance information criterion and the group differences in the model parameters were evaluated using Bayesian statistics. Our results demonstrate strong evidence that age-related decline in discrimination performance is indeed based on reduced discrimination (i.e. memory) in older adults and not based on differences in other cognitive processes.

Title: Functional connectivity in the default mode network and medial temporal lobe network changes in the course of Alzheimer's disease in individuals with Down syndrome

Authors: *N. D. DIPROSPERO[1], M. SATHISHKUMAR[1], L. MCMILLAN[1], D. B. KEATOR[2], E. DORAN[3], C. HOM[2], D. NGUYEN[3], H. D. ROSAS[4], F. LAI[4], A. M. BRICKMAN[5], N. SCHUPF[5], W. SILVERMAN[3], I. T. LOTT[3], M. A. YASSA[1];
[1]Neurobio. and Behavior, [2]Psychiatry and Human Behavior, [3]Pediatrics, Univ. of California, Irvine, Irvine, CA; [4]Neurol., Massachusetts Gen. Hosp., Charlestown, MA; [5]Taub Inst., Columbia Univ., New York, NY

Abstract: By age 40, virtually all people with Down syndrome (DS) have sufficient beta-amyloid and tau pathologies present to meet the criteria for pathological Alzheimer's disease (AD). Determining the timing and location of neurobiological changes caused by AD is critically important for effective intervention within this high-risk population and more broadly in the general population, but little is known about the brain changes associated with clinical onset of AD in DS. Previous studies in sporadic AD showed default mode network (DMN) hyperconnectivity in those with mild cognitive impairment (MCI) and hypoconnectivity in those with AD, likely driven by progression of amyloidosis. Additionally, evidence from neurotypical individuals suggests DMN functional connectivity with the medial temporal lobe (MTL) is vulnerable to AD-related impairment. The purpose of the present study is to determine how DMN and MTL functional connectivity differs in people with DS ages 40+ depending on dementia status.
One hundred seven individuals with DS (mean age 49.6±6.4, 38% women) from a subset of the Alzheimer's Biomarkers Consortium - Down Syndrome study underwent MRI, including a 1mm MPRAGE scan and a resting state fMRI scan (resolution varied between 2-3mm). Participants completed a battery of neuropsychological tests and were assigned a consensus diagnosis for the presence or absence of MCI or AD dementia. Seventy-one participants were classified as cognitively stable (CS) (mean age 48.7±6, 46% women), 23 participants had MCI-DS (mean age 51.1±5, 23% women), and 13 participants had AD dementia (mean age 56±6.4, 42% women). We hypothesized that participants with MCI-DS would have greater functional connectivity between the DMN and MTL compared to the CS and dementia groups. We also hypothesized that participants with DS who had dementia would have lower functional connectivity between the DMN and MTL compared to the CS and MCI-DS groups. We found that those with MCI-DS had greater functional connectivity between the posterior DMN and the posteromedial entorhinal cortex (pMEC) relative to the CS and dementia groups, in line with our hypothesis. However, those with dementia had lower functional connectivity within the MTL, specifically between the anterolateral entorhinal cortex (aLEC) and the pMEC, compared to the CS and MCI-DS groups. Changes in pMEC functional connectivity with the posterior default mode network and the medial temporal network track with the progression of clinical symptoms of AD-DS and may reflect synaptic changes stemming from AD pathology.

Title: Theta-specific noninvasive modulation of cerebellar contributions to episodic memory in healthy aging

Authors: *S. DAVE, S. L. WERT, E. CHUNG, S. VANHAERENTS, J. L. VOSS; Northwestern Univ., Chicago, IL

Abstract: The human cerebellum interacts with the large-scale brain network that supports episodic memory. A prevailing hypothesis suggests that these long-range interactions are guided by synchronous neural oscillations in function-specific frequency bands, e.g., at the theta (~3-8 Hz) frequency pattern dominant across hippocampal network regions during encoding and retrieval. Recent evidence in young adults supports this hypothesis (Dave et al., 2020), demonstrating that cerebellar contributions to episodic memory can be selectively enhanced by application of noninvasive brain stimulation (i.e., TMS) at a theta rhythm (theta burst) versus at a control beta-frequency rhythm. It is unclear whether similar rhythmic and location-specific factors can guide selective effects of cerebellar stimulation in older adults. Cognitively typical older adults show widespread and highly variable atrophy across the hippocampal-cortical memory network. In brain regions with relatively high levels of atrophy (e.g., the parietal cortex), selective effects of theta-patterned stimulation on episodic memory performance emerge in young adults but are not found in healthy older adults (Hermiller et al., 2021). As cerebellar volume is relatively better preserved in healthy aging, we investigated whether this site might serve as a location for influencing memory function. In 17 cognitively healthy older adults (9 women, ages 63-83), we found that cerebellar theta-burst TMS improved episodic memory encoding relative to both control-location theta-burst TMS of nearby occipital cortex ($p = 0.01$) and to control-rhythm beta TMS ($p = 0.05$). These findings suggest that the cerebellum be an ideal target for stimulation-based interventions for age-related memory impairment. Further, as is the case for younger adults, stimulation at theta rhythm is effective for episodic memory enhancement in older adults.

Title: Translating time across the lifespan in humans and chimpanzees

Authors: *J. SCHWARTZ[1], B. RIGBY DAMES[2], K. OFORI[1], C. BAUCUM[3], A. VAN DER KOUWE[4], E. TAKAHASHI[4], C. J. CHARVET[1];

Abstract: How biological programs evolved to support human cognition is an enduring question of interest. Yet, we still lack appropriate procedures to align ages across species. We collected 228 time points from abrupt and gradual changes in behavior, neuroanatomy, and transcription in humans and chimpanzees to identify corresponding ages across the two species. We also collected time points (e.g., mortality curves) from diverse populations (e.g., hunter-gatherers) in males and females to account for individual variation in corresponding ages across humans and chimpanzees. Corresponding ages are similar in the two species early in development (shortly after birth) but gradually diverge with age in the two species. The lifespan is extended across diverse human populations relative to chimpanzees, and is concomitant with biological pathways (e.g., brain atrophy) clearly observed in aged humans but difficult to detect in chimpanzees. The inclusion of time points from diverse populations yields improved estimates in predicting ages in humans and chimpanzees, and shows that very old age as a distinctly human characteristic.

Title: Optimization of Protein Precipitation from Human Nails to Facilitate Early Detection of Mental Health Disorders

Authors: *E. MOELKER, E. NGUN CER SUNG, N. KOORNDYK, M. STEPHAN, P. RIVERA;
Biol., Hope Col., Holland, MI

Abstract: The National Alliance on Mental Illness (NAMI) reports that 1 in 5 adults will experience mental illness every year, and 1 in 20 adults will experience serious mental illness every year. 50% of lifetime disorders begin by the age of 14, and 75% of lifelong disorders begin by the age of 24. Early detection and intervention is key to improving patient outcomes, however research exploring potential biomarkers as early indicators is still limited. Thus far, biomarkers have been assessed almost exclusively in blood samples, which can be invasive to obtain and expensive to preserve and assess. The objectives of this project were twofold: optimization of protein precipitation in human nail samples, and identification and quantification of immune proteins present in human nails with potential to be biomarkers. We developed a one day extraction and precipitation protocol allowing for fast and efficient recovery of protein. Survey data and nail samples were collected from 68 individuals over a period of two months in the spring of 2021. Survey data (demographic information, GAD-7, PHQ-8, and TAPS-I) were used to categorize samples by screening tool scores. The optimized protein precipitation method was used to obtain protein pellets from participant nail samples. Protein concentration was ascertained using gel electrophoresis and Coomassie staining. Survey data responses were used to aggregate 1mg/mL stocks of extracted protein to detect immune cytokine presence via a Human XL Proteome Profiler Cytokine Array and were verified via Western blots. Future work aims to collect samples from psychiatric patients and utilize the same precipitation protocol as a comparison. The broader impact of this project is developing a resource to aid in working toward early detection and intervention for mental health disorders.

Nacional del Sur, Inst. de Investigaciones Bioquímicas de Bahía Blanca (INIBIBB) CCT UNSCONICET, Bahia Blanca, Argentina

Abstract: We herein describe an optimized and scalable workflow to prepare and analyze cultures of human donor-derived Schwann cells (hSCs) from mature and developing nerve tissues. We recommend the following steps for optimal growth and purity of both the primary and established cell cultures: (1) pre-culturing perineurium-free nerve fibers in suspension and delaying tissue dissociation for at least one week to facilitate enzymatic cell release; (2) plating the initial cell suspensions in the form of individual droplets onto dishes double-coated with poly-L-lysine and laminin to increase the recovery of adherent cells; (3) introducing a step of purification via magnetic-activated cell sorting at passage-zero to rapidly and efficiently eliminate fibroblasts from the onset; and (4) culturing the tissues and the isolated cells in heregulin-supplemented medium to accelerate hSC mitogenesis before and after enzymatic dissociation. This protocol can render >100 million highly viable, proliferative hSCs depending on the size of the nerve biopsy and the level of amplification. The hSCs obtained in this manner are suitable for variety of downstream applications including cryopreservation and labeling using vital fluorophores, plasmids or lentiviral vectors. The cells are metabolically active, phenotypically stable, and capable to engulfing and degrading myelin even after undergoing 3 to 5 successive rounds of expansion. Nevertheless, heterogeneity and donor variability of individual cultures are expected. For this, we recommend a routine characterization of the populations to unequivocally identify non-glial cells, senescent cells, and cells at different stages of differentiation immediately after plating and at all levels of passage.

Title: Identification of a novel blood-brain-barrier-penetrant AAV capsid in both rodents and primates

Authors: Y. YAO, J. WANG, Y. LIU, Y. QU, K. WANG, Y. ZHANG, Y. CHANG, Z. YANG, J. WAN, H. NAKASHIMA, S. E. LAWLER, C.-F. CHO, E. A. CHIOCCA, *F. BEI;
Brigham and Women's Hospital, Harvard Med. Sch., Boston, MA

Abstract: Recombinant adeno-associated viruses (rAAVs) have been increasingly explored as a vector for gene therapy in the central nervous system (CNS). Recently, we reported two new blood-brain-barrier (BBB)-penetrant AAV variants, namely AAV.CPP.16 and AAV.CPP.21, by engineering AAV9 capsid. Importantly, the superiority of AAV.CPP.16 over AAV9 translated from mice to non-human primates, showing 5-10 folds enhancement in CNS transduction with intravenous delivery. Here, we further report that both AAV.CPP.16 and AAV.CPP.21 showed enhanced transcytosis in human brain microvascular endothelial cells (hBMEC) in an *in vitro* BBB model. Increased viral bindings to hBMECs by both variants were observed. In addition, increased transduction of and viral binding to primary human astrocytes were also observed for both AAV variants. These results point to potential factor(s) in cytoplasmic membranes of endothelial cells and CNS cells that could account for enhanced CNS transduction by the variants. Furthermore, to demonstrate proof-of-concept for application in CNS gene therapy, we utilized AAV.CPP.16 to develop a systemic, PD-L1-antibody-based gene therapy that had a significant pro-survival effect in a mouse model of glioblastoma. In comparison with AAV9, AAV.CPP.16 improved systemic delivery of the PD-L1 antibody to the tumor and thus increased infiltration of $CD3^+$ lymphocytes and $CD8^+$ cytotoxic T cells in the tumor microenvironment. In summary, our follow-up studies provide more mechanistic insight into the newly engineered, BBB-penetrant AAV variants, and demonstrate their prospect for translational applications in CNS gene therapy.

Title: Development of conjugate vaccines providing differential selectivity profiles against ketamine and 6-hydroxynorketamine

Authors: Z. ZHENG, **J. L. KYZER**, A. WOROB, *C. J. WENTHUR;
Sch. of Pharm., Univ. of Wisconsin-Madison, Madison, WI

Abstract: While the anesthetic drug ketamine has dissociative and hypnotic properties that drive its misuse and abuse, it also has rapidly acting antidepressant properties that have supported its use as a breakthrough therapy in treatment resistant depression. Given this mixed risk/benefit profile, there has been significant interest in identification of distinct mechanisms that support ketamine's antidepressant activity without inducing rewarding or dissociative effects. Notably, ketamine administration *in vivo* results in coincident exposure to multiple active metabolites, including norketamine and multiple 6-hydroxynorketamine diastereomers. Therefore, to enable assessment of the functional contributions from each of these molecular species, we aimed to generate highly selective anti-drug immunoglobulins that could prevent each of these small molecule targets from crossing the blood-brain barrier to elicit their psychoactive effects. We first used synthetic organic chemical approaches to generate three novel bioconjugate haptens, KET-N-COOH, NK-N-COOH, and 6-HNK-N-COOH. Vaccination of mice with these bioconjugates, co-formulated with alum and CpG ODN 1826, was then undertaken using a 28-day, three injection protocol. Serum antibody titers were assessed using an enzyme-linked immunosorbent assay (ELISA) against KET-BSA, NK-BSA, and HNK-BSA coated plates. Midpoint titers from CRM-KET and CRM-NK were highest against KET-BSA, while those from CRM-HNK were highest against HNK-BSA. The resulting IgG antibodies were isolated from serum and their affinity was assessed using competitive surface plasmon resonance (SPR) measurements against ketamine, norketamine, or 6-hydroxynorketamine. Antibodies from CRM-KET sera demonstrated an affinity ratio of approximately 1:90:1 for ketamine, norketamine, and 6-hydroxynorketamine; this ratio was 1:16:1 for CRM-NK antibodies; and 33:105:1 for CRM-HNK antibodies. Mice were challenged with 0 - 50 mg/kg ketamine, and ketamine's effects in the open field test, tail flick test, and hotplate test were found to be blunted by vaccination with CRM-KET. Overall, these novel vaccines have demonstrated the potential to enable mechanistic assessment of metabolite-driven polypharmacologic contributions to ketamine's rewarding and antidepressant effects, and may potentially be useful for therapeutic reversal of ketamine overdose.

Title: Understanding Kinases Important in GBM Survival

Authors: *K. CHUGH[1], Z. SHENG[2];
[1]Virginia Tech. Carilion Sch. of Med., Roanoke, VA; [2]Fralin Biomed. Res. Inst., Roanoke, VA

Abstract: BACKGROUND: Glioblastoma (GBM) is the most common and deadly brain tumor in adults with a 5 year survival rate of 5%. Even with aggressive treatment, the prognosis of GBM is poor. Current standard of care for chemotherapy is with TMZ, a methylating agent. However, at least 50% of patients treated with TMZ do not respond to it. It is therefore necessary to identify other possible therapies for GBM.
OBJECTIVE: The primary objective of this study is to identify existing chemotherapies that may have a role in regulating the expression of genes that are necessary for GBM survival (known as survival kinase genes). We hypothesize that current existing chemotherapies, particularly those that target EGFR, will be negatively correlated with survival kinase gene expression.
METHODS: Survival kinase gene expression, chemotherapeutic agents and sensitivity of GBM cells (IC50) from 27 cell lines were obtained from data base The Cancer Dependency Map. The 15 survival kinase genes for GBM were established from previous studies.
RESULTS: Expression for 14 of the 15 survival kinase genes studied were significantly positively or negatively correlated with an existing therapeutic agent. Negative correlation indicated that cells with a high level of that survival kinase are sensitive to the given chemotherapeutic agent. Positive correlation indicated that GBM cells with a high expression of a particular survival kinase were not sensitive, and therefore may not be a good target for treatment. It was identified that cells with a high level of expression of survival kinase gene ROR2 had the most chemotherapeutic agents negatively regulating gene expression, while MAP4K3 had 5 therapies that were positively correlated, indicating that this site may not be sensitive to chemotherapeutic treatment. Furthermore, drugs that targeted c-MET, XIAP, CDK41and EGFR are consistently negatively correlated with expression of their respective survival kinase gene. This research is exploratory.
FUTURE DIRECTIONS: Given these significant correlations, drugs that target c-MET, XIAP, CDK4 and EGFR may be useful areas to research further and target as therapies for GBM. Drugs that targeted TOP1 sites (Irinotecan and topotecan) were consistently positively correlated with their survival gene expression, indicating that their respective kinases may be a poorer prognostic marker and target for treatment. Given that these are correlations, next steps include an *in vitro* study to understand the viability of cells with both high and low levels of the given survival gene in response to the chemotherapeutic compounds, to ensure that high expression of that given gene indicates a sensitivity to the compound.

Title: Multiplexed multispectral imaging to visualize cancer cell subtypes and evaluate the immune landscape in glioblastoma

Authors: *A. E. HAGGERTY[1], N. MAMMADOVA[1], C. E. BROWN[2], M. E. BARISH[3]; [1]Akoya Biosci., Marlborough, MA; [2]City of Hope, Duarte, CA; [3]Neurosciences, Beckman Res. Inst. City of Hope, Duarte, CA

Abstract: Abstract: Glioblastoma (GBM) is an aggressive and almost universally fatal brain cancer. Glioblastoma tumor masses are highly vascularized and infiltrated with cells mediating both innate and adaptive immunity. The presence and organization of various immune cells within the tumor microenvironment varies between patients and within individual tumors. This variability in the immune landscape influences responses to different treatment modalities, including immunotherapies. Understanding reciprocal immune-tumor cell interactions will enhance design and implementation of novel therapies. Currently, review of GBM patient tissues by neuropathologists is done visually using single or low-plex biomarker panels whose complexity is constrained by limitations of traditional immunohistochemistry, including the lack of well characterized primary antibody clones, limited antibody selection due to species-dependent workflows, and inaccuracies such as false signal intensities introduced by autofluorescence (AF) and spectral overlap from traditional immunofluorescence imaging methods. Multiplex immunofluorescence (mIF) and multispectral imaging (MSI) allows for fast, accurate imaging on a single tissue section of up to eight fluorophores (using Phenoptics technology), cell type-specific AF spectra, and DAPI/Hoechst. Of note, purported cancer stem cells have been shown to have unique AF signatures that can be isolated utilizing MSI technology in the context of mIF and nuclear markers. Utilizing MSI technology and spectral unmixing leads to improved signal-to-noise ratios and accuracy of cellular phenotyping, ultimately culminating in greater data confidence and reproducibility. Here, we have used pre-validated mIF kits that use Opal fluorophores together with the Vectra Polaris Automated Quantitative MSI system on human formalin-fixed, paraffin embedded GBM tissue samples to further characterize immune-tumor microenvironments, with consideration for spatial distributions of interacting cells. Pre-optimized immunofluorescent kits targeting immune cell subsets, checkpoint inhibitors, and other biomarkers have been shown to provide clinically relevant information in other cancer types (such as lung cancer and melanoma). Our study indicates that widespread use of these reagents would better characterize the complex immune landscape of tumors and enhance design and implementation of therapeutics for GBM.

Abstract: Ligands can induce G protein-coupled receptors (GPCRs) to adopt a myriad of conformations, many of which play critical roles in determining the activation of specific signaling cascades associated with distinct functional and behavioral consequences. For example, the 5-hydroxytryptamine 2A receptor (5-HT2AR) is the target of classic hallucinogens, atypical antipsychotics, and psychoplastogens. However, currently available methods are inadequate for directly assessing 5-HT2AR conformation both in vitro and in vivo. Here, we developed psychLight, a genetically encoded fluorescent sensor based on the 5-HT2AR structure. PsychLight detects behaviorally relevant serotonin release and correctly predicts the hallucinogenic behavioral effects of structurally similar 5-HT2AR ligands. We further used psychLight to identify a non-hallucinogenic psychedelic analog, which produced rapid-onset and long-lasting antidepressant-like effects after a single administration. The advent of psychLight will enable in vivo detection of serotonin dynamics, early identification of designer drugs of abuse, and the development of 5-HT2AR-dependent non-hallucinogenic therapeutics.

Abstract: A longstanding goal in neuroscience is to understand how spatiotemporal patterns of neuronal electrical activity underlie brain function, from sensory representations to decision making. An emerging technology for noninvasive monitoring membrane electrical dynamics is voltage imaging using Genetically Encoded Voltage Indicators (GEVIs) — light-emitting protein indicators whose brightness reports membrane voltage. GEVIs are promising tools for monitoring voltage dynamics at high spatiotemporal resolution in genetically defined cell types in vivo. While significant screening efforts had been made to improve sensors' performance, existing pipelines are usually restricted to evolve one or a few properties of GEVIs, leading to biased champions that do not enable robust single-trial two-photon imaging of voltage dynamics in behaving rodents. Therefore, GEVIs have yet to be broadly adopted. To fill in the gap between the demand for robust neuron imaging and the imperfect performance of existing GEVIs, we developed a pipeline for high-throughput screening of GEVI libraries, followed by detailed characterization of the most promising candidates. Here, we will present our efforts on developing the screening platform to evolve GEVIs in all performance metrics and semi-rational engineering of GEVIs guided by structure and evolutionary studies, using indicators of the

Accelerated Sensor of Action Potential (ASAP) family as a starting point. The best indicator identified during our screening, which we named Jellyfish-derived Electricity-reporting Voltage Indicators (JEDIs), were used report light-evoked graded potentials with subcellular resolution in mice retinal explants and living flies. JEDI also enabled single-trial recording of spiking activity in awake behaving mice with both resonant scanning and ULoVE random-access microscopy. These results demonstrate the utility of JEDI across model systems and imaging modalities, paving the way for its broader deployment by the neuroscience community.

Title: JEDI2: A second-generation indicator for two-photon imaging of voltage dynamics

Authors: *M. LAND[1], M. BARUCH[1], K. L. COLBERT[1], Y. GOU[1], S. LAI[1], Z. LIU[2], X. LU[3], A. J. MCDONALD[1], S. YANG[4], E. N. ZAABOUT[1], F. ST-PIERRE[1,5];

Abstract: Genetically Encoded Voltage Indicators (GEVIs) are emerging tools for non-invasive monitoring of voltage dynamics in genetically defined cell types. GEVIs promise to enable a wide range of applications from detecting changes in the membrane potential of subcellular compartments to monitoring large scale neuronal activity *in vivo*. However, current sensors suffer from low sensitivity to changes in membrane potential and are relatively dim, limiting our

ability to image smaller transients and voltage dynamics in deeper layers of the cortex. Finally, poor photostability of previously reported GEVIs means these sensors can only be used to image continuously for a few minutes and thus cannot be used to measure neuronal activity during many standard behavioral paradigms. Here, we report novel GEVIs optimized for long-term *in vivo* imaging under two-photon illumination, a method of choice for deep-tissue imaging. Our starting point was JEDI (see separate poster from Xiaoyu Lu et al.), a sensor based on the ASAP family of sensors in which a voltage-sensitive domain (VSD) is coupled to an extracellular circularly permuted GFP (cpGFP). Using a high-throughput screening platform, we screen variants with mutations in the cpGFP and the VSD, including junction points between these two domains. Using this platform, we identified a next-generation GEVI named Jellyfish-derived Electricity-reporting Designer Indicators 2 (JEDI2). JEDI2 shows significant improvements in brightness and response amplitude as compared with our first-generation sensor, JEDI. We anticipate this sensor will facilitate more robust high-throughput and real-time neural recording over longer time-spans, thus advancing our understanding of neuronal processing in health and disease.

Abstract: Understanding brain development and neuronal disease progression requires imaging over hours, weeks, or even months. Fluorescent proteins (FPs) are commonly used to study these processes by reporting changes in cellular morphology, gene expression, or protein localization. However, the low brightness and photostability of many FPs limit the duration or temporal resolution of longitudinal studies. Therefore, it is imperative to engineer brighter and more photostable FPs. The traditional approach for FP engineering is to use directed evolution in *Escherichia coli*. This process is tedious and low throughput. Furthermore, the performance improvements of FPs developed in bacteria and characterized *in vitro* may not necessarily apply when expressed in neurons. To address these issues, we developed SPOTlight, an imaging-based single-cell platform for screening both brightness and photostability in eukaryotic cells. SPOTlight can screen millions of cells immobilized in a culture dish and retrieve the desirable variants by *in situ* optical tagging. We have fully automated the screening process using only commercially available software and hardware, allowing easy implementation and dissemination of the platform. Furthermore, the platform supports the versatile nature of microscope-based screening as it can work with different cell types: bacteria, yeast, mammalian cells, and organoids. We successfully utilized the platform to screen millions of yellow FP (YFP) variants for improved brightness and photostability. Using SPOTlight, we engineered a new YFP variant, mGold2, that is around ten times more photostable than commonly used YFPs such as mVenus. We anticipate broad adaption of mGold2 as a visualization probe for longitudinal studies. We also believe that SPOTlight will be rapidly adapted for a wide range of applications for retrieving rare cells based on spatial or temporal phenotypes.

Title: High-density, Micro-contact Stereo-EEG Array for Submillimeter Monitoring of Epileptic Activity

Authors: *I. RACHINSKIY[1], C. CHIANG[1], C. WANG[1], M. TRUMPIS[1], S. DURAIVEL[1], K. BARTH[1], W. LU[1], S. R. SINHA[2], D. G. SOUTHWELL[3], G. B. COGAN[4], J. VIVENTI[1];

[1]Biomed. Engin., [2]Neurol., [3]Neurosurg. and Neurobio., [4]Dept. of Neurosurg., Duke Univ., Durham, NC

Abstract: Epilepsy surgery can be an effective treatment against refractory epilepsy, which occurs in 30% of epilepsy cases is resistant to pharmaceutical treatments. However, surgical resection halts seizures only in about 60% of cases. Due to the low level of successful outcomes and severity of the procedure, epilepsy surgery remains underused. Surgical outcomes are governed by the ability to locate and completely remove the seizure onset zone (SOZ). Stereo-EEG (SEEG) is a common pre-surgical brain mapping procedure used to locate the SOZ and eloquent cortex by temporarily implanting depth electrodes and recording ictal and inter-ictal activity. Pre-surgical mapping governs resection location and extent, but is often imprecise due to large electrode size and sparse electrode density. This can lead to incomplete removal of epileptic tissue and therefore continuation of seizures. To enhance pre-surgical mapping techniques and improve surgical outcomes, we have designed a hybrid SEEG electrode array with both cylindrical macro (2.4x1.3mm size, 5mm pitch) and round micro (200µm size, 500µm pitch) contacts along the shank. The electrode arrays were fabricated in the Shared Materials Instrumentation Facility using a standard lithographic process on thin film liquid crystal polymer substrate and rolled into a cylindrical shape that mimics the dimensions and form-factors of standard SEEG electrodes. Macro contacts mimic current SEEG devices while micro contacts provide higher density sampling and smaller contact size, enabling collection of rich neural signals with higher spatial resolution and improved sensitivity to high frequency activity, including high-frequency oscillations and micro-seizures. Additionally, having electrodes in a 3-dimensional configuration around the shank could help in localizing signal sources, as compared to standard cylindrical electrodes. Electrode impedances at 1kHz were 1kΩ and 20kΩ for the macro and micro electrodes respectively. We tested the rolled devices in a rat model, recording evoked activity over the auditory cortex while presenting sound stimuli. The electrodes showed ability to decode stimulus tones on the auditory cortex at an accuracy of 69% (8% chance) in the high-gamma (HG) power envelope (70-150Hz). Meanwhile, standard SEEG recordings in patients had far lower signal to noise ratio in the higher frequency bands than micro-electrodes, 2dB and 12dB respectively. This novel electrode design could improve SOZ mapping and surgical outcomes. *Parts of the technology described are patent pending: "Electroencephalography (EEG) Electrode Arrays and Related methods of Use" U.S. Patent App. #PCT/US2020/051400.*

Title: Design and simulation of an actively multiplexed 2500 channel micro-electrocorticography (μECoG) array

Authors: *G. SHULL[1], T. JOCHUM[1], C. CHIANG[1], J. C. MORIZIO[2], J. VIVENTI[1];
[1]Biomed. Engin., [2]Electrical and Computer Engin., Duke Univ., Durham, NC

Abstract: High-density, micro-electrocorticography (μECoG) provides the ability to resolve fine features of local field potentials (LFPs) from the surface of the brain. These signals have been used to decode motor intention in brain computer interfaces (BCIs), and to control an exoskeleton in a patient with paraplegia. Additionally, μECoG can record multi-unit activity from the cortex if the electrodes are sufficiently small (<~1000 μm^2). However, creating small dense arrays limits the number of channels and recording area due to constraints imposed by connectors and individually wired electrodes and thus limits the performance of μECoG-based BCIs.Active μECoG arrays have significant potential to address this limitation using transistor-based time division multiplexing (TDM). TDM is implemented by adding a switch transistor to each recording site to allow multiple channels to share the same output, effectively increasing the number of recording channels without increasing the number of output wires. This enables high-density recordings without compromising the recording area. A significant limitation of TDM based active μECoG is the additional noise (~50 μV rms in 0.1 - 10KHz) caused by 1) TDM-based aliased thermal noise, 2) fabrication-based defects due to university clean room processing, and 3) transistor-based noise. The present work sought to design a 2500 channel μEcoG array with 50 μm pitch electrodes to address these challenges by adding filters, an amplifier, and a buffer before the multiplexing switch transistor at each electrode recording site. To accomplish this, we leveraged recent developments in commercial complementary-metal-oxide-semiconductor (CMOS) foundry fabrication combined with post-fabrication processing to create flexible electronics. This lowered noise from fabrication defects, while our design of a novel amplifier lowered noise due to aliasing and minimized transistor noise. Using simulations, we iterated through various amplifier architectures and achieved input-referred noise values of 10 μV rms in in the band 0.3 - 200 Hz, 11 μV rms in 300 - 3000 Hz. The amplifier gain was 40 dB, bandwidth 0.3 - 10 KHz, and 0.8 μW/channel power consumption. We will next fabricate the design and perform in vitro and in vivo testing. This electrode array will expand the capabilities of μECoG by enabling recording from the cortex with low noise, high resolution, and broad coverage.

Abstract: Epilepsy affects over 65 million people, but anti-seizure medications alone fail to control seizures in ~30% of cases. Two alternative treatment options are surgical removal of seizure-generating brain tissue or implantation of a responsive neurostimulator. The success of either treatment depends on accurate identification of the seizure onset zone (SOZ), or the area of brain from which seizures are generated. However, precise SOZ localization is limited by a mismatch between the fine micro-scale electrophysiology of epilepsy and the coarse spatial scale of clinical recording arrays. Specifically, long-standing research from penetrating micro-electrode arrays (MEAs) has demonstrated that epileptic signals initiate in confined brain areas of less than $1mm^2$ (Schevon, et al. 2008). Past research has also demonstrated a relationship between the SOZ and interictal events recorded in the local field potential (LFP), such as high-frequency oscillations (HFOs, 80-500 Hz) (Staba, et al. 2014). However, the micro-scale spatiotemporal dynamics of HFOs in the epileptic brain are not well understood. We have sought to determine the spatial scale of HFOs in human epilepsy and evaluate how micro-scale recordings of epileptic tissue may provide a more robust picture of HFO activity. We used novel micro-electrocorticography (μECoG) arrays made of a flexible liquid crystal polymer thin film

(LCP-TF) substrate to record intraoperatively from human subjects with epilepsy undergoing resective surgery (Chiang, et al. 2021). Our µECoG arrays have between 244 - 512 recording sites with coverage between 16 mm^2 - 1560 mm^2, thus offering both high resolution recordings while maintaining spatial coverage comparable to standard clinical ECoG grids. We successfully identified HFOs in our µECoG recordings using an automated detection algorithm along with automated and visual artifact rejection. We found that the rate of HFOs varies between recording sites, with specific regions of elevated HFO activity. Through analysis of signal covariance between HFO events and surrounding activity, we found a majority of HFOs occurred on single channels. For those events occurring on multiple channels, the average spatial extent of the HFOs fell between 0.8 - 6.8 mm, which was variable between subjects. Our results indicate that HFOs occur in micro-domains and that micro-scale recordings of HFOs may offer a more accurate tool for SOZ localization and improved epilepsy treatment. Parts of the technology described here are patent pending under "Electroencephalography (EEG) Electrode Arrays and Related Methods of Use" U.S. Patent Application # PCT/US2020/051400.

Abstract: Previous work on speech decoding using cortical signals demonstrated that the human sensorimotor cortex encodes kinematic properties of speech motor articulation (Chartier *et al.*, 2018). Effective decoding of these features combine to form elemental phonemic sounds which can be used to develop speech prostheses using electrocorticography (ECoG). Standard clinical ECoG, however, is limited by low spatial resolution (4 - 10 mm) and this limitation is evident from studies that estimate distinctive neural signals at resolutions below 4 mm (Muller *et al*., 2016). This suggests a need for higher density neural recordings to enable more robust speech decoding for neural prostheses. In this study, we demonstrated that high-density micro-ECoG (µECoG) electrodes can decode spoken speech. We recorded cortical signals using a 128 channel array (11 x 21 mm coverage, 1.33 mm electrode spacing) placed on the sensorimotor cortex of two Parkinsonian patients during awake DBS implantation. The subjects repeated a set of auditorily presented single-and bi-syllabic non-words. Our recordings revealed a significant increase in high gamma power (HG: 70-150 Hz) compared to baseline in at least 110 out of 128 channels for both subjects. We identified that HG signal to noise ratio is significantly higher in µECoG (5 dB) electrodes compared to standard ECoG and SEEG (2.5 dB). To decode individual speech sounds, we constructed a linear model using HG power for each phoneme position in the non-word. Results demonstrate above-chance decoding performance in predicting phonemes across syllabic positions for both subjects (S1: 48.7 ± 9%, S2: 55.98 ± 6.2%; chance: 11.11%), and significantly higher decoding compared to standard ECoG (29.21 ± 4.3%). Further, we observed that the model's decoding error is predominated by confusing phonemes that use similar articulators. These neural activation patterns also demonstrate spatial clustering patterns for articulators, revealing high-resolution phonetic feature cortical maps. In the time domain, we created a moving-window decoding model which shows that the peak decoding ability was sequentially dependent on syllabic-positional encoding of phonemes. Subsequently, using these sequential activations, we created a recurrent-neural-net phoneme sequence generator that can simultaneously generate phonemes with an average decoding accuracy of 46.3% and 50% (chance = 11.11%) for the first and second subjects respectively. Overall, we show the importance of high-resolution cortical sampling using µECoG electrodes for effective speech prosthetic technologies.

Title: High-performance, Conformable, Stencil Fabricated Graphene µ-ECoG Arrays

Authors: *J. HU[1], R. HOSSAIN[1], Z. NAVABI[1], A. TILLERY[2], S. KODANDARAMAIAH[1]; [1]Mechanical Engin., The Univ. of Minnesota, Twin Cities, Minneapolis, MN; [2]Bioengineering, Univ. of Maryland, Col. Park, College Park, MD

Abstract: Minimally invasive, flexible, electrocorticography (ECoG) arrays have the ability to monitor surface field potentials across large areas of the cortical surface and have revealed key insights on how neuronal activity distributed across multiple brain regions mediating behavior. However, ECoG devices are commonly fabricated using microfabrication techniques in a cleanroom environment, which greatly hinders the accessibility and cost-effectiveness of the device to the neuroscience labs lacking the facilities and skills. We have developed a fully desktop-fabricated stencil-based ECoG sensor. A customize synthesized Cyrene-graphene ink was deposited on a flexible 50 µm thick PI film using a laser-cut stencil to pattern the electrodes, which was subsequently encapsulated by spin-coated PDMS for insulation and protection. Using this procedure, we achieved 16-channel flexible ECoG sensors with inter-electrode pitch of 450µm and individual electrode/tissue interface area of diameter 200 µm. We performed benchtop tests to evaluate the ECoG sensor's electrical performance. A corrosion test on a 16-channel ECoG sensor was conducted in 65°C saline for 15 days where the impedances of all the 16 channels reduced at least by an order of magnitude from its initial values on day 1. Electrode impedances at 1000 Hz were measured in saline prior to implantation indicated average impedances of 64.05±58.5 KΩ (n=4 devices, 48 working channels) with a maximum impedance of 161.61 KΩ. The devices were chronically implanted for up to 72 days on 4 wild-type mice C57/BL6 mice with all devices having 16 functioning channels measuring average impedances of 73.50±49.113 KΩ post-implantation. Presentation of whisker stimulus in awake mice resulted in robust activation of electrodes in the contralateral hemisphere. The electrodes had an average signal-to-noise-ratio (SNR) of 3.08±0.80 when measuring sensory stimulus-evoked activity. The simple desktop fabrication methodology can be easily deployed in everyday neuroscience laboratories to create and use these high-performance flexible graphene ECoG electrode arrays.

Title: The mechanisms of plasticity following ischemic stroke and cortical stimulation in non-human primates

Authors: *J. ZHOU[1], K. KHATEEB[1], Z. IP[1], A. YAZDAN-SHAHMORAD[2];
[1]Bioengineering, [2]Bioengineering and Electrical Engin., Univ. of Washington, Seattle, WA

Abstract: Brain plasticity has been widely observed during behavioral tasks and functional recovery after damage. As a result, brain stimulation protocols can be designed to take advantage of this natural plasticity and serve as a potential therapy for various disorders. In particular, ischemic stroke is a major cause of brain injury that results in lifelong disability. Although past works in rodents have demonstrated protective effects and neuroplasticity induced by stimulation following stroke, few of these results have been replicated in humans due to the huge anatomical differences between rodent and human brains and a limited understanding of the underlying plasticity mechanisms. Therefore, we combined electrophysiology and immunohistochemistry to study the mechanisms of neuroplasticity following cortical ischemic stroke and electrical stimulation in non-human primates (NHPs). To produce controlled focal lesions, we used the photothrombotic method on the cortical surface to cause targeted vasculature damage. In two adult Rhesus Macaques, we generated an ipsilateral lesion in the sensorimotor cortex while collecting electrocorticography (ECoG) signals bilaterally. In another two animals, we followed the same lesioning procedures and applied repeated electrical stimulation via an ECoG electrode 8 mm away from the lesion center. We assessed the neural activity changes within the sensorimotor cortex as quantified by ECoG signal power. In addition, we performed histological analysis that consists of Nissl staining with thionin and immunostaining with antibodies against NeuN and two common plasticity markers, postsynaptic density-95 (PSD-95) and growth-associated protein-43 (GAP-43). Our ECoG signals showed decreased power at the lesioned site and reduced power at all sites post-stimulation. Given that Nissl staining revealed a smaller lesion volume following stimulation, this suggests that stimulation may exert a neuroprotective effect by reducing energy consumption. In addition, we observed strong immunoreactivity of PSD-95 and GAP-43 outside the lesion boundary. We will quantify the expression of these two markers in all animals by the number and size of immunoreactive puncta within the sensorimotor cortex using confocal microscopy to study the level of stimulation-induced plasticity. These results will shed light on the mechanisms governing neuroplasticity following injury and subsequent stimulation in NHPs. With the similarity between NHP and human brains, it paves the path for developing effective stimulation-based therapy for stroke rehabilitation in clinical studies.

Title: Electrical stimulation evoked neuronal activation patterns after chronic cortical microelectrode implantation

Authors: *G. WU, K. SOLARANA, D. X. HAMMER, M. YE;
CDRH/OSEL/DBP, U.S. Food and Drug Admin., Silver Spring, MD

Abstract: Multiple neuromodulation devices have gained FDA-approval for treating a spectrum of neurological and psychiatric disorders in the past decade. These devices deliver electrical stimulation below the safety threshold level determined by animal and computational studies on macroelectrodes, for example, a threshold charge density of 30 $\mu C/cm^2$. Novel technology allows fabrication of multi-channel microelectrodes with geometric surface areas (GSA) much less than 2000 μm^2. The safe level of electrical stimulation from these electrodes must be re-evaluated before their therapeutic effects can be investigated in human clinical trials. In this study, we chronically implanted 16-channel microelectrode arrays (GSA of 177 μm^2 per individual electrode) in the motor/somatosensory cortices of transgenic mice (Thy1-GCaMP6s), and used a combination of optical coherence tomography, two-photon calcium imaging, and extracellular recording to evaluate the stimulation effect for activating layer 2/3 neurons. Monopolar stimulation was delivered at various levels of charge/phase, with cathodic-first biphasic currents, at 50 Hz. This multimodal approach allowed us to examine the relationship between stimulation levels and the activity patterns of neurons proximal or distal to the stimulation electrode. Three patterns of neuronal activation were observed, sustained calcium signals throughout the stimulation period, transient calcium activity at the initiation of stimulation, and rebound neuronal activity after the termination of the stimulation. Our results showed a reduction in the electrical threshold to evoke calcium activity from 7 days post-implantation to 21 days post-implantation. In addition, neurons distal to the electrode appeared more responsive to electrical stimulation compared to neurons in the proximal field. It suggests that the neurons near the electrodes remain suppressed or damaged from the penetrating electrodes or by very low stimulation. Further study is needed to investigate whether neurons distal to the electrodes are activated directly by the stimulation electrical field, or indirectly via collateral axons of neurons near the electrode. Our result indicates that the change of neurostimulation threshold needs to be scrutinized during and after the early recovery phase to avoid overstimulation and excitotoxicity.

Title: A user-friendly, universal closed-loop phase-locked stimulation controller based on oscillatory episodes in the LFP

Authors: *J. DITTERICH;
Univ. of California, Davis, CA

Abstract: Synchronized oscillatory activity has been proposed to play important roles in modulating functional connectivity between populations of neurons and in memory storage/retrieval processes. Testing these hypotheses requires techniques that allow manipulation of the timing relationship between neural activity in different brain areas. Closed-loop phase-locked stimulation is such a technique. We have recently published a user-friendly, universal, robust algorithm for the detection of oscillatory activity in the LFP and prediction of its phase. Oscillatory episodes are detected based on analyzing the short-time power spectrum. An adjustable zero-phase bandpass filter in combination with the Hilbert transform are used for phase estimation. Linear extrapolation based on a Bayesian frequency estimate is used for phase prediction. Here we present a real-time implementation of this algorithm on an embedded device, which serves as a user-friendly, universal, standalone closed-loop phase-locked stimulation controller. The device is provided with an analog LFP signal, which is sampled at 1 kHz, and outputs a digital control signal for gating a stimulator. It can therefore be used with virtually any recording system and any stimulator. The algorithm was optimized for real-time implementation by performing the bandpass filtering in the frequency domain instead of the time domain, which reduces the number of required spectral transformations, and by replacing one of the time-consuming robust linear regressions with a standard linear regression after artifact rejection, which did not impact the overall detection and prediction performance. The embedded device features an FPGA, which is used for the time-critical input and output operations as well as a coprocessor for the spectral transformations, and a dual-core ARM processor running a real-time Linux operating system, which handles the remaining aspects of the algorithm and the user interface. Only a few milliseconds are needed between retrieving the last LFP sample of an analysis window and scheduling the time intervals, when the stimulator will be activated. The only primary parameters that have to be specified by the user are the range of frequencies, within which oscillations are to be tracked, and the phase range, during which the stimulator should be active. Other parameters, like frequency-dependent detection thresholds for the presence of

oscillatory activity and filter parameters, are adjusted automatically by the algorithm, which makes the device easy to use.

Title: Intermittent access to sucrose for rat pups: the short and longer-term effects

Authors: *G. SENTHINATHAN[1], R. EIKELBOOM[2];
[1]SUNY Buffalo State, Buffalo, NY; [2]Wilfrid Laurier Univ., Waterloo, ON, Canada

Abstract: Availability can have profound influence on the consumption of foods and drinks. The 2-phase intermittent-continuous protocol (ICP) examines sucrose solution intake in two groups of rats and finds intermittent access (24h out of every 72h) significantly increases intake (Eikelboom & Hewitt, 2016). In Phase I, groups receive intermittent or continuous access to a 4% sucrose solution, and with adults this results in a long-term elevation (a doubling) in the intermittent group. In Phase II the groups are shifted to a common alternate-day sucrose schedule and the difference is maintained. Adult rats given 16% sucrose in Phase I do not differ in consumption, but in Phase II with 4% sucrose, an unexpressed elevation in the intermittent rats becomes evident. Other work suggested that pups do not show the ICP associated intake elevation (Senthinathan & Eikelboom, 2013). In four parallel experiments using the ICP, male Sprague-Dawley pups were randomly assigned to every day (ED) or every third day (E3D) access to sucrose in Phase I for 16 days (22-37 days of age). In Exp. 1 the groups were given 4% sucrose in Phase I, and in subsequent experiments the groups were given 16% sucrose in Phase I. In all experiments, rats were given alternate-day access to 4% sucrose in Phase II (starting at 39 days old). No consumption differences were evident in Phase I with either 4 or 16% solutions. In Exp. 1 no differences between groups were evident in Phase II but in Exp. 2 & 3 the intermittent rats showed a gradual elevation in consumption in mid to late adolescence relative to the continuous rats even though both groups were now on the same alternate day schedule. In Exp. 4, pups were tested with the ICP and 16% in Phase I, followed by a 10-day gap without sucrose for some groups (+Gap groups) between Phase I-II to examine the robustness of developing sucrose intake differences. A robust sucrose intake difference slowly emerged in Phase II, with the gap itself inducing an additional elevation in consumption (an elation effect) that was independent of the intermittent vs. continuous difference. Sucrose availability with more concentrated solutions, while not showing an immediate difference, can have a profound delayed

influence on pups as the potentially maladaptive effects of intermittent sucrose access remains latent until later in life.

Title: Effects of Consumption of a Western Diet and Physical Exercise Before and During Pregnancy in Adult Female CD1 Mice.

Authors: *S. ROSALES-HERRERA[1], M. ORTIZ VALLADARES[2], R. PEDRAZA-MEDINA[2], J. GUZMÁN-MUÑIZ[2], N. MOY-LÓPEZ[2];
[2]Lab. de neurociencias, [1]Univ. de Colima, Colima, Mexico

Abstract: One of the main health problems in the world is obesity, it defines itself as an increase in fat and is characterized by unleashing effects that can be harmful to health. There are factors that influence this pathology, among those, genetic and environment factors. Gestation is a vulnerable period for habit modification that can affect the mother and offspring's health. This precise period demands great physical and psychological changes, which together with social demands can affect optimal development during this stage, exposing various pathologies including obesity. The World Health Organization mentioned that in the world more than 650 million adults between 18 and older ages are obese individuals. Recent scientific research shows that some of the causes of this suffering are related to lifestyle modifications, these involve bad dieting life habits and low or even non-existing physical activity; therefore, focusing the attention on these styles can be the key not only to solve the problem but to prevent it. Know the effects of western diet (WD) and physical exercise (PE) before and during adult female CD-1 mice gestation. Four groups of females were established and classified as follows: Group 1 WD with PE, Group 2 WD without PE, Group 3 Balanced diet (BD) with PE, and Group 4 BD without PE. The PE consisted of 1 hour on a treadmill at a speed of 10m / min, from Monday to Friday, 4 weeks before gestation, then during the first two weeks of gestation. The WD administration started from gestation day 1 (G1) until postnatal day 7 (PN7). We made a weekly record of weight and a daily record of food and drink (water) consumption before and during pregnancy. The results showed that the PE during pregnancy helps to prevent excessive gain when accompanied by a DB, however, speaking of a WD, there is a trend of weight gain compared to those females that had a DB without PE. The WD + PE mothers had a higher weight compared to the other groups; however, this may be due to the increase in muscle mass from physical activity rather than from the effect of diet alone. On the other hand, it was

observed that PE does not modify the intake of a DB during pregnancy, but it does increase the consumption of WD. Regarding caloric consumption with WD, it was higher regardless of whether he does PE. In turn, a decrease in water consumption was observed in mothers with WD, as it was a food with higher humidity compared to regular food. A BD in conjunction with PE becomes important for the prevention of excessive weight gain, thus contributing to metabolic disorders that may be detrimental to health in the future. Optimal health before and during gestation also ensures the physical and mental development of the offspring.

Title: Adolescent High Fat Diet Exposure Influences Microglial Activation in the Frontal Cortex

Authors: *A. B. DAVIS, K. R. LLOYD, T. M. REYES;
Pharmacol. & Systems Physiol., Univ. of Cincinnati, Cincinnati, OH

Abstract: Both obesity and high fat diets (HFD) have been associated with an increase in pro-inflammatory gene expression within the brain. Microglia play an important role in early brain development and may be responsive to HFD. We hypothesized that HFD during adolescence would increase proinflammatory microglial gene expression at baseline, and potentiate the response to an immune challenge (lipopolysaccharide (LPS), IP). From 3-7 weeks of age, male and female mice were fed standard chow (SC) (20% energy from fat) or HFD (60% energy from fat). One hour before sacrifice, mice were randomly assigned to either LPS or saline. Microglia were extracted using a Percoll density gradient and fluorescence-activated cell sorting (FACS) from the frontal cortex of the brain, and pro-inflammatory gene expression was examined. Results will be discussed in the context for early life high fat diet to affect brain development through functional changes in microglia.

Title: Ethanol-induced conditioned taste aversion and neural activation in adult male rats following adolescent intermittent ethanol exposure

Authors: *J. K. GORE-LANGTON, L. P. SPEAR, E. I. VARLINSKAYA, D. F. WERNER; Psychology, Binghamton Univ., Binghamton, NY

Abstract: Alcohol use is common during adolescence, with binge drinking being the most prevalent pattern of drinking at this age. Adolescent intermittent ethanol (AIE) exposure is a frequently used rodent model of human adolescent binge drinking. One consequence of AIE exposure is reduced sensitivity to the aversive effects of ethanol (EtOH) in adulthood commonly assessed using a conditioned taste aversion (CTA) paradigm. The present study was designed to determine if AIE exposure [4 g/kg, intragastrically, every other day, from postnatal day (P) P25 to P45) in male c-Fos LacZ+ transgenic Sprague-Dawley rats would result in attenuated EtOH-induced CTA and alter neuronal activation in CTA-processing brain regions in adulthood relative to water-exposed controls. On P70, animals were given 1h access to a novel solution (0.9% NaCl) in a new cage, followed immediately by an intraperitoneal injection of a single dose of EtOH (20%) (0, 1.5, or 2.5 g/kg). Testing for EtOH-induced CTA occurred on P70 when animals were again given 1h access to the NaCl solution. with brains collected immediately after the test for ß-galactosidase (proxy for c-Fos) quantification in CTA-associated regions of interest (ROIs) including the prelimbic cortex (PrL), infralimbic cortex (IL), dorsal and ventral subdivisions of the agranular insula (AID and AIV), nucleus accumbens core (NAcC), basolateral and central amygdala (BLA and CeA). AIE attenuated EtOH-induced CTA, with AIE males only developing CTA at the 2.5 g/kg EtOH dose and water-exposed controls demonstrating CTA at both EtOH doses. In general, neural activation of the ROIs did not differ as a function of adolescent exposure, with significant decreases of ß-gal expression relative to saline controls evident in the IL of animals conditioned with 1.5 or 2.5 g/kg ethanol as well as in the AIV of rats conditioned with the 2.5 g/kg EtOH dose. The linear regression analyses showed that intake of the NaCl on test day was a significant predictor of ß-gal expression in almost all ROIs. Functional connectivity was assessed via Pearson bivariate correlations (pairwise comparisons of ß-gal+ cell counts in each ROI). Water-exposed controls had significant connections between the AIV, PrL, IL, and NAcC that were not evident in AIE exposed rats. AIE exposure may reduce functional connectivity between brain regions implicated in aversion, with this reduced functional connectivity contributing to relative insensitivity of AIE exposed males to EtOH-induced CTA.

Title: Cognitive impairments induced by chronic delta-9-tetrahydrocannabinol exposure during adolescence are prevented by concomitant N-acetylcysteine supplementation

Authors: *H. J. SZKUDLAREK, K. B. WIECZERZAK, R. S. MANN, T. C. UZUNESER, M. DE FELICE, S. SUSANNE, B. L. ALLMAN, S. R. LAVIOLETTE;
Univ. of Western Ontario, London, ON, Canada

Abstract: Cannabis use during critical developmental periods in adolescence can cause long-lasting cognitive impairments and schizophrenia-like symptoms that extend into adulthood. Previous research has demonstrated that chronic delta-9-tetrahydrocannabinol (THC) treatment during adolescence causes pronounced deficits in memory tasks and sensorimotor gating and persistent anxiety symptoms in adulthood. Moreover, changes in intracellular signaling pathways and disruptions in neuronal communication manifesting as increased VTA dopaminergic activity, excessive neuronal firing and abnormal high frequency oscillatory patterns in the prefrontal cortex (PFC) are also observed. As more jurisdictions move towards full legalization of cannabis there is an increased need for developing effective prevention strategies against these deleterious side-effects. Multiple studies point to the role of oxidative stress in the pathophysiology of schizophrenia and antioxidant treatments have proven to be effective in preventing the development of cognitive symptoms in multiple animal models of psychosis. In the present study we explored the potential efficacy of antioxidant treatment in preventing deteriorating effects of adolescent THC treatment on cognitive function in rats, using N-Acetylcysteine (NAC). Adolescent male Sprague Dawley rats (Postnatal day (PND) 35-45) were given twice daily intraperitoneal infusion of either Veh or THC (PND35-37: 2.5 mg/kg; PND38-41: 5mg/kg; PND42-45: 10mg/kg) and a subset of animals from each group received NAC treatment in drinking water (900mg/L; PND35-65). Behavioral and electrophysiological procedures commenced at adulthood (starting at PND75). We demonstrate that rats with adolescent THC treatment displayed significantly reduced recognition memory scores in object recognition tests, have impaired reversal memory and deficits in paired-pulse startle responses. Moreover, electrophysiological recordings in freely moving animals showed that the rats that underwent adolescent treatment with THC displayed increased power of gamma oscillations accompanied with decreased power of delta oscillations in the PFC. Interestingly, NAC

treatment fully prevented THC-induced behavioral impairments and was able to rescue abnormal delta and gamma cortical oscillation patterns. These data suggest that adolescent THC treatment might increase oxidative stress and that dietary antioxidant supplementation may be a safe and effective strategy in preventing pathophysiological changes associated with aberrant adult PFC function following chronic adolescent cannabis exposure.

Title: Sex-specific effects of late adolescent morphine exposure on adult thermal nociception

Authors: *J. R. BOURGEOIS[1], A. M. KOPEC[2];
[1]The Ctr. for Neuropharm. and Neurosci., [2]Neurosci. & Exptl. Therapeut., Albany Med. Col., Albany, NY

Abstract: While often studied in the context of reward circuitry, the nucleus accumbens (NAc) also plays an important role in nociceptive processing. Microglial-mediated refinement of synaptic circuitry in the NAc during adolescence is a necessary component of healthy neurodevelopment, and sex differences in the timing of NAc synaptic pruning have been documented. The opioid morphine can directly activate microglia, and thus may lead to abnormal microglia-mediated neural and behavioral development. We hypothesized that exposure to morphine during sex-dependent critical periods of NAc synaptic development would lead to sex-specific changes in analgesic response to morphine in adulthood. To test this, we treated male and female rats with morphine or saline during late adolescence (P55-59), a time period in which female, but not male, microglial activity is high in the NAc. We subsequently performed a thermal gradient test to determine their preference between a cold zone (10° C), a hot zone (47° C), and an ambient zone in adulthood. No change in baseline temperature preference was observed in either sex following late adolescent morphine exposure. However, an acute 1.5 mg/kg morphine injection resulted in an aversion to the cold zone in the late adolescent morphine-treated female, but not male, rats. Neither adolescent treatment nor sex affected mechanosensation. Together, these data suggest that modality-specific nociceptive circuit refinement is occurring in a sex-dependent manner in late adolescent rats. We are now determining whether morphine alters microglial signaling in the NAc to cause female-specific nociceptive responding in adulthood.

Title: Ethanol-induced neuronal activation in adolescent rats: Impact of age, sex, and prior history of ethanol exposure

Authors: *H. J. COLEMAN[1], T. T. TOWNER[1], K. M. PAPASTRAT[3], S. VILLARREAL[1], E. I. VARLINSKAYA[1], D. F. WERNER[2];
[1]Psychology, [2]Psychology and Behavioral Neurosci., Binghamton Univ., Binghamton, NY;
[3]Univ. of Maryland Sch. of Med., Matyland, MD

Abstract: Adolescence is characterized by a gradual maturation of the brain and is a period when alcohol use is often initiated. Adolescents drink more per occasion than adults, often in the form of binge drinking. Adults with a history of heavy alcohol use in adolescence tend to exhibit deficits in cognitive control. Similar alterations have been reported in rodent models of adolescent intermittent ethanol (AIE) exposure, with some sex-specific effects of AIE recently being identified. AIE exposure also alters sensitivity to ethanol in adulthood, blunting ethanol-induced activation of the medial prefrontal cortex (mPFC) indexed via c-Fos expression. However, c-Fos expression in the PFC during AIE as well as at different adolescent periods has not been investigated. The present study was designed to assess patterns of neuronal activation of the prelimbic (PRL) and infralimbic (IL) regions of the mPFC in adolescent male and female rats in response to ethanol. Experimental subjects male and female transgenic cFos-LacZ rats were acutely challenged with either 0 (water) or 4 g/kg ethanol given via intragastric gavage (IG) on postnatal day (P) 25 or P45. In addition, P45 rats with a previous history of AIE (10 prior exposures to 0 or 4 g/kg ethanol given IG every other day from P25) were included as a chronic exposure condition. As a marker for neuronal activation, we measured β-galactosidase (β-gal) which is a proxy for c-Fos expression. In general, β-gal expression was not affected by ethanol challenge, with a significantly higher number of β-gal+ cells seen following both acute water and ethanol IG administration relative to home cage controls. In females, but not males, activation of the PRL significantly increased with age. In males, however, activation of the IL by water and ethanol was evident in P45, but not P25 adolescents. Activation of the IL in females did not differ as a function of age, with both ages demonstrating significant increases in β-gal expression following IG water and ethanol relative to home cage controls. Chronic exposure to both water

and ethanol blunted β-gal expression in the PRL, but not IL, of males when compared to P45 ethanol-naïve subjects, with this effect evident in both PrL and IL of females. These data suggest that the PRL and IL cortices undergo changes throughout the adolescent period that may differ between males and females, implicating both age and sex in responding of these regions to manipulation rather than ethanol. Further examination of subcortical brain regions that mature earlier in adolescence is needed to better identify acute and chronic effects of ethanol during adolescence.

Title: Prefrontal cortical development over adolescence in mouse

Authors: *K. MASTRO[1,3,4], W. WANG[4], B. A. STEVENS[2,3,5], B. L. SABATINI[4,5];
[2]Harvard Med. Sch. Neurobio., [1]Boston Children's Hosp., Boston, MA; [3]Broad Inst., Cambridge, MA; [4]Neurobio., Harvard Med. Sch. Dept. of Neurobio., Boston, MA; [5]HHMI, Chevy Chase, MD

Abstract: Adolescence, the transition from juvenile to adulthood, is a developmental period marked by a prolonged structural change in brain circuits that coincides with an increase in cognitive capacity, sensory seeking, and risk-seeking behaviors. Concurrent with these behavioral changes is the neurodevelopment across prefrontal cortex (PFC). From humans to monkeys to rodents, there is evidence for changes across the adolescent window in prefrontal cortical structure, connectivity, and function. While inroads have been made to understand the developmental mechanisms that drive PFC maturation and how the PFC contributes to an array of cognitive tasks, *the connection between the PFC's developmental changes and its impact on circuit dynamics remain unclear*. To understand how risk genes for psychiatric disease and environment shape this developmental trajectory, we must first establish what is neurotypical. Here, we employ a range of anatomic and electrophysiological techniques to map changes PFC inputs in mice. To track the development of excitatory synapses, we performed slice electrophysiology and recorded miniature excitatory postsynaptic currents across weeks of postnatal development. We found that the frequency and amplitude of these excitatory events

undergo a prolonged change until reaching their stable state in adulthood. To understand how this change in excitatory inputs may impact local circuitry, we used electrical stimulation to measure the direct monosynaptic and feedforward inhibition that pyramidal neurons receive at various stages of development. These results revealed a systematic shift in the organization of prefrontal cortex that far extends the traditional window of adolescence. Moreover, we found that the major source of inhibition, parvalbumin-positive (PV) interneurons underwent a delayed and opposite maturation of their synaptic inputs. These data were supported by optogenetic assisted mapping of two major sources of inputs, cortico-cortical and thalamocortical inputs. In addition to the inputs, we assess changes in excitability that parallel the changes in local and long-range circuitry. Together, these results provide a detailed timeline of how the PFC mature across the full adolescent window and provide the baseline for perturbations to genes and environment.

Title: Sensitive period for emergence of contextual fear memory persistence in developing mice

Authors: *A. L. LANJEWAR[1], K. L. EAGLESON[2], P. LEVITT[3];
[1]Pediatrics, Univ. of Southern California, CHLA, Los Angeles, CA; [2]Pediatrics, CHLA, Keck Sch. of Med. of USC, Los Angeles, CA; [3]Children's Hosp. Los Angeles, Los Angeles, CA

Abstract: Sensitive periods are times of heightened plasticity, in which developing circuits have optimal opportunity to undergo experience-based refinement that ultimately shape long-term brain function. In contrast to sensory systems, the timing and cellular and molecular regulators for cognitive sensitive periods remain poorly understood. Here, we first focused on determining the age of onset of contextual fear memory persistence capabilities, a cognitive function defined as the ability to retain a fear memory for at least 7 days, in C57Bl/6J male and female mice. Two groups of mice were conditioned in a fear chamber. The ‘shock’ group received a series of foot shocks during a single session, while the ‘no shock’ group, which were littermate controls, received no foot shocks but were in the chamber for the matched amount of time. Seven days

later, mice were returned to the same chamber for testing, at which time freeze responses were recorded over a five-minute interval. The onset of contextual fear memory persistence was considered the earliest age of conditioning that produced a freezing response on testing day in 'shock' mice that was significantly different from 'no shock' mice. We demonstrated that contextual fear memory persistence emerges rapidly during the fourth postnatal week, with no sex differences in age of onset. A separate cohort of mice further show that from the age of onset, these memories last for at least 30 days, indicating the ability to form remote memories. With the onset of contextual fear memory persistence determined, we next addressed potential molecular mechanisms underlying the emergence of this behavior. Previous studies have shown that the temporally regulated receptor tyrosine kinase MET (MET) modulates the pace of synapse maturation and that extending the normal temporal window of MET expression shifts the timing of critical period plasticity for ocular dominance in the visual cortex. To determine if MET plays a similar role in regulating the timing of the emergence of contextual fear memory persistence, *Met* expression was sustained past its normal window of peak expression through expression of a transgene. There was, however, no shift in the onset of contextual fear memory persistence in these mice compared to control genotypes. In conclusion, we have defined precisely the onset of contextual fear memory persistence in C56BL/6J mice and demonstrate that a decline in MET signaling is not necessary for the emergence of this cognitive function. The age of onset of contextual fear memory persistence can be used in future studies to test other candidate regulators that may be responsible for the temporal emergence of this cognitive capability.

Title: A two-hit model of early immune activation in rats reveals sex-dependent alterations in anxiety and sociability behaviors

Authors: *L. K. DAVIS[1], K. SANCHEZ[2], M. BELL[3], L. K. FONKEN[2], A. C. GORE[2]; [1]Univ. of Texas at Austin Dept. of Neurosci., Austin, TX; [2]Div. of Pharmacol. and Toxicology, [3]Univ. of Texas at Austin, Austin, TX

Abstract: Early life represents a time of significant change and growth in many neurological processes; therefore, environmental stressors during this critical period may result in lasting

perturbations in neurological function. We coupled two environmental challenges: the endocrine-disrupting chemical (EDC), polychlorinated biphenyl (PCB), and lipopolysaccharide (LPS), to explore the long-term effects of environmental stressors given during critical periods of development. Rats were exposed to daily PCBs during early perinatal development (embryonic day (E) 8 through postnatal day (P) 4), followed by a single LPS hit prior to puberty on P24. Upon reaching adulthood, rats underwent a battery of affective and social behavioral testing prior to tissue collection for immunohistochemistry and gene expression analyses. We report here that perinatal PCB exposure increased anxiety-like behavior in the elevated plus maze, as measured by increased time spent in the closed arms. A later hit of LPS enhanced these anxiogenic effects. Male rats given PCBs and LPS showed similar anxiety-like behavior in the light dark box, though this effect was not seen in females. Sociability appeared to be bidirectionally affected by EDCs: males exposed to PCBs showed mild enhancement in social preference during the three-chambered sociability test, while females given PCBs showed decreased preference for a same-sex stimulus rat during the same test. Though PCBs alone did not affect social investigation behavior during the juvenile social exploration test, the additional hit of LPS resulted in diminished investigation behavior, although only in males. This is one of the first studies to explore how EDCs may prime the neuroimmune system to a later immune challenge, and our findings are in line with other two hit models of immune activation. Our results lend evidence to the idea that females may be more resilient to early life stressors that may contribute to the appearance of neurodevelopmental disorders such as Autism Spectrum Disorder, a disorder that disproportionately affects men. Future research aims to examine how this two-hit model alters microglial morphology and activation in the hippocampus and prefrontal cortex.

Title: Effects of two PDE10A inhibitors on alcohol self-administration and striatal gene expression in naïve and post-dependent rats

Authors: *L. B. BERTOTTO[1], D. LAMPSON-STIXRUD[1,2], A. SINHA[1,3], E. SAKOULAS[1,3], E. P. ZORRILLA[1];

Abstract: Alcohol use disorder (AUD) is a chronic, relapsing disorder that afflicts 29% of Americans in their lifetime, can be disabling and increases mortality. New drug targets and neurobiological insight for AUD are needed. Compulsive drinking putatively involves a relative underactivity of indirect pathway medium spiny neurons (iMSNs) that subserve adaptive behavioral selection vs. overactive direct pathway MSNs (dMSNs) that drive drinking behaviors. Compulsive drinking also putatively involves a shift to dorsal (caudate-putamen) from ventromedial (nucleus accumbens) striatal control of ethanol-related behavior. We hypothesized that decreasing the activity of phosphodiesterase 10A (PDE10A), an enzyme differentially expressed in striatal MSNs, reduces compulsive drinking. To test our hypothesis, we studied ethanol post-dependent male and female adult Wistar rats in operant fixed-ratio self-administration of ethanol vs. water after 1-hr pretreatment with either MR1916 or AMG579 (i.p., 0, 0.4, 0.2, 0.1 and 0.05 μmol/kg) (n = 10/drug/sex), two PDE10A inhibitors, in a within-subject manner. To avoid nonspecific motor effects, a bar test was performed to identify the minimum dose of each compound that elicits cataleptic-like behavior; doses below that were used for the self-administration studies. In separate rats, we investigated the expression of pathway marker and immediate-early genes of interest (*Pde10a, Drd1, Drd2, Adora2a, Penk, Pdyn, Tac1, Egr1, Fos, Fosb*) in the caudate-putamen and nucleus accumbens of ethanol-naïve and post-dependent, chronic intermittent ethanol vapor-exposed rats (n = 12/sex and 18/drug/sex, respectively). Preliminary results show that equimole doses of AMG579 elicit a stronger state of catalepsy in female compared to male rats. Additionally, MR1916 dose-dependently reduced self-administration of alcohol by post-dependent male rats in relation to whether they were high (>0.6 g/kg) vs. low drinker rats. Collectively, our study sheds light on the neurobiological role of PDE10A in distinct striatal circuits on post-dependent drinking behaviors as well as the potential impact of novel translatable PDE10A inhibitors to treat AUD.

Title: Trapping insular cortex ensembles in a mouse operant self-administration model of loss of control eating

Authors: *G. MACEDO[1], S. BAGSIC[1], A. KREISLER[1], B. HUI[2], J. HUANG[2], C. WILLIAMS[2], E. ZORRILLA[1];
[1]Scripps Res. Inst., San Diego, CA; [2]UCSD- Univ. of California, San Diego, CA

Abstract: Loss of control (LOC) eating, the sense of being unable to control one's intake, is a hallmark of binge eating disorders. Many models of binge-like eating have been developed that study overeating within a brief time; however, less work has examined the substrate underlying loss of control, modeled as eating compulsively persisting despite adverse consequences or incorrect outcomes. The anterior insular cortex (AIC) subserves visceral-emotional functions, including taste processing, and is implicated in drug craving and relapse. The AIC sends inputs to the nucleus accumbens core (AcbC), which subserves reward and reinforcement. AIC-AcbC projections have been implicated in compulsive-like drinking in a model of alcohol addiction and in compulsive-like food self-administration in our model of binge eating. Previous data in our laboratory showed that rats with intermittent access to a preferred palatable (P) food developed increased PR breakpoints and footshock punishment-resistant FR food self-administration, validating this as a model of compulsive consumption. Here, we have adapted this model to C57BL/6J mice and are applying it for neuronal activity-dependent analysis. Male and female mice were allowed to acquire fixed-ratio (FR1, FR2, FR3 and finally FR5) 5TUM chow self-administration over 2 weeks via nosepoke responses in daily sessions at dark onset. Matched for weight, daily chow intake, and baseline FR5 self-administration, mice then were assigned to 1 of 3 groups: *ad lib* chow (C), *ad-lib* Palatable food (P; high-sucrose, chocolate flavored 5TUL)), 3) or intermittent Palatable (INT) mice that received 24 hr access to P on 3 non-consecutive days each week (Monday, Wednesday, Friday), with chow otherwise available. All mice received operant self-administration sessions at dark onset on access days. Over subsequent weeks, INT mice developed cycling food intake and body weight in relation to the availability of P food, reduced latencies to respond for food, increased FR5 self-administration, increased PR breakpoints, and increased responding during extinction, as compared to *ad lib* fed controls. Now, we are using neuronal activity-dependent ribosomal profiling in H2B-TRAP mice to identify AIC ensembles that are activated by binge eating in INT mice that developed substantially increased PR breakpoints. The results inform the role of intermittent access in the etiology and modeling of behavioral LOC for translational studies. Molecular identification of LOC-associated AIC ensembles may identify novel targets and will enable future causal study of specific cell types via combinatorial genetic approaches.

Title: Identified peptidergic neurons arise after metamorphosis in the nudibranch mollusc, Berghia stephanieae

Authors: A. SHEEHAN[1], C. A. WHITESEL[2], M. D. RAMIREZ[1], D. C. LYONS[2], *P. S. KATZ[3];
[1]Biol., Univ. Massachusetts Amherst, Amherst, MA; [2]Scripps Inst. of Oceanograph, Univ. of California San Diego, San Diego, CA; [3]Neurosci. and Behavior Program, Univ. of Massachusetts Amherst, Amherst, MA

Abstract: Gastropod molluscs play important roles in neuroscience research because they have large individually identifiable neurons. However, the developmental origins of identified neurons are not known. The nudibranch, *Berghia stephanieae*, is easily raised in the lab, allowing developmental studies to be performed. We observed the development of central ganglia from four larval stages, through metamorphosis, and six juvenile stages using immunohistochemical labeling for small cardioactive peptide (SCP) co-stained with DAPI to determine how the central ganglia grow and add peptidergic neurons. We found that the ganglia formed during the early veliger larval stage. When first detected, the ring ganglia, which consist of the cerebral, pleural, and pedal ganglia, had about 130 neurons. By the first juvenile stage (10 days post-oviposition, DPO), the number of cells increased to about 620. Over the course of juvenile development, the number of neurons continued to increase and some neuronal somata began to increase in size. The first neurons exhibiting SCP-like immunoreactivity appeared in the periphery before gangliogenesis. The first SCP-immunoreactive (SCP-ir) neurons in the ganglia were only on the left side in the early veliger stage. The number of SCP-ir neurons increased from about 10 at the veliger stage to 47 in the early juvenile. This increased further to 62 by juvenile stage 5. The rhinophore ganglia first appeared at metamorphosis and were innervated by a pair of SCP-ir neurons that were also present in the adult. Thus, this identified neuron could be traced to the metamorphic transition. Many SCP-ir neurons appeared between juvenile stages 2 and 3, with the majority of the neurons that were identifiable by soma size and position present by stage 4.

While most SCP-ir neurons appeared early in development, the relative size and position of these cells continued to change through stage 5. The later juvenile stages (4-6) corresponded to the fastest rate of ganglionic growth. Careful analysis of cell counts and patterns throughout development revealed that many identifiable SCP-ir neurons formed before juvenile stage 4 and a notable pair could be traced back to the metamorphic transition. Elucidating the birth of identifiable neurons in the gastropod central nervous system can provide insights into the formation of distinct neuronal circuits seen in the adult and allow for comparisons between species that have homologous identified neurons.

Abstract: The cellular substrate of developmental learning is thought to be ‘synaptic pruning’, the idea being that neurons in baby brains establish and receive numerous connections, and over development, connections are pruned, as influenced by experience. This sculpting occurs without significant addition or removal of neurons or birth of new neurons, suggesting that developmental learning is mediated primarily by experience dependent refinements of neuronal connections at large scale. Surprisingly, despite its seeming importance, large gaps remain in our understanding and appreciation of synaptic pruning. To address this gap, we used serial electron microscopy (‘connectomics’) to investigate pruning in the primary visual cortex (V1) in the neonatal and adult brains of both mouse and rhesus macaque, two well-defined model systems of neuroscience. To our surprise, we find that the mouse shows little evidence of net synapse loss over developmental life. We are now investigating the primate to determine whether synaptic pruning over development is a species-specific phenomenon.

Title: Developmental expression of CRF receptors and binding protein in the chicken telencephalon

Authors: *A. H. METWALLI, A. PROSS, *A. ABELLAN, L. MEDINA;
Univ. of Lleida - IRBLLEIDA, Lleida, Spain

Abstract: Stress is a protective mechanism for animal adaptation to internal or external stressors, which aim is to prepare the body to challenging physiological and/or environmental conditions. Upon a stressful event, three major responses are activated: autonomic, endocrine and behavioral responses. The hypothalamus plays an essential role in control of both the autonomic nervous system and the endocrine system by way of the hypothalamo-pituitary-adrenal axis (HPA). Hypothalamic function is in turn regulated by several telencephalic structures, among which the amygdala and the hippocampus play critical roles. In mammals, neurons expressing corticotropin-releasing factor (CRF) play a major role in regulating the stress response, but very little is known on CRF pathways in chicken. Knowledge on the expression of receptors throughout development can help to identify brain areas playing a role in the stress response, and can provide insights into neural pathways behind the aversive effects of early-life stress. In this project we focused on the developmental expression of evolutionarily conserved CRF receptors and binding protein. We performed chromogenic *in situ hybridization* in chicken embryonic brains (E8-E18) and hatchlings (P0) for the CRF receptors 1 (CRF-R1) and 2 (CRF-R2), and CRF-binding protein (CRF-BP). Our results demonstrate that, from early stages (E8), CRF-R1 and CRF-R2 are moderate- to highly expressed in many parts of the pallium, as follows: CRF-R1 expression is high in the hippocampus, most subdivisions of the dorsal ventricular ridge, and septohippocampal area, and moderate in the piriform cortex (among other areas); CRF-R2 expression is high in the hippocampus, mesopallium and nucleus basorostralis of nidopallium. In contrast, at E8 CRF receptors show low or negligible expression in the subpallium. At this age, CRF-BP, which buffers extracellular CRF and weakens transmission, is only present in the developing striatum. These general expression patterns remain similar or show small modifications during subsequent stages. For example, at E18 receptors expression in the hippocampus decreases a bit or becomes restricted to specific subdivisions, while they are observed in parts of the central extended amygdala (peri-intrapeduncular island field and oval central nucleus). However, at P0, expression of CRF receptors and binding protein is mostly

negligible in the lateral bed nucleus of the stria terminalis. Overall, our findings suggest that, untill P0, telencephalic CRF transmission occurs mainly in the pallium and open the venue to further studying the role of CRF receptors in the stress response throughout development in chicken.

Title: Fluctuating brain asymmetry: A tool for studying the evolutionary developmental ecology (Evo-Devo) of early trauma, maltreatment, and neglect

Authors: *S. B. SERAPHIN;
Neurosci. Program, Trinity Col., Hartford, CT

Abstract: Studies of human neuroanatomy have advanced from the pseudoscience of phrenology, to the localization of functions with ablation research, and recently culminated in studies of brain wiring or the “connectome”. Future innovations in brain science depend on some departure from the typical laser focus on disease models, and the adoption of holistic approaches for understanding the individual variation in brain anatomy and function that emerge from complex gene-environment interactions or epigenetic processes. In this regard, an emphasis on evolutionary developmental ecology (Evo-Devo) has the potential to integrate cross-species comparisons of neuroanatomy with studies of developmental plasticity. For example, fluctuating brain and body asymmetries have been linked to developmental instability, such as adverse childhood experiences. Using sample data from the published literature, including the new analysis of cortical surface area, volume and thickness data from a well characterized sample of 202 maltreated and 131 control human magnetic resonance imaging (MRI) subjects, I will explore how the evolutionary biological concept of fluctuating asymmetry can be used to describe the brain footprint of early life. It will be argued that together, tractography, measures of hemispheric asymmetry and qualitative ethnographic methods can be used to capture the heterogenous outcomes of the environmentally-specific developmental responses to early trauma, maltreatment and neglect.

Abstract: A brain atlas serves as a key spatial framework to co-localize structural and functional data and examine different neuronal and non-neuronal cell types across brain regions. For the adult mouse brain, the Allen Common Coordinate Framework (CCF) with 3D anatomical labels currently serves as the standard atlas resource with which to map and integrate results from different studies. In contrast, only 2D atlases based on histological sections are currently available for the developing mouse brain, significantly limiting our understanding of the spatial and temporal development of cellular architecture of the brain. Further, the lack of developmental CCFs significantly hinders progress on cell type mapping of the developing mouse brain by limiting the reproducibility and integration of data from different studies. To address this deficiency, we are working to generate developmental CCFs with associated ontology and undistorted 3D anatomical labels in key embryonic and postnatal ages. Here, we present our ongoing progress to create atlases at postnatal day (P)14 and 56. We first used Magnetic Resonance Imaging (MRI) to acquire ex vivo in skull distortion-free images of C57BL/6 mice at target ages. Then, we computed a morphological and intensity average of 10 brain samples (5 male, 5 female) at each developmental age to create a population-averaged symmetric MRI template brain. Independently, we used tissue clearing and 3D histological labeling methods combined with light sheet fluorescent microscopy (LSFM) imaging to acquire high-resolution histology images of additional brain samples. We co-registered LSFM images to the MRI templates to create multimodal atlas templates. Simultaneously, we imported existing 2D anatomical labels from the Allen Developing Mouse Brain Atlas into our new template. Using these labels to define the ontology, we are manually creating true 3D anatomical labels for the CCFs based on high-resolution LSFM data that is co-registered to undistorted MRI. Once complete, our developmental CCFs will enable a broad field of scientists to leverage modern brain mapping technologies more effectively in studying the developing mouse brain.

Introduction: During the last decades, scientific and technological advances in neonatology have allowed the survival of children up to 23 weeks of gestational age with various health problems that impact their brain development. The volumes generated from different brain structures by magnetic resonance imaging have become an indispensable tool to detect neurodevelopmental abnormalities [1,2,3]. The knowledge of an abnormal volume in brain tissues gives us the possibility to detect diseases such as seizures, dementia, multiple sclerosis, aneurysms, cancer or stroke. [4,5].
Methodology: 5 neonates with hypoxia were studied to obtain 3D-T1 images using a 3 T SIEMENS Skyra with a TR= 2200ms, TE=2.45 ms. Volumes were analyzed in the neuroimaging data analysis software (FreeSurfer) of different brain structures. Results: The difference in volume between the structures of both groups was obtained hypoxia vs [5] healthy. The structures with significant differences between both groups were: caudate lobe (0.11±1.45), putamen (0.068±1.6), pallidum (0.62±4.92), hippocampus (0.48±1.2), and amygdala (0.513±3.47) cm3.
Conclusion: According to the results obtained in the studies, the structural regions of the left hemisphere appear more asymmetric, which can be attributed to the hypoxia suffered by neonates in the studies analyzed in this work. The comparison of the volumes allows us to know exactly the affected brain areas, and the subsequent evolution of neurodevelopment, which is a

very useful tool to guide subsequent therapeutic interventions in a focused way and improve the final results.

Title: Developmental shifts in tau splicing regulate interaction with 14-3-3 β

Authors: *R. BETTERS[1], A. GOTTSCHALK[1], K. FIOCK[1], M. SMALLEY[1], E. LUHMANN[2], L. RADOSHEVICH[2], M. HEFTI[1];
[1]Pathology, [2]Microbiology and Immunol., Univ. of Iowa, Iowa City, IA

Abstract: Alzheimer’s disease (AD) and other dementias are the leading cause of disability in older individuals, the prevalence of which has more than doubled in the last thirty years. Although recent AD clinical trials suggest that early or presymptomatic treatment with beta-amyloid targeted therapies may be effective in limiting disease progression, the tau protein is thought to be the primary mediator of neurodegeneration in the later stages of disease. Our preliminary data shows that tau is extensively phosphorylated in both AD and, interestingly, the developing human brain. During development, this phosphorylation does not appear to have any adverse effects. We therefore sought to identify mechanisms for the resilience of the fetal brain to tau toxicity. We first used co-immunoprecipitation (Co-IP) with bead-linked anti-tau antibodies followed by liquid chromatography-tandem mass spectrometry (LC-MS^2) to identify

differences between the tau interactome in human fetal and AD brain tissue obtained from the Iowa NeuroBank or the NIH NeuroBioBank. Spectra were identified using standard reverse-decoy technique in MaxQuant and differential expression analysis was done using Perseus. We found that tau interaction with 14-3-3 proteins β, γ and η were significantly upregulated in AD compared to the fetal brain. Expression of these proteins does not vary during development or in AD in publicly available proteomic or transcriptomic data sets, suggesting that the difference in tau interaction is driven by other factors. We followed up on our results in human tissue by validating this interaction in HEK 293T cells by conducting a FLAG-tagged 14-3-3 β Co-IP in the presence of either 4R or 3R tau**.** We found that 14-3-3 β interacts exclusively with the longer (4R) tau isoform, and that this interaction is largely unaffected by the phosphorylation state of the tau protein. We reversed the Co-IP in our HEK system through the pulldown of tau, which similarly showed 14-3-3 β binding activity with 4R tau but not 3R tau. Our findings identify a novel interaction between tau and 14-3-3 β at least partially dependent on the inclusion of the second microtubule repeat domain, potentially altering the conformation of tau's two 14-3-3 binding sites and therefore the kinetics of their interaction. We have shown that this additional repeat is only present in the adult brain, suggesting that the presence of 4R tau may be necessary but not sufficient for tau toxicity in both mixed isoform (AD) and 4R (CBD, PSP) tauopathies, and may explain the relative rarity of 3R tauopathies such as Pick's disease.

Title: Extracellular tau oligomers cause nuclear deformation in neurons

Authors: *X. SUN, G. S. BLOOM;
Univ. of Virginia, Charlottesville, VA

Abstract: Neuronal nuclei are normally quasi-spherical. In Alzheimer's disease (AD) and other tauopathies, though, this structure is interrupted by deep invaginations of the nuclear lamina, a meshwork of intermediate filaments on the inner face of the inner nuclear membrane. The lamina is involved in numerous nuclear activities including chromatin organization, nucleocytoplasmic

trafficking of macromolecules, cell cycle regulation, and apoptosis. However, little is known regarding to the mechanism leading to lamina structure disruption and its pathological consequences in AD. Previous work showed that expression of pathogenically mutated human tau in *Drosophila* neurons causes nuclear lamina invagination (Frost, et al. 2016, *Current Biology*, 26; 129-136). To shed further light on the mechanism, we tested the hypothesis that it could be induced in mammalian neurons by extracellular tau oligomers, which are known to be crucial factors in AD pathogenesis. We used primary mouse neuron cultures exposed to extracellular oligomers of human 2N4R tau. Wild type neurons had lamina invagination within 30 minutes of exposure to tau oligomers, as revealed by immunostaining for lamin B1, a major subunit protein of nuclear lamina. This effect of tau oligomers was found to depend on intracellular tau, because nuclear lamina invaginations were not detected in neurons derived from tau knockout mice, unless they expressed tau by lentiviral transduction. Taken together these results raise the possibility that extracellular tau oligomers trigger nuclear deformation in AD and other tauopathies by a mechanism dependent on intracellular tau. Moreover, the results add to the currently short list of known cell biological effects of extracellular tau oligomers on neurons.

Title: Brain-specific transmembrane transport receptor 2 is a novel modulator in tauopathies

Authors: *H. LIU[1,2], C. CHEN[1,2], *N. WANG[1,2], X. YANG[1,2], S. SU[1,2], C. RASTEGAR[1,2], S. KOTHA[1,2], V. L. DAWSON[1,2], T. M. DAWSON[1,2], X. MAO[1,2];

Abstract: In Alzheimer's disease (AD), the hyperphosphorylation of tau (p-tau) and fibrillar tau inclusions are the major components that lead to the filamentous tau aggregation. This abnormal tau aggregation is the characteristic neuropathological hallmark of tauopathies in AD. At present there is no cure or prevention of the disease pathology, and currently there are no effective therapeutic strategies that directly target tauopathies to rescue the abnormalities and memory deficit. Recent understanding of the disease mechanism leads us to focus in developing new drugs towards slowing down the progression of AD by prevention of abnormal accumulation of p-tau and the clearance of aggregated tau fibrils in the neuron. In our current strategy, we initially employed an in-vitro system to perform a high-throughput screening to determine the specific receptors that bind tau aggregates, and we determined the binding efficiency of these

receptors. During this preliminary screening we over-expressed the receptors in the SH-SY5Y cells with biotin labeled tau aggregates to determine receptor binding. In the study, we found that Brain-specific transmembrane transport receptor 2 (BTTR2) had high binding efficiency to the tau aggregates. We also verified the novel role of BTTR2 in mediating the internalization of tau aggregates in neurons using specific BTTR2 antibodies. The aim of the current study is to explore the role of BTTR2 in the mouse model of AD. BTTR2 knockout ($BTTR2^{(-/-)}$) mice show dementia at 6 months of age, so we choose different time-points to evaluate the functional rescue of tau related abnormalities. Our result shows that there is significant increase in the tau phosphorylation in $BTTR2^{(-/-)}$ mice compared with their littermates. The injection of AAV9-CBA-eGFP-2a-P301Ltau caused increased cell-to-cell transmission of tau and tau phosphorylation in $BTTR2^{(-/-)}$ mice. Altogether, our data strongly support that BTTR2 has a critical role in regulating tauopathy. Considering the downregulation of BTTR2 in aged mice, the upregulation of BTTR2 is becoming a promising way to rescue hyperphosphorylation of tau and further abnormal aggregation in AD.

Title: Domain requirements and mechanisms of axonal Tau sorting

Authors: *M. BELL, S. BACHMANN, J. KLIMEK, H. BREUER, H. ZEMPEL;
Inst. of Human Genet., Univ. Hosp. Cologne, Cologne, Germany

Abstract: In Alzheimer’s disease (AD) and related tauopathies, somatodendritic missorting of the axonal Tau protein is a major pathological hallmark. Previous work suggest a critical role for the axon initial segment (AIS) in maintaining polarized Tau distribution. However, the exact mechanisms of AIS-mediated Tau trafficking, i.e. AIS-specific interaction partners and necessary Tau domains or motifs are not fully understood.We perform sorting analysis using a Tau construct library, EB3-based live-cell imaging and leading-edge proximity labelling techniques in three different neuronal cell models (hiPSC-derived neurons, primary rodent neurons, SH-SY5Y-derived neurons) to elucidate the interplay between Tau and AIS

components during the process of axonal Tau sorting.First results revealed the insufficiency of the Tau N-terminal half to target the axonal compartment. More detailed analyses will help to pinpoint Tau domains or motifs that are necessary and sufficient for Tau sorting.Further, successful Tau sorting in SH-SY5Y-derived neurons question the previously reported importance of Ankyrin-G (ANKG) and tripartite motif-containing protein 46 (TRIM-46) for i) axonal Tau enrichment and ii) microtubule orientation at the AIS. For performing the recently developed TurboID proximity labelling, we will introduce fusion constructs of Tau and the promiscuous biotin ligase BirA into hiPSC-derived neurons via lentiviral delivery. This will enable us to unravel the Tau interactome domain- and sorting-dependent by using truncated or modified Tau in the first step, and conduct compartment- and even AIS-specific Tau interaction studies in the future. Gaining these data would not only improve the understanding of axonal Tau enrichment in healthy neurons, but it would help to understand the detrimental cascades that underlie pathological Tau missorting in AD and other tauopathies.

Title: Resistance to Alzheimer's pathology is associated to a decrease in tau seeding activity and pro-inflammatory response

Authors: *N. JURY GARFE[1], Y. YOU[1], J. REDDING[2], H. KARAHAN[1], A. LEE-GOSSELIN[1], J. KIM[1], J. TRONCOSO[2], C. LASAGNA-REEVES[1];

Abstract: The neuropathologic hallmarks of Alzheimer disease (AD) are Aβ-amyloid deposits, neurofibrillary tangles (NFTs) and the degeneration of vulnerable neurons and their synapses. Asymptomatic AD (AsymAD) is described as the status of subjects with preserved cognition assessed but with identifiable AD pathology at autopsy. Currently there is no clear understanding of the mechanisms involved in this resistance to AD pathology nor even a detail characterization of these AsymAD cases. Therefore, the detail analysis of these cases might prove a significant knowledge to human resilience for AD. Considering that decreased inflammatory response and

the tau pathology seems to be uncoupled from neuron death in AsymAD compared to typical demented AD, we conducted a detailed histological and biochemical analysis using postmortem brain samples from age-matched control, demented AD and AsymAD subjects. Our analysis identified lower levels of phospho-tau species and seeding activity in AsymAD compare to AD. Using subcellular fractionation, we found accumulation of seed-competent tau predominantly in cytosolic compartment in AsymAD samples, while in AD cases the distribution in cytosolic and synaptic fractions was similar. Biochemical measurements revealed differences in total and cytosolic Aβ40 but not Aβ42 in AsymAD compared to AD cases, whereas in the synaptic fractions both Aβ42 and Aβ40 did not change. RNA expression analysis by Nanostring revealed a distinct neuroinflammatory response in AsymAD versus AD patients. Our data suggest that the main differences between non-demented individuals with high loads of AD's pathology and typical demented AD patients lies on the structural diversity of tau aggregates, its ability to reach the synapse and distinct neuroinflammatory response.

Title: Characterization of biologically active tau oligomeric species

Authors: *R. KAYED[1], U. SENGUPTA[2], F. LO CASCIO[2], N. PUNGUALMALI[2], M. MONTALBANO[2], N. BHATT[2], A. BITTAR[2], C. JEREZ[2];
[1]Univ. of Texas Med. Br., Galveston, TX; [2]UTMB, Galveston, TX

Abstract: Tauopathic neurodegenerative diseases, including Alzheimer's disease (AD), are characterized by the appearance of extracellular lesions composed of aggregated and post-translationally modified tau proteins. The resulting tau pathology is an established marker for differential disease diagnosis and staging, a surrogate marker for neurodegeneration, a potential vector for disease propagation, and a source of toxicity in biological models. In comparison to

the well-established methods for isolation/preparation and biochemical and structural characterization of stable tau filaments from tauopathy brain, the characterization of smaller and much dynamic oligomeric tau aggregates has not been investigated to the same degree. As a result, tau oligomers that may associate most closely with disease propagation and toxicity as suggested by a large body of research, are not fully established. Herein, we leverage our well-optimized brain-derived tau oligomers (BDTOs) from well-vetted human tauopathy cases of AD, progressive supranuclear palsy (PSP) and dementia with Lewy bodies (DLB). In addition to our rigorous biochemical characterization of the BDTOs by immunological probing, and structural characterization by proteolysis and microscopic analyses, we have optimized Fluorescent Amyloid Multi Emission Spectra (FLAMES) microscopy for cataloging and comparing tau conformational variants across a wide range of samples, from brain tissue sections and BDTOs to in vitro aggregated tau assemblies. For selective immunodetection of the BDTOs, we have used our novel four fully sequenced and epitope mapped Tau Oligomer Monoclonal Antibodies (TOMAs), which recognize non-continuous sequences on tau. Furthermore, the bioactivity of the BDTOs was assessed by evaluating their seeding propensity in biosensor cells and primary cortical neurons from tauopathy mice and their effects on synaptic function by electrophysiological studies. We observed that the BDTOs differed in their immunological properties, morphology, and sensibility/stability to proteolysis. The BDTOs were distinguished based on FLAMES spectral signature. Distinct seeding propensity and impairment of long-term potentiation (LTP) indicated their differences in bioactivity as well. Our thorough investigation/characterization of biologically active disease-relevant tau oligomers will provide new opportunities to diagnose and evaluate therapeutics beyond the current capabilities for AD and related tauopathies by developing specific tau aggregation inhibitors and/or diagnostic probes for pathological tau protein.

Title: Interferon-induced transmembrane protein 3 and Tau in Alzheimer’s Disease

Authors: *L. JONAS[1], Y. LI[2], G. FROST[2];
[1]Cornell University: Weill Cornell Med. Col., New York, NY; [2]Chem. Biol., Mem. Sloan-Kettering Cancer Ctr., New York, NY

Abstract: Interferon-induced transmembrane protein 3 and Tau in Alzheimer's Disease Lauren Jonas[1, 2], Georgia Frost[2], Yueming Li[1, 21]Weill Cornell Graduate School of Medical Sciences, Weill Cornell Medicine, New York, NY, 10021, USA, [2]Chemical Biology Program, Memorial Sloan-Kettering Cancer Center, New York, NY, 10021, USA,
Alzheimer's disease (AD) is a neurodegenerative disease characterized by extracellular amyloid plaques and intracellular hyperphosphorylated tau. Recent work highlights Interferon-induced transmembrane protein 3 (IFITM3), an innate immunity protein, as being a key contributor to amyloid-associated AD pathology. Upregulated in post-mortem AD patients and by AD-associated inflammatory cytokines, in vitro and *in vivo* work has shown IFITM3 to play a role in amyloid processing, as well as in the disease-associated immune response. While much remains to be understood on IFITM3's role in amyloid-related pathology, little is known of the relationship between IFITM3 and tau. Current behavioral and biochemical studies indicate that an IFITM3 deficit in the tau (PS19) mouse model contributes to preserved cognitive function, altered hyperphosphorylated tau deposition, and reduced neuronal degeneration. This project aims to elucidate the mechanism through which IFITM3 functions, as current studies highlight IFITM3's critical role in AD, as well as its potential as a novel target for pharmacological intervention.

Title: TDP-43 promotes pathological tau phosphorylation and selective neurodegeneration

Authors: *C. S. LATIMER[1], J. STAIR[2], C. D. KEENE[1], B. C. KRAEMER[2], N. F. LIACHKO[2];
[1]Lab. Med. and Pathology, Univ. of Washington, Seattle, WA; [2]Geriatrics Res. Educ. and Clin. Ctr., Veterans Affairs Puget Sound Hlth. Care Syst., Seattle, WA

Abstract: Although the neuropathology of Alzheimer's disease (AD) is classically defined by amyloid β (Aβ) and tau aggregates, accumulating evidence suggests that TDP-43 may also play an important role in AD pathophysiology. The presence of both AD and TDP-43 pathology at

autopsy is associated with more severe cognitive impairment and accelerated cognitive decline; however, the mechanisms underlying TDP-43 toxicity in AD are not currently known, necessitating models of combined pathology. The nematode *C. elegans* has been widely used to study amyloid, tau and TDP-43 proteotoxicity separately, and we have previously shown that co-expression of tau and TDP-43 in the same organism has synergistically deleterious effects. Recently we developed new low-expression models of combined Aβ and TDP-43 proteotoxicity (Aβ+TDP Tg-low) and tau and TDP-43 proteotoxicity (tau+TDP Tg-low) in *C. elegans* to further explore relationships between these pathologic peptides. Our results show that very low levels of TDP-43 are sufficient to enhance tau but not Aβ neurotoxicity, and that synergism between tau and TDP-43 is largely rescued by loss-of-function of the potent tau modifier *Suppressor of Tau Pathology 2 (sut-2)*. We also demonstrate progressive neuronal degeneration in a cell-type dependent manner, suggesting a degree of selective vulnerability to the combined effects of tau and TDP-43. Understanding TDP-43 and tau synergy *in vivo* is critical to ultimately treating mixed pathology AD. Ultimately this model will be useful for identifying additional genetic modifiers of mixed tau and TDP-43 neurotoxicity and aid in a deeper dissection of the biology underlying these phenotypes.

(HKUST), Kowloon, Hong Kong

Abstract: Oleanolic acid (OA), **1**, (**Fig. 1A**), is a pentacyclic triterpene natural product found abundantly in numerous edible and medicinal plants. Both OA and its derivatives are active against several diseases, including Alzheimer's disease (AD)[1]. Previously we have shown that OA benzyl carbamate, **2**, reduces production of Aβ peptides in an AD cell model through inhibiting γ-secretase cleavage of Amyloid precursor protein (APP) and rescues impairment of synaptic plasticity in double transgenic AD mice[2]. We have now tested several new analogs of compound **2**, including OA-(2-pyridine)methylamine carbamate, **3**, and OA-morpholine carbamate, **4** (**Fig. 1A**), using N2a695 mouse neuroblastoma cells expressing human APP or using 3D human neural cell culture assay[3]. The latter model carries familial AD mutations in APP and Presenilin 1 and induces robust extracellular Aβ deposition and high levels of pTau protein in soma and neurites. It provides a unique platform to test effects of a compound on both the Aβ pathology and tauopathy. Here, we report that most OA carbamates reduced production of Aβ peptides in N2a695 cells. Two compounds, **3**and **4**, also reduced Aβ levels and Tau phosphorylation in 3D assay (**Fig. 1B-D**).

Title: Tau-immunoreactive thorn-shaped astrocytes in brain neurodegeneration and aging

Authors: *A. T. HARRIS[1], L. B. SOLANO[1], J. M. WALKER[1], T. E. RICHARDSON[1], D. W. DICKSON[2], K. F. BIENIEK[1];

[2]Neuropathology and Microscopy Lab., Mayo Clin., Jacksonville, FL

Abstract: Aggregated microtubule associated protein tau in neurofibrillary tangles is a pathological hallmark of Alzheimer's disease (AD). In other tauopathies, such as corticobasal degeneration (CBD) and progressive supranuclear palsy (PSP), astrocytic tau inclusion bodies, astrocytic plaques (AP) and tufted astrocytes (TA), define pathognomonic lesions. New evidence suggests astrocytic tau pathology plays an important role in age-related neurodegeneration (like AD), demonstrated by the recent definition of aging-related tau astrogliopathy (ARTAG). Thorn-shaped astrocytes (TSA) found in ARTAG are also a prominent feature of chronic traumatic encephalopathy (CTE), a mixed tauopathy linked to repetitive head trauma. Understanding similarities and differences of TSA from traumatic and aging etiologies has important ramifications in elucidating disease pathogenesis in CTE and ARTAG. Our goals herein are two-fold: A) identify differences in astrocytic tau proteoforms between these disorders and B) evaluate astrocytic diversity to understand which astrocyte subpopulations are susceptible to developing pathology. To address these goals, immunohistochemistry was performed on postmortem human frontal cortex tissue of CTE (N=4), AD/ARTAG (N=4), PSP (N=2) and CBD (N=2) cases with antibodies against phosphorylated tau (AT8, AT180), N-terminal cleaved tau (C3), 3-repeat and 4-repeat tau (RD3, RD4), as well as astrocytic markers glial fibrillary acidic protein (GFAP), vimentin and complement 3. Color deconvolution digital pathology analysis was employed to quantitatively measure differences between AT8 and AT180. TSA in CTE and AD/ARTAG were negative for C3 and RD3, but positive with AT8, AT180 and RD4. Quantitative analysis revealed equal AT8:AT180 staining in TA and AP, but higher expression of AT8 vs. AT180 in gray matter TSA for both CTE ($p=0.0023$) and AD/ARTAG ($p=0.0006$) by Mann Whitney tests. Similar findings were observed for white matter TSA ($p<0.0001$) combining CTE and ARTAG cases. While astrocytic lesions across all diseases largely

demonstrated GFAP expression, complement 3 was variable between cases. Importantly, vimentin-positive astrocytes were pronounced in CBD and AD/ARTAG but typically absent in PSP and CTE. Gray matter TSA in CTE were rarely immunoreactive for vimentin, yet white matter TSA in ARTAG often exhibited vimentin positivity. Overall, results indicate that while tau proteoforms may be broadly comparable between CTE and ARTAG TSA, differences in astrocytic selective vulnerability could differentiate these pathologic entities. Future astrocytic cell profiling studies will provide further insight on these findings.

Title: Comparison of amyloid and tau pathology in the small and large intestines of individuals with Alzheimer’s disease, Parkinson’s disease, and Dementia with Lewy Bodies

Authors: *A. M. FLODEN[1], G. D. MANOCHA[2], N. I. FROLOV[1], A. E. LERICK[1], C. K. COMBS[1];

Abstract: Neurodegenerative diseases such as Alzheimer’s disease (AD), Parkinson’s disease (PD) and Dementia with Lewy Bodies (DLB) all present with protein aggregation histopathologies in the central nervous system. In particular, AD is characterized by accumulations of phosphorylated tau in the form of neurofibrillary tangles and Aβ peptide containing plaques. Since enteric neurons of the gastrointestinal system express tau and the amyloid precursor protein, we asked whether phosphorylated tau containing neurofibrillary tangles and Aβ aggregates were present in AD small and large intestines similar to brains. For comparison, we also assessed healthy controls and individuals with PD and DLB. Three male and three female samples were examined from healthy controls, AD, PD, or DLB donors that

ranged in age from 62-95 years. Samples from the mid temporal gyrus (MTG), duodenum, jejunum, ileum, and colon were immunostained for amyloid beta (Aβ) and phosphorylated tau. We employed a semi-quantitative analysis of the immunohistochemistry using a score that ranged from 0 (no staining) to 3 (frequent staining). The MTG served as a positive control for disease pathology. Myenteric and submucosal neurons in both sexes and all groups demonstrated intraneuronal Aβ immunoreactivity with no clear association with AD. However, there was no evidence of extracellular Aβ plaque-like aggregation in contrast to brains. Surprisingly, there was a clear overall increased immunoreactivity in the colons of all groups although there was no increase in AD versus the other groups. Phospho-tau immunoreactivity for p-Ser 199/202 using the AT8 antibody was notably absent from the intestines of all groups in contrast to brains. However, p-Ser 396/404 immunoreactivity, recognized by the PHF-1 antibody, demonstrated myenteric and submucosal staining in both sexes and all intestinal regions of all groups with no clear predominance in AD or one intestinal region versus another. These data indicate that the enteric nervous system appears to be unique from the central nervous system in AD with regard to accumulation of neurofibrillary tangles and amyloid plaques.

Abstract: Background: Neurofibrillary tangles (NFT) are a hallmark histopathological feature of Alzheimer’s disease and other neurodegenerative diseases. NFT undergo a morphological

progression that correlates with disease severity. Improved approaches for measurement and quantification of the evolution of NFT using machine learning would facilitate diagnosis and disease staging.
Methods: We deployed a novel method to analyze NFT morphometry by investigating the latent space of a generative adversarial network (GAN). We trained StyleGAN2 using 537,455 images of immunohistochemically-labeled NFT derived from 526 slides from post-mortem human hippocampal tissue from patients detected using a pre-trained model. Detection of semantically meaningful latent directions was also performed.
Results and Conclusions: Our GAN achieved an Fréchet inception distance score of 8.76. Qualitative assessment of generated NFTs showed the model captured a wide spectrum of NFT morphology. Analysis of the latent space revealed several meaningful latent directions that correlated to tau inclusion density, color, size, and neurite loss. We proposed that when combined, these directions can be used to stage neurofibrillary degeneration.

Title: Development of tau pathology in the aged rhesus macaque as compared to humans

Authors: *G. STONEBARGER[1,2], D. I. BROWN[3], R. L. WOLTJER[4], H. F. URBANSKI[1,2], S. G. KOHAMA[5];

Univ., Portland, OR; [5]ONPRC, Beaverton, OR

Abstract: During clinical aging, physiological microtubule-associated protein tau becomes hyperphosphorylated in the brain and forms pathological intracellular aggregates. These fibrillous protein structures accumulate in the cytoplasm to become pathological by forming

tangles, which are a hallmark in many neurodegenerative diseases including Alzheimer's disease (AD). While non-AD patients also develop phosphorylated tau (p-tau) tangles in old age, p-tau tangles are correlated with cognitive decline in mid- to late- stage tauopathies. In AD patients, tangles spread from transentorhinal regions to the limbic system, and finally to the isocortex; this system is widely accepted in the clinic as the primary method to determine the advancement of AD postmortem.The rhesus macaque is a widely used laboratory monkey due to its genetic, hormonal, social, and behavioral similarities to humans. Within the last half decade, p-tau tangles have been discovered to arise naturally in very aged rhesus macaques. Herein we used clinical staging in postmortem brains of extremely old rhesus macaques (range: 22.4 - 44.1 years). The entorhinal cortex, hippocampus, and prefrontal cortex were immunohistochemically stained for p-tau in order to encapsulate all three clinical stages and determine whether tauopathy in the rhesus macaque follows a typical spread pattern of AD tangles. Only the very oldest animals showed fully formed neurotoxic tangles, and the few monkeys to reach a tangle load likely sufficient to induce functional alterations were over the age of 39 years—well beyond the average and even previously cited maximum lifespans. This indicates that a primary factor in p-tau detection in this species is age. Most primate researchers do not have monkeys that live to the maximum lifespan, and therefore the phenomenon of natural p-tau was not historically documented. Further, neuronal tangle spread seems to follow an AD-like pattern, but is severely delayed relative to lifespan. However, glial p-tau is the primary tauopathy in this population. While glial tauopathy occurs in aging humans, it is not generally comorbid with AD, suggesting that rhesus macaques—like other nonhuman primates—have pathways to p-tau accumulation which differ from those in AD. These mechanisms may protect from overt dementia, as monkeys do not present with neurodegeneration and dementia, even in the oldest animals. However, deciphering these mechanisms in the monkey model could be key to establishing early clinical interventions into AD, and conversely, clinical data may inform how to best utilize the rhesus macaque model of brain aging to further the AD field.

Title: Exploring the mechanisms of pathological Tau on synaptic vulnerability in Primary Age Related Tauopathy (PART)

Authors: *S. KADAMANGUDI, M. MARCATTI, G. TAGLIALATELA;
Mitchell Ctr. for Neurodegenerative Dis., Univ. of Texas Med. Br., Galveston, TX

Abstract: In the pathogenesis of aging and dementia, many molecular events converge at synaptic damage or dysfunction. Recent studies demonstrate the detrimental effects of pathological Tau (particularly oligomeric Tau) on synaptic structure and function, thus necessitating further investigation of the mechanisms by which pathological Tau mediates cognitive dysfunction at the synaptic level. Primary Age Related Tauopathy (PART) is a diagnostic term that was coined recently to explain features of a dementia-related illness, characterized by pathological Tau in the absence of amyloid (Aβ) plaque burden. Further, post-mortem studies in PART patients demonstrate the localization of pathological Tau to the medial temporal lobe, avoiding infiltration of the neocortex. Probing the molecular mechanisms which underlie PART thus presents an ideal opportunity to understand the differential effects of Tau (excluding Aβ) on the synapse and study the mechanisms of synaptic resilience in the neocortex. To this end, we sought to compare the levels of (1) toxic oligomeric Tau (TauO) and (2) TauO synaptic binding events between the hippocampus (region with vulnerable synapses) vs. superior medial temporal cortex (SMT; region with resilient synapses). Synaptosomal tissue fractions of the hippocampus and SMT, prepared from 7 post-mortem patients with PART, were used to compare (1) levels of oligomeric Tau by way of Western Blot (Tau5 1^{o}Ab) and (2) number of synapses bound to ('exogenously derived') labeled TauO using size-gated flow cytometry (Guava®, easyCyte™). Results of the Western Blot and flow cytometry analyses revealed no significant difference between the hippocampus and SMT in the amount of toxic oligomeric tau ($p = 0.42$) and synaptic binding of TauO ($p = 0.77$) in PART patients ($n=7$). These results suggest the possibility that, in PART, TauO's cytotoxic effects may lie outside the synaptic interface (i.e. somatic, axonal, or dendritic) or the effects of molecular signaling events downstream of and independent of Tau synaptic binding. These findings should be considered within the context of their limitations, and warrant further investigation (including probes for different Tau isoforms, in different tissue preparations, and immunohistology) and provide a unique opportunity to study the effects of pathological Tau on both synaptic vulnerability and resilience within the brain of individual patients as seen in a singular tauopathy (i.e. PART).

Title: Evaluating the efficacy of young blood plasma as a treatment for alzheimer's disease in h-tau mouse models

Authors: *A. N. PERLBERG, K. A. PEDEMONTE, R. E. BARKEY, R. E. TAPP, J. M. FLINN;
George Mason Univ., Fairfax, VA

Abstract: Alzheimer's Disease (AD) is a progressive neurodegenerative disorder that is characterized by the development of tau tangles within neurons, resulting in impairments in cognition and memory. As increased levels of oxidative stress are seen early in the disease and could activate various pathways that result in further AD development, a measure of oxidative stress, superoxide dismutase (SOD), was chosen as the enzyme of interest. In order to counteract these impairments, four-month-old transgenic (Tg, 4510 hTau) and wildtype (Wt) mice were treated with either plasma or saline. Mice were injected with plasma drawn from young, healthy mice over the course of seven treatments. Saline injections acted as a control. To determine if these treatments were effective in reversing AD side effects in the transgenic mice, we performed western blot analysis (n = 4 for each group) to compare concentrations of SOD. Western blot analyses were run with an Oxidative Stress cocktail. Data was analyzed through a two-way ANOVA and analysis of the western blots identified that there were, surprisingly, not significant differences between concentrations of SOD within the brains of Tg mice treated with plasma and the brains of Tg mice treated with saline, as the AD mice did not appear to have existing significantly high measures of oxidative stress. However, plasma injections of the Wt mice showed a significant trend of reduction of SOD when compared to the Wt mice that received saline injections. While plasma injections into Tg mice did not appear to decrease measures of oxidative stress, plasma injections of Wt mice may indicate the potential to use plasma injections to reduce AD pathways and mitigate AD impairments.

Title: Young blood plasma treatment reduces neuronal loss and neuroinflammation in h-tau Alzheimer's type mice

Authors: *R. E. BARKEY[1], K. A. PEDEMONTE[2], A. N. PERLBERG[2], R. E. TAPP[2], J. M. FLINN[3];
[1]George Mason Univ., Centreville, VA; [3]Psychology, [2]George Mason Univ., Fairfax, VA

Abstract: This study examined the effects of young blood plasma treatment on inflammation, neuronal loss, and synaptic plasticity in human tau (h-tau) Alzheimer's disease (AD) type mice. AD is defined neurologically by the accumulation of tau tangles and amyloid plaques. AD is also associated with increased neuroinflammation, including chronic microglia and astrocyte activation, neuronal loss, and a down-regulation of synaptic plasticity. Injections of blood plasma from young mice have been shown to reduce the accumulation of neuroinflammation and increase synaptic plasticity and stability in transgenic (tg) AD type mice, as well as rescue behavioral deficits associated with brain pathology. Specifically, CREB and phosphorylated CREB are found to be lowered in AD. Previously, young blood plasma has shown to increase CREB signaling within the hippocampus (HC) in aged mice. Chronic microglia activation may accelerate the progression of neurodegeneration and is reduced in tg mice following young blood plasma injection. In this study, h-tau mice and wildtype mice were injected with either 1.5microliters of young blood plasma or saline 7 times over 21 days. Mice were then assessed for neuronal loss using Cresyl-Violet. The levels of CREB, phosphorylated CREB, brain derived neurotrophic factor (BDNF), and Iba-1 were determined through Western blot analysis. Genotype by treatment interaction effects were found in the infralimbic region of the prefrontal cortex ($p = 0.031$) and in the cortex above the hippocampus ($p = 0.034$) where AD mice treated with saline have significantly lower cell density than all other groups. In these brain regions, AD mice treated with young blood plasma had similar cell density to the wildtype mice. There was also a significant interaction in the white matter density at midline corpus callosum, with the AD saline groups showing significantly lower white matter density than all other groups ($p = 0.014$). Plasma treated mice had significantly higher white matter density at midline corpus callosum than saline treated mice ($p = 0.002$). Plasma treated mice also had significantly higher cell density in the lateral cortex than saline treated mice ($p < 0.001$). Western blot analysis showed a genotype by treatment trend for levels of Iba-1 ($p = 0.10$) with plasma treatment reducing the levels of Iba-1 found in h-tau mice. Western blot analysis showed no differences in the levels of p-CREB, CREB, or BDNF. These results suggest that the prevention of cell loss in AD plasma treated mice may be a result of the reduction of inflammation due to lower levels of chronic microglial activation following plasma injections.

Title: The Effects of Young Blood Plasma Transfusions on Older hTau Mice Modeling Alzheimer's Disease

Authors: *K. A. PEDEMONTE, A. N. PERLBERG, R. E. TAPP, R. E. BARKEY, J. M. FLINN;
George Mason Univ., Fairfax, VA

Abstract: Alzheimer’s disease (AD) is a neurodegenerative disorder affecting nearly 6 million individuals in the United States alone. The hallmarks of AD include declines in spatial and episodic memory as well as the build-up of amyloid plaques and tau tangles. In this study, 4-month-old h-Tau P301/CaMKII mice received 7 (150 microliter) saline or plasma injections, taken from young wildtype mice, via intravenous tail injections over 3 weeks. One week after the completion of the injections, the mice were evaluated in Morris Water Maze (MWM) paradigm to measure spatial memory, nesting building to measure activities of daily living and Circadian Rhythm to assess their sleep wake cycles. After completion of the behavioral tasks, the mice were sacrificed, and brain tissue was evaluated using Western Blot and thioflavin-S staining. The amount of hyperphosphorylated tau protein and tau tangles in the mice that received plasma injections were compared to those receiving saline injection. The Morris Water Maze did not find significance across the days, but the 24-hour probe showed that the AD mice injected with plasma found the platform significantly faster than the AD mice injected with saline. It was found that the AD mice injected with plasma built significantly better nests than the AD mice injected with saline. There were no significant findings on Circadian Rhythm. Additionally, Western Blot analysis showed that there was significantly less phosphorylated tau in the AD mice that were injected with plasma when compared to the AD mice injected with saline. There were no significant differences in total tau between the animals. This is in contrast to the Hernandez (2019) findings with similar injections at 8 months old, where there were no behavioral difference but significant differences in Western Blot analysis of phosphorylated tau. These findings indicate that early plasma injections are important in decreasing the amount of hyperphosphorylated tau. This study will provide support for plasma injections as a possible treatment for tau pathology found in AD.

Title: Tau expression in the brain of normal and hemiparkinsonian rhesus macaques

Authors: *J. C. GAMBARDELLA, W. SCHOEPHOESTER, V. BONDARENKO, J. M. METZGER, M. E. EMBORG;
Univ. of Wisconsin, Madison, WI

Abstract: Tau is a neuronal protein involved in microtubule stabilization and intracellular vesicle transport in axons. In Alzheimer's disease, frontotemporal dementia, and Parkinson's disease, the tau protein becomes hyperphosphorylated and forms pathological aggregates. Rhesus macaques are widely used for studying such neurodegenerative disorders. In this study, we aim to characterize tau expression in the brains of normal (n=2) and hemiparkinsonian (n=3) rhesus macaques (1 female, 4 males; 3.5-6 years; 4.98-7.45 kg). Hemiparkinsonism was induced by administration of a single, unilateral, intracarotid artery injection of MPTP (3 mg/20ml sterile saline). The animals were necropsied 3 months post-MPTP by transcardiac perfusion with heparinized PBS followed by 4% PFA. The brains were extracted and processed for immunohistochemistry (IHC) against tau (HT7, 1:2000) and immunofluorescence (IF) against tau (HT7, 1:100) and β-III tubulin (1:500). Tau protein expression was blindly quantified across 16 brain structures using a semiquantitative rating scale and NIH ImageJ software. The brain regions included prefrontal cortex, anterior cingulate cortex, primary motor cortex, corpus callosum, internal capsule, anterior commissure, caudate, putamen, substantia nigra, globus pallidus external and internal, thalamus, subthalamic nucleus, amygdala, hippocampus, and entorhinal cortex. Tau was ubiquitously expressed in the brains of normal and MPTP-treated monkeys. In both treatment groups, the greatest tau-ir was in the anterior cingulate and entorhinal cortices, while the weakest tau-ir was in the subthalamic nucleus. IHC revealed patterns of intracellular tau-ir across regions with the greatest soma expression in the thalamus and the greatest fiber tau-ir in the substantia nigra. IF colocalization of tau and β-III tubulin confirmed neuronal expression in cell bodies and fibers in all regions. Preliminary comparison of tau-ir in the substantia nigra, globus pallidus, caudate, and putamen of hemiparkinsonian and control subjects suggest nonsignificant differences between groups. Overall, our study is the first to characterize endogenous tau expression in the rhesus macaque brain.

Title: Tauopathy causes increased synchronisation of low frequency rhythms and disruption of stimulus-induced gamma in mouse visual cortex

Authors: *F. RIBEIRO RODRIGUES[1], A. PAPANIKOLAOU[1], J. HOLENIEWSKA[1], A. B. SALEEM[1], S. G. SOLOMON[2];
[1]Univ. Col. London, London, United Kingdom; [2]Exptl. Psychology, Univ. Col. London, London, United Kingdom

Abstract: Dysfunction of the microtubule-associated protein tau is a prominent feature of neurodegenerative disorders including dementia. Mutant tau forms hyperphosphorylated aggregates that impair neuronal function and synaptic connections. These impairments should have correlates in the electrical activity in the brain that may facilitate diagnosis and detection. Previous work in mouse models of tauopathy show changes in local field potentials (LFP) in hippocampal and frontal brain areas, but the functional organisation of these areas is poorly understood.
We therefore measured the influence of tauopathy on LFP signals in a sensory brain area (primary visual cortex, V1), in the well-characterised rTg4510 mouse model of tauopathy, at 5 months (early in degeneration) or 8 months (more advanced degeneration). We made chronic LFP measurements from V1 of awake head-fixed male (1) rTg4510 mice, (2) rTg4510 mice in which mutant tau expression was suppressed from the age of 2 months, and (3) wild-type littermates, in the presence and absence of visual stimulation, while monitoring their locomotion and pupil dimension. We used multitaper analysis to measure the power spectra of the LFP in each condition.
We found an overall decrease in gamma power at more advanced stages of tauopathy, that was accompanied by a reduction in stimulus-induced gamma oscillations (ca. 75-85Hz). In addition, we found substantially increased low frequency power (2-10Hz) in both 5m and 8m tauopathic animals during resting state (when animals were stationary, pupils were small, and in the absence of visual stimuli). The increased low frequency power at rest arose when these animals

intermittently entered states of high synchronisation, in which low frequency oscillations were strongly coupled with each other. Mild states of arousal, as indexed by increases in pupil size without locomotion, reduced the likelihood of entering highly synchronised states.
We conclude that during tauopathy, neuronal ensembles in visual cortex enter brief periods of increased low frequency synchronisation, likely reflecting reduced drive to the local network. Reductions in activity within specific high gamma sub-bands may reflect the increased impact of tau dysfunction on functional connectivity within the cortex. Future studies could evaluate if degeneration has distinct impact on different sub-bands of gamma activity in human patients.

Title: Bull-headed: tauopathy distribution in relation to traumatic brain injury in muskoxen

Authors: *N. L. ACKERMANS[1], B. WICINSKI[2], T. M. WILLIAMS[4], N. J. GRIMALDI[2], M. VARGHESE[5], J. S. REIDENBERG[3], P. R. HOF[5];
[1]Neurosci., Icahn Sch. of Med. At Mount Sinai,, New York, NY; [2]Neurosci., [3]Anat., Icahn Sch. of Med. at Mount Sinai, New York, NY; [4]Biol., Univ. of California, Santa Cruz, CA; [5]Neurosci., Icahn Sch. of Med. At Mount Sinai, New York, NY

Abstract: Traumatic brain injury (TBI) remains one of the leading causes of death worldwide, with low success of clinical therapy translation from rodent models. Alternative models with extreme behavior may be more representative of the populations most vulnerable to TBI such as athletes and military personnel and offer a new perspective on TBI recovery and prevention. Muskoxen (*Ovibos moschatus*) have thick skulls and large horns, used in headbutting clashes during the seasonal rut. During extended fights, bulls clash heads up to 20 times, at forces around 3000 N. Despite the common belief that their headgear protects their brains from extreme impacts, it has never been investigated experimentally. TBI can be detected in the brain by using histological staining to highlight tau protein, which accumulates in instances of neuronal damage. Our preliminary results indicated TBI-like pathology in these animals in the form of tau-positive histological staining. Brain sections (10 sections, 50 µm thick, each 10 sections apart) from the prefrontal cortex of one male and two female muskoxen were stained by

immunohistochemistry, using the CP13 antibody to detect tau phosphorylated at serine 202. For each specimen, sections were subjected to exhaustive stereological counting, to estimate the density and distribution of tau-positive structures in cortical layers I to VI and white matter. These structures were categorized as neurites, neuropil thread clusters, or neurons stained with fibrillary tau. In all specimens, the highest count of neurites and neuropil thread clusters occurred in layers I-III, and the highest densities occurred in the depths of the sulci. The oldest specimen showed up to four times more tau-positive neuropil threads than the younger specimens, but followed a similar distribution. A concentration of pathological tau in the sulcus depths is a characteristic sign of TBI. In addition, the higher incidence of pathological tau in the superficial brain layers resembles the pattern described for early stages of chronic traumatic encephalopathy (CTE) progression in humans. The repetitive nature of headbutting in not only muskoxen, but bovids in general, presents them as a logical real-world model for instances of CTE and repetitive TBI seen in vulnerable populations such as athletes and military personnel.

Title: Reduced voltage-dependent anion-selective channel protein 1 protects against phosphorylated Tau-induced mitochondrial dysfunction and synaptic damage in Alzheimer's disease

Authors: *M. VIJAYAN, S. KUMAR, P. JANGAMPALLI ADI, H. MORTON, L. BUNQUIN, H. REDDY;
Texas Tech. Univ. Hlth. Sci. Ctr., Lubbock, TX

Abstract: Abstract: The purpose of our study is to understand the protective effects of reduced levels of mitochondrial outer membrane protein voltage-dependent anion-selective channel protein 1 (VDAC1) against phosphorylated tau (p-Tau) induced mitochondrial abnormalities and

synaptic deficiencies in AD pathogenesis. AD is a progressive nervous disorder that eventually destroys all mental and physical functions. AD affects over 50 million people worldwide, but there is no effective disease-modifying treatment for it. AD is associated with phosphorylated tau, neurofibrillary tangles (NFTs), and extracellular amyloid-beta (Aβ) plaques in regions of the brain that are responsible for learning and memory. Mounting evidence suggests that p-Tau-induced mitochondrial dysfunction and synaptic damage are largely involved in AD progression and pathogenesis. We recently found that abnormal physical interaction between VDAC1 and p-Tau led to excessive mitochondrial fragmentation and reduced mitochondrial fusion. **Methods:** In the current study, we crossed VDAC1 heterozygote knockout (VDAC1+/-) mice +/- mice with transgenic Tau mice and created double mutant (VDAC1+/- X Tau) mice. We studied cognitive behavior (Morris-water maze, Open-Field, Y-maze, and Rotarod), molecular, cellular, ultrastructural changes (mitochondrial number and length) and dendritic spines in 6-month-old WT, VDAC1, Tau and double mutant (VDAC1+/- X Tau) mice. **Results:** We found reduced cognitive decline, reduced mitochondrial fission proteins and also enhanced mitochondrial fusion, mitochondrial biogenesis, autophagy, mitophagy and synaptic proteins and dendritic spines (length and number) in double mutant (VDAC1+/- X Tau) mice relative to Tau mice. Mitochondrial number is reduced and length is increased in VDAC1+/- X Tau mice. **Conclusions:** Our findings suggest that a partial reduction of VDAC1 increased synaptic buttons (Golgi-cox) may potentially ameliorate cognitive function. In addition, reduced p-Tau production in VDAC1+/- X Tau mice eventually reduced mitochondrial dysfunction, maintains mitochondrial dynamics, and enhances mitochondrial biogenesis, synaptic plasticity, autophagy, and mitophagy. Thus, partial reduction of VDAC1 may serve as the therapeutic regime in preventing Alzheimer's disease.

Title: Chop is not a main contributor to tau-mediated toxicity

Authors: *M. CRIADO-MARRERO, L. J. BLAIR;
Univ. of South Florida, Tampa, FL

Abstract: There are many ways cells in the brain can die. In Alzheimer's disease (AD), the accumulation of tau is linked with cell death, but the major cell death pathway remains to be identified. Prior work has shown that pathogenic tau promotes endoplasmic reticulum (ER) stress and subsequent unfolded protein response (UPR) activation. However, the contribution of ER stress-induced cell death to tau-mediated neurotoxicity is unknown. Interestingly, mice lacking CHOP/*Ddit3*, an important regulator of ER stress-induced cell death, have been shown to be protected from ER stress-induced neuronal loss. We hypothesized that silencing CHOP would prevent tau toxicity through the ER stress pathway and reveal the contribution of tau toxicity that is mediated through this pathway. To investigate this, we generated a mouse-targeting CHOP/Ddit3 shRNA AAV9 that also expresses GFP by a separate promoter. We injected shCHOP AAV9 or a shScrambled control AAV9 in the brains of 8-month-old male and female rTg4510 tau transgenic mice and harvested them at 12-months of age, when ER stress is activated, and neuronal loss is occurring in these mice. We performed behavioral studies using the Y-Maze, Open field, and 2-day Radial-Arm water maze task with a reversal paradigm. Unbiased stereology was used to determine neuronal health and the effect of CHOP shRNA on CHOP levels was evaluated by immunofluorescence. We found that AAV9 CHOP shRNA did not alter learning and memory in tau transgenic mice. Evaluation of the tissue revealed a modest, but non-significant increase in neuronal loss from CHOP knockdown, while the dentate gyrus shows a non-significant decrease in neuronal loss. Tissue volume was unchanged in both regions. Very surprising to us, and the opposite of what was expected, we found that in these regions of interest the CHOP levels increased in the animal expressing the CHOP. Overall, this suggests that shCHOP AAV9 does not alter tau-modified behaviors such as learning and memory, particularly at this timepoint. Our results also suggest that there may be a compensatory increase in CHOP signaling in neighboring cells, suggesting that the activation of the UPR in the brains of these mice may be a protective mechanism.

Title: Adeno-associated viral gene delivery of wild-type human tau induces progressive neurodegeneration and formation of insoluble tau species in the hippocampi of middle-aged rats

Authors: *G. GABRIELSON[1], C. BURGER[1], N. T. KEHOE[2], R. GORZEK[3], S. OSTING[2], K. R. NASH[4];

Abstract: Tauopathies are a broad class of diseases, including Alzheimer's disease (AD), characterized by hyperphosphorylation and aggregation of the microtubule associated protein tau (MAPT). Tau pathology in AD is sporadic and not associated with any known mutation to the MAPT gene. To recapitulate this tauopathy we used bilateral AAV-injections of wild type 0N4R human tau (htau) into the CA1 region of hippocampus of 6-month-old adult male Fischer 344 rats. Controls included AAV coding for green fluorescent protein (AAV-GFP) and uninjected rats. We observed neuronal loss in hippocampal areas CA1 and CA2 at 3-, 8- and 12-weeks post-injection, with significant loss beginning at 8 weeks as measured by Nissl stain, when compared to AAV-GFP or uninjected controls. Immunohistochemical analysis of the hippocampal region of AAV-htau rats using a human specific tau antibody revealed htau expression by 3 weeks and continued at 8 and 12 weeks. Western blot analysis of total tau revealed an elevated but not significant difference in tau expression at 3 weeks, followed by a significant 1.5-fold increases at 8 weeks and 12 weeks. By 8 weeks, AAV-htau animals exhibit hyperphosphorylation of tau at S202, T205, and S396 phosphorylation sites, as measured by western blot analysis. Hippocampal extracts analyzed via sarkosyl fractionation, allowing for separation of tau aggregates into monomeric, oligomeric, and polymeric aggregate species, show aggregation of monomeric and oligomeric tau species by 3 weeks post injection. Our preliminary data indicates aggregation in monomeric and oligomeric fractions (n=2 animals; 4 hemispheres), and polymeric in one of the two rats analyzed at 12 weeks post-injection. No significant behavioral deficits in fear conditioning or Morris water maze were observed at any timepoint, but a trend towards significance was found in cued fear conditioning at 12 weeks post-injection. Investigation of behavioral phenotypes at later time points is currently in progress. In conclusion, the use of AAV-mediated gene delivery of human tau offers a fast and reliable novel approach to generate progressive tauopathy models, which have the advantage of administration at any age to study age as a variable in disease progression. It also may be useful test hypotheses in future studies exploring tau spreading.

Title: Updates on seeding studies: SOD1 prions transmit aggregation and fatal ALS-like disease - Introducing Strain C

Authors: *E. EKHTIARI BIDHENDI[1], P. M. ANDERSEN[1], S. L. MARKLUND[2], T. BRÄNNSTRÖM[2];
[1]Dept. of Clin. Sciences, Neurosciences, Umeå, Sweden; [2]Dept Med. Biosci., Umeå, Sweden

Abstract: ***Background:*** In the last decade, evolving evidence suggest the presence of propagating prion-like species in severaltypes of neurodegenerative diseases associated with misfolding of host-encoded non-mutated proteins. Among theseare AD, PD, the tauopathies, HD and ALS. A hallmark of prions is the presence of different conformational aggregatestrains with different biological activities. Another characteristic of prions is that subsequent prion passage within thesame host can lead to a shorter incubation period. In ALS, using binary epitope mapping (BEM) we have identifiedtwo structurally different strains of mutant hSOD1 aggregates (named A and B) in the CNS of Tg mice modelsexpressing full-length hSOD1 variants. When seeded into spinal cords of adult hSOD1^{G85R} Tg mice, these strainstransmit exponentially propagating templated hSOD1 aggregation selectively in the motor system with concomitantdevelopment of muscle wasting and paresis. ***Objective:*** To further investigate prion-like properties of hSOD1 strainsin ALS, and explore the spreading characteristic of the disease *in vivo*. ***Methods:*** Stereotaxic inoculation of hSOD1aggregate strains into spinal cords of pre-symptomatic Tg-hSOD1^{D90A} mice were performed. This mutation isessentially wt-SOD1 like. Normally, Tg-hSOD^{D90A} only develop motor neuron disease phenotype when the transgeneis homozygous. Mice hemizygous for the hSOD1^{D90A} transgene insertion do not spontaneously develop ALSpathology and have a normal murine lifespan (>700 days). First & second passage studies were performed toinvestigate further prion-like properties of hSOD1. ***Results:*** Inoculations of either strain A or B seeds into the lumbarspinal cord of 100-day-old hemizygous hSOD1^{D90A} mice induced progressive hSOD1 aggregations and prematurefatal ALS-like disease after ≈250 and ≈350 days, respectively. BEM analysis of aggregates in the terminal stage leadto a surprise discovery: Inoculation of strain A into hemizygous hSOD1^{D90A} mice gave rise to a new strain named C,which has the C-terminal end apparently recruited to the aggregate core.

Second passage inoculations were thenperformed in hemizygous hSOD1^{D90A} mice, using spinal cord homogenates with strain C aggregates as seeds. Thenovel prion strain was much more efficient, and transmitted progressive hSOD1 aggregation and ALS-like diseasewhich was fatal already 100 days after inoculation. The resulting conformational changes are under investigation.***Conclusion:*** We provide further evidence of the similarities between hSOD1 and the prion protein. Our data suggestthat mutations in SOD1 are inducing aggregation and ALS pathology via a prion mechanism.

Title: Linking molecular abnormalities to behavioral deficits using a zebrafish model for tauopathies

Authors: *Y. ZHU[1], P. LEARY[1], Q. BAI[2], E. A. BURTON[2,3], D. SCHOPPIK[1];
[1]Neurosci. Inst., NYU Langone Med. Ctr., New York, NY; [2]Neurol., Univ. of Pittsburgh Sch. of Med., Pittsburgh, PA; [3]Geriatric Res. Educ. and Clin. Ctr., Pittsburgh VA Healthcare Syst., Pittsburgh, PA

Abstract: Tauopathies are neurodegenerative diseases characterized pathologically by accumulation of abnormal Tau in the brain. However, it remains unclear how these molecular and cellular dysfunctions lead to behavioral deficits, especially during the early stages of pathogenesis. To dissect disease mechanisms across multiple biological scales, we generated a zebrafish model of progressive supranuclear palsy (PSP), a primary tauopathy causing unexpected falls in patients early in disease progression, by expressing human 0N/4R-Tau in the evolutionarily conserved vestibulospinal (VS) nucleus. Human Tau-expressing zebrafish exhibit impaired balance control during free-swimming while maintaining normal locomotor ability compared to their siblings. Functional imaging of the VS nucleus shows decreased calcium signals in Tau-expressing neurons in response to tilt stimulus. This altered neuronal activity correlates with Tau phosphorylation in VS neurons. Interestingly, we also observed ectopic accumulation of acidic organelles in the cell bodies of Tau-positive neurons, suggesting abnormal lysosomal function. Taken together, our zebrafish PSP model allows us to understand

molecular and cellular mechanisms of balance deficits in tauopathies and can be a powerful system for preclinical drug screening and evaluation of potential therapeutic targets.

Title: Protective Effects of a Small Molecule Inhibitor, DDQ Against phosphorylated tau in Alzheimer's Disease

Authors: *M. GEORGE, M. VIJAYAN, L. BUNQUIN, C. BOSE, H. REDDY;
Intrnl. Med., Texas Tech. Univ. Hlth. Sci. Ctr., Lubbock, TX

Abstract: Abstract: The purpose of our study is to determine the protective effects of the newly discovered molecule DDQ (diethyl (3,4-dihydroxyphenethylamino) (quinolin-4-yl) methylphosphonate) against mutant Tau and phosphorylated tau (p-Tau) in Alzheimer's disease (AD). To achieve our objective, we used a well-characterized Tau (P301L) transgenic mouse model. **Methods:** We administered DDQ, a 20 mg/kg body weight (previously determined in our laboratory) intra-peritoneally 3-times per week for 2 months, starting at the beginning of the 12^{th} month until the end of the 14^{th} month. Further, using biochemical and molecular methods, we measured the levels of DDQ in the blood, skeletal muscle, and brain. Using q-RT-PCR, immunoblotting, and immunofluorescence, we studied mRNA and protein levels of mitochondrial dynamics, mitochondrial biogenesis, synaptic, and sirtuins, in DDQ-treated Tau mice. **Results:** Our extensive pharmacodynamics analysis revealed high peak levels of DDQ in the skeletal muscle, followed by serum and brain. Interestingly, mitochondrial dynamics, mitochondrial biogenesis, synaptic, sirtuin mRNA, and protein levels were upregulated in DDQ-treated Tau mice relative to untreated Tau mice. Our immunostaining data concurred with mRNA (q-RT-PCR) and protein (immunoblotting) data. **Conclusions:** Together with our previous study observations, current study findings strongly suggest that DDQ has anti-aging and anti-p-Tau effects and a promising molecule to reduce age-and p-Tau-induced toxicities in AD.

Abstract: Tauopathies are a class of neurodegenerative diseases characterized by abnormal intracellular aggregations of the microtubule-stabilizing protein tau. Symptomology of tauopathies includes impaired cognition—including difficulties with learning and memory—caused by progressive neuronal and synaptic degeneration. Tau pathology is often characterized by an accumulation of hyperphosphorylated tau protein resulting in the formation of neurotoxic tau aggregates, also known as neurofibrillary (NFT) and gliofibrillary (GFT) tangles. These aggregates may hinder neural glycolytic metabolism and result in degradation of the myelin sheath and other glial components. Ketone bodies (KBs), metabolites of the putatively-neuroprotective high-fat and low-carbohydrate ketogenic diet (KD), bypass cytoplasmic glycolysis and enter directly into mitochondrial metabolism. The KD and KBs serve to elevate cellular ATP/ADP ratio and thus may rescue neural energetics. We have obtained evidence strongly suggesting that KBs may exhibit neuroprotective effects in a *Drosophila melanogaster* model of traumatic brain injury (TBI); repeated TBI may lead to the progressive neurodegenerative condition termed Chronic Traumatic Encephalopathy (CTE), which is characterized in part by intracellular aggregation of tau protein in neural cells. We employed a *Drosophila* model of tauopathy that allows for spatial restriction of tau protein overexpression to glial cells and for temporal restriction of tau overexpression to adulthood, so as to avoid developmental effects of neural tau protein overexpression. We directly applied a racemic mixture of the KD metabolite beta-hydroxybutyrate (β-HB)—the major circulating ketone body (KB)—to a standard high-carbohydrate *Drosophila* diet to determine whether dietary KB supplementation can ameliorate tauopathy-associated learning deficits. We found that β-HB markedly improves tauopathy-induced learning deficits in mixed-sex groups of adult *Drosophila* and reduces levels of phosphorylated tau in the brains of male flies subjected to induced glial tauopathy.

Title: Inhibition of P2X7/NLRP3/Caspase-1 pathway in chronic muscle pain

Authors: *K. HAYASHI, J. B. LESNAK, L. RASMUSSEN, K. A. SLUKA;
Univ. of Iowa, Iowa, IA

Abstract: Activity-induced muscle pain is a significant clinical problem that contributes to disability and reduced function. We developed an animal model of activity-induced muscle pain that is dependent on local macrophage activation and release of interleukin-1β (IL-1β). Production of IL-1β in macrophages occurs via activation of purinergic receptor-7 (P2X7), NOD-like receptor protein 3 (NLRP3), and Caspase-1. We hypothesized that pharmacological blockade of P2X7, NLRP3, Caspase-1 before induction of the pain model will prevent development of muscle pain through release of inflammatory cytokines. Muscle pain was induced by 2, 20μl pH 5.0 injections, 5 days apart, in the gastrocnemius muscle combined with fatiguing muscle contractions in male and female C57BL6/J mice. To assess hyperalgesia, muscle withdrawal thresholds (MWT) of the gastrocnemius muscle were measured bilaterally before and 1, 3 and 7 days after induction of the model in the following groups injected intramuscularly: P2X7 antagonist A740003 (0.12-1.2μM, 20μl), NLRP3 inhibitor MCC950 (2-20nM, 20μl), Caspase-1 inhibitor Z-WEHD-FMK (1.2-12μM, 20μl), IL-1β immunizing antibody. Release of cytokines and mRNA expression of P2X7, NLRP3 and Caspase-1 were assessed from muscle and resident macrophages using multiplex and qPCR, respectively. The decrease in MWT in male, but not female, mice was prevent by intramuscular blockade of P2X7 ($p<0.01$; 1,507 ± 22mN with 1.2μM vs. 1,151 ± 31mN vehicle), NLRP3 ($p<0.01$; 1,467 ± 17mN with 20.0nM vs. 1,197 ± 18mN vehicle), and Caspase-1 ($p<0.01$; 1,448 ± 54mN with 12.0μM vs. 1215 ± 37mN vehicle). Blockade of IL-1β before induction of the model prevented hyperalgesia in male and female mice; while blockade 1 day after induction of the model blocked hyperalgesia in males only. In parallel, after induction of the model, there was an increase in interleukin-6 (M, 9.9pg/ml vs. 7.2pg/ml; F, 9.2pg/ml vs. 8.6pg/ml), tumor necrosis factor alpha (M, 1.7pg/ml vs. 0.8pg/ml; F, 4.5pg/ml vs. 1.1pg/ml), and interferon-gamma (M, 1.0pg/ml vs. 0.6pg/ml; F, 2.5pg/ml vs. 1.0pg/ml) protein, and P2X7 (M, 1.7-; F, 4.3-fold), NLRP3 (M, 1.9-; F, 4.0-fold), Caspase-1 (M, 3.5-; F, 3.2-fold), and IL-1β (M, 33.4-; F, 19.2-fold) mRNA expression in muscle tissue when compared to controls in male and female mice. The current data suggests

activation of P2X7, NLRP3, and Caspase-1 initiates development of muscle pain in male, not in female mice, and is associated with increased release and expression of inflammatory cytokines in male and female mice. Thus, we show sex-dependent mechanisms for development of activity-induced pain that uses a P2X7-NLRP3-Caspase-1 pathway in males to produce hyperalgesia.

Title: Characterization of behavioral pain phenotype and pharmacology in the rat monoiodoacetate model of osteoarthritis pain.

Authors: *M. URBAN[1], E. DUGAN[1], K. BUBAN[1], J. HAGEDORN[1], P. WIG[1], S. A. WOLLER[2], S. IYENGAR[2], T. HANANIA[1];
[1]PsychoGenics, Paramus, NJ; [2]NINDS, Rockville, MD

Abstract: In collaboration with the NIH HEAL Initiative Preclinical Screening Platform for Pain (PSPP), we evaluated a variety of pain behaviors in the rat monoiodoacetate (MIA) model of osteoarthritis in male and female Sprague Dawley rats for a period of 4-6 weeks following MIA injection (0.3 - 3 mg). Effects of reference analgesic compounds were also evaluated following acute and chronic treatment to examine pharmacology. Intraarticular injection of MIA (1, 3 mg) into the hindlimb knee joint produced unilateral hind paw tactile hypersensitivity in male and female rats which was maximal at Week 2. Unilateral knee joint hypersensitivity to pressure and pinch stimuli was observed in female, but not male, rats at Week 2. Weight bearing deficits associated with the affected hind limb were modest when measuring static weight bearing, and were more pronounced when measuring dynamic weight bearing in male and female rats, with maximal effects observed at Week 1. Changes in gait were also observed in male and female rats following MIA injection, with significant differences observed in hind paw speed, rhythmicity, and paw position at Weeks 1 and 2. The optimal dose of MIA to examine pharmacological effects in this model was determined to be 1 mg, based on lower variability in weight bearing responses. Acute treatment with morphine (3 mg/kg s.c.) reduced hind paw tactile hypersensitivity and weight bearing deficits in male and female rats, whereas acute treatment with ketoprofen (6 mg/kg s.c.) or duloxetine (60 mg/kg p.o.) was partially effective or ineffective. In contrast, chronic treatment with ketoprofen or duloxetine (4 days b.i.d.)

significantly reduced tactile hypersensitivity and weight bearing deficits. The results from this study demonstrate that a variety of pain behaviors associated with knee joint osteoarthritis can be measured using the rat MIA model. An acute and chronic treatment paradigm may be used to identify and differentiate novel mechanisms for the treatment of pain associated with osteoarthritis.

Title: Evaluation of sucrose induced antinociception on long term effects of neonatal noxious stimulation in rats

Authors: *K. NUSEIR, K. ALZOUBI, *A. ALTARIFI;
Jordan Univ. of Sci. and Technol., Irbid, Jordan

Abstract: Pain during infancy have dire consequence both short and long term. Procedural pain is induced as tests and treatments are needed when premature and mature babies are admitted to NICU. Sadly, pain management is either not available or not adequate. Sweet solutions have been shown to decrease some of this pain, as well as prevent negative sequalae of neonatal pain. Mechanism of sweet solution induced pain relief is largely unknown yet. To explore the effects of sucrose solution on induced repetitive nociceptive stimulation and its long-term effects, this work is proposed. Briefly, a small needle will be inserted and removed quickly in rat pups' paws during their first two weeks of life. Sucrose or saline will be applied to the tongues of these pups just before noxious stimulation. At adulthood, a battery of behavioral tests will be run in sequences in order to explore deficiencies and inadequacies that result from pain. By employing both male and female rats to examine sex differences if any. Biochemical markers will also be tested to add to our knowledge of the mechanisms of sweet induced analgesia.

Title: Contribution of main olfactory system to mechanical hyperalgesia in mice exposed to bedding from CFA-treated conspecifics

Authors: *Y. ZHANG, A. E. RYABININ;
Dept. of Behavioral Neurosci., Oregon Hlth. & Sci. Univ., Portland, OR

Abstract: Rodents can develop nociceptive hypersensitivity after interacting with familiar conspecifics in painful conditions. Our laboratory has previously shown that mice repeatedly exposed to, but not physically contacting, the bedding from conspecifics in persistent painful conditions also developed long-lasting nociceptive hypersensitivity. This finding provided evidence that the nociceptive behavior of mice could be socially modulated without direct interaction, potentially via olfactory system. To further understand this phenomenon, the current study aimed to investigate whether a brief exposure to the bedding from conspecifics in pain would modulate the nociception in mice, and whether the olfactory system was involved in such modulation. Female C57BL/6J mice were singly housed in separate cages with only wire lids but no filter covers. After habituation, they were randomly selected as test mice and stimulus mice. Test mice were further assigned to four treatment groups that were exposed to one of the four different stimuli: a familiar stimulus mouse treated with Complete Freund's Adjuvant (CFA), a familiar stimulus mouse treated with saline, and the bedding from a CFA- or saline-treated stimulus mouse. The von Frey mechanical thresholds of the test mice were measured before and at 1, 2, 4 and 24hr after a one-hour exposure to the stimuli. We found that exposure to the bedding from CFA-treated stimulus mice induced an acute mechanical hypersensitivity in the test mice from 1hr to 4hr after the exposure, similar to the effect of exposure to a CFA-treated stimulus mouse itself. In contrast, in female mice with dichlobenil-induced lesion in the olfactory epithelium, the bedding from CFA-treated stimulus mice did not produce mechanical hypersensitivity. This result indicates that the nociception modulatory effect of the bedding exposure requires the functional olfactory epithelium in test mice. Taken together, this study demonstrates that a single no-contact exposure to the bedding of conspecifics in pain leads to transient nociceptive hypersensitivity in mice that is likely mediated via the main olfactory system.

Abstract: The lack of robust quantifiable behavioral assessments of pain in preclinical models, especially of ongoing pain, has been a major limitation for both pain neurobiology research and the development of novel analgesics. Conventional methods typically require extensive animal-human observer interaction and are often followed by manual, thus subjective, scorings, which are susceptible to bias and variability, and are labor-intensive and time-consuming. With recent advancements in both high-speed videography and machine-learning-powered video processing and behavioral analysis, conventional methods have been automated, modified, and new methods have been developed. However, behavioral data analysis with advanced machine learning remains a technical niche, with limited accessibility to the more general pain research community and for large-scale pre-clinical novel analgesic screening. Here we demonstrate that, by leveraging modern machine vision and machine learning tools, quantifiable features of the spontaneous behavior, recorded in a dark and observer-free environment from a bottom-up view, with simultaneous surface contact measurements, can be directly used to detect and infer both the internal state of pain and analgesia in an animal, in an objective manner. We further optimize and automate a robust pain behavioral assay, with a complete hardware and software solution that is user-friendly, for exploring the biology of pain, one readily scalable for pre-clinical drug efficacy assessment.

Title: Sex differences in orofacial sensitivity, visceral sensitivity, and brain activity in an animal model of stress-induced pain hypersensitivity

Authors: L. HERNANDEZ[1], J. DA SILVA[1], S. HANSON[1], A. J. SCOTT[2], R. K. ERNST[2], O. K. MELEMEDJIAN[1], D. A. SEMINOWICZ[1], *R. J. TRAUB[1];
[1]Neural and Pain Sci., [2]Microbial Pathogenesis, Univ. of Maryland Sch. of Dent., Baltimore, MD

Abstract: Temporomandibular Disorder and irritable bowel syndrome are two of ten Chronic Overlapping Pain Conditions, conditions that tend to co-occur and are predominant in women. However, mechanisms underlying the comorbidity of chronic pain originating in distally unrelated tissue types are unknown. We hypothesize changes in brain function initiated by pre-existing pain combined with stress contributes to development of *de novo* pain in susceptible individuals. Using an animal model (orofacial pain plus stress) that induces *de novo* Comorbid visceral Pain Hypersensitivity (CPH) in rats, we reported more robust and longer duration CPH in female rats compared to males (Da Silva, IASP 2021 abstract). fMRI revealed enhanced activity in the insula, parabrachial nucleus, and gigantocellular reticular nucleus in naïve females. Activity in the anterior cingulate cortex, nucleus accumbens, thalamus, hippocampus, and substantia nigra was increased over time in females. In contrast, males were hypersensitive to distention at one week, with hypersensitivity resolved by four weeks. Brain activity in males at seven weeks was similar to the baseline state, which showed increased activation of the thalamus and periaqueductal gray, as compared to one week. In the present study, the effects of stress alone (Stress-Induced Hypersensitivity, SIH) were examined. The relative percentage of male (9/12) and females (8/14) rats susceptible to stress (increased visceral pain one week post stress) was comparable. The stress resilient rats were excluded from further analysis of visceral pain. Preliminary data from both males and females showed SIH four weeks post stress, resolving by seven weeks in females (ANOVA, females p=.0250); data collection ongoing in males. Additional preliminary data show stress alone increased orofacial mechanosensitivity in females (p=.0210, n=5), but not males (p=0.4, n=5). In the female cohort, the increased orofacial pain was only apparent in the susceptible females and not the resilient females. Analysis of functional connectivity using fMRI is underway. Ultimately, changes in functional connectivity

in SIH rats will be compared to CPH rats. This study supports our previous work comparing SIH and CPH conditions showing many similarities, but also differences, especially duration of pain hypersensitivity that is correlated with changes in brain function contributing to sex differences in chronic pain.

Title: 10kHz spinal cord stimulation alleviates mechanical hypersensitivity in a rat model of painful diabetic neuropathy

Authors: *D. WANG, K. LEE, Z. KAGAN, D. LEE, K. BRADLEY;
Nevro Corp, Redwood City, CA

Abstract: Painful diabetic neuropathy (PDN) is a serious complication of diabetes and occurs in approximately 50% of older patients with diabetes mellitus. In a recent randomized controlled clinical trial, 10kHz spinal cord stimulation (10kHz SCS) was shown to be a promising therapy for PDN, in both pain reduction and possible neurological improvements (Petersen et al 2021). In this study, we aimed to observe the behavioral and neural effects of 10kHz SCS on PDN using streptozotocin (STZ)-induced diabetic rats. We established four testing groups: naïve controls, STZ controls (STZ injection only), STZ+Sham (STZ injection with implanted-but-unstimulated epidural spinal electrode), and STZ+10kHz SCS (STZ injection with implanted-and-stimulated epidural spinal electrode). A single effective dose (60 mg/kg) of the cytotoxic agent STZ caused the rats to become hyperglycemic (>270 mg/dl) within 72 hours and lasted for several weeks. These STZ-injected rats also showed a significant and continuous reduction in body weight in comparing to naïve control rats. In behavioral assessments, we observed that 7 days of continuous (24h/day) low-intensity (30% of motor threshold) 10kHz SCS appeared to restore von Frey paw withdrawal thresholds to approximately 96% of naïve controls, showing statistically significant improvement from the Pre-SCS baseline after 7 days of 10kHz SCS, and versus STZ control or STZ+Sham animals ($p<0.05$). In addition, we performed electrophysiologic testing just prior to termination in all groups. We observed normalization of the receptive field area of wide dynamic range dorsal horn neurons with 10kHz SCS: STZ control and STZ+Sham rats demonstrated significantly expanded receptive fields compared to naïve, while STZ+10kHz SCS rats trended towards reduction of receptive field size towards

naïve controls.
Our results suggest that 10kHz SCS resulted in behavioral outcomes reflective of pain reduction, as well as normalization trends of central neuron processing in PDN animal model. These findings provide supporting evidence for recent randomized clinical trial data of 10kHz SCS and underscore the conclusion that 10kHz SCS can effectively treat patients with refractory PDN.

Title: Behavioral characterization of humanized mice: a platform to understand chronic graft-versus host disease-associated pain?

Authors: E. HEZARKHANI[1], A. S. ANDRIESSEN[1], J. ZHAO[1], S. BANG[1], B. A. MOCK[5], J. W. MAYS[6], R.-R. JI[1,2,3], J. T. NGUYEN[6,5], C. R. DONNELLY[1,4];

Inst. of Hlth., Bethesda, MD

Abstract: Humanized mice - immunodeficient mice with stably engrafted and functional human cells - have emerged as a leading preclinical platform to study a wide variety of human diseases. Since its development in 2014, the triply immunodeficient “NCG” mouse model, which bears mutations in *Sirpa, Prkdc* and *Il2rg* loci, has emerged as a leading platform to produce humanized mice, enabling the engraftment of human peripheral blood mononuclear cells (huPBMCs) or human umbilical cord derived CD34+ hematopoietic stem cells (huCD34-HSCs). In this study, we characterized the behavioral phenotypes in huCD34-NCG mice 12-15-weeks post-engraftment. Interestingly, although huCD34-NCG mice appear to be overly normal in size and gross health assessment measures compared to non-engrafted NCG mice, we found that huCD34-NCG mice exhibited a variety of behavioral features suggestive of ongoing chronic

pain, including: (1) mechanical hypersensitivity, as determined by von Frey testing and Randall-Selitto testing; (2) thermal hyperalgesia, as determined by hot plate testing; (3) cold allodynia, as determined by plantar acetone testing and cold plate testing; and (4) orofacial allodynia, as determined by consumption of capsaicin-laden drinking water. Neither non-engrafted NCG nor huCD34-NCG mice exhibited signatures of spontaneous pain at baseline. Notably, huCD34-NCG mice and un-engrafted NCG mice appear similar in behavioral tests assessing cognitive function, anxiety, and depression. Given the abundance of literature demonstrating that various humanized mouse models develop graft-versus-host disease after xenogeneic transplants, we posit that huCD34-NCG mice may be a useful platform to study the neurological sequalae associated with chronic graft-versus host disease (GVHD), including chronic pain and its associated comorbidities. Ongoing work is focused on analyzing signatures of neuroinflammation in the peripheral and central nervous systems of huCD34-NCG mice relative to non-engrafted controls. This model may yield new insights into the pathogenesis of pain in GVHD, prompting new therapeutic targets.

Title: Examiner gender effect on pain responses

Authors: *N. G. BAILEY[1], J. MCDOUGALL[2], R. BANGA[3], L. D. LINDE[3], J. L. K. KRAMER[1];
[1]Anesthesiology, pharmacology & therapeutics, [2]Rehabil. Sci., [3]Kinesiology, Univ. of British Columbia, Vancouver, BC, Canada

Abstract: Introduction: Pain is reportedly influenced by the sex and gender of the participant and the examiner. This has been chiefly examined using static measurements (e.g., pain thresholds), which are susceptible to bias. This study investigated the influence of examiner and participant's gender and sex on tonic heat responses.**Methods**: 38 participants (18 males, 20 females) attended two identical testing sessions. Participants were randomly assigned to a male or female examiner on day 1, and the opposite examiner on day 2. Rating- and temperature-based methods of evaluating tonic heat were conducted. The rating-based method required participants to rate stimulus intensity using a computerized visual analog scale (CoVAS). Participant controlled temperature (PCT) was used as a temperature-based method. During PCT,

participants changed the temperature of the probe in real-time to reflect shifts in their heat perception, with the goal of maintaining their initial awareness. Participants verbally rated their pain at the start and end of both tests.**Results**: Female participants verbally report higher pain ratings to tonic heat compared to their male counterparts (main effect: F=5.77, p=0.02). Neither CoVAS nor PCT were significantly different based on the sex of the participant (main effects: CoVAS, F=1.20, p=0.28; PCT, F=1.02, p=0.32). Female participants had significantly greater verbal pain ratings during CoVAS when tested by the female examiner (F=5.61, p=0.02). Similarly, females reported greater CoVAS non-verbal pain ratings when tested by the female examiner, albeit non-significant (F=2.70, p=0.11). PCT outcomes were not modulated by the examiner (interaction effect: F=0.45, p=0.51).**Conclusions**: In line with previous studies, female participants tended to verbally report higher pain ratings to tonic heat stimulation compared to males. Non-verbal methods of reporting pain may be less susceptible to gender differences. Temperature-based non-verbal approaches may provide less biased estimates of neurophysiological processes underlying pain.

Title: Euphorbia bicolor latex extract reduces mechanical allodynia in a rat model of thermal injury

Authors: *T. P. OLAOLUWA, C. MAIER, D. L. AVERITT;
Texas Woman's Univ., Denton, TX

Abstract: Burn injury is associated with oxidative stress and prolonged inflammation which can lead to chronic pain. Current treatment for pain associated with burns include oral and intravenous analgesics such as non-steroidal anti-inflammatory drugs, opioids, and gabapentinoids which have all been linked to undesired negative side effects. As burns represent a particularly challenging type of injury to treat, novel strategies that mitigate pain related to burns are needed. Our previous studies indicate that the extract of *Euphorbia bicolor,* a plant native to the southern United States, may provide a novel analgesic as it demonstrates anti-inflammatory, antinociceptive, and antioxidant properties. Phytochemicals in the *E. bicolor* extract can directly reduce nociceptor activity, reduce proinflammatory cytokines/chemokines, and reduce reactive oxygen species (ROS). Further, *E. bicolor* latex extract induces long-lasting, non-opioid peripheral analgesia in two rat models of inflammatory pain. As burn pain involve sensory neuron damage, oxidative stress, and inflammation, *E. bicolor* extract may effectively target each of these mechanisms providing a multimodal therapeutic for treating burn pain. We hypothesized that *E. bicolor* latex extract will reduce mechanical allodynia in a rat model of pain associated with full thickness thermal injury. Two concentrations of *E. bicolor* ethanol latex extract, 100 μg/mL and 500 μg/mL, in 0.9% sterile saline, were used. Adult male Sprague-Dawley rats (200-300 g) received a full thickness thermal injury to the plantar surface of the right hind paw by applying a soldering iron tip at 100°C for 30 seconds. Mechanical allodynia was then recorded 24, 48, and 72 hrs post-injury to confirm development of pain behaviors. Rats then received one intraplantar injection of either vehicle or *E. bicolor* latex extract immediately adjacent to the thermal injury and mechanical allodynia was re-examined at 1, 3, 6, 24, 48, and 72 hrs post-injection then once weekly until the thermal injury resolved. Here we report that mechanical allodynia develops at 24 hrs following thermal injury, similar to our previous reports characterizing this model. Peripheral analgesia was then detected within 24 hrs of injection of the 500 μg/mL dose of *E. bicolor* extract. These data confirm that *E. bicolor* latex extract contains phytochemicals that evoke potent analgesia in a rat model of burn pain. Our current studies are focused on determining the individual phytochemicals that contribute to the anti-inflammatory, antioxidant, and antinociceptive properties of *E. bicolor* that account for the observed analgesia to develop into novel non-opioid pain therapeutics.

Title: Opioid-sparing effects of the Nrf2 activator diroximel fumarate in mice

Authors: *M. S. U. RASHEED, F. R. CHERRY, P. M. GRACE;
Labs. of Neuroimmunology, Dept. of Symptom Research,MD Anderson Pain Res. Consortium, The Univ. of Texas MD Anderson Cancer Ctr., Houston, TX

Abstract: Opioids are widely used to treat acute and chronic pain. However, their long term administration can result in tolerance and paradoxical opioid-induced hyperalgesia (OIH). Underlying mechanisms include induction of reactive oxygen and nitrogen species (ROS/RNS) in the periaqueductal gray, hippocampus and prefrontal cortex regions of the brain and the dorsal horn of the spinal cord that disrupts glutamate homeostasis, contributing to dysregulation of opioid analgesia. We hypothesized that activating the antioxidant transcription factor Nrf2 would alleviate morphine tolerance and OIH. Diroximel fumarate (DRF), an FDA approved drug, was used to activate Nrf2. For the OIH experiment, naïve mice were implanted with subcutaneous osmotic minipumps to infuse morphine dose for 7 days (10 mg/kg/day). Oral DRF (100 mg/kg/day) or vehicle was administered the day before minipump implantation, and then daily for the 7-day morphine infusion. For the tolerance experiment, naïve mice were implanted with subcutaneous osmotic minipumps to infuse morphine for 5 days (10 mg/kg/day). Oral DRF (100 mg/kg/day) or vehicle were administered the day before minipump implantation, and then daily for the 5-day morphine infusion. On day 5, cumulative doses of morphine (1.8, 3.2, 5.6, 10.0 and 18.0 mg/kg) were injected after every 20 min. Withdrawal thresholds to heat and mechanical stimuli were assessed using hot plate tests and Von Freys, respectively. Male and female mice treated with morphine alone had decreased withdrawal thresholds to heat and mechanical stimuli by day 7, indicating development of OIH. However, DRF co-treatment blunted development of OIH. Mice treated with DRF alone did not show any change in withdrawal thresholds. Effects of DRF on morphine tolerance will be presented. Expression of antioxidant genes/proteins in the spinal cord and brain will also be presented and Nrf2 positive cells identified. Future studies will investigate the effects of DRF on other adverse effects of opioids, including abuse liability, respiratory depression, and withdrawal. These promising results suggest that DRF has opioid-sparing properties.

Title: Truncating intracellular C-termini encoded by exon 7 of mu opioid receptor gene, Oprm1, in C57BL/6J mice attenuates fentanyl and methadone tolerance and reward

Authors: *Y. PAN[1,2], J. XU[1], T. ZHANG[2], V. P. LE ROUZIC[2], S. LIU[1], W. KANG[1], A. ABRIMIAN[1], A. MALIK[1], T. KRAFT[1], R. CHIEN[1];
[1]Rutgers New Jersey Med. Sch., Newark, NJ; [2]Neurol., Mem. Sloan-Kettering Cancer Ctr., New York, NY

Abstract: The single-copy gene (*OPRM1*) encoding the mu opioid receptor (MOR) undergoes extensive alternative pre-mRNA splicing, generating multiple splice variants or isoforms conserved from rodents to humans. One splice variant type includes full-length, seven-transmembrane (7TM) carboxyl (C)-terminal variants that are identical except for sequences located at the tip of the intracellular C-terminal tail. The functional relevance of these 7TM C-terminal variants has been demonstrated using *in vitro* cell models showing differences in mu agonist-induced G protein coupling, phosphorylation, internalization, and postendocytic sorting and by differential region- and cell-specific expression. The *in vivo* function of the C-terminal tails has been investigated in C-terminal truncation mouse models. In particular, truncating exon 7 (E7) of the C-terminus in C57BL/6J mice (mE7M-B6) diminishes morphine tolerance and reward without altering physical dependence. The current study further investigates the effect of E7-truncation on fentanyl and methadone actions including tolerance, physical dependence and reward. We observed that in wild-type (WT) B6 mice, both fentanyl (1 mg/kg/day, subcutaneously (s.c.) osmotic pump for 7 days) and methadone (10 mg/kg, s.c. twice a day for 7 days) produced robust tolerance. However, in mE7M-B6 mice both fentanyl and methadone tolerance were significantly attenuated. Fentanyl and methadone reward determined by conditioned place preference were significantly reduced in mE7M-B6 mice when compared to WT B6 mice. These results were like those seen in morphine tolerance and reward in mE7M-B6 mice. On the other hand, fentanyl-induced dependence determined by naloxone- precipitated withdrawal was slightly increased, while methadone dependence was no change. The similarities

and dissimilarities between mE7M-B6 and β-arrestin2 knockout mice in these mu opioid actions suggest that E7-encoded C-terminal sequences are involved in both β-arrestin2-dependent and β-arrestin2-independent signaling pathways. Fentanyl and methadone-stimulated G protein coupling in brain regions of mE7M-B6 mice were examined using [^{35}S]GTPγS autoradiography and [^{35}S]GTPγS binding assay with isolated brain membranes to determine whether region-specific desensitization mechanisms are involved. Fentanyl and methadone-induced β-arrestin2 recruitment in mMOR-1O, a full length E7-associated 7TM variant, was investigated in Be(2)C cells using with a Nanobit-based β-arrestin2 recruitment assay. Together, these data further support the functional relevance of E7-associated splice variants in opioid pharmacology.

Title: Brainstem opioid receptor architecture and neuromodulation of respiratory, sensory, and motor circuits

Authors: *N. F. HUG[1,4], N. MERCER LINDSAY[2,4,3], W. M. MCCALLUM[4], G. SCHERRER[4,5];
[1]Sch. of Med., Stanford Univ., Palo Alto, CA; [2]Dept. of Biology, CNC Program, [3]Howard Hughes Med. Inst., Stanford Univ., Stanford, CA; [4]Dept. of Cell Biol. and Physiology, UNC Neurosci. Ctr., [5]New York Stem Cell Fndn. – Robertson Investigator, Univ. of North Carolina, Chapel Hill, Chapel Hill, NC

Abstract: Opioids profoundly alter respiratory activity, sensory responses, and motor behaviors, yet the distribution pattern of opioid receptors in brainstem circuits has not been elucidated. Opioid-induced respiratory depression (OIRD) is the leading cause of opioid-related overdose deaths. While there is significant evidence for the direct action of opioids on brainstem

respiratory networks, on which nuclei and cells opioids act to produce OIRD is unclear. Given the differential effects on respiration of selective agonists for the mu, delta, kappa, and nociceptin opioid receptors (MOP, DOP, KOP, and NOP), elucidating brainstem expression of each receptor is critical for comprehensively understanding OIRD. Further, examination of receptor expression throughout the brainstem is important for understanding opioid-mediated neuromodulation of sensory and motor functions. Here we labeled MOP, DOP, KOP, and NOP using immunohistochemistry and knockin reporter mice, and used 3-D reconstructions to reveal each receptor expression across brainstem circuits. We found that the different receptors are occasionally co-expressed in neurons in a few brainstem regions but are most often found in discrete nuclei. Structures where more than one receptor is expressed are typically multimodal or integrative centers e.g., the parabrachial nuclei (PB), Kölliker-Fuse (KF), deep layers of the superior colliculus, or olivary nuclei. Secondary sensory and motor nuclei generally exhibited discrete receptor expression patterns, such as notable DOP labeling in the ventral cochlear nucleus or MOP labeling in the paratrigeminal nucleus and nucleus ambiguous (NA). Segregation of receptor types was even seen within nucleus subregions, i.e., MOP and NOP labeling in the dorsal cortex of the inferior colliculus while DOP is isolated in the central nucleus. We examined all respiratory brainstem nuclei: pattern generators [e.g., preBötzinger complex (preBötC)], sensorimotor integrators (e.g., PB, KF), and motor output (e.g., NA, hypoglossal nucleus). There is structure-specific organization of receptor type, such as dominant MOP expression in the preBötC, contrasting with overlapping expression of KOP and MOP in the KF. Together, the results establish the brainstem opioid receptor architecture, detailing the specific expression pattern of all four receptors, and provide an essential anatomical basis for constructing hypotheses for how the different MOP-expressing neural populations and co-expression with other receptors in respiratory nuclei modulates respiratory function to produce OIRD.

Opioids are commonly used for managing pain across the US. However, the side effects such as tolerance and dependence limit the clinical use of opioid drugs. Our previous studies demonstrated that treatment with Hsp90 inhibitors in the spinal cord enhanced the morphine antinociception and reduced the tolerance in different pain models. However, serious adverse effects, such as liver toxicity, have been demonstrated associated with universal Hsp90 inhibition; Therefore, a better approach targeting the Hsp90 cascade becomes highly demanded. Activator of Hsp90 ATPase Homolog 1(Aha1) is a co-chaperones of Hsp90 and promotes ATPase activity that is necessary for the function of Hsp90. This study aimed to determine the impact of Aha1 inhibitor, KU-177, on morphine antinociception can have an impact on the extent of antinociception effect of opioids. Male and female CD-1 mice were treated with KU-177 via intrathecal injection. The tail-flick was performed to determine the impact of KU-177 on morphine antinociception and tolerance. Further, we chose a murine microglial cell line, BV-2, to investigate the potential mechanisms. Cells were treated with KU177 for measuring the activation of Nrf2 signaling and the expression of downstream genes. We found that treatment with KU-177 enhanced morphine antinociception. KU-177 could also rescue the tolerance induced by continuously being treated with 10 mg/kg morphine for 3 days. Furthermore, KU-177 dose-dependently increased the Nrf2 activation in the BV-2 cells with or without lipopolysaccharides (LPS) stimulation. These findings demonstrate that Aha1 inhibitor could be a potential approach for improving opioid therapy for pain management.

Title: Preference for morphine is attenuated in the presence of the dopamine 3 receptor agonist pramipexole

Authors: J. YOW[1], E. PATEL[1], M. SCHAUB[1], S. CLEMENS[2], *K. BREWER[1];
[2]Physiol., [1]East Carolina Univ., Greenville, NC

Abstract: Despite excellent analgesic properties, opioids carry significant risk of misuse, abuse, and addiction, underscoring the need for adjuvants that can maintain effective analgesia while minimizing the dose of opioids needed to achieve the analgesia. Our previous studies demonstrated that combining morphine with the dopamine D3 receptor agonist pramipexole (PPX) enhanced the analgesic effects of morphine even at low doses of morphine and PPX that were ineffective on their own. We hypothesize that this drug combination will provide significant analgesia but not result in the development of drug preference, suggesting a lower addictive potential than the opioid alone.Two-bottle choice was used to test for the development of preference for morphine/PPX combination (10 male and 10 female Long-Evans rats), and for morphine alone (6 male and 6 female rats). Animals had 28 days of continuous access to pairings of: 1) a bottle containing morphine sulfate (0.05mg/ml) + PPX (0.0008mg/ml) dissolved in water with 2% sucrose and a second bottle (control) containing 2% sucrose, or 2) a bottle containing morphine sulfate (0.05mg/ml) dissolved in water with 2% sucrose and a control bottle containing 2% sucrose. Daily fluid intake was measured in ml, and drug consumption expressed as mg of drug/kg for 24 hours. Locomotor testing was performed prior to the start of drug exposure and at 1 and 4 weeks after initiation of exposure to determine effects of drugs on spontaneous behaviors. Preference was determined by comparing mg/kg consumption rates of the 2 solutions each day and as a total consumed over a 21-day exposure period.On days 2-21 of exposure, male rats consumed significantly more morphine solution (mg/kg) than morphine + PPX (mean daily consumption = 1.03 ± 0.16 vs. 0.27 ± 0.06 mg/kg; 95% CI of the mean = 0.4-1.1). Female rats consumed significantly more morphine from the first day of exposure throughout the exposure period (mean daily consumption = 2.74 ± 0.19 vs. 0.64 ± 0.09 mg/kg; 95% CI of the mean = 1.64-2.54). No rats escalated their consumption of morphine/PPX over the exposure period. In contrast, 33% of rats (both male and female) increased consumption from the bottle of morphine alone. Animals exposed to the morphine/PPX combination displayed no changes in locomotor activity, while animals exposed to morphine alone showed increased locomotor activity at 1 week (males) or 4 weeks (females).In conjunction with previous studies showing that PPX enhances the analgesic effects of low dose morphine, these results suggest that the morphine/PPX drug combination represents a potential pain therapy that can be used long-term without producing addictive behaviors.

Title: Advanced age and sex modulate multiple mu opioid receptor signaling mechanisms in the rat midbrain periaqueductal gray: Implications for analgesia

Authors: *E. F. FULLERTON[1], M. C. KAROM[1], J. M. STREICHER[2], A. Z. MURPHY[1]; [1]Neurosci. Inst., Georgia State Univ., Atlanta, GA; [2]Pharmacol., Univ. of Arizona, Tucson, AZ

Abstract: Chronic pain is exceedingly prevalent in individuals over 65 years of age but is under-managed in this population, due in part to a dearth of knowledge regarding the suitable dosing of opioids for chronic pain management. We have shown that advanced age and sex alter morphine modulation of persistent inflammatory pain (induced by intraplantar administration of Complete Freund's adjuvant (CFA)), where morphine potency is highest in adult male rats (2mos), with a 2-fold rightward shift in the dose-response curve for aged males (18mos) and females regardless of age. In this study, we tested the hypothesis that advanced age attenuates μ-opioid receptor (MOR) signaling in the ventrolateral periaqueductal gray (vlPAG), a critical region for the modulation of pain. Using a combination of molecular and pharmacological techniques on vlPAG tissue from adult and aged, male and female rats collected 72h following CFA administration, we find that aged males exhibit reduced vlPAG MOR expression (Bmax) compared to adult males, and both aged males and aged females exhibit reduced vlPAG MOR affinity (Kd) compared to adult males. Further, aged males and females, regardless of age, show reduced vlPAG MOR binding potential and reduced G-protein activation efficiency compared to adult males. Together, these results suggest that age- and sex-induced alterations in MOR machinery contribute to reduced opioid potency. The regulation of opioid-induced G-protein signaling was further assessed using RNAscope to analyze mRNA expression of Regulator of G-Protein Signaling (RGS) family members RGS4 and RGS9-2. Our analyses of RGS mRNA revealed increased expression of RGS4 and RGS9-2 in the vlPAG of aged animals compared to adults, indicating that MOR signaling is subjected to greater negative regulation in the aged vlPAG. The observed age-related reductions in vlPAG MOR expression, MOR agonist binding, and opioid-induced G-protein activation, along with the observed increase in vlPAG RGS4 and RGS9-2, as a function of age, have significant implications in pain management in the aged population. We are currently assessing age and sex differences in vlPAG MOR phosphorylation using immunoprecipitation of MOR phosphorylated at serine 375 and assessing opioid-induced cAMP inhibition using TR-FRET cAMP immunoassay to elucidate the mechanisms whereby morphine potency is reduced in aged animals. These novel findings of age-induced attenuation in MOR signaling within the PAG provide potential therapeutic targets to improve pain management in the elderly.

Title: Heat shock protein 90 inhibition in spinal cord enhances opioid anti- nociception by suppressing EGFR and AMPK signaling

Authors: *K. GABRIEL[1], J. M. STREICHER[2];
[2]Pharmacol., [1]Univ. of Arizona, Tucson, AZ

Abstract: Opioid misuse is a prevailing problem for chronic pain treatment and is accompanied by side effects such as constipation, tolerance, and addiction. Mu opioid receptor (MOR) signal modulation has been heavily studied in an attempt to optimize opioids and to decrease their side effects. Our lab has demonstrated an important role for the chaperone protein Heat shock protein 90 (Hsp90) in regulating ERK MAPK signaling and pain relief downstream of the MOR. When 17-AAG, an Hsp90 inhibitor, is administered to the spinal cord (intrathecally, IT), there is an augmentation in morphine induced antinociception in mice. This signifies that Hsp90 acts to repress ERK MAPK signaling to reduce antinociception in the spinal cord. This led us to perform quantitative proteomic analysis on the spinal cords of CD-1 mice treated with 0.5 nmol 17-AAG, in order to elucidate the signaling network that activates opioid anti-nociception in the spinal cord. Network analysis of this data revealed that epidermal growth factor receptor (EGFR) was downregulated by 1.4-fold and 5'-AMP-activated protein kinase subunit beta-1 (AMPK) was also downregulated by 1.4-fold. Previous studies have implicated EGFR in promoting opioid receptor internalization and AMPK activation in preventing pathological pain. This result suggested that a reduction in EGFR and AMPK activity could lead to enhanced opioid signaling and pain relief. We tested EGFR agonist EGF (0.01nmol, IT) and found that it decreased 0.5nmol 17-AAG enhanced morphine (3.2 mg/kg, subcutaneous, SC) antinociception in the 52°C tail flick test in both male and female mice. Conversely, when testing the EGFR inhibitor Afatinib (10nmol, IT), there was an enhancement of antinociception in males but not females. Similarly, when using an AMPK agonist AICAR (100nmol, IT) there was a decrease in 17-AAG's enhanced antinociception, but it also decreased morphine's effect in the vehicle group only in male mice. Consequently, when using the AMPK inhibitor dorsomorphin (20 nmol, IT), we were able to see an enhancement of morphine antinociception greater than 17-AAG alone in both males and females. Our data supports our hypothesis that Hsp90 inhibition in spinal cord

enhances opioid pain relief by decreasing EGFR and AMPK signaling that varies between male and female mice. This suggests that these molecules act as negative feedback breaks on opioid anti-nociception in the spinal cord which leads to the enhanced opioid antinociception. This can be reversed when either an EGFR or AMPK agonist is administered, thus elucidating key molecular mechanisms to establish the basic science foundation by which Hsp90 is regulating opioid signaling.

Title: Inhibition of Heat shock protein 90 in the Spinal Cord Enhances Opioid Anti-Nociception by Disabling an Inhibitory GABA Circuit

Authors: *C. CAMPBELL[1], J. M. STREICHER[2], P. LANGLAIS[3];
[1]Neurosci., Univ. of Arizona Grad. Interdisciplinary Program In Neurosci., Tucson, AZ; [2]Pharmacol., Univ. of Arizona, Tucson, AZ; [3]The Univ. of Arizona, Tucson, AZ

Abstract: Opioid drugs used in the treatment of pain are in desperate need of replacement due to their deleterious side effects. One strategy on offer is developing dose-reductive compounds that, when co-administered with palliatives, can reduce the dose of opioid required for treatment, retaining analgesic efficacy while reducing unwanted side-effects such as addiction, respiratory depression, and death. We previously showed that intrathecal (IT) administration of the heat shock protein 90 (Hsp90) inhibitor 17-AAG potentiated the efficacy of morphine induced antinociception, while reducing or not changing opioid side effects, enabling a dose-reduction strategy. Proteomic analysis of the translational alterations induced by IT 17-AAG administration revealed an upregulation of GABA transporter 2 (GAT-2). To elucidate the role of GAT-2 in mediating the enhancement of morphine antinociception, 17-AAG treated mice were administered a GAT inhibitor, Nipecotic Acid (NA), in the tail flick assay. NA effectively blocked the 17-AAG enhancement of antinociception compared to controls, while not changing responses in Vehicle-treated mice, suggesting that GAT-2 mediates 17-AAG's antinociceptive enhancement. Since GAT-2 takes up GABA into the cell and reduces GABA activity, we hypothesized that an inhibitory GABA circuit is present in the spinal cord which reduces opioid

antinociception and is disabled by Hsp90 inhibition and GAT-2 upregulation. To test this GABA hypothesis, mice were treated with IT GABA-A or GABA-B agonists (muscimol, baclofen) prior to systemic morphine administration. The GABA-A agonist reversed 17-AAG enhanced antinociception much like NA, supporting our hypothesis. Intriguingly, the GABA-B agonist reversed 17-AAG antinociception in males but not females, suggesting a GABAergic sex-specific difference. To further test the inhibitory GABA circuit hypothesis, naïve mice (no 17-AAG) were injected with IT GABA-A or GABA-B antagonists (bicuculline, CGP54626) prior to morphine and tail flick. Males showed enhanced morphine antinociception with either antagonist, supporting the GABA inhibitory circuit hypothesis; however, neither drug had an impact on female mice, again suggesting mechanistic sex differences. These results taken together suggest that IT 17-AAG potentiates morphine-induced antinociception via upregulation of GAT-2, relieving an inhibitory GABAergic brake on opioid antinociception. This study provides mechanistic insight into how Hsp90 inhibitors can be used to boost opioid antinociception and may have identified a novel inhibitory circuit of opioid antinociception.

Title: Functional Consequences of Mu Opioid Receptor Pharmacogenomics

Authors: *L. LEE[1,2], A. HAUSER[2], J. ENGLISH[1];
[1]Univ. of Utah, Salt Lake City, UT; [2]Univ. of Copenhagen, Copenhagen, Denmark

Abstract: G-protein-coupled receptors (GPCRs) are a superfamily of 7-transmembrane protein receptors with diverse physiological functions in the human body. Targeted by >30% of all FDA approved drugs, GPCRs are critical targets of clinical intervention; however, human genome sequencing initiatives have revealed a number of high-frequency coding variations in drug-targeted GPCRs with uncharacterized pharmacological consequences. Recent evidence has highlighted that these mutations can fundamentally alter the intended pharmacology of the signal-ligand interaction and impact the GPCR transducerome profile, yet understanding the breadth of these variations is an emerging and still unmet need in clinical settings due to limitations in technology capable of translating pharmacogenomic impacts in-vitro to information of clinical significance. Among GPCRs, genetic variation in opioid receptors is of incredible pharmacogenomic significance due to their role in mediating neurotransmitter activity by both endogenous and exogenous ligand interactions. The potential hazards of uncharacterized mutations in opioid receptors is of particular importance with respect to the ongoing opioid

epidemic, as exogenous opioid compounds classically have analgesic properties yet pose a high risk for tolerance, dependence, and addiction in certain individuals. We are addressing this inscience with an optimized bioluminescence resonance energy transfer-based (BRET2) technology (TRUPATH) that is capable of methodically profiling GPCR pharmacological agents in real time. Our goal is to use TRUPATH to characterize the pharmacogenomic significance of human genetic variation in opioid receptors in-vitro and translate it into information that may be clinically relevant in understanding differences among opioid drug responses in patients. In this study, we assessed how common and previously unstudied mutations in the μ-opioid receptor alter the activity of endogenous and small molecule ligands. Drug- and dose-response activity was measured exclusively to the intended G-protein subfamily using robust tissue culture assays (N=3, n=4), and effects of opioid receptor mutations on the GPCR transducerome profile were analyzed and reported using standard controls and practices in the field of GPCR pharmacology. Preliminary interrogation of G-proteins that canonically bind to the μ-opioid receptors has shown that many high-frequency variants have altered receptor efficacy, potency, and transmutation of G-protein signaling identity, indicating that action of both endogenous and exogenous opioid compounds are perturbed by common μ-opioid receptor variants.

Title: Do sugars and artificial sweeteners activate identical subsets of gustatory sensory ganglion neurons?

Authors: *S. HAYOZ[1], G. DVORYANCHIKOV[1], W. M. CONNELLY[3], N. CHAUDHARI[1], *S. D. ROPER[2];
[1]Physiol. and Biophysics, [2]Dept. of Physiol. and Biophysics, Miller Sch. of Medicine, Univ. of Miami, Miami, FL; [3]Sch. of Medicine, Univ. of Tasmania, Hobart, Australia

Abstract: Sugars and artificial sweeteners activate the dimeric taste receptor, Tas1R2+Tas1R3, to elicit sweet taste. However, certain sugars such as glucose also stimulate taste cells by blocking K_{ATP} channels, following sugar uptake via SGLT1 and GLUT transporters and generation of ATP. Interestingly, independent of Tas1Rs, glucose uptake by taste cells initiates an important physiological reflex−cephalic phase insulin release (**CPIR**). Yet, the two transduction pathways (initiated by Tas1Rs or glucose transporters) co-exist in the same taste

receptor cells. This raises the question: how do certain sugars (e.g., glucose) activate an ascending pathway for perception (sweet) as well as initiate a medullary reflex (CPIR), whereas others (e.g., fructose) only evoke sweet perception? That is, do the two neural pathways diverge at the first central relay (neurons in the Nucleus of the Solitary Tract), or are there two distinct afferent sensory fiber types that innervate taste bud cells and transmit signals from the two transduction pathways? We used *in vivo* Ca^{2+} imaging of geniculate ganglion neurons in transgenic mice (n=68 neurons, 4 mice) that express GCaMP6s in these sensory neurons to test if separate geniculate ganglion neurons might subserve these two pathways. We tested (a) **fructose** and **sucralose** as activators only of Tas1Rs; (b) **glucose**, which is transduced by both pathways; and (c) **SolCarb**, a non-sweet oligosaccharide that activates only the K_{ATP} pathway. Concentration-response relations were obtained for each compound to determine isoeffective concentrations: 800 mM glucose, 800 mM fructose, 16 % SolCarb, and 1-2 mM sucralose. To obtain a broader view of the spectrum of taste-evoked responses in these geniculate ganglion neurons, we also tested a panel of 5 prototypic basic tastes: 10 mM citric acid (sour); 300 mM sucrose (sweet); 100 mM MSG + 1 mM IMP (umami); 250 mM NaCl (salt); and 1 µM cycloheximide + 0.3 mM quinine (bitter). Unexpectedly, only about half the geniculate neurons (32 out of 68 neurons) that responded to fructose, glucose, SolCarb, or sucralose also responded to sucrose. Moreover, glucose and SolCarb responses were consistently smaller (ΔF/F) and more transient than responses to sucrose and sucralose. Preliminary analyses suggest that a restricted subset of neurons may respond to glucose and SolCarb. Correlations across other sweeteners are in progress.

Title: Intergenerational inheritance of conditioned taste aversion

Authors: *C. W. LIFF[1], E. R. SHERMAN[1,3], E. C. JAEGER[1], R. AXEL[1,2], B. J. MARLIN[1,2]; [1]Zuckerman Inst., [2]Dept. of Neurosci., Columbia Univ., New York, NY; [3]Barnard Col., New York, NY

Abstract: Rationale: Following the Dutch Hunger Winter famine of 1944-1945, the children and grandchildren of survivors — who had not experienced this stress directly — exhibited elevated rates of both metabolic illness (e.g. obesity, diabetes) as well as adverse psychological outcomes (e.g. schizophrenia, anxiety). This phenomenon of physical or emotional trauma being transmitted to offspring via epigenetic modifications, called transgenerational epigenetic inheritance (TEI), is an intriguing mechanism by which a learned behavior in a parent can become an innate behavior in their offspring.
Dias and Ressler (2014) has demonstrated that pairing an odor with a foot shock leads to an increase in the number of olfactory sensory neurons expressing the receptor for the conditioned odor, in both the conditioned mice and their untrained offspring. This study examines whether a conditioned taste aversion (CTA) can also be inherited.
Methods: We utilize behavioral assays to manipulate flavor preferences in male C57BL/6J mice (F0) and their offspring (F1). To produce CTA, we pair consumption of 5.5mM saccharin with injection of either lithium chloride (LiCl), which induces nausea, or PBS. The treated males are mated with female C57BL/6J mice and removed from the cage before the litter is born to prevent father-offspring interaction. The males' saccharin preferences are tested in a 10-minute 2-bottle test, measuring how much time they spend drinking from saccharin v. water. The offspring are exposed to 5.5mM saccharin for 5h to eliminate neophobia effects, and later given the same 2-bottle test.
Results: Our results demonstrate a highly significant difference ($p<0.0001$) between the saccharin preferences of F0 PBS-injected and LiCl-injected male mice, with PBS mice exhibiting a preference for saccharin and LiCl mice showing a strong aversion (F0 PBS n = 12, F0 LiCl n = 11). We have also found a very significant difference ($p=0.0002$) between the saccharin preferences among the offspring of PBS-paired fathers and LiCl-paired fathers, with the F1 of LiCl males demonstrating an innate aversion to what is innately appetitive in controls (F1 PBS n = 12, F1 LiCl n = 23).
Conclusions: The brain's memory of trauma is much more complex than the memory of a single sense during a traumatic event. While instances of TEI have been demonstrated in the olfactory system in mice, there is limited evidence of this phenomenon in other sensory systems. This project elucidates whether this mechanism of epigenetic inheritance is also inherent in the gustatory system. Furthermore, an understanding of how to intervene when these adaptations no longer benefit the offspring would be of immense translational value.

Title: Integration and segregated processing in the Drosophila taste circuit

Authors: J. U. DEERE, H. A. UTTLEY, N. MARTINEZ SANTANA, ***A. V. DEVINENI**; Zuckerman Mind Brain Behavior Inst., Columbia Univ., New York, NY

Abstract: The taste system is essential for regulating feeding. Sweet-sensing neurons promote the consumption of sugar, while bitter-sensing neurons inhibit feeding to prevent the ingestion of potential toxins. In Drosophila, each taste modality comprises multiple channels of sensory input - neurons that reside in different organs or express different combinations of taste receptors. How are these multiple channels of input translated into behavioral output? One possibility is that different input channels converge in the brain and elicit the same behaviors, reflecting an "integrative model". Alternatively, different input channels may activate separate pathways to regulate distinct behaviors, a "segregated processing" model.
We first used optogenetic activation to characterize how sweet and bitter inputs influence behaviors beyond feeding. Activating sweet- or bitter-sensing neurons elicited opposing effects on locomotion, positional preference, and associative learning. Next, we activated different subsets of bitter sensory neurons. Each neuronal subset influenced multiple behaviors and each behavior was affected by multiple subsets, with the strongest effects observed only when all bitter neurons were activated. These results support an integrative model in which multiple channels of bitter input are integrated to regulate a diverse set of behaviors.
To test whether this integration occurs early in the taste circuit, we used trans-synaptic tracing to label downstream second-order bitter neurons that receive input from bitter sensory cells. These experiments revealed multiple types of second-order bitter neurons projecting to distinct brain regions. We imaged the activity of one type and found that it integrates bitter input from multiple organs. Optogenetic manipulations showed that these neurons regulate feeding, but not other behaviors such as locomotion, preference, and learning. Thus second-order neurons integrate across multiple channels of bitter input, but have segregated outputs that regulate distinct behaviors. The integration of inputs enables the circuit to pool sensory information, whereas segregated outputs could allow for different behaviors to be differentially modulated by context or state.

Title: Human similarity judgements of appetizing foods include estimates of sweetness and caloric density

Authors: *M. CARRINGTON[1], A. LIU[1], J. AVERY[1], C. ZHENG[2], L. MUTTENTHALER[3], F. PEREIRA[2], A. MARTIN[1];
[1]Lab. of Brain and Cognition, [2]Machine Learning Core, Natl. Inst. of Mental Hlth., Bethesda, MD; [3]Vision and Computat. Cognition Group, Max Planck Inst. for Human Cognitive and Brain Sci., Leipzig, Germany

Abstract: Food-related scientific studies often select food items to include based on specific criteria, such as relative levels of fat and sugar content, and use these categorizations for further analyses. While they frequently make intuitive sense, it is unclear whether these lab-generated groupings align with the ways in which individuals naturally compare different foods. Hebart et al., (2020) used a simple 'odd-one-out' triplet task to collect similarity judgements of a wide variety of common objects. From these data, they were able to identify the most salient dimensions underlying the similarity judgements of these objects and used them to create categories. In our study, participants on Amazon Mechanical Turk performed this "odd-one-out" triplet task on a variety of food images. We used 36 images in total that had been selected to be evenly distributed among 4 categories based on high or low levels of fat and sugar (high fat high sugar, high fat low sugar, etc). Out of 7,140 possible triplets, each participant rated 20. We collected two full sets of triplet data from a total of 487 unique participants. The similarity matrices of these two sets were highly similar ($r = 0.91$, $p < 0.001$), thus allowing us to combine the two sets. Multi-dimensional scaling of the resulting similarity matrix and k-means clustering revealed five emergent food groupings: sweets, fats, starches, fruits, and vegetables. A subsequent Principal Components Analysis indicated that the first two components accounted for approximately 75% of the variability of the data. The first component was significantly related to the caloric density of the foods, rather than fat content specifically ($r = 0.88$, $p < 0.001$), while the second component was significantly related to sugar content ($r = -0.63$, $p < 0.001$). A Non-Negative Matrix Factorization (NNMF) analysis of f sparse non-negative embeddings learned from the triplet data revealed a similar categorization of the foods used in our dataset. Our results suggest that naturalistic categorizations may differ from lab-generated groupings and that these differences should be considered and explored when developing methods for scientific food studies. Avery et al (2021) previously established that it is possible to use fMRI to decode the inferred taste of food pictures within cortical taste-responsive regions. Future studies might explore whether a similar decoding approach could be used to identify the neural substrates associated with the emergent food categories that we identified.

Title: The role of cortical D1R-expressing neurons in taste-based sensorimotor transformations

Authors: *J. CHEN, A. FONTANINI;
Dept. of Neurobio. & Behavior, SUNY Stony Brook, Stony Brook, NY

Abstract: To survive, animals must use gustatory stimuli to guide oromotor behaviors like licking and chewing. The anterior-lateral motor cortex (ALM) is involved in the genesis of sensorimotor decisions related to licking. Although licking and taste are invariably linked, it remains unknown if ALM plays a role in taste-based decisions, and how the underlying circuits are modulated during this process. One candidate mechanism for taste-based sensorimotor transformations involves dopamine transmission through D1 receptor (D1R). Blockade of D1R signaling within ALM affects both sensory cue-evoked responses and motor planning of licking, suggesting a potential role for D1R-expressing (D1R+) neurons in sensorimotor decisions related to licking. We tested the hypothesis that D1R+ neurons in ALM exhibit patterns of activity that represent taste cues and preparation of licking, and that these specific and distinct representations are required to drive lick decisions during a taste-guided 2-alternative choice (2-AC) task. In this task, mice must use distinct taste cues to guide different licking actions (lick left vs lick right) after a delay period. To monitor activity of D1R+ neurons during the task, 2-photon calcium imaging was performed using transgenic D1R reporter mice to identify and record populations of D1R+ neurons located in the superficial layers (L1, L2/3, z < 350 um) and deep layers of ALM (L5 z > 350 um) of ALM. We found that individual D1R+ neurons in both laminar locations exhibit responses to specific taste cues, preparatory activity predicting licking direction and coding of reward presentation during the response period. The majority of taste and lick direction coding occurred during the sampling and delay periods of the task, respectively. D1R+ neurons in the deep layers showed weaker tuning for taste and lick direction during these behavioral periods, suggesting differential coding of task variables based on cell-type and laminar location. To determine if and when activity of D1R+ neurons, in both superficial and deep layers, is required to generate taste-based lick decisions, we will rely on optogenetics to bilaterally silence D1R+ neurons during different behavioral periods of the 2-AC task. We expect silencing D1R+ neurons during the delay will produce motor deficits in licking execution and duration as found previously. In addition, we anticipate a decrease in task performance when D1R+ neurons are inhibited during the sampling or delay periods of the task, indicative of their critical role in taste-guided licking. Altogether, these findings will provide novel understanding of the link between gustatory decision-making and neurons expressing D1Rs.

Title: Serotonergic neurons translate taste detection into internal nutrient regulation

Authors: *Z. YAO, K. SCOTT;
Univ. of California, Berkeley, Berkeley, CA

Abstract: The nervous and endocrine systems coordinately monitor and regulate nutrient availability to maintain energy homeostasis. Sensory detection of food regulates internal nutrient availability in a manner that anticipates food intake, but sensory pathways that promote anticipatory physiological changes remain unclear. Here, we identify serotonergic (5-HT) neurons as critical mediators that transform gustatory detection by sensory neurons into the activation of insulin-producing cells and enteric neurons in *Drosophila*. One class of 5-HT neurons responds to gustatory detection of sugars, excites insulin-producing cells and limits consumption, suggesting that they anticipate increased nutrient levels and prevent overconsumption. A second class of 5-HT neurons responds to gustatory detection of bitter compounds and activates enteric neurons to promote gastric motility, likely to stimulate digestion and increase circulating nutrients when food quality is poor. These studies demonstrate that 5-HT neurons relay acute gustatory detection to divergent pathways for longer-term stabilization of circulating nutrients.

Title: Taste Response Profiles of Nodose/Petrosal Ganglia Neurons

Authors: *B. FOWLER, S. HUMAYUN, L. MACPHERSON;
Univ. of Texas, San Antonio, San Antonio, TX

Abstract: In vivo calcium imaging of the geniculate ganglion has provided a way to categorize the response profiles of individual neurons to taste stimuli. Neurons of the geniculate ganglion innervate the fungiform papillae (FP) of the anterior tongue via the chorda tympani. The circumvallate (CV) papillae in the posterior tongue are innervated through the glossopharyngeal nerve by a separate population of neurons housed in the nodose/petrosal ganglion complex. Here we used in vivo calcium imaging approaches to determine the responses of nodose/petrosal neurons to taste stimuli, and to determine if this population differs from the geniculate ganglion. To image the activity of geniculate and nodose/petrosal neurons to taste stimuli, we used transgenic animals of both sexes expressing GCaMP6s under the Snap25 promoter. We surgically exposed the ganglia and imaged the GCaMP fluorescence changes while perfusing the tongue with a panel of taste stimuli. Comparing the nodose/petrosal taste response profiles to those obtained from the geniculate ganglion showed significant differences in the proportion of neurons responding to some classes of taste stimuli. In the nodose/petrosal, a smaller proportion of neurons respond to sweet, while larger percentages of neurons respond exclusively to bitter or umami tastants. No significant differences in the proportions of neurons responding to sour, or multiple stimuli were observed. Additional calcium imaging experiments were conducted to determine if high salt concentrations recruit responses from bitter and sour responding nodose/petrosal neurons. We find that a greater proportion of taste-activated nodose neurons respond to bitter and umami tastants compared to those of the geniculate ganglion. These data support previous experiments showing enhanced responses to bitter and umami stimuli in glossopharyngeal nerve recordings. Further research will address whether these differences in taste responses from the front and back of tongue are important for signaling reward or aversion, if they serve as preparatory signals to digestion, or a combination.

Title: Ancillary autonomic changes accompanying mechanical neuromodulation for migraine and trigeminal neuropathy pain

Authors: *V. LUBERA[1], R. K. HARPER[1], D. N. SNODGRASS[2], R. L. MERRILL[3], E. SAUERLAND[4], R. M. HARPER[1];
[1]Neurobio., [2]Auditory Clin., [3]Orofacial Pain, UCLA, Los Angeles, CA; [4]Physiol. and Cell Biol., Univ. of Nevada, Reno, NV

Abstract: Non-invasive, mechanical neuromodulation of sensory fields of cranial nerves V, VII, IX, and X, and cervical nerves C2 and C3 sited near the auditory canal reduces acute migraine and trigeminal neuropathy pain. Several of these cranial nerves are accompanied by autonomic fibers which are also activated by neuromodulatory stimulation. While evaluating vibratory stimulation effectiveness, autonomic responses appeared in addition to pain resolution; these included heart rate slowing, increased respiratory-related heart rate variation, and blood pressure normalization. However, other autonomic aspects appeared, principally related to secretory gland outflow; we evaluated that expression.
All procedures were approved by the UCLA Institutional Review Board. Neuromodulatory devices consisted of bilateral silicon impressions of the auditory canals, each containing a vibration device which reached the cranial and cervical sensory fields within the auditory canals and pinnae. Subjects with diagnosed migraine or trigeminal neuropathy pain (N=56, female=37, male=18) were referred by UCLA or Mayo Clinic neurologists or pain specialists and subjected to 5 min sham, 15 min low, and 10 min high amplitude vibration, and a second 10 min sham vibration to affected nerves. Pain was reduced (Mean= 5.7 pre-stimulation, 1.8 post-stimulation ($p < 0.0001$) on (0-10 pain scales).
Increased activation of secretory tissue appeared, particularly nasal, oral, and lacrimal secretions. Of the 56 subjects evaluated, over half of subjects showed one or more increased secretions; the most common being increased oral saliva expression, followed by enhanced nasal discharge and lacrimal outflow. The salivary secretions, unlike lacrimal actions, were sustained for several days.The oral secretions were perceived as beneficial; trigeminal neuropathy pain is commonly accompanied by xerostomia which is associated with loss or altered taste, disturbed olfaction, increased dental caries, demineralization of teeth, opportunistic infections, impaired swallowing, and bad breath. The intervention for migraine was accompanied by enhanced parasympathetic-regulated secretory expression, with oral secretions more frequently affected. The preferential effects on saliva most likely derive from the major influences on trigeminal sensory fields on the pinnae and auditory canals; the trigeminal fibers are accompanied by autonomic nerves targeting ganglia of the head. The intervention offers a low-cost, drug-free, and simple means to overcome xerostomia.

Title: Methyl CpG Binding Protein 2 Knockout in Auditory Cortex Parvalbumin Cortical Interneurons Alters Temporal Structure of Responses to Ultrasonic Vocalizations

Authors: *D. D. RUPERT[1,2], A. H. PAGLIARO[1], S. D. SHEA[1];
[1]Cold Spring Harbor Lab., Cold Spring Harbor, NY; [2]Med. Scientist Training Program, Stony Brook Univ., Stony Brook, NY

Abstract: Rett Syndrome (RTT) is a pervasive, neurodevelopmental disorder previously classified as a syndromic form of Autism Spectrum Disorder. Unlike ASDs, RTT is monogenic- caused by loss of function mutations in the X-linked gene methyl CpG binding protein 2 (*MeCP2*). *MeCP2* codes for the protein by the same name, a ubiquitously expressed transcription factor with a known role in the plasticity of mature synapses. In humans with Rett syndrome, and in corresponding animal models, tissues comprise a mosaic pattern of cells expressing normal MeCP2 and those with absent expression. Whether certain cell-types within that mosaic contribute more or less to phenotypic characteristics is unknown. We previously reported that adult animals that are heterozygous for *Mecp2* mutation demonstrate impaired auditory processing characterized by altered responses of auditory cortex (ACtx) cells to ultrasonic vocalization (USV) playbacks, and upregulation of anti-plasticity molecular markers by those cells. Here we hypothesized that aberrant audition may result in the relative dependence of ACtx, inhibition interneurons on MeCP2. **That is, our goal was to determine the contribution of cell-type specific *Mecp2* mutation to disruptions of auditory cortical circuitry and plasticity that degrade social vocal perception.** To achieve this goal, we used conditional (cell-type restricted) *Mecp2* mutant mouse models in combination with a pup retrieval assay- an ethologically relevant, auditory-dependent behavior; pup retrieval is cued by ultrasonic vocalizations (USVs)- high-pitched distress calls emitted by isolated infants. We report the consequences of cell-type restricted *Mecp2* knockdown on that behavior, single-unit *in vivo* neural circuit activity of excitatory and inhibitory populations, and calcium imaging of ACtx, parvalbumin cells. Our findings expand our understanding of ACtx plasticity in neurotypically developing animals, cell-type specific contributions to that plasticity, and how it is affected by *Mecp2* mutation.

Title: Age-related changes in excitatory and inhibitory intra-cortical circuits in mouse primary auritory cortex

Authors: *B. XUE[1], X. MENG[2], J. KAO[3], P. KANOLD[1];
[1]Johns Hopkins Univ., Baltimore, MD; [2]Biol., Univ. of Maryland, College Park, MD; [3]Physiol., Univ. of Maryland, Baltimore, MD

Abstract: A common impairment in aging is age-related hearing loss (presbycusis), which manifests as impaired spectrotemporal processing. Aging is accompanied by alteration in normal inhibitory (GABA) neurotransmission, and changes in excitatory (NMDA and AMPA) synapses in the auditory cortex (ACtx). However, the circuit mechanisms responsible for age-related hearing loss remain unknown. Here we investigated how auditory cortical microcircuits change with age. We performed laser scanning photostimulation (LSPS) combined with whole-cell patch clamp recordings from Layer (L) 2/3 cells in primary auditory cortex (A1) in young adult {postnatal day (P) 30-45} and aged (P370-P443) C57BL/6J mice. We found that L2/3 cells in aged animals display functional hypoconnectivity of both excitatory and inhibitory circuits. Compared to cells from young adult mice, cells from aged mice have fewer excitatory connections with weaker connection strength. Whereas young adult and aged animals have similar amounts of inhibitory connections, the strength of local inhibition is weaker in the aged group. We confirmed these results by recording
miniature excitatory (mEPSCs) and inhibitory synaptic currents (mIPSCs), which showed a reduction in mEPSC amplitude and frequency but only a reduction in mIPSC amplitude in the aged group. These results suggest a specific reduction in excitatory and inhibitory intralaminar cortical circuits in aged mice compared with young adult animals. We speculate that these unbalanced changes in cortical circuits contribute to the functional manifestations of age-related hearing loss.

Title: The role of fragile X mental retardation protein in cellular and synaptic dynamics of developing auditory circuits

Authors: *X. YU, Y. WANG;
Dept. of Biomed. Sciences, Program in Neurosci., Florida State Univ. Col. of Med., Tallahassee, FL

Abstract: The establishment of central sensory systems is influenced by afferent experience during development. In the auditory system, hearing loss at young ages leads to neuronal cell loss and circuit reorganizations, yet the responsible molecular players have not been identified. We addressed this question by investigating the neuropathology of fragile X syndrome (FXS), a leading genetic cause of neurodevelopmental disorders with prominent auditory dysfunction. FXS results from a loss of fragile X mental retardation protein (FMRP) encoded by Fmr1 gene. Studies of Fmr1 knockout (KO) rodents revealed abnormal circuit development and altered neuronal plasticity in the auditory system. However, little is known about how FMRP regulates neuronal integrity and synaptic connectivity in response to changes in afferent input. This study aimed to determine the consequences of FMRP absence in auditory processing, with and without intact afferent input, during early development. We first examined afferent-regulated neuronal integrity in the ventral cochlea nucleus (VCN), the first brain station of auditory afferent input. In wildtype (WT) mice, VCN exhibited a critical period (CP) of neuronal cell loss following afferent deprivation, showing 30% cell loss if the deprivation occurred within the first postnatal (P) 11 days but no cell loss if it was induced later. We found the presence of a CP and a comparable level of cell loss within the CP in *Fmr1* KO mice. However, the timing of CP closure was significantly delayed in *Fmr1* KO mice, evident by substantial cell loss following afferent deprivation at P14, an age beyond the CP in WT. Next, we examined synaptic development and plasticity in the medial nucleus of the trapezoid body (MNTB), which receives the excitatory input from the VCN and serves as an inhibitory station in the auditory brainstem. In WT mice, we discovered a distinct topographic gradient in the level of several key synaptic proteins before P7 and this gradient was not significant after hearing onset at P10-12. *Fmr1* KO mice exhibited a delayed progress of this developmental event. Following afferent deprivation, WT mice showed a significant increase in the density of inhibitory synapses on MNTB neurons. This response was diminished in *Fmr1* KO mice, demonstrating a requirement of FMRP for inhibitory synaptic plasticity. Finally, using auditory brainstem responses as a functional assessment of hearing ability, we revealed an impair hearing sensitivity in *Fmr1* KO mice at P14. Together, these findings demonstrate that FMRP is required for selective aspects of afferent-regulated neuronal dynamics in the auditory brainstem at cellular, connective, and functional levels.

Title: Faulty GABAergic inhibition and perineuronal net integrity in the inferior colliculus of subjects with schizophrenia

Authors: *V. W. KILONZO[1], R. A. SWEET[2], J. R. GLAUSIER[2], M. W. PITTS[1];
[1]Dept. of Cell and Mol. Biol., Univ. of Hawaii, Honolulu, HI; [2]Dept. of Psychiatry, Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Aberrant processing of auditory stimuli is a prominent feature of schizophrenia (SZ). Prior studies have chronicled histological abnormalities in the auditory cortex of SZ subjects, but whether deficits exist at upstream, subcortical levels has yet to be established. En route to the auditory cortex, ascending information is integrated in the inferior colliculus (IC), a highly gamma-aminobutyric acid (GABA) ergic midbrain structure that is critically involved in auditory processing. The IC contains a dense population of parvalbumin-immunoreactive interneurons (PVIs), a cell type characterized by increased metabolic demands and enhanced vulnerability to oxidative stress. During development, PVIs are preferentially surrounded by perineuronal nets (PNNs), specialized extracellular matrix structures that promote redox homeostasis and excitatory/inhibitory balance. Moreover, in SZ, deficits in PVIs, PNNs, and the GABA synthesizing enzyme, glutamic acid decarboxylase (Gad67), have been extensively documented in cortical regions. Yet, whether similar impairments exist in the IC is currently unknown. Thus, we compared IC samples of age- and sex-matched pairs of SZ and unaffected control subjects. SZ subjects exhibited lower levels of Gad67 immunoreactivity and a decreased density of PVIs and PNNs within the IC. These findings provide the first histological evidence of IC GABAergic abnormalities in SZ and suggest that SZ-related auditory dysfunction may stem, in part, from altered IC inhibitory tone.

Title: Vip+ interneurons modulate tinnitus-related hyperactivity of A1 L5 pyramid neurons

Authors: *M. GHIMIRE, R. CAI, L. LING, K. BROWNELL, D. M. CASPARY;
Pharmacol., Southern Illinois Univ. Sch. of Med., Springfield, IL

Abstract: Tinnitus, commonly referred to as ringing in the ear, is believed to reflect maladaptive plastic changes at various levels of the central auditory pathway. Primary auditory cortex (A1) houses complex microcircuitry of excitatory and inhibitory neurons, responsible for higher order processing and integration of auditory information. Deeper layers of A1 are believed to be engaged in top-down modulation of ascending signals, as well as the cortico-cortical auditory processing. The net excitability of Layer (L) 5 pyramid neurons (PNs) is modulated by a delicate balance of excitation, inhibition and disinhibition. Vasoactive intestinal polypeptide positive (VIP+) interneurons serve as a key regulator of PN excitability via disinhibitory mechanisms. The impact of tinnitus on the intrinsic properties of A1 L5 PNs and VIP+ neurons is the focus of the present study. Using a well-established condition-suppression animal model of tinnitus, we hypothesize that: 1) changes in intrinsic properties and neurotransmission underpin the tinnitus-related hyperactivity of A1 L5 PNs; and 2) tinnitus-related altered VIP+ neuronal function indirectly contributes to PN hyperactivity underpinning tinnitus pathology. In the present study, wild type and VIP*TdTomato Long Evens (LE) rats were unilaterally sound exposed for 1 hour, to an octave band noise centered at 16 kHz frequency. Three months following noise exposure, most exposed rats show psychophysical evidence of tinnitus which persists throughout their lifetime. Both group of animals were classified as control and exposed tinnitus based on their exposure history and tinnitus score. Animals were used to perform whole cell patch clamp recordings from A1 L5 PNs and VIP+ neurons, and spontaneous and evoked responses were recorded from these neurons. A1 L5 PNs showed a significant tinnitus-related increase in spontaneous and evoked, pre- and post-synaptic excitatory currents. Additionally, we observed a tinnitus-related decrease in spontaneous and evoked, pre- and post-synaptic inhibitory currents. Increased glutamatergic excitability was mostly polysynaptic, suggesting involvement of local microcircuitory in tinnitus pathology. VIP+ neurons in A1 were found to be significantly depolarized, with smaller rheobase current and increased excitability in tinnitus animals. VIP+ neurons when activated, are known to depolarize the PNs, and increase their excitability. In conclusion, we report that changes in intrinsic properties and neurotransmission underpin tinnitus related hyperactivity of A1 L5 PNs, and these changes, in part, reflect tinnitus-related maladaptive plastic changes in VIP+ neuronal function.

Title: Comparison of Active Avoidance and GPIAS for Tinnitus Assessment in Mice

Authors: E. FABRIZIO-STOVER[1], A. L. BURGHARD[2], C. M. LEE[1], *D. L. OLIVER[3]; [1]Neurosci., Univ. of Connecticut - UCONN Hlth., FARMINGTON, CT; [2]Univ. of Connecticut Hlth. Ctr., Farmington, CT; [3]Neurosci., Univ. of Connecticut, Farmington, CT

Abstract: Tinnitus, a phantom perception of sound with no external auditory stimulus, is experienced by over 15 million Americans. Research towards new treatments for tinnitus can be expensive and time-consuming due to the behavioral training needed to assess laboratory animals for tinnitus. There are several different behavioral tests for tinnitus, but little direct comparison of these tests. CBA/CaJ mice were trained in two types of tinnitus behavioral tests: the gap-induced pre-pulse inhibition of acoustic startle (GPIAS) and an active avoidance (AA) test (n=19). Additional mice were only trained in one test (AA n=8, GPIAS n=18). Tinnitus was induced in awake mice by a unilateral continuous sound exposure using a 2 kHz wide, 16 kHz centered noise at 113- or 116-dB SPL. Behavioral testing was repeated 8 weeks after sound exposure to determine tinnitus frequency. Of sound exposed mice trained in both tests, the majority (63%, n=12) showed tinnitus behavior in at least one of the two tests. Evidence of tinnitus was found in 50% (n=4) of mice trained only in AA and 33% (n=6) of GPIAS-tested mice. When mice were tested with both methods, 37% (n=7) did not show any evidence of tinnitus behavior. However, 52% (n=10) were positive in AA, while only 26% (n=5) were positive in GPIAS. Only 15% (n=3) mice were positive in both tests and only 5% (n=1) were positive in both tests at the same tinnitus frequency. Spontaneous firing rates of neurons in the inferior colliculus were collected from the tinnitus positive and negative mice. Neurons were sorted based on the characteristic frequency (CF), and the spontaneous activity of neurons with the CF at 16 kHz was compared to those with CFs above and below. In mice tested in AA, if the CF was higher than the exposure frequency, the spontaneous firing was higher in tinnitus-positive mice than in tinnitus-negative mice. This pattern was not evident in mice tested with GPIAS. These results suggest that the GPIAS and AA tests are not equally valid for diagnosing tinnitus in mice, as they do not often show the same frequencies of deficit. Furthermore, increased spontaneous rate, shown to be increased in the IC in tinnitus mice (Berger & Coomber, 2015) is associated with the AA behavioral test. This suggests that the AA test may be a more reliable behavioral measure of tinnitus.

Title: A first-in-human study of OTO-413, an intratympanic sustained-exposure formulation of BDNF, for the treatment of hearing loss

Authors: V. SANCHEZ[1], J. M. ROBINSON[2], A. C. FOSTER[2], J. GULL[3], P. G. VOLSKY[4], D. MOORE[5], J. J. ANDERSON[2];
[1]Univ. of South Florida, Tampa, FL; [2]Otonomy, Inc., California, CA; [3]ENT Specialists, Salt Lake City, UT; [4]Eastern Virginia Med. Sch., Norfolk, VA; [5]Cincinnati Children's Hosp., Cincinnati, OH

Abstract: Synaptic connections between inner hair cells (IHCs) and type 1 spiral ganglion neurons (SGNs) in the cochlea may be lost after noise exposure and with aging, even without notable hair cell damage. Loss of cochlear synapses in the absence of changes in auditory thresholds has been proposed as a mechanism of speech-in-noise hearing impairment and may be one of the earliest manifestations of sensorineural hearing loss. Treatment with brain-derived neurotrophic factor (BDNF) repairs synaptic processes and restores hearing function in animal models. OTO-413, a thermo-sensitive formulation of BDNF which provides sustained exposure of BDNF to the cochlea after intratympanic (IT) administration, is under clinical evaluation for the treatment of hearing loss. This was a randomized, double-blind, placebo-controlled Phase 1/2 study. Men and women aged 21-64 years were enrolled between December 2019 and August 2020. Pure tone thresholds ranged from normal levels to moderately severe hearing loss (PTA of ≤ 70 dB at 1, 2, and 4 kHz). Subject's self-reported difficulty hearing in noise was confirmed by Digits-in-Noise (DIN) test scores greater than -12.5 dB signal-to-noise ratio (SNR) in the study ear. Four ascending dose-cohorts of at least 8 subjects each received a single IT injection of OTO-413 or placebo. Safety and hearing function were monitored over a 12-week follow-up. Hearing assessments included DIN, Words-in-Noise (WIN) test, and American English Matrix test (AEMT). OTO-413 was well-tolerated across all dose cohorts (n = 29) with similar frequency of adverse events compared to placebo (n = 10). There were no serious adverse events. Six of 9 (67%) subjects treated with the highest dose of OTO-413 (0.30 mg) showed a clinically meaningful improvement on at least one of the three speech-in-noise tests at both Day 57 and 85 versus 0 of 8 (0%) for placebo. A clinically meaningful improvement was defined as a minimum change of -3 dB SNR (DIN) or -2 dB SNR (WIN and AEMT). Performance on the sentence-based AEMT favored OTO-413, with 4 of 9 (44%) OTO-413 subjects experiencing a clinically meaningful improvement at both Day 57 and 85 compared to 0 of 7 (0%) placebo subjects at any single timepoint. These results demonstrate safety of OTO-413 and suggest therapeutic benefit

over placebo in a small sample size. These findings support further clinical development of OTO-413 for the treatment of hearing loss.

[1]Otonomy, Inc., San Diego, CA; [2]Piedmont ENT, Winston-Salem, NC; [3]Advanced ENT & Allergy Associates, Louisville, KY; [4]Univ. of Auckland, Auckland, New Zealand; [5]Univ. of Nottingham, Nottingham, United Kingdom

Abstract: Tinnitus, a perception of sounds without a correlated external auditory stimulus, is widely prevalent and often associated with distress. Excessive activation of NMDA receptors within the hair cell complex due to noise or other cochlear insults may be of particular importance in altering activity of the auditory nerve and generating subjective tinnitus. OTO-313 is a lipid-based formulation of the potent and selective NMDA receptor antagonist gacyclidine that provides sustained exposure to the cochlea after a single intratympanic (IT) injection. The safety, plasma pharmacokinetics (PK), and exploratory efficacy of OTO-313 was evaluated in a randomized, double-blind, placebo-controlled, Phase 1/2 study. An initial safety and plasma PK cohort of 8 patients with tinnitus received a single IT injection of either 0.11 mg OTO-313 or placebo (PL). A follow-on exploratory efficacy cohort included 35 patients with unilateral tinnitus of moderate to severe intensity (score of $\geq$ 25 on the Tinnitus Functional Index [TFI]) and a duration of tinnitus of 1 to 6 months since onset. Following a 2-week lead-in period, patients received a single IT injection of either 0.32 mg OTO-313 or PL (1:1). Safety and exploratory efficacy (TFI, daily ratings of tinnitus loudness and annoyance, and PGIC) were evaluated over an 8-week follow-up period. OTO-313 was well-tolerated with a lower incidence of adverse events than placebo. In the exploratory efficacy cohort, the mean TFI reduction from baseline trended in favor of OTO-313 at each timepoint (Day 15: -9.3 points OTO-313 vs -4.1

points PL; Day 29: -9.4 points OTO-313 vs -6.6 points PL; Day 57: -12.9 points OTO-313 vs -4.3 points PL). A clinically meaningful, 13-point improvement on the TFI was observed in 43% (6/14) of OTO-313 patients at both Day 29 and Day 57 versus 13% (2/16) of PL patients (*adhoc* p-value < 0.05). Treatment with OTO-313 led to reduction in the daily ratings of tinnitus loudness and annoyance as well as improved PGIC scores. Among responders, strong correlation was observed between the various endpoints in favor of OTO-313. Plasma concentrations of gacyclidine were below the limit of assay quantitation (≤ 0.1 ng/mL) confirming limited systemic exposure. These findings demonstrate safety and exploratory efficacy of OTO-313 and support further clinical development for the treatment of tinnitus.

Title: Ultrahearing: stimulation with complex signals via ultrasound for a new type of hearing technology

Authors: *G. RODRIGUEZ ORELLANA, J. BASILE, H. H. LIM;
Biomed. Engin., Univ. of Minnesota, Minneapolis, MN

Abstract: Ultrasound stimulation (US) is an exciting new technique to noninvasively modulate neural activity with high spatial precision. However, recent studies have demonstrated that US, when coupled to the subject, induces activation of the auditory system. Guo et al. (Neuron, 2018) have provided convincing data that the method of activation is via a fluid pathway, in which the ultrasound waves induce vibrations of the cerebrospinal fluid and travel into the cochlea via the cochlear and vestibular aqueducts. This finding suggests that the stimulus will have different

characteristics from traditional air- and bone-conduction stimuli. Recent work in our lab has demonstrated that amplitude-modulated ultrasound signals can effectively encode and transmit information relevant for sound perception. However, these experiments have been limited to pure-tone modulations, and thus the range and information capacity of ultrasound is still unknown.
In this study, we investigated the neural activity in response to complex signals transmitted via bone-, air-, and fluid-conduction (ultrasound). For this purpose, we used a rich library of 11 different guinea pig vocalizations that have been used in previous published research. To create the ultrasound stimuli, vocalizations were upsampled, the envelope was extracted using the Hilbert transform, and then used to modulate a 220 kHz sinusoid carrier. Neural activity was recorded using a two-shank 32-channel NeuroNexus electrode array placed in the inferior colliculus (ICC) of five young and female, anesthetized guinea pigs. A B-81 bone conduction device was coupled to the animal as described by Curthoys et al.(Exp Brain Res, 2006). In response to the stimuli, we created post-stimulus time histograms (PSTHs) to assess multi-unit activity and identify the temporal behavior of the neural responses. We utilized the Earth Mover's Distance metric to compare different PSTHs.
Our results demonstrate that ultrasound can encode complex signals. ICC activity reliably followed the envelope, including fast temporal transitions, particularly ICC regions that encode for high frequencies. PSTHs in response to ultrasound and air stimuli have a high degree of similarity, when the same signal is presented via both modalities; however, PSTHs in response to bone conduction differed significantly. Further analyses will explore and quantify the differences between the response of these stimulation modalities. Better understanding of ultrasound stimuli on the auditory system can help guide the development of next-generation hearing devices in addition to combination technologies levering different stimulation modalities.

Title: Fibre-specific white matter structural abnormalities differentiate acoustic neuroma patients with one-sided hearing loss from individuals with normal hearing

Authors: *P. M. TSAI[1,2], T. H. LATYPOV[1,2], P. S.-P. HUNG[1,2], J. RUTKA[3], K. A. GORDON[2,5,3], M. HODAIE[1,2,4];
[1]Krembil Res. Inst., Univ. Hlth. Network, Toronto, ON, Canada; [2]Inst. of Med. Sci., [3]Otolaryngology - Head and Neck Surgery, [4]Div. of Neurosurg., Univ. of Toronto, Toronto, ON, Canada; [5]Neurosci. and Mental Hlth., The Hosp. for Sick Children, Toronto, ON, Canada

Abstract: Objectives
Acoustic neuroma (AN) tumours are a chief cause of one-sided hearing loss in adults. One-sided hearing loss results from auditory nerve compression by the tumour at the pontine level of the brainstem. Treating one-sided hearing loss will require identifying targets of white matter nerve fibre abnormalities above the tumour site. We used a state-of-the-art technique called a "fixel-based analysis" to identify fibre-specific, or "fixel"-level differences in white matter structure between AN patients with one-sided hearing loss and individuals with normal hearing (NH). We hypothesized wide-spread abnormalities in white matter structure in the AN group.
Methods
Diffusion-weighted MRI data was collected from left- and right-sided AN patients treated at the Toronto Western Hospital, and NH healthy controls tested at Toronto Western. The fixel-based analysis was used to identify microstructural differences in nerve fibre density (FD), macrostructural differences in fibre cross-section (FC), and changes in a combined metric of density and cross-section (FDC) between groups. Pure-tone audiometry (PTA) scores were used to identify ipsilateral and contralateral hearing thresholds for each AN patient.
Results
We included 138 subjects, with left- (n = 48; 21 men and 27 women; mean age ± SD: 57.3 ± 12.3 years) and right-sided (n = 44; 19 men and 25 women; mean age ± SD: 59.0 ± 13.1 years) surgically naive AN patients, and NH healthy controls (n = 46; 24 men and 22 women; mean age ± SD: 54.0 ± 11.7 years). PTA scores prior to surgery were collected for 75/92 AN patients, and were significantly poorer at the ipsilateral ear compared to the contralateral ear in this group ($p < 0.05$). Whole-brain fixel-based analysis accounting for age and sex between either right- or left-sided AN patients and NH healthy controls showed increased FD, FC, and FDC ($p < 0.05$) within non-auditory cortical and brainstem tracts for the AN patients. There were no relationships between duration or severity of hearing loss with the combined fibre density and cross-section metric at each significant tract identified with the fixel-based analysis in the AN group.
Conclusion
We found significant white matter micro- and macrostructural increases in the AN group across non-auditory tracts from the brainstem to the cortex. Our findings suggest whole-brain abnormalities in AN patients with one-sided hearing loss, which may comprise a target list of regions important for auditory therapies and neuro-prosthetic design. Future analysis will assess whether auditory tract structure is linked to changes in the non-auditory tracts and to the degree of hearing loss in this patient group.

Title: Attentional load modulates bottom-up processing of biological motion in the occipito-temporal cortex

Authors: *H. NIZAMOGLU, B. A. URGEN;
Bilkent Univ., Ankara, Turkey

Abstract: Humans can detect biological motion (BM) even when the stimulus is a point-light display of an actor. The gender, emotional state, and social intentions of the performer can be distinguished easily. Thus, it can be said that BM perception occurs effortlessly in an automated manner. Thornton and Vuong (2004) showed that task-irrelevant BM in the periphery interfered with task performance at the fovea. However, the neural underpinnings of the bottom-up processing of BM lacks thorough examination in the field. Under selective attention, BM perception is supported by a network of regions in the occipito-temporal cortex including motion and form sensitive areas and superior temporal sulcus, in addition to the frontal regions such as premotor cortex (PMC) and inferior frontal gyrus (IFG). A retinotopy study by Saygin and Sereno (2008) showed that task-irrelevant BM stimuli recruit retinotopic maps in occipito-temporal cortex. Based on this finding, we investigated how bottom-up perception of BM would be processed under attentional load. Participants (N=25) underwent a functional magnetic resonance imaging (fMRI) study. They performed a visual detection task at the fovea while attentional load was manipulated (high vs low load). At the same time, task-irrelevant BM stimulus was shown in the periphery. The univariate analysis and MVPA results showed that the bottom-up processing of BM was associated with the motion-sensitive areas in the occipito-temporal cortex. Furthermore, during the low attentional load condition, BM related activation was found stronger compared to that of in high attentional load condition. Thus, it can be concluded that BM is processed even when it is away from the focus of attention, and this processing is modulated by attentional load.

Title: Persistent representation of image speed in visual area MT even during poor steady-state smooth pursuit eye movements

Authors: *S. C. BEHLING, S. G. LISBERGER;
Neurobio., Duke Univ., Durham, NC

Abstract: Primates use smooth pursuit eye movements to track moving objects. Smooth pursuit is initiated by sensory estimates of stimulus speed represented in the middle temporal (MT) area of extrastriate visual cortex. After initiation, steady-state tracking can be almost perfect and, because perfect tracking eliminates image motion, it must be supported by extra-retinal motor feedback to maintain eye speed at target speed. However, situations exist where steady-state eye speed is persistently less than target speed, yet the tracking error goes uncorrected. For example, we showed previously that reducing the coherence in a patch of dots that a monkey is tracking degrades the eye speed during both the initiation and steady-state of pursuit. Steady-state eye speed lagged target speed persistently even in the presence of image motion. To understand the representation of image motion during steady-state tracking and to ask why persistent image motion is not corrected by the pursuit system, we recorded from isolated single neurons in extrastriate visual area MT. We sought to determine whether steady-state eye speed lags behind target speed for low dot coherence because (i) the speed representation in MT is reduced or (ii) the representation of image speed remains accurate in MT and eye speed is eroded further downstream within the motor feedback loop. We presented moving patches of dots of varying speeds and coherences while recording neurons in area MT. During pursuit initiation, the amplitude, but not the tuning, of MT responses depends on dot coherence. Comparison of neural responses during pursuit initiation and steady-state tracking shows that activity during initiation is largely able to predict activity throughout pursuit based solely on the motion of the stimulus relative to the eye. We conclude that MT consistently represents speed across the full pursuit response for all dot coherences. Visual motion may not have a strong impact on steady-state eye speed because the output from MT is lower in amplitude and is interpreted as having lower signal-to-noise even though the signal itself is not disrupted. Or, the extraretinal signals that normally sustain steady-state eye speed may be compromised by low dot coherences. Further exploration of neural responses in downstream parts of the pursuit circuit will be needed to fully understand why the pursuit system fails to correct persistent visual motion during steady-state tracking.

Title: Neural processing of perturbed self-motion in macaque area VIP

Authors: *J. C. B. SCHWENK[1,2], J. CHURAN[1,2], D. ENGEL[1,2], A. KAMINIARZ[1,2], F. BREMMER[1,2];
[1]Neurophysics Dept., Philipps-Universität Marburg, Marburg, Germany; [2]Ctr. for Mind, Brain and Behavior, Philipps-Universität Marburg and Justus-Liebig-Universität Giessen, Marburg, Germany

Abstract: The visual perception of self-motion is fundamental to our navigation through an environment. The neural processing of self-motion signals is often studied using optic flow patterns that simulate a smooth and continuous movement. However, the optic flow available naturally, e.g. during walking, is less regular, owing to movements of the observer or often unrelated movements in the environment. Here, we investigated how perturbations impact neural responses in the ventral intraparietal area (VIP), which shows strong representations of visually simulated self-motion. Previous studies have demonstrated predictive activity in VIP associated with expected motion onset (Churan et al., JNP, 2021). Accordingly, we were also interested whether the predictability of a perturbation would modulate its impact on ongoing activity.
We performed extracellular recordings from single neurons in area VIP of one macaque monkey. Stimulation consisted of simulated self-motion through a 3D cloud of random dots along one of two orthogonal axes in the horizontal plane. On every trial, the velocity of the self-motion followed a sinusoidal profile, oscillating at 1 cycle/second between opposite movement directions. This regular pattern was perturbed by a brief (40 ms) jerk of linear motion along the axis orthogonal to the main self-motion, at varying time points in the trial. Between different experimental blocks, the onset of the perturbation was either predictable or random.
Self-motion stimuli induced strong responses, characterized by ON (movement in the preferred direction) and OFF (non-preferred direction) states. Perturbations induced transient increases in activity. These were subadditive to the ongoing self-motion response, with largest incremental activity during a neuron's OFF-state. Early and late phases of the self-motion were differentially affected by the predictability of a perturbation. The transient response to self-motion-onset was unselectively suppressed within blocks including a perturbation, independent of its expected onset. In contrast, responses to predictable perturbations during the oscillatory steady-state were selectively attenuated.
These findings provide further evidence for a predictive role of area VIP in the processing of visual self-motion. The suppression of activity associated with the expectation of a perturbation is in line with the theoretical framework of predictive coding. Our results also confirm previous

observations that VIP neurons signal the onsets of visual events independently of their tuning for self-motion. This supports a more general role of area VIP in the monitoring of self-motion through space.

Title: Non-rigidities from motion-energy are turned rigid by tracking salient features

Authors: *A. MARUYA, Q. ZAIDI;
Grad. Ctr. for Vision Res., State Univ. of New York, New York, NY

Abstract: How does the brain make objects appear rigid across multiple views when retinal images are deformed non-rigidly by observer or object motion, especially for objects where motion parallax and correspondence between perspective views are not sufficiently informative? To get an answer, we used perceptual experiments and neural modeling on rotating rigid objects that can appear rigid or non-rigid depending on speed, to test whether it is tracking of salient features that counteracts nonrigidity. When two 3-D circular rings are rigidly linked at an angle and rotated around an axis oblique to both at a moderate speed, they appear as if they're rolling on each other and wobbling. This illusion of a non-rigid connection is striking enough to have been used in shop windows and in movies. Using a model of arrays of V1 direction selective cells, we show that despite the object being physically rigid, because of the oblique axis rotation, the pre-dominant motion energy at the contours of the rings supports a percept of the rings wobbling non-rigidly against one another instead of rotating rigidly. There are no physical cues that could support the illusion of rolling in the pair of circular rings, suggesting that this illusion is generated purely by the brain to make the wobbling appear physically feasible. That contention is supported by the presence of the rolling illusion when the rings are physically wobbled but not rolled. By asking observers to make forced-choice judgments between the link being rigidly connected or not, we quantified that the circular rings appear non-rigid at moderate speeds (6.0 deg/sec) but rigidly connected at slow speeds (0.6 deg/sec). However, the rings appear rigid at 6.0 deg/sec if the link is painted or replaced by a gap, or the rings are octagons with prominent vertices. Phenomenologically, the motion of painted segments, gaps, or vertices provides cues for rotation and against rolling, which in turn eliminates the now unfeasible

illusion of wobble. A model of arrays of MT pattern-motion cells tracks the rotational motion of the vertices of polygonal rings, and thus contributes to a percept of rigid rotation. However, at high speeds (60 deg/sec), all of these configurations appear non-rigid. Salient features thus contribute to rigidity at slow and moderate speeds, but not at high speeds. An image-based model being obviously insufficient, a generative model that combines motion-energy signals from the contours, with signals from MT pattern cells tracking salient features, explains the rigidity and non-rigidity of the rings and other rotating objects, by incorporating a minimum speed threshold for motion energy and a maximum speed cut-off on feature tracking.

Title: Neural encoding of multiple moving surfaces and choice-related activity in cortical area MT - role of disparity in image segmentation

Authors: *A. CHAKRALA, J. XIAO, X. HUANG;
Dept. of Neurosci., Univ. of Wisconsin Madison, Madison, WI

Abstract: Motion and binocular disparity provide crucial cues for image segmentation. We investigated the role of MT, a cortical area important for motion and disparity processing, in segmenting multiple surfaces. We recorded from neurons in two macaque monkeys as they performed a task requiring segmentation. The visual stimuli were overlapping random-dot patches moving in two directions separated by 60° or 120°. One patch was presented at a near disparity and the other at a far disparity. We varied the vector-average direction of the two patches to measure response tuning to the bi-directional stimuli and presented a stationary disparity cue before each trial. The animals were trained to report the direction at the cued disparity. The disparity preference of each neuron was determined by the response to a single patch. Animal B performed equally well at discriminating the direction of near or far patch of the overlapping stimuli, whereas animal G performed significantly better at discriminating the near patch direction. We found that, for animal B, the direction tuning of a neuron to two patches was significantly biased toward the patch located at a more preferred disparity of the neuron, more than expected by response averaging. In contrast, MT neurons in animal G showed a significant

bias toward the near patch, regardless of the disparity preference of a neuron or the cued disparity. Nevertheless, the bias toward the near patch was significantly stronger for the near- than the far-preferred neurons. We recorded from a third animal while the attention was directed away from the receptive fields. We found the same bias toward the patch at a more preferred disparity, as in animal B. Interestingly, MT neurons showed choice-related activity that depended on the disparity of the target patch, the disparity preference of the neuron, and the behavioral/neuronal bias. For animal B, choice probability calculated based on the responses of neuronal populations suggests that the activity of near-preferred neurons is linked to the choice of the near direction of overlapping stimuli, whereas the activity of far-preferred neurons is linked to the choice of far direction. For animal G that showed a significant bias toward the near patch, activity of both near- and far-preferred neurons is linked to the choice of near direction. Our results suggest that MT neurons encode multiple stimuli by preferentially representing the stimulus located at a more preferred disparity of a given neuron. The disparity tuning and choice-related activity in MT allow individual components of multiple stimuli to be represented by different groups of neurons and therefore provide a population code that aids segmentation.

Title: Role of MT disparity tuning biases in figure-ground segregation

Authors: *T. S. MANNING[1], E. ALEXANDER[1], G. C. DEANGELIS[2], X. HUANG[3], E. A. COOPER[1];
[1]Sch. of Optometry, Univ. of California, Berkeley, Berkeley, CA; [2]Brain Cognitive Sci., Univ. of Rochester, Rochester, NY; [3]Dept. of Neurosci., Univ. of Wisconsin Madison, Madison, WI

Abstract: Segregating salient figures in visual scenes from the surrounding context is a fundamental process in spatial perception, often referred to as figure-ground segregation. While several visual cues exist to support this process, binocular disparity and motion have been identified as key cues in primate vision. Figure-ground segregation likely depends on multiple

cortical areas, but area MT appears uniquely suited for supporting this task given its tuning for disparity and motion. Previous work investigating natural scene statistics found that multiple surfaces with different disparities are often present within visual field regions of similar size to MT receptive fields (RFs). MT neurons have also been shown to nonlinearly modulate their responses when multiple surfaces with different binocular disparities fall within their RFs. Given these findings, we hypothesized that the neuronal population in MT represents disparity information in a way that facilitates efficient figure-ground segregation. To address this hypothesis, we created model MT populations with biased or unbiased tuning characteristics. For example, neurons in MT more frequently exhibit odd-symmetric disparity tuning curves than neurons in V1 and they also generally prefer crossed disparities over uncrossed disparities. We used a database of stereoscopic natural images as input to the model MT population and used laser range measurements registered to each image to recover the ground truth disparities in each model neuron's RF. The figure-ground boundaries in each image were previously labeled by human participants, which we used to separately calculate the distribution of disparities in figure and ground regions. We find that MT-like biases in disparity tuning improve the mutual information between the scene disparities at each RF location and the MT responses. Next, we compared the distribution of disparities found in figure regions of the images with those in the ground regions, and formulated their discimination as a signal detection problem. The results suggest that the MT disparity tuning biases can increase the discriminability of figure regions by allocating more neural resources to the disparities surrounding the criterion value that maximizes correct classification. Thus, the representation of disparity in MT may support figure-ground segregation both by exploiting the first-order disparity statistics present in natural scenes and by maximizing sensitivity to the most informative disparities for figure-ground segmentation.

Title: A single neuron correlate for long-range apparent motion in the primate brain

Authors: *A. BIGELOW[1], T. NAMIMA[2], T. KIM[2], W. BAIR[2], A. K. PASUPATHY[2];
[2]Biol. Structure, [1]Univ. of Washington, Seattle, WA

Abstract: When a stimulus saltates across the visual field with relatively large spatial displacements (dX) and slow temporal steps (dT), it induces a strong motion percept known as long-range apparent motion. Despite decades of study, no neuronal correlate to has been identified along the primate dorsal visual stream, the quintessential motion processing pathway. This may be because, as psychologists have long argued, the percept of long-range motion relies on object-based, higher-order tracking processes along the ventral visual stream. To test this hypothesis, we studied responses of individual neurons in primate cortical area V4, a fundamental, mid-level ventral stream area for object form processing that has strong interconnections with key motion processing areas along the dorsal stream, such as areas MT and LIP. We measured the responses of 115 neurons in two monkeys to noise and sinusoidal patches that moved across the visual display with spatial and temporal displacements that satisfied the constraints of long-range motion (dX > 0.5 deg, dT = 100 ms) in 8 directions at 45° increments. Using a standard direction index (DI), we found that 30% neurons in V4 (34/115) are direction selective for long-range motion (DI $\geq$ 0.5). Because the mean luminance of the noise patches were equal to that of the background, this motion direction selectivity may be based on second-order cues. We also found that V4 direction selectivity was position invariant and preserved across a range of spatial and temporal displacements that spanned short- and long-range regimes. Surprisingly, however, we find that direction selectivity in many neurons disappears in response to local drift, i.e., motion behind an aperture, raising the intriguing prospect that the direction selectivity we observed may be specific to the movement of object boundaries. To explicitly test this hypothesis, we measured neuronal responses to sinusoidal patches that either drift behind a static aperture or jump across the visual display. At identical speeds, neurons exhibit direction selectivity to a stimulus that translates across the visual field but not to one that drifts, further supporting the notion of a higher-order, object-based motion detection system in V4 that differs substantially from models that explain direction selectivity in V1 and MT. Finally, we find compelling evidence that V4 direction selectivity can be driven by higher-order (e.g., 3rd-order) cues, such as chromatic boundaries. These results support a complementary motion processing system in the ventral stream that may be critical for tracking object motion in occluded environments where information may be intermittently available.

Title: Coordinated cortico-cerebellar neural dynamics underlying neuroprosthetic learning

Authors: *A. ABBASI[1], N. DANIELSEN[1], T. GULATI[1,2];
[1]Cedars-Sinai Med. Ctr., Los Angeles, CA; [2]Bioengineering and Med., Univ. of California Los Angeles, Los Angeles, CA

Abstract: Introduction: Brain-machine interfaces (BMIs) or neuroprosthetics allow neural control over assistive devices. They also provide an important framework for studying neural plasticity. Recent studies have suggested that optimal engagement of learning is essential for robust neuroprosthetic control. However, little is known about the neural processes in subcortical regions that support learning a neuroprosthetic skill. We performed electrophysiologic recordings in the motor cortex (M1) and the cerebellum (Cb) of rodents while they engaged M1 neurons in BMI control. By monitoring neural ensembles in both regions, we found robust indirect modulation of neurons and emergence of coordinated activity in the local field potentials (LFPs) of M1 and Cb. **Methods:** We have recorded single units and LFPs in adult Long-Evans rats (n=6) while they performed a neuroprosthetic task by implanting microwire arrays (Tucker-Davis Technologies, FL) in M1 and silicon tetrodes (Neuronexus, MI) or drivable polytrodes (Cambridge Neurotech, UK) in Cb. During the task, activity of a subset of M1 neurons was transformed into the angular velocity of a feeding tube using a simple linear decoder. Rats modulated the activity of these 'direct' neurons to obtain a water reward. We analyzed how the activity in these direct neurons, as well as all other recorded (indirect) neurons in M1 and Cb changed while learning the neuroprosthetic task. We also analyzed band-limited oscillatory activity in both regions. Furthermore, we performed optogenetic silencing of Cb by injecting red-shifted halorhodopsin (Jaws), while rats (n=2) performed the neuroprosthetic task and analyzed how cerebellar silencing affected the M1 activity and neuroprosthetic learning. **Results:** We found that learning successful BMI control was associated with robust modulation of 'direct' neurons in M1, as well as robust 'indirect' neuron's modulation in M1 and Cb. Furthermore, we observed the emergence of task-related 3-6 Hz synchronous oscillatory activity in cortico-cerebellar LFPs which also modulated the task-related neural spiking. We found that these trends emerged late in learning once skillful BMI control was exerted. Additionally, we found that correlations between rat forelimb movement and the movement of the feeding pipe reduced with BMI learning. **Conclusion:** Our work has identified neural mechanisms in M1 and Cb which are associated with learning of a cortically-controlled neuroprosthetic task. This underscores the importance of optimal engagement of neural learning mechanisms in an offsite motor region- the cerebellum, for successful learning of M1-controlled neuroprosthetic task.

Title: Low-frequency neural dynamics emerge across cortico-cerebellar networks with motor skill learning

Authors: P. FLEISCHER[1], A. ABBASI[1], N. DANIELSEN[1], *T. GULATI[1,2];
[1]Ctr. for Neural Sci. and Med., Cedars-Sinai Med. Ctr., Los Angeles, CA; [2]Bioengineering and Med., Univ. of California Los Angeles, Los Angeles, CA

Abstract: *Introduction*: Performing skilled actions that involve reaching, grasping and manipulating objects in our environment is a defining ability of mammals with prehensile forelimbs. Such skillful movement control requires coordination between several brain areas that are reciprocally connected through mono- or polysynaptic pathways. We have performed extracellular electrophysiologic recordings from the motor cortex (M1) and the cerebellum (CB) while rats learn a skilled reach-to-grasp (RTG) task and report the emergence of low-frequency oscillatory (LFO, 1.5-4Hz) activity in these regions with learning this skill. *Methods*: Single-unit and local field-potential (LFP) recordings were collected from the M1 and CB's Simplex, Crus I, and Crus II lobules while the rats (n=4) were trained in the RTG task for five days. We analyzed the behavior changes from early days of training to late days and the associated power-spectral changes in M1 and CB. We also analyzed movement-related LFP power and neural synchrony across the M1 and CB. Finally, we explored the representation of single neuronal activity in M1 and CB during learning by evaluating sequential activity of neurons in relation to movement onset. *Results*: During movement we observed coordinated low-frequency activity across the M1 and CB that was closely related to the reach onset in the RTG task. Movement-related LFO power in M1 and CB LFPs increased from day 1 to day 5 by ~59% and ~63%, respectively. Furthermore, we also found that this LFO activity in LFPs modulated the phasic spiking activity of the neurons in each region. Single neuronal activity sequences showed stronger modulation around the start of the reaching motion. *Conclusions*: Our work shows that coordinated neural activity emerges across M1 and CB with the dexterous skills associated with RTG task learning. Understanding this phenomenon has implications for neurological disorders such as cortical stroke or cerebellar disorders where dexterous motor control is impaired. Our next goal is to develop a neural network model of the changing neural dynamics over the course of learning.

Title: An activity map of the cerebellum underlying motor planning

Authors: *J. ZHU[1], H. HASANBEGOVIC[2], Z. GAO[2], N. LI[1];
[1]Dept. of Neurosci., Baylor Col. of Med., Houston, TX; [2]Dept. of Neurosci., Erasmus MC, Rotterdam, Netherlands

Abstract: The neocortex and the cerebellum are thought to interact during cognitive functions. The two brain regions are reciprocally linked through the pons and the thalamus to form cortico-cerebellar loops. However, the anatomical and functional organization of cortico-cerebellar loops underlying specific behavior remain unclear. During motor planning, a localized region of the mouse frontal cortex (anterior lateral motor cortex, ALM) exhibits preparatory activity instructing upcoming movements. Recent evidence shows that preparatory activity in ALM is dependent on the cerebellum (Gao et al., Nature 2018; Chabrol et al, Neuron 2018). ALM and the fastigial nucleus (FN) are parts of a cortico-cerebellar loop that mediates motor planning of directional licking. Here we mapped cortico-cerebellar input-output connectivity in the cerebellar cortex and present the first activity map of the cerebellar cortex supporting motor planning. Using trans-neuronal anterograde viral tracing, we mapped ALM inputs to the cerebellar cortex via the mossy fibers. Labeled mossy fiber boutons were comprehensively imaged and annotated across the cerebellar cortex. Using monosynaptic rabies tracing, we labeled the Purkinje cells targeting thalamus-projecting fastigial nucleus neurons, which provide the output back to ALM. Complementing these anatomical connectivity maps, we densely surveyed activity across the cerebellar cortex using silicon probe recordings during a delayed response task in which mice used short-term memory to plan directional licking. Anatomy and electrophysiology data were aligned into the Allen Mouse Common Coordinate Framework, facilitating comparisons of the connectivity and activity maps. ALM provided diffused inputs to the cerebellar cortex and large swaths of the cerebellar cortex sent output back to ALM. Yet only a localized region (spanning crus 1 & 2) with conjunction of input-output connectivity with ALM was selectively enriched in preparatory activity. A second region in the posterior vermis (lobule 7-9) with only output

connectivity to ALM also exhibited preparatory activity. Optogenetic perturbation of Purkinje cells in these regions, but not other regions, during motor planning biased subsequent licking direction. These results identified two regions of the cerebellum that formed functional connections with ALM to mediate motor planning and suggest that precise reciprocal connections between localized regions of frontal cortex and cerebellum mediate specific cognitive functions.

Title: Integration of cerebro-cerebellar loops improves virtual brain models of neurodegenerative diseases

Authors: A. MONTEVERDI[1,2], ***F. PALESI**[2], C. GANDINI WHEELER-KINGSHOTT[3,2,1], E. U. D'ANGELO[2,1];
[1]Brain Connectivity Ctr., IRCCS Mondino Fndn., Pavia, Italy; [2]Dept. of Brain and Behavioral Sci., Univ. of Pavia, Pavia, Italy; [3]NMR Res. Unit, Queen Square MS Centre, Dept. of Neuroinflam., UCL Inst. of Neurol., London, United Kingdom

Abstract: The Virtual Brain (TVB) is a novel neuroinformatic platform allowing to simulate whole-brain dynamics starting from individual structural (SC) and functional connectivity (FC). To date, TVB has been used to characterize brain dynamics both in healthy and pathological subjects but cerebellar nodes and their connections have been overlooked. This is at odd with the recent observation that integrating cerebro-cerebellar connections can improve TVB predictive capability in healthy subjects. This raises an issue because cerebellar impairment has been reported in neurodegenerative diseases, like Alzheimer's disease (AD), Frontotemporal Dementia (FTD) and Amyotrophic Lateral Sclerosis (ALS). In this work we integrated cerebro-cerebellar connections in TVB to assess the cerebellar impact on simulated brain dynamics both in physiological conditions (healthy controls) and neurodegenerative states (AD, FTD, ALS). Simulations were performed using three different combinations of connections and nodes: (i) whole-brain nodes and connections, (ii) cerebral cortex nodes and connections only, (iii) cerebral cortex nodes considering cerebro-cerebellar connections ("embedded cerebro-cerebellar subnetwork"). The Wong-Wang model was chosen to gain information on global brain dynamics and local excitatory/inhibitory balance. Pearson Correlation Coefficient (PCC) was computed

between experimental FC and simulated FC for all groups and networks. Within each pathological group, the PCC values obtained with the embedded cerebro-cerebellar subnetwork were significantly higher than those obtained otherwise. These findings demonstrate that the integration of cerebro-cerebellar connections in TVB improves the predictive power of the model in pathological conditions, supporting the cerebellar involvement in neurodegenerative states. In addition, the biophysical parameters derived from TVB were different between the clinical phenotypes considered. In backward regressions, TVB parameters significantly contributed to explain the variation of neuropsychological scores in physiological and pathological conditions. Moreover, cluster analysis provided a unique description of the excitatory/inhibitory balance at the single subject level. In summary, this work highlights the cerebellar involvement in neurodegenerative states, opens new perspectives in the use of TVB to explore neurodegenerative mechanisms and lays the basis for future personalized diagnosis and therapy.

Title: Organization of the locus coeruleus-norepinephrine projection to the rodent cerebellum.

Authors: *B. WATERHOUSE[1], H. PREDALE[1], D. J. CHANDLER[1], N. PLUMMER[2], P. JENSEN[2];
[1]Cell Biol. and Neurosci., Rowan Univ. Sch. of Osteo. Med., Stratford, NJ; [2]Lab. of Neurobio., NIEHS/NIH, Research Triangle Park, NC

Abstract: The brainstem nucleus locus coeruleus (LC) projects widely throughout the forebrain, brainstem, cerebellum, and spinal cord and is a major source of the small molecule transmitter norepinephrine (NE) in these areas. While we know much about the organization of the LC-NE system with respect to sensory and cognitive circuitries and the impact of LC output on sensory guided behaviors and executive function, much less is known about the role of the LC-NE pathway in motor network operations and movement control. As a starting point for closing this gap in understanding, we are using the intersectional recombinase-based viral-genetic strategy TrAC (Tracing Axon Collaterals) to characterize LC-NE projections to sub-regions of the rodent cerebellum, a structure that is prominently engaged in maintaining posture, and planning and executing movement. This technique allows us to not only map the distribution of LC-NE axons

to target regions of the cerebellum, but also to examine the distribution of their cell bodies within the LC and their dendritic fields within the peri-coerulear space. Initial results indicate the fastigial and interposed nuclei of the cerebellum receive input from a large number of NE-containing neurons distributed with an ipsilateral bias; 55-65% of total labeling in the ipsilateral LC and 35-45% of the total labeling in the contralateral LC. LC cells that project to cerebellum are displaced dorsally throughout the rostral-caudal extent of the nucleus. This pattern contrasts sharply with the scattered and predominantly ipsilateral (95%) distribution of the NE-containing cells that project from LC to cerebral cortex including the primary motor cortex. The dendritic fields of cerebellar-projecting LC neurons are concentrated laterally and medially within the peri-coerulear space. Overall, these studies begin to provide a detailed map and characterization of LC noradrenergic projections to sub-regions of the cerebellum. The initial results reveal substantial differences in the organization of the LC-NE projection to cerebral cortex vs cerebellum and identifies the regions of the peri-coerulear space where inputs to LC-cerebellar projecting cells can occur.

Title: The role of locus coeruleus-driven neuromodulation in the deep cerebellar nuclei for associative learning

Authors: *J. LEE, H.-J. BOELE, S. S.-H. WANG;
Princeton Neurosci. Inst., Princeton Univ., Princeton, NJ

Abstract: The locus coeruleus (LC) modulates the activity of many brain regions, including the cerebellar nuclei. LC may play a modulatory role during cerebellum-dependent learning based on lesion, pharmacological, and microdialysis evidence. However, these methods lack temporal precision. Here we investigated the relationship between endogenous patterns of noradrenergic signaling in delay eyeblink conditioning, both over the course of learning and during trial-by-

trial performance after learning has taken place. First, we confirmed that LC indeed innervates cerebellar nuclei, including the interpositus, which supports eyeblink conditioning. Second, we showed that photostimulation of ChR2-expressing LC terminals in cerebellar nuclei releases norepinephrine using fast-scan cyclic voltammetry. Third, we performed eyeblink conditioning experiments in adult mice while simultaneously measuring activity of axonal GCaMP8f-expressing LC axons in the cerebellar nuclei and jRGECO1a-expressing cerebellar nuclei using fiber photometry. For eyeblink conditioning, a blue-LED conditional stimulus (CS) was repeatedly paired with an unconditional stimulus (US) corneal airpuff, which led to the acquisition of conditioned eyeblink responses in response to the CS. After learning, we analyzed trial-by-trial correlation of LC activity and the probability of conditioned eyelid responses. We found an inverse correlation between pre-CS LC activity and the probability of a conditional response. In addition, we found an inverted-U-shaped relationship between during-CS GCaMP8f signal in LC axons and the conditioned response probability. Fourth, we found that photostimulation of ChR2-expressing LC terminals in cerebellar nuclei impairs motor learning. Our findings suggest an inverse or inverse-U-shaped relationship between norepinephrine levels in the cerebellar nuclei and both learning and expression of conditioned motor responses, consistent with proposed linkages between noradrenaline, arousal, and learning (Aston-Jones & Cohen, Annu. Rev. Neurosci., 2005).

Title: Cerebellar modulation of the hypothalamus: a potential role in regulation of survival behaviors?

Authors: *N. S. J. CAYLA[1], M. G. OÑATE[1], J. A. WILLETT[3], J. A. VERA[2], K. KHODAKHAH[4];
[2]Neurosci., [1]Albert Einstein Col. of Med., Bronx, NY; [3]Biol. Sci., North Carolina State Univ., Raleigh, NC; [4]Dept Neurosci., Albert Einstein Col. Med., Bronx, NY

Abstract: Although it constitutes a mere 10% of the total volume of the human central nervous system, the cerebellum contains more than half of our neurons. It is well-known for its involvement in motor control and coordination, but recent observations made on patients

suffering from a myriad of mental disorders, or those with cerebellar lesions have led to a growing appreciation for its roles in the regulation of cognitive and somatic functions as well. To delineate the non-motor functions of the cerebellum it is important to have a detailed map of its connectivity with other brain regions. So, we used anatomical neuronal tracings to explore the potential presence of monosynaptic projections from the deep cerebellar nuclei (DCN) to the hypothalamus. To do so, we injected an AAV1-cre virus in the DCN of a reporter mice (RCE:LoxP), in which neurons require Cre to express GFP. This virus possesses transsynaptic spread properties and allows for the labelling of the somas of monosynaptic target-cells. With this approach, DCN target-cells in several hypothalamic regions were identified: in the Medium Pre-Optic Area (MPOA), in the Lateral Hypothalamic Area (LHA), and in the Paraventricular Nucleus of the Hypothalamus (PVH). In the PVN immunostaining revealed that oxytocin- and vasopressin-expressing neurons receive direct projections from the DCN. Functionally, using in vivo electrophysiology, we found that optogenetic activation of cerebellar axons in the Paraventricular Nucleus of the Hypothalamus increased the firing rate of the target neurons. In addition, we found that optogenetic activation of DCN projections in the hypothalamus increased cFos expression in the PVN. Optogenetic activation of cerebellar axons in the PVN did not produce any overt motor dysfunction. These results suggest that the cerebellum may have a modulatory role in the hypothalamus and may be involved in PVN-regulated behaviors such as social behaviors, and stress or circadian regulation among others. In future experiments, I plan to characterize this novel brain circuit by combining cell-type specific neuroanatomical tracing with in *vivo* and *in vitro* electrophysiological assays in behavioral tasks.

[1]Harvard Med. Sch., Boston, MA; [2]Athinoula A. Martinos Ctr. for Biomed. Imaging, Charlestown, MA

Abstract: Beyond the staggering number of infections and deaths, the COVID-19 pandemic has caused lifestyle, societal, and other disruptions, impacting our lives in multiple ways. Following the beginning of the March 2020 lockdown, even non-infected and otherwise healthy individuals have begun commonly reporting fatigue, depression, “brain fog” and other “sickness behaviors”. As these may be behavioral manifestations of neuroimmune activation, we tested the hypothesis that the COVID-19 pandemic-related disruptions may have caused neuroinflammation. To this end, we conducted a multimodal, retrospective evaluation of Positron Emission Tomography / Magnetic Resonance (PET/MR) data collected in healthy subjects pre- and post- lockdown in our Center. 57 ‘pre-lockdown’ subjects (scan dates: 04/2012-02/2020) were compared against 13 ‘post-lockdown’ subjects (08/2020-04/2021), negative to COVID-19 PCR antibody test. All subjects were scanned with a PET/MR tomograph and [11C]PBR28, which binds to the glial marker TSPO. A subset (13 pre-lockdown; 10 post-lockdown) were also scanned with Magnetic Resonance Spectroscopy (MRS). Pre- and post-lockdown [11C]PBR28 standardized uptake value ratios were compared in both region-of-interest analyses in areas previously associated with stress or depression (accumbens, hippocampus, thalamus, anterior cingulate cortex) and in voxel-wise analyses (FSL randomise; cluster-forming threshold of p=0.01; cluster size threshold of p = 0.05). Concentrations of the glial marker myo-inositol (mIns) and, for reference, Creatine (Cr; a cellular energetic marker) and N-Acetyl Aspartate (NAA; a marker of neuronal integrity) were extracted from an 15mm isotropic voxel placed in the left thalamus. Elevations in both PET and MRS neuroinflammatory markers were seen in the ‘post-lockdown’ cohort. Significant post-lockdown [^{11}C]PBR28 uptake elevations were observed in all the a-priori ROIs ($0.005<p<0.035$), as well as in the voxel-wise group contrast (sensory, motor and higher order association areas, as well as white matter). MRS data also revealed significantly higher concentrations of mIns in the post-lockdown cohort (p=0.005), whilst no statistically significant differences in Cr and NAA were observed across groups (p>0.20), as expected. Our results suggest that COVID-19 related disruptions may have caused neuroinflammation, though the clinical significance of our observations awaits further investigation. Elevated neuroimmune responses may help explaining the pandemic-related "sickness behaviors", which are symptoms commonly reported also among individuals that were never infected by the virus itself.

Title: Progressive dysregulation of the cholinergic anti-inflammatory network in a rodent model of Gulf War Illness

Authors: *H. E. BURZYNSKI[1,2], V. A. MACHT[3,2], J. L. WOODRUFF[1,2], J. M. ERICHSEN[1], C. A. GRILLO[1,2], J. R. FADEL[1,2], L. P. REAGAN[1,2];

Abstract: Soldiers who served in the 1990-1991 Gulf War returned with an unexplained, multi-symptom illness that continues to affect over 250,000 veterans. This constellation of symptoms, which includes cognitive disturbances, immune dysregulation, and cardiovascular abnormalities, is now termed the Gulf War Illness (GWI). The cause of this unique symptomatology is still unknown; however, researchers have identified the prophylactic use of the acetylcholinesterase inhibitor, pyridostigmine bromide (PB), and the stress of combat as two potential contributing factors. GWI is especially problematic as the symptoms have become progressively worse in affected individuals, while long-term, pre-clinical studies evaluating this progression remain limited. As inflammation has been suggested as a mechanistic mediator of the progressive nature of GWI pathology, the goal of this study was to determine the long-term effects on the cholinergic anti-inflammatory network in both the central nervous system and the periphery in our previously established rat model of GWI, consisting of PB treatment in combination with repeated restraint stress (RRS). Specifically, we used in vivo microdialysis to assess cholinergic neurochemistry in the prefrontal cortex (PFC) and hippocampus following a mild immune challenge (lipopolysaccharide; LPS) and measured inflammatory markers in these brain regions and in plasma 3 months after the treatment paradigm. We found that PB treatment produces a long-lasting attenuation of the cholinergic response to LPS in both the PFC and hippocampus and this is accompanied by neuroinflammation in these regions. Interestingly, this attenuation in cholinergic neurochemistry is not seen when PB treatment is combined with RRS, but this combination also produces neuroinflammation. In the periphery, PB treatment, alone and in combination with RRS, elicited dysregulation of the cholinergic anti-inflammatory network. In this regard, while LPS-induced increases in plasma levels of IL-6 were reduced in PB-treated

rats, these rats exhibited an unexpected enhancement of plasma levels of C-reactive protein. Collectively, these findings provide evidence that neuroinflammation may be a mechanistic mediator of the progression of the neurochemical and neurocognitive deficits in GWI.

Abstract: The underlying biological mechanisms of depression in the brain differ between men and women. Recent work has demonstrated the peripheral immune system influences the brain's response to stress and subsequent behavior. The peripheral immune system is altered in patients with depression and may contribute to sex differences in the prevalence and symptoms of depression. We took an unbiased approach to examine differences in plasma cytokine expression between pre-menopausal women and age-matched men with depression. We found that women who failed to respond to at least two rounds of treatment with traditional anti-depressants had a unique and stronger immune response than women who had only been treated for an initial bout of depression, or men in either stage. We modeled these changes in immune activity with mouse stress paradigms to uncover the relationship between peripheral cytokine expression and behavior. We used Multiplex ELISA to quantify plasma expression levels of 29 different cytokines in plasma samples from men and women diagnosed with depression (treatment resistant vs. non treatment resistant), as well as from mice of both sexes following chronic variable stress for both 6 and 28 days. Female mice exhibited a stronger immune response to stress than males. Four Core Genotype Mice (FCG) are bred to either express the Sry gene on an

autosome or to have it deleted, which allowed us to investigate the contribution of gonadal sex versus chromosomal sex. Mice with female chromosomes had either male gonads or female gonads, and mice with male chromosomes had either female gonads or male gonads. There is a behavioral sex-difference in wild-type mice following 6 days of variable stress, in which females are stress susceptible, but males remain resilient. The FCG mice were run through the same 6-day variable stress paradigm. In the forced swim test, which measures active versus passive coping, karyotypically female (XX) mice with male gonads (testes) showed resilience equal to that of XY mice with proper testes development. These results confirm sex-specific immune system activation in depression, and demonstrate the translational potential for using stress paradigms in mice to model specific immune responses. Results suggest that the immune response to stress is influenced by both chromosomal and gonadal sex.

Title: The contribution of interleukine-1β in susceptibility to psychological trauma in a mouse model of PTSD

Authors: P. LEVESQUE[1,2], M.-È. ROBERT[1], S. LÉTOURNEAU[1,2], C. CANIVET[2], *J. DESLAURIERS[1,2];
[1]Univ. Laval, Québec, QC, Canada; [2]Neurosciences, CRCHU de Québec-Université Laval, Québec, QC, Canada

Abstract: Background and hypothesis: Posttraumatic stress disorder (PTSD) is a psychiatric condition that affects over 9% of the general population with rates up to 20% in veterans. PTSD dramatically decreases patients' quality of life and can persist for multiple years. The only FDA-approved drugs available to treat PTSD are antidepressants and have very limited effectiveness. It is therefore urgent to better understand the pathophysiological mechanisms of PTSD in order to develop new therapeutic avenues. Several studies support a role of inflammation in the development of PTSD symptoms, but the mechanisms underlying immune function and PTSD risk remains unclear. In a unique mouse model of PTSD, we found increased plasma and brain levels of the pro-inflammatory cytokine interleukin-1β (IL-1β). However, the contribution of this cytokine in the development of PTSD, as well as its underlying mechanisms, remains to be

investigated. We hypothesized that IL-1β is critical for the onset of PTSD-like phenotype.
Methods: To test this hypothesis, male and female wild-type (WT) and IL-1β-deficient (IL-1βKO) mice were exposed to predator stress (physical contact with a cat for 10 min). Seven to nine days after stress, anxiety-like and PTSD-like behaviors, including avoidance of trauma-related cues were evaluated using the open field, light-dark box, and trauma-reminder tests. Ten days after exposure, brain tissues were collected to measure the levels of the inflammatory markers (C-reactive protein, interleukin-6 and tumor necrosis factor-α) using ELISAs.
Results: In both males and females, predator stress increased anxiety-like and PTSD-like behaviors in WT mice ($p < 0.001$, vs. non-stressed WT mice), but did not induce the same phenotype in IL-1β-deficient mice. We observed no effect of stress or IL-1β deficiency on neuroinflammation.
Conclusion: These results suggest that IL-1β plays a causal role in the development of PTSD, and therefore in vulnerability and resilience to psychological trauma. Data on plasma levels of inflammatory markers shortly (24 hrs) after stress exposure, as well on the integrity of the blood-brain barrier (BBB) will also be presented to provide additional key insights on the mechanisms underlying the association between IL-1β and PTSD risk.

Title: A mediating role for microglia in the sex-dependent cognitive and neurostructural consequences of neonatal and juvenile adversity

Authors: *K. GILDAWIE, M. FANIKOS, L. THAMARAI KANNAN, A. VALENTINE, A. PARAKOYI, T. ALEXANDER, L. EIN, H. C. BRENHOUSE;
Northeastern Univ., Boston, MA

Abstract: Early life is rife with sensitive periods during which aberrant experiences can have lasting effects on plasticity and cognitive development. Formation of perineuronal nets (PNNs) - specialized extracellular structures that preferentially enwrap fast-spiking parvalbumin (PV)-expressing interneurons - is essential for proper neurodevelopment. We have previously observed female-specific prefrontal cortex (PFC) PNN degradation following multiple hits of developmental adversity. Importantly, microglia - the main immune cells in the brain - have been

implicated in regulating cell plasticity and PNN modification in healthy and disease states. To determine whether microglial presence in the neonatal brain mediates the sex-dependent behavioral and neurostructural consequences of early life adversity, pups underwent bilateral intracerebroventricular infusions of liposomal clodronate (LC) or vehicle liposomes at postnatal day (P)2 to transiently deplete microglia. Pups were then exposed to maternal separation (MS) 4h per day from P2-20 (or control rearing), followed by juvenile social isolation (SI) from P21-35 (or standard pair-housing). In adulthood (P70-71), working memory (spontaneous alternation in the Y-maze), social preference, and social recognition was assessed, followed by quantification of the density and structural integrity of PFC PV+ PNNs, as well as the transcriptional factor ΔFosB, that regulates neuronal and behavioral plasticity. We found female-specific deficits in social and working memory following MS that was prevented by LC treatment. Notably, juvenile SI improved working memory, but exerted the opposite effect in LC-treated females. Here, we reveal sex-specific neurostructural and cognitive consequences of early life adversity at distinct developmental stages that are mediated by developmental neuroimmune activity.

Title: Microglial P2Y12 mediates stress-induced structural remodeling of neurons in the prefrontal cortex and associated behavioral deficits

Authors: *J. L. BOLLINGER, D. T. DADOSKY, I. L. RAINER, S. C. WOODBURN, J. K. FLURER, E. S. WOHLEB;
Pharmacol. & Systems Physiol., Univ. of Cincinnati, Cincinnati, OH

Abstract: Recent studies demonstrate that chronic unpredictable stress (CUS) drives microglia-mediated neuronal remodeling, which contributes to synapse loss in the prefrontal cortex (PFC) and cognitive-behavioral dysfunction. Despite this work, it remains unclear what mechanisms guide microglia-neuron interactions in stress. Recent studies show that neuronal activity-dependent purinergic signaling directs microglia-synapse interaction via the purinergic receptor,

P2Y12, which is selectively expressed by microglia in the brain. Thus, microglial P2Y12 may contribute to stress-induced structural remodeling of neurons in the PFC and associated behavioral consequences. To investigate this, we used genetic (*P2ry12-/-*) or pharmacological (clopidogrel, ticagrelor) approaches to block P2Y12 signaling in the context of CUS. Various behavioral, physiological, and cytometric endpoints were analyzed. Both P2Y12-deletion and treatment with clopidogrel prevented stress-induced increases in forced swim test immobility and attenuated deficits in temporal object recognition. Genetic ablation of P2Y12 or treatment with clopidogrel diminished microglial P2Y12 and altered surface receptor levels of CX3CR1, CSF1R, and CD11b, independent of CUS. Blocking microglial P2Y12 prevented stress-induced increases in microglial CD68 and the proportion of microglia with neuronal inclusions, and attenuated dendritic spine loss in the PFC. Together, these findings indicate that microglial P2Y12 contributes to stress-induced dendritic remodeling in the PFC and subsequent behavioral deficits.

Abstract: The phenomena of sickness behavior is not well understood, but is a behavioral response driven by the immune system in response to a pathogen that is usually transient in nature. Lipopolysaccharide (LPS) administration can induce sickness behaviors at specific doses through stimulation of the immune system and the HPA axis. Though the immune system

matures, LPS effects have not been well elucidated during adolescence. Here, we explored the dose-dependent effects of acute LPS during early adolescence and adulthood. Rat subjects were injected with a single dose of LPS (0.1, 1.0, 10.0, 100.0 µg/kg) or vehicle (0.9% saline) and placed in an open field to assess general locomotion. Serum and brains were harvested following behavior to assess peripheral inflammation and neuronal activation. In adults, LPS had a main effect on distance traveled and increased immobility when administered at 100.0 µg/kg. In adolescents, 100.0 µg/kg of LPS decreased distance traveled but immobility time did not change across LPS doses. Though cytokine production did not differ between age-groups administered with 0.1 and 1.0 µg/kg LPS, the low doses produced age-dependent effects on open field distance traveled. Adult 0.1 and 1.0 µg/kg LPS treated subjects exhibited hyperactivity and adolescent behavior did not change. 100.0 µg/kg LPS increased immobility in both age groups, but trended towards a larger effect in adults relative to adolescents. Collectively, these results suggest that at similar peripheral inflammatory states, LPS-induced inflammation has an age-dependent effect on sickness-like behavior.

Title: Brain endothelia activated by social stress increase prostaglandin E2 signaling, neuronal activation, and augment anxiety-like behavior

Authors: *W. YIN, R. G. BILTZ, E. J. GOODMAN, S. P. SWANSON, J. F. SHERIDAN, J. P. GODBOUT;
The Ohio State Univ., Columbus, OH

Abstract: Chronic psychosocial stress can increase neuropsychiatric complications including anxiety and depression. We have reported that Repeated Social Defeat (RSD) in mice increased the accumulation of inflammatory monocytes within the brain vasculature. This accumulation of cells with RSD corresponded with increased interleukin (IL)-1R mediated activation of endothelial cells and the augmentation of anxiety-like behavior after RSD. One unknown, however, is the role of IL-1 activated endothelia in regulating the behavioral and physiological

responses to RSD. Thus, the goal of this study was to determine the RNA profile of activated endothelia and to begin to delineate the pathway by which with endothelial cells communicate with neurons to influence behavioral responses. In the first experiments, mice were exposed to RSD and brain endothelial mRNA profiles were determined using RiboTag immunoprecipitation and RNA sequencing. RSD increased the active translation of cell adhesion molecules (*Icam1*, *Vcam1*), innate inflammatory proteins (*Lrg1*, *Lcn2*, *Ackr1*), and cyclooxygenase-2 (*Ptgs2*/COX-2). In the prelimbic cortex, activated endothelia reduced expression of tight junction proteins *Cldn5* and *Mfsd2a*. Overall, these RNA-sequencing data showed an increased adhesion molecule and prostaglandin signaling signature of brain endothelia activated by RSD. Based on these data, we next examined the role of prostaglandin (PG)E2 in the peripheral and central immune responses to stress. In these experiments, mice received celecoxib, a selective COX-2 inhibitor, prior to each cycle of RSD. As expected, RSD increased the PGE2 concentration in the brain and this increase was abrogated by inhibition of COX-2. Moreover, inhibition of COX-2 blocked anxiety-like behavior and working memory deficits after RSD. Inhibition of COX-2 also reduced the stress-induced activation of neurons in the paraventricular nucleus of the hypothalamus and increase in IL-6 in the plasma. Taken together, synthesis of PGE2 after RSD, in part by endothelial cells, influences neuronal activity and behavior.

Title: Consumption of dietary emulsifiers increases social stress sensitivity in mice

Authors: *A. R. ARNOLD[1], K. LAKHANI[1], T. WILKINSON[3], K. L. HUHMAN[2];
[2]Neurosci. Inst., [1]Georgia State Univ., Atlanta, GA; [3]Mercer Univ., Atlanta, GA

Abstract: Chronic low-grade inflammation and stress exposure are key contributing factors in the etiology and progression of many neuropsychiatric disorders. Dietary emulsifiers are commonly added to processed foods and are classified by the Food and Drug Administration as safe. Recently, however, it has been revealed that these additives can cause inflammation in the gut and may even increase baseline anxiety-like behavior. It is not known, however, whether emulsifier-treated mice exhibit normal behavioral and hormonal responses to stress. In this study,

we tested the hypothesis that chronic consumption of either polysorbate 80 (P80) or carboxymethylcellulose (CMC), two common emulsifiers, sensitizes the behavioral response to social stressors. C57Bl6/J mice (n=10 per group) were subjected to social defeat (3, 5 min pairings with aggressive CD1 opponent with a 5 min break between pairings) or no defeat after 12 weeks of emulsifier (1% in drinking water; P80 or CMC) or plain water consumption. 24 hours post defeat social avoidance testing was conducted. Our results show that when subjected to social defeat, emulsifier-treated mice show increased social avoidance and greater increases in the stress hormone corticosterone compared to water-treated controls. Subsequently, we investigated the role of the COX pathway as a possible inflammatory mechanism driving emulsifier induced social stress sensitivity. A previous RNA-Seq study conducted in our lab showed increased differential expression of PTGS2 (COX-2), a gene that codes a protein responsible for the conversion of arachidonic acid to proinflammatory prostaglandins, in the amygdala following emulsifier consumption. We therefore tested the hypothesis that increased inflammation, specifically through the COX pathway, is a mechanism driving emulsifier-induced stress sensitivity. Groups were as described above, but mice were also divided into aspirin (25mg/kg/day) intervention groups. Aspirin was added to drinking water or respective emulsifier at week six for a duration of six weeks (n=7 per group). Results suggest that aspirin, a COX pathway inhibitor, may block the increased social avoidance observed in emulsifier-treated mice. Taken together, these data demonstrate that ingestion of dietary emulsifiers at concentrations commonly ingested by humans increases sensitivity to social stress and that the COX pathway may be a prime mechanistic candidate by which emulsifiers increase sensitivity to social stress. Title: Molecular Mechanisms of Reduced Ethanol Drinking in Calcineurin-Mediated Immunosuppression Treated Rodents

Authors: *P. J. RONAN[1,2], S. A. FLYNN[2], T. P. BERESFORD[3];
[1]Sioux Falls VA, Sioux Falls, SD; [2]Psychiatry and Basic Biomed. Sci., Univ. of South Dakota Sanford Sch. of Med., Sioux Falls, SD; [3]Psychiatry, RMRVAMC-SOM U Colorado, Aurora, CO

Abstract: We have shown that calcineurin (CLN)-meditated immunosuppressants reduce alcohol intake in mice. Calcineurin plays key roles in reward, stress, and neuroinflammatory signaling. Ethanol use causes enhanced neuroinflammation and increased stress signaling. Similarly, stress also induces neuroinflammatory responses. Here we sought to determine the effects of cyclosporine A (CsA) on stress-induced neuroinflammatory markers in brain. Rats (n=8) were given either CsA (30 mg/kg, I.P.) or vehicle, exposed to 30 minutes of restraint stress and returned to their home cage for 90 minutes. Brains were rapidly dissected and frozen in isopentane on dry ice. The CeA and PVN were microdissected from 300 um frozen sections and qRT-PCR was performed. Overall, Cyclosporine inhibited the expression of a wide range of neuroinflammatory markers in these regions including cytokines such as IL-2, IL-1β, IL-6, TNFα; markers of glial activation: CD45 and Iba-1; chemokine and chemoattractant molecules such as CCR2 and CCL2; as well as other inflammatory signaling molecules such as COX-2. Some of the largest effects were seen on IL-1 β and IL-6 expression in both CeA and PVN. While CsA inhibited the expression of CD45 and iba1 in the CeA, in the PVN these effects were striking. This suggests that stress rapidly induces glial activation in these regions which is inhibited by CsA. Together these data suggest that rapid, stress-induced neuroinflammatory signaling is attenuated by inhibition of CLN activity. This has implications for the treatment of multiple disorders in which stress is an etiological or maintenance factor such as PTSD and AUD.

Abstract: Glucocorticoids are a class of steroid hormones produced by the adrenal gland in response to stress. Chronic elevation of glucocorticoids is known to cause neurological and metabolic impairments. Glucocorticoids are commonly prescribed as anti-inflammatories and the side effects of long term administration include overeating and excess weight gain. Recent reports suggest that selenium, an essential micronutrient with antioxidant capabilities, may help combat the negative impact of glucocorticoids on the brain. In this study, a mouse hypothalamic cell line was treated with corticosterone (CORT), the primary active glucocorticoid in mice, to investigate the neurological underpinnings of glucocorticoid-induced metabolic dysfunction. Additionally, the potential protective role of selenium was assessed. Seven days of CORT potentiated tunicamycin-induced endoplasmic reticulum stress (ER stress), which was correlated with a non-transcriptional downregulation of the selenium-containing selenoprotein M (SELENOM). Supplementation with excess selenium prevented SELENOM downregulation and reversed the exacerbating effect of CORT on ER stress. These data suggest that chronic CORT may disrupt hypothalamic function by decreasing SELENOM expression, thereby making neurons more susceptible to ER stress. Moreover, selenium supplementation may help mitigate this effect.

Title: Assessing neuroinflammation in Veterans with Gulf War Illness: A pilot study using whole-brain magnetic resonance spectroscopy

Authors: *C. JONES[1], A. MAUDSLEY[2], S. SHERIFF[2], E. WETZEL[1], J. ROBINSON[1], J. YOUNGER[1];
[1]Univ. of Alabama, Birmingham, Birmingham, AL; [2]Radiology, Univ. of Miami, Miami, FL

Abstract: Background: Nearly one-third of the Veterans who served in the 1991 Persian Gulf War suffer from a chronic condition involving fatigue, pain, cognitive impairment, respiratory issues, gastrointestinal complaints, and/or mood disorders. Mounting evidence suggests that this condition, named Gulf War Illness (GWI), results from abnormal neuroinflammatory processes. This pilot study is the first to use a whole-brain magnetic resonance spectroscopic imaging (MRSI) technique to assess markers of widespread neuroinflammation in GWI.
Methods: Whole-brain MRSI was used to quantify four neuroinflammatory markers across the brains of Veterans with GWI, and healthy Gulf War Veterans (HGWV). The four measured metabolites of myo-inositol (MI), lactate, choline, and N-acetyl-aspartate (NAA) were expressed as ratios over Creatine (Cr). For this pilot investigation, data from 5 male HGWV and 5 male GWI, ages 49-62, were analyzed with independent sample t-tests (significance threshold of $p < 0.05$). Higher levels of MI, choline, and lactate, and lower levels of NAA, were expected in the GWI group, indicating inflammation.
Results: Our preliminary analyses revealed 15 significant metabolite group differences in 14 out of 47 brain regions. The GWI group showed elevated lactate/CR in the left Rolandic operculum, the right insula, the right calcarine sulcus, and the right caudate nucleus. The GWI group also showed lower Choline/Cr in the left frontal cortex, the left Rolandic operculum, the right mid cingulum, bilateral posterior cingulum, the left postcentral gyrus, the left parietal cortex, bilateral precuneus, and the left paracentral lobule. There was one additional significant finding of lower NAA in the left anterior cingulum in the GWI group.
Interpretation: These preliminary findings provide additional support for the hypothesis that GWI involves neuroinflammation. Low choline in the brain may also indicate abnormalities in acetylcholine synthesis. If replicable in larger samples of Gulf War Veterans, whole-brain MRSI may be used to identify targets for improved treatments.

Title: Sex differences in cortical-hypothalamic circuitry mediating stress reactivity

Authors: *D. SCHAEUBLE, T. WALLACE, B. MYERS;
Biomed. Sci., Colorado State Univ., Fort Collins, CO

Abstract: Endocrine and autonomic stress responses adapt the body to real or perceived threats by engaging physiological pathways to maintain homeostasis. Unfortunately, the burden of prolonged stress contributes to maladaptive stress responding, increasing risk for pathologies including cardiometabolic disorders. However, the circuit mechanisms integrating endocrine and autonomic stress responses have yet to be defined. Our previous studies found that glutamate neurons of the infralimbic cortex (IL) have sex-specific effects on endocrine and cardiovascular stress reactivity. While the IL is important for coordinating behavioral and physiological responses to stress, these cortical cells do not directly innervate the secretory or pre-autonomic cells that initiate endocrine and autonomic stress responses. However, we previously found that the posterior hypothalamus (PH) receives dense stress-activated inputs from the IL. Thus, the current study tests the hypothesis that IL glutamate release in the PH mediates sex-specific effects on stress integration. To test this hypothesis, adult male and female Sprague-Dawley rats received stereotaxic injections in the IL of a viral-packaged construct expressing channelrhodopsin-2 and bilateral fiber optics targeting the PH to stimulate IL synapses in the PH. After recovery and acclimatization to handling, rats were tested in the real-time place preference paradigm to examine behavioral preference or aversion for circuit stimulation. These data indicate that IL-PH signaling is preferred by males and that females have neither preference nor aversion for IL-PH stimulation. Additionally, acute restraint was used to examine glucose and corticosterone responses to stress. Results found that IL synapses in the PH decrease stress-induced glucose mobilization without affecting corticosterone in male rats. In contrast, IL-PH stimulation in females increases corticosterone responses to restraint but does not affect glucose mobilization. Furthermore, non-invasive assessment of hemodynamics indicate that IL-PH stimulation increases heart rate in females but not males. Thus, the IL-PH circuit increases place preference and reduces glucose responses to stress in males, while increasing corticosterone stress responses and heart rate in females. Taken together, these data suggest that the PH represents a key node for sex-specific integration of descending cortical signals with endocrine and autonomic stress reactivity. Ultimately, sex-specific delineation of stress-regulatory neurocircuitry may provide insight into the differential impact of stress pathologies in men and women.

Title: Prefrontal-medullary circuit activation attenuates stress reactivity

Authors: *S. A. PACE, E. LUKINIC, T. WALLACE, D. SCHAEUBLE, J. MOORE, B. MYERS;
Biomed. Sci., Colorado State Univ., Fort Collins, CO

Abstract: Organismal survival and adaptation to stress rely on brainstem catecholaminergic neurons. In particular, catecholaminergic neurons in the rostral ventrolateral medulla (RVLM) drive sympathetic activity and enable physiological adaptations, including vasoconstriction, corticosterone release, and glycemic mobilization. However, it is unclear how brain regions involved in the cognitive appraisal of stress regulate the activity of RVLM neurons. Our previous studies found that the rodent infralimbic prefrontal cortex (IL) integrates behavioral and physiological responses to stress. Thus, a potential IL-to-RVLM connection would represent a crucial link between stress appraisal and sympathetic reactivity. In the current study, we investigated a direct IL-to-RVLM circuit by targeting a genetically-encoded anterograde tracer under the control of the CaMKIIα promoter to the IL of adult male and female rats. Analysis revealed that IL terminals apposed RVLM neurons expressing the catecholamine-synthesizing enzyme, dopamine beta-hydroxylase. Further, IL input to catecholamine cells was widespread throughout the rostral-to-caudal extent of the VLM in both male and female rodents. Quantification of innervation density revealed that males had a larger proportion of VLM catecholamine neurons receiving IL inputs than females. Additionally, IL appositions were identified on GABAergic and glycinergic neurons in both sexes. Accordingly, we hypothesized that IL projections may activate local RVLM inhibitory cells to limit sympathetic output. To test this hypothesis, we injected a viral vector coding for channelrhodopsin-2 (ChR2) in the IL of males and females. Next, a fiber optic cannula was implanted dorsal to the RVLM to evoke IL synaptic glutamate release. Animals then received photostimulation during restraint stress with blood sampled to determine stress reactivity. Compared to controls, male rats expressing ChR2 on IL terminals had suppressed glycemic stress responses. In contrast, stimulation of the IL-RVLM circuit in females did not affect glucose mobilization. However, ChR2 decreased corticosterone responses to stress relative to control rats in both sexes. Thus, both male and female rats have a direct circuit from the IL portion of the mPFC to catecholamine-synthesizing cells of the RVLM that limits glucocorticoid stress responses, likely through the activation of local inhibitory neurons. However, the density of this circuit is greater in males, potentially accounting for reduced glycemic responses. Ultimately, excitatory/inhibitory balance at IL synapses in the RVLM may be critical for the health consequences of stress.

Title: Chronic stress impacts on ventromedial prefrontal encoding of social behavior, stress responding, and reward are stimulus and sex dependent.

Authors: *T. WALLACE, B. MYERS;
Biomed. Sci., Colorado State Univ., Fort Collins, CO

Abstract: The rodent infralimbic cortex (IL) is anatomically homologous to Brodmann area 25, a prefrontal region implicated in depressive etiology and treatment. Thus, understanding how specific neural populations within the IL encode and modulate depression-relevant behaviors is critical for developing more specific neuro-behavioral interventions. In the current study, we hypothesized that chronic stress reduces the in vivo activity of excitatory IL pyramidal neurons based on prior ex vivo and histological studies suggesting enhanced IL inhibition. To address this hypothesis, we utilized a fluorescent calcium indicator to record the activity of IL glutamatergic pyramidal neurons during behavioral tests. In brief, adult male and female rats received unilateral injections in the IL of an adeno-associated virus carrying a construct expressing the fluorescent calcium indicator GCaMP6s under the pyramidal neuron promoter CaMKIIα. In the same surgery, a fiber optic cannula was implanted in the IL for the collection of calcium-induced changes in GCaMP fluorescence. Rats were then assigned to either a chronic variable stress (CVS) group or a stress-naïve group. Following two weeks of CVS or handling, rats were exposed to a modified social assay, 3-day repeated restraint stress, and hedonic food reward. Our results indicate that both male and female IL glutamatergic neurons increase activity during both novel object and social interactions. However, CVS increased activity during objection interactions in females while decreasing activity during social interactions in males. During repeated restraint, both male and female IL glutamatergic neurons had increased activity. Further, CVS sensitized male and female corticosterone responses to restraint while increasing glucose responses in males only. In addition, CVS-exposed males had diminished IL activity during the last 5 minutes of restraint compared to stress-naïve rats on the first day, though this effect was gone by the third day. Both males and females had increased IL activity associated with food reward (chocolate) acquisition. In males but not females, CVS exposure increased the IL food-acquisition response, an effect partially accounted for by reduced food intake. In summary, chronic stress appears to alter IL activity in behaving males more than females. Ongoing studies aim to determine if ovarian hormones protect females from CVS-induced activity changes. Altogether, our data indicate that IL glutamatergic neurons are responsive to novel non-social stimuli, novel social stimuli, acute stressors, and food reward acquisition. Further, CVS alters this activity differently based on stimulus and sex.

Title: Crh release from sparse “eccentric” medium spiny neurons in the nucleus accumbens is required for adaptive novelty responses

Authors: *C. L. PETERSEN[1], J. J. STOLLEY[1], M. A. FUSARO[1], A. E. INGEBRETSON[1], E. A. SOUTER[1], M. BOCARSLY[2], D. DA SILVA E SILVA[3], V. A. ALVAREZ[4], J. C. LEMOS[1]; [1]Neurosci., Univ. of Minnesota, Minneapolis, MN; [2]Natl. Inst. on Alcohol Abuse and Alcoholism, NIH, Bethesda, MD; [3]NIH, Rockville, MD; [4]Lab. on Neurobio. of Compulsive Behaviors, Natl. Inst. on Alcohol Abuse and Alcoholism, Bethesda, MD

Abstract: Corticotropin releasing hormone (CRH) is expressed broadly across the brain and is released in response to stressor exposure as well as other salient environmental stimuli. Within the nucleus accumbens (NAc), a crucial hub for limbic and cortical convergence and a key regulator of motivated behaviors, resides a population of CRH neurons whose neurochemical identity and function remains unknown. Here, we characterize the neurochemical identity and the electrophysiological properties of CRH neurons in the NAc. First, we used fluorescent *in situ* hybridization (FISH) to visualize markers for direct or indirect pathway medium spiny projection neurons (dMSNs vs. iMSNs, respectively) as well as different accumbal interneurons. We found that >85% of *Crh* neurons coexpressed *Drd1* in male mice where only 46% of *Crh* neurons coexpressed *Drd1* in females. Interestingly, only 25% of male and 46% of female *Crh* positive neurons coexpressed the iMSN marker *Drd2*. Together CRH neurons in the male NAc are predominantly dMSNs, whereas in females they are predominantly iMSNs. Consistent with this neurochemical characterization, electrophysiological recordings from CRH-Reporter mice indicate that putative NAc CRH+ neurons have both classic MSN and atypical electrophysiological signatures which are consistent with a recently described “eccentric” MSN population. Next, we deleted *Crh* from the NAc using viral transduction of CRE:eGFP into $Crh^{loxP/loxP}$ male and female mice. Conditional knockout (cKO) mice decreased exploration during the first minute of open field trials, which along with a modest disruption in locomotion as the session continued suggest reduced habituation to the arena. Further, cKO mice increased entries into a zone containing a novel object, but not into a zone containing palatable food. We also found an interaction where cKO females increased sucrose preference relative to controls, whereas male cKO mice tended to decrease sucrose preference. Characterizing CRH neurons in the NAc sheds insight into the contribution of this discrete population to naturalistic behaviors,

with the goal to further understand how CRH signaling may be effected during stress-related psychopathologies.

Title: Investigating CRF receptor type 1 and estrogen receptor alpha regulation of cholinergic interneurons in the nucleus accumbens shell

Authors: *A. E. INGEBRETSON, K. L. OLSON, P. G. MERMELSTEIN, J. C. LEMOS; Univ. of Minnesota, Minneapolis, MN

Abstract: Sex differences in stress encoding as well as the distribution and function of the stress-associated peptide corticotropin-releasing factor (CRF) throughout the brain have been well documented. However, the mechanisms through which ovarian hormones and CRF signaling converge on cells and circuits of the brain modified by stress is unclear. The nucleus accumbens (NAc) in the ventral striatum is a key region that integrates limbic and cortical inputs to shape reward-related behavior. CRF receptor type 1 (CRFR1) is present within the NAc on cholinergic interneurons (ChIs), large aspiny interneurons that constitute 1% of cells in the NAc but broadly modulate striatal circuitry. Activation of CRFR1 robustly potentiates the firing rate of ChIs, indicating that CRF can regulate striatal circuitry through modulating ChIs. Here, we investigated sex- and estrous cycle-dependent differences in CRF regulation of NAc ChIs. Using the fluorescent *in situ* hybridization technique RNAscope, we found that 95% of ChIs in female mice expressed *Crhr1* compared to 81% in male mice. Additionally, we probed for the estrogen receptor *Esr1* (ERα) since rapid membrane-initiated estrogen receptor signaling can participate in modifying neuronal activity and plasticity in the NAc. In female mice, 24% of ChIs expressed both *Crhr1* and *Esr1*, while only 15% co-expressed both markers in male mice. Across stages of the estrous cycle, we observed significant differences in the expression of *Crhr1* and *Esr1*. We next performed cell-attached patch-clamp electrophysiology recordings in ChIs to investigate sex and estrous cycle differences in the CRF-induced enhancement of ChI firing. We observed that ChIs from females displayed lower firing rates at baseline compared to males (females: 2.52 Hz; males: 3.62 Hz), but there were no differences between sexes in the sensitivity of ChIs to CRF.

Interestingly, ChIs from estrus stage females displayed lower CRF-induced firing rates compared to cells from other stages, suggesting that low levels of circulating estrogen during estrus may dampen ChI responsivity to CRF. Current investigations are focused on examining the temporal firing pattern of ChIs, which are characterized by tonic or bursting patterns. Our findings indicate that estrus stage females at baseline display an increased prevalence of ChIs with bursting patterned activity. Understanding the action of estrogen and its receptors on cells and circuits of the brain modified by stress may provide improved treatment options for neuropsychiatric disorders that differ in prevalence or severity by sex.

Title: High levels of hippocampal estrogen contribute to the memory-impairing effects of multiple concurrent acute stresses in female and male mice

Authors: *R. E. HOKENSON, A. K. SHORT, Y. H. ALAM, S. JUNG, Y. CHEN, A. PHAM, S. A. SAMRARI, C. JANG, C. M. GALL, T. Z. BARAM;
Univ. of California, Irvine, Irvine, CA

Abstract: Background: Chronic stress may provoke memory problems, and these vary by sex. More recently memory problems are being recognized following short, traumatic/ stressful events, including mass shootings, assault, or natural disasters, which comprise physical, social, and emotional components. We have established in male mice that multiple acute concurrent stresses (MAS) impair hippocampus dependent spatial memory in the object location and spatial Y-maze, and destroy dorsal CA1 synaptic integrity. In females, MAS impair memory in an estrous cycle-dependent manner, specifically, impairing hippocampal memory in early-proestrous mice, characterized by high levels of estrogen, yet sparing memory of mice stressed during estrus (low estrogen). Notably, hippocampal estrogen levels are higher in males and proestrous females, the mice that are vulnerable to MAS compared to resilient estrous females. Surprisingly, these findings suggest that high levels of hippocampal estrogen may augment

MAS-induced memory disruptions.
Methods: To understand how differences in the relative levels of systemic and hippocampal estrogen may promote susceptibility or resilience of memory to MAS, we examined the impacts of MAS when estrogen activity was pharmacologically blocked, either by blocking estrogen production or selectively blocking estrogen receptor (ER) subtypes. Pharmacological agents were delivered systemically or directly in hippocampus through indwelling cannulae. We quantified estrogen levels by enzyme-linked immunosorbent assay (ELISA) and mass spectrometry.
Results: Blocking estrogen production by administering an aromatase inhibitor for one week leading up to stress prevented memory deficits after MAS compared to vehicle-treated males or proestrous females. In a separate experiment, blocking estrogen receptor (ER) activation by administering ERα or ERβ antagonists, MPP and PHTPP respectively, 90 minutes prior to stress, protected mice from memory impairments. These findings implicate a role of estrogen in promoting memory disruptions following MAS. Studies are underway to expand these findings to hippocampus-specific manipulations.

Title: Acute prolactin increases stress-induced passive coping and corticosterone responses but reduces anxiety-like behavior in ovariectomized female rats

Authors: *J. MEDINA, J. L. WORKMAN;
Psychology, Univ. at Albany State Univ. of New York, Albany, NY

Abstract: Beyond its role in promoting lactation, prolactin (PRL) influences multiple aspects of physiology and behavior including neural plasticity, stress responses, and anxiety-like behavior in rodent models. Stress is a significant risk factor for depression and abnormalities in the hypothalamic-pituitary-adrenal axis have been implicated in the etiology of depression. Previous work from our laboratory suggests chronic PRL treatment reduces several depression-relevant characteristics including anhedonia, passive coping, and basal corticosterone (CORT) concentrations. We sought to determine whether acute PRL treatment reduces stress-induced depression-like behavior and endocrine responses in female rats. Passive coping was assessed with the forced swim test (FST) across two consecutive days: FST 1 for 15 minutes and FST 2

for 5 minutes. Thirty minutes prior to FST 2, rats received a single injection of PRL (1 mg/kg i.p. or s.c.) or saline vehicle. Blood samples from the tail vein were taken 30 minutes after FST 2 to assess stress-induced CORT concentrations. Acute PRL treatment (i.p.) increased passive coping and post-stress CORT concentrations compared to saline or PRL treatment (s.c.). Locomotor and anxiety-like behaviors were assessed in the elevated plus maze. Acute PRL treatment (i.p.) decreased the latency to first open arm entry compared to saline but had no significant effects on measures of locomotor activity. Additionally, we assessed whether PRL alters acute stress-induced cell proliferation and dendritic spine density. Sections containing the hippocampus were processed for Ki-67, a marker for cell proliferation. Golgi-Cox impregnated tissue sections containing the hippocampus and medial prefrontal cortex (mPFC) were selected for dendritic spine tracing of granule cells (hippocampus) and pyramidal cells (mPFC). Acute PRL did not significantly alter dendritic spine density in the hippocampus or mPFC but tended to increase cell proliferation in the ventral hippocampus. Taken together, these findings further our understanding of neuroendocrine mechanisms underlying stress resilience and susceptibility in females.

Title: A crosstalk between Transient Receptor Potential Vanilloid 1 and Cannabinoid Receptor 1 within limbic brain regions regulates depression-like behaviors triggered by stress in rats.

Authors: *W. NORZE, A. RAMOS ROLON, P. MUÑOZ RODRIGUEZ, L. MENDEZ SANTACRUZ, A. RODRIGUEZ LEON, V. SCHLEIER ALBINO, A. ACEVEDO JETTER, M. APONTE REYES, K. TORRES MONTERO, C. MALDONADO VLAAR;
Univ. of Puerto Rico, San Juan, Puerto Rico

Abstract: Clinical studies provide strong evidence that stress is an environmental risk factor that can trigger the onset of several neuropsychiatric disorders such as anxiety and depression in humans. Pre-clinical evidence suggests that the endocannabinoid and endovanilloid system within the brain are important neuronal substrates involved in emotional responses to stress. Specifically, studies have proposed that the Transient Receptor Potential Vanilloid 1 (TRPV1) a member of the Transient Receptor Potential (TRP) superfamily, within the brain regulate anxiety and depression behaviors through its interactions with the cannabinoid receptor 1 (CB1R).

However, little is known about the cellular mechanisms that regulate these receptors' interactions across the brain and its impact in neuropsychiatric disorders. We investigated the role of TRVP1 and CB1R within several brain regions including the medial prefrontal cortex as part of the dopamine mesocorticolimbic system, the hippocampus and the amygdala in anxiety and depression like-behaviors using rats as animal model. To examine the role of these two receptors in depression like-behaviors, male and female Sprague Dawley rats were treated for 4 days with vehicle or FAAH inhibitor URB597 [0; 0.1 ;0.2mg/kg/ip] 2 hours before testing in the forced swim test (FST) for 6 min. Another group were treated for 4 days with either vehicle or Olvanil, a TRPV1 receptor inhibitor [0; 0.3; 0.5 mg/kg/ip] 30 min before testing in the FST for 6 min, a third group of animals were treated for 4 days with either vehicle or URB597 [0; 0.1 ;0.2mg/kg/ip] and Olvanil [0; 0.3; 0.5 mg/kg/ip] 2 hours before testing in the FST for 6 min. Floating and swimming behaviors were observed during the FST session. Our results suggest that URB597 significantly decreased depression like-behavior. In contrast, treatment with olvanil increased depression-like behaviors in the experimental animals when compared to controls. Dual treatment of experimental compounds decreased depression like-behaviors. Ongoing biochemical analysis of the changes in expression of TRPV1 and CB1 receptors following treatment with URB597 and olvanil will support mechanistic explanations for the present behavioral results.

Title: The BNST mediates the expression of two-way signaled avoidance in male rats

Authors: *D. P. GUERRA, J. M. MOSCARELLO;
Texas A&M Univ., College Station, TX

Abstract: Although avoidant behavior is a unifying symptom of many anxiety disorders, its underlying neural circuitry has yet to be elucidated. Here, we report a series of experiments using a signaled active avoidance (SAA) procedure to model avoidant behavior in rats. In SAA, the

subject first acquires an association between a tone (CS) and a shock (US) and then learns to perform an avoidance response during the CS in order to prevent US delivery. Over the course of SAA training, the US becomes less frequent and thus goes from being a certain/imminent threat to a possible/distal threat as the avoidance response is acquired. Though the bed nucleus of the stria terminalis (BNST) has been shown to mediate defensive responses to possible/distal threats, its role in SAA has yet to be examined. We used a chemogenetic approach to test the hypothesis that BNST is necessary for the expression of the avoidance response. Male rats received intra-BNST infusions of AAV containing the gene construct for either the inhibitory hM4Di DREADD or GFP. After recovery, animals received four days of SAA training in order to reach stable levels of avoidance. This was followed by two additional days of SAA training preceded by counterbalanced IP injections of either the DREADD ligand CNO or vehicle. We found that CNO decreased avoidance responses in hM4Di subjects but not in GFP controls, demonstrating that the BNST is necessary for the avoidance response. Because some subjects showed hM4Di expression in the medial septum (MS), we followed up with an anatomical control experiment specifically targeting this region. We found no evidence of a role for MS, indicating that the effects observed in our initial experiment were BNST-specific. We then compared chemogenetic activation (hM3Dq) and inhibition (hM4Di) of BNST in a test of avoidance under extinction conditions. Because stimuli were delivered in an invariant way that was not contingent upon the subjects' response, this design allowed us to test all groups under common conditions. After AAV infusions and recovery, subjects received six days of avoidance training. 24 hours later, all subjects were exposed to 10 unreinforced CSs preceded by either CNO or vehicle. We found that CNO decreased avoidance in hM4Di subjects and increased avoidance in hM3Dq subjects relative to GFP and vehicle controls, confirming that BNST is not only necessary for normal levels of avoidance but is also sufficient to potentiate the response. These results demonstrate that BNST, a region known to mediate behavioral defense against low imminence threats, is a crucial substrate of avoidant behavior.

Title: A systems consolidation-like process recruits the retrosplenial cortex to the long-term maintenance of signaled avoidance

Authors: *M. R. KREITLOW[1], J. M. MOSCARELLO[1], L. J. KEPPLER[2];
[1]Texas A&M Univ., College Station, TX; [2]UT Hlth. San Antonio, San Antonio, TX

Abstract: The acquisition and expression of two-way signaled active avoidance (SAA) are supported by a changing neural substrate. Though recent work has begun to explore the circuitry underpinning the early stages of SAA, less is known about the mechanisms responsible for long-term maintenance of the response. Because of its established role in long-lasting forms of aversive memory, we hypothesized that the retrosplenial cortex (RSC) would be recruited to support SAA with extensive training. In our first experiment, male rats received intra-RSC injections of an AAV5 containing the gene construct for either the inhibitory hM4Di DREADD or GFP on a CamKII promoter. Following recovery, animals underwent an SAA training paradigm in which they learned to shuttle across a divided chamber during a tone in order to avoid foot shock. Animals were trained for 4 days to achieve asymptotic levels of avoidance. Subjects then received two SAA test sessions on days 5 and 6 that were preceded by counterbalanced IP injections of either CNO (3mg/kg) or VEH (saline + 10% DMSO). Animals received 2 more days of training, followed by another pair of test sessions on days 9 and 10. Though CNO inactivation of RSC had no effect on avoidance behavior after 4 days of training, RSC inhibition caused a robust decrement at the latter timepoint, demonstrating that long-term maintenance of the avoidance response requires RSC. We then set out to determine whether recruitment of the RSC was brought about by extensive training or whether time following initial acquisition would result in the RSC-dependence of SAA. hM4Di or GFP was expressed in RSC pyramidal neurons, as previously described. After recovery, subjects received either 4 days of training immediately followed by 2 SAA test sessions preceded by CNO or VEH, or 4 days of training followed by 4 days off in the homecage prior to 2 SAA test sessions. CNO inactivation of RSC attenuated avoidance behavior only in animals that received 4 days off in the homecage, suggesting that time following acquisition is sufficient to recruit RSC to SAA. These data confirm that RSC plays a role in the long-term maintenance of the avoidance response, and demonstrate that continued training beyond initial acquisition is not necessary for recruitment of RSC. To confirm the anatomical specificity of our results, we performed a control experiment in which we chemogenetically inactivated a neighboring region highly interconnected with RSC, the dorsal hippocampus, after 4 or 8 days of SAA. These manipulations had no effect on SAA. Collectively, our data demonstrate that RSC is a key substrate underlying the long-term maintenance of SAA and is recruited via a systems consolidation-like mechanism.

Title: Expression of active avoidance in rats depends on the experience of a social partner that is present during conditioning.

Authors: *G. ERICKSON, A. SCOTT, T. MAZE, K. RODRIGUEZ, M. M. DIEHL; Psychological Sci., Kansas State Univ., Manhattan, KS

Abstract: Active avoidance of perceived danger is essential for survival. In rats, active avoidance can be studied under controlled laboratory settings using the platform-mediated avoidance (PMA) task, in which a rat learns to avoid a tone-signaled footshock by stepping onto a safe platform (Bravo-Rivera et al., 2014). Because PMA has only been studied in the absence of social cues, we were interested in whether prior PMA experience of a social partner would facilitate the learning and memory of avoidance in a naïve rat. We therefore modified the PMA task, in which two rats underwent PMA conditioning simultaneously, each with individual access to a food bar and platform. Male and female rats underwent PMA conditioning in the presence of a same-sex partner that was either naïve to the task or experienced (i.e. previously PMA-conditioned). The rats were separated by a perforated plexiglass barrier allowing for transmission of visual and olfactory cues. Across 10 days of conditioning, we measured percent time on platform and freezing to the tone. Preliminary analyses show no differences in avoidance or freezing between rats with an experienced (n = 6) vs. naïve partner (n = 11), nor were there differences in the number of shocks received (i.e., failures to successfully avoid), suggesting that the presence of a social partner does not affect PMA acquisition. After 10 days of social partner conditioning, rats underwent an additional conditioning session on Day 11 without their social partner. Preliminary data show that rats with an experienced partner (n = 6) spent more time avoiding compared to rats with a naïve partner (n = 3; experienced partner mean = 86% vs. naïve partner mean = 67%). Rats with an experienced partner also exhibited lower average freezing across all 9 tones compared to rats with a naïve partner (experienced partner mean = 34% average freezing vs. naïve partner mean = 49%). Together, these data suggest that the presence of an experienced partner during acquisition may improve performance of active avoidance when facing the same situation alone, but not affect performance during the learning period.

Title: Prefrontal function in threat and safety learning during normal and stress conditions, using a novel paradigm involving thermal stimuli

Authors: A. C. FELIX-ORTIZ[1], M. C. GARZA[3], D. T. ARRIAGA[1], D. T. HAJALI[1], S. M. LOPEZ[4], H.-G. LEE[2], *A. BURGOS-ROBLES[1];
[1]Neurosci., [2]Biol., Univ. of Texas at San Antonio, San Antonio, TX; [3]Neurosci., Univ. of Texas At San Antonio, San Antonio, TX; [4]Computer Sci., St. Mary's Univ., San Antonio, TX

Abstract: Optimal learning of threat and safety is fundamental for animals to thrive in their environment. Growing evidence implicates the prefrontal cortex (PFC) in this ability during motivational conflict. However, it is still a matter of debate how distinct PFC divisions, such as the infralimbic (IL) and prelimbic (PL) cortices, contribute to the learning and coordination of behaviors associated to threat and safety during situations of conflict. Furthermore, it remains unclear how these PFC divisions contribute to alterations in threat and safety conflicts after prolonged psychological stress. In this study, we developed a novel task in mice using naturalistic thermal stimuli, cold (5°C) versus warm (30°C) zones in an acrylic apparatus, to simulate threat and safety, respectively. Discrete visual cues on the walls helped mice to distinguish the threat and safety zones during training. Mice were then required to remember these visual cues during a long-term memory test session while all zones had a uniform temperature. During the test session, mice avoided the previously cold zones, and spent most of the time in the previously warm zones. Mice in control groups that underwent training on an apparatus with a uniform temperature spent equal times in all zones during test. These findings indicate that mice can optimally distinguish, learn, and remember threat-like and safety-like areas of an environment using thermal stimuli. We next used a social isolation stress paradigm in which mice underwent isolated housing for 12 days, followed by 14 days of group housing prior to the thermal stimuli conflict task. This history of social isolation stress did not affect threat and safety detection during training in the thermal stimuli conflict task. However, stress produced a robust impairment in subsequent memory recall during the long-term test session. We finally tested the functional role of the IL and PL divisions of PFC using an ArchT-mediated optogenetic silencing strategy. Performance in the thermal stimuli conflict task during training was unaffected by either IL or PL silencing. However, IL silencing led to a robust impairment in memory recall in no-stress controls during the subsequent test session, thus mimicking the stress-related effect. In contrast, PL silencing during training fully prevented the memory recall impairment observed in stressed mice. Collectively, these findings suggest that the IL and PL divisions of PFC play important roles for both threat and safety learning associated to thermal stimuli, and that alterations in IL and PL activity play major contributions during stress-related alterations in threat and safety learning.

Title: Mapping the brain-wide axonal projection patterns of anatomically-defined prefrontal neurons

Authors: *M. W. GONGWER, C. KLUNE, R. CHEN, L. A. DENARDO;
Physiol., David Geffen Sch. of Med. at UCLA, Los Angeles, CA

Abstract: Descending projections from medial Prefrontal Cortex (mPFC) to its downstream targets are critical in the regulation of adaptive behaviors including decision making, social behavior and conditioned fear. Studies utilizing optogenetic and chemogenetic techniques have demonstrated that specific mPFC projections have distinct behavioral roles. It is known that long range projection neurons can innervate multiple target regions. However, the anatomical collateralization patterns of mPFC projection neurons is not well understood. Understanding the collateralization patterns of mPFC projections is necessary to understand how mPFC projections may simultaneously affect downstream brain regions to produce specific behaviors. In this study, we used a dual-viral strategy to label the brain-wide collateralization patterns of projections from mPFC to Nucleus Accumbens (NAc), Ventral Tegmental Area (VTA), and contralateral mPFC (cmPFC) in mice. An AAV expressing Cre recombinase was injected unilaterally into either VTA, NAc, or cmPFC. Then, a Cre-dependent AAV expressing a membrane-bound GFP fluorophore was injected unilaterally into mPFC. The membrane-bound nature of the GFP fluorophore allowed for the visualization of any axon collaterals innervating other target regions. Following six weeks of expression, brains were collected and cleared using the Adipoclear protocol. Light sheet fluorescence microscopy was used to image the entire left hemisphere of the intact brain. TRAILMAP, an axon classifier pipeline based on machine learning, was used to identify axons and quantify their density within brain regions. We observed that mPFC projections to NAc, VTA and cmPFC each display collateralization with multiple other brain areas. Our analyses revealed distinct collateralization patterns based on the projection target, with distinctions in cortical, amygdalar, thalamic, and hypothalamic axonal density. These data further our anatomical knowledge of mPFC projections and allow us to better understand how mPFC orchestrates behavior through its descending influence. The findings of this study can be

used to more accurately design and interpret experiments that manipulate neuronal projections to gain a more comprehensive understanding of mPFC function.

Title: BehaviorDEPOT: a tool for automated behavior classification and analysis in rodents

Authors: *C. GABRIEL, Z. ZEIDLER, B. JIN, A. WU, L. A. DENARDO;
UCLA, Los Angeles, CA

Abstract: Quantitative descriptions of animal behavior are essential to understand the underlying neural substrates. Fear conditioning in rodents is a widely used assay that allows neuroscientists to probe the neural mechanisms of memory. To date, quantification of freezing behavior, a proxy for fear memory strength, is usually performed by hand or with expensive and inflexible commercial software. To overcome these barriers, we developed BehaviorDEPOT (DEcoding behavior based on POsitional Tracking), a MATLAB-based application containing six independent modules. The Experiment Module runs fear conditioning experiments using an Arduino-based design that interfaces with commercial hardware. The Analysis Module classifies freezing and analyzes spatiotemporal behavioral statistics in user-defined ways. The remaining modules can develop custom classifiers. Of note, the Inter-Rater Module establishes reliable 'ground-truth' human labels, making it broadly useful for scientists developing classifiers with any application. BehaviorDEPOT provides a simple, flexible, automated pipeline to move from pose tracking to reliably quantifying task-relevant behaviors.

Title: Functional connectomes of amnesic and persistent memories

Authors: *B. JIN[1], A. WU[2], L. DENARDO[3];
[1]Molecular, Cellular, and Integrative Physiol., [2]Inst. for Society and Genet., [3]Dept. of Physiol., UCLA, Los Angeles, CA

Abstract: In infantile amnesia, memories formed early in life are short-lived, while those formed later can last a lifetime. We model this phenomenon in mice using contextual fear conditioning. Infant mice that undergo fear conditioning exhibit amnesia of fearful associations while adults exhibit long-lasting memories. To respond adaptively to fearful stimuli, the brain depends on the coordination of a broad network of cortical and subcortical brain regions. While the neural substrates underlying conditioned fear have been well-studied in the adult, the organization of fear memory networks in the developing brain remains poorly understood. We hypothesize that immature brain connectivity in development may cause infantile amnesia. Yet, whether and how the infant fear network undergoes reorganization or refinement across development to facilitate memory stability remains unclear. To address this issue, we performed whole brain mapping of activated neuronal populations using TRAP2 mice (Targeted Recombination in Active Populations) in combination with brain clearing and light sheet fluorescence microscopy. To identify neural signatures of memories that will become amnesic, we labeled neuronal ensembles activated by recent (1 day) fear memory at key developmental timepoints P17, 25, and 60 characterized by amnesic and lasting memories, respectively. Network analyses reveal that the functional organization of fear memories is dynamic across development. Importantly, our analyses suggest that there is increased cortical regulation of subcortical structures from adolescence to the young adult stage at P60. This age-dependent shift parallels the transition from shorter-lasting memories in infancy to longer-lasting memories in adolescent and adult mice, highlighting potential mechanisms that underlie the emergence of persistent fearful memories across development.

Title: Development of medial prefrontal cortex circuitry and its role in the maturation of adaptive avoidance in mice

Authors: *C. KLUNE[1], C. GOODPASTER[1], R. CHEN[2], L. A. DENARDO[1];
[1]Physiol., [2]Computer Sci., UCLA, Los Angeles, CA

Abstract: The medial prefrontal cortex (mPFC) and its circuitry regulate numerous adaptive functions in both humans and rodents, including decision making, social behaviors, and mood. Many mPFC-dependent behaviors mature from adolescence to adulthood, which may reflect the protracted developmental period of mPFC. Despite the critical control that mPFC exerts over behavioral functions, when specific mPFC circuits mature and how they regulate behavior across development is poorly understood. This study aims to define the temporal development of mPFC projections to the nucleus accumbens (NAc) and basolateral amygdala (BLA) and their contribution to adaptive avoidance behavior from the postnatal period to adulthood in mice. A platform-mediated avoidance (PMA) task was modified to accommodate testing during the postnatal period. PMA, in which a fear-conditioned tone prompts rodents to navigate to a safety platform, has previously shown to be bidirectionally modulated by mPFC projections to NAc and BLA in rats. In a single training session, adult mice learned to avoid the shock by entering the platform upon presentation of the tone. The next day, avoidance memory was tested in a retrieval session during which tones were presented without the shock. Adult mice spent more time on the platform during the tone periods than is expected by chance, suggesting retention of the learned avoidance response. Our data demonstrate that adaptive responding in this task is developmentally regulated. At postnatal day (P)17, mice do not learn to avoid the shock. By P23, mice learn to avoid the shock during training but do not show robust levels of avoidance during retrieval. At P28, mice learn to avoid and demonstrate retention of learned avoidance 1 day later. Developmental viral tracing data reveals that mPFC axon density in both NAc and BLA increases from P16 to P28 and declines from P28 to adulthood. These changes in axonal innervation density may reflect arborization and pruning events. Finally, optogenetics was used to assess the functional role of mPFC projections to NAc and BLA during PMA at the developmental timepoints. In both adulthood and at P28, optogenetic activation of mPFC to NAc projections during the tone period of the retrieval session significantly decreased time on the platform. Excitation of mPFC to BLA neurons is expected to augment avoidance in adults and

may be able to increase avoidance in P23 mice. The findings of this study will elucidate how mPFC projections develop and contribute to the emergence of adaptive behavior. Understanding how mPFC circuits develop in the typical brain is foundational to how their development may be perturbed and contribute to disease states.

Title: The neurosteroid 3alpha-androstanediol does not confer state dependence to contextual fear in male rats

Authors: *R. BLAIR[1], N. NAGAYA[2];
[1]Texas A&M Univ., Bryan, TX; [2]Texas A&M Univ., College Station, TX

Abstract: Sex steroids and their neuroactive metabolites can modulate emotional behavior in both humans and rodents. We have previously shown that allopregnanolone (ALLO), a progesterone metabolite, can confer state dependence to contextual fear when infused into the bed nucleus of the stria terminalis (BNST) of adult male rats. The testosterone metabolite, 3α-androstanediol (3α-diol), is similar to ALLO such that it produces anxiolysis and acts as a positive allosteric modulator of the $GABA_A$ receptor. In the present study, we hypothesized that 3α-diol, like ALLO, may confer state dependence to contextual fear via modulation of GABAergic tone. To this end, we bilaterally infused 3α-diol (7.3 μg/μL) or vehicle (VEH; 30% 2-hydroxypropyl-β-cyclodextrin) into the BNST of adult male rats (n = 40) 10 min prior to Pavlovian fear conditioning with 5 tone (CS; 2 kHz, 10 s, 80 dB)-footshock (2 s, 1 mA) pairings. On subsequent days, fear retention was tested by separate exposures to context (10 min) and cue (4 CS-alone trials in a novel context) following infusion of either the same or different drug (3α-diol or VEH). Acquisition and expression of contextual and cued fear were similar for all animals, regardless of drug treatment. Further, no significant interaction was found between drug infused on conditioning and testing days, suggesting that 3α-diol does not confer state dependence to either contextual or cued fear. A subset of animals (n = 15) was subjected to extinction training and testing sessions consisting of 45 CS-only presentations each in a novel context. After infusion of either 3α-diol or VEH, rats received extinction training followed by an extinction retention test 24 h later. Acquisition of extinction differed between drug treatment groups. Compared to VEH-treated animals, those treated with 3α-diol showed enhanced cued

fear extinction, especially over the first 20 trials. Extinction retention did not differ between treatment groups. Overall, these findings suggest that, unlike the neurosteroid ALLO, 3α-diol does not confer state dependence to contextual fear via the BNST but may modulate cued fear extinction.

Title: Maternal presence during threat learning modulates functional connectivity and community structure in infant rats

Authors: *A. M. WHITE[1,2,3], J. DEBIEC[1,2,3];
[1]Michigan Neurosci. Inst., [2]Dept. of Psychiatry, [3]Neurosci. Grad. Program, Univ. of Michigan, Ann Arbor, MI

Abstract: As infant rats begin to develop independence from their mother, their nervous system must start responding to and learning about threats. However, it remains ecologically relevant for threat learning to be under the control of the mother until the infant has matured to full independence. Previous studies have shown that pups in the second week of life that undergo Pavlovian odor-shock conditioning in the presence of an anesthetized mother will not demonstrate threat responses to future presentations of the conditioned odor. This is mediated in part by the mother's ability to suppress amygdala activity during threat learning. There has been a growing appreciation that patterns of neuronal activity between groups of brain areas, rather than simple absolute increases or decreases in activity, are essential for this type of learning. We used a graph theoretical approach to analyze patterns of immediate early gene expression and investigate differences in functional networks engaged by postnatal day 12-15 male and female infant rats that underwent Pavlovian odor-shock conditioning without or with maternal presence. Functional connectivity between regions of interest previously shown to be critical for threat learning and processing of social cues shifted depending on whether the mother was present during threat learning. A community detection algorithm revealed that maternal presence during threat learning altered network structure and which regions function as hubs. Our results demonstrate the power of the graph theoretical approach and the power of the mother's ability to modulate coordinated neural activity within her pups during a critical developmental timepoint.

Title: New insights on the role of distinct prefrontal cortical divisions using a novel task for active avoidance learning that involves a dynamic option for safety.

Authors: *M. GARZA;
Univ. of Texas At San Antonio Dept. of Biology/Neurobiology, San Antonio, TX

Abstract: Active avoidance is a learned, complex, adaptive behavior that helps animals prevent harm associated with imminent threat. Although previous studies have implicated the prefrontal cortex (PFC) in active avoidance, the functional role for distinct PFC divisions - such as the infralimbic cortex (IL), prelimbic cortex (PL), and anterior cingulate cortex (ACC) - still remain unclear. To address this, we developed a novel variation of the platform-mediated avoidance paradigm (Diehl, Bravo-Rivera, and Quirk 2019) that isolates threat-related behaviors and active avoidance responses while eliminating appetitive reward components and motivational conflict. In this new task, mice received auditory cues (80 dB, 20 sec) that predicted mild electric shocks (0.30 mA, 2 sec, co-terminating with cues). As mice learned the tone-shock association (20 trials per session), they also learned to avoid shocks by stepping onto a motorized, non-electrified dynamic platform that was inserted into one corner of the apparatus before the beginning of each trial, and retracted shortly after the termination of each trial. In this way, the platform was only available when mice needed it to perform active avoidance responses and minimized passive avoidance responses (i.e., staying on the platform during the inter-trial intervals). Results showed that mice initially exhibited conditioned freezing responses that gradually transitioned into active avoidance responses. We next implemented an ArchT-mediated optogenetic inhibition approach to silence glutamatergic outputs from the distinct PFC subregions and tested their roles during the new avoidance task. These experiments revealed that selective silencing of the IL-PFC glutamatergic outputs significantly impaired the gradual decay of conditioned freezing and strongly affected the acquisition of active avoidance responses. Selective silencing of the PL-PFC glutamatergic outputs produced no significant effects on freezing or avoidance behaviors. Current experiments are testing the role of the ACC-PFC in this task. Therefore, while previous studies suggest crucial functional roles for the distinct PFC divisions in active avoidance, new studies should consider that integration of appetitive components and motivational conflict could plausibly confound findings on active avoidance learning.

Title: Evidence of the potential therapeutic utility of a selective PDE4B inhibitor for reducing methamphetamine-taking in two substrains of C57BL/6 mice

Authors: *K. M. HONEYWELL[1], E. VAN DOREN[2], K. K. SZUMLINSKI[1];
[2]Psychological and Brain Sci., [1]Univ. of California, Santa Barbara, Santa Barbara, CA

Abstract: Tolerability issues accompanying the targeting of neuroinflammation using inhibitors of the cAMP-hydrolyzing enzyme, phosphodiesterase 4 (PDE4), may limit therapeutic utility for reducing drug-taking and -craving. Herein, we examined the effects of a PDE4B-selective inhibitor, A33, on methamphetamine (MA) intake by female and male mice of genetically distinct C57BL/6J (B6J) and C57BL/6NJ (B6NJ) substrains that differ both in their behavioral sensitivity to MA and their innate immune response. Mice were first trained to acquire oral MA self-administration (100 mg/L) under operant-conditioning procedures. Then, the dose-response function (0-1.0 mg/kg) for A33's effects upon the maintenance of oral MA intake was determined. Females and B6J mice more readily acquired MA self-administration and self-administered more MA than males and B6NJ mice. Irrespective of sex or substrain, A33 pretreatment reduced the intake of 100 mg/L MA. We next compared the dose- and demand-response functions for oral MA intake and detected no sex or substrain differences in MA reinforcement or intake. Finally, mice were pretreated with either 0 or 1.0 mg/kg A33 prior to tests for cue-reinforced responding under extinction conditions. However, we failed to detect any significant effect of A33 pretreatment on cue-reinforced responding, nor did we detect significant sex or substrain differences. These data provide the first evidence that selective PDE4B inhibition is an effective strategy for reducing MA reinforcement, but not MA cue-reactivity, in mice. A33 was equally effective in males and females and exerts a quantitatively similar reduction in MA intake in mice with a genetic predisposition for high versus moderate behavioral sensitivity to MA. Such findings support the potential clinical utility of selectively targeting PDE4B for reducing active MA-taking in individuals with MA Use Disorder.

Title: Camkii-dependent homer2 phosphorylation does not alter alcohol reinforcement in mature adult or middle-aged mice.

Authors: *F. J. CANO[1], S. L. SCUDDER[1], M. DOOR[1], K. M. HUBER[2], K. K. SZUMLINSKI[1];
[1]Univ. California-Santa Barbara, Santa Barbara, CA; [2]Neurosci., Univ. of Texas Southwestern Med. Ctr. at Dallas, Dallas, TX

Abstract: Homer2 is a glutamate receptor-related post-synaptic scaffolding protein that is up-regulated throughout the extended amygdala, affecting both alcohol intake and intoxication. Homer2 is phosphorylated on S117/S216 by calcium-calmodulin kinase II alpha (CaMKII) and this phosphorylation causes a rapid dissociation of mGluR5-Homer2 binding. congenic C57BL/6J mice with alanine point mutations at S117/216 that prevent Homer2 phosphorylation (AA mice) exhibit blunted binge alcohol-drinking, but do not differ from wild-type (WT) littermates in terms of alcohol consumption under continuous-access procedures. Herein, we compared alcohol reinforcement between AA and WT mice. Female and male mice were trained for 2 weeks (Cohort 1; mice approximately 12 months old) or 4 weeks (Cohort 2; mice approximately 6 months old) to nose-poke for 20% alcohol under an FR1 schedule of reinforcement during daily 30-min sessions. During early acquisition training, AA mice from the older Cohort 1 exhibited significantly lower responding and consumed significantly less 20% alcohol than WT animals, with strong trends detected also for lower reinforced responding and reinforcers earned. However, this genotypic difference in early alcohol responding did not replicate in the younger Cohort 2 animals. No genotypic differences were observed in either cohort for the proportion of mice meeting the acquisition criteria or for the alcohol dose- and demand-response functions, although a sex difference in responding was detected in Cohort 2 that was not apparent in the older mice. Taken together, the present data do not support a key role for Homer2 phosphorylation in alcohol reinforcement or intake under operant-conditioning procedures. Such findings further the notion that CaMKII alpha-dependent phosphorylation of

Homer2 plays a relatively selective role in regulating binge-drinking, which likely reflects dynamical interactions between Homer2 and mGlu5 within the extended amygdala. Title: Effects of inhibiting AMPA and NMDA-type glutamate receptors in the ventromedial prefrontal cortex on sucrose self-administration

Authors: *L. L. HUERTA SANCHEZ, M. LANZ, K. K. SZUMLINSKI;
Univ. of California, Santa Barbara, Santa Barbara, CA

Abstract: The glutamatergic system is purported to play an important role in the self-administration of both drug and non-drug reinforcers, such as sucrose. However, sucrose-experienced rats exhibit blunted glutamate release within the ventromedial prefrontal cortex (vmPFC), calling to question the role for glutamate receptor activation within this region in driving sucrose reinforcement. To address this question, this study investigated the role of vmPFC AMPA- and NMDA -type glutamate receptors in sucrose-taking. For this, male Sprague-Dawley rats were implanted with bilateral guide cannulae aimed over the vmPFC and were trained to self-administer sucrose pellets (6hr/day) for 10 days . Using a within-subjects design, rats were microinjected (0.5 µl per side) with the GluA2-lacking selective AMPA antagonist Naspm (40 µg), the non-selective AMPA receptor antagonist NBQX (1 µg), the GluN2A-selective NMDA antagonist PPPA (1.65 nmol), the GluN2B-selective NMDA antagonist TCN-237 (10 µM) and the non-selective NMDA receptor antagonist D-AP5 (2.5 µg). Following each microinjection, rats underwent a 2-hr test for sucrose self-administration. Microinjection of D-AP5 increased responding for sucrose reinforcement, while no significant effects were observed for the other compounds tested. These results indicate that activation of NMDA receptors within the vmPFC suppress sucrose self-administration, whereas AMPA receptors do not appear to be involved.

Title: Expression of immediate early genes after an acute administration of novel synthetic cathinones in mice.

Authors: *E. URQUIZU[1,2], M. ESPINOSA-VELASCO[2], N. NADAL-GRATACOS[1,2,3], P. PUIGSESLLOSES[2], M. BUENROSTRO-JÁUREGUI[1], X. BATLLORI[3], X. BERZOSA[3], D. PUBILL[2], J. CAMARASA[2], E. ESCUBEDO[2], R. LÓPEZ-ARNAU[2];
[1]UNIVERSIDAD IBEROAMERICANA, Álvaro Obregón, Mexico; [2]Dept. of Pharmacology, Toxicology and Therapeut. Chem., UNIVERSITY OF BARCELONA, Barcelona, Spain; [3]IQS Sch. of Engineering, Univ. Ramon Llull, Barcelona, Spain

Abstract: Synthetic cathinones, one of the most prevalent group of new psychoactive substances, have become a global phenomenon because of their easy accessibility and similar effects to cocaine or MDMA. It is known that continuous drug exposure causes neuroadaptations in dopaminergic neurons of several brain regions, which are thought to be involved in the transition from recreational drug use to drug addiction. However, these changes begin with variations on immediate early genes (IEGs), underlying the addictive potential of these drugs. Thus, the aim of this project was to study the changes in IEGs expression involved in the addictive process after an acute administration of novel synthetic cathinones: pentedrone, pentylone, N-ethyl-pentedrone (NEPD), N-ethyl pentylone (NEP), 4-methyl pentedrone (4-MPD) and 4-methyl--ethylaminopentedrone (4-MeAP). CD-1 male mice were injected the corresponding synthetic cathinone (10 mg/kg, i.p.) or saline solution. RNA was extracted from ventral striatum (VS), dorsal striatum (DS) and medial prefrontal cortex (mPFC) in order to analyze the expression of the IEGs *Arc*, *c-fos* and *bdnf 30* or 120 min after administration by a quantitative RT- PCR technique. Results revealed that an acute injection of pentylone, NEPD, NEP and 4-MeAP induced a significant increase of *Arc* gene expression in VS and DS 120 min after administration. However, only NEP significantly increased mRNA levels in VS 30 min after injection. All the synthetic cathinones tested in this study induced a significant increase in *c-fos* expression in DS 30 and/or 120 min post-administration, except for 4-MPD. Regarding VS, only NEPD, NEP and pentedrone administrations were able to significantly increase *c-fos* levels. Although a tendency to increase *bdnf* expression was observed after an acute administration of all compounds tested, only NEP-treated mice showed a significant overexpression of mRNA

bdnf levels. This study evidences that novel synthetic cathinones are able to up-regulate the expression of some IEGs in mouse DS, VS and mPFC. This overexpression may lead to prolonged neuroadaptations, memory formation, neuroplasticity and in changes in behavior to psychostimulants. These modifications could lead to cellular cascades and be a sign of the early stage of drug addiction.

Title: Distinct DNA methylation signatures in mouse nucleus accumbens in alcohol use disorder susceptibility.

Authors: *G. KAPLAN[1], Y. LI[1], R. S. JASROTIA[1], J. CHITAMAN[1], N. WADDELL[1], K. ABREU[1], H. XU[1], R. HEDINGER[1], C. REMEDIES[1], G. XU[2], J. FENG[1];
[1]Biol. Sci., Florida State Univ., Tallahassee, FL; [2]Inst. of Biochem. and Cell Biology, Chinese Acad. of Sci., Shanghai, China

Abstract: Most adults consume some alcohol, yet only around 10% of them develop an alcohol use disorder (AUD). Elucidating the neural mechanisms underlying susceptibility to AUD represents an expeditious approach to relieving the alcohol disease burden. Dysregulation of DNA methylation, a major epigenetic mechanism, is increasingly implicated in the etiology of AUD. In this study, we utilized a mouse model of alcohol behavioral sensitization - a form of behavioral plasticity thought to underlie the transition from recreational to compulsive drug use - to explore the DNA epigenetic underpinnings of alcohol use disorder susceptibility differences. Adult male C57BL6/J mice were given daily i.p. injections of alcohol or saline. Based on their locomotor response on day 21, mice from the top and bottom quartiles of the alcohol-treated group were classified as sensitized or non-sensitized, respectively. In subsequent self-administration experiments, sensitized mice consumed significantly more alcohol, but not sucrose, demonstrating relevance to AUD susceptibility. We then profiled whole-genome DNA methylation in the nucleus accumbens (NAc) using enzymatic methylation sequencing (EM-seq). We identified substantial DNA methylation differences between sensitized and non-sensitized mice enriched in addiction related gene categories. Differential methylation was also associated with phenotype-specific alterations in chromatin accessibility and gene expression. Furthermore, we found DNA methylcytosine dioxygenase *Tet3* was differentially expressed between

sensitized and non-sensitized mice. Knocking down *Tet3* in the NAc of alcohol-naïve mice attenuated alcohol sensitization and recapitulated some DNA methylation changes associated with AUD. Our study therefore demonstrates that behavioral sensitization differences to alcohol are associated with distinct DNA methylation signatures in mouse nucleus accumbens, which supports a functional role of DNA methylation in AUD susceptibility.

Title: Reprogramming ZFP189 transcription factor function within the nucleus accumbens regulates drug specific behaviors and transcription

Authors: *J. A. PICONE[1], G. SILVA[2], X. CUI[1], P. J. HAMILTON[1];
[1]Anat. and Neurobio., [2]Pharmacol. and Toxicology, Virginia Commonwealth Univ., Richmond, VA

Abstract: Understanding the molecular drivers of the stages of drug addiction may allow for the design of pharmacotherapies that block or reverse key events of the progression of drug addiction. *Zfp189* is a CREB-target gene which itself encodes an unstudied nucleus accumbens (NAc) neuronal transcription factor that has been demonstrated to regulate transcriptional networks in neuropsychiatric disorders. In rodents, *Zfp189* gene expression increases following exposure to psychostimulants, like cocaine. To further examine the downstream relationship between ZFP189 and physiological response to different classes of drugs of abuse, three re-engineered ZFP189 variants were designed to interrogate ZFP189-mediated gene regulation and subsequent behaviors following exposure to psychostimulants (cocaine) or opiates (morphine). The three ZFP189 variants used were: $ZFP189^{WT}$ (the endogenous gene with transcriptionally inhibitory KRAB domain), $ZFP189^{DN}$ (maintains binding domain but lacks KRAB domain), and $ZFP189^{VPR}$ (KRAB domain was replaced with the transcriptional activator VP64-p65-Rta (VPR)). A luciferase reporter gene possessing ZFP189 response element illuminated that $ZFP189^{WT}$ functions as gene repressor and $ZFP189^{VPR}$ exerts opposite function as a robust gene

activator. The nucleus accumbens of male and female C57/BL6J mice were transduced with ZFP189 variant constructs via viral-mediated gene transfer. We then performed a drug locomotor sensitization assay for repeated injections of saline, cocaine, or morphine. Mice expressing $ZFP189^{VPR}$ exhibit heightened cocaine locomotor sensitization relative to $ZFP189^{WT}$ and $ZFP189^{DN}$. Interestingly, this increased locomotion is unique to cocaine, as there is no difference in locomotor activity between the ZFP189 variant groups in response to saline or morphine administration. Microdissecting virally manipulated NAc and performing RNA sequencing revealed striking differences in the ability of $ZFP189^{VPR}$ to regulate endogenous gene expression, with cocaine treated animals possessing far more differentially regulated genes (DEGs) than similarly manipulated morphine treated mice. These results suggest a drug-specific role for the function of ZFP189 in driving brain transcriptional and behavioral responses to cocaine, but not morphine.

Title: Histone demethylase JMJD3 mediates opioid-induced cellular and behavioral plasticity

Authors: *S. MITRA[1], P. H. GOBIRA[2], C. T. WERNER[1], J. A. MARTIN[1], S. THOMAS[1], C. AN[1], M. IIDA[1], S. SWENSON[1], R. CHANDRA[3], R. L. NEVE[4], M. LOBO[5], D. M. DIETZ[6]; [1]Dept. of Pharmacol. & Toxicology, State Univ. of New York at Buffalo, Buffalo, NY; [2]Univ. of São Paulo, Ribeirao Preto, Brazil; [3]Anat. and Neurobio., Univ. of Maryland Baltimore, Baltimore, MD; [4]Neurol., Massachusetts Gen. Hosp., Cambridge, MA; [5]Anat. and Neurobio., Univ. of Maryland Sch. of Med., Baltimore, MD; [6]State Univ. of New York, Buffalo, NY

Abstract: Opioid use disorder is a chronic and debilitating disease that is marked by relapse after periods of abstinence. A multitude of drug-elicited neuroadaptations in brain regions governing reward such as the Nucleus Accumbens (NAc), mediate maladaptive craving behaviors leading to relapse. One of the persistent changes underlying neuroadaptive mechanisms during abstinence from drugs of abuse is epigenetic modifications of DNA and histones. Here we show that following prolonged abstinence (AD14) from heroin self-administration, histone demethylase, JMJD3 is increased in the NAc. Further, we demonstrate that this increase is specific to D2+ MSNs, demonstrating a cell-type-specific regulation. To demonstrate the functional significance of these changes, we employed both pharmacological

and viral-mediated approaches to modulate JMJD3 expression in the NAc, which demonstrated that JMJD3 levels/activity are sufficient to regulate cue-induced heroin seeking. Finally, we present data that the epigenetic factors are themselves regulated through the TGF-β super-family which we have previously demonstrated to be essential for drug-seeking behaviors. Together these data highlight that JMJD3 is essential in mediating persistent cellular and behavioral adaptations following heroin exposure.

Title: Molecular Profiling of the Ventral Pallidum in Mice

Authors: *R. CAMPBELL[1], H. NAM[2], M. BASU[1], M. ENGELN[3], R. CHANDRA[3], S. A. AMENT[4], M. LOBO[5];
[1]Univ. of Maryland, Baltimore, Baltimore, MD; [2]Dept. of Anat. and Neurobio., [3]Anat. and Neurobio., Univ. of Maryland Baltimore, Baltimore, MD; [4]Inst. for Genome Sci. and Dept. of Psychiatry, [5]Anat. and Neurobio., Univ. of Maryland Sch. of Med., Baltimore, MD

Abstract: The ventral pallidum (VP) is a critical brain region for drug-seeking behaviors, as it is a primary output to the several regions within the reward system. Further, this region is unique because it receives dense input from both ventral striatal (nucleus accumbens) projection neuron subtypes compared to other brain regions that display more segregated input. Recent circuitry mapping revealed that distinct VP cell types and projections regulate specific behavioral responses to rewarding and aversive stimuli, including drugs of abuse. However, a comprehensive molecular characterization of these cell types and circuits have not been performed. Here, we generated several sequencing data sets to examine the molecular architecture of the VP. First, using Cre-dependent retrograde labeling and Ribotag-transgenic mice, we characterized the translatome of distinct mouse VP-projection cells. Retrograde Cre virus was infused into either the Lateral Hypothalamus (LH), Ventral Tegmental Area (VTA), Lateral Habenula (LHb) or Medial Dorsal Thalamus (MDT) of floxed-Ribotag male mice. Following viral expression, ventral pallidum tissue was extracted and ribosome-associated

mRNA was isolated to prepare libraries for RNA-sequencing. From our bioinformatic analyses, we identified genes and gene networks enriched within a specific VP projection cell-type. Additionally, using gene ontology analysis, we detected biological processes specific to each VP-projection cell type. Currently, we are performing single-nucleus RNA-sequencing on VP tissue from male and female mice. Through subclustering analysis, we will identify several distinct VP neuronal populations and new marker genes for each transcriptionally distinct population. Altogether, these investigations aim to detect the cellular populations present within the VP and identify novel gene makers to study in VP function and drug use disorders.

Title: Using immediate early gene expression to characterize properties of behavioral ensembles in the nucleus accumbens

Authors: *A. MASKERI[1], D. A. BURKE[2], V. A. ALVAREZ[3];
[1]NIH/NIAAA, Rockville, MD; [2]Natl. Inst. On Alcohol Abuse and Alcoholism, Rockville, MD; [3]Lab. on Neurobio. of Compulsive Behaviors, Natl. Inst. on Alcohol Abuse and Alcoholism, Bethesda, MD

Abstract: The nucleus accumbens (NAc) functions as a “central hub” of the brain reward pathway and is a critical site of dysfunction in cases of substance use disorders. The primary cell type of this region is the projection medium spiny neuron (MSN), which has two subtypes: D1 and D2 MSNs, with opposing roles in driving motivated behavior. The NAc is generally thought to function as a collection of ensembles -- sparsely distributed neurons that drive specific NAc-dependent behaviors. To better understand the properties of these ensembles, we first characterized behaviors and methods for identifying and manipulating ensembles associated with responses to rewarding and aversive stimuli. Mice expressing a tamoxifen inducible Cre under the promotor for the immediate early gene Fos (TRAP2 mice) were used to label NAc ensembles underlying cocaine-sensitized locomotion. After quantifying the proportions of each MSN subtype, we found them to be present in approximately equal amounts within the ensemble. However, only the D2 MSNs were shown to correlate with locomotion. Current experiments are aimed at characterizing TRAP2 ensembles in the NAc during the expression of aversive learning, specifically foot shock-conditioned freezing. The goal for future experiments is to compare the neuronal overlap and exclusivity of ensembles underlying opposing behaviors, as well as to

measure the synaptic connectivity between and among distinct ensembles. Understanding the properties of these ensembles will ultimately lead us to a better understanding of motivated behavior and substance use disorders.

Title: Extinction of conditioned memory modulation

Authors: *T. FRANCIS, F. LERI;
Psychology, Univ. of Guelph, Guelph, ON, Canada

Abstract: It has been established that exposure to drug conditioned stimuli (CS) can enhance memory consolidation, indicating that drug CSs not only produce changes in behaviour, but can also impact cognition. Therefore, it is possible that conditioned memory modulation, like other conditioned responses, will display extinction. The current study used classical and operant conditioning techniques to test this hypothesis in male Sprague-Dawley rats performing an object location (OL) memory task. To establish the CS in Experiment 1, rats were injected with heroin (0, 0.3, 1 mg/kg, S.C.) and immediately placed in operant chambers for 1 hr, once a day for 5 consecutive days. It was found that exposure to the heroin-CS four days after conditioning dose-dependently enhanced object location memory. In addition, when tested after 6 exposures to the CS without receiving heroin, the CSs ability to modulate memory was significantly reduced. In Experiment 2, rats were trained to intravenously self-administer heroin (0.05 mg/kg/inf) on a continuous reinforcement schedule for 12 days. It was found that exposure to the heroin-CS four days after training also enhanced object location memory, and when tested after 6 exposures to the CS without receiving heroin, the CSs ability to modulate memory was attenuated. Taken together, these data indicate that conditioned memory modulation, similarly to other conditioned drug effects, displays both pavlovian and instrumental extinction.

Title: Biased memories for different components of alcohol-related events

Authors: *B. B. HARRIS, E. V. GOLDFARB;
Dept. of Psychiatry, Yale Sch. of Med., New Haven, CT

Abstract: Memory plays a key role in addiction development and relapse. Crucially, memories of a single event can be broken down into items (individual parts of a memory) and contexts (integrations of different elements of a memory). Recent work indicates that individuals with alcohol use disorder are biased to remember precise alcohol-related contexts, while disproportionately forgetting items. However, the neural mechanisms underlying the formation of distinct components of alcohol-related memories are unclear. We hypothesize that alcohol-related events will be remembered differently from neutral events in social drinkers, and that alcohol-related memories will be associated with stronger BOLD responses in the dorsolateral striatum and perirhinal cortex (items) and hippocampus (contexts). We first developed and validated a set of 320 matched alcohol-related and neutral handheld object stimuli for use in a two-day memory task. Next, we enrolled 8 participants (mean age = 29.25, 63% female, AUDIT = 5.50, target N = 28) in an ongoing fMRI experiment. During the study, participants encoded 160 associations between pairs of objects (50% alcohol, 50% neutral) and neutral scenes. 24 hours later, memories for items (object recognition), contexts (cued recognition of scenes associated with objects) and affect were assessed, followed by an Alcohol Taste Test. Preliminary analyses show that, as expected, alcohol stimuli elicited stronger craving and affective responses at encoding ($p = .01$). After 24 hours, participants showed a slight memory bias for neutral items ($p = .11$) and "gist" memory for alcohol-related contexts ($p < .01$). Interestingly, preliminary evidence demonstrates that these memory biases (particularly item memory) predicted subsequent alcohol consumption ($p < .05$). Ongoing subsequent memory analyses are leveraging fMRI data to identify regions in which BOLD signal at encoding supports successful memory formation for alcohol-related items and contexts (i.e., remembered vs forgotten for alcohol vs neutral). This research has the potential to uncover the neural mechanisms supporting memories associated with addiction and may help guide treatment. Future research should strive to elucidate these mechanisms in clinical and non-drinking participant populations.

Title: Contribution of impulsivity and contextual cues to the addictive effects of caffeine

Authors: J. CEBRIAN[1], ***G. GONZALEZ-CUEVAS**[2];
[1]European Univ. of madrid, Madrid, Spain; [2]Idaho State Univ., Meridian, ID

Abstract: Caffeine is currently the most widely used psychoactive drug worldwide. Although, as such, it has the potential for developing addiction, the implications of caffeine use in addictive processes such as impulsivity and contextual cues' induced craving are still largely unknown. The present investigation, consisting of a correlational study and two experiments, aimed at studying these associations and to manipulate experimentally both caffeine acute consumption (and its expectancies) as well coffee-related cues to clarify the effects of caffeine on impulsivity and craving. Our sample comprised a total of 201 participants counting all three studies. Our results indicated that caffeine consumption was positively associated with higher levels of impulsive behavior as well with an enhancement of cue-induced coffee craving. Even though the manipulation of caffeine acute consumption and its expectancies did not alter impulsive behavior, the contextual cue associated with coffee produced increased perceived activation together with a deficit in response inhibition. All in all, these findings suggest that a lack of impulse control linked to contextual cues may be key to the addictive effects of caffeine. Nonetheless, future research is warranted to continue unraveling the causal role of impulsivity and contextual cues in the development of caffeine-related addiction, especially in relation to poly-drug use.

Title: Conditioned antidepressant effects of ketamine: a comparison to bupropion and escitalopram

Authors: B. MELANSON[1], M. WOLTER[1], Z. LEATHAM[1], T. D. LAPOINTE[1], *F. LERI[2]; [1]Univ. of Guelph, Guelph, ON, Canada; [2]Univ. Guelph, Guelph, ON, Canada

Abstract: The rapid and long-lasting antidepressant effects of ketamine (KET) set this drug apart from clinically established antidepressants like the selective serotonin reuptake inhibitor escitalopram (ESC) and the norepinephrine-dopamine reuptake inhibitor bupropion (BUP). There are suggestions from studies in animals that the antidepressant effect of KET may involve a drug-environment interaction, whereby a context paired with a psychoactive drug acquires the ability to influence behavior. Thus, in Experiment 1, male Sprague-Dawley rats were conditioned with 0.9% saline (w/v; SAL) in a vehicle-paired context (CS-), and with 10 or 20 mg/kg KET, 10 mg/kg ESC, or 10 mg/kg BUP in a drug-paired context (CS+) on alternating days (10 days total, 5 pairings in each context). One week later, rats were exposed to 3 sessions of forced swim stress (FSS) over 3 consecutive days (FSS_{1-3}; 10 mins/session), with exposure to the CS- and CS+ prior to FSS_2 and FSS_3, respectively, and immobility was recorded on each session. In Experiment 2, the same conditioning protocol was employed to conducted to assess unbiased conditioned place preference and investigate conditioned locomotion and conditioned approach to a KET-paired context. It was found that exposure to the CS+ paired with KET, but not ESC, or BUP reduced immobility without affecting horizontal motor activity. Moreover, the KET CS+ did not produce conditioned approach (or withdrawal), indicating that the anti-immobility effect of the KET CS+ context was not the byproduct of conditioned hyperactivity. Therefore, the current data suggests that KET, differently from other common antidepressant medications, can elicit a conditioned antidepressant response which may play a role in its sustained therapeutic effects.

Title: Inhibition of noradrenergic and corticotrophin-releasing factor systems block enhancement of memory consolidation by heroin withdrawal and conditioned heroin withdrawal

Authors: *N. BAIDOO[1], F. LERI[2];
[1]Univ. of Guelph, Guelph, ON, Canada; [2]Psychology, Univ. Guelph, Guelph, ON, Canada

Abstract: AIM: It is well established that opioid withdrawal can be associated to environmental stimuli through classical conditioning to produce conditioned withdrawal. We have recently found that conditioned withdrawal has significant cognitive effects as, similarly to acute precipitated withdrawal, it enhances consolidation of memory. The aim of the current study was to explore the role of noradrenaline and corticotrophin-releasing factor (CRF) in memory modulation induced by unconditioned and conditioned heroin withdrawal. **METHODS:** Male Sprague-Dawley rats were implanted with osmotic mini-pumps releasing 3.5 mg/kg/day heroin, and received injections of 3 mg/kg naloxone preceded by 0.1 - 0.6 mg/kg lofexidine (alpha-2 adrenergic agonist) or 10 - 20 mg/kg antalarmin (CRF 1 receptor antagonist) immediately after the sample phase of spontaneous object recognition memory task. To produce conditioned withdrawal, a contextual conditioning procedure was employed whereby heroin-exposed rats were confined for 2 hours in a context (CS+) following injections of 3 mg/kg naloxone and in another context (CS-) following vehicle injections. Seven days after removal mini-pumps, the effects of immediate exposure to the CS+ (or CS-) preceded by 0.6 mg/kg lofexidine or 20 mg/kg antalarmin were tested. **RESULTS:** It was found that both lofexidine and antalarmin blocked the enhancement of object memory consolidation by post-training naloxone precipitated withdrawal and by conditioned withdrawal. **CONCLUSIONS:** These experiments suggest that pharmacological and psychological withdrawal have significant effects on memory storage by activating noradrenergic and CRF systems.

Title: The Effects of Escalated Fentanyl Intake on Decision-Making Dynamics

Authors: *T. K. SHAVER, M. J. STEPHENS, M. A. HALLORAN, J. BECKMANN;
Psychology, Univ. of Kentucky, Lexington, KY

Abstract: Opioid Use Disorder (OUD) is a major public health problem in the United States. There is evidence to suggest that substance use disorders are, at least partially, disorders of decision-making, consisting of persistent drug choice over alternatives. As such, two competing

hypotheses regarding the role of decision-making in OUD are: 1) OUD is representative of a deficit in decision-making processes; 2) OUD is the result of relative value processes. In order to tease apart hypotheses above, we utilized both isomorphic (food-food) and allomorphic (remifentanil-food) choice in tandem with 1-hr and 6-hr fentanyl access, a preclinical model of escalated opioid intake. If OUD is the result of decision-making deficits, 6-hr fentanyl access should disrupt isomorphic decision-making. Conversely, if OUD is representative of relative value processes, 6-hr fentanyl access should systematically shift allomorphic choice, while leaving isomorphic choice unaffected. First, rats were trained on either a food-food (isomorphic) or remifentanil-food (allomorphic) choice procedure, where both the magnitude (1, 2, and 4 food pellets or 1, 3, and 10 ug/kg of remifentanil) and probability of outcomes were manipulated unpredictably, until choice was stable. Rats were then trained on a fentanyl self-administration (0.25 ug/kg to the animal's weight) under an FR1 schedule with 1-hr access until intake was stable. Rats were then split into 1-hr and 6-hr fentanyl access groups, matched for both choice performance and fentanyl acquisition intake; each group was subsequently trained such that they underwent choice (isomorphic or allomorphic) in the morning and fentanyl access (1-hr or 6-hr) one hour after completing choice. The results to date suggest that 6-hr fentanyl access had no effect on isomorphic choice; however, 6-hr fentanyl access systematically shifted allomorphic choice, producing increased sensitivity to changes in remifentanil dose during choice. Collectively, the current results suggest that OUD may be the result of relative valuation processes, not necessarily representative of a deficit in decision-making processes generally.

Title: Acute Stress Effects on Mood, Cannabis Urges and Motives in Heavy Cannabis Users

Authors: *S. L. BRASSARD[1], K. MANUJA[2], J. MACKILLOP[4], I. M. BALODIS[3]; [1]Neurosci., [2]Dept. of Psychology, Neurosci. & Behaviour, [3]Dept. of Psychiatry & Behavioural Neurosciences, McMaster Univ., Hamilton, ON, Canada; [4]Peter Boris Ctr. for Addictions Res., St. Joseph's Healthcare Hamilton, Hamilton, ON, Canada

Abstract: Many people report using cannabis as a way to cope with stress. Acute, low doses of THC have been reported to induce stress relieving effects, which may drive continued use for

individuals looking to cope with stress. It is unclear whether heavy cannabis users have alterations in their stress response, and whether this relates to coping motivations. Currently, there is also limited data on how stress reactivity may play a role in cannabis craving. Therefore, the aim of the current study is to assess the effects of acute stress on mood and cannabis craving in individuals who self-report heavy cannabis use. Participants included 56 heavy cannabis users and 50 healthy controls who were randomly assigned to stress and no-stress conditions. Participants completed mood questionnaires, from which a total mood disturbance score was calculated, and questionnaires on cannabis use urges throughout the experiment. Cannabis users also completed a questionnaire on motives for cannabis use. Participants assigned to the stress condition underwent a validated psychosocial stressor. Acute stress increased self-report total mood disturbance scores in both control and cannabis groups, however, the cannabis group consistently reported higher total mood disturbance, including at baseline and throughout the experimental session. Acute stress had no effects on cannabis craving; however, craving was greater in cannabis users in the no-stress conditions, compared to cannabis users in the stress condition. Within the stress condition, higher coping motives for cannabis were consistently correlated with greater total mood disturbance scores across the experimental session. Our findings shed light on momentary subjective stress responses in cannabis users and reinforce trait-like patterns of stress reactivity. These results reinforce previous findings of elevated stress in heavy cannabis users, and demonstrate links with coping motives. Further, these data show that acute stress does not induce cannabis craving; unexpectedly, craving scores were elevated in the no-stress cannabis group without the presence of a stressor. These findings suggest that craving may be a result of trait-like, rather than state factors. Future studies can examine the underlying physiological mechanisms, including relationships with specific cannabinoids as well as the time course of reactivity alterations in heavy cannabis users.

Title: Acute effects of legal market high potency THC-dominant vs. CBD-dominant cannabis concentrates: objective and subjective intoxication outcomes

Authors: *M. DRENNAN[1], H. KAROLY[2], L. BIDWELL[3];
[1]Colorado State Univ., Severance, CO; [2]Psychology, Colorado State Univ., Fort Collins, CO; [3]Univ. of Colorado Boulder, Boulder, CO

Abstract: As the market for cannabis concentrate products continues to grow, the lack of research regarding the combined and differential effects of concentrated forms of the two most prominent cannabinoids, THC and CBD, becomes more glaring. The present study analyzes cannabinoid blood levels and subjective outcomes of physical sensation and affective state after *ad libitum* use of legal market concentrate products. Participants were randomly assigned to either a THC or CBD-dominant concentrate product and completed a baseline session, followed by an experimental mobile laboratory session consisting of 3 timepoints - before, immediately after, and one-hour after *ad libitum* concentrate use. As expected, the THC-dominant concentrate induced higher intoxication effects, as well as higher ratings of drug effect and drug reward than the CBD-dominant concentrate. Both products induced immediate feelings of elation that diminished over the subsequent hour. Differential subjective outcomes were seen between products, with the CBD-dominant group seeing immediate decreases in tension and anxiety, while the THC-dominant group saw significant decreases in anxiety only after one hour. Paranoia spiked immediately post-use in the THC-dominant concentrate group, which decreased back to baseline levels with an hour. Overall, the positive effects of the CBD-dominant concentrate on mood accompanied a lower level of intoxication and absence of undesirable effects such as paranoia experienced with the THC-dominant concentrate. The results herein support the need for further investigation of the harm-reduction potential of concentrated CBD, both alone and in conjunction with THC.

Title: Transcranial Magnetic Stimulation as an intervention for cannabis use disorder in undergraduates

Authors: *J. M. KELLY[1], R. S. ASTUR[2], S. M. SKLENARIK[3], F. HOEFT[4], V. R. STEELE[5];
[1]Univ. of Connecticut, Killingworth, CT; [2]Dept. of Psychological Sci., Univ. of Connecticut, Storrs, CT; [3]Univ. of Connecticut, Cheshire, CT; [4]Psychological Sci., Univ. of Connecticut, Storrs, CT; [5]Psychiatry, Yale Sch. of Med., New Haven, CT

Abstract: Cannabis use is globally prevalent among college undergraduates. According to a 2016 survey, 35.3% of young adults between 19 and 28 years of age use marijuana at least annually (Schulenberg et al., 2016). Importantly, nearly 25% of U.S college students meet the requirements for a clinical diagnosis of cannabis use disorder (CUD) (Caldeira et al., 2008). CUD is associated with adverse consequences such as impaired cognition, poor academic performance, lower income, and lower IQ (Pearson, et al., 2017). Additionally, the misuse of cannabis is correlated with increased anxiety and depression (Volkow et al., 2014). With the legalization of cannabis spreading across the U.S, it is imperative that informed research be conducted regarding the treatment of CUDs in young adults.
TMS is a noninvasive method of neural modulation that when used to stimulate the dorsolateral prefrontal cortex (DLPFC), has been shown to reduce nicotine cravings (Hauer et al., 2019). The theory behind its effectiveness in reducing substance cravings involves the stimulation of dopaminergic reward pathways (Sahlem et al., 2018). The purpose of the current study is to investigate the effects of TMS to DLPFC on cannabis cravings and use in college undergraduates who are at risk for CUD.
Sixty undergraduates who meet clinical diagnosis for CUD and want treatment are being recruited for two in-person TMS sessions and an online follow-up one week later. We are using a within-subjects design where the participant receives either active or sham TMS for the first session, and then receives the opposite condition for the second session. Prior to receiving either stimulation condition, participants complete the marijuana craving questionnaire (MCQ). The active TMS session stimulates left DLPFC with intermittent Theta Burst Stimulation (iTBS) for 3 minutes at 100% of motor threshold. Before, during, and after stimulation, participants look at various cannabis stimuli and complete the MCQ again at the end of the session. So far, we have collected data on 4 participants. The stimulation is well-tolerated, and we see reductions in marijuana cravings in 75% of participants. Data collection is ongoing, but we hypothesize that participants will experience reduced cannabis cravings after the iTBS at the end of the session and reduced real life cannabis use compared to the sham stimulation condition. Our aim is to produce an effective and noninvasive intervention to help reduce CUDs in college students.

Title: The neurological effects of recent cannabis use on processing emotional facial expressions: An ERP study

Authors: H. DAMRA, B. DIXON, *R. TORRENCE;
Psychology, St. Xavier Univ., Chicago, IL

Abstract: Cannabis use has residual effects on neurological responses to fearful facial expressions. Other research has shown that cannabis can have acute effects on cognition for 24 hours after use. This study examined the effects of cannabis use within the last 24 hours on processing fearful faces as measured by the event-related potential, N170. We had 16 participants that were identified as cannabis users and 9 of these participants used cannabis with 24 hours (but not with 8 hours) of the study. The participants were asked to view emotional facial expressions and identify the emotion (either fear, neutral, or happy). We used NeuroScan to acquire the ERP data. An average reference was used electrode P8 with a time window of 150-190 ms for N170. Three separate t-tests were used (Bonferroni correction was used to adjust critical p-value, $p = .016$) to examine group differences within each condition. The N170 amplitude for the participants without recent cannabis use was significantly more enhanced than the participants with recent use for fear ($t(14) = 2.955$, $p = .010$) and happy ($t(14)$ 3.225, $p = .006$), but not neutral ($t(14) = 2.529$, $p = .024$). The results indicate that cannabis use within 24 hours reduces face processing.

Title: Development of Cross-Reactive Antibodies for the Identification and Treatment of Synthetic Cannabinoid Receptor Agonist Toxicity

Authors: *A. WOROB, C. WENTHUR;
Univ. of Wisconsin, Madison, Madison, WI

Abstract: Synthetic cannabinoid receptor agonists (SCRAs) are compounds which mimic the pharmacology of psychoactive components in cannabis. These compounds are inexpensive, commercially available and difficult to identify with modern analytical methods, making them highly accessible for recreational use. The diverse nature of SCRA structures contributes to their unique pharmacological profile, resulting in increased potency and toxicity compared to cannabis. Suspected SCRA toxicity, which can present with a breadth of cardiovascular, gastrointestinal and neurological disturbances, is currently addressed through symptom

management followed by toxicological screening after patient discharge. We can address the dual need for improved diagnostic and therapeutic intervention against SCRA toxicity with antibodies generated in the presence of SCRA-resembling small molecule haptens conjugated to immune-activating proteins. Similar antibody strategies employed for opioids, nicotine and other commonly misused drugs have shown potential in both detecting these drugs *in vitro* and sequestering them to the periphery *in vivo*, blunting their psychotropic effects. As most SCRAs incorporate one or more previously identified structural motifs across their tail, core, linker and head group, we generated antibodies in mice against haptens incorporating several common motifs that have been observed across different generations of SCRAs. Vaccinated animals were then challenged with structurally matched SCRAs to determine if the vaccines could prevent SCRA-induced physiological changes in locomotion, body temperature and nociception. Furthermore, these antibodies were then tested against a panel of SCRAs with a broader range of structural congruency to the test haptens, using competitive ELISA methods, to evaluate their diagnostic potential. We determined that haptens containing valine-like head groups linked to a heterocyclic core generated robust immune responses resulting in antibodies capable of binding SCRAs with bioisosteric changes to the core and tail groups compared to the hapten. Contrastingly, our naphthyl head group haptens stimulated considerably weaker immune responses, resulting in antibodies with poor potency and little ability to bind even structurally similar SCRAs. Future expansion of hapten diversity to address cross-reactivity of antibodies within and across structural families is thus warranted, and such efforts are underway.

Title: Investigating the effect of cannabidiol on habit-formation and striatal dopamine release

Authors: *C. R. MOREHOUSE[1], C. J. MADDOX[1], R. MCLAUGHLIN[1], J. R. SCOTT[1], E. S. RAMSSON[2], C. D. HOWARD[1];
[1]Oberlin Col. Neurosci. Dept., Oberlin, OH; [2]Grand Valley State Univ., Allendale, MI

Abstract: Habits are inflexible behaviors that persist despite changes in action outcomes or outcome value. While habits allow for efficient behavioral responding, neuropsychiatric diseases such as drug addiction and obsessive-compulsive disorder are characterized by overreliance on habits and overactive brain regions involved in habit formation. The transition from goal-

directed to habitual responding is mediated by the striatum and dopamine inputs to the striatum. Additionally, the CB1 cannabinoid receptor is necessary for both habit formation and normal dopamine release. The commercially popular drug cannabidiol (CBD) may influence habit formation by decreasing CB1 receptor efficiency, by modifying striatal dopamine release, or by a serotonin-mediated mechanism. To explore this, we trained mice on random ratio (RR20) or random interval (RI60) schedules designed to elicit goal-directed or habitual lever-pressing, respectively. Throughout training and habit probes, mice were administered either CBD (20 mg/kg) or vehicle as a control. Mice were tested for habitual responding using probe trials following reinforcer-specific devaluation as well as omission trials, where mice had to withhold responding to earn rewards. Our results suggest that CBD modestly increased goal-directed responding in the random interval but not the random ratio group. Further, we utilized the optical dopamine sensor dLight to conduct fiber photometry recordings of real-time changes in dorsal striatal dopamine levels in an open field exploratory task before and after 20 mg/kg CBD injections. CBD did not significantly modify the amplitude or frequency of spontaneous dopamine events, suggesting alterations in habit formation may be due to a dopamine-independent mechanism. These results indicate CBD may be a potential therapeutic agent in disorders characterized by maladaptive habit formation and that CBD does not modify habits through changes in striatal dopamine levels.

Title: Effects of oral cannabidiol administration on sleep and pain responses and potential underlying pathways in male rats

Authors: *J. M. SKULLY[1], J. KINA[2], A. TROMBLEY[2], A. PALOPOLI[2], L. M. RICHARDSON[2], N. KULAGLIC[2], C. M. WALLIN[1], S. BRUMMELTE[1], S. BOWEN[1]; [1]psychology, [2]Wayne State Univ., Detroit, MI

Abstract: There has been an increase in popularity for Cannabidiol (CBD), the non-psychoactive component of Marijuana. Research assessing CBD's use as a therapeutic (e.g., anxiolytic, analgesic, anti-inflammatory, anti-stress, etc.) in both human and animal models showed some promising results, however, CBD's effects and mechanisms of action still need

further exploration. This project aimed to evaluate the potential therapeutic outcomes associated with administration of a hemp derived 99% pure CBD compound provided from Ellipse Analytics (Denver, CO). Moreover, we sought to evaluate CBD's influence on brain-derived neurotrophic factor (BDNF) and transient receptor potential cation channel subfamily V member 1 (TRPV1) expression. CBD (0, 20, or 40 mg/kg) was administered by oral gavage to male rats over 10 days (n=16/group), with behavioral assays being run on the 1st, 5th, and 10th day of administration to assess pain and sleep behaviors. Rats were sacrificed on day 11, and brains were collected for analysis. Western blotting will be used to analyze protein concentrations (pro-BDNF, BDNF, TRPV1) in different brain regions of interest. Behavioral results revealed an effect of the 20mg/kg, but not 40mg/kg dose of CBD to reduce the time spent in an inactive sleep state and to increase response time to a heat stimulus. These findings offer further support for a potential therapeutic effect of CBD on sleep regulation and anti-nociception and future brain analysis will provide insight on the potential involvement of the BDNF and TRPV1 pathways in producing CBD's effects. Further studies are necessary to assess dose-dependent effects with acute or prolonged exposures, as well as study the effectiveness in females.

Title: Effects of CB2 receptor activation in the anterior cingulate cortex on binge-type behavior induced by limited acces to a palatable diet.

Authors: *J. RODRÍGUEZ-AGUILAR[1], L. RODRIGUEZ-SERRANO[2], F. CORTÉS SALAZAR[3], J. MANCILLA-DIAZ[4], R. ESCARTIN-PEREZ[1];
[1]UNAM, FES Iztacala, Tlalnepantla de Baz, Mexico; [2]Depertamente de Psicología, Univ.

Iberoamericana, Ciudad DE Mexico, Mexico; [3]Univ. Nacional Autónoma de México, Facultad De Estudios Superiores Iztacala, Mexico; [4]Univ. Nacional Autonoma De Mexico, Tlalnepantla, Mexico

Abstract: The anterior cingulate cortex (ACC) plays a role in processing the relationship between motivational and emotional information. Moreover, the ACC has connections to the nucleus accumbens (NAc) and ventral tegmental area, structures of the mesocorticolimbic system that participate in the modulation of mechanisms controlling reward. The endocannabinoid system contributes differentially to the modulation of reward and aversion, depending on the receptor activated. Activation of CB1 receptors (CB1r) induces rewarding effects, while activation of CB2 receptors (CB2r) induces aversive effects. Consistently, some studies reported that the activation of the CB1r increases food intake, while CB2r activation has an inhibitory effect on feeding. Furthermore, rats with binge-type behavior induced by restricted access to a palatable diet have altered the tone of particular endocannabinoids (2-arachidonoylglycerol and Anandamide) in specific brain areas related to the perception of the hedonic properties of palatable foods (prefrontal cortex,NAc, amygdala). Considering that ACC expresses CB2r, we hypothesized that activation of CB2r in the ACC would decrease consumption of a palatable diet. Accordingly, this study aimed to evaluate the effects of CB2r activation in the ACC on the consumption of a palatable diet in male Wistar rats. The standard diet (SD, chow) was available ad libitum, while the palatable diet (PD, evaporated milk added with 10% sucrose) was provided 60 min per day, during 35 days in the light phase of the light/dark cycle. We measured thedaily SD consumption (24 h) and the SD intake during the 60 min previous to the presentation of the PD. Then, we measured the consumption of PD (60 min). On day 20, when the consumption of the PD stabilized (variations less than 20% in 3 consecutive sessions), microinjection cannulas were stereotaxically implanted in the ACC, and animals continued accessing the PD for eight additional days after recovery (n= 8). Subsequently, rats received intra-ACC injections of the CB2 receptor agonist (GW838972A, 0.25 µg/µl),the CB2 receptor antagonist (AM630, 0.75 µg/µl) or both (GW838972A, 0.25 µg/µl+ AM630, 0.75 µg/µl) 15 min before the access to the PD and food intake was measured (SD and PD, 60 min). We found that rats with limited access to the PD (60 min per day) increased their energy intake (>50% from the total daily caloric intake), expressing binge-like eating after 31 days of limited access to the PD. Unexpectedly, we found that activation of CB2r in the ACC with GW838972A did not change the PD intake. We conclude that the activation of CB2r in the ACC does not prevent the induced binge-type eating.

Introduction: With recent publications of a CB2 agonist preventing opioid induced respiratory depression (OIRD) in CD1 male mice, there is urgency to determine if this is preserved across strains to continue movement to reduce opioid harms in humans. **Objective:** Cannabinoid receptor-2 (CB2R) agonism is reported to prevent OIRD in CD1 mice, yet whether this holds true across strains in the C57 mouse is unknown.**Methods:** Utilizing whole-body plethysmography chambers, sought to evaluate the influence of CB2 activation on respiratory depression using selective agonists alone and in combination with morphine across C57 wild-type and knock-out mice, compared to CD1 male mice. **Results:** AM2301, the novel CB2 agonist did not induce respiratory depression across strains. Moreover, it significantly attenuated morphine -induced respiratory depression in C57 mice, as it did in CD1 mice. **Conclusion:** Building on past literature, findings suggest prevention of OIRD via CB2R activation is maintained across strains, supporting CB2R agonism as a possible harm reduction method in opioid therapy.

Title: Effects of Edible Delta-9-Tetrahydrocannabinol at Low Doses on Locomotor Behavior in Adult Rats

Authors: *M. C. AZUMA[1], D. A. LAUX[2], T. J. MOSER[3], M. CAIN[4];
[2]Psychological Sci., [3]Dept. of Psychological Sci., [1]Kansas State Univ., Manhattan, KS;
[4]Psychological Sci., Kansas Sate Univ., Manhattan, KS

Abstract: Recent state legalization and acceptance of cannabis across the US has made it one of the most commonly used illicit drugs. Using edible forms of cannabis has become an increasingly popular method of consumption. Previous literature has primarily investigated behavioral changes resulting from inhalation, intraperitoneal, subcutaneous, and intragastric administration of delta-9-tetrahydrocannabinol (THC), the main psychoactive component of cannabis. Each has been tested using similar dose ranges (5 - 20 mg/kg). However, medical use of cannabis in edible form is commonly prescribed at doses of 0.1 - 1 mg/kg. Importantly, THC is metabolized differently when ingested compared to the other methods of use. Therefore, it is imperative to investigate the behavioral and neurobiological changes following ingestion of low doses of THC. In the current experiment, we utilized a rodent model of edible THC across a range of low doses to determine if it would alter locomotor activity in an open-field arena (OFA). Male Sprague Dawley adult rats received vehicle- or THC- dissolved cookies (0.625, 1.25, and 2.5 mg/kg) 30min prior to each 2-hour OFA test. Eight sessions were performed every other day for a total of 16 days. On rest days, all animals consumed vehicle- dissolved cookies. Our data suggest that there is a dose-dependent increase in distance traveled (cm) following ingestion of low doses of THC during the initial sessions. Interestingly, by the final session, vehicle and all doses of THC result in similar patterns of locomotor activity, suggesting behavioral desensitization to low dose THC. Previous data has shown that high THC doses in edible form dose dependently decrease locomotor activity. The highest dose tested in the current experiment is comparable to the lowest doses used in past research with edibles along with other administration routes. The results of our current experiment suggest dose-dependent locomotor effects from using THC at high vs low doses in edible form.

Title: Depletion of the gut microbiomealters transcriptional homeostasis and reduces persistence of cocaine sensitization

Authors: *K. R. MECKEL[1], R. S. HOFFORD[2], N. L. MERVOSH[2], N. TUKURU[2], J. B. HANKS[3], J. J. FAITH[3], P. ROUSSOS[3], D. D. KIRALY[4];

Abstract: Psychostimulant addiction represents a devastating public health crisis leading to extensive morbidity and mortality. Despite this, there are currently no FDA-approved medications for treatment of psychostimulant use disorders. A growing body of literature suggests that the bacterial composition of the gut microbiome significantly affects brain and behavior in animal models of psychiatric disease. Prior work from our laboratory has demonstrated that depletion of the gut microbiome significantly affects the formation of cocaine conditioned place preference and locomotor sensitization. However, no currently published studies have examined the role of the gut microbiome in modulating the persistence of cocaine-induced changes in neuronal or behavioral plasticity. Given that the prevention of relapse following abstinence is the most clinically challenging issue in treating patients with substance use disorders, studies examining the effects of microbiome manipulations in relapse-relevant animal models are critical for the development of translational strategies in this space. For these studies mice had their microbiome depleted with non-absorbable antibiotics in their drinking water and were compared to untreated controls. Locomotor sensitization was induced with five daily injections of cocaine, and after 28 days of withdrawal a cocaine challenge was given to assess the persistence of locomotor sensitization. Despite normal development of sensitization, antibiotic-treated mice exhibited significantly reduced persistence of locomotor sensitization after prolonged withdrawal. To identify molecular signatures underlying these behavioral changes, animals were sacrificed one hour after a challenge injection of cocaine, and the nucleus accumbens was dissected out for RNA-sequencing analysis. While cocaine-challenged control animals showed changes in approximately 200 genes, antibiotic-treated mice had significant changes in 3,610 genes. To further interrogate the effects of microbiome composition on behavior, locomotor sensitization to cocaine was induced in germ-free mice and compared to specific-pathogen-free controls. Animals were maintained under gnotobiotic conditions for the duration of the study, and germ-free mice demonstrated altered persistence of sensitization after 28 days of withdrawal compared to controls with an intact microbiome. Taken together, these findings suggest that the microbiome may serve as a key homeostatic regulator of behavioral

response and gene expression in the brain, and suggest that the microbiome has potential as a translational research target.

Title: Changes in DNA methylation underlie differences in extinction of cocaine conditioned place preference

Authors: *M. R. BAKER, C. E. BURGDORF, F. TAKI, E. BRINDLEY, A. RAJADHYAKSHA, M. TOTH;
Weill Cornell Med., New York, NY

Abstract: Cocaine addiction is a chronic condition in which craving and subsequent drug seeking can be elicited by drug-associated cues. In rodents, this can be modeled using conditioned place preference (CPP), where animals acquire a preference for a chamber where they receive cocaine. Once place preference is acquired, the drug-associated memory can be extinguished by repeatedly exposing animals to the previously cocaine-paired environment in the absence of the drug. However, some mice fail to extinguish, continuing to prefer the previously cocaine-paired side even without the drug. Animals that fail to extinguish the previously drug-associated memory could provide insight to individual differences in vulnerability to drug dependence. One possible underlying mechanism is DNA methylation. To first identify the epigenetic differences between these groups, we analyzed the methylomes of the dorsal dentate gyrus of Extinction and Failed Extinction male mice. These animals showed differentially methylated regions (DMRs; genomic regions with significantly different methylation between groups). Genome-wide methylation analysis showed that acquiring cocaine CPP led to a shift from bimodal methylation (i.e. either unmethylated (0% methylation) or methylated (100% methylation)) to intermediate levels of methylation (methylation between 15-85%) in the animals that acquired cocaine CPP. This intermediate level then shifted to hyper- or hypomethylated after successfully extinguishing the drug-paired memory. An Ingenuity Pathway Analysis of extinction DMRs showed enrichment for genes within an activity-dependent calcium and glutamate pathway. One differentially methylated gene in this pathway is *cacna1c*, which encodes the $Ca_v1.2$ isoform of the L-type voltage-gated calcium channel, a gene implicated in

drug dependence. One DMR in this gene had decreased methylation in the mice that extinguished compared to those that did not. This DMR maps onto a putative distal enhancer, so we tested the effect of this region and its methylation on the activity of a reporter gene. We found that, as predicted, this DMR demonstrated enhancer activity in vitro that was decreased by methylation. Supporting this methylation data, there was an increase in *cacna1c* mRNA and protein in the animals that successfully extinguished that was not present in the animals that failed to extinguish. Taken together, this preliminary work suggests differences in DNA methylation within the dorsal dentate gyrus could dictate underlying differences that lead to a propensity to develop drug dependence.

Title: Cocaine memory reactivation induces functional adaptations within parvalbumin interneurons in the rat medial prefrontal cortex

Authors: *E. T. JORGENSEN[1], A. E. GONZALEZ[3], J. H. HARKNESS[5], D. M. HEGARTY[6], A. THAKAR[2], J. AADLAND[1], S. A. AICHER[7], B. A. SORG[4], T. E. BROWN[2];

L334, Oregon Hlth. & Sci. Univ., Portland, OR

Abstract: Substance use disorder is a complex disease created in part by maladaptive learning and memory mechanisms following repeated drug use. Exposure to drug-associated stimuli engages prefrontal cortex circuits; and dysfunction of the medial prefrontal cortex (mPFC) is thought to underlie drug-seeking behaviors. Growing evidence supports a role for parvalbumin containing fast-spiking interneurons (FSI) in modulating prefrontal cortical microcircuit activity by influencing the balance of excitation and inhibition, which can influence learning and memory processes. Most parvalbumin FSIs within layer V of the prelimbic mPFC are surrounded by specialized extracellular matrix structures called perineuronal nets (PNN). Previous work by our group found that cocaine exposure altered PNN-surrounded FSI function,

and pharmacological removal of PNNs reduced cocaine-seeking behavior. However, the role of FSIs and associated constituents (parvalbumin and PNNs) in cocaine-related memories was not previously explored and is still unknown. Here, we found that reactivation of a cocaine conditioned place preference memory produced changes in cortical PNN-surrounded parvalbumin FSIs, including decreased parvalbumin intensity, increased parvalbumin cell axis diameter, decreased intrinsic excitability, and increased excitatory synaptic input. Further investigation of intrinsic properties revealed changes in the inter-spike interval, membrane capacitance, and afterhyperpolarization recovery time. Changes in these specific properties suggest an increase in potassium-mediated currents, which was validated with additional electrophysiological analysis. Collectively, our results indicate that cocaine memory reactivation induces functional adaptations in PNN-surrounded parvalbumin neurons, which likely alters cortical output to promote cocaine-seeking behavior.

Title: Differential effects of short and extended cocaine access on astrocytes in rat nucleus accumbens

Authors: *M.-F. XIA[1], P. I. ORTINSKI[2];
[2]Neurosci., [1]Univ. of Kentucky, Lexington, KY

Abstract: Nucleus accumbens is involved in motivational and affective behavioral processing, and plays a significant role in the development and maintenance of substance use. The release of dopamine from the ventral tegmental area into the nucleus accumbens regulates incentive salience and facilitates reinforcement and reward-related motor function learning. Recent studies reveal that, in the context of cocaine exposure, dopamine transmission in the ventromedial striatum is pivotal in the control of initial drug use. In addition, astrocyte morphology has been shown to be affected by cocaine, but the functional role of astrocytic signaling in cocaine use remains unknown. The goal of this study is to address astrocytic adaptions within nucleus accumbens under two different cocaine exposure regimes.We have observed morphological and functional changes under elevated extracellular dopamine in cultured astrocytes. Physiological

increases in dopaminergic signaling over the course of cocaine self-administration were shown to alter astrocyte morphology and expression profile of genes.To characterize the astrocytic effects on cocaine-induced dopamine elevation and how it contributes to neural circuit functions, we used a rat self-administration model. Two groups of animals went through short- (1h/day) and extended- (6h/day) access cocaine self-administration for 14 days. To identify the functional effects of cocaine on astrocytes, we imaged astrocytes expressing calcium indicator, GCamp6f and performed whole-cell patch-clamp recordings.We noted the extended-access to cocaine leads to an elevation of drug-taking behavior, but not in the short-access group. The intracellular level of calcium within NAc astrocytes is differentially affected by short- or extended- access cocaine self-administration. Extended exposure significantly decreased the amplitude of spontaneous Ca2+ transients at both plasma membrane and endoplasmic reticulum. Calcium transients at two compartments were differently affected by mGluR or IP3 antagonists, suggested compartmentalized mechanisms of calcium signaling regulation. On-going experiments examine how astrocyte membrane properties are regulated by cocaine exposure regimes and how cocaine may alter coupling within astrocytic networks.Astrocytes adapt to cocaine exposure differently through short- and extended- access self-administration, both morphologically and functionally. Our results indicate a potential regulatory role of astrocytic signaling in the NAc on neural mechanisms underlying substance use.

Title: The effects of cocaine self-administration on astrocyte mitochondria morphology

Authors: *E. A. WITT[1], A. TESTEN[2], J. G. JACKSON[3], K. J. REISSNER[4];
[1]UNC Chapel Hill, Chapel Hill, NC; [2]Psychology and Neurosci., UNC, Chapel Hill, NC; [3]Pharmacol. & Physiol., Drexel Univ. Col. of Med., Philadelphia, PA; [4]Dept. of Psychology and Neurosci., Univ. of North Carolina at Chapel Hill, Chapel Hill, NC

Abstract: Rat cocaine self-administration leads to both structural and functional impairments in astrocytes in the nucleus accumbens (NAc), a region key to the brain's reward circuitry. In particular, cocaine impairs the ability of NAc astrocytes to maintain glutamate homeostasis, the balance between extra-synaptic and synaptic levels of glutamate. This impairment is mediated in

part by decreased expression of the astroglial glutamate transporter GLT-1, which is responsible for 90% of synaptic glutamate uptake. Glutamate uptake carries a high energetic cost, which is met by mitochondria. Mitochondria colocalize with GLT-1 in astrocytes and inhibition of mitochondria in astrocyte cultures reduces glutamate uptake. Moreover, degradation of astrocytic processes has been attributed to reduced mitochondrial function in cultured astrocytes. Given the cocaine-induced impairments in glutamate homeostasis and altered astrocyte morphology, and the role mitochondria may play in both of these processes, it is reasonable to hypothesize that astrocytic mitochondria function may be compromised following cocaine self-administration. To investigate this hypothesis, confocal imaging of NAc astrocytes was performed using two AAV5s: mitochondrially-targeted enhanced green fluorescent protein as well as a membrane-targeted Td-tomato fluorescent protein, both under control of an astrocyte-specific promoter in male rats, 24hrs following 12 days of short-access (2hrs/day) cocaine self-administration. Morphological properties of mitochondria were assessed using the MitochondriaAnalyzer ImageJ plugin. Results indicate that following cocaine self-administration mitochondria in NAc astrocytes exhibit significantly increased volume, surface area, and diameter as compared those within saline self-administering animals. This is likely indicative of oxidative stress; however, further analysis is needed. Interestingly, this effect was not observed in a separate cohort of rats trained in 12 days of self-administration and 16-17 days of extinction, suggesting this effect is associated with early abstinence, similarly as has been reported for dendritic mitochondria. Experiments designed to test the effect of sex on this observation, as well as expression of mitochondria stress-related genes and markers of oxidative stress in astrocytes, are ongoing.

Title: Astrocyte proximity to glutamate synapses in the rat nucleus accumbens core: effect of cocaine self-administration

Authors: *S. SESACK[1], T. PLUTE[1], J. BALCITA-PEDICINO[1], J. WANG[1,2], Y. DONG[1]; [1]Neurosci., Univ. of Pittsburgh, Pittsburgh, PA; [2]Neurosci., Icahn Sch. of Med. at Mount Sinai, New York, NY

Abstract: Glutamate's importance as an excitatory neurotransmitter requires multiple regulatory mechanisms to control extracellular levels and plasticity changes associated with learning and memory. Astrocytes represent a major factor in regulating glutamate through expression of the main glutamate transporter and cysteine-glutamate exchanger. Maintenance of normal glutamate levels within the nucleus accumbens contributes to adaptive goal-directed behavior, a function compromised by exposure to psychostimulants like cocaine that disrupt astrocytic glutamate homeostasis. We sought to investigate potential morphological changes in astrocytes surrounding glutamate synapses within the nucleus accumbens core that might underlie the physiological and behavioral alterations identified in cocaine seeking. We also directly compared astrocytic associations with glutamate synapses in naïve rats versus the saline animals used as controls for cocaine self-administration. Adult male rats were trained to self-administer cocaine or saline 2 hours a day for 5 days and then sacrificed by intracardial perfusion with fixative 24 hours after the last session. Serial brain sections through the nucleus accumbens core were imaged by electron microscopy from cocaine self-administering, saline-treated, and naïve rats. *Reconstruct*^{TM} was used to generate 3-dimensional reconstructions of excitatory type axospinous synapses and nearby astrocytes. Within each rat group, extensive variation was observed in the degree to which astrocytes contacted glutamate synapses on spines. No significant differences were observed between cocaine (n = 77 synapses in 2 rats) and saline-treated animals (n = 72 synapses in 2 rats) in: 1) the size of axons, spines or synapses, 2) the extent to which astrocytes contacted glutamate synapses, or 3) the shortest extracellular distance between the active zone and the nearest astrocyte. We did, however, find significantly reduced mean spine and synapse volumes with overall lower variance in the saline-treated versus naïve animals (n = 166 synapses in 6 rats). Similar reductions were seen in cocaine self-administering rats, and these outcomes matched qualitative observations of an increased number of small spines in both treated groups. These results are consistent with the induction of spinogenesis, primarily by exposure to an enriched environment as opposed to drug. The short duration of self-administration might be a factor in this outcome. Additional animals are needed to improve statistical power in testing potential differences in astrocytic coverage of glutamate synapses between cocaine and saline self-administering animals.

Title: Ibudilast attenuates cocaine self-administration and prime- and cue-induced reinstatement of cocaine-seeking rats

Authors: *X. LIU[1], L. MU[1], H. YU[1], M. HU[1], V. FRIEDMAN[1], L. ZHAO[2], Q.-S. LIU[1];
[1]Med. Col. of Wisconsin, Milwaukee, WI; [2]Beijing Sport Univ., Beijing, China

Abstract: Ibudilast is a non-selective phosphodiesterase (PDE) inhibitor and glia cell modulator which has been used clinically to treat asthma and other inflammatory diseases. It has shown great promise for the treatment of drug and alcohol use disorders in recent clinical studies, but it is unknown whether and how ibudilast affects cocaine seeking behavior. Here we show that ibudilast pretreatments reduced cocaine self-administration under fixed- and progressive-ratio reinforcement schedules, and cocaine prime- and cue-induced reinstatement of cocaine seeking. However, ibudilast did not significantly affect sucrose self-administration. These results indicate that ibudilast was effective in reducing the reinforcing effects of cocaine and relapse to cocaine seeking without altering motivation to pursue and consume a natural reward. Chronic cocaine exposure induces cAMP-related neuroadaptations in the reward circuitry of the brain. To investigate potential mechanisms for ibudilast-induced attenuation of cocaine seeking, we recorded from ventral tegmental area (VTA) dopamine neurons in midbrain slices *ex vivo*. We found there was a decrease in inhibitory postsynaptic currents (IPSCs), an increase in the AMPAR/NMDAR ratio, and an increase in the excitation to inhibition (E/I) ratio. Ibudilast pretreatments enhanced GABAergic inhibition but did alter cocaine-induced potentiation of excitation, leading to normalization of the E/I ratio. In addition, ibudilast increased D_2 autoreceptor-mediated inhibition of VTA dopamine neurons. Thus, the restoration of the balance between excitation and inhibition and enhancement of D_2 autoreceptor-mediated inhibition in VTA dopamine neurons might contribute to the attenuation of cocaine seeking and relapse by ibudilast.

Title: Chronic cocaine craving and cue-elicited activity of the left middle/inferior frontal gyrus and skin conductance response

Authors: *C.-S. R. LI[1], S. ZHANG[2], W. WANG[3], S. ZHORNITSKY[1], T. M. LE[3], Y. CHEN[1], S. CHAUDHARY[1];
[1]Psychiatry, [2]Yale Univ. Sch. of Med., New Haven, CT; [3]Psychiatry, Yale Univ. Sch. of Med., New Haven, MA

Abstract: Background: Previous studies have examined cue reactivity as a behavioral and neural marker of cocaine addiction. Cocaine vs. non-drug cues elicited cortical and subcortical activities and some of regional responses may predict clinical outcomes. It is posited that drug cues are highly arousing and may elicit contextual memory that conduces to craving and drug seeking. However, no studies have specifically examined how cocaine vs. non-drug cues elicit changes in physiological arousal or how regional brain responses to these changes relate to chronic cocaine craving. **Methods:** We examined this issue in 39 cocaine users (CU) who met DSM criteria of a cocaine use disorder. During fMRI CU were exposed to cocaine and non-drug cues in alternative blocks. Skin conductance was recorded via a Biopac system throughout the experiment (Zhang et al., 2021, Biological Psychiatry: Global Open Science). We followed published routines in imaging and skin conductance data analyses and evaluated the results at a corrected threshold. **Results:** CU showed higher activation in fronto-parietal, visual, ventromedial prefrontal and mid-cingulate cortices as well as the striatum and midbrain, and lower activation in bilateral hippocampi during cocaine vs. nondrug blocks (Wang et al., 2021, Neuropsychopharm. 46: 851). Skin conductance response (SCR) showed a gradual decline over the 36-s block period but significantly less so during cocaine than during nondrug cue blocks. With the differences in SCR over the last 12 s as a regressor and age, sex, years of smoking and drinking as covariates, whole-brain regression identified activities in the left middle/inferior frontal gyri (M/IFG) in positive correlation with the SCR differences. Further, both M/IFG activities and SCR were significantly correlated with the severity of chronic cocaine craving, as assessed with the Cocaine Craving Questionnaire (CCQ) score. Mediation analyses showed that SCR completely mediated the correlation, bi-directionally, between CCQ score and M/IFG cue-elicited activities. **Conclusion:** These findings substantiate higher physiological arousal in response to cocaine vs. nondrug cues, M/IFG response as a neural marker of elevated physiological arousal, and a central role of physiological arousal in inter-relating cue-elicited prefrontal cortical activity and chronic cocaine craving. The roles of M/IFC in contextual memory and/or cognitive-emotional control during cue exposure remain to be investigated.

Title: Effects of sex and estrous cycle on cocaine-induced changes in excitatory synaptic transmission in the basolateral amygdala

Authors: *C. M. CORBETT[1,2], E. N. DUNN[1], B. D. ROOD[1], D. J. CHANDLER[1], J. A. LOWETH[1];
[1]Cell Biol. and Neurosci., Rowan Univ. Sch. of Osteo. Med., Stratford, NJ; [2]Rowan Univ. Grad. Sch. of Biomed. Sci., Stratford, NJ

Abstract: Sex differences in cocaine addiction liability and relapse vulnerability are influenced by fluctuations of ovarian hormones across the reproductive cycle. In rodent models in which cue-induced cocaine seeking increases or "incubates" during withdrawal from extended-access cocaine self-administration, females in the estrus stage of the estrous cycle (Estrus Females) show an increase in the magnitude of incubated craving compared to both males and females in all other stages of the cycle (Non-Estrus Females). However, the cellular and synaptic mechanisms contributing to these sex differences are unknown. One region known to play a critical role in the expression of incubated cocaine craving is the basolateral amygdala (BLA). We have previously reported an increase in the spontaneous firing rate of glutamatergic pyramidal neurons in the BLA in male rats during early withdrawal (2-3 weeks) from extended-access cocaine self-administration which correlates with changes in the magnitude of incubated cue-induced cocaine craving. Here we test the hypothesis that sex differences in incubated craving may be due, in part, to changes in BLA excitatory synaptic transmission. *Ex vivo* whole-cell patch clamp recordings from BLA pyramidal neurons were conducted following 2-3 weeks of withdrawal from extended-access cocaine self-administration or drug-naive conditions in adult male and female rats. Our preliminary data from male rats show a significant increase in spontaneous excitatory postsynaptic current (sEPSC) amplitude but no change in sEPSC frequency in cocaine-exposed rats compared to drug-naïve controls, suggestive of postsynaptic changes in excitatory transmission. Patch clamp recordings of BLA pyramidal neurons from cocaine-exposed females showed an increase in sEPSC frequency but not amplitude in Estrus compared to Non-Estrus Females, suggestive of presynaptic changes in glutamatergic transmission. To determine whether effects observed across the estrous cycle are estrogen-dependent, hormonal depletion and replacement studies were performed. Patch clamp recordings conducted in ovariectomized animals undergoing 2-3 weeks withdrawal from extended-access cocaine self-administration revealed an increase in sEPSC frequency but not amplitude in animals receiving chronic estradiol compared to vehicle-treated controls, mimicking effects observed in cocaine-exposed Estrus Females. Together our data indicate sex differences in BLA excitatory synaptic transmission during cocaine withdrawal that are influenced by estrous cycle fluctuations and that may contribute to known sex differences in incubated cocaine craving.

Title: Adolescent Social Isolation Disrupts Developmental Profiles in Males and Females

Authors: *A. A. MILIAN, C. J. BENDERSKY, E. WOO, D. M. WALKER;
Behavioral Neurosci., Oregon Hlth. and Sci. Univ., Portland, OR

Abstract: Adolescence is a crucial developmental period in which neural systems associated with motivation are particularly sensitive to rewarding and stressful stimuli. Social isolation (SI) during adolescence has been shown to result in long-term behavioral changes associated with anxiety and reward in adulthood in both males and females. Specifically, it has previously been reported that SI results in opposite effects on cocaine CPP and marble burying behaviors in male and female mice. However, little is known regarding how adolescent social isolation may disrupt somatic markers of development as well as development of specific reward and motivation-associated brain regions. Here we tested the hypothesis that adolescent social isolation disrupts developmental parameters and excitatory and inhibitory signaling within the reward circuitry which culminates in disruptions of sex-specific behaviors in adulthood. Mice were bred in-house and litters were weaned into either group housed or isolation housed mixed litter groups. After 3 weeks of isolation, around postnatal (P) 42, animals were re-socialized and housed 5 per cage until animals reached adulthood. To determine how SI disrupts development, the timing of puberty was monitored beginning on around P22 and animals were weighed every 10 days. Animals were euthanized either 4-6 hours after isolation, 10 days post-isolation, 4-6 hours after rehousing, or on P72, with brains collected for gene expression at each time point. Finally, previously published transcriptomic data was mined to determine if GABA and glutamatergic gene expression is disrupted by adolescent SI in reward-associated brain regions. Preliminary analysis revealed that SI advances the timing in puberty in males and females. While no effects on body weight were observed in females, isolated males were slightly larger than their control counterparts on P22 and P32 but weighed less than group housed males after rehousing. In adulthood, SI disrupted marble burying, elevated plus maze and cocaine CPP in a sex-specific manner. Mining of previously published transcriptomic data from the prefrontal cortex revealed sex-specific regulation of GABAergic receptor expression by cocaine after SI but had no effects on glutamate receptor expression. These data suggest that adolescent social isolation disrupts sex-specific development, behavior and gene expression. Current work is investigating how developmental profiles of glutamatergic and GABAergic related genes are disrupted by SI in the reward circuitry.

Title: Mitochondrial gene ontology pathways and transcriptional regulators impacted by cocaine self-administration in C57Bl/6 mice

Authors: *C. A. CALARCO, S. M. KEPPETIPOLA, M. ENGELN, M. LOBO;
Anat. and Neurobio., Univ. of Maryland Sch. of Med., Baltimore, MD

Abstract: Exposure to illicit drugs and subsequent chronic use profoundly impacts behavior, neuronal structure and firing, and gene expression through multiple brain regions. Some of these sweeping changes are mediated by and supported by changes in cellular energy homeostasis and mitochondrial function. Recent work has shown that cocaine self-administration significantly alters mitochondrial size in nucleus accumbens medium spiny neurons, and that disruption of proper mitochondrial fission is sufficient to blunt responding for cocaine. Beyond mitochondrial fission, other aspects of the mitochondrial energy cycle are impacted by cocaine exposure. At the transcriptional level, many genes altered by cocaine self-administration are related to cellular metabolism and mitochondrial function. In this study we conducted gene ontology analysis on an RNA-seq data set generated from mice that had undergone cocaine self-administration, with a focus on mitochondrial-related ontology terms. The sequencing data set included tissue from the prefrontal cortex, nucleus accumbens, dorsal striatum, ventral pallidum, amygdala, hippocampus, and ventral tegmental area. We found significant representation of transcriptionally regulated genes in metabolism and mitochondrial related gene ontology terms in multiple brain regions. Further, predictive analysis of transcription factor regulation of identified mitochondrial-related genes identified a number of transcription factors across brain regions that may control cocaine-related changes in mitochondrial function. Future work will be needed to validate these predicted targets *in vivo* and understand their role in regulating the cellular and behavioral responses to cocaine self-administration.

Title: Cell Subtype Transcriptional Role of Nab2 in Cocaine Seeking Behavior

Authors: *E. CHOI[1,2], R. CHANDRA[1], M. MCGLINCY[1], A. CHOW[1], M. LOBO[1];
[1]Dept. of Anat. & Neurobio., [2]Grad. Program in Life Sciences, Mol. Biol. & Biochem., Univ. of Maryland Sch. of Med., Baltimore, MD

Abstract: Substance use disorder is a debilitating chronic disease which is a leading cause of disability around the world. Drug seeking after repeated drug exposure is prevalent despite the devastating personal consequences. The nucleus accumbens (NAc, a.k.a. ventral striatum) is a major brain hub that mediates reward behavior. The NAc plays a role in drug seeking and addiction related behaviors in response to drug exposure. Studies have shown that exposure to psychostimulants, such as cocaine, is associated with molecular and functional imbalance in the two medium spiny neuron subtypes (MSNs) in the NAc, the dopamine receptor 1 and 2 enriched MSNs (D1-MSNs and D2-MSNs). While the study of D1-MSNs in the NAc with exposure to cocaine has been and is being extensively done, molecular changes and functional imbalance in the D2-MSNs remain largely elusive. We have previously reported the down regulated expression of a transcription factor, early growth response 3 (Egr3), in D2-MSNs in the NAc with exposure to cocaine. Furthermore, mice with Egr3 overexpression in D2-MSNs in the NAc showed altered extinction of cocaine seeking behavior after forced abstinence from cocaine self-administration. In this study, we show that the NGFI-A binding protein 2 (Nab2), corepressor of Egr3, is altered in bidirectional manner to Egr3 expression in D2-MSNs of mice repeatedly exposed to cocaine. Furthermore, we show that Nab2 overexpression leads to decreased levels of Egr3, and Nab2 inhibition leads to increased levels of Egr3. A2A-Cre mice with D2-MSN specific knock-down of Nab2 in the NAc showed decreased cocaine reduced locomotion. We then tested if Nab2 perturbation in D2-MSNs has a behavioral impact in cocaine self-administration. A2A-Cre mice with D2-MSN specific knockdown of Nab2 in the NAc showed reduced cocaine seeking after 10 days of cocaine self-administration. Our future plan is to study the brain tissue collected from these animals to elucidate transcriptomic changes occurring in selective cell types in the NAc via single nuclei RNA-seq. Collectively, our studies identify distinct cell type specific molecular mechanisms involved in behavioral responses to cocaine including drug seeking behavior.

Title: Adolescent social isolation stress and cocaine exposure disrupt sex-specific reward-related behavior and dopaminergic transcriptional programs in the medial amygdala of adult mice

Authors: *N. FOWLER, A. MILIAN, *C. BENDERSKY, D. WALKER;
Oregon Hlth. & Sci. Univ., Portland, OR

Abstract: Adolescence is associated with the onset of sex-specific drug-reward-related behaviors and an increased sensitivity to reward and stress. Given dopamine's role in drug reward, transcriptional alterations within the mesocorticolimbic dopaminergic system may play a role. Most studies that have examined this system have focused on brain regions already implicated in reward (e.g., nucleus accumbens). However, the medial amygdala (meAMY), a region traditionally thought to be outside of the canonical reward circuitry, is also rich in dopamine receptors and plays a crucial role regulating sex-specific drug reward during adolescence. Despite this, little is known about how adolescent stress or drug exposure influence dopaminergic transcriptional programs in the meAMY in a sex-specific manner. Therefore, this study examined dopaminergic gene expression in the meAMY of adult female and male mice following adolescent social isolation stress and/or cocaine exposure. Female and male mice were exposed to social isolation stress or group housed during adolescence (P22-P42) and then group housed until adulthood (P90). In adulthood, animals underwent behavioral testing in novelty suppressed feeding and cocaine CPP to measure animals response to a novel and rewarding stimulus. Additionally, publicly available transcriptomic data were mined for gene expression changes associated with dopaminergic receptor expressing neurons after the first dose of cocaine in males and females (Walker et al., 2020). Sex differences in novelty suppressed feeding were lost after adolescent social isolation and a previously described sex-specific effect on cocaine CPP was observed. In addition to baseline sex differences in dopaminergic Drd1 gene expression in the meAMY of adult mice (female > male), we found that sex-specific expression was lost following adolescent social isolation stress. We also found that cocaine only induced expression of Drd1 and Drd2 associated genes in isolated males. These data suggest that adolescent isolation disrupts adult sex-specific behavior as well as drug-induced dopaminergic transcriptional programs in the meAMY which may promote long-lasting synaptic and behavioral adaptations associated with addictive-like behaviors. Current work is focused on investigating how adolescent isolation disrupts developmental profiles of Drd1 and Drd2 expression.

Title: Progressive hyperpolarization-activated cation current (I_h) reduction: a response mechanism to decrease cocaine-induced excitability in VTA DA neurons.

Authors: *K. Y. BOSQUE CORDERO[1], R. VAZQUEZ-TORRES[2], C. CALO-GUADALUPE[2], D. CONSUEGRA-GARCIA[2], G. R. FOIS[3], F. GEORGES[3], C. A. JIMENEZ-RIVERA[2];
[1]Biol. Dept., Univ. of Puerto Rico Rio Piedras Campus, San Juan, Puerto Rico; [2]Physiol., Univ. of Puerto Rico Med. Sci. Campus, San Juan, Puerto Rico; [3]Neurodegeneratives Dis. Inst., Univ. of Bordeaux, Bordeaux, France

Abstract: The hyperpolarization-activated cation current (I_h) is a contributing factor of intrinsic neuronal excitability in different cells, including dopaminergic neurons (DA) of the ventral tegmental area (VTA). In contrast to other cellular conductances, I_h is activated by hyperpolarization and produces a time-dependent depolarizing current. Our laboratory demonstrated that cocaine sensitization, a non-contingent cocaine model, significantly reduces I_h amplitude in VTA DA neurons. However, the role of I_h in controlling VTA DA excitability is still poorly understood. It has been shown that VTA DA cell's spontaneous activity remains unchanged when compared to the saline control groups after cocaine sensitization. Our hypothesis is that I_h reduction could function as a homeostatic regulator compensating for the cocaine-induced alteration in excitability thus, explaining the above-mentioned results. Using *in vivo* single-unit extracellular electrophysiology in isoflurane-anesthetized rats, we explored the Ih contribution on acute cocaine-induced VTA neuronal spontaneous activity. We locally perfused an I_h blocker (ZD7288, 8.3 μM) and evaluated its effect on VTA DA spontaneous firing

patterns. I_h blockade significantly reduced acute cocaine-induced spontaneous firing rate, bursting frequency, and percent of spikes within a burst. I_h local inhibition also significantly increased the mean interspike interval (ISI) in VTA DA neurons. These findings suggest that I_h blockade can significantly reduce cocaine-induced firing activity in VTA DA neurons in part due to an increase in the mean ISI. Furthermore, using whole-cell patch-clamp, we found a significant reduction in I_h after 24 but not 2hours (hrs) of acute cocaine administration (15mg/kg, i.p). Using a current clamp rebound spiking protocol, we determined at different intervals of acute cocaine administration (2hrs, 24hrs and, 24hrs following 7-days cocaine administration) that there was a significant increase in rebound action potentials. This increase was progressively diminished as the sensitization protocol developed. In addition, the I_h blockade significantly reduced rebound action potentials. These results suggest that a progressive Ih reduction could serve as a homeostatic regulator of cocaine-induced spontaneous firing patterns which are correlated to an enhanced VTA DA excitability.

Title: Cross-frequency coupling in a macroscopic model of collective neural activity

Authors: *A. SHEREMET[1], Y. QIN[2];
[2]Civil & Coastal Eng., [1]Univ. of Florida, Gainesville, FL

Abstract: Collective neural activity, i.e., spatiotemporal patterns of activity that entrain a large subset of the neural population, such as oscillations, propagating waves, Turing patterns, spiral waves and others, is macroscopic with respect to cell scale, in the sense that the details of the behavior of any single cell have no detectable expression in its dynamics. In physics, the evolution of large scale systems has been traditionally modeled in the framework of statistical physics, or its thermo-/hydrodynamic limits, which represent the physical system as a continuum. These approaches have been successfully used to investigate phenomena such as phase transitions, that bear little resemblance to microscopic dynamics.
The application of such models to brain activity, however, poses a fundamental challenge: there are no neurons, as "cell individual", in these models. These models do not describe pairwise

communication between neurons, or deterministic interconnections between small groups of neurons. If brain activity depends crucially on the dynamics of cell individuals, rather than populations, these models might not be of much use.
However, measurements reveal intriguing macroscopic features of brain activity such as strong nonlinear deformation of the theta rhythm in rats running at high speed, cross-frequency coupling between theta and gamma rhythms, and cross-scale coupling in transient processes such as sharp waves and ripples, or slow waves and spindles. These features are similar to those observed in large scale systems such as wave turbulence, where they have been successfully studied using statistical models. Here, we present an investigation into the properties of a macroscopic model of collective activity and demonstrate that cross-frequency coupling is a fundamental phenomenon that originates in the stochastic and nonlinear character of macroscopic dynamics.

Title: A macroscopic formulation of collective neural activity based on the Hodgkin-Huxley model

Authors: *Y. QIN[1], A. SHEREMET[2];
[2]Engin. Sch. for Sustainable Infrastructure and Envrn. (ESSIE), [1]Univ. of Florida, Gainesville, FL

Abstract: Collective activity is defined by the emergence of spatiotemporal patterns of activity that entrain a large subset of the neural population, such as oscillations, propagating waves, Turing patterns, spiral waves and others. Collective activity is macroscopic with respect to the cell size, in the sense that many details of cell-scale dynamics, such as the exact shape of the action potential of any given single cell, are ignorable. In the cortex, collective activity is mesoscopic, with characteristic scales of 0.1 - 10 mm and 5 - 500 ms. While one could conceivably attempt to model collective activity by integrating a cell-scale model (e.g., the Hodgkin-Huxley equations) for every participating neuron, the large number of cells involved and the lack of accurate information about the individual cells and the structure and characteristics of the interneuronal connections, make this an impossible task. It is also an unnecessary task, because the details of the behavior of a single cell have no detectable

expression in collective activity. In physics, the evolution of large scale systems has been traditionally modeled in the framework of statistical physics, or its thermo-/hydrodynamic limits, which represent the system as a continuum. This approach was used successfully to explain phenomena such as phase transitions, that are fundamentally macroscopic in nature and bear little resemblance to microscopic dynamics.
Here, we present a statistical formulation of collective activity dynamics and explore further macroscopic simplifications. Starting from the dynamical equations of Hodgkin and Huxley, we formulate a Fokker-Plank-type statistical model describing evolution of the distribution of the neural population in the parameter space of the Hodgkin-Huxley model. In the long-wave limit we reduce the dimensionality of the Fokker-Plank representation to a small number of state variables that are observable at macroscopic scale (e.g., through LFP measurements). The resulting model is similar in functionality to a hydrodynamic description of gas. We compare the model with other existing formulations of the same type (e.g., Wilson-Cowan models), and present a preliminary analysis of the linear properties of the model.

Title: Mechanisms underlying non-deterministic computation in cortical neural networks

Authors: *E. A. STOLL;
Western Inst. for Advanced Study, Denver, CO

Abstract: Unlike peripheral neurons, which have highly deterministic signaling outcomes, cortical neurons exhibit probabilistic firing patterns, permitting random electrical noise to gate signaling outcomes. While statistical tools have proven successful at modeling probabilistic firing patterns in the cortex, there is no established mechanism for computational units to achieve optimal coding by relying on stochastic membrane potential fluctuations. Here, a mechanistic process is proposed to explain how neurons achieve non-deterministic signaling outcomes during up-state, by retaining sensitivity to stochastic charge flux and using this noise to drive computational work. Here, the voltage state of each neuron is modeled as a mixed sum of pure states, accounting for the relative position and atomic orbital of every local electron after some time evolution. This mixed sum of component states is a complex-valued probability density, representing the total information or von Neumann entropy of the system. The probability amplitudes constructively and destructively interfere in a physical manner on the complex plane to yield a non-deterministic computational outcome for each neuron in the network. The quantity

of energy expended to create information is partially recovered during a computational cycle, as predictive value is extracted; that quantity of predictive value is equivalent to the quantity of information compression and the quantity of free energy released back into the system. This model demonstrates how cortical neurons can temporally bind and parse information to extract predictive value, undergoing cycles of information generation and compression to compute the most likely state of the local environment.

Title: from structure to dynamics in combinatorial threshold linear networks

Authors: *C. LIENKAEMPER[1], K. MORRISON[2], C. P. CURTO[3];
[1]Pennsylvania State Univ., State College, PA; [2]Sch. of Mathematical Sci., Univ. of Northern Colorado, Greeley, CO; [3]Mathematics, The Pennsylvania State Univ., University Park, PA

Abstract: Neural circuits display nonlinear dynamics. The structure of network connectivity is a key feature determining network dynamics, but many questions remain as to how structure shapes activity. We study this relationship in a simple model of neural activity, combinatorial threshold linear networks (CTLNs), whose activity is governed by a system of threshold-linear ordinary differential equations determined by a directed graph (Figure A). CTLNs display the full spectrum of nonlinear behavior, including multistability, limit cycles, and chaos.
Much is known about fixed points of CTLNs, but much less is known about their dynamic attractors. Here we go beyond fixed points and relate the structure of a CTLN to its dynamics. We focus on a structural relationship, graphical domination, and show that if one neuron graphically dominates another, then the firing rate of the dominating neuron eventually becomes greater than the firing rate of the dominated neuron. This constrains trajectories of the dynamical system. Using this fact, we show that many CTLNs have only static (fixed point) attractors. Specifically, we prove that if a CTLN's underlying graph is a directed acyclic graph, neural activity must converge to a stable fixed point supported on one of the sinks (Figure B). This type of convergence result was previously only known in the case of symmetric TLNs.

We also construct a family of sequential memory networks. Each network consists of m layers of n neurons connected cyclically (Figure C). The network has m^n limit cycles. Different initial conditions lead to different limit cycles (Figure C). Our domination result allows the network to "remember its place" once it comes back around to a previously visited layer. These networks have a large capacity to encode dynamic patterns via limit cycles, giving a richer set of memory patterns than stable fixed points. Thus, these networks can model sequential memories, rhythms, or central pattern generators.

Abstract: Combinatorial threshold-linear networks (CTLNs) are a mathematically tractable subfamily of threshold-linear networks whose dynamics are determined by the structure of a directed graph. Threshold-linear networks have been widely used to model neural networks with associative memory. ln spite of their simplicity, CTLNs exhibit the full range of nonlinear dynamics: multistability, limit cycles, quasiperiodic and chaotic attractors. One of the most remarkable features of CTLNs is the strong relationship between the attractors of the dynamics and the collection of fixed points. Critically, these fixed points can often be completely determined by the structure of the graph. When the fixed points are confined to a subset of the neurons, neural activity has been observed to converge to this subset. In this sense, attractors live where the fixed points live. This motivates the idea of directional graphs, networks that exhibit feedforward dynamics without requiring a feedforward architecture, as a proxy for the expected flow of activity. Specifically, any subnetwork that is a directional graph acts like a single directed edge in terms of the flow of activity through the larger network. We find that whenever a large network can be covered by directional graphs, then we can associate a simplified nerve graph where each directional subnetwork is replaced by a directed edge. Many properties of the larger network can then be understood in terms of those of the nerve graph, resulting in a dramatic dimensionality reduction. We will present a number of results relating the fixed points of the nerve graph to those of the larger network. We will also show examples of how to engineer complicated network architectures with desired dynamic properties and how to investigate the dynamics of complex networks using this powerful dimensionality reduction technique.

Title: Combinatorial threshold linear networks: a unifying framework for temporal pattern generation.

Authors: *J. LONDONO ALVAREZ[1], K. MORRISON[2], C. P. CURTO[1];
[1]Mathematics, The Pennsylvania State Univ., University Park, PA; [2]Sch. of Mathematical Sci., Univ. of Northern Colorado, Greeley, CO

Abstract: Threshold-linear networks (TLNs) are widely used as a framework for modeling recurrent neural networks, including associative memory networks. Here we focus on a special family of TLNs, known as Combinatorial Threshold Linear Networks (CTLNs), a firing rate model with binary synapses and simple perceptron-like neurons. The dynamics of CTLNs are controlled solely by the structure of a directed graph, thus isolating the role of connectivity in

network dynamics. Moreover, its piecewise-linear dynamics provide a mathematically tractable framework where all types of nonlinear dynamics can still arise (multistability, limit cycles, chaos, quasiperiodicity). This simple mathematical setup makes it suitable for engineering circuits performing common neural functions, yet still allowing flexibility in terms of the kind of dynamics that might be observed. Our aim here is to present a few interesting cases that exemplify how connectivity alone gives rise to a diverse range of neural functions. Our first example is a CTLN that can count the number of pulse inputs it has received via the position of the attractor in a linear chain of attractor states; this network is a simple yet robust alternative to the neural integrators typically used to maintain a count in working memory of some number of input cues. With a small variation in the previous network, we can obtain a signed counter, where the dynamics can now travel back to the previous attractor on the chain as well. This proves valuable for tracking the relative number of left and right cues as in various two-alternative forced-choice tasks or tracking position in a linear track. Finally, we present a CTLN capable of producing five coexisting quadrupedal gaits. These gaits coexist as distinct limit cycle attractors in the network, without needing to change parameters to access different gaits (Fig. 1). Instead, different gaits are obtained by changes in initial conditions, or by stimulation of a specific neuron involved in the gait. These examples illustrate the power of CTLNs as a unifying framework for modeling a wide range of neural computations.

Title: Sparse expander graph connections for efficient long-range cortical information flow and distributed working memory

Authors: *A. DE, R. CHAUDHURI;
Univ. of California, Davis, Davis, CA

Abstract: Long-range connections in the cortex are sparse. For example, the number of connections in the primate neocortex falls off exponentially with distance (Ercsey-Ravasz et al., 2013). How could distant cortical circuits effectively communicate given these extremely sparse interactions? To address this question, we draw on recent mathematical results in the theory of expander graphs. Expander graphs are sparse networks that are well-connected despite their sparsity. They have found widespread recent use in computer science in designing powerful algorithms for efficient communication, error correction, dimensionality reduction, and sparse signal recovery. Moreover, large, sparse, random networks are expander graphs thus making them attractive candidates for modeling biological connectivity.
We consider a model of two interacting brain areas, connected by sparse expander connections. We first show that a small number of such connections between the source and target area is sufficient to preserve information about sparse patterns in the source area, thus allowing these input patterns to be efficiently communicated to the target area. Next, we show how such sparse connections can be used to sense and reconstruct sparse sensory input patterns using simple neurally-plausible dynamics and only a small number of reconstruction neurons ("compressed sensing"). Importantly, the sparsity of the connections is essential in allowing errors to be identified and the signal to be reconstructed using simple dynamics. We show that, among other uses, such sparse signal reconstruction could be used as part of a sensory-cognitive loop to maintain stimulus-specific persistent activity for a wide range of stimuli, providing theoretical support for recent models of flexible distributed working memory (Bouchacourt & Buschman, 2019). Finally, we investigate when such sparse connections could allow a control signal in one area to efficiently shape neural dynamics and computation in the other area, as could be done for information gating and cognitive control.
Our results provide a novel mathematical framework in which to model sparse long-range interactions in the cortex, with possible applications to efficient information flow, error correction, distributed working memory, and cognitive control.

Title: Multiple Spike Sequences Inherent in Random Networks

Authors: *H. GERMAINE, P. MILLER;
Brandeis Univ., Waltham, MA

Abstract: The mammalian hippocampus contains place cells which fire in a sequence representing a traversal through space. Interestingly, the same cells can represent different locations in different environment traversals, meaning spike sequences for unique environments can contain overlapping neuron populations. Further, research has shown that the trajectory-representing spike sequences can be observed prior to an animal ever experiencing an environment, pointing to an inherent tendency for sequences to exist and then be mapped onto environments upon experience. Computational models of these sequences traditionally employ a spatially organized lattice network of neurons, with spatially organized connectivity, representing a two-dimensional set of place fields in an environment. These models can accurately represent firing patterns in relation to one environment, but not multiple. In this study, we aim to test a non-spatially organized network organization for inherent spike sequences which are numerous and orthogonal. To do so, we utilize a leaky integrate-and-fire model of neuronal firing and create a neural network structure organized into randomized and overlapping clusters of neurons, within which connectivity is sparse and randomized. To mimic an environmental stimulus causing a sequence of firing, we set one cluster of neurons to threshold, and observe the trajectory of firing through the network. Using this model, we show that a non-spatially organized network of neurons is able to achieve unique sequences of firing representing different environmental trajectories, where individual neurons take part in multiple trajectories. This means that the set of neural spikes which follow the spiking of a particular neuron depends on the set of spikes which preceded its firing. Analysis using a matching index (MI) metric as well as Spearman's rank order correlation results in values of 0.19 ± 0.09 and 0.30 ± 0.10 respectively, indicating a low degree of similarity in the firing sequences, but overall supporting a strong differentiation for different initiations of sequences. We further present how Hebbian strengthening of one trajectory causes a deterioration of other trajectories. These results not only contribute to more biologically relevant modeling of hippocampal activity but also support the inherent tendency of networks to generate "preplay" sequences, which can then be mapped onto particular environments and strengthened through learning.

Title: Spectral analysis of a recurrent circuit model implementing normalization

Authors: *S. RAWAT[1], D. J. HEEGER[2], S. MARTINIANI[1];
[1]Chem. Engin. and Materials Sci., Univ. of Minnesota, Twin Cities, Minneapolis, MN; [2]Dept Psychol & Ctr. Neural Sci., New York Univ., New York, NY

Abstract: Background: Divisive normalization (DN) is a canonical neural computation in which the response of a neuron is divided by the total activity of an ensemble of neurons. Experimental evidence suggests that DN operates via recurrent amplification. Several circuit models implementing DN have been proposed, but they do not rely on recurrent amplification to achieve DN and/or they do not exhibit oscillatory dynamics linked to normalization and/or they only approximate DN (which has practical consequences for making experimentally-testable predictions and for fitting data). Oscillatory Recurrent Gated Neural Integrator Circuits (ORGaNICs) are a recently proposed family of recurrent circuit models that implement DN via recurrent amplification. Methods: We implemented a multistage ORGaNICs model to simulate and study the dynamics of neural activity and communication across cortical hierarchies in the primate visual system. We derived closed-form expressions for the power spectral density and coherence of the responses within a local circuit and across multiple stages using the properties of continuous-time stochastic processes. Results: We found, in agreement with electrophysiological measurements in non-human primates, that: 1) the power spectrum of the local field potentials (LFPs) is shaped by recurrent normalization to exhibit a resonant peak in the gamma frequency range (~40-80 Hz); 2) the peak frequency and the amplitude of oscillatory activity are dependent on stimulus contrast; and 3) the shape of the LFP power spectra remains largely unchanged across cortical areas, except for a modest increase in the peak resonant frequency. Analysis of the coherence between stages reveals that inter-area communication is frequency and contrast dependent, so that coherence is maximized at low frequencies for low contrast stimuli, while coherence is maximized in the gamma-frequency range for high contrasts. Conclusion: Our theory offers a novel link between a local circuit-model of DN and large-scale neural dynamics.

Title: All-optical experiments across cortical areas enabled by novel transgenic mouse lines expressing the red-shifted opsin ChRmine

Authors: *A. DRINNENBERG[1], S. QUIRIN[1], C. RAMAKRISHNAN[1], T. L. DAIGLE[2], B. TASIC[3], L. SIVERTS[3], S. RANDLES[1], A. GERBINO[1], H. ZENG[4], K. For Brain Sci., Seattle, WA; [4]Structured Sci., Allen Inst. for Brain Sci., Seattle, WA; [5]Bioengin & Psych, Stanford Univ. Dept. of Psychology, Stanford, CA

Abstract: In all-optical experiments, the simultaneous readout and manipulation of neuronal activity is achieved by combining 2-photon calcium imaging with 2-photon holographic photostimulation. Experimental success of all-optical approaches depends on carefully optimized expression levels of both opsin and indicator to ensure high fidelity photostimulation and high SNR activity readout, with minimal crosstalk. Viral approaches have proven to be challenging to ensure well-titrated, stable, and widespread co-expression of opsin and indicator. Here, we present a transgenic approach for all-optical neuroscience. We developed four novel TIGRE-based transgenic reporter lines (*Ai219, Ai228, Ai229, Ai230*). All four lines are Cre-dependent and express the red-shifted, excitatory opsin ChRmine, targeted to the soma to facilitate single cell precision of the photostimulation. *Ai219* is a ChRmine-oScarlet reporter that can be combined with various indicators - either virally delivered, or by breeding to a second reporter line. *Ai228* is a GCaMP6m and ChRmine-oScarlet reporter that leads to high quality all-optical preparations with stable expression levels for >2 months. *Ai229* is a GCaMP6m and ChRmine reporter without fluorophore, adding further flexibility for cell-type or projection-specific labeling. *Ai230* co-expresses ChRmine-oScarlet and the fast indicator XCaMPG upon viral delivery of Cre and tTA. We demonstrate the utility of the four reporters for all-optical experiments by using various Cre delivery strategies. In *Ai219*, for example, we used a bicistronic AAV to deliver Cre and GCaMP6m to excitatory cortical neurons and achieved high fidelity photostimulation (>90% stimulation-responsive cells of all targeted cells, 5mW per cell). For all-optical access throughout cortex, we employed a full transgenic approach using *Ai228xCaMK2aCre-ERT2*, resulting in widespread and homogenous expression of ChRmine and GCaMP6m in excitatory neurons with virtually no neurons (<1%) having filled nuclei. Using 2nd generation multiSLM scopes, we performed all-optical experiments (FOV >1mm2) across areas of visual cortex, after defining area boundaries using retinotopic maps. From a pool of ~1500 neurons, we chose ensembles of up to 65 neurons for simultaneous stimulation and obtained a high fraction (>90%) of stimulation-responsive cells (at 6mW per cell), with the maximal distance between successfully targeted cells >1.5mm. Our suite of transgenic reporter lines for all-optical experiments can be flexibly combined with existing cell-type specific viral or transgenic targeting strategies, and offers new possibilities for all-optical neuroscience.

Abstract: All-optical electrophysiology is a promising methodology for studying neural dynamics in vivo, as it offers the ability to image and perturb membrane voltage in multiple cells simultaneously. The “Optopatch” constructs combine a red-shifted archaerhodopsin (Arch)-derived genetically-encoded voltage indicator (GEVI) with a blue-shifted channelrhodopsin actuator (ChR). We used a video-based pooled screen to evolve Arch-derived GEVIs with improved signal-to-noise ratio (QuasAr6a) and kinetics (QuasAr6b). Both constructs enabled minutes-long continuous high-speed voltage imaging in vivo through multiple imaging sessions. Using an Optopatch construct based on QuasAr6a, we showed that optogenetically-triggered activation of a single Ndnf-expressing neuron in visual cortex may lead to a significant reduction of the spike rate in neighboring interneurons, in a distance-dependent manner. Using QuasAr6b-based Optopatch, we characterized the excitability of fast-spiking parvalbumin (PV)-expressing interneurons in hippocampus CA1. We further examined the spontaneous spiking of multiple PV neurons and discovered an increased probability of near-synchronous spikes in closely spaced cells. Together, these results demonstrate powerful new tools for all-optical microcircuit dissection in live mice.

Abstract: Brain circuit architecture includes reciprocal connections between independent populations of neurons that are defined by their electrophysiological and transcriptional properties. To characterize the flow and transformation of information through these neural circuits, it will be important to achieve simultaneous measurement and perturbation of activity within distinct cell populations during behavior, and concurrently measuring and controlling cell type-specific neural activity using all-optical molecular tools is becoming a powerful relevant approach. While many microbial opsins have been discovered and engineered for optical control, current optogenetic tools for all-optical neuroscience are limited in speed and combinatorial spectral compatibility with activity sensors (e.g. GCaMP). To resolve this shortcoming and enable multiple-population all-optical neural circuit interrogation, we solved the cryo-EM structure of the channelrhodopsin ChRmine and created novel variants (designed based on the structure) including rsChRmine (which exhibits a reduced blue light shoulder and enhanced red light response, and responds to infrared light (750 nm) *in vivo*. Here, we have compared this new opsin to other class members and validate utility with both 1-photon and 2-photon implementation. Furthermore, we have combined this opsin with multiple genetically-encoded calcium indicators through frame-projected independent-fiber photometry to develop a novel

method for neural circuit interrogation termed ‘type-to-type synaptic weight’. This approach writes-in activity patterns to defined neural circuit elements and simultaneously reads-out the response of multiple defined cell types within the same network *in vivo*. Applying this approach to the mPFC of freely-behaving mice, we have identified quantitative dynamics of information transmission between feedforward and feedback circuitry in prefrontal excitatory and inhibitory networks that depended upon spike train length and frequency. These results establish an all-optical neural circuit interrogation approach for uncovering principles of interaction between cell types in the mammalian brain during behavior.

Abstract: Learning and memory have been associated with changes in synaptic strength and circuit dynamics, yet the precise plasticity mechanisms naturally employed for information storage in the brain have remained largely unclear. Here we investigated plasticity mechanisms in the hippocampus in vivo during behavior by combining genetically-targeted voltage imaging with optogenetic activation. Voltage imaging in the head-fixed virtual-reality setting revealed physiological circuit properties and dynamics expected for mouse behavior, including complex spikes, theta oscillations, and place cells (n = 11 place cells out of 57 recorded spiking cells, N = 4 mice). We showed that targeted optogenetic activation of cells at specific locations in the virtual-reality context induced stable cellular representation of these locations. In characterizing neuronal excitability before and after this opto-plasticity, we found no significant change, consistent with a synaptic mechanism for the plasticity. We next developed optical methods to

probe synaptic transmission between presynaptic CA3 cells and postsynaptic CA1 cells, by simultaneous optogenetic stimulation of CA3 cells during optical recording of postsynaptic voltage responses in CA1 cells. We optically resolved both excitatory and inhibitory postsynaptic potentials (EPSPs and IPSPs) generated by optogenetic stimulation of CA3 neurons (n = 8 out of 22 recorded spiking cells showed EPSPs; n = 12 out of 22 recorded spiking cells showed IPSPs, N = 4 mice). These results establish methods for all-optical electrophysiology that can reveal synaptic and circuit-dynamics properties and plasticity in behaving mammals.

Dept. of Psychology, Stanford, CA

Abstract: A long-sought goal in neuroscience is read/write access to an entire vertebrate brain at single-neuron resolution. In moving toward this aim, we solved the cryo-EM structure of the channelrhodopsin ChRmine and created three new transgenic zebrafish lines featuring novel ChRmine variants (designed based on the structure) with pan-neuronal expression during the larval stage when the whole brain is optically accessible. Using 3D two-photon imaging (512 pixels x 512 pixels x 10 planes) with 3D spatial light modulator (SLM) two-photon holographic stimulation (1536 pixels x 1536 pixels), we image tens of thousands of neurons at cellular resolution while stimulating up to 128 neurons across multiple brain regions, including the habenula and raphe nucleus. To guide and interpret collection of these datastreams, we

developed a new unsupervised denoising technique, based on Long Short-Term Memory networks (LSTMs), that automatically rejects stimulation artifacts as well as salt-and-pepper imaging noise. Together, this new approach permits single-trial analysis of brain-wide responses to concurrent optogenetic stimulation of specified cell-resolved ensembles. Across multiple fish (n=10), we observed that stimulating either the left or right habenula reliably allows measurement of the habenular projective field including distinct subpopulations of neurons in the medulla and raphe, and identification of putative interpeduncular nucleus (IPN) somata. Parametrically-titrated single-neuron stimulation in the habenular ensemble, from 2-32 neurons, revealed a ramping recruitment in the medulla commensurate with the number of neurons stimulated. For (n=2) fish, we explored the hypothesis that the raphe and habenula act in opposing fashion, as observed in prior work on behavioral state transitions. Using online analysis, we perform an initial demonstration of projective field tracing: we identify 32 neurons in the medulla/IPN that are recruited from optogenetic stimulation of the habenula, and use anatomy to identify 32 neurons in the raphe nucleus. We measure the projective field in response to these two stimulation groups across the entire medulla, as well as for a sham stimulation of 32 targets outside of the brain. A pixel is said to be contained in a projective field if the response exceeds a threshold that yields a 5% false discovery rate. By separately stimulating anatomically-identified raphe neurons or optogenetically-identified habenular efferents in the medulla, we find that these stimulations recruit largely orthogonal downstream cell populations, with a projective field overlap of only 7% despite the close proximity of recruited neurons.

Title: Brainwide neural circuitry for controlling orofacial movements

Authors: *T. A. MACHADO[1], I. V. KAUVAR[1], Y. CHEN[1], J. KOCHALKA[1], S. BRADBURY[1], K. DEISSEROTH[2];
[1]Bioengineering, Stanford Univ., Stanford, CA; [2]Bioengineering and Psychiatry, Stanford Univ. and HHMI, Stanford, CA

Abstract: Even many simple movements are planned, initiated, and executed by the joint activity of neural circuitry distributed across the brain. But how does this widely-distributed circuitry influence downstream motor structures to control behavior? Mammalian orofacial motor nuclei in the brainstem represent an accessible target for comprehensive study of relevant circuitry in addressing this question. We first studied these behaviors in head-restrained mice using a new widefield optical imaging method, Cortical Observation by Synchronous Multifocal Optical Sampling (COSMOS) (Kauvar*, Machado*, et al., Neuron, 2020), to record with true simultaneity from over a thousand neuronal sources spread across the entirety of curved mouse dorsal neocortex at ~30 Hz; analysis suggests that individual COSMOS sources represent mixtures of signals from 1-15 neurons. Using a memory-guided lick-to-target task, we found that distributed neural activity throughout cortex encodes targeted licking actions, with no apparent spatial structure ($p < 0.05$, permutation test for spatial clustering of sources with similar tunings; 4 mice). We also found that across cortex, unaveraged (but not trial-averaged) activity correlations showed local structure (at distances < 1 mm, unaveraged correlations were consistently lower than trial-averaged correlations; $p = 0.0001$, paired t test; 4 mice). Finally, analysis of population dynamics revealed similar encodings of history-guided motor plans in unrelated cortical areas. We next asked how these distributed cortical representations are read out by the brainstem to drive movement. To address this question, we measured neural activity in brainstem circuits (that integrate descending inputs from cortex and elsewhere in the brain to drive orofacial movements) while similar movements were made in different behavioral contexts. During behavior in this paradigm, we simultaneously employed optogenetic inhibition in cortex, multiregion Neuropixels recordings from various brainstem nuclei, and 3D kinematic tracking of orofacial movements. These data were aligned to the Allen Atlas Common Coordinate Framework, where we co-registered information about neuronal connectivity (from rabies tracing and hydrogel-based brain clearing) and neuronal cell typology (using STARmap for in situ sequencing of the transcriptome in the brainstem). Combining these diverse data streams into a single coherent map may advance understanding of how distributed representations and descending commands drive specific movements--and of the essential differences between volitional and reflexive actions.

Title: Multi-region network models of brain-wide interactions underlying adaptive and maladaptive state transitions

Authors: *M. G. PERICH[1], T. BENSTER[2], A. S. ANDALMAN[3], C. SPENCER-SALMON[1], E. CARTER[1], K. DEISSEROTH[4], K. RAJAN[1];

Abstract: During prolonged periods of stress, animals can switch from active to passive coping strategies to manage effort-expenditure. Such normally adaptive behavioral state transitions can become maladaptive in disorders such as depression. Here, we studied the neural mechanisms underlying behavioral state transitions using whole-brain neural recordings during maladaptive passivity induced by inescapable stress. Larval zebrafish expressing nuclear-localized GCaMP6s were exposed to a behavioral challenge protocol with repeated electric shocks. Initially, the fish showed vigorous tail movements, indicating an active coping (adaptive) strategy. The fish reduced movements as the shocks persisted, entering into a passive coping (maladaptive) state. We imaged whole-brain neural activity using two-photon microscopy and developed multi-region recurrent neural network (RNN) models to infer brain-wide directed interactions driving such maladaptive behavior by directly targeting the neural dynamics from upwards of 10,000 simultaneously-recorded neurons. Analysis of the trained RNN models revealed a specific change in directed interactions between two critical brain regions - the habenula and raphe nucleus - during the transition into passivity.
Using the directed interaction weights derived from the RNN models, we then performed Current-Based Decomposition (CURBD) to estimate the input currents from up to thirteen different brain regions driving each habenular neuron. We computed neural manifolds spanning these input currents across all habenular neurons to define subspaces within the habenular activity that independently captured the communication between other individual brain regions. At the onset of stress, there was an immediate and unique increase in currents from the raphe nucleus to the habenula. However, RNN models identified no similarly rapid change in the strength of directed interactions between these regions. As the animal lapsed into passivity, the strength of the raphe inputs to habenula decreased, with a concomitant change in the habenular interactions inferred from the RNN weights. This coincided with increases in currents to

habenula from other brain regions including the telencephalon and thalamus. This innovative combination of network modeling and neural dynamics analysis points to dual mechanisms with distinct timescales driving the behavioral state transition: early response to stress is mediated by reshaping the neural dynamics within a preserved network architecture, while long-term state changes correspond to altered directed interactions between neural ensembles in distinct brain regions.

Title: Cardiogenic control of affective behavioral state

Authors: B. HSUEH[1], ***R. CHEN**[1], S. RANDLES[1], D. D. TANG[1], C. RAMAKRISHNAN[1], Y. JO[1], M. RAFFIEE[1], Y. KIM[1], M. INOUE[1], S. KIM[1], L. TAN[1], D. KIM[1], A. CROW[1], C. RAJA[1], K. E. EVANS[1], M. GOUBRAN[2], K. DEISSEROTH[3];

Abstract: Physiological theories of emotion, proposed over a century ago, hypothesized that (rather than a unidirectional brain to body flow of information) the reverse direction could be important and even dominant (for example, that rapid heartbeats alone might induce fear responses and serve not merely as a consequence of central emotional processing). This important hypothesis had not been formally and precisely testable until now, since to test (for example) how altered cardiac rhythms might affect emotional or affective state, nonspecific interventions such as broadly-active stimulants or painful shocks would be required. In fact, even with optogenetics this would not have been possible until recently, since existing opsins were not sensitive enough to control a large organ like the heart with enough precision and power. To

address this question, we developed a noninvasive optogenetic pacemaker utilizing 1) ChRmine under control of the mouse cardiac troponin T promoter delivered via AAV9 for enhanced tropism in cardiac tissue (AAV9-mTNT::ChRmine-2A-oScarlet) and 2) wearable micro-LED optics, which enabled precise control of cardiac rhythms up to 1000 beats per minute in freely-moving mice within a safe range of illumination power similar to conventional optogenetics. We tested the behavioral impact of truly precise and specific induced cardiac changes on behavior and affective state. We found that this primary and direct tachyarrhythmia indeed potently enhanced anxiety-like behavior, demonstrating causal impact of the body to brain axis (n=16). This effect could only be observed in risky contexts, appreciable by the brain, revealing that both directions (brain to body and body to brain) are synergistically required to understand behavior (n=16). Then, using a whole brain activity screen in in double transgenic TRAP2:Ai14 mice, we mapped regions of the brain that were activated by these imposed cardiac rhythms, and identified posterior insular cortex as a potential mediator of bottom-up cardiac signal processing (n=8). We then showed that simultaneous optogenetic inhibition of posterior insular cortex with iC++ during optical cardiac pacing was sufficient to reverse the induced behaviors, implicating this region as a necessary site for mediating cardiogenic anxiety-like and apprehensive behavior (n=8). Our findings offer insights into the specific mechanisms by which such bodily signals can causally influence complex behaviors, reveal that body and brain must be considered together; we also present robust and generalizable tools for non-invasive, temporally precise control of precision-targeted cells, tissues, and organs throughout the body.

Title: Mapping Postnatal Dynamics of Single-cell 3D Genome Architecture in the Developing Mouse and Human Cerebellum

Authors: *L. TAN[1], R. CHEN[1], J. SHI[1], I. COBOS[2], L. DUNCAN[3], K. DEISSEROTH[1,3,4]; [1]Bioengineering, [2]Pathology, [3]Psychiatry and Behavioral Sci., [4]Howard Hughes Med. Inst., Stanford Univ., Stanford, CA

Abstract: Throughout neurodevelopment, spatiotemporal expression patterns of thousands of genes are precisely orchestrated, in ways that presumably help guide the proper formation of massive interconnected neural and glial networks. How does such complex regulation of gene expression occur at the cellular level? One emerging mechanism involves three-dimensional (3D) genome architecture. Recently, alteration in 3D genome architecture has been implicated in multiple neurodevelopmental disorders, including autism spectrum disorder (ASD), schizophrenia, and intellectual disability. Despite its importance, our understanding of 3D genome architecture in the developing brain is severely limited by the lack of high-resolution in vivo technology for comprehensive single-cell datastreams. To bridge this longstanding technology and knowledge gap, we previously developed a high-resolution single-cell chromatin conformation capture (3C/Hi-C) method—Dip-C—and resolved the first 3D genome structure of a single human cell with 20 kb (~100 nm) resolution. Recently, we applied Dip-C to 3,517 cells from the developing mouse cortex and hippocampus. We found 3D genome "structure types" that underlie diverse transcriptional cell types in the brain. Surprisingly, we discovered a multi-scale 3D genome transformation in 3 main cell lineages (neurons, astrocytes, and oligodendrocytes) in the first month of life. For example, in neurons, many regions across the genome—including the majority of chromosomes 7, 17, and 19—move inward.
Here we turn to the cerebellum, which harbors the majority of neurons in the mammalian brain and which undergoes unusually late development. For example, generation of granule cells occurs almost entirely after birth in mice and persists until the first postnatal year in humans. The cerebellum is also the most consistently affected brain region in ASD. However, little is known about the dynamics of 3D genome architecture in the developing cerebellum. We created the first single-cell 3D genome atlas of 3,797 cells from developing mouse and human cerebellum of both sexes. Unexpectedly, 3D genome changes that we previously observed in the mouse cortex and hippocampus (as well as in olfactory sensory neurons) were mostly absent from the cerebellum, suggesting a fundamental dichotomy in 3D genome regulation between forebrain and hindbrain. Instead, 3D genome of cerebellar granule cells undergoes highly cell type-specific rewiring throughout life (0-2 years in mice). Our findings provide new molecular insight into the cerebellum's unique mode of development, and may point to critical processes relevant to altered development as in ASD.

Title: Microglia Distribution in Early Postnatal Cerebellum

Authors: E. C. PLUNK[1], M. B. STOESSEL[2], M. Y. CEALIE[2], P. D. DREW[4], K. D. PHELAN[5], *A. K. MAJEWSKA[3];

Abstract: Microglia are traditionally known to be the resident immune cells of the brain; however, recent research has shown that they serve several other functions, including synaptic plasticity, phagocytosis of apoptotic cells, and phagocytic removal of debris. Microglia also have brain region specific morphologies, transcriptome profiles, and roles, and cerebellar microglia in particular seem to be distinct from microglia in other brain areas. Cerebellar microglia are less dense, have fewer processes, show different dynamic movements and have a different transcriptomic profile compared to those in other regions of the brain. Developmentally, cerebellar microglia are more phagocytic than those in other brain areas, clearing Purkinje cells that undergo developmental apoptosis. Microglial phenotype may be altered by these developmental events as well as the cerebellum's distinct structure and cell types, and its late development in comparison to the rest of the brain. To further characterize the development of cerebellar microglia, we analyzed the migration of microglia from the white matter to the grey matter of the mouse cerebellum by examining multiple developmental time points starting at post-natal day (P) 3.5 in Cx3Cr1 G/- mice, which fluorescently label all microglia in the brain. We investigated microglial density and distribution in white and grey matter at each time point and found that microglial migration into cerebellar gray matter occurs late in development after P10. At this time point, Purkinje cells are starting to form a monolayer and extend dendritic processes, suggesting that this early development does not require direct microglial contact. Understanding the behaviors of developing cerebellar microglia could give insight as to why they differ from microglia in other brain regions, as well as shedding light on their role in neurodevelopmental and neurodegenerative diseases involving the cerebellum.

Title: Cas Adaptor Proteins Regulate Cortical Migration and Lamination

Authors: *W. WONG[1], B. ZAREIAN[2], Y. C. WONG[1], E. ZAGHA[2], M. M. RICCOMAGNO[1]; [1]Molecular, Cell, & Systems Biol., [2]Psychology, Univ. of California, Riverside, Riverside, CA

Abstract: Laminar organization of the cortex requires neurons to exit the cell cycle, locomote, and assemble into six distinct layers. During migration, neurons encounter multiple permissive and repulsive cues, yet how these guidance cues are integrated within migrating cells is not well understood. To uncover the signaling events essential for radial migration, we studied how the three embryonically expressed Cas signaling adaptor proteins (p130Cas, CasL, and Sin) function during cortical development. The Cas family of proteins have been hypothesized to mediate integrin and guidance cue signal transduction during neural development. Here, we provide *in vivo* genetic evidence that Cas proteins serve a functional and redundant role during cortical lamination and axon guidance. Cas triple conditional knockout (*CasTcKO*) mice display severe cortical phenotypes that resemble cobblestone lissencephaly. In *CasTcKO* brains, ectopic clusters of neurons form beyond the marginal zone and sometimes invade the subarachnoid space. These ectopias are innervated by L1-CAM+ axon bundles. Furthermore, both deep and superficial layer neurons are mislocalized in *CasTcKO* mutants. Defects in neuronal positioning appear to be non-neuronal autonomous and may be due to a breakage in the basal lamina. Electrophysiological and behavioral studies revealed distinct functional deficits in *CasTcKO* mice, providing insights into the consequences of altered lamination on cortical processing. Overall, our data support an essential role for Cas adaptor proteins during the formation of cortical circuits.

Title: Embryonic retinopetal projections in human

Authors: *I. BYSTRON[1], C. BLAKEMORE[2];
[1]Univ. of Oxford, Oxford, United Kingdom; [2]Hong Kong Inst. for Advanced Study, Kowloon Tong, Hong Kong

Abstract: It is universally accepted that all neurons of the retina, in all mammalian species, are produced from progenitor cells in the retinal neuroepithelium, and that locally-generated ganglion cells are the first neurons to appear in the embryonic eye. Here we provide the evidence that the human eye, at the earliest stages of its development, contains a unique neuronal population **precocious retinopetal neurons (PRN)** that is generated in the brain.
We have developed a new approach to reconstructing cells in sections of the embryonic human brain and retina by rapid, high-resolution volume rendering of multichannel 3D confocal data-sets to reveal neurogenesis in the embryonic eye and the possible contribution to retinal development of neurons born elsewhere. Early embryonic tissue was obtained from the Human Developmental Biology Resource UK. Here we provide preliminary evidence that neuronal development in the human retina starts with precocious neurons invading the retina from ventral diencephalon. These cells, might be important in the cascade of developmental events leading to the formation of the human retina and the optic nerve. Long processes of the first neurons in the retina are not conventional nerve fibres. Although they do not express MAP2, GAP43, Tag1- the markers which we found in the first ganglion cells at E40-43 - it is possible that PRN neurons signal chemically to the processes of stem cells in neural and pigmental retina, with which they make intimate contacts. Moreover we also found bipolar TU-20-positive neurons scattering through the periocular mesenchyma. Some of them extended TU20-positive processes into the neural retina. We applied a battery of molecular markers to reveal that these periocular neurons do not belong to the diverse neural crest cell population delaminating from the closing neural tube and migrating through the cephalic mesenchyme. Invasion of the developing retina by extraretinal neurons from the diencephalon and by processes of neurons in the mesenchyme has not been described in any other mammalian species. The genetic and molecular mechanisms that underlie the relationship between PRN, periocular neurons and retinal stem cells remain to be elucidated.

Title: Postnatal streams of young migrating interneurons contribute to late temporal lobe development in the infant human brain

Authors: *S. BIAGIOTTI[1], M. A. NASCIMENTO[2], V. HERRANZ-PÉREZ[5], S. GONZALEZ[5], J. GARCIA-VERDUGO[5], E. J. HUANG[3], A. ALVAREZ-BUYLLA[4], S. F. SORRELLS[1];

Abstract: In the infant human brain, young neurons continue to migrate in the subventricular zone along the walls of the lateral ventricles into the rostral migratory stream and the olfactory bulb. It has recently been demonstrated that this postnatal migration also includes multiple regions of the forebrain through a coalesced medial migratory stream and distributed arc of migratory cells into the cingulate and superior frontal gyrus. Continued postnatal recruitment of migrating neurons into other parts of the infant human brain has not been investigated. In this study we examined the temporal lobe from ages 18 gestational weeks through 2 years of age to look for migrating neurons expressing doublecortin (DCX) and polysialylated neural cell adhesion molecule (PSA-NCAM). We find that the human temporal lobe lateral ventricles are surrounded by a distributed arc of migratory neurons similar to what is observed in the forebrain as well as individual young neurons with an elongated nucleus and a leading process indicative of migration. These neurons are DLX2+ and TBR1-, suggesting that this is a late migration of interneurons into the temporal lobe. Following this, we sought to determine the subtype of interneuron these young cells were becoming. We found that this late migration correlates with an increase in Calretinin+ cells. Our study reveals a late contribution of young migrating interneurons into the temporal lobe that aid in the development of the infant human brain. This late migration of young neurons throughout the human infant brain may indicate critical times when circuits are plastic, as well as sensitive periods when environmental disturbances could impact brain development.

Title: Characterization of neuroblast migration along key cellular substrates in the developing porcine brain

Authors: *D. D. L. PORTER[1], S. N. HENRY[2], S. AHMED[2], P. D. MORTON[2];
[1]Translational Biology, Medicine, and Hlth. (TBMH), [2]Biomed. Sci. and Pathobiology, Virginia Polytechnic Inst. and State Univ., Blacksburg, VA

Abstract: Neurogenesis, the birth of new neurons, and neuronal migration underlies the development of the human cerebral cortex. In postnatal and adult mammalian brains, immature neurons called "neuroblasts" generated in the subventricular zone (SVZ), undergo protracted migration (millimeters to centimeters, depending on the species) to reach their final destinations in the expanding neocortex and contribute to brain development/plasticity. Recent analyses of postmortem tissue revealed that humans possess robust migratory pathways of late arriving interneurons oriented towards the frontal lobe, namely the prefrontal cortex. However, the cellular mechanisms enabling these unique migratory routes remain unclear. Currently, our understanding of this process in human brain development is fragmentary, largely due to the diverging developmental features of well-studied rodent models during postnatal development. Here we use the neonatal piglet (*Sus scrofa domesticus*) to study the occurrence, anatomical distribution, and expression profile of SVZ-derived neuroblasts in a larger, gyrencephalic brain that more closely resembles its human counterpart. Tissue at postnatal day 0 (p0), p16, and p42 was used to evaluate the number of neuroblasts associated with cellular substrates in key regions of the SVZ of newborn piglets. Using a combined approach of multiplex labeling and microscopy, our current results demonstrate that the porcine SVZ contains a large, heterogeneous population of DCX^+ neuroblasts that are maintained throughout early postnatal development at all ages. Immunohistochemical analyses revealed DCX^+ clusters co-express the neuronal cell migration marker polysialylated neural cell adhesion molecule (PSA-NCAM) as well as the GABAergic interneuron marker ($GABA^+$) and regionally specific transcription factors ($SCGN^+SP8^+$) from the caudal- (CGE) and lateral ganglionic eminence (LGE) progenitor domains in the ventral forebrain. Moreover, we found that DCX^+ neuroblasts are encased by astrocytic ($GFAP^+$) processes and tightly associated with blood vessels ($IB4^+$) in the SVZ. Taken together, these data suggest that the vast majority of the SVZ-derived DCX^+ clusters are GABAergic interneurons that originate in the subpallial region of the telencephalon and migrate tangentially utilizing vascular scaffolds to the neocortex, which is likely to contribute to cortical plasticity in the postnatal piglet. Findings from this study will better inform future studies evaluating human cortical development and neuronal migration in normal and diseased states.

Title: Suppression of WNT5A-mediated chemoattraction by atypical cadherin CELSR1 prevents inappropriate migration of facial branchiomotor neurons

Authors: *D. HUMMEL[1], A. BECKS[1], H. MEN[2], E. BRYDA[3], D. GLASCO[4], A. CHANDRASEKHAR[1];
[1]Biol. Sci., [2]Dept. of Vet. Pathology, [3]Dept. of Vet. Pathobiology, Univ. of Missouri, Columbia, MO; [4]Dept. of Biol., Bob Jones Univ., Greenville, SC

Abstract: As the central nervous system develops, differentiating neurons often migrate extensively prior to forming the circuits vital to cognitive and motor function. Within the vertebrate hindbrain, Facial Branchiomotor (FBM) neurons migrate caudally from rhombomere 4 (r4) to r6 and assemble into the circuits that drive facial and jaw movements. While several components of the Wnt/PCP (Planar Cell Polarity) pathway have been investigated based on their required role in initiating FBM neuron migration, much less is known regarding the mechanisms regulating directionality. Our lab discovered that in mice lacking the Wnt/PCP component CELSR1, many FBM neurons inappropriately migrate rostrally into r3. Tissue-specific knockouts of *Celsr1* indicate that *Celsr1* acts non-cell autonomously in the ventricular zone rostral to r4 to block rostral migration of FBM neurons. Intriguingly, *Celsr1* and *Wnt5a* are expressed in overlapping domains within the ventricular zone rostral to r4. Based on these findings, we hypothesize that *Celsr1* suppresses WNT5A activity rostral to r4 to block inappropriate rostral migration of FBM neurons. We have now successfully tested three predictions of this model.
If WNT5A functions as a chemoattractant allowing for rostral migration in *Celsr1* mutants, then rostral migration should be suppressed in *Celsr1; Wnt5a* double knockouts. Indeed, FBM neurons in *Celsr1; Wnt5a* double knockout embryos never migrate rostrally and undergo normal caudal migration. Next, if WNT5A is the chemoattractant inducing rostral migration of FBM neurons in *Celsr1* knockouts, then rostral migration should be induced in wildtype hindbrains with WNT5A-coated beads placed in r3. We found that FBM neurons migrate rostrally toward WNT5A beads placed in r3 and r2 in >80% of wildtype explants, suggesting that excess WNT5A can overcome endogenous *Celsr1*-mediated suppression. Importantly, rostral migration toward the beads is significantly reduced in *Dvl2* mutants, demonstrating that migration is dependent on WNT5A-DVL2 signaling. Finally, our model predicts that rostral migration of FBM neurons should be greatly enhanced in *Celsr1* mutants overexpressing *Wnt5a* in r3. As expected, when a *Wnt5a* gain-of-function allele is used to overexpress *Wnt5a* in r3 of *Celsr1* mutants, the population of rostrally migrating FBM neurons is substantially larger than in control mutants, further supporting the chemoattractant model. These results reveal a novel role for a Wnt/PCP component in regulating neuronal migration by suppressing chemoattraction.

Abstract: Brain injury and neurodegenerative disease can result in long-term neuronal loss that is exacerbated by the limited regenerative capacity of the central nervous system. The rostral migratory stream (RMS) facilitates neuroblast migration from the subventricular zone to the olfactory bulb throughout adulthood. Brain lesions attract neuroblast migration out of the RMS, but resultant regeneration is insufficient without experimental intervention. Our lab has biofabricated a “living scaffold” that is implanted to enhance and redirect endogenous neuroblast migration from the subventricular zone to neuron-deficient brain regions. This approach utilizes the first implantable, biomimetic tissue-engineered RMS (TE-RMS), designed to leverage the brain’s natural mechanism for sustained neuronal replacement by replicating the native RMS in order to direct neuroblasts to distal sites of injury. Our previous work has characterized the structure of the TE-RMS fabricated from primary rat postnatal cortical astrocytes (rat TE-RMS). We have recently demonstrated that astrocyte-like cells can be non-genetically derived from adult human gingiva mesenchymal stem cells (n = 3 de-identified donors) and used for TE-RMS fabrication (human TE-RMS), and that key proteins (ezrin, robo2, and glial fibrillary acidic

protein) enriched in the endogenous adult male rat RMS (n = 5) are also enriched in the rat (n = 9) and human (n = 5) TE-RMS, but not in planar astrocyte sister cultures (n = 6 for rat and human). Additionally, we demonstrate that astrocytes in the endogenous RMS possess an elongated nuclear shape and distinct cytoskeletal arrangement compared to surrounding protoplasmic astrocytes, and that astrocytes in the rat TE-RMS mimic this distinct astrocytic nuclear shape and intermediate filament arrangement whereas planar astrocyte sister cultures do not. Furthermore, the human TE-RMS facilitates directed migration of immature rat cortical neurons *in vitro* (n = 4) at an average migration rate of at least 56 microns/hour which is comparable to neuroblast migration through the endogenous RMS, whereas acellular collagen (n = 4) and acellular collagen and laminin (n = 5) control columns do not direct immature neuronal migration *in vitro*. Finally, human TE-RMSs implanted in athymic rat brains redirect migration of neuroblasts out of the endogenous RMS (n = 6). The rat and human TE-RMS mimic the basic structure and function of the endogenous rat RMS. By emulating the brain's most efficient means for directing neuroblast migration, the TE-RMS offers a promising new regenerative medicine therapy for endogenous neuronal replacement following brain injury.

Title: Intrinsic and synaptic mechanisms alter thalamic neuron function in a Dravet syndrome mouse model

Authors: *C. STUDTMANN[1,2], M. TOPOLSKI[1], M. SAFARI[2,1], S. A. SWANGER[1,3,4];

Abstract: Dravet Syndrome (DS) is an infantile epileptic encephalopathy caused by mutations in the voltage-gated sodium channel $Na_V1.1$, which leads to hyperexcitable brain activity during development. This altered excitability causes persistent dysfunction across brain circuits, resulting in a broad phenotypic profile including non-convulsive (absence) seizures, attention deficits, and sleep disruption. Corticothalamic (CT) circuits are responsible for diverse informational processing and play a particularly important role in regulating attention and sleep. Disrupted CT circuit activity contributes to a variety of phenotypes in DS models and thus offers a promising therapeutic target. However, the precise cellular and synaptic mechanisms underlying CT circuit dysfunction remain elusive. Here, we sought to identify the cellular and synaptic mechanisms underlying pathological somatosensory thalamic circuit activity in a DS mouse model with $Na_V1.1$ haploinsufficiency, thereby revealing therapeutic targets to correct circuit function. Electrophysiological results revealed synaptic-level alterations in the somatosensory thalamus, including an input-specific reduction in glutamatergic synaptic input to the ventral posterolateral (VPL) thalamic nucleus and a significant increase in GABAergic input to the same region. Interestingly, synaptic input to the adjacent ventral posteromedial (VPM) thalamic nucleus remained unaltered. Glutamatergic synaptic input to the reticular nucleus of the thalamus (nRT), an inhibitory neuron population providing the primary inhibitory input to the VPL and VPM, exhibited an input-specific reduction without a change in overall glutamatergic input. Furthermore, all three neuron populations exhibited distinct alterations to intrinsic excitability in the disease model. VPL neurons exhibited hypoexcitability in response to depolarization, while VPM neurons were hyperexcitable in DS mice. We also revealed two nRT neuron populations with altered responses to depolarization including a low tonically firing population and a burst firing population. These changes in depolarization-induced firing were accompanied by alterations in resting membrane potential and hyperpolarization-induced rebound burst firing in both nRT and VPL neurons. These data indicate that diverse synapse- and cell-type-specific mechanisms in multiple neuron populations may contribute to somatosensory thalamic dysfunction in this DS model, thus providing new opportunities for therapeutic intervention.

Title: Characterization of the Okur Chung Neurodevelopmental Syndrome associated CK2K198RMutation

Authors: *D. M. CAEFER[1], N. Q. PHAN[1], J. P. O'SHEA[1], J. C. LIDDLE[2], J. L. BLASBAUGH[2], A. V. TZINGOUNIS[1], D. SCHWARTZ[1];

Abstract: Okur-Chung Neurodevelopmental Syndrome (OCNDS) was first described in 2016 and since then over 120 additional cases have been reported. The syndrome is characterized by delayed psychomotor development, intellectual disability, behavior abnormalities, and variable dysmorphic facial features. Genetically, OCNDS is associated with heterozygous mutations to the CSNK2A1 gene, which encodes the alpha subunit of casein kinase II (CK2). Numerous OCNDS associated mutations have been identified, with the most frequent being lysine-198 to arginine (K198R). Lysine-198 is located in the activation segment of the kinase, a well-conserved region important for kinase activity and substrate recognition. Despite the expanded number of identified mutations since the first characterization of OCNDS, little is known about the underlying molecular mechanisms, beyond speculation of altered CK2 activity. As a first step towards understanding how the CK2K198R mutation ultimately results in a disease phenotype, we generated high resolution specificity motifs of CK2WT and CK2K198R using the Proteomic Peptide Library approach (ProPeL). These experiments revealed that contrary to prior speculation the OCNDS associated CK2K198R mutation does not result in a loss of function, but rather shifts the substrate specificity of CK2. Broadly speaking the mutation leads to a decreased preference for acidic residues in the +1 position and an altered phosphoacceptor preference. To elucidate how the CK2K198R mutation contributes to the OCNDS disease phenotype we developed a probabilistic strategy to identify phosphorylation sites that could be differentially phosphorylated by CK2K198R relative to CK2WT. Due to the neurodevelopmental nature of OCNDS, and the known enrichment of CK2 in the axonal initial segment, we focused our predictions of altered phosphorylation sites to ion channels localized to the axon. This search identified several known CK2 targets, including KCNQ2. To test our predicted shifts in phosphorylation, HEK293T cells were transfected with KCNQ2 and CK2WT, CK2K198R, or

CK2KD, lysed, enriched for KCNQ2 by immunoprecipitation, and analyzed by LC-MS/MS. Preliminary analyses of immunoprecipitated KCNQ2 indeed suggest differing phosphorylation states dependent on co-expression with either CK2WT or CK2K198R. Future experiments will expand on these results to further investigate the effect of CK2K198R on KCNQ2 phosphorylation and additional CK2 targets with the aim of revealing the molecular mechanisms underlying OCNDS.

Title: Mechanistic and phenotypic convergence of congenital dm1 and rett syndrome

Authors: *K. MORELLI, W. JIN, S. SHATHE, G. W. YEO;
UCSD, La Jolla, CA

Abstract: Myotonic dystrophy type 1 (DM1) is a multisystem disorder caused by a CTG microsatellite repeat expansion (MRE) in the *DMPK* gene. While DM1 is the most common adult-onset muscular dystrophy, CTG expansions greater than 1500 bases result in congenital forms (cDM1) that manifest as neurodevelopmental defects. However, the molecular mechanism for how CTG MREs affect human cortical development is unknown. We detected CUG foci early during differentiation of three-dimensional cortical organoids from cDM1 patient-derived induced pluripotent stem cells. Toxic RNA expression causes disruption of widespread protein-RNA substrate interactions due to hyper-phosphorylation of RNA binding protein CELF2, which we reverse by CRISPR/Cas13d-mediated elimination of expanded CUG RNA. Enhanced CLIP analysis reveals impaired RNA metabolism of genes that are critical for excitatory synaptic signaling, including genes that are principal components of the MECP2 pathway responsible for Rett Syndrome (RTT). Strikingly, we uncover that cDM1 and RTT cortical organoids have

convergent phenotypes such as glutamate toxicity and neuronal loss, preventable by a NMDA antagonist. Our findings explain the molecular etiology of, and provide treatment avenues for, cDM1.

Title: Pharmacological blockage of Kcnn2 improves the impaired cognitive flexibility in the mouse model of FASD

Authors: *S. MOHAMMAD, L. WANG, M. TORII, K. HASHIMOTO-TORII;
Ctr. for Neurosci. Res., Children's Natl. Med. Ctr., Washington, DC

Abstract: Both genetic and environmental factors affect the embryonic brain development. Alcohol exposure is one of such environmental factors, and thus increases the risk of intellectual disability and other neuropsychiatric conditions. Our recent studies revealed that molecular responses against alcohol exposure happen in a stochastic and heterogeneous manner among neural progenitor cells. Those prenatal molecular events are associated with the changes of the gene expression in adulthood. Among those changes of the gene expressions, the expression of Potassium Calcium-Activated Channel Subfamily N Member 2 (Kcnn2) is highly increased in the pyramidal neurons in the motor cortex of prenatally alcohol-exposed (PAE) mice. Furthermore, postnatal blockage of Kcnn2 improves motor skill learning deficits in the PAE mice. Similarly, the increased expression of Kcnn2 was found in the prefrontal cortex (PFC) in PAE mice that show reversal learning deficits in the water T-maze. Therefore, we administered a Kcnn2 blocker, Lei-Dab7, intranasally starting at postnatal day 40 to the PAE mice. 10 minutes post intranasal application of Lei-Dab7, the binding to the neurons that express Kcnn2 was confirmed in the PFC as well as other brain regions. Daily administration of Lei-Dab7 starting one day before reversing the platform in the water T-maze improved reversal learning deficits in the PAE mice. Altogether, these results suggest Kcnn2 blocker as a new pharmacological intervention for cognitive inflexibility and other learning disabilities in the Fetal Alcohol Spectrum Disorders (FASD).

Title: Electrophysiological Properties of Neurons in Cortical Organoids Derived from Rett Syndrome and CDKL5 Deficiency Patients

Authors: *W. WU[1], P. NEGRAES[5], H. YAO[2], J. WANG[1], C. A. TRUJILLO[6], A. R. MUOTRI[3], G. G. HADDAD[4];
[2]Dept Pediat, [3]Pediatrics/Cellular Mol. Med., [4]Dept. of Pediatrics, [1]UCSD, La Jolla, CA; [5]Locanabio, Inc., San Diego, CA; [6]Pediatrics, Univ. of California - San Diego, La Jolla, CA

Abstract: CDKL5 deficiency disorder (CDD) and Rett syndrome (RTT) are two severe forms of X-linked Autism Spectrum Disorder with largely overlapping clinical symptoms. Epileptic seizures during early childhood are common, suggesting common alterations in neuronal function between CDD and RTT. Recently, we generated cortical organoids derived from CDD and RTT patients, as well as control individuals (i.e., healthy parental subjects). To investigate whether/how electrophysiological properties are altered, we performed whole-cell patch-clamp recordings in neurons of CDD and RTT organoids. We found that the # of action potentials (APs) (evoked from -70 mV to 200 ms-long injections of 50 pA current) in CDD neurons (1.90±0.15, n = 40) and RTT neurons (1.43±0.15, n = 23) were significantly higher than those in CDD control (1.07±0.08, n = 35) and RTT control (1.12±0.09, n = 33) ($p<0.05$, 1-way ANOVA). Further, the minimum currents (rheobase) injected to evoke an AP in CDD neurons (12.0±1.1 pA, n = 21) and RTT neurons (8.75±1.48 pA, n = 12) were significantly lower than those in CDD control (18.9±1.3 pA, n = 20) and RTT control (16.1±1.73 pA, n = 16), ($p<0.05$, 1-way ANOVA), suggesting increased neuronal excitability in both CDD and RTT organoids. Since voltage-gated ion channels are required for AP firings, we further used voltage-clamp techniques to dissect the densities of Na^+ and K^+ currents (I_{Na}, I_K). The peak I_{Na} densities (at -20mV) from CDD organoids and RTT organoids were 143.5±36.1% and 87.5±17.9% higher than those in corresponding controls ($p<0.01$, n=32-40). Additionally, the peak I_K densities (at +80mV) from CDD organoids and RTT organoids were 59.9±13.6% and 73.2±15.5% higher than those in corresponding controls ($p<0.01$, n=32-40), indicating increased channel activities in early CDD and RTT neurons. Together, our study revealed intrinsic neuronal hyperexcitability and upregulated function of voltage-gated Na^+ and K^+ channels in both CDD and RTT

organoids, which may contribute to the cellular electrophysiologic basis for their common symptoms such as early epilepsy.

Title: Epigenetic and transcriptomic post-mortem analyses in BA17 cortex of CDKL5-deficiency disorder patients

Authors: R. PIZZO, D. COMAI, A. LAURIA, S. DEVI, F. ANSELMI, A. GURGONE, S. OLIVIERO, *M. GIUSTETTO;
Univ. of Torino, Torino, Italy

Abstract: Cyclin-dependent kinase-like 5 (CDKL5) deficiency disorder (CDD) is a rare neurodevelopmental disease (NDD) caused by mutations in the CDKL5 gene, located on the X chromosome. The clinical features of CDD patients span from intellectual disability to poor language skills, impaired motor development, autistic-like tendencies, and severe early onset epileptic seizures. Moreover, CDD patients suffer from sensory defects, such as auditory and cortical visual impairments. CDKL5, a serine/threonine kinase, can shuttle between the nuclear and the cytoplasmic compartments. In the cytoplasm, CDKL5 regulates the formation and the functional maturation of dendritic spines as well as controlling cellular cytoskeleton dynamics. On the other hand, it has been suggested that CDKL5 interacts with epigenetic factors, i.e.: MeCP2, DNMT1 and HDAC4, raising the hypothesis that CDKL5 might regulate gene expression. However, the impact of CDKL5 mutation in the nucleus remains largely obscure even though mounting evidence place chromatin regulation, along with synaptic function, as the most affected molecular pathways of NDD-causative gene mutations. In the present study, by exploiting post-mortem BA17 cortex samples from two CDD individuals and two neurotypical age- and sex-matched controls (from: Harvard Brain Bank; Boston - USA), we investigated, the epigenetic profile. Both immunofluorescence and reduced representation bisulfite sequencing (RRBS) analyses showed that in CDD brains there are profound abnormalities of the epigenetic landscape that impact both histones' modifications and DNA methylation pattern. Moreover, we assessed whether such epigenetic alterations were associated with changes in gene expression. RNA-seq followed by the application of bioinformatics tools for gene expression analysis

revealed robust changes in transcript levels, and myelination-related genes were identified, by gene ontology, as the mostly affected in CDD. Finally, we found that the myeloarchitecture is affected both in the BA17 cortex of CDD individuals and in the V1 cortex of CDKL5-KO mice. Our data, collected on a limited dataset, suggest that CDKL5 is an important player in the regulation of both epigenetic and gene transcription and point to myelination as a novel sign underlying CDD pathogenesis.

Abstract: The rhombic lip is a dorsally located germinal zone in the hindbrain that produces ~80% of all neurons in the human brain and assists in the production of all glutamatergic neurons in the cerebellum. While the mouse rhombic lip is a transient structure present between embryonic days 12.5 and 17.5 lacking apparent structural compartmentalization, by contrast, in humans, the rhombic lip is temporally expanded, long-lived and seen throughout gestation. It is also uniquely compartmentalized into a ventricular (RL^{VZ}) and subventricular zone (RL^{SVZ}) separated by a distinct vascular bed. The RL^{VZ} is composed of proliferative self-renewing

SOX2+ cells, while the RL^{SVZ} is made up of progenitors of two main RL derivatives, Granule Cell Precursors (GCPs) and Unipolar Brush Cells (UBCs). The levels of GCPs vs UBC-progenitors changes over time with GCPs produced in higher numbers initially followed by UBCs. The human RL also exhibits human-specific expansion of bi-potential UBC-progenitors. Histopathological and immunohistochemical analyses of developing 31 Dandy Walker Malformation (DWM) and Cerebellar Vermis Hypoplasia (CVH) samples suggest that rhombic lip disruption is associated with cerebellar hypoplasia which disproportionately affects the posterior vermis and is correlated with reduced proliferation and self-renewal of the rhombic lip progenitor pool. Our findings are significant and add to the understanding of the human cerebellar development as well as the developmental pathogenesis of cerebellar birth defects like DWM and CVH.

ABSTRACTObjective: Adrenomyeloneuropathy (AMN), the slow progressive phenotype of

adrenoleukodystrophy (ALD) has no clinical biomarker for disease progression. This study aimed to identify plasma biomarkers for AMN disease severity in human blood plasma. Biomarker discovery for AMN severity would facilitate clinical trial placement and fulfill an unmet need in determining disease severity in clinical practice.**Methods:** A cross-sectional discovery study using GC/MS-based metabolomics and RNA-seq based miRNA was performed in human blood plasma. Integrated pathway-, clustering- and regression analyses were performed.**Results:**14 AMN and 6 healthy control subjects were assayed. Categoric comparison betweencontrol, mild, and moderate/severe AMN shows strong metabolic and miRNA clustering signatures. Individual clinical biomarker performance was assessed via regression against patient's clinical Expanded Disability Status Score (EDSS). Strong clinical correlations were shown for: 7-alpha-hydroxy-3-oxo-4-cholestenoate (7-HOCA) ($r2=0.83$, $p<0.00001$), dehydroepiandrosteronesulfate (DHEA-S) ($r2=0.82$, $p<0.00001$), hypoxanthine (0.q82, $p<0.00001$), as well as miRNA-451a ($r2=0.68$, $p<0.00001$) Kyoto Encyclopedia of Genes and Genomes (KEGG) pathway analysis identified downstream systems and pathways as a function of disease progression, by comparing mild vs severe disease: GAREM, IGF-1, CALCRL, SMAD2&3, Glutathione peroxidase, LDH and NOS.**Interpretation:** This is the first report of unique miRNA and metabolic signatures for AMN disease severity. We identify several candidate markers with strong correlations with clinical EDSS, providing potential biomarkers for clinical use and clinical trial. Network analysesidentify and implicate vascular, inflammatory, and oxidative stress pathways altered as a function of disease progression.

Abstract: Background: CDKL5 Deficiency Disorder (CDD) is a rare X-linked brain disorder characterized by severe early-onset seizures, intellectual disability, motor and social impairment. CDD is the result of a heterogenous mutation on the *CDKL5* gene. Microtubules (MT) are cytoskeletal elements formed by the polymerization of α/β-tubulin heterodimers and MT dynamics are fundamental for brain development and are involved in the pathogenesis of CDD. Here, we examined brain and plasma α-tubulin post translational modifications (PTMs) associated with MT dynamics in *Cdkl5*-KO mice and human CDD samples. **Method:** α-tubulin PTMs were measured using Infrared western blot in the hippocampus and plasma of *Cdkl5*-KO (exon 4) male mice compared to age-matched wild-type mice at postnatal day (P) 20, 60 and 180 and in plasma samples of CDD patients (n=11, female; mean age: 11, age range: 2-27) and healthy controls (female n=6 and male n=3; mean age: 39, age range: 27-49). Acetylated-Tubulin (Acet-Tub, less dynamic MT) was normalised to Total-Tubulin (Tot-Tub) and Tyrosinated-Tubulin (Tyr-Tub; dynamic MTs) and Detyrosinated-Tubulin (Glu-Tub; less dynamic MTs) were analysed as a ratio. Data were analysed by two-way ANOVA followed by Fisher's LSD *post hoc* or student's t-test. $P<0.05$ was deemed significant.**Results:** At P180, Acet/Tot-Tub is significantly overexpressed, and Tyr/Glu-Tub is significantly downregulated in the hippocampus of *Cdkl5*-KO mice compared to WT. While not significant, similar trends are evident at P20 and P60. Acet/Tot-Tub tends to be overexpressed in the plasma of *Cdkl5*-KO mice. In line with this latter data, our human results showed a significant plasma Acet/Tot-Tub overexpression in CDD patients compared to controls. This increase suggests similar MT dynamics dysfunction in *Cdkl5*-KO mice and CDD patients. Tyr/Glu-Tub is unaltered in the plasma of CDD patients. **Conclusion:** *Cdkl5*-KO mice and CDD patients exhibit alterations in α-tubulin PTMs consistent with dysregulated MT dynamics during neurodevelopment, indicating that MTs may serve as a novel therapeutic target for CDD. Moreover, plasma Acet-Tub may represent a potential biomarker of disease progression in CDD.**Acknowledgements:** This work is funded by the Lou Lou Foundation.

Title: The calcium sensor Synaptotagmin-1 is critical for phasic dopamine release, but is dispensable for motor behaviors in mice

Authors: *B. DELIGNAT-LAVAUD[1], J. KANO[1], C. DUCROT[1,2], I. MASSÉ[2], S. MUKHERJEE[1], N. GIGUÈRE[1,3], L. MOQUIN[3,4], C. LÉVESQUE[4], S. BURKE NANNI[1], M.-J. BOURQUE[1], P. ROSA-NETO[3], D. Abstract: Midbrain dopamine (DA) neurons, a population of cells that are critical for motor control, motivated behaviors and cognition, release DA via an exocytotic mechanism from both their axonal terminals and their somatodendritic (STD) compartment. Some of this release depends on axon potential firing, calcium influx and activation of exocytosis calcium sensors, while other forms can be triggered locally by afferent inputs or occur spontaneously. The mechanisms and physiological roles of these different forms of DA release are unclear. Here we conditionally deleted the synaptotagmin 1 (Syt1) gene in DA neurons (cKO^{DA} mice) to determine the roles of activity-dependent DA release. We found that in these mice, while, evoked axonal DA release is largely abrogated in the striatum and strongly reduced in the ventral mesencephalon, Syt1 cKO^{DA} mice show intact performance in multiple DA-dependent motor tasks, suggesting that activity-dependent DA release is dispensable for basic motor functions. Strikingly, basal extracellular levels of DA in the striatum, measured by microdialysis/HPLC, were unchanged, suggesting that a basal tone of extracellular DA is sufficient to sustain basic movements. We also found multiple adaptations in the DA system in cKO^{DA} mice, similar to those happening at early stages of Parkinson's disease. Overall, while validating the involvement of Syt1 as the critical calcium sensor controlling evoked-DA release, our study reveals the striking resilience of DA-dependent motor functions in the context of a near-abolition of phasic DA release, shedding new light on why extensive loss of DA innervation is required to reveal motor dysfunctions in Parkinson's disease.

Title: Dissecting differential dopamine dynamics in the dorsal and ventral striatum using the genetically encoded sensor dLight 1.3b

Authors: A. L. EJDRUP[1], S. H. JØRGENSEN[1], M. D. LYCAS[1], L. P. POSSELT[1], L. TIAN[2], J. K. DREYER[3], F. HERBORG[1], A. T. SØRENSEN[1], *U. GETHER[1];

Abstract: Dopamine neurotransmission in the striatal forebrain modulates movement, learning and reward. The transmission dynamics differ from classic, fast neurotransmission as dopamine is thought to mainly exerts its action through extrasynaptic volume transmission, acting exclusively on metabotropic receptors. Interestingly, there is evidence in the temporal dimension for signalling profiles across timescales, ranging from slow changes in basal levels to release-events with sub-second precision. However, a full understanding of extracellular dopamine dynamics has to a large extent been challenged by the methods available, as e.g., microdialysis suffers from poor temporal resolution and fast-scan cyclic voltammetry measurements are difficult to carry out over extended time periods. Here, we employ fiber photometry together with the genetically encoded dopamine biosensor dLight1.3b to concurrently measure fast dopamine dynamics in the mouse dorsal (DS) and ventral striatum (VS). Our data reveal remarkably different transmission dynamics with a rapidly fluctuating signal in the DS, containing both transients and asynchronous release, and a much more slow-paced signal in the VS, consisting of mostly dopamine transients. The release pattern in the two regions correlated, as dorsal dopamine release predicted ventral release at both a sub-second timescale and across tens of seconds. By recording in the two regions during both a novel environment and a reward seeking behavioural paradigm, we observed widely different responses of the regions with the VS signal exhibiting ramp-like release features. VS dopamine was also linked to locomotion, as ultra-slow fluctuations in ventral dopamine levels correlated with likelihood of movement initiation. Finally, we found that blocking the dopamine transporter with cocaine changed the dynamics of both regions and shifted the predictive power of movement to the dorsal region. This highlights the dopamine transporter as a key regulator of dopamine dynamics and match up well with findings of regional differences in expression levels of the protein.

Title: Multimodal Detection of Dopamine by Sniffer Cells Expressing Genetically Encoded Fluorescence Sensors

Authors: C. K. HERENBRINK[1], J. F. STØIER[1], W. D. REITH[1], A. DAGRA[2], M. A. C. GREGOREK[1], Y. LI[3], L. TIAN[4], U. GETHER[1], ***F. HERBORG**[1];

Abstract: Dopamine serves an important role by supporting both locomotor control and higher brain functions such as motivation and learning. Dopaminergic dysfunction is implicated in an equally multidimensional spectrum of neurological and neuropsychiatric diseases. Extracellular dopamine levels are known to be tightly controlled by presynaptic dopamine transporters (DAT), which is also a main target of psychostimulants. Still, detailed data on dopamine dynamics in space and time is needed to fully understand how dopamine signals are encoded and translated into cellular and behavioral responses, and to uncover the pathological effects of disease on dopamine neurotransmission to potentially discover new treatment options. The recently developed genetically encoded fluorescent dopamine sensors enable unprecedented monitoring of dopamine dynamics and have changed the field of *in vivo* dopamine recording. However, the potential of these sensors to be used for *in vitro* and *ex vivo* assays remains unexplored. Here, we demonstrate a generalizable blueprint for making “sniffer” dopamine cells for multimodal detection of dopamine *in vitro* and *ex vivo*. We generated six different sniffer cell lines with inducible expression of dopamine sensors and performed a head-to-head comparison of sensor properties to guide users in sensor selection. In proof-of-principle experiments, we show how the sniffer cells can be applied to measure release of endogenous DA from cultured neurons and striatal slices, and for determining total DA content in striatal tissue. Furthermore, we use the sniffer cells to quantify DAT-mediated dopamine uptake, and AMPH-induced and constitutive DA efflux as a radiotracer free, high-throughput alternative to electrochemical- and radiotracer-based assays. Importantly, the sniffer cells framework can readily be applied to other transmitter systems for which the list of genetically encoded fluorescent sensors is rapidly growing.

Title: Decoding the functional role of ventral tegmental area-olfactory tubercle dopamine transmission in methamphetamine-induced behaviors

Authors: *R. BHIMANI[1], C. E. BASS[2], J. PARK[1];
[1]Univ. At Buffalo, Buffalo, NY; [2]Pharmacol. & Toxicology, Univ. at Buffalo, Buffalo, NY

Abstract: The olfactory tubercle (OT) is a limbic structure located at the ventral most portion of the ventral striatum and receives some of the densest dopamine (DA) innervation in the brain from the ventral tegmental area (VTA). In addition, the OT is only a few hundred micrometers thick in rodents and is positioned within close proximity to many other DA-rich brain areas (e.g. nucleus accumbens, caudate putamen). Increasing evidence has highlighted that DA transmission in the OT may play a critical role in the reinforcing effects of many drugs of abuse. However, due to the anatomical and neurochemical limitations of traditional techniques to selectively modulate and determine VTA-DA signaling in the relatively small OT, very little is known about the functional link between VTA-DA in the OT and its role in mediating aversion, reward and addiction processes. In this study, we integrated immunohistochemical, neurochemical, and pharmacological approaches coupled with chemogenetics to selectively determine and modulate VTA-DA signaling in the OT. Through use of a combinatorial viral targeting system and *in vivo* fast-scan cyclic voltammetry, we restricted designer receptors exclusively activated by designer drugs (DREADDs) to VTA-DA neurons in order to inhibit neuronal activity and monitor real-time DA transmission in awake-behaving rats. Our findings demonstrate selective transfection of DREADDs to VTA-DA neurons in wild-type rats and highlight that chemogenetic inhibition of VTA-DA transmission in the OT inhibits the behavioral and reinforcing effects of methamphetamine (METH) as well as attenuates METH-induced VTA-DA transmission in the OT. These findings will provide a novel understanding of the VTA-DA-OT circuit and how it is involved in processing psychostimulant-induced reward and drug addiction.

Title: A Novel Allosteric Dopamine Transporter Modulator, SRI-32743, Reverses HIV-1 Tat Protein-Induced Changes in Extracellular Dopamine Levels in the Caudate Putamen of Inducible Tat Transgenic Mice

Authors: *S. DAVIS[1], M. FERRIS[2], S. ANANTHAN[3], O. MOUKHA-CHAFIQ[3], S. K. SAIN[3], C. E. AUGELLI-SZAFRAN[3], J. ZHU[1];

Abstract: Inhibition of the dopamine (DA) transporter (DAT) by the HIV-1 protein transactivator of transcription (Tat) has been implicated as a mediating factor of HIV-1 associated neurocognitive disorders (HAND). Our published work has demonstrated that DA uptake through DAT is decreased in the prefrontal cortex of the inducible Tat transgenic (iTat-tg) mouse model. This model recapitulates many neurocognitive impairments observed in HIV infected individuals. Further, our preliminary studies show that the Tat-induced inhibition of DA transport can be attenuated by SRI-32743, a novel DAT allosteric modulator. This study utilized Fast Scan Cyclic Voltammetry (FSCV) to determine the effects of *in vivo* Tat expression on extracellular DA levels and the impact of SRI-32743 on the Tat effect in iTat-tg mice. Following a 7-day administration of doxycycline (Dox, induces Tat expression) or saline, the baseline of tonic (1 Hz) or phasic (20 Hz, 5 pulses) DA release in the caudate putamen was measured. We found a significant increase (~50%) in phasic but not tonic DA release in Dox-treated iTat-tg mice compared to saline control mice. To distinguish the distinct Tat inhibitory effects on DAT and vesicular monoamine transport-2, we investigated whether iTat-tg mice treated with Dox or saline display differential changes in phasic DA levels in response to nomifensine, a selective inhibitor for DAT. Both saline- and Dox-treated iTat-tg mice displayed enhanced phasic DA release in response to nomifensine in a concentration-dependent manner (1 nM-10 μM), in which the nomifensine-induced increase in DA level in Dox-treated iTat-tg mice was about 30-50% greater than that observed in saline control mice. This suggests that Tat expression impairs DAT function, leading to the increased extracellular DA release. Finally, we determined whether systemic administration of SRI-32743 can reverse the Tat-increased phasic DA release. A single

injection of SRI-32743 (10 mg/kg, i.p.) was given to these mice 30 min prior to the mice being sacrificed. Results show that SRI-32743 reversed the increase in baseline of phasic DA release and nomifensine-augmented DA levels in Dox-treated iTat-tg mice, while SRI-32743 alone did not alter baseline of DA release. These findings suggest that *in vivo* exposure of mouse brain to HIV-1 Tat protein increases the extracellular DA levels, in which SRI-32743, through a positive allosteric modulation of DAT, reverses the Tat-mediated changes in the DA levels. Thus, this study demonstrates that developing allosteric modulatory ligands will aid in the drug discovery efforts for therapeutic interventions for HIV-infected patients.

Title: Mutational effects of the human norepinephrine transporter on basal and Tat-induced inhibition of dopamine transport

Authors: *K. D. PORTER[1,3], S. E. DAVIS[1], M. J. STRAUSS[1], Y. YUAN[3], S. LIN[1], P. MCQUILLEN[1], K. H. DAVENPORT[1], C.-G. ZHAN[3], J. ZHU[2];

Abstract: The HIV regulatory protein, transactivator of transcription (Tat)-induced dysregulation of dopaminergic transmission has been implicated as a central factor in the development of HIV-1 associated neurocognitive disorders (HAND). Our recent report revealed that dopamine (DA) transport through the norepinephrine (NE) transporter (NET) is reduced in the prefrontal cortex of inducible Tat transgenic mice. The prefrontal cortex is an important brain region for higher cognitive function, where the NET plays a critical role in the reuptake of DA and NE. Our recently developed three-dimensional computational model of Tat-human NET (hNET) showed that Tat-hNET binding is highly dynamic and that Tat preferentially binds to

hNET in its outward-open state. HIV-1 Tat forms hydrogen bond interactions with side chain hNET residue threonine544. Our previous study demonstrated that mutation of histidine547 (H547A) on the human DA transporter (hDAT) enhances DA uptake and attenuates Tat-inhibited DA transport. Based on these findings, this study examined the mutational effects of threonine544 on human NET (hNET), the corresponding residue of hDAT histidine547, on basal and Tat-induced inhibition of DA uptake through hNET. Compared to WT hNET, the kinetic property (V_{max}) of [^{3}H]DA uptake in PC12 cells expressing WT hNET and mutants was retained as normal in mutation of hNET threonine544 to alanine (T544A) but reduced in a different substitution, threonine544 to proline (T544P). No change in K_m was found in both mutants relative to WT hNET. Results from biotinylation assay show that expression of total and surface hNET protein was not altered in T544A but reduced in T544P relative to WT hNET. Additionally, we also examined the effects of T544-associated hNET residues Y545, D546, D547, and Y548 on DA uptake by mutating these residues to Y545H, D546L, D547L and Y548H. Compared to WT hNET, the V_{max} values of [^{3}H]DA uptake was retained as normal in Y545H, decreased in D546L, and increased in D547L and Y548H. The K_m values were not altered in Y545H and D546L but increased in D547L and Y548H, suggesting that the increased DA uptake in D547L and Y548H is accompanied with decreased K_m. Further, no changes in IC_{50} values for DA inhibiting [^{3}H]DA uptake were found among these mutants. Our ongoing effort is investigating the effect of these mutants on Tat-induced inhibition of DA uptake through hNET, which will help to further understand the mechanism of Tat interacting with hNET. These current findings provide a novel insight into the molecular basis for developing selective compounds for Tat-NET interactions in the context of HAND.

Abstract: Derivatives of (2-aminopropyl)indole (API) and (2-aminopropyl)benzofuran (APB) are new psychoactive substances which produce stimulant effects *in vivo*. (2-Aminopropyl)benzo[β]thiophene (APBT) is a novel sulfur-based analog of API and APB that has not been pharmacologically characterized. In the current study, we assessed the pharmacological effects of six APBT positional isomers *in vitro*, and three of these isomers (3-APBT, 5-APBT, and 6-APBT) were subjected to further investigations *in vivo.* Uptake inhibition and efflux assays in human transporter-transfected HEK293 cells and in rat brain synaptosomes revealed that APBTs inhibit monoamine reuptake and induce transporter-mediated substrate release. Despite being non-selective transporter releasers like MDMA, the APBT compounds failed to produce locomotor stimulation in C57BL/6J mice. Interestingly, 3-APBT, 5-APBT, and 6-APBT were full agonists at 5-HT_2 receptor subtypes as determined by calcium mobilization assays and induced the head-twitch response in C57BL/6J mice (a 5-HT_{2A}-mediated behavior), which mirrors the actions of known psychedelic drugs. A comparison of APBT compounds with their APB counterparts demonstrated that replacing the oxygen atom with sulfur results in enhanced releasing potency at the serotonin transporter and more potent and efficacious activity at 5-HT_2 receptors fundamentally changing the *in vitro* and *in vivo* profile. Our data suggest that APBT isomers may exhibit psychedelic or entactogenic effects, with minimal psychomotor stimulation. Whether this pharmacological profile translates into potential therapeutic potential, for instance as candidates for drug-assisted psychotherapy, warrants further investigation.

Title: Inflammasome assembly as a potential mechanism of microglial activation and neuroinflammation in schizophrenia

Authors: *R. GOBER[1], A. BARREDA[4], S. P. GARAMSZEGI[5], X. SUN[4], W. SCOTT[2], R. VONTELL[3], L. DUQUE[4];
[1]Neurosci. Grad. Program, [2]Hussman Inst. for Human Genomics, [3]Neurol., Univ. of Miami Miller Sch. of Med., Miami, FL; [4]Neurol., Univ. of Miami, MIAMI, FL; [5]Neurol., Univ. of Miami, Miami, FL

Abstract: Schizophrenia (SCZ) is a debilitating psychiatric disorder that afflicts around 1.1% of the world population with symptoms including of disorganized thoughts, hallucinations, and lack of emotions. Although[VRT1] the disorder has been studied for decades, the etiology and biological causes underlying SCZ have been difficult to characterize. Studies have proposed that immune-mediated neuroinflammation may be driving the disease onset and early progression. The inflammatory response may be triggered by over activated microglia, the immune cells of the central nervous system that can create a host of inflammatory mediators. One potential inflammatory pathway is the inflammasome complex which is a multi-protein complex that forms in response to the detection of foreign antigens and results in the production of several pro-inflammatory cytokines. These complexes are of interest in SCZ, because their assembly and the cytokines produced by the formation of inflammasome are thought to occur in microglia. In this study we investigate if the inflammasome complex is seen in microglia in donor brains with SCZ. Additionally, we hypothesis that the morphological changes seen in the microglia from postmortem brain samples of SCZ donors can be correlated to an increase in the inflammasome assembly. To investigate if the inflammasome proteins are increased in SCZ we assembled a cohort of postmortem human brains with SCZ and neurotypical controls (N= 13 SCZ; N= 16 control) and prepared sections from the frontal cortex, superior temporal cortex, and the anterior cingulate cortex. The identification of cells expressing the inflammasome protein, apoptosis-associated speck-like protein containing a CARD (ASC), was achieved using immunohistochemical staining performed on donor brains with SCZ and neurotypical controls. Results show the number of cells expressing ASC protein in cases with SCZ increased by 43% in the frontal cortical gray matter and 51% in the superior temporal cortical gray matter in brains with SCZ compared to controls. The results suggest that inflammasome assembly occurs in cases of SCZ and the incidence of assembly may be region specific. These results suggest that the inflammasome complex may be pathologically important in SCZ and may serve as a future therapeutic target that could lead to the development of novel and much needed treatment strategies.

Title: Microglia-specific knockdown of the circadian clock gene Bmal1 reduces anxiety and alters LPS-induced neuroinflammation in a time-of-day and sex-specific manner

Authors: *L. M. INCE, L. K. DAVIS, L. K. FONKEN;
Div. of Pharmacol. and Toxicology, Univ. of Texas at Austin, Austin, TX

Abstract: Microglia are key cells regulating neuroimmune function, learning & memory, and behavior. Microglia activity varies throughout the day, driven by the animal's circadian rhythm which is itself entrained by external factors such as light-dark cycles and food availability. This daily cycle is evident in microglia inflammatory responses, with microglia isolated during the rest phase (light/day) producing more pro-inflammatory cytokines after LPS stimulation than microglia isolated during the active phase (dark/night). However, it remains unclear to what extent this is driven by the cell-intrinsic clock within microglia themselves versus cell-extrinsic cues. To analyze the effects of the cell-intrinsic circadian clock on microglia function, we generated mice with microglia-specific knockdown of the core clock gene Bmal1 ($Bmal1^{flox/flox}Tmem119^{CreERT2}$, microglia-$Bmal1^{KD}$) and performed a battery of baseline behavior tests along with *in vivo* and *in vitro* inflammatory challenge. Compared with Bmal1-proficient littermates ($Bmal1^{flox/flox}$), male microglia-$Bmal1^{KD}$ mice showed increased activity in the open field test, with greater time spent moving and increased distance travelled. Females were more active than males but did not show a genotype effect. This pattern of hyperactivity was also observed in the elevated plus maze, with male microglia-$Bmal1^{KD}$ mice moving significantly further than wild type littermates, and showing a trend for increased time spent in open arms. This may indicate that Bmal1 in microglia plays a role in anxiety-like behavior in male mice, but not in females. In contrast, no genotype effects were observed in novel object recognition or in sucrose anhedonia. We next tested the impact of microglia-$Bmal1^{KD}$ after peripheral inflammatory challenge by injecting mice with LPS (0.5mg/kg i.p.) during the middle of their rest phase (mid-light) or the middle of their active phase (mid-dark) and collected tissue samples 3 hours later. Whilst wild type females showed time-of-day variation in both *Il6* and *Il1b* mRNA expression in the hippocampus, with higher expression during the rest phase, microglia-$Bmal1^{KD}$ females showed a rhythm in *Il6* but not in *Il1b*. These results implicate microglial Bmal1 in regulation of behavior and neuroinflammation in a time-of-day and sex-specific manner. Future work will determine: 1) how the sex-specific effects of microglia-$Bmal1^{KD}$ in anxiety-like behavior are generated; 2) how sickness behavior is modulated by microglia-$Bmal1^{KD}$; and 3) how Bmal1 modulates additional microglial functions such as phagocytosis, autophagy, synaptic pruning, and vesicular exocytosis.

Title: Microglia respond to extracellular ATP release during opioid withdrawal by increasing intracellular calcium via P2X4 and P2X7 purinergic receptors

Authors: *D. BERGKAMP[1], J. EL KHOURY[3], G. D. STUBER[2], J. F. NEUMAIER[4];
[1]Pharmacol., [2]Anesthesiol. and Pain Med., Univ. of Washington, Seattle, WA; [3]Massachusetts Gen Hosp, Charlestown, MA; [4]Dept Psych, Box 359911, Univ. Washington, Seattle, WA

Abstract: Neuroimmune activation in the central nervous system during opioid withdrawal occurs in conjunction with major changes in activity of neural circuits. Microglia respond to changes in neuronal firing rates by releasing inflammatory factors such as interleukin-6 and TNF-alpha. These signaling molecules contribute to dysphoria and the unpleasant experiences of withdrawal, especially in structures such as the striatum, which are essential to animal motivation and habitual behaviors. We hypothesize that extracellular ATP released during opioid withdrawal increases intracellular microglial calcium and initiates neuroimmune signaling to address abnormal synaptic plasticity associated with addiction.
We prepared coronal brain slices including striatum from male and female mice following five days of fentanyl administration and naloxone precipitated-withdrawal, and used two photon imaging to visualize changes in fluorescence of two biosensors: virally expressed iATPSnFR1 to measure extracellular ATP or GCaMP6f expressed selectively in microglia, using a transgenic strategy, to observe changes in calcium dynamics. We are currently testing whether precipitated opioid withdrawal rapidly increases extracellular ATP in striatum using iATPSnFR1. Additionally, we predict that either bath-applied ATP or naloxone-precipitated withdrawal increases the rate and magnitude of calcium influx events in microglia in the striatum. All statistical analyses are performed with custom written scripts to run ANOVA and tests for adjusted p-values for multiple comparisons where appropriate. In future experiments, we will investigate whether incubation of slices with P2X7 or P2X4 purinergic receptor antagonists is sufficient to block changes in intracellular microglial calcium occurring during opioid withdrawal. These complex neuroimmune signaling events may indicate that microglia are a promising therapeutic target for mitigating withdrawal and reducing the propensity to relapse to opioid seeking.

Title: Protective role of Microglia and T cells in a mouse model of temporal lobe epilepsy

Authors: *M. MORENO-MONTANO[1], P. NOBILI[1], L. MARTINS[1], J. MATEOS-LANGERAK[2], A. VIRENQUE[1], V. DARDALHON[3], H. HIRBEC[1], V. GARCIA[1], N. MARCHI[1], E. AUDINAT[1];

Abstract: Protective role of microglia and T lymphocytes in a mouse model of temporal lobe epilepsy. Temporal lobe epilepsy (TLE) is a chronic neurological disease affecting brain structures implicated in cognitive functions. The disease is manifested by the appearance of disabling, spontaneous, recurrent seizures caused by the hyper-excitability and hyper-synchronization of a more or less extensive group of neurons in the temporal lobe structures. Seizures are accompanied by neuronal death, gliosis and structural and synaptic reorganization. Sixty percent of patients do not respond to anti-epileptic and the only curative intervention is the surgical resection of the epileptic focus. It is therefore urgent to better understand the mechanisms involved in pathogenesis in order to identify new therapeutic targets.It is now well documented that neuroinflammation is critically involved in this disease. Accumulated data suggest that microglia develop a dual profile, pro and anti-inflammatory, and that the balance between these two states determines the evolution of the disease. Using a TLE mouse model lacking T cells (CD3 -/- mouse), we observed a loss of the microglial anti-inflammatory response and an increase of neuronal death in the hippocampus together with an increase of spontaneous seizure frequency. Regulatory T cells (Treg) have been shown to promote anti-inflammatory reactions in different models of CNS disorders. In preliminary experiments we therefore depleted Treg by administrating anti-CD25 antibodies during early epileptogenesis and we observed a loss of the microglial anti-inflammatory response and an increased neuronal death. We will confirm these results and test whether this treatment alters the development of seizure events. Our working hypothesis is that, interactions between microglia and T cells drive a protective anti-inflammatory effect in the epileptic hippocampus. We will therefore assess whether microglial

depletion phenocopies Treg depletion. These findings may allow the identification of new therapeutic targets to enhance the endogenous anti-inflammatory response and ultimately improve the treatment of TLE.

Title: Inhibiting CSF1 receptor signaling dampens microglial proliferation and reduces Tau deposition in mice

Authors: C. BRIFAULT, L. FOURGEAUD, A. BOTTELBERGS, S. ALLHANDS, H. KIM, L. ZHOU, P. TE RIELE, R. GUPTA, *A. BHATTACHARYA;
Janssen R&D, San Diego, CA

Abstract: Microglia are the resident immune cells of the central nervous system. They maintain brain homeostasis by eliminating pathogens, dead cells, toxins and remodeling synapses. In part, they rely on colony-stimulating factor-1 receptor (CSF1R) signaling to proliferate, activate and self-renew, in both health and disease. Proliferation and activation of microglia around amyloid plaques is an eminent feature of Alzheimer's disease (AD). CSF1R is a tyrosine kinase activated by CSF1 and IL-34. CSF1 is produced by astrocytes, oligodendrocytes and microglia while neurons express IL-34. Reduced plasma levels of CSF1 predicts rapid progression of mild cognitive impairment to dementia. Amyloid activated microglia proliferate producing cytokines like TNFα that worsens neuroinflammation. In preclinical models of AD, microglia depletion has been associated with reduced inflammation, decreased amyloid and Tau pathology and reduced cognitive dysfunction. Mice with conditional microglial CSF1R KO showed elevated expression of IL-34, TREM2, and β-Catenin genes associated with improved cognition and reduced Aβ burden. Here we tested selective brain penetrant small molecule CSF1R antagonist: JNJ-40346527 (JNJ527) to inhibit microglia proliferation. In human iPSC-derived microglia JNJ527 dose-dependently inhibits CSF1/IL34 induced proliferation. *In vivo*, CSF1R inhibition reduced microglia proliferation following LPS challenge. We also tested JNJ-527 in preclinical models of Alzheimer's disease including the APP/PS1 (amyloid) and the human Tau P301S model (Goedert) that recapitulate several molecular and cellular features of human Tauopathies. Animals that received JNJ527 show reduced microglia proliferation (cell number, Ki67 labeling, scRNAseq) compared to vehicle. Inhibition of microglia proliferation correlated with reduction

of pathology including microglia activation (morphology), inflammation (cytokines) and deposition of hyperphosphorylated Tau. CSF1R inhibition with JNJ-527 also resulted in elevation of CSF1 and IL34 in CSF of mice. These ligands can potentially serve as target engagement biomarkers for clinical investigation of CSF1R inhibitors. Overall, these findings strongly support the inhibition of CSF1R to reduce microglial proliferation as a promising immunomodulatory strategy for the treatment of AD.

Title: Microglia mediate early corticostriatal synapse loss in Huntington's Disease through complement-dependent mechanisms

Authors: *D. K. WILTON[1], K. J. MASTRO[1], M. D. HELLER[1], F. W. GERGITS[1], C. WILLING[1], A. FROUIN[1], A. DAGGETT[3], X. GU[4], A. Y. KIM[1], R. L. FAULL[5], S. JAYADEV[6], X. W. YANG[7], B. A. STEVENS[2];

Abstract: Synaptic dysfunction is becoming increasingly recognized as a common pathological event in many neurodegenerative diseases, including Huntington’s disease (HD). Despite HD being a monogenetic disease with a well characterized pathology, the molecular mechanisms underlying synaptic dysfunction remain poorly understood. In this study, we show that loss of specific synaptic connections can be observed prior to the onset of motor or cognitive

impairment in multiple slow progressive Huntington's disease mouse models and that microglia contribute to this via a complement-dependent mechanism.
During development, synapse loss as a result of pruning is a normal and highly regulated process required for the correct wiring of the brain. Microglia together with complement proteins, a key component of the innate immune system, play a key role in regulating this process (Stevens et al, 2007; Schafer et al., 2012; Paolicelli et al., 2011). Here we provide evidence that this developmental mechanism is aberrantly reactivated in Huntington's disease mouse models leading to loss of specific synaptic inputs. Using super resolution imaging, genetic ablation, viral-mediated labeling and slice electrophysiology, we demonstrate that complement proteins selectively target corticostriatal connections for engulfment by microglia and show that this process requires mutant huntingtin expression in both striatal and cortical neurons. Moreover, strategies to block this mechanism using genetic or antibody mediated approaches are able to not only prevent loss of synaptic structures and restore excitatory input to the striatum but also rescue early deficits in visual discrimination learning and reversal touchscreen tasks. Together these results demonstrate that elements of the innate immune system, previously only thought to be involved in late stage inflammation, mediate the loss of specific synaptic connections early in Huntington's disease pathology.
Notably, we find that aspects of this synaptic elimination mechanism can also be observed in human disease, as post-mortem tissue from Huntington's disease patients reveals evidence of synapse loss, complement deposition at synapses and phagocytic microglia. Moreover, complement protein levels in the CSF of premanifest HD patients correlated with measures of disease burden. We're currently building on these findings to develop additional fluid and imaging biomarkers that can hopefully be used to predict symptom onset as well as other aspects of clinical progression.

Title: Loss of the L-type calcium channel Cav1.2 in microglia is protective in the MPTP model of Parkinson's disease

Authors: S. SMITH, J. WICKLINE, A. M. WELLS, ***S. C. HOPP**;
UT Hlth. Sci. Ctr. San Antonio, SAN ANTONIO, TX

Abstract: Microglia activation is a noted feature of Parkinson's disease (PD) pathology. Microglia phenotype changes occur early during PD and may be an initiating factor in disease pathology. One driver of microglia phenotype is intracellular calcium. Cohort studies suggest that L-type calcium channel (LTCC) antagonists reduce the odds of developing PD. Studies in PD mouse models suggest that LTCC antagonists protect dopaminergic neurons of the substantia nigra (SN) by reducing age-associated neuronal intracellular calcium oscillations and subsequent mitochondrial stress. We previously reported that the LTCC antagonist nimodipine did not reduce loss of tyrosine hydroxylase (TH) in the SN but did improve motor deficits and reduce microglia activation in the SN in a lipopolysaccharide (LPS)-induced rat model of chronic neuroinflammation (Hopp et al., 2014, J Neuroimmune Pharmacol). Thus, LTCC antagonists may protect neurons from PD pathophysiology by directly modulating microglia intracellular calcium and microglia phenotype. To test this, we first confirmed that the BV2 mouse microglia cell line expresses LTCCs by measuring Cav1.2 and Cav1.3 gene expression. We then tested whether LTCC antagonists directly modulate microglia phenotype by treating BV2 microglia with LPS and increasing doses of the LTCC antagonists isradipine, nimodipine, verapamil, and diltiazem. We found that LTCC antagonists dose-dependently reduced BV2 microglia activation as measured by reduced gene expression of the pro-inflammatory markers IL1β, TNFα, and iNOS. Interestingly, we found that BV2 microglia increased Cav1.2 gene expression after LPS treatment, suggesting that microglia activation induces Cav1.2 expression. To test whether the LTCC Cav1.2 contributes to microglia activation and neurotoxicity, we generated CX3CR1CreERT2$^{+/-}$Cav1.2$^{fl/fl}$ mice with inducible conditional knockout (iCKO) of Cav1.2 on microglia following tamoxifen induction of Cre. Cav1.2$^{fl/fl}$ controls and iCKO experimental mice were induced with tamoxifen and then treated with MPTP to induce neurotoxicity in the SN. We found that Cav1.2 knockout altered microglia and TH immunoreactivity in the SN and modulated motor behavior performance in the open field and rotarod tests. Overall, these data demonstrate that microglia express the LTCCs Cav1.2 and Cav1.3, that LTCC antagonists directly reduce microglia activation *in vitro*, and that Cav1.2 contributes to microglia activation *in vivo*. This suggests that the neuroprotective action of LTCC antagonists may be at least in part via direct modulation of microglia phenotype via action of LTCCs such as Cav1.2 and Cav1.3.

Title: Microglia TAM receptors are modulators of pathology in Amytrophic Lateral Sclerosis

Authors: *Y. HUANG, G. E. LEMKE;
MNL-L, Salk Inst., La Jolla, CA

Abstract: Amyotrophic Lateral Sclerosis (ALS) is an irreversible and uniformly fatal neurodegenerative disease characterized by selective degeneration of motor neurons (MNs) and progressive muscle dystrophy that is accompanied by chronic neuroinflammation. Reactive microglia are thought to play crucial roles in ALS pathogenesis by mediating the death of MNs and the secretion of pro-inflammatory agents. These cells, among all tissue resident macrophages, express the TAM receptor tyrosine kinases Mer (gene name *Mertk*) and Axl. Our lab and others have previously demonstrated important roles of TAM receptors in microglia and other immune sentinels, including the phagocytic clearance of apoptotic cells and the feedback inhibition of the innate immune response. Recent transcriptomic evidence identifies Axl as part of a small group of 'disease-associated microglia' genes in the $SOD1^{G93A}$ mouse model of ALS. These findings notwithstanding, whether and how microglial TAM receptors participate in ALS disease progression has yet to be explored experimentally. We found a persistent up-regulation of both microglial Mer and Axl, as well as their ligand Gas6, in the $SOD1^{G93A}$ spinal cord beginning at symptomatic onset, suggesting a strong activation of the TAM signaling pathway throughout disease. Interestingly, $SOD1^{G93A}$ mice in the absence of Axl and Mer have significantly advanced symptom onset, but their disease course is almost twice the length of that of TAM-expressing $SOD1^{G93A}$ mice. We showed this delayed arrival of end-stage of disease may be accompanied by dampened microglial activation and reduction in the loss of ALS-vulnerable MNs in the spinal cord, as well as a partial rescue of neuromuscular junction loss and preservation of muscle fiber in the skeletal muscle that may be mediated by TAM deficiency in muscle-resident macrophages. Our work demonstrates a critical and differential involvement of TAM receptors in early and late stages of ALS in both the central and periphery nervous system. Given that TAM inhibitors are already in clinical trials as cancer therapeutics, discoveries from our studies will not only further our understanding of how the innate immune system mediate ALS pathology through TAM signaling, but may potentially be translated into novel therapeutic targets for the treatment for ALS and other neurodegenerative diseases.

Title: Peripheral nerve injury induced microglia proliferation involves two distinct phases

Authors: *P. SU[1], W. TAN[1], J. LEFF[1], Z. GUAN[2];
[2]Pain Mgmt. Ctr., [1]UCSF, San Francisco, CA

Abstract: Introduction: Adult microglia proliferate to self-renew at baseline, and to expand their population upon stimulation. Microglia proliferation is hallmark to a myriad of neurological disorders, including nerve injury; More importantly, inhibition of microglia proliferation attenuates the development of neuropathic pain, indicating the critical contribution of microglia proliferation in the pathogenesis. However, the underlying mechanism is largely unknown.
Methods: All animal research protocols were approved by the institutional animal care and use committee. We crossed *Cx3cr1-yfp-CreER* mice with *Myc*^{fl} or *Tnfaip3*^{fl} mice to genetically delete the respective genes from microglia. Sciatic nerve transection was used as the model for peripheral nerve injury. Single cell RNA sequencing (scRNA-Seq): Single microglia cells from lumbar spinal cord were isolated by fluorescence-activated cell sorting (FACS) and processed for single cell RNA sequencing using 10X Genomics platform. Flow cytometry: Dissociated single cells from spinal cord were stained for cell viability, specific microglia marker (CX3CR1), and Ki67 and analyzed by a flow cytometer. Gene Expression is evaluated by quantitative RT-PCR (qRT-PCR) of RNA isolated from FACS sorted microglia.
Results: Our scRNA-Seq reveals that the time course of microglia proliferation can be divided into early and late phases, corresponding to our qRT-PCR results of early and transient *Myc* upregulation and prolonged *Tnfaip3* downregulation in spinal lumbar cord microglia after nerve injury. Our flow cytometry results demonstrate that deletion of *Myc* specifically abolished the early microglia proliferation 2 days after nerve injury. On the other hand, downregulation of *Tnfaip3* regulates late phase of proliferation day 3 and beyond after nerve injury; and our scRNA-Seq shows that *Tnfaip3* deletion in naïve animals resulted in transcriptomic signature similar to late phase nerve injured animals with increased baseline microglia proliferation. In addition, *Myc* and *Tnfaip3* expression returned to baseline at the termination of microglia proliferation, and over-expression of *Myc* or deletion of *Tnfaip3* prevented the cessation of microglia proliferation.
Conclusions: Microglia proliferation after nerve injury consists of an *Myc* upregulation-mediated early and a *Tnfaip3* downregulation-mediated late phase; and termination of microglia proliferation requires the normalization of *Myc* and *Tnfaip3* expression.

Title: Identification of Kv1.3 channel interacting proteins using proximity labeling

Authors: *C. BOWEN[1], T. DOWLING[1], P. BAGCHI[1], H. M. NGUYEN[2], H. WULFF[2], N. T. SEYFRIED[1], S. RANGARAJU[1];

Abstract: Alzheimer's disease (AD) is a devastating neurodegenerative disease characterized by progressive neuronal loss, accumulation of amyloid-beta(Aβ) plaques, and neuroinflammation. Microglia, the immune cell of the brain, transition to disease associated microglia (DAM) in AD.A subset of DAM, known as proinflammatory DAM, promote neuronal injury, release proinflammatory cytokines, fail to phagocytose Aβ effectively, and adopt a glycolytic metabolic signature. Our lab established that proinflammatory DAM highly express Kv1.3 potassium channels, which regulate potassium efflux, membrane potential, and calcium signaling. Our studies show Kv1.3 blockade reduces immune responses in mouse models of AD. Intracellular domains of Kv1.3 channel subunits contain motifs that could interact with proteins associated with immune signaling pathways, however there is little evidence for this. This study aims to identify unique molecular interactors of Kv1.3 channels in mammalian cells using proximity labeling by the biotin ligase, TurboID, which biotinylates proteins within a 10nm radius. We fused TurboID to N- or C-terminus Kv1.3 using a 15 amino-acid inert linker and transfected the constructs into HEK293 cells. TurboID not fused to Kv1.3 and sham transfection acted as controls. Flow cytometry and patch-clamp electrophysiology confirmed the presence of functional Kv1.3 channels on the cell-surface. Biotinylated proteins were streptavidin bead affinity-enriched from cell lysates and confirmed using western blots. Using label free quantitation mass spectrometry (LFQ-MS), we identified 2,195 biotinylated proteins of which very few were enriched in negative controls. There were 313 proteins as N-term interactors, 385 as C-term interactors, and 226 proteins common to both N and C term fusions, potentially representing proteins indirectly associated with Kv1.3 channels. we identified 14 unique N-term interactors (including metabolic proteins eg. Naca, Txnl1, Stub1, Dnaja1) and 38 unique C-term interactors (including membrane trafficking proteins, eg. Ank3, Plekha7, Erlec1, Tp53bp2). We packaged these plasmids into lentiviruses to transduce into mouse microglial cell lines. Our findings will identify novel molecular mechanisms of immune regulation by Kv1.3 channels in microglia.

Title: The voltage-gated K^+channel Kv1.3 as a target for modulating neuroinflammation

Authors: *H. M. NGUYEN, Y.-J. J. CHEN, R. LEE, Y. CUI, R. H. IBRAHIM, H. WULFF; Pharmacol., Univ. of California, Davis, CA

Abstract: Chronic neuroinflammation contributes to the pathogenesis of many neurodegenerative, neuropsychiatric, and neurodevelopmental diseases. However, approaches aiming to relieve neuroinflammation should only target the secondary inflammatory damage without compromising beneficial immune functions. Microglia are the principal macrophages of the brain responsible for the maintenance of homeostasis during normal physiology. Microglia not only can rapidly initiate but can also prolong neuroinflammation in response to pathogenic insults. During microglia activation, many membrane receptors and ion channels undergo significant expression changes. The voltage-gated potassium channel Kv1.3 is an effective regulator of membrane potential and is overexpressed in activated human and rodent microglia associated with numerous inflammatory conditions. We and others have demonstrated that blocking Kv1.3 significantly inhibits microglial activation, proliferation, and production of the inflammatory mediators IL-1β, TNF-α, IL-6, and NO. Blocking microglial Kv1.3 also inhibits components of the inflammatory pathway, including the activation of NFκ-B, p38 MAPK, and the NLRP3 inflammasome. The mechanism underlying this anti-inflammatory action of Kv1.3

inhibition in microglia involves, in parts, the disruption of membrane calcium influx associated with activation of the purinergic P2X4 receptors. In vivo treatment with Kv1.3-selective inhibitors prevent inflammation in multiple preclinical rodent models of neurodegenerative diseases. Here, we show that the genetic deletion or pharmacological inhibition of Kv1.3 with the selective small-molecule PAP-1 improve neurological deficits, reduce infarct size, and brain levels pro-inflammatory cytokines in both mouse and rat ischemic stroke models. We further show that deleting Kv1.3 is also effective in aged mice and mice of both sexes. Importantly, blocking Kv1.3 does not affect phagocytosis of neuronal debris or levels of IL-10 and brain-derived nerve growth factor. Thus, our findings suggest that selective targeting of $Kv1.3^{high}$ microglia is an attractive therapeutic approach that fulfills the criteria required of an immunomodulator to not act as a general immunosuppressant for treating neuroinflammation.

Title: Neuroinflammatory Mechanisms in a Sterile Acute Lung Injury Model

Authors: *H. LI[1,2], J. DAVID-BERCHOLZ[5], A. I. CACERES[5], N. TERRANDO[5], H. A. GELBARD[1,2,3,4];
[1]Ctr. for Neurotherapeutics Discovery, [2]Dept. of Neurol., [3]Dept. of Neurosci., [4]Dept. of Microbiology and Immunol., Univ. of Rochester Med. Ctr., Rochester, NY; [5]Dept. of Anesthesiol., Duke Univ., Durham, NC

Abstract: With the advent of vaccines for SARS-CoV-2, attention has turned towards “long haulers”, those that have survived the acute infection but are still experiencing a spectrum of symptoms. One of the most significant being the neurological symptoms such as brain fog, delirium, and fatigue. Without a therapeutic intervention, COVID syndrome may soon become a significant burden on the healthcare system. Although the etiology of COVID syndrome is unknown, there has been inconsistent data regarding the possibility of direct neuro-invasion. As such we believe that COVID syndrome may be the result of lung injury and cytokine storm. In line with this theory, we developed a sterile lung injury model utilizing repeated intranasal administrations of lipopolysaccharide (i.n. LPS). We found that repeated i.n. LPS causes a robust

acute lung injury (ALI) particularly an elevation of bronchoalveolar lavage fluid (BALF) protein and BALF leukocytes (neutrophils, lymphocytes, and macrophages) at 24h after the last dose. We then assayed for neuroinflammatory effects at 6h, 24h, and 72h after the last LPS dose. We found that brain endothelial cells are activated acutely, but breakdown of the blood-brain-barrier (BBB) and peripheral leukocyte infiltrates were chronically elevated up to 72h after the last dose. Further, we see a robust elevation of microglial phagocytic and activation markers up to 72h after the last dose of LPS. This in turn causes degeneration of CA1 hippocampal synapto-dendritic architecture. We believe these results provide a framework for a mechanism of neuroinflammation and degeneration as a result of ALI, particularly those living with COVID syndrome. Further, this study opens the potential for therapeutic strategies to alleviate neurological symptoms.

Title: Deletion of the Abi3 locus influences age-progressive amyloid β and tau pathologies in distinctive ways

Authors: K. IBANEZ[1], K. N. MCFARLAND[2], M. ALLEN[3], L. ZOBEL[1], E. GONZALEZ DE LA CRUZ[1], S. SHAH[1], Q. VO[1], C. LESSARD[1], D. RYU[1], C. C. FUNK[4], N. ERTEKIN-TANER[3], T. E. GOLDE[5], *P. CHAKRABARTY[1];

Abstract: The recently identified S209F variant of the immune gene *ABI3* increases the risk for Alzheimer's disease (AD). How ABI3 is related to AD pathophysiology is unknown. We used a constitutive *Abi3* knock out mice to study the effects of microglial gene deletion on AD-typical Aβ pathology and tau pathology. In this mouse model, velocigene mediated knock-down of the *Abi3* locus resulted in deletion of *Abi3* gene and its overlapping neighboring gene, *Gngt2*. We first confirmed that the sequence alignment of the *Abi3* and Gngt2 genes is conserved among mice and humans. Secondly, using the AMP-AD consensus datasets and 24 independent mouse

datasets, we confirmed that Abi3 and Gngt2 expression changes were concordant. This shows that expression of *Abi3* and *Gngt2* are strongly correlated and thus these genes are co-regulated. We then went on to examine the effects of *Abi3* locus deletion in APP mice. Both partial and complete deletion of *Abi3* locus reduced Aβ levels in young *APP* mice. RNAseq analysis revealed that these mice, in spite of reduced Aβ, displayed gene expression patterns reminiscent of damage associated microglial phenotype. Next, using somatic brain transgenesis technology to overexpress an aggregation prone human tau construct, we found that *Abi3*-/- mice showed exacerbated tau phosphorylation, NFT pathology and astrocytosis. Our data shows that loss of *Abi3/Gngt2* differentially affects gliosis in a gene-dosage and age-dependent manner such that this leads to initial beneficial effect on Aβ pathology but deleterious effect on tau aggregation and Aβ-associated gene signatures. We also found that the recombinant S209F mutant ABI3 protein was phosphorylated to a lower extent compared to wild type ABI3. Further, mutating the Phe at position 209 to an Ala or Asp reverses this deficit in phosphorylation to levels similar to WT protein. Since, phosphorylation of Abi family of proteins is related to their stability and function, this would imply that the Ser to Phe mutation could render the ABI3 protein inactive. Together, this suggests that the AD-associated *ABI3* variant likely represents a loss-of-function mutation associated with dysregulated immunity.

Title: Differential effect of tau seeding based on Apolipoprotein E isoform

Authors: *T. M. L. WILLIAMS[1], A. J. RUIZ[1], G. ANTEZANA[1], E. GONZALEZ DE LA CRUZ[1], P. SULLIVAN[2], D. R. BORCHELT[1], P. CHAKRABARTY[1];
[1]Neurosci., Univ. of Florida, Gainesville, FL; [2]Duke Univ., Durham, NC

Abstract: Alzheimer's disease (AD), neuropathologically characterized by amyloid β (Aβ) plaques and tau neurofibrillary tangles (NFT), is the most prevalent neurodegenerative disease. The major risk factor for sporadic AD is the presence of the E4 allele of the gene coding for

Apolipolipoprotein E (APOE). The E3 allele in considered the neutral allele whereas the E2 allele is protective for AD. While presence of the E4 allele exacerbates Aβ pathologies clinically and in rodent models, the relative roles of the different APOE alleles in tau aggregation pathways is less clear. In this study, we first examined if APOE affects lifespan in a mouse model of tauopathy. Using the PS19 model of tauopathy that gets paralyzed by 12 months of age, we found that human APOE heterozygous mice had variable median lifespans ranging from 335 days to 372 days (E3<E2<E4) with sex-based differences. PS19 mice homozygous for human APOE alleles showed a trend for early death for APOE4 mice at 317 days (E4<E2<E3). All PS19/APOE mice showed robust tauopathy at end-stage with no clear differences in tau immunoreactivity patterns. We next analyzed whether presence of a specific APOE allele increases the propensity of tau prions to induce pathology at younger ages of these PS19 mice. Using unilateral K18 tau aggregate injections in the hippocampus of 2.5-month-old PS19 mice humanized for APOE, we show that APOE3 mice presented significantly higher burden of tau pathology in the ipsilateral and contralateral hippocampus ($p<0.01$) and cortex ($p<0.05$) (n=6-8 mice). At the age of analysis (7.5 months), the sham-seeded mice had little to no tau pathology. The Iba-1 immunoreactivity followed the trends shown by increased tauopathy in APOE3 mice, while astrocytosis levels remained unchanged among the three APOE mouse lines. Additionally, K18 aggregate injected PS19 mice with endogenous Apoe allele displayed hippocampal tauopathy that was significantly lower than the PS19 mice carrying the human APOE3 allele, suggesting functional differences. Thus, our study shows that human APOE3 increases the propensity of tau seeding, which is concordant with the higher prevalence of primary age-associated tauopathy cohorts carrying E3 allele. The significance of our data, vis-à-vis data from clinical case studies and previously reported rodent models, will be discussed.

Title: Elucidating the role of tau in cortical neuronal networks

Authors: *B. S. ULM[1,3,4], C. HANSEN[2], S. VELASCO[2], W. HACHMEISTER[2], M. BU[1,3,4], B. I. GIASSON[1,3,4], J. M. LEWIS[1,3,4], H. KHOSHBOUEI[1,3];

[1]Neurosci., [2]Univ. of Florida, Gainesville, FL; [3]McKnight Brain Inst., Gainesville, FL; [4]Ctr. for Translational Res. in Neurodegenerative Dis., Gainesville, FL

Abstract: *Rationale and Objective:* Tau is one of the most prevalent proteins found in protein aggregates of Alzheimer's disease and certain frontotemporal dementias. Despite this, the connection between tau regulation of neuronal activity and neurodegenerative decline is less understood. The objective of this study was to determine the influence of tau dysregulation on neuronal activity and functional connectivity, at baseline and following pharmacologic modulation of neuronal activity.
Methods: Murine primary cortical cultures were co-transduced with custom split vector mCherry-expressing AAV with or without 0N4R human tau (WT or P301L mutant) and GCaMP6f (a fluorescent calcium indicator). Live-cell imaging was used to quantify the spontaneous neuronal activity, as measured by increase in fluorescence intensity of GCaMP6f, at baseline and following inhibition of $GABA_A$ R (10μM) or NMDAR antagonism (20μM). The data were analyzed via manual segmentation and custom coded analysis to determine features of individual neuronal activity, such as calcium spike rates, inter-spike interval coefficient of variation, and mean increase in intensity (from the minima). In addition, we employed graph theory-based analysis of neuronal networks to determine changes in functional connectivity; these include normalized node degree, degree assortativity, and clustering coefficient. To determine tau-induced pathological progression, the cortical neuronal cultures were assessed at three time-points: 10 days, 15 days, and 20 days after tau (or control AAV) transduction (n=12-14 per condition). To determine whether or not effects of tau requires fibrillization, we also investigated the effect of tau fibril administration on neuronal activity and neuronal network features.
Results: While preliminary, our results thus far suggest that increased 0N4R human tau expression in cortical neurons does not substantially change individual neuronal activity or functional neuronal network structure. These results indicate that tau regulation of functional connectivity in early stages of tau overexpression in cortical neurons is negligible, below our detection limit, or importantly is limited by the model (overexpression of tau as an incomplete facsimile of primary tauopathy). Ongoing studies investigate the effects of tau fibrils on cortical neuronal activity and functional connectivity to model late-stage tau pathology.

Title: Reduced expression of the cell intrinsic clock protein Bmal1 in myeloid cells accelerates cognitive decline and alters microglial function in aging mice

Authors: *C. AGBAEGBU IWEKA, E. BLACHER, C. TSAI, Q. WANG, K. ANDREASSON;
Stanford Univ., Stanford, CA

Abstract: The circadian clock plays a fundamental role in the temporal coordination of the external environment with internal physiological processes. These processes include regulation of the sleep/wake cycle, feeding behavior, core body temperature, and immune responses. With aging, the ability to rhythmically regulate these processes progressively declines. Aging is associated with development of chronic inflammation that is linked to multiple age-associated diseases, including cognitive decline. Several studies have demonstrated that tissue-specific deletion of Bmal1, a transcription factor and regulator of circadian rhythms, can accelerate organ-specific aging, for example the development of sarcopenia in muscle, bone calcification in bone and cataracts in the eye. Here, we show that in myeloid cells, conditional knockout of Bmal1 increases systemic inflammation and accelerates cognitive decline in aging mice. In the brain, we found increased numbers of microglia displaying less morphological complexity and reduced levels of CD68 in microglia, suggesting that loss of Bmal1 in microglia disrupts lysosomal function. Moreover, myeloid Bmal1 deletion led to significant increases in pre- and post-synaptic proteins in aged mice, as well as decreased levels of C1q, which is required for synaptic pruning. Thus, loss of circadian regulation in brain microglia accelerates age-associated cognitive decline by a mechanism that may involve a deficit in synapse removal.

Abstract: Emerging evidence suggests that aging-related dysfunction in the neurovascular unit (NVU) can potentially trigger chronic neurodegenerative processes such as Alzheimer's and Parkinson's disease. Among the brain regions prone to neurodegeneration, the striatum is a particularly vulnerable brain region, demonstrating a high percentage of lacunar infarcts, the accumulation of toxic protein aggregates, and an increased propensity for the loss of blood brain barrier (BBB) integrity. Since astrocytic endfeet are thought to regulate NVU function via spontaneous Ca^{2+} signals, we asked if aging is associated with specific changes in spontaneous Ca^{2+} signals within astrocytic endfeet from live brain slices of the dorsolateral striatum (DLS). The DLS of young (2-month-old) and aged (24-month-old) mice were stereotaxically injected with an adeno associated virus (AAV) expressing the membrane tagged genetically encoded Ca^{2+} indicator, lck-GCaMP6f, driven by an astrocyte specific GfaABC1D promoter (AAV-lck-GCaMP6f). Prior to obtaining DLS slices, mice were transcardically perfused with tomato-lectin in order to visualize capillaries within the DLS. Spontaneous endfoot Ca^{2+} events surrounding capillaries were imaged in DLS brain slices from young and aged mice using confocal microscopy. We found that in aged mice, endfoot Ca^{2+} events were 77% larger with a 50% increase in event half width. Additionally, we found that endfoot Ca^{2+} waves in aged mice displayed a 2-fold greater velocity than young mice. Sequential depletion of extracellular Ca^{2+} followed by endoplasmic reticulum (ER) Ca^{2+} stores revealed an increase in the dependency on ER Ca^{2+} only in aged mice. Because the ER is a major Ca^{2+} source for mitochondria, we utilized GCaMP6f directed to astrocytic mitochondria (AAV-mito-GCaMP6f) to record mitochondrial Ca^{2+} events in endfeet. These experiments revealed a 50% increase in the frequency of spontaneous Ca^{2+} events in aged astrocytic endfoot mitochondria. In addition, we found a significant 2-fold reduction in the major ER Ca^{2+} buffering protein, calreticulin in aged mice. Together, these data suggest that astrocytic endfeet in aged mice display altered ER Ca^{2+} and Ca^{2+} buffering mechanisms that could potentially contribute to NVU dysfunction and a loss of BBB integrity.

Title: Kaolin mouse model of normal pressure hydrocephalus

Authors: *M. TISH, J. C. GEERLING;
Neurol., Univ. of Iowa, Iowa City, IA

Abstract: Normal pressure hydrocephalus (NPH) is a chronic form of communicating hydrocephalus in older adults, in which cerebral ventricles expand due to poor absorption of cerebrospinal fluid (CSF). NPH is often idiopathic but may develop following subarachnoid hemorrhage, meningitis, or other cerebral processes that impair CSF circulation. NPH produces a triad of progressive symptoms: gait impairment, urinary incontinence, and cognitive dysfunction. A mouse model for NPH would help accelerate neuroscience research into the mechanisms of these symptoms. Kaolin has been used to induce hydrocephalus in cats and rodents for decades, but usually produces a rapidly progressing lethal hydrocephalus. Additionally, the complete triad of symptoms in human NPH has not been reported on following kaolin induced hydrocephalus. We developed a chronic, survivable model of communicating hydrocephalus with symptoms similar to human NPH. Injecting 5 µL of a 10-15% kaolin (aluminum silicate) suspension into the cisterna magna of adult mice produces gradually progressive enlargement of the cerebral ventricles. We use brain MR imaging to measure the cerebral ventricular volume every two weeks through week 10 post-surgery, along with weekly tests of bladder function (Micturition Video Thermography), gait and balance, plus a variety of behavioral testing before and 10 weeks after surgery. Hydrocephalic mice, but not saline-injected controls, develop impairments in gait and balance and urinary frequency with incontinent features. Intracranial pressure is not elevated at any time points measured (3 days, 1, 2, 8-12 weeks). Ventricular enlargement is correlated with weight loss in the two weeks following kaolin injection. Brain tissue from these mice shows several abnormalities near the ventricles that may help account for differential symptoms. This mouse model allows us to investigate the pathophysiology of chronic hydrocephalus, specifically including mechanisms that link ventricular enlargement in NPH to disabling gait and bladder symptoms.

Title: Exercise protects against inflammation by modulating rat hippocampal NF-kB and nucleus accumbens FosB/ΔFosB

Authors: *C.-M. LEE[1], L. POINTS[1], K. ALGANEM[2], B. POPE[1], R. MCCULLUMSMITH[2], L.-L. YUAN[1];
[1]Dept. of Physiol. and Pharmacol., Des Moines Univ., Des Moines, IA; [2]Dept. of Neurosci., Univ. of Toledo, Toledo, OH

Abstract: It is well-established that exercise exerts beneficial effects on the central nervous system, such as protecting against neuronal aging and inducing stress-resilience. However, significant individual differences exist in exercise motivation, and the underlying mechanisms linking exercise to brain health remain unclear. Using rat voluntary wheel running, we modeled for acute exercise: rats were allowed to run during a 5-hour session after 4 days of training and subsequent 2 days of rest. They were then grouped based on running distances. With high throughput active kinome profiling on rat hippocampus, we discovered exercise significantly reduces the activity of several kinases in the NF-kB activation pathway responsible for cellular inflammation, including COT, IKK, PKD, and RIPK. Subsequent validation with transcriptional analysis showed that with an acute bout of running, NF-kB activity in the hippocampus is significantly repressed compared to sedentary controls, especially in high-running rats. Additionally, we found that acute exercise induces FosB/ ΔFosB expression in the nucleus accumbens, which drives motivation in reinforced behaviors. This is intriguing because while FosB/ΔFosB canonically responds to repeated and chronic exposure to certain antidepressants or drugs of abuse, here we show that a single period of exercise is sufficient to induce its expression. In summary, we propose that acute exercise may exert anti-inflammatory effects via downregulation of NF-kB pathway in the hippocampus, and the motivation underlying exercise may be related to FosB/ΔFosB expression in the nucleus accumbens. Future directions include explicating individual differences in exercise motivation and examining other brain regions.

Abstract: Cognitive impairment is a major consequence of aging and is associated with many aging-related diseases. We have identified a detrimental enzyme, leukotriene A4 hydrolase (LTA4H), that is increased in the plasma of humans with age, and high circulating levels of this enzyme are correlated with cognitive impairment in an Alzheimer's patient population. We found that dosing mice with recombinant enzyme at concentrations found in aged human plasma drives cognitive impairment in young mice indicating that it can act as a detrimental factor. Furthermore, inhibition of enzyme activity in aged mice improves cognitive decline and blood brain barrier permeability. Using unbiased single cell RNA sequencing, we identified changes in brain endothelial cells and astrocytes that may contribute to these improvements. Taken together these results identify a novel aging-related pathway that may be targeted to treat age-related cognitive decline.

Title: Tlr4 antagonism ameliorates persistent post-operative cognitive dysfunction

Authors: *S. M. MUSCAT[1], N. P. DEEMS[1], K. C. RICE[3], S. F. MAIER[4], R. M. BARRIENTOS[2];

[2]Inst. for Behavioral Med. Res., [1]The Ohio State Univ., Columbus, OH; [3]Natl. Inst. on Alcohol Abuse and Alcoholism, Bethesda, MD; [4]Dept. of Psychology and Neurosci., Univ. Colorado, Boulder, CO

Abstract: Post-operative cognitive dysfunction (POCD) is a complication experienced by many surgical patients. POCD is characterized by cognitive impairments ranging from mild confusion to difficulty with executive functions to inability to form long-term memories to dementia. Persistent POCD, lasting weeks to months, is most commonly experienced by older individuals and is associated with an increased vulnerability to developing Alzheimer's Disease. Our previous work demonstrated that, in older rats, surgery alone evoked a neuroinflammatory response and hippocampal-dependent long-term memory dysfunction lasting 4 days. Treating the rats with morphine, often administered post-operatively for pain management, exaggerated and prolonged this surgery-induced inflammatory response, leading to persistent POCD lasting at least 8 weeks. Here, we explored the role of toll-like receptor 4 (TLR4) in this process. TLR4 is an innate immune pattern recognition receptor and is expressed by microglia. Importantly, activation of TLR4 initiates a proinflammatory cytokine cascade. With age, microglia naturally become sensitized, exhibiting greater expression of TLR4 and increasing the likelihood of exaggerated neuroimmune responses following a challenge. Of note, exaggerated neuroinflammation potently inhibits synaptic plasticity necessary for long-term memory. Interestingly, morphine has recently been shown to have an inflammatory role via TLR4 activation. We hypothesized that surgery, aging, and morphine synergize via TLR4 activation to cause persistent POCD. To test this, we subjected 24 month old male rats to laparotomy as a model of POCD and administered analgesic morphine for 1 week. Two experiments were performed: the TLR4-specific antagonist lipopolysaccharide from the bacterium *Rhodobacter sphaeroides* (LPS-RS) was centrally administered either 1) 1x immediately before surgery or 2) 1x/d x7d beginning the day after the last morphine injection post-operatively. In both experiments, hippocampal-dependent long-term memory was assessed 4 weeks after surgery using a contextual fear conditioning paradigm. Both pre- and post-operative treatment with the TLR4 antagonist prevented the persistent POCD memory impairment. These results indicate that TLR4 plays a mediating role in the development of persistent POCD, although the specific mechanisms of this process remain to be elucidated. These data also suggest that blocking central TLR4 activation may be a promising therapeutic to treat POCD.

Title: Astrocyte immunosenescence in IL-10 and cholesterol signaling in the aged brain impairs microglial regulation following peripheral immune activation.

Authors: *S. M. O'NEIL, E. E. HANS, S. JIANG, L. M. WANGLER, J. P. GODBOUT; Dept. of Neurosci., The Ohio State Univ., Columbus, OH

Abstract: Microglia, the innate immune cells of the CNS, develop a pro-inflammatory, "primed" profile with age. Using single-cell RNA-sequencing (scRNA-Seq), we confirmed microglia in the brain of aged mice (18 months old) had an amplified (4 h) and prolonged (24 h) neuroinflammatory response to peripheral lipopolysaccharide (LPS) challenge compared to adults (3 months old). Overall, we observed several age-, LPS-, and time-dependent differences in the scRNA-Seq subclusters of microglia. Ingenuity Pathway Analysis of upstream regulators and canonical pathways revealed impaired regulation of an activated, neuroinflammatory state within microglia. In parallel, astrocytes in the aged brain exhibited a profile consistent with "immunesenescence" both 4 and 24 h after peripheral LPS challenge. For example, aged astrocytes showed reduced anti-inflammatory signaling and cholesterol biosynthesis, two pathways by which astrocytes regulate the inflammatory profile of microglia. One of the pathways reduced in the aged brain was interleukin 10 receptor (IL-10R) signaling. This pathway increases astrocytic expression of transforming growth factor beta (TGFβ), an anti-inflammatory cytokine with abundant receptor expression on microglia. Therefore, transgenic astrocytic *Il10ra*^{KO} mice were generated to determine if impaired IL-10R/TGFβ signaling within astrocytes is sufficient to cause a dysfunctional neuroinflammatory response in microglia. Indeed, astrocytic *Il10ra*^{KO} induced exaggerated sickness behavior and a prolonged neuroinflammatory response to peripheral LPS challenge, including increased social avoidance with amplified *Il1b* and *Tnf* mRNA expression in microglia. In summary, these novel data show astrocytes display an immunosenescent profile with age and, in response to peripheral LPS challenge, exhibit IL-10R signaling deficits and a lack of cholesterol biosynthesis, both leading to the inability to resolve microglia activation.

Title: Aging triggers an upregulation of a multitude of cytokines in the male and especially the female rodent hippocampus but more discrete changes in other brain regions

Authors: N. GORNY[1], L. PORCHER[1], S. BRUCKMEIER[1], S. D. BURBANO[2], J. FINNELL[2], J. KLETT[2], S. K. WOOD[2], *M. KELLY[1];

Abstract: Background: Despite widespread acceptance that neuroinflammation contributes to age-related cognitive decline, studies comparing protein expression of cytokines in young versus old brains are surprisingly limited in terms of the number of cytokines and brain regions studied. Complicating matters, discrepancies abound—particularly for interleukin 6 (IL-6)—possibly due to differences in sex, species/strain, and/or the brain regions studied. Methods: As such, we clarified how cytokine expression changes with age by using a Bioplex and Western blots to measure multiple cytokines across several brain regions of both sexes, using 2 mouse strains bred in-house as well as rats obtained from NIA. Parametric and nonparametric statistical tests were used as appropriate. Results: In ventral hippocampus of C57BL/6J mice, we find age-related increases in IL-1α, IL-1β, IL-2, IL-3, IL-4, IL-6, IL-9, IL-10, IL-12p40, IL-12p70, IL-13, IL-17, eotaxin, G-CSF, interfeuron δ, KC, MIP-1a, MIP-1b, rantes, and TNFα that are generally more pronounced in females, but no age-related change in IL-5, MCP-1, or GM-CSF. We also find aging is uniquely associated with the emergence of a module (a.k.a. network) of 11 strongly intercorrelated cytokines, as well as an age-related shift from glycosylated to unglycosylated isoforms of IL-10 and IL-1β in ventral hippocampus. Interestingly, age-related increases in extra-hippocampal cytokine expression are more discreet, with prefrontal cortex, striatum and cerebellum of male and female C57BL/6J mice demonstrating robust age-related increase in IL-6 expression but not IL-1β. Importantly, we found this widespread age-related increase in IL-6 also occurs in BALB/cJ mice and Brown Norway rats, demonstrating conservation across species and rearing environments. Conclusions: Thus, age-related increases in cytokines are more pronounced in the hippocampus compared to other brain regions and can be more pronounced in females versus males depending on the brain region, genetic background, and cytokine examined.

Abstract: Non-canonical base pairing between four guanines (G) within single-stranded G-rich sequences and self-stacking of G-quartets result in the formation of a columnar four-stranded DNA structure-the G quadruplex (G4 or G4-DNA). G4-DNA regulates a wild variety of DNA-dependent processes including transcription, replication, and telomere function. Overly stabilized G4-DNA may form at a nucleosome-depleted, transcriptionally active site, acting as a physical barrier for a DNA polymerase and eventually leading to DNA damage. Genomic instability contributes to neurodegenerative disorders, but potential G4-DNA associated mechanisms of genomic instability in neurons are not understood. Using cultured rat primary neurons, we found that the neuronal nucleolus is enriched in G4-DNA. Pharmacologically stabilizing G4-DNA leads to DNA damage primarily in the nucleolus. We conclude that nucleolar G4-DNA may be an important driver of genomic instability, contributing to neuronal aging and neurodegeneration.

Title: Human brain-derived extracellular vesicles contain full-length mRNAs

Authors: *L. RANSOM[1], C. LIU[1], C. PALMER[1], J. CHUN[2];
[1]Univ. of California San Diego, La Jolla, CA; [2]Sanford Burnham Prebys Med. Discovery Inst., La Jolla, CA

Abstract: Exosomes are 30-150nm extracellular vesicles (EVs) released by fusion of the multivesicular body, a type of late endosome, with the plasma membrane. Exosomes contain nucleic acids and proteins and are thought to be a means of intercellular communication. Within the brain, exosomes are known to be released upon neuronal depolarization, and to be exchanged between both neurons and glia. The protein contents of brain-derived exosomes have garnered interest in the field of neurodegeneration, for example as conduits for transmission of misfolded proteins. However, transcriptomic RNAs in EVs have been less studied. We hypothesize that neural cells may communicate intercellularly through the exchange of mRNAs transported in EVs. We isolated bulk and EV mRNA from human post-mortem frontal cortex of 24 brains: 12 from donors with Alzheimer's Disease and 12 that were neurologically non-diseased. Short-read sequencing revealed EV enrichment of transcripts relating to oxidative phosphorylation and mitochondrial function. Long-read sequencing was used to identify transcripts that could potentially be functional upon translation, revealing the presence of diverse full-length transcripts. We also identified novel RNA isoforms that contained structures such as intra-exonic junctions (IEJs), previously associated with somatic gene recombination. Our data suggest that brain-derived EVs can transfer full-length mRNAs between and amongst cells of the brain, expanding the transcriptome of neural cells.

Title: A Prodromal View of the TgF344-AD Rat Model of Alzheimer's Disease Using Single Nuclei RNA sequencing.

Authors: *A. TIPTON[1], J. GEORGE[2], V. KUMARESAN[3], M. RATNER[2], D. H. FARB[4], S. J. RUSSEK[5];
[2]Dept. of Exptl. Therapeut., [3]Lab. of Mol. Neurobiology, Dept. of Pharmacol., [1]Boston Univ. Sch. of Med., Boston, MA; [5]Pharmacol. and Grad Prog for Neurosci., [4]Boston Univ. Sch. Med., Boston, MA

Abstract: Alzheimer's disease (AD) is a devastating disorder characterized by gradual decline in memory and cognitive functioning, leading to eventual loss of independence and significant caregiver burden and healthcare costs at a societal level. Despite extensive investment into development of AD treatments, no disease modifying drugs are available. Recent failures of phase 3 clinical trials for mAb's targeting Aβ plaques have led to renewed interest in early signatures of disease in hopes of altering disease trajectory through early intervention. Key to such efforts is capturing a molecular window into prodromal stages. The TgF344-AD rat shows overt pathology (including Aβ plaques, frank neuronal loss, and endogenous tau pathology) at 16 and 26 mo, but not at 6 mo (Towne, 2013). However, variable behavioral phenotypes in 6 mo Tg rats, including heightened anxiety and impaired spatial reversal learning, have been reported (Pentkowski, 2018; Rorabaugh, 2017). Our recent discoveries (doi: 10.1101/2021.05.10.443512), using *in vivo* recordings during awake immobility, have uncovered an early dysfunction in the transgenic tri-synaptic hippocampal circuit not previously appreciated. To determine its molecular basis, we used 10x Genomics' v3 gene expression assay to perform snRNA-seq on freshly dissected hippocampi from 6 mo male and female littermate pairs of Tg and Wt rats (n=16). ~2000 cells/subject were collected, and cDNA libraries were sequenced (NovaSeq 600) to a depth of ~120k reads/nuclei. Cell Ranger Pipeline demultiplexed and aligned reads to rat pre-mRNA reference and generated gene count matrices. QC metrics were used to filter out dying cells, empty wells, and likely multiplets, resulting in a final dataset of 33,079 high quality nuclei. Nuclei were clustered (Louvain graph-based) and identity determined with cell-type specific markers curated from the literature. Identity was collapsed into broad neuronal and glial cell types for differential gene expression (DEG) across genotype (Hurdle Model). DEGs revealed profound alterations between Tg and Wt in oligos, dentate granule cells (DGCs), and excitatory neurons (ExcNs). (FDR cutoff, 0.05 and 1111 (DGCs) and 1070 (ExcN's) DEGs in Tg vs Wt.) Pathway enrichment revealed dysregulation relevant to memory function: including decreased synaptogenesis, neurite branching, proliferation, and microtubule and cytoskeleton dynamics. DEG's were enriched for neurological signs including epilepsy, seizures, hyperactivity, and dementia. Validation efforts are ongoing via multiplexed ISH and RTqPCR of sorted nuclei populations. Future work includes earlier timepoints and network rescue experiments.

Title: Ad knowledge portal and agora: resources that empower the research community to find, access, and re-use data and tools related to dementia and aging

Authors: *J. SCHNEIDER, A. VANDER LINDEN, M. FAZZA, J. GOCKLEY, A. K. GREENWOOD, D. HAN, L. HEATH, N. KAUER, K. LEAL, Z. J. LEANZA, K. MONTGOMERY, L. OMBERG, N. PERUMAL, P. PUGALENTHI, M. A. PETERS, W. POEHLMAN, S. K. SIEBERTS, C. SUVER, T. THYER, R. H. YAXLEY, J. WILEY, L. MANGRAVITE;
Sage Bionetworks, Seattle, WA

Abstract: To identify disease modifying therapies and drug targets for Alzheimer’s disease (AD), it is necessary to assess the impact of cellular and molecular dysfunction on disease etiology. The AD Knowledge Portal (Portal) (https://adknowledgeportal.org) and Agora (https://agora.adknowledgeportal.org) are community-driven resources that have been developed to support researchers as they: 1) identify new molecular hypotheses and mechanisms, 2) evaluate hypotheses via independent experimental assessments, and 3) prioritize new molecular mechanisms for therapeutic development. The Portal and Agora are free, open access tools built to maximize therapeutic discovery by enabling researchers to re-use data from 41,000+ biospecimens collected from 12,000+ individuals across four species, as well as access analytical results related to putative drug targets. The Portal and Agora empower the research community with a trusted repository of data, computational and experimental tools and potential gene targets to effectively and efficiently test target hypotheses and therapeutics.
The Portal was created to support research outputs from the National Institute on Aging funded Accelerating Medicines Partnership-Alzheimer’s Disease, and has expanded to support 55 grants generating data and computational/experimental tools related to dementia and aging. Generated from central and peripheral measurements from brain banks, longitudinal cohorts, and multiple model systems, available data spans 55+ assays ranging from genomic variants to metabolomics, imaging, cognitive assessments, and more. Model systems represented in the Portal include iPSC-derived cell types and organoids, and novel Late Onset AD mouse models based on gene targets identified from human data. These mouse models are available with no limitation on use. Most data types in the Portal are available in both raw and processed formats. The Portal also features a cloud-based analytical workspace providing access to preconfigured computational

resources to process, integrate, and analyze data. A subset of the processed data is also presented in Agora, a visual results explorer that compiles evidence for the association of genes with AD. Agora hosts a list of nominated targets and presents results of 'omics analyses generated from Portal data, and now, also includes a catalogue of details and results from targeted validation studies. The AD Knowledge Portal and Agora offer the research community an accessible, rich source of data, tools, and results.

Abstract: The pathogenic mechanism of copy number variations (CNVs) in late-onset Alzheimer's disease (LOAD) lacks genome-wide systematically study, even though CNVs have been found to play a significant role in many neurological diseases such as Parkinson's disease, schizophrenia, and mental retardation. A systematic functional study of CNVs through omics-

levels can provide valuable insights into the mechanism of LOAD. In this study, we employed four complementary CNV calling approaches to comprehensively identify CNVs in the whole genome sequencing data from 1,603 North American Caucasian individuals across three LOAD cohorts including the Mount Sinai/JJ Peters VA Medical Center Brain Bank (MSBB) AD cohort, the ROSMAP cohort, and the Mayo Clinic cohort. Integrative analysis of the identified CNVs and the matched transcriptomic, clinical, and pathological data was then performed to determine the functional impacts of these CNVs.By comparing 701 LOAD cases with 710 non-AD cases, we identified 3,012 rare AD-specific CNVs which are enriched for transcriptional regions involved in biological processes such as cellular glucuronidation, neuron projection, and multicellular organismal signaling. By further integrating clinical, pathophysiological, and transcriptomic data, we found that common CNVs affect the transcription levels of genes involved in MHC Class II receptor activity and interferon-gamma mediated signaling across seven brain regions, supporting previous reports of the increased immune response in AD. Three CNVs are significantly negatively correlated with the Braak score in the DLPFC region. CNV-centered correlation networks integrating matched multi-omics and clinicopathological data pinpoint one novel CNV, a key regulator for immune response, and further provide many novel gene targets which connect CNVs and clinical and pathological traits of AD. All consensus CNVs of the three cohorts have been uploaded to the UCSC genome browser track (http://genome.ucsc.edu/s/c6ming2/AMPAD.CNVs).In summary, we systematically identified AD-specific CNVs and further established their functional contexts using CNV-gene correlation networks. These findings deepen our understanding of genetic mechanisms underlying AD.

Title: Association of Polygenic Risk Scores with Age-at-Onset and Rate of Cognitive Decline in Alzheimer's Disease

Authors: D. CHRISTY[1], E. GUSTAVSSON[3], D. EVANS[2], G.-Y. HSIUNG[2], M. J. FARRER[4], ***H. B. NYGAARD**[2];
[2]Neurol., [1]Univ. of British Columbia, Vancouver, BC, Canada; [3]Queen Square Inst. of Neurol.,

Univ. Col. London, London, United Kingdom; [4]Clin. and Translational Sci. Inst., Univ. of Florida, Gainesville, FL, Canada

Abstract: Background: Alzheimer's disease (AD) is a complex and heterogeneous neurodegenerative condition for which genetic susceptibility is one of the most important risk factors. Genome-wide association studies (GWAS) have identified 32 disease associated genomic loci, each with limited clinical applicability due to small effect size. Polygenic risk scores (PRS) provide an opportunity to assess the cumulative association by combining the effect of each susceptibility loci into a single value. Methods:We genotyped 50-disease associated single nucleotide polymorphisms (SNPs) in 227 patients clinically diagnosed with AD for which we had longitudinal clinical information. We assessed the cumulative association of the SNP set to age-at-onset (N=227) and rate of cognitive decline as defined by the linear regression of Mini-Mental State Examination (MMSE) scores (N=176) through use of two PRS. Moreover, due to *APOE*'s large effect size we investigated it individually for association to age-at-onset. Results: The polygenic risk scores form a significant inverse association with age-at-onset ($r= -0.36$, $p<0.0001$) and positive association with annualized MMSE rate of decline ($r=0.56$, $p<0.0001$). We additionally see a significant positive association between age-at-onset and annualized MMSE decline ($r=0.33$, $p<0.0001$). Lastly, we observe APOE ε4 allele dose dependent effects which lower age-at-onset dependent on the number ε4 alleles a subject possesses. Conclusions: These results suggest recent GWAS disease associated SNPs not only associate with disease but with other phenotypic attributes.

Title: Associations between polygenic hazard score (PHS) and Alzheimer's Disease (AD) progression and biomarkers following the stratifying by ApoE genotypes and sex

Authors: *X. ZHUANG[1], R. TILLETT[2], R. YOUNG[2], D. CORDES[3], E. OH[2];
[1]Cleveland Clin. Nevada; Univ. of Nevada, Las Vegas Neurosci. Grad. Program, Las Vegas, NV; [2]Univ. of Nevada, Las Vegas, Las Vegas, NV; [3]Cleveland Clin. Nevada, Las Vegas, NV

Abstract: Introduction. Polygenic hazard scores (PHS), derived by integrating AD-associated SNPs into a cox regression model, reveals age-associated AD risks. Previous studies have reported various associations between PHS and AD progressions and biomarkers. However, the additional effects of PHS beyond ApoE genotypes remain unclear since different ways of adjusting ApoE led to various conclusions. Moreover, a sex-dependent autosomal effect has been reported on AD progression clinically, but whether sex will moderate the above associations remains unclear. In this study, using data from Alzheimer's Disease Neuroimaging Initiatives, we examined the association between PHS and AD progression (stable/progressive mild cognitive impairment (MCI)) and biomarker (PET-amyloid (Ab)) after stratifying by ApoE genotypes. We further examined whether these associations were moderated by sex. **Methods.** 703 subjects with an initial clinical diagnosis (DX) of MCI and follow-up visits were included, with 306 MCI subjects progressed to AD (MCI-p) longitudinally and 397 MCI subjects remained stable (MCI-s). 297 MCI-s subjects and 133 MCI-p subjects went through AV-45 PET imaging while maintaining a clinical MCI DX. Subjects' demographics, clinical DX, ApoE genotype, PHS, and whole brain Ab standardized uptake value ratio (SUVR) at every visit were obtained. PHS was first compared between MCI-s and MCI-p groups, with sex as the 2nd factor in the ANOVA analysis. Linear regression was used to determine whether there was an association (1) between PHS and MCI to AD progression time in MCI-p subjects; and (2) between PHS and Ab level in all MCI subjects. All regressions analyses were repeated with sex as a moderator, and within each ApoE genotype. **Results.** *PHS and AD progression.* MCI-p subjects share significantly higher PHS (p<0.001) than MCI-s subjects. Only E3E3 MCI-p subjects have marginally higher PHS than E3E3 MCI-s subjects (p=0.07). In MCI-p subjects, higher PHS is significantly associated with shorter MCI to AD progression time (p<0.001). This association holds only in E3E4 MCI-p subjects (p=0.01). *PHS and AD biomarkers.* PHS is significantly associated with whole brain Ab level in all MCI subjects (p<0.001). This association significantly differs by sex (p=0.03) but does not differ between MCI-p and MCI-s subjects. This association further holds significant for only E3E4 MCI subjects (p=0.05) and is mostly driven by E3E4 MCI women (p=0.04). **Conclusion.** PHS is significantly associated with AD progression. Non-ApoE SNPs contribute to clinical conversion times from MCI to AD. PHS is also significantly associated with whole brain Ab burden, and this association differs by sex.

Title: Resolving racial differences in the brain proteome of African Americans with Alzheimer's disease

Authors: *E. MODESTE, L. PING, D. M. DUONG, M. GEARING, J. J. LAH, A. I. LEVEY, N. T. SEYFRIED;
Emory Univ., Atlanta, GA

Abstract: Chronic health conditions including cardiovascular disease and diabetes, lower quality and level of education, higher rates of poverty, and greater exposure to discrimination disproportionally affect African Americans, putting this population at a heightened risk for Alzheimer's disease (AD) and related dementias. Neuropathological hallmarks of AD include accumulations of amyloid-beta (Aβ) plaques and tangles of hyperphosphorylated tau in the brain. Levels of Aβ and tau in cerebrospinal fluid (CSF) can act as proxies for AD pathology in the brain, thus providing the unique ability to monitor AD in living patients. Emerging biomarker studies in CSF show that African Americans have lower levels of tau, compared to Caucasians. This suggests that race may influence tau and related AD pathophysiology in African Americans. Whether race impacts tau levels or other pathologies in brain is not well established. Here, we sought to characterize the brain proteome of Caucasians and African Americans with AD. Using multiplexed mass spectrometry-based proteomics coupled with off-line fractionation, we quantified ~8,000 proteins across 129 matched African-American and Caucasian AD and control postmortem brain tissues. Interestingly, we were able to stratify cases by their self-identified race using a subset of race-specific proteins identified by variance partition. Notably, characteristic hallmarks of AD, including increases in Aβ peptide and total tau levels, did not differ by race. Following phosphopeptide enrichment using iron-chelated magnetic beads, greater than 60 tau phosphopeptides were identified and quantified, but none showed statistically significant differences between African Americans and Caucasians with AD. Co-expression network analysis, however, did reveal pathways reflective of ribosomal function, vascular biology, and RNA splicing that differed between African Americans and Caucasians in AD. Together, this data suggests that race is involved in the manifestation of AD beyond, the pathological hallmark proteins, Aβ and tau.

Abstract: Microglia are the population of functionally and transcriptionally diverse macrophages of the central nervous system (CNS). As the main phagocytes of the brain, microglia are critical for clearance of debris generated by diseased cells through phagocytosis. Microglia engulf heterogeneously and abnormal engulfment is linked to neurodegenerative diseases including Alzheimer's disease. However, the transcriptional profile of phagocytic microglia remains relatively unexplored in humans. To investigate the transcriptional profile that drives microglia engulfment, we exposed human stem cell derived microglia to various brain-related substrates and identified transcriptional correlates of substrate-specific phagocytosis using single-cell RNA sequencing. We found gene expression pathways of human microglia exposed to apoptotic neurons, synapses, amyloid beta, and myelin correlate with microglia transcriptional states observed in disease. We validated the expression changes of a subset of these genes in independent microglia differentiations by qPCR. Our study will lay the groundwork for further engulfment assays in which candidate genes are up- or down-regulated and provide insight into phagocytosis as a potential therapeutic target.

Title: Differential gene expression and transcript usage at single-cell resolution in a mouse model of Alzheimer's disease

Authors: *A. E. WELLER, G. A. DOYLE, B. C. REINER, R. C. CRIST, W. H. BERRETTINI;
Psychiatry, Univ. of Pennsylvania Perelman Sch. of Med., Philadelphia, PA

Abstract: Alzheimer's disease (AD) is the most common form of dementia and is a source of significant morbidity and mortality for patients and their families. However, the specific cause of AD remains poorly understood. In humans, APOE4, an isoform of the *APOE* gene, is the strongest known genetic risk factor for late-onset AD. The *Apoe* knockout mouse has been used as a mouse model in the study of neurodegenerative diseases and is suitable for the study of AD. Single-cell (or single-nucleus) RNA sequencing (scRNAseq or snRNAseq) allows the analysis of the transcriptomes of single cells that can be used to identify cellular functions of various cell types, as well as differences in cellular transcriptomes between normal and disease states. SnRNAseq studies conducted in AD mouse models will aid in identifying the cells and genes with altered transcription that result in development of AD phenotypes. Using this rationale, we employed a publicly available dataset of snRNAseq data from 7 pooled hippocampi samples from 9-month-old C57BL/6J wild type (WT) mice and those from 7 9-month-old *Apoe* knockout (EKO) mice. We then used Seurat and Sierra programs to assess effects on differential gene expression and transcript usage, respectively, in hippocampal cell types mediated by constitutive *Apoe* gene knockout in mice. Seurat identified genes with differential expression between the WT and EKO samples by cell type (cluster). These cluster-specific genes were then used in Ingenuity Pathway Analysis (IPA). IPA identified 11 canonical pathway terms with FDR-adjusted p-values < 0.05, many of which have been implicated in AD. Additionally, Sierra identified several genes with differential transcript usage between WT and EKO samples, including *Sipa1l1*. The *Sipa1l1:* chr12:82235539-82235845:1 peak corresponded to a transcript variant (*Sipa1l1*-209) that was highly expressed in WT mice but had low levels of expression in the EKO mice. Furthermore, this *Sipa1l1* gene peak identified an alternative non-canonical polyadenylation signal and a putative cytoplasmic polyadenylation element (CPE). In humans, SIPA1L1 is a Rap GTPase-activating protein (RapGAP) involved in the regulation of dendritic spine morphogenesis in neurons. Our study data implicate differential transcript usage of *Sipa1l1* in CA1, CA2, and CA3 pyramidal cells; neurons known for having prominent dendrites and are

affected in neurodegenerative disorders such as AD, indicating that in humans SIPA1L1 may play a role in AD pathogenesis. Taken together, our results suggest that Apoe is involved in regulation of gene transcription and co-transcriptional RNA processing which may underlie AD.

Title: Phenotypic characterization of an APOE mouse model of Alzheimer's Disease

Authors: *J.-P. WIEGAND, R. D. BRINTON;
Ctr. for Innovation in Brain Sci., Univ. of Arizona, Tucson, AZ

Abstract: Apolipoprotein E (APOE4) is the most prevalent genetic risk factor for Alzheimer’s Disease (AD), with a penetrance of ~50-60%. Transgenic APOE4-Alzheimer’s disease models are widely available, but many studies do not account for APOE4’s penetrance in their sample sizes. To address this gap, we assessed translational feasibility of the JAX APOE4 mouse model. We conducted population-level studies on monthly weights, survival rates, and clinical observations across early, midlife, and late development in APOE3/3, 3/4, and 4/4. Outcomes of these analyses indicated APOE4 mice consistently exhibited a divergence in weight at 15mo persisting throughout subsequent aging, showed significantly reduced survival rates, and more dermatitis, as compared to APOE3 controls. Thus, conclusions regarding metabolism, survival rates, and peripheral inflammation within the APOE4 mouse model advance translatability to human APOE4-AD.

Title: Breast Cancer Therapies Reduce Risk of Alzheimer's Disease and DementiaL Clinic to Bench Translation for Protective Mechanism

Authors: *G. L. BRANIGAN[1], G. TORRANDELL HARO[1], R. D. BRINTON[2];
[1]Pharmacol., [2]Ctr. for Innovation in Brain Sci., Univ. of Arizona, Tucson, AZ

Abstract: Background: Worldwide, breast cancer is the most common non-skin cancer in women. Approximately 1 in 8 women will be diagnosed with breast cancer during their lifetime. Currently, Alzheimer's disease (AD) affects 1 in 9 persons in the US over the age of 65, two thirds of whom are women. The high global prevalence and economic impact of AD presents a significant public health challenge while the identification of therapies to prevent AD remains a challenge. Previous studies have suggested that estrogen modulating therapies (EMT) used for the treatment of breast cancer are associated with a decreased risk of AD.
Methods: The objective of this study is to identify potential mechanisms by which EMTs alter biological pathways associated with AD prevention. E18 rat neurons cultures were treated with EMTs, vehicle or estradiol (E2) at clinically equivalent concentrations. The impact of EMT on neuron morphology was determined using MAP2 staining and confocal microscopy. Next, electrophysiologic recording were conducted using multi-electrode array (MEA). Finally, the impact of EMT on mitochondrial bioenergetics and dynamics were determined using Metabolic flux analysis.
Results: Data indicate that tamoxifen, exemestane and anastrozole treated neurons exhibit morphological features (e.g. increased cell area, dendrite length and branch patterns) comparable to E2 exposure when compared to vehicle ($p<0.001$) whereas raloxifene induced a less arborized structural phenotype ($p<0.01$). This trend was consistent across estrogen phenotypes in electrophysiologic (decreased interspike interval and increased burst firing) and mitochondrial bioenergetic parameters (increased mitochondrial respiration and ECAR) where tamoxifen and the aromatase inhibitors show similar responses to E2 when compared to vehicle ($p<0.001$) whereas raloxifene does not elicit an estrogen-like response.
Conclusion: Mechanistically, tamoxifen and raloxifene are known to act in a tissue-specific manner acting as receptor antagonists in breast tissue but show divergent actions in brain tissue. Results are suggestive that specific EMTs (tamoxifen) act as estrogen-like agonists in neurons. If tamoxifen and aromatase inhibitors are acting to increase estrogen-related actions in brain tissue, the argument for the protective association of estrogen with AD-related outcomes is strengthened.

Title: Dismantling of estrogenic control of the bioenergetic system in brain during female brain midlife aging: implications for preventing Alzheimer's disease

Authors: Y. WANG, F. YIN, ***R. D. BRINTON**;
Ctr. for Innovation in Brain Sci., Univ. of Arizona, Tucson, AZ

Abstract: Decline in brain glucose metabolism is a hallmark of late-onset Alzheimer's disease (LOAD). Chronological and endocrinological aging are associated with brain glucose hypometabolism and mitochondrial adaptations in female brain. Estrogen is a master regulator of the bioenergetic system in the female brain which requires integrating nuclear and mitochondrial genomic compartments. We sought to determine the process by which estrogenic control of the bioenergetic system in brain is dismantled during midlife endocrine aging. Using a rat model recapitulating fundamental features of the human menopausal transition, results of transcriptomic analysis revealed stage-specific shifts in bioenergetic systems of biology that were paralleled by bioenergetic dysregulation in midlife aging female brain. The first components of estrogenic control of bioenergetics to be dismantled were upstream transcription factors required for estrogenic control of mitochondrial gene expression. Consistent with early decline in NRF1 and TFAM, mitochondrial gene expression exhibited decline that paralleled the change in TFAM and its regulator NRF1. Mitochondrial-encoded oxidative phosphorylation (OxPhos) gene transcription rebounded, as did NRF1 and TFAM, which was followed by a significant decline which is in register with nuclear-encoded OxPhos genes. The second stage of components to be dismantled, that in part overlapped with the first wave, were genes required for estrogenic control of mitochondrial biogenesis and auxiliary fuel utilization. The third and final stage of components to be dismantled were transcription of genes required for OxPhos and encoded by both the nuclear and mitochondrial genomes. These findings indicate that the first dismantling point of estrogen regulation of the bioenergetic system is communication between the nuclear and mitochondrial genomes followed by dismantling of estrogen control of mitochondrial biogenesis which was followed by decline in transcription of both nuclear and mitochondrial genes required for oxidative phosphorylation required for ATP generation. Collectively, these results indicate that estrogenic control of the bioenergetic system in brain is systematically dismantled in stages. Further, these findings have implications for therapeutic intervention to prevent decline in glucose metabolism and mitochondrial function to prevent and reduce risk of Alzheimer's disease later in life.

Title: Statins as Alzheimer's disease risk modifiers: Responder analysis for precision prevention

Authors: *G. TORRANDELL[1], G. L. BRANIGAN[3], R. D. BRINTON[2];
[2]Ctr. for Innovation in Brain Sci., [1]Univ. of Arizona, Tucson, AZ; [3]Pharmacol., Univ. of Arizona Hlth. Sci., Tucson, AZ

Abstract: Previously we reported reduced risk of Alzheimer's disease (AD) in persons treated with statins (Relative Risk [95% Confidence Interval]: 0.4643 [0.44-0.49]; *P* < .001) in a study population of 288,515 participants (Torrandell-Haro et al, 2020). Our current analysis aimed to validate these findings in a larger dataset and to identify responder vs non-responder phenotypes to statin therapy to advance precision medicine for prevention of AD and other age-related neurodegenerative diseases (NDD).A retrospective analysis was conducted using an insurance claims dataset including health and prescription records from 53 million people across the United States. Identified records included claims from persons 45 years or older and with no prior history of neurosurgery or NDD for analysis. An enrollment criterion which required that patients were enrolled in the dataset for at least 6 months before to first statin prescription and at least 3 years after was applied. A propensity score matching based on age, gender, cci and comorbidities was used to reduce bias in group assignment. Claims from 1,293,952 were surveyed for a diagnosis of AD and other age-related NDD 1 year after statin exposure. A series of sensitivity analyses were performed to compare the subset of responders to statin therapy to the non-responders group.Of the 1,293,952 participants included, 646,976 patients were treated with statin therapy, and 646,976 matched patients were not for the duration of analytic period. Statin use was associated with decreased risk of AD (RR [95% CI]: 0.54 [0.52-0.57]; *P* < .001), dementia (RR [95% CI]: 0.66 [0.64-0.68]; *P* < .001), non-AD dementia (RR [95% CI]: 0.72 [0.70-0.75]; *P* < .001), Multiple Sclerosis (RR [95% CI]: 0.20 [0.17-0.23]; *P* < .001), Parkinson's disease (RR [95% CI]: 0.39 [0.37-0.42]; *P* < .001), and ALS (RR [95% CI]: 0.46 [0.36-0.59]; *P* < .001). Relative risk analysis including sex differences indicated that men exhibited greater risk reduction benefit than women for AD, dementia, non-AD dementia and Parkinson's disease. Analysis of responders vs non-responders showed that the responder group was younger and overall healthier than the non-responders. Instead, women were predominant in the non-responder group.Results reported herein replicate previous findings of an association

between statin therapy and reduced risk of AD and other age-related NDD (Torrandell-Haro et al, 2020). Further, results of our current analyses characterize responders vs non-responders with women comprising the majority of non-responders. Outcomes of these analyses advance a precision medicine approach for preventing AD and multiple age-related neurodegenerative diseases.

Title: Infiltration of Peripheral Immune Cells in Human Brain During Mid-life

Authors: *H. VAN ROSSUM[1], A. MISHRA[1], N. DELATORRE[1], M. PADILLA-RODRIGUEZ[1], R. D. BRINTON[2];
[2]Ctr. for Innovation in Brain Sci., [1]Univ. of Arizona, Tucson, AZ

Abstract: Background: Inflammation is a well-documented feature of Alzheimer's disease (AD) in human brain. Two critical issues relevant to understanding the role of inflammation in AD that remain unresolved are: 1) the initiation phase of inflammation and 2) sex differences in the inflammatory cascade. Previous preclinical findings from our group indicated elevated immune transcripts including CD3, CD4, and MHCII. Herein, we extend and translate our preclinical discoveries to test the hypotheses that: 1) the inflammatory phenotype of LOAD is initiated in midlife of the human aging process and 2) the inflammatory cascade in brain is initiated by microglial activation in brain that promotes infiltration of peripheral immune cells into the brain. **Methods:** Both fixed and frozen human tissue samples were obtained from NIH NeuroBioBank (University of Maryland, University of Miami, and Mt. Sinai) that included the corpus callosum, hippocampus, and hypothalamus of 40 brain donors that were sex and age matched. For the purposes of this study, samples were sub-classified into 3 groups, healthy aging 40-49 years-old, healthy aging 50-59 years-old, and AD age 60-80 years-old. Neuro-inflammatory markers included microglia (IBA-1), activated microglia (HLA), and T-cells (CD3, CD4, CD8) were detected using 3,3'-diaminobenzidine immunohistochemistry. Transcriptomic analyses were conducted to confirm neuroinflammatory expression.
Results: Cell phenotyping analyses indicated presense of CD3+, CD4+ and CD8+ positive cells in human brain consistent with infiltration of peripheral T cells into brain. Magnitude of T-cell

indicators increased with age and was detectable in mid-life consistent with infiltration during midlife. In addition to CD3+, CD4+ and CD8+ T-cells activated and HLA+ microglia were present. **Conclusion:** These results provide evidence for early midlife infiltration of T-cells into brain which is coincident with activated microglial suggestive of immune signaling between the central and peripheral immune compartments. Outcomes of these and future analyses are relevant to effective immuno-therapeutics to target the earliest stages of AD to reduce risk and or delay AD.

Title: Characterizing genetic susceptibility of white matter tracts and hippocampal volume within humanized APOE mice

Authors: *A. BHATTRAI, A. RAIKES, A. MISHRA, R. D. BRINTON;
Ctr. for Innovation in Brain Sci., Univ. of Arizona, Tucson, AZ

Abstract: Apolipoprotein (APOE) has been identified as one of the strongest risk factors associated with Late-Onset Alzheimer’s disease (LoAD). The *e*4 allele confers the highest susceptibility to developing cognitive dysfunction with females exbiting a two-fold higher incidence compared to males. LoAD MRI studies have shown a link between APOE-*e*4 gene load and reduced white matter integrity (WMI) in limbic and medial temporal regions as well as increased hippocampal volume loss (Bagepally, 2012). Female aging brain mouse models show catabolism of lipids and fatty acids, a potentially contributing factor to reduction in WMI (Klosinski, 2015). However, very few translational mouse models have utilized neuroimaging to identify the translatability of human LoAD etiology. We hypothesized that our hAPOE mice will exhibit reduced hippocampal volume and WMI, with more pronounced effects in e4 carriers and females.
APOE *e*3 and *e*4 genotype skull-extracted ex-vivo mouse brains (M/F; N=53; mean age = 17.95 month) were imaged (7T Bruker Biospec MRI scanner). Imaging sequences included isotropic structural and diffusion weighted imaging. Using the Dorr mouse brain atlas, bilateral hippocampal volumes and total brain volume (TBV) were extracted (Dorr, 2008). WMI was

quantified using fractional anisotropy (FA) whereas between-group comparisons were made using a groupwise connectometry approach (Yeh, 2013; Yeh, 2016).
Genotypic comparisons indicated lower mean FA values in APOE-*e*4 carriers (mean tractography FA =0.263+0.043) compared to the APOE-*e*3/3 carriers (mean tractography FA = 0.311+0.067) in a total of 8489 tracts (FDR corrected $p < 0.018$). Contrary to our hypothesis, females APOE-*e*4 carriers exhibited greater FA values (mean tractography FA = 0.289+0.036) compared to the males APOE-*e*4 carriers (mean tractography FA = 0.266+0.051) in a total of 5240 tracts (FDR corrected $p < 0.008$).
No between-genotype differences were observed for left or right hippocampal volumes; however, sex differences were observed for the right hippocampus with males having a significantly greater volume than females ($p = 0.007$). No such effect was observed for the left hippocampus.
MRI analyses indicate a significant reduction in FA values and in turn white matter integrity across the brain in APOE-*e*4 carriers, irrespective of sex. In line with human sex-differences literature, males exhibited greater total brain volume as well as greater right hippocampal volume compared to females, irrespective of genotype. These findings may provide evidence of deficits in lipid transport or lipid catabolism, resulting in decreased WMI in this hAPOE mouse model.

Title: Mitochondrial gene transcriptional expression coupled with Alzheimers Disease risk factor in the aging brain

Authors: *Y. SHANG, F. YIN, R. D. BRINTON;
Ctr. for Innovation in Brain Sci., Univ. of Arizona, Tucson, AZ

Abstract: Mitochondrial dysfunction has been widely associated with various neurodegenerative diseases, yet the mechanisms regulating mitochondrial DNA (mtDNA) versus nuclear DNA (nDNA)-encoded genes in aging and Alzheimer’s disease (AD) brains are largely unknown. We used regression models to evaluate the association between mtDNA- and nDNA-encoded genes

at the transcript (ROSMAP, Mayo, MSBB datasets) and protein (ROSMAP) levels. The mtDNA- and nDNA-encoded oxidative phosphorylation (OXPHOS) genes were positively correlated at the protein level but were differentially regulated at the transcript level. In AD brains, while nDNA-encoded OXPHOS genes were downregulated, mtDNA encoded genes were mostly upregulated at transcript level. Furthermore, the transcriptional correlations between these two gene sets were reduced in AD brains. Using pathway analysis and cell-type deconvolution, we identified biological pathways and brain cell types that were correlated with mtDNA-encoded gene expression. In both normal and AD brains, mtDNA transcripts correlated positively with notch signaling, while negatively with synapse-, bioenergetics-, translation-, and ubiquitin-mediated protein degradation pathways. Neuronal cell fractions were negatively correlated with mtDNA transcripts whereas fractions of oligodendrocyte precursor cells, astrocytes, and pericytes exhibited positive correlations. Our analysis suggest an underappreciated correlation between the bigenome-controlled mitochondrial gene expression with the risk of AD. The crosstalk between mitochondrial genome and nuclear were reduced in AD, where nDNA-encoded OXPHOS genes were mostly down-regulated, suggesting potential therapeutic opportunities to rehabilitate mitochondrial function by targeting nDNA-encoded OXPHOS genes in AD brains.

Title: Behavioral and metabolic characterization of a humanized APOE mouse model of Alzheimer's disease

Authors: *J. W. MCLEAN, A. BHATTRAI, J.-P. WIEGAND, A. RAIKES, R. D. BRINTON; Ctr. for Innovation in Brain Sci., Univ. of Arizona, Tucson, AZ

Abstract: Alzheimer’s Disease (AD) is the largest contributor to neurodegenerative dementia worldwide, with a correspondingly global impact upon communities, economies, and healthcare. AD is a complex systems biology challenge, with multiple pathways implicated ranging from immune response and lipid metabolism to cognitive function. This emphasizes AD’s multifactorial nature and the importance of knowing how AD risk factors interact with its

systems biology. Age is the greatest risk factor for AD and *APOE* polymorphism is the most important genetic risk factor for the predominant late-onset type of AD, where *APOE4* heterozygosity and homozygosity respectively confer three- and twelve-fold greater risk of developing AD compared to *APOE3* homozygosity. To address the translational validity of the Jackson Laboratory mouse model of AD with targeted replacement of mouse *Apoe* with either human *APOE3* or *APOE4*, behavioral and metabolic analyses were conducted in aged (18-25 months) mice of both sexes. Locomotive behavior, comprehensively assessed via open field analysis, revealed no sex or genotype differences; this observation was corroborated by no observed travel speed difference in the CatWalk assay. Additionally, cognitive performance in a novel object recognition (NOR) task was not measurably altered across genotypes or sexes. However, EchoMRI-based body composition analysis revealed significant ($p<0.05$) differences in adipose index (AI) between *APOE3* and *APOE4* aged mice. This was differentially regulated by sex, with male *APOE4* mice having the lowest AI, male and female *APOE3* mice having similar AI, and female *APOE4* having the highest AI. Another sex-dependent impact of the *APOE4* risk factor upon metabolism was observed in male *APOE4* mice exhibiting significantly ($p<0.01$) lower fasting blood glucose (FBG) than male *APOE3* mice, female *APOE3*, and female *APOE4* mice. However, *APOE* genotype did not influence female FBG. Lastly, ^{18}F-FDG-PET on a subset of these animals revealed less cerebral glucose uptake in *APOE4* females compared to males ($p=0.066$), highlighting a potential bioenergetic deficit where females have higher circulating blood glucose but decreased transport to the brain. No within-sex genotype effects were observed. Collectively, these results indicate that *APOE4* differentially impacts metabolism in male and female systems and follow-up metabolomics may potentially inform sex-based precision interventions. Additional ongoing correlational analysis between behavioral, metabolic, genetic, and sex components will help further apprise the strengths and weaknesses of this humanized *APOE* mouse model in AD-focused translational research.

Title: Generation and characterization of iPSC-derived cranial pericyte-like cells

Authors: *A. SAGARE[1], J. CHEN[2], K. KISLER[2], C. GRIFFIN[3], Z. DAI[2], B. ZLOKOVIC[2];
[2]Physiol. and Neurosci., [3]Ctr. for Craniofacial Mol. Biol., [1]USC, Los Angeles, CA

Abstract: Brain vascular dysfunction contributes to the development of neurodegenerative disorders, including Alzheimer's disease (AD). We and others have shown that pericytes, which are vascular mural cells embedded in the wall of brain microvessels, play an essential role in the central nervous system (CNS) in regulating blood-brain barrier (BBB) integrity, controlling cerebral blood flow, clearing neurotoxins, providing neurotrophic support, and angiogenesis. Previous studies by our group have shown that pericyte degeneration and loss occurs in AD and that pericyte loss in the AD mouse model results in a significant increase in BBB leakage, increase in brain Aβ levels, tau pathology, and neuronal loss. The goal of the present investigation is to generate and characterize induced pluripotent stem cells (iPSC)-derived cranial pericyte-like cells (iPSC-PCs) by a two-step process via either mesoderm or neural crest cells intermediate for their potential use in a human patient-specific isogenic 3-D microfluidic system for CNS disease modeling studies and as a cell therapy treatment to repair and improve neurovascular functions in neurodegenerative disorders. Here using RNAseq and Western blotting analyses, we show that iPSC-PCs not only express pericyte specific proteins PDGFRβ, NG2, CD13, at similar levels as primary human adult forebrain pericytes, but also possess functional properties. The fully-characterized unlimited resource of iPSC-PCs that share molecular and phenotypic similarities with endogenous human adult brain microvascular pericytes hold potential in developing future non-neuronal pericyte-based cell therapy for AD and related neurodegenerative disorders.

Title: Tackling Alzheimer's disease using a cellular platform

Authors: *K. C. SONNTAG, W. RYU, B. M. COHEN;
Psychiatry, McLean Hospital, Harvard Med. Sch., Belmont, MA

Abstract: Sporadic neurodegenerative disorders are complexly determined, with single causes rarely determining more than a modest proportion of risk. Nevertheless, key processes may be

identified that can be altered by targeting control points for entire pathways of pathology. Essential to understanding and targeting complexly determined disorders is the construction and application of suitable model systems. The cause of the progressive deterioration and death of neurons in sporadic or late-onset Alzheimer's disease (LOAD) is still poorly understood, but its pathology is multifactorial and closely related to various changes with age that are abnormally expressed in those at risk. To identify core pathogenic pathways and mechanisms and test therapeutic interventions, we developed a cellular platform consisting of skin fibroblasts derived from LOAD patients and AD-unaffected control individuals and therefrom generated induced pluripotent stem cells (iPSC) that are differentiated to brain-like cells, permitting to determine LOAD pathogenic processes in context of age, disease, genetic background, cell development, and cell type. To this end, the model has revealed that LOAD is associated with a multitude of bioenergetic and metabolic alterations, providing evidence for an innate inefficient cellular energy management in LOAD as a background to the development of neurodegenerative disease with age. Among the most striking bioenergetic anomalies in LOAD cells was a reduction of the redox reagent nicotinamide adenine dinucleotide (NAD) whose supplementation or increase has been suggested to reduce the risk of aging-associated conditions. To investigate NAD as a metabolic target, we used our platform to test nicotinamide riboside (NR), a dietary precursor for NAD *de novo* synthesis, and caffeine, which increases mitochondrial function and the expression of NMNAT2, an essential enzyme in NAD production. Supplementation with NR and caffeine partially restored NAD levels, however, did not correct the LOAD-associated bioenergetic phenotype. These data indicate that NAD alone may not be a sufficient control point to address dysfunctional energy management in LOAD, and they demonstrate the value of the platform in detecting abnormalities and testing interventions. Altogether, this cellular model allows for patient-oriented examination of numerous mechanisms and interactions in LOAD pathogenesis, which ultimately could be used as a basis for a personalized medicine approach to predict altered aging and risk for development of dementia, and to test or implement (customized) therapeutic or disease-preventive intervention strategies.

Title: ApoE4 confers Mitochondrial Substrate Oxidation defects that can be bioenergetically compensated by a Ketogenic substrate Beta-Hydroxy butyrate (BHB)

Authors: C. GARCIA[1], ***A. TOMILOV**[1], J. SANDOVAL[1], G. A. CORTOPASSI[2];
[1]UC Davis, Davis, CA; [2]Univ. of California, Davis, Davis, CA

Abstract: Background: Mitochondria are at the center of neural biogenergetics, and ApoE4 is the single most impactful risk factor for AD. We investigated the impact of ApoE on insulin sensitivity, on mitochondrial substrate utilization and bioenergetics. Persons with ApoE4 have reduced brain carbohydrate metabolism. To test for ApoE4 conferred neural mitochondrial metabolic differences, we constructed a novel stable-ApoE 2, 3 and 4 N2a cell model, and tested ApoE's effects on Insulin sensitivity, and mitochondrial glucose, lipid and ketone oxidation.
Method: Binding of ApoE isoforms E2, E3 and E4 to Insulin Receptor (IR) was measured by BLI and Co-IP, the impact of ApoE isoforms on mitochondrial glucose, lipid, and ketone oxidation was measured using Seahorse-XF.
Result: ApoE3 was found to sensitize to insulin about 2-fold more potently than ApoE4. ApoE isoforms directly bind Insulin Receptor; the binding constants were in the range of 200-300nM. Consistent with the previous insulin-sensitivity finding, ApoE3 caused a significant increase of the glycolytic rate and glucose oxidation relative to ApoE4. As there was no difference in oxidation of TCA cycle intermediates substrates in permeabilized cells, or isolated ApoE4 mitochondria we infer ApoE3's glucose advantage is the result of increased insulin sensitivity. ApoE4 contributed a significant palmitate oxidation defect relative to ApoE2 and ApoE3. We observed that the relative defect in ApoE4-dependent glucose and palmitate oxidation can be overcome by BHB. Thus, at the neural cell level, the metabolic defects contributed by ApoE4 appear to be rescued by a ketogenic molecule, that requires neither insulin nor apolipoprotein particle to reach neural mitochondria and provide alternative metabolic support.
Conclusion: ApoE4 confers 'double trouble' in mitochondrial glucose and lipid oxidation. ApoE4 confers a defect in mitochondrial lipid oxidation relative to all other isoforms. Simultaneously, ApoE4 lacks the benefit in glucose oxidation conferred by ApoE3, which appears to be driven by the reduced insulin sensitization potency of ApoE4. We also find that BHB can be an alternative source of neural bioenergy that enters mitochondria directly and thus is not affected by ApoE4 'double trouble'.

Title: Dysregulation of activity-dependent alternative splicing events in tauopathy mice is normalized by in vivo modulation of p75 neurotrophin receptor signaling

Authors: *A. LATIF-HERNANDEZ[1], P. MORAN-LOSADA[1], T. YANG[1], K. C. TRAN[1], H. LIU[1], D. SIMMONS[1], S. M. MASSA[2], F. LONGO[1];
[1]Stanford Univ., Stanford, CA; [2]Dept. of Neurol., SFVAMC & UCSF, San Francisco, CA

Abstract: Tau pathology is associated with altered synaptic function, as measured by activity-dependent long-lasting changes of synaptic plasticity. Previously, we showed that synaptic dysfunction and changes in synapse-relevant gene expression profiles occur in the P301S (PS19) tauopathy mouse model and that treating with LM11A-31 (C31), a small molecule modulator of p75 neurotrophin receptor (NTR) signaling, normalized these abnormalities. Since neuronal activity produces changes in RNA splicing, we investigated whether mis-regulation of alternative splicing occurs in the context of plasticity in PS19 mice, and if so, whether it can be mitigated by C31. Wildtype (WT) and PS19 mice at 6 months of age were treated with vehicle or C31 (oral gavage) for 3 months. Acute hippocampal slices were prepared 24h after the last C31 dose and theta burst stimulation (TBS) was used to induce synaptic long-term potentiation [LTP]. RNA sequencing was performed on the non- [(-) TBS] and on the stimulated [(+) TBS] slices to generate activity-dependent profiles of alternative splicing events at the isoform level. Splicing analyses from (-) and (+) TBS slices in PS19 mice identified down-regulated isoforms enriched in *glutamatergic synapse, GABAergic synapse, calcium signaling, long-term potentiation,* and *axon guidance* KEGG pathways in (+) TBS slices relative to (-) TBS, suggesting specific activity-dependent changes at the isoform level. Further, comparison of (+) TBS PS19 and WT slices found that 1147 isoforms were significantly (FDR<0.05) altered in PS19 mice, with 264 down- and 883 up-regulated. C31 significantly decreased the total number of significantly altered isoforms in PS19 mice to 352, of which 158 were down- and 194 were up-regulated. Characterization of splicing events relevant to synapse dysfunction in tauopathy revealed that *glutamatergic synapse, calcium signaling, long-term potentiation,* and *axon guidance* were the most significant KEGG pathways associated with the down-regulated isoforms in PS19 mice, each of which were up-regulated in slices from PS19 mice treated with C31. Among these, we identified the following candidate components, via which C31 might restore synapse dysfunction: Gria1-202, Grin1-205, Grin2a-202, Cacna1h-203 and Lrrc40-206, which are implicated in signaling pathways crucial for synaptic transmission. Further exploration of these transcripts at the level of changes in protein isoforms is planned. In conclusion, modulation of $p75^{NTR}$ with C31 normalized tauopathy-related changes in synapse-relevant isoform levels suggesting that alternative splicing events regulated by C31 might contribute to neuronal plasticity in PS19 mice.

Title: Neural Stem Cell-derived Extracellular Vesicle Therapy Slows Down the Progression of Disease in the 5XFAD model of Alzheimer’s disease

Authors: *M. LEELAVATHI NARAYANA[1], R. UPADHYA[1], S. ATTALURI[2], M. KODALI[1], L. MELISSARI[1], A. VOGEL[1], B. SHUAI[1], M. KHA[1], J. JAIMES[1], A. K. SHETTY[1]; [1]Inst. For Regen Med, Texas A&M Univ. Coll Med., College Station, TX; [2]Inst. For Regen Med. Texas A&M Univ. Coll Med., College Station, TX

Abstract: In the early stage of Alzheimer's disease, cognitive and mood impairments are typically associated with increased oxidative stress, neuroinflammation typified by activated microglia and astrocyte hypertrophy, and decreased hippocampal neurogenesis. These changes are also accompanied by a significant deposition of amyloid plaques in the brain. In the current study, using the 5XFAD mouse model, we examined the efficacy of intranasal (IN)treatment of extracellular vesicles (EVs) derived from the rat subventricular zone neural stem cells (SVZ-NSCs) for delaying the progression of AD. The EVs from the SVZ-NSC culture media were first purified by anion-exchange chromatography and then characterized using NanoSight and markers of EVs. Next, 3-months old 5XFAD mice received IN administration of EVs (once weekly for two weeks, 150 billion EVs/week) or the vehicle. Two months later, the animals were interrogated with a series of behavioral tests, following which the animals were euthanized, and the hippocampal tissues were examined for neuroinflammation, oxidative stress, neurogenesis, and amyloid plaque deposition. Compared to AD mice receiving the vehicle, EV-treated AD mice displayed improved cognitive function to discern minor changes in the environment in an object location test and better spatial recognition memory in an object-in-place test. EV-treated AD mice also displayed no anhedonia in a sucrose preference test. The functional benefits in EV-treated AD mice were associated with reductions in oxidative stress, neuroinflammation, and better neurogenesis in the hippocampus. Reduced oxidative stress was evident from lower

malondialdehyde and protein carbonyl levels and elevated catalase and superoxide dismutase levels. Diminished neuroinflammation could be gleaned from the reduced concentration of TNF-alpha and IL1-beta, diminished astrocyte hypertrophy, and reduced concentration of complement C3. In addition, microglia displaying activated NLRP3 inflammasomes and the extent of microglial cell clustering were reduced. Neurogenesis analysis using the birth-dating marker 5'-bromodeoxyuridine and the newly born neuron marker doublecortin revealed maintenance of a higher level of hippocampal neurogenesis in EV-treated AD mice compared to vehicle-treated AD mice. Notably, the extent of amyloid plaques was also reduced. Thus, intranasal administration of NSC-derived EVs in the early phase of AD has the promise to slow down the progression of AD.

Title: Ablation of C5aR1 delays onset of hippocampal inflammatory gene expression and microglial activation in Arctic mice

Authors: *N. D. SCHARTZ, K. CARVALHO, G. BALDERRAMA-GUTIERREZ, H. YAHAN LIANG, S.-H. CHU, P. SELVAN, A. MORTAZAVI, A. J. TENNER;
Univ. of California, Irvine, Irvine, CA

Abstract: The Arctic APP transgene results in rapid accumulation of fibrillar amyloid plaques surrounded by dystrophic neurites which contribute to cognitive deficits and hippocampal neuronal loss by 10 months of age. Arctic mice also have increased gliosis and inflammatory gene expression in the brain at 5-10 months of age. As shown in our previous study, deletion of C5aR1 in the Arctic model (ArcticC5aR1KO) attenuates microglial activation, neuronal loss, and cognitive decline. To identify potential pathways that promote hippocampal injury, we assessed gene expression and microglia profiles of Arctic and ArcticC5aR1KO mice throughout disease progression. WT, C5aR1KO, Arctic, and ArcticC5aR1KO mice were aged to 2.7-10 months and hippocampi were isolated for bulk RNA-seq. MaSigPro was used to identify clusters of genes

that shared similar temporal expression patterns. In parallel, coronal sections from fixed brains of mice at 5, 7, and 10 months were stained for CD11c, CD11b, and AmyloGlo. Percent field area was analyzed with Imaris. We identified 15 clusters with maSigPro and compared the genes in those clusters with previously identified genes from Arctic microglia isolated from hippocampus and cortex and to bulk hippocampal sequencing from 5xFAD mice. Two of the clusters we identified contained many genes that were identified as upregulated in Arctic microglia and 5xFAD mice. Gene ontology of these two clusters identified inflammatory and cholesterol metabolism pathways. AD genes Cd33, Trem2, Tyrobp and Cst7 showed increased expression in the Arctic hippocampus with a peak at 7 months of age while in ArcticC5aR1KO the expression increased at a lower rate and did not peak until 10 months of age. Similarly, immunohistochemical quantification of CD11b- and CD11c-positive microglia showed an increase in these markers in Arctic mice compared to WT. While ArcticC5aR1KO mice also had higher levels compared to WT, at 7 months, CD11b and CD11c field area were lower compared to Arctic, suggesting a delay in microglia inflammatory activation. Early components of the classical complement pathway may aid in clearance of amyloid plaques and debris, while the downstream activation product C5a interacting with its receptor C5aR1 can cause inflammation and a feed-forward loop of neurodegeneration. By blocking only C5aR1, the beneficial functions of early complement remain intact, as does the lytic membrane attack complex which are useful for clearance of cellular debris and protection from infection. These findings provide support for C5aR1 as a potential drug target in the treatment of AD.

Title: C5ar1 antagonist alters microglial cells in a mouse model of alzheimer's disease

Authors: *A. GOMEZ ARBOLEDAS, G. BALDERRAMA GUTIERREZ, P. SELVAN, S.-H. CHU, H. YAHAN LIANG, A. MORTAZAVI, A. TENNER;
Univ. of California Irvine, Irvine, CA

Abstract: Alzheimer's disease (AD) is a devastating neurodegenerative disorder that impairs memory and causes cognitive decline and memory loss. The etiology underlying late onset AD is very complex and multi-factorial, where inflammation and the complement system are known to be essential contributors. Activation of the complement system by fAβ (and by neurofibrillary tangles) can generate C5a, that binds to its receptor C5aR1 on microglial cells and contributes to neuroinflammation. Previous results from our lab have shown a beneficial effect using either a genetic ablation of C5aR1 (C5aR1KO) or a pharmacological inhibition of it (C5aR1 antagonist, PMX205) in AD mouse models. Here, we further examined the effect of PMX205 on microglial gene expression and gliosis in a mouse model of Alzheimer's disease. Tg2576 mice (and WT littermates) have been treated with PMX205 in the drinking water for 12 weeks. Mice were perfused and brains were harvested and further processed for single cell RNA-sequencing and immunohistochemical analysis. As expected, an intense microglial response, demonstrated by enhanced Iba1 staining, increased with age and amyloid pathology. However, Tg2576 treated with PMX205 showed a reduced expression of multiple microglial markers, such as Iba1, CD11b or CD11c (37%, 65% and 82% reduction in the hippocampus). Moreover, single cell RNAseq analysis revealed significant changes in the proportions of microglial clusters when AD animals were treated with PMX205. Homeostatic microglial clusters were downregulated in AD mice, while Disease Associated Microglial clusters (characterized by the expression of ApoE, Tyrobp, Cst7, Csf1 and Axl, among others) were enhanced after the treatment with PMX205. Of the 9 microglial clusters identified, 3 were reduced with PMX205 while 3 others were enhanced by PMX205 treatment. Our results are consistent with the pharmacological inhibition of C5aR1 in a mouse models of Alzheimer's disease being linked to polarizing the disease associated microglia towards disease mitigating vs disease enhancing and is reflected in reduced neuroinflammatory pathology. Thus, modulation of C5a-C5aR1 could be a valuable therapeutic strategy for Alzheimer's disease patients.

Title: Acute dosing with a small molecule inhibitor of tau self-association in tau P301L JNPL3 mice to identify pharmacodynamics readouts.

Authors: *D. PATEL[1], C. SUSSMAN[1], M. GRECO[1], P. LOPEZ[1], E. DAVIDOWITZ[1,2], J. MOE[1,2];
[1]Oligomerix, Inc., 1300 Morris Park Ave., Room 1211, Bronx, NY; [2]Oligomerix, Inc., 2 Westchester Park Drive, Suite 208, White Plains, NY

Abstract: There is a critical unmet need for a disease modifying therapeutic for Alzheimer's disease (AD). Key requirements for treating early-stage AD include safe, efficacious, and cost-effective therapeutic interventions. Presently, we have developed a novel series of small molecule inhibitors of tau self-association (TSA). Our target approach is agnostic to the multiple strains of tau aggregates that form in disease, and to mutations in tau associated with tauopathies and is highly differentiated from other programs that target fibril formation or tangle disaggregation at the end of the aggregation cascade. Earlier, we reported the in vivo preventive efficacy of our small molecule lead in two tau-based transgenic mice models (htau mice; Davidowitz et al., 2020 and human tau P301L JNPL3 mice). The tau P301L mutation found in the inherited forms of progressive supranuclear palsy (PSP) and frontotemporal dementia (FTD) causes tau aggregation and neurodegeneration. In female homozygous JNPL3 mice, expression of the human P301L tau 4R0N construct in the hindbrain and spinal cord causes hind limb motor impairment to develop with age. The objective of this study is to identify acute pharmacodynamic (PD) measures of efficacy that will ultimately be used for modelling PK/PD relationship of our inhibitors. Acute dose range-finding studies were performed using multiple routes of administrations. C57BL/6 (WT) mice (n = 30; 15 males, 15 females) were administered vehicle (n = 3 mice/gender) or a single dose of TSA inhibitor ranging from 2 to 200 mg/kg (n = 3 mice/gender/dose). Brain and whole-blood specimens were collected at one-hour post-dose. Samples of serum and brain homogenates are being analyzed to evaluate compound concentrations by LC-MS/MS. PK studies in male and female WT mice will be performed with and without fasting to determine the food effects on bioavailability. The results of this study will be used to select the dose and route of administration for PK studies in homozygous female JNPL3 mice aged to 9 months. To determine the selective dose for the PD evaluation, PK studies will be performed using three doses. Some of the PD measures that will be evaluated are tau self-association, tau hyperphosphorylation, and motor behavior. In summary, understanding PK/PD relationships from this study will be crucial for determining appropriate dosing levels of TSA inhibitors in future clinical studies for AD and related tauopathies.

Title: Nsmase2 inhibition reduces phosphorylated tau in mouse model of alzheimer's disease

Authors: *K. COLEMAN[1], B. S. SLUSHER[2], B. J. BELL[3], C. TALLON[4], T. JOE[4];
[1]Neurol., Johns Hopkins Univ. - Sch. of Med., Baltimore, MD; [2]Neurol., Johns Hopkins Drug Discovery, Baltimore, MD; [3]Human Genet., Johns Hopkins Sch. of Med., Baltimore, MD; [4]Neurol., Johns Hopkins University- Sch. of Med., Baltimore, MD

Abstract: Alzheimer’s Disease (AD), the most common form of dementia, currently affects 50 million people and is set to increase substantially with the aging population, yet there remain no effective treatments. Therefore, it is imperative to explore new targets and mechanisms for slowing or halting the progressive propagation of toxic hyperphosphorylated tau that likely contributes to the neurodegenerative process. One such approach is by targeting extracellular vesicles (EVs). These small cargo-containing vesicles have been demonstrated to transport phosphorylated tau species in AD brains, enabling its propagation from affected to naïve neurons. Previously, our lab and others have shown that genetic knockdown or pharmacological inhibition of the enzyme neutral sphingomyelinase 2 (nSMase2) reduces the biogenesis and release of EVs. nSMase2 catalyzes the hydrolysis of sphingomyelin into ceramide, a necessary component of EV synthesis. nSMase2-inhibiting tool compounds, such as GW4869, have shown promise in ameliorating the buildup of toxic tau species in mouse models of AD, but they have poor potency, solubility, and limited CNS penetrance. Given the significant clinical potential of this target, our lab conducted a high throughput screening campaign of over 400,000 compounds against human nSMase2 followed by extensive medicinal chemistry efforts which identified 1-(3-(3,4-dimethoxyphenyl)-2,6-dimethylimidazo[1,2-b] pyridazin-8-yl) pyrrolidin-3-yl) carbamate (PDDC), a potent nSMase inhibitor (IC_{50}=300 nM) wth excellent oral bioavailability (F%=87) and brain penetration (AUC_{brain}/AUC_{plasma}=0.6). PDDC has been shown to inhibit the release of EVs in a dose-dependent manner in both *in vitro* and *in vivo*. To examine the

therapeutic potential of PDDC for AD, we dosed 4-month old PS19 mice for 5 months with PDDC-containing chow at a dose equivalent to 100 mg/kg/day which consistently delivered PDDC concentrations to the brain > its nSMase2 IC_{50}. After 5 months of therapy, we sacrificed the mice and extracted protein from the hippocampus and cortex. Total, pThr181, pSer202/Thr205, and pThr217 phosphorylated tau levels were quantified via western blot and compared to age and sex-matched control mice treated with vehicle chow. We observed a significant reduction in total and pThr181 tau in mice treated with PDDC compared to controls. pSer202/Thr205 and pThr217 were also lower in treated animals, however, these did not reach significance. These results demonstrate PDDC is capable of reducing pathological tau burden further supporting the clinical relevance of SMase2 inhibition for the treatment of AD.

Title: Altered sodium channel inactivation status in a Drosophila model of Alzheimer's disease

Authors: V. SANCHEZ FRANCO, A. N. HUTSON, S. D. DANIELS, *M. TABUCHI; Dept. of Neurosciences, Case Western Reserve Univ. Sch. of Med., Cleveland, OH

Abstract: While neuronal hyperexcitability has been implicated in the etiology of Alzheimer's disease (AD), its mechanistic causality is poorly understood. Not only has early neuronal hyperexcitability of cortical inhibitory interneurons been identified in mammalian models of AD, but the synergistic interaction between sleep loss and AD pathogenesis to further enhance neuronal hyperexcitability has also been demonstrated. Previous research using a Drosophila model of AD, which allows for genetic manipulations in specific cell types, has shown altered intrinsic membrane properties due to decreased conductance of voltage-gated potassium channels. Here we found that in addition to voltage-gated potassium currents, voltage-gated sodium currents have also been altered in a Drosophila model of AD. Specifically, we found that sodium channel inactivation status was significantly prolonged in Drosophila neurons expressing human β-amyloid (Aβ) and Tau. Further, we found that this prolonged sodium channel inactivation was synergistically enhanced by chronic sleep deprivation, suggesting an exacerbation loop between sleep and AD pathogenesis in shaping neuronal hyperexcitability.

Strikingly, we also observed that providing Drosophila with both Levetiracetam (LEV) and brivaracetam (BRV) within food negated the prolongation of the sodium channel inactivation status. Together, our results indicate that changes in sodium channel inactivation could be a novel predictor to suppress neuronal hyperexcitability induced by sleep and AD, which has the potential to reduce attrition in the late phases of neuroprotective medication development.

Title: The effects of presenilin knockdown on longevity, learning, and memory in a Drosophila melanogaster model of Alzheimer's disease

Authors: *K. M. ESTES[1], M. D. CHARLES[1], E. WOO[2], D. D. LENT[1];
[1]Biol., [2]Psychology, California State University, Fresno, Fresno, CA

Abstract: Alzheimer's disease (AD) is a progressive neurodegenerative disease that results in decline in cognition and behavior. Considering the impact AD has on individuals, there is a need to study the disease from multiple perspectives. This study is designed to characterize the effects of presenilin dysfunction, a gene that is the most common cause of familial AD, in our *Drosophila melanogaster* model of AD. Presenilin-1 loss of function is thought to underlie the pathogenic beta-amyloid production. Drosophila melanogaster has a homolog of presenilin, dPsn, and our study examines the effect of dPsn loss of function via knockdown on the fruit fly's longevity and spatial cognition. We first generated three lines that knocked down the expression of dPsn using dsRNA of dPsn. These lines included knockdown either pan-neuronally, in the mushroom bodies, or ellipsoid body, as the latter two have been shown to be important in learning, memory and spatial cognition. To assess the effect on lifespan, flies from each line were collected and the number of deaths recorded each day. The knockdown of dPsn in the fruit fly had a demonstrable effect on longevity and resulted in a shortened lifespan. A visual place learning assay was used to examine the cognitive abilities and behavior in the fruit fly. Flies were trained to locate a hidden cool spot on a hot surface using visual cues and were then tested for memory of that location. Flies were assessed on learning over ten trials and memory for up to one hour after training. The knocked down expression of dPsn in different brain areas had a

noticeable impact on the fruit flies' learning and memory. These findings suggest knockdown of dPsn in the fruit fly resulted in an observable effect on longevity, health, and behavioral deficits. Specifically, the ability to quantify changes in spatial cognition helps advance the fruit fly model of AD to better reflect the cognitive decline observed in humans.

Title: Rescue of lysosomal storage disorder phenotypes caused by Grn loss of function with a brain penetrant progranulin biologic

Authors: *M. J. SIMON, T. LOGAN, A. RANA, G. M. CHERF, S. S. DAVIS, R. L. Y. LOW, C.-L. CHIU, M. FANG, F. HUANG, A. BHALLA, M. PIZZO, J. HSIAO-NAKAMOTO, Y. RAJENDRA, J. WANG, Y. ROBLES-COLMENARES, D. KIM, H. NGUYEN, T. K. EARR, B. TSOGTBAATAR, R. CHAU, R. RAVI, R. MEISNER, D. DIAZ, K. R. HENNE, K. A. SCEARCE-LEVIE, R. WATTS, J. H. SUH, J. W. LEWCOCK, S. L. DEVOS, G. DI PAOLO; Denali Therapeut., South San Francisco, CA

Abstract: Mutations in the Grn gene are a risk factor for frontotemporal dementia (FTD), with progranulin (PGRN) haploinsufficiency observed in 10-15% of all FTD cases (GRN-FTD). Complete PGRN loss-of-function is linked to the lysosomal storage disorder Neuronal Ceroid Lipofuscinosis, which is defined pathologically by CNS lipofuscin deposition. Various lysosomal functions of PGRN have also been described preclinically including pH maintenance and lipase activity regulation. Based on these genetic data and the similarities between PGRN loss-of-function and lysosomal storage disorders, we hypothesize that CNS-penetrant PGRN replacement approaches represent a viable therapeutic mechanism for treating PGRN deficiency phenotypes. Using a mouse model of PGRN deficiency (Grn KO mice), here we further profile the role of PGRN in regulating lysosomal lipid composition and lipase activity. We also evaluate the viability of a brain penetrant, recombinant progranulin fusion protein as a potential therapeutic approach. To achieve this, we utilized our investigational therapeutic, PTV:PGRN, which is composed of recombinant human PGRN, fused to an Fc fragment engineered to contain a transferrin-receptor (TfR) binding site, that facilitates blood brain barrier transcytosis.Using a broad-panel lipidomic/metabolomic approach, we found that Grn KO mice exhibit age-independent deficiency of the lysosomal phospholipid bis(monoacylglycero)phosphate (BMP), and age-dependent accumulation of the sphingolipid glucosylsphingosine (GlcSph). Next, using Grn KO mice expressing humanized transferrin receptor (Grn KO x $TfR^{mu/hu}$ KI), we

demonstrate that PTV:PGRN exhibits superior brain uptake relative to a non-TfR binding PGRN molecule and rapid correction of brain BMP deficiency. We also demonstrate across a dose range, a single dose of PTV:PGRN can correct brain BMP and GlcSph phenotypes for up to 6 weeks. Finally, we show with repeat dosing, PTV:PGRN also rescues neuroinflammatory and neurodegenerative phenotypes observed in Grn KO mice (elevated gliosis marker expression, lipofuscin deposition and CSF Nf-L accumulation). Our data further support the link between PGRN loss of function and lysosomal lipid dysregulation and illustrate that certain lipid phenotypes can be targeted with PTV:PGRN. Moreover, the data suggest that lysosomal phenotypes may underlie glial activation and neuronal degeneration observed in Grn KO mice, which are also rescued with PTV:PGRN treatment. Taken together our data provide preclinical proof of concept for PTV:PGRN, supporting its use as a potential therapeutic in the treatment of PGRN loss-of function and GRN-FTD.

Title: Chronic intranasal oxytocin treatment restores social memory loss in the APPswe/PS1dE9mouse model of Alzheimer's disease

Authors: *M. SELLES[1], J. T. S. FORTUNA[2], Y. P. R. DE FARIA[2], B. M. LONGO[3], R. C. FROEMKE[4], M. V. CHAO[5], S. T. FERREIRA[6];

Langone Med. Ctr., New York, NY; [6]Fed. Univ. Rio de Janeiro, Rio de Janeiro, Brazil

Abstract: Alzheimer's disease, the main cause of dementia in the elderly, is accompanied by social memory deficits. Oxytocin is a pro-social neuropeptide that has recently been shown to be neuroprotective. Here, we characterized oxytocin production in the APPswe/PS1ΔE9 mouse model of Alzheimer's disease, and evaluated the potential of oxytocin to correct social memory impairments in those mice. Therefore, we used qPCR to quantify oxytocin mRNA levels in the hypothalamus of 12 month old male mice (n=7-9 mice per group) and observed a decrease trend in the levels of oxytocin in APPswe/PS1ΔE9 compared to wild type mice (p=0.08). Aiming to increase cerebral oxytocin levels, we developed and validated a protocol to deliver oxytocin via intranasal in mice. This protocol was efficient in increasing oxytocin peptide levels in the hippocampus of mice (p=0.05), and to reduce fear response in the fear conditioning paradigm (p=0.03) – a known effect induced by central oxytocin (n=10-15 mice per group). Next, we implemented this protocol to evaluate the consequences of oxytocin on social memory in APPswe/PS1ΔE9 using the 5-trial social task. APPswe/PS1ΔE9 treated with oxytocin were protected against social memory loss, which was present in APPswe/PS1ΔE9 treated with

vehicle (n=14-15 per group, $p<0.01$). Together, our results suggest that oxytocin could be a potential therapeutic approach to correct social memory deficits in Alzheimer's disease.

Title: Bdnf reduces aβ in 3d cultures of alzheimer's disease

Authors: *G. BAKIASI, M. PANIER, B. GONG, R. E. TANZI, S. CHOI;
Genet. and Aging Res. Unit, McCance Ctr. for Brain Health, MassGeneral Inst. for Neurodegenerative Dis. (MIND), Dept. of Neurology, Massachusetts Gen. Hosp. and Harvard Med. School, Charlestown, MA, 02129, USA, Boston, MA

Abstract: Alzheimer's disease (AD) is an irreversible, progressive neurological disorder that is characterized by memory loss and cognitive disturbance. Two pathological hallmarks of AD are: 1) amyloid plaque, primarily composed of amyloid-β (Aβ) which is derived from the amyloid precursor protein (APP) via serial cleavage of β- and γ-secretase; and 2) neurofibrillary tangle which is composed of filamentous accumulations of aggregated hyperphosphorylated tau (pTau). Brain-derived neurotrophic factor (BDNF) is a member of the nerve growth factor family and has been the focus of intense interest in AD research. While it is widely accepted that BDNF has an important role in modulating cognitive function as well as synaptic and neuronal dysfunction, the direct roles of BDNF on Aβ and tau pathologies are unknown or inconclusive. We previously developed a three-dimensional (3D) "human" neural cell culture model of AD which displays robust Aβ deposits and tauopathy (referred as 3D cultures; *Choi et al.,* Nature 2014). Here, we found that BDNF treatment significantly reduced the levels of Aβ40 and Aβ42 as well as Aβ42/Aβ40 ratio in the conditioned media of 3D cultures that harbor APP Swedish/London mutations. BDNF also reduced the levels of APP C-terminal fragment α and β (APP-CTFα and APP-CTFβ, respectively). Further mechanism study is warranted.

Title: Modifying glutamatergic neurotransmission rectifies synaptic plasticity and memory deficits in a 3xTg Alzheimer's disease model

Authors: *J. PFITZER[1], P. D. PINKY[2], I. A. QURESHI[4], R. M. BERMAN[4], V. D. SUPPIRAMANIAM[3], M. REED[5];
[2]Drug Discovery and Develop., [3]Harrison Sc Pharm., [1]Auburn Univ., Auburn, AL; [4]Biohaven Pharmaceuticals, New Haven, CT; [5]Aubrun Univ., Auburn, AL

Abstract: Alzheimer's disease (AD) poses a public health crisis with an urgent need for effective treatments and disease-modifying therapies. Glutamate dysfunction is a core feature of AD, and glutamatergic neurotransmission is a validated target for treating AD. In this preclinical study, we examined the effects of the novel glutamate modulator, troriluzole, on synaptic function, memory deficits, and glutamate release using the triple transgenic (3xTg) AD model. 3xTg mice received the troriluzole (25 mg/kg/day) from 5-8 months of age. At eight months of age, drug-treated 3xTg mice were compared to vehicle-treated 3xTg and transgene negative (TgNeg) controls for alterations in behavioral memory, synaptic plasticity, and glutamate release. Treatment attenuated the hippocampal-dependent reference memory deficits observed in 3xTg mice in Morris water maze probe trials. Treatment also the attenuated basal synaptic transmission deficits seen in 3xTg mice. Paired-pulse facilitation (PPF), a measure of the probability of glutamate release, was significantly reduced in vehicle-treated 3xTg slices, indicating an increase in presynaptic glutamate release probability; drug treatment restored PPF in 3xTg mice to that of controls. We also observe an increase in KCl-evoked hippocampal glutamate release in the of 3xTgs that was brought toward that of controls with drug treatment. The amount of readily releasable pool (RRP) of synaptic vesicles was also significantly reduced in 3xTg mice, indicating increased vesicle docking, and treatment significantly increased RRP in 3xTg mice. Long-term potentiation, a cellular correlate of learning and memory, was reduced by 25% in vehicle-treated 3xTg mice compared to controls. Notably, drug treatment completely restored the synaptic plasticity deficits observed in 3xTg mice. Together, these results suggest that troriluzole may restore synaptic deficits in 3xTg mice via modulation of glutamatergic neurotransmission and highlight its potential as a novel therapy for AD.

Title: A Novel sulfono-γ-AApeptide, 125-6b, as Therapeutic for Alzheimer's Disease

Authors: *N. SHEN[1], L. WEI[2], H. YANG[1], Y. WANG[1], J. KIM[1], T. ZIENELDIEN[1], J. CAI[2], C. CAO[1];
[1]Taneja Col. of Pharm., [2]Chem., Univ. of South Florida, Tampa, FL

Abstract: Mounting evidence suggests that the accumulation and aggregation of Aβ peptides are major and early etiological factors for Alzheimer's disease (AD), and the Aβ oligomers and fibrils are the major cause of AD due to their toxicity to neurons. Thus, the anti-Aβ aggregation approach has more potential to become a therapeutic treatment of AD, compared to the approach that targets the monomeric Aβ, which is believed to have an important physiological function. 125-6b is a sulfono-γ-AApeptides, which mimics the α-helical domain of proteins and could prevent degradation by proteases. This peptide mimic is one of the series of the helical sulfono-γ-AApeptides that stabilizes monomeric helical Aβ and potently inhibit Aβ aggregation and further aim to prevent the development or reverse AD. Our results demonstrated that 125-6b could inhibit Aβ aggregation, enhance neuronal survival and mitochondria function, and dramatically improved the memory of mice in the behavior test. The anti-aggregation result has been captured by the western blot assay. N2a/APP cell line and the primary neuron of newborn mice were treated with 125-6b and used to observe cell growth and mitochondria function. Aged APP/PS1 mouse model was used for the drug efficient test by intranasal delivery for 2.5 months. All the mice were evaluated by Radial Arm Water Maze (RAWM) and plasma Aβ levels before and after the treatment. 125-6b could significantly inhibit the Aβ aggregation, and promote the cell growth of both N2a/APP and primary neuron cell confirmed by MTT and Cell Titer-Glo Assay. Compound 125-6b could enter cell mitochondria, and increase the mitochondrial function. *In vivo,* post-treatment RAWM results demonstrated that 126-6b can statistically significantly improved the vulnerability of transgenic mice. The plasma Aβ40 and 42 levels had no differences among transgenic groups, however, the Aβ42/40 ratio increased with treatment. The mechanism of the drug is still undergoing further research, and this peptidomimetic has outstanding potential to be a therapeutic drug for AD.

Title: Molecular effects of intranasal insulin in the rodent brain: Examination of insulin receptor signaling and the glutamatergic system

Authors: *J. M. ERICHSEN[1], J. L. WOODRUFF[1], J. N. J. CRAWFORD[1], C. A. GRILLO[1,2], L. P. REAGAN[1,2], J. R. FADEL[1];
[1]Univ. of South Carolina Sch. of Med., Columbia, SC; [2]WJB Dorn VA Med. Ctr., Columbia, SC

Abstract: As brain insulin resistance has been identified as a pathological feature of age-related cognitive decline (ARCD), intranasal insulin (INI) is being explored as a potential treatment for patients with ARCD. Previous studies have demonstrated that INI enhances memory, but the underlying mechanisms remain unclear. To investigate the mechanistic basis for the pro-cognitive effects of INI, insulin receptor (IR) signaling and the expression of glutamate receptors and transporters, due to the role of the glutamatergic system in hippocampal synaptic transmission, was examined. Adult male Sprague-Dawley rats received bilateral hippocampal injections of a control lentiviral vector (LV-Con) or one containing a selective insulin receptor antisense sequence (LV-IRAS) to induce hippocampal-specific insulin resistance. Seven months later, *in vivo* microdialysis was used to assess brain neurochemistry and on a separate day, these animals were administered INI 30 minutes before euthanasia. In another cohort of Fischer 344 x Brown Norway F1 hybrid male rats (no virus) we investigated the effects of acute and chronic (10 days) INI dosing paradigms in young (3 months old) and aged (26 months old) rats, with a final INI administration 30 minutes before euthanasia. In both experiments, the hippocampus was processed for immunoblot analysis to assess changes in central IR signaling and phosphorylation/expression of glutamate receptor subunits and transporters. We previously observed that LV-IRAS injection selectively downregulated hippocampal IR expression and signaling without affecting peripheral insulin sensitivity. In this study, LV-IRAS animals showed reduced hippocampal basal glutamate levels and decreased phosphorylation/expression of glutamate receptor subunits. Additionally, vesicular glutamate transporter 2 (vGluT2)

expression, but not vGluT1, was significantly decreased in the hippocampus of LV-IRAS animals after INI administration. Immunofluorescence analysis was also used to determine that LV-IRAS animals exhibited decreases in the major presynaptic vesicle protein in the hippocampus. In the other cohort, age- and dosing paradigm-dependent effects were observed vis-à-vis IR signaling and glutamate receptor phosphorylation/expression. These data indicate that INI may improve cognition through the enhancement of IR signaling in the brain and/or through exerting synaptic effects on glutamate neurotransmission. More studies are needed to fully understand the mechanistic changes following INI and to determine the most effective treatment strategies, as INI could eventually be used in the broader clinical setting to treat ARCD.

Title: Identifying the multifactorial therapeutic mechanisms of irisin against emerging neuropathology in htau and 3xtg mice

Authors: *K. A. BRETLAND[1], K. M. BRETLAND[2], L. LIN[1], S. TERRILL[1], G. LEONE[1], C. M. DENGLER-CRISH[1];
[1]Northeast Ohio Med. Univ., Rootstown, OH; [2]Kent State Univ., Kent, OH

Abstract: Alzheimer’s disease (AD) is an age-related neurodegenerative disorder that continues to exact a disabling and lethal toll on patients. Late-onset AD, the most common form of dementia, has a multifactorial etiology that has challenged the development of disease-modifying drugs due to the need for these agents to address multiple mechanisms. However, the recently-discovered exercise-evoked hormone irisin could provide a unique therapeutic opportunity to address all of the key pathologies seen in AD: amyloid-beta plaques, neurofibrillary tangles, and neuroinflammation, as well the major midlife metabolic diseases that confer increased risk for late-onset AD (e.g. diabetes, obesity). Previously, our lab published work showing that four weeks of exogenous irisin treatment prevented the emergence of hippocampal pathology in female htau mice, a transgenic model of AD-like tauopathy. Here, we present data expanding this work that a) investigated irisin’s effects in 3xtg mice that develop both amyloid and tau pathology, and b) identified specific cytokines altered by irisin treatment in htau mice that

support its anti-inflammatory effects in the hippocampus. Adding further complexity to irisin's potential, we identified sex-divergent effects in irisin treatment-response in both AD mouse models. Our results further support irisin's potential as a neuroprotectant against AD-related etiology and emphasize the importance of identifying critical sex differences in treatment response.

Title: Kifc1, a microtubule-associated motor protein, provides a novel avenue towards ameliorating synapse loss during neurodegenerative disease

Authors: *S. GUHA, H. MURALIDHARAN, P. W. BAAS;
Neurobio. and Anat., Drexel Univ. Col. of Med., Philadelphia, PA

Abstract: Microtubules serve as tracks along which cellular organelles are transported in the axon by molecular motor proteins. Certain motor proteins also organize the microtubules themselves. We are exploring one such kinesin, namely KIFC1, which is a member of the kinesin-14 sub-family. Also called HSET in humans, KIFC1 has been studied extensively as a potential oncotarget due to its upregulation of expression in various cancers. However, inhibition of KIFC1 as a cancer therapy comes with potential deleterious side-effects due to its role in germ cell development and, as suggested by our previous work, might imperil axonal microtubule organization. Here we show that interactions of KIFC1 with the plus end of the microtubule and membrane proteins are necessary for the maintenance of synaptic connections. Specifically, we show that pharmacological inhibition of KIFC1 leads to a reduction in the number of synapses and dendritic spines. Given that synapse loss is a hallmark of many neurodegenerative diseases resulting in cognitive as well as sensory and motor impairments, we wondered if KIFC1 dysregulation may be a common downstream effector of synapse loss during such diseases. Oxidative stress often serves as a prelude to synaptic loss brought on by the release from surrounding activated astrocytes of molecules such as NO (nitric oxide) and ROS (reactive oxygen species). Our data show that in conditions of oxidative stress, KIFC1 levels are indeed diminished at the synapse. On this basis, we propose that fortifying KIFC1 in axonal terminals

and dendrites may provide a novel avenue toward ameliorating synapse loss in a variety of neurodegenerative diseases.

Title: Contributions of Tau and TDP-43 Hippocampal Pathology in Amnestic Dementia

Authors: *G. MINOGUE[1], *G. MINOGUE[2], A. KAWLES[2], N. GILL[2,3], M. KOCHHEISER[2], R. KESZYCKI[2,4], V. LUBBAT[2], K. AJROUD[2,5], C. SPENCER[2], J. LILEK[2,5], Q. MAO[2,5], M. E. FLANAGAN[2,5], H. ZHANG[2,3], M.-. M. MESULAM[2,6], C. GEULA[2,7], T. GEFEN[2,4];
[1]Northwestern Univ., Chicago, IL; [2]Mesulam Ctr. of Cognitive Neurol. and Alzheimer's Dis., Feinberg Sch. of Med. at Northwestern Univ., Chicago, IL; [3]Dept. of Preventive Med., [4]Dept. of Psychiatry and Behavioral Sci., [5]Dept. of Pathology, [6]Dept. of Neurol., [7]Dept. of Cell and Developmental Biol., Northwestern Univ. Feinberg Sch. of Med., Chicago, IL

Abstract: Introduction. Dementia syndromes are often not related to a single pathophysiologic process, leading to multiple neuropathologies found at autopsy. For example, an amnestic dementia syndrome can be associated with comorbid phosphorylated transactive response DNA-binding protein 43 (TDP-43) and Alzheimer's disease (AD). These pathologies are typically observed in hippocampal regions (mainly the CA1 sector) early in disease course. Those with comorbid AD and TDP-43 pathology ("AD/TDP") show worse long-term recall abilities compared to those with amnestic dementia due to AD. Here, we investigated neuronal integrity, pathologic burden, and hemispheric distributions of TDP-43 inclusions and neurofibrillary tau-positive tangles (NFTs) in the hippocampus, and its CA1 sector, in amnestic dementia due to AD/TDP and due to AD alone.
Participants and Methods. Twelve individuals with AD/TDP [mean age at death=81.31 (SD=11.14)], and 12 individuals with AD [mean age at death = 81.85 (SD=9.3)] were identified from the Northwestern AD Center brain bank. Cases carried an antemortem diagnosis of

amnestic dementia and met criteria for high AD neuropathologic change; AD/TDP were positive for at least medial temporal TDP-43. Left and right hippocampi were stained immunohistochemically with phosphorylated TDP-43 and AT-8 to visualize TDP-43 inclusions and NFTs, respectively. The HALO software (Indica Labs) was used to generate number of inclusions per mm^2 and % area occupied by immunopositivity in hippocampus and its CA1 sector. A linear regression was used to determine group differences with disease duration and APOE-4 allele status (0,1,2) included as covariates.
Results. There was no difference between the AD and AD/TDP groups in amount of NFTs or neuronal counts; however, compared to the AD group, the AD/TDP group showed significantly higher counts of *total* inclusions (NFTs + TDP-positive) after controlling for neuronal density in the CA1 sector (p=0.008). Distributions of pathology in CA1 and hippocampus were symmetric (ie., L=R) in both groups. Within the AD/TDP group, there was significantly more tau positivity (% area covered) compared to TDP-43-positivity in CA1 (p=0.036), but not the hippocampus in entirety.
Conclusions. The contribution of TDP-43 inclusions within the hippocampus to the amnestic phenotype appears to be additive, and perhaps represents a distinct pathophysiologic process from Alzheimer tau pathogenesis. Future studies will address questions of clinicopathologic concordance between markers of neurodegeneration and cognition during life.

Title: Proximity-based labeling reveals DNA damage-induced N-terminal phosphorylation of fused in sarcoma (FUS) leads to distinct changes in the FUS protein interactome

Authors: *M. JOHNSON, T. A. NUCKOLS, P. MERINO, P. BAGCHI, S. NANDY, J. ROOT, G. TAYLOR, N. T. SEYFRIED, T. KUKAR;
Emory Univ., Atlanta, GA

Abstract: Fused in sarcoma (FUS) is an RNA/DNA binding protein that participates in both nuclear and cytoplasmic functions. However, accumulation of FUS in the cytoplasm can lead to the formation of pathologic inclusions related to two neurodegenerative disorders, frontotemporal lobar degeneration (FTLD) and amyotrophic lateral sclerosis (ALS). While most ALS-FUS cases are caused by pathogenic mutations in *FUS*, the vast majority of FTLD-FUS cases are not caused by *FUS* mutations. Therefore, identification of non-genetic mechanisms that cause FUS to accumulate in the cytoplasm is crucial to understanding FTLD and ALS pathogenesis. To this end, DNA damage can trigger the DNA dependent protein kinase (DNA-PK) to phosphorylate FUS at N-terminal residues leading to FUS accumulation in the cytoplasm. However, the functional consequences of FUS phosphorylation are unknown. Proximity labeling approaches paired with mass spectrometry (MS) allow identification of a target protein's interactome by labeling its potential interacting partners. In this study, we performed proximity-dependent biotin labeling via ascorbate peroxidase 2 (APEX2) paired with MS to investigate whether phosphorylation shifts the FUS interactome and protein function. We mapped the interactome of wild-type FUS, phosphomimetic FUS (a proxy for phosphorylated FUS), and P525L FUS (a pathogenic mutation that causes ALS). We demonstrate that expression of phosphomimetic FUS shifts the FUS interactome toward more cytoplasmic functions including mediation of mRNA metabolism and translation. Our findings reveal that phosphorylation of FUS may disrupt homeostatic translation and steady state levels of certain mRNA transcripts. These results highlight the importance of phosphorylation as a modulator of FUS interactions and functions with a potential link to disease pathogenesis. Data are available via ProteomeXchange with identifier PXD026578.

Title: Investigating the pathological crosstalk between cerebral amyloid angiopathy and arteriolosclerosis

Authors: *V. PEROSA[1], M. ZANON ZOTIN[2], C. A. AUGER[3], S. GREENBERG[1], A. VISWANATHAN[1], S. J. VAN VELUW[1,4];

Abstract: Cerebral small vessel disease (CSVD) is the leading cause of haemorrhagic stroke and a contributing pathology to dementia[1,2]. The most common subtypes of CSVD are cerebral amyloid angiopathy (CAA), characterized by the thickening of the walls of leptomeningeal and cortical vessels and loss of smooth muscle cells, as a result of amyloid-β (Aβ) accumulation, and arteriolosclerosis, which mainly affects the white matter vessels and is associated with hypertension. It remains poorly understood to what extent these pathologies overlap[3] and how they contribute to the development of different types of microvascular injury. We aimed to address these knowledge gaps in a cohort of 19(74.1±8.2y, 7F) autopsy cases with a clinical diagnosis of probable CAA.Formalin-fixed intact hemispheres were scanned on a 3T MRI scanner, including a 500μm^3 T2-weighted sequence, on which cortical microinfarcts (CMIs) and cerebral microbleeds (CMBs) were counted[4] and MRI-visible perivascular spaces (PVS) in the centrum semiovale were rated. Arteriolosclerosis was assessed on hematoxylin&eosin (H&E) stained sections in the white matter of four pre-defined juxtacortical areas using a semiquantitative score[5]. Furthermore, the area occupied by enlarged PVS (EPVS) was calculated on ImageJ with an in-house developed tool. Deep learning-based models were used to quantify leptomeningeal and cortical CAA, as previously described[6].All CMBs were located in the cortex, as typically seen in CAA, whereas no CMBs were found in subcortical locations. Cumulative score of arteriolosclerosis severity and CAA percentage area were not associated with total number of CMIs, CMBs, and EPVS severity on ex vivo MRI (Spearman's ρ_{CMIs}=-0.49, p=0.842; ρ_{MBs}=-0.18, p=0.450; ρ_{EPVS}=-0.35, p=0.138). Instead, bothtotal CAA percentage area and arteriolosclerosis were a predictor of EPVS percentage area on histopathology (no. of sections = 71; arteriolosclerosis: β=0.34, p<0.001; total CAA percentage area: β=0.34, p=0.014). CAA percentage area was not associated with arteriolosclerosis severity (no. of sections=71; total CAA: β=0.02, p=0.787).These preliminary findings suggest that the severity of arteriolosclerosis is not directly related to CAA burden in the overlying cortex in patients with a clinical diagnosis of CAA. However, these pathologies frequently co-exist and appear to both contribute to the burden of EPVS, a potential indicator of impaired paravascular clearance. Future directions include understanding how the burden and distribution of arteriolosclerosis (and other co-existing pathologies)contribute to creating a spectrum of clinical phenotypes within CAA.

Title: Investigating the ability of granulin subunits to rescue lysosome dysfunction, inflammation, and neurodegeneration in a mouse model of Frontotemporal Dementia

Authors: *J. ROOT[1,2], M. WANG[2], G. TAYLOR[2], T. L. KUKAR[2];
[1]Emory Univ. Sch. of Med. Neurosci. Grad. Program, Atlanta, GA; [2]Pharmacol., Emory Univ., Atlanta, GA

Abstract: Frontotemporal dementia (FTD) is the second most common dementia diagnosis after Alzheimer's disease. Heterozygous, loss- of-function mutations in the granulin gene (*GRN)* cause FTD by reducing the production of the progranulin (PGRN) protein. These genetic discoveries demonstrate that PGRN is important for neuronal health, but it is unclear why the loss of PGRN causes FTD. Interestingly, homozygous *GRN* mutations cause neuronal ceroid lipofuscinosis (NCL; *CLN11*), a lysosomal storage disorder (LSD) defined by dementia, lipofuscinosis, and neurodegeneration. The discovery that homozygous *GRN* mutations cause an LSD and that FTD-*GRN* patients share pathological features of NCL, strongly suggests lysosomal dysfunction underlies all PGRN deficient disorders, including FTD. The Kukar lab discovered that PGRN is rapidly processed into stable granulins in the lysosome, supporting the idea granulins have a beneficial function in the lysosome (Holler et al, *eNeuro*, 2017). Other groups have found a lysosomal origin of granulins and a beneficial function in multiple model systems. In contrast, some reports have suggested granulins are pro-inflammatory and could be neurotoxic. To help resolve these conflicting results, we designed a study to compare the ability of progranulin and granulins to ameliorate FTD-like phenotypes in a mouse model of PGRN deficiency. Here we report *in vivo* efficacy studies testing the hypothesis that delivery and replacement of a single granulin protein (granulin-2) to the brains of $Grn^{-/-}$ mice is sufficient to ameliorate neuroinflammation and neuropathology. This was accomplished by injection of various recombinant adeno-associated virus (rAAV2/1) into the cerebral ventricles of neonatal $Grn^{-/-}$ mice. Cohorts of $Grn^{-/-}$ and wild-type (WT) mice were injected with rAAV2/1 encoding granulin-2, full-length PGRN (positive control for delivery of all GRNs), or GFP (negative control). Following injections, mice were aged for 12 months, and tissues were harvested. We are now assessing biochemical and histopathologic markers of lysosomal dysfunction, neuroinflammation, and neurodegeneration. Galectin-3 (LGALS3), LAMP1, lipofuscin, Iba1, GPNMB, NeuN, and p62 will be measured via immunohistochemical staining, ELISA, or immunoblot. Using these measures, we will evaluate the extent to which an individual granulin subunit can rescue FTD-like phenotypes in aged $Grn^{-/-}$ mice. This study will provide clarity whether granulins are beneficial to neuronal health, and provide important insight into whether single granulin subunits may serve as effective therapeutics to treat diseases caused by PGRN deficiency.

Abstract: It has been widely reported that the effects of SARS-CoV-2 infection tend to affect certain groups of individuals disproportionately, such as for the elderly and those with existing severe mental disorders. Recent research has shown increased COVID-19 symptom severity for individuals with dementia, although there are no reports showing an association between COVID-19 and the conversion from mild to major cognitive impairment. We present the 6-year longitudinal case of a woman with bipolar disorder who develops major vascular neurocognitive impairment following SARS-CoV-2 infection. This patient presented stable mild cognitive impairment for six years prior to switching to major cognitive impairment following positivity for SARS-CoV-2 complicated by a urinary tract infection. We discuss the cognitive and neuroanatomical repercussion prior to and following the infection of SARS-CoV-2 for this patient. We highlight that patients with low-grade inflammation due to severe mental health conditions may be uniquely susceptible to worse outcomes if they become infected by SARS-CoV-2. Additionally, this report indicates that there may be a compounding effect of COVID-19 on top of existing neuroinflammation in bipolar patients which may result in accelerated neurodegeneration and, ultimately, the conversion to dementia.

Title: Triple Transgenic Alzheimer's' Disease Mice Display Cerebrovascular Dysfunction, Compounded by Chronic Stress

Authors: *E. N. BURRAGE, T. COBLENTZ, S. PRABHU, J. FRAZIER, R. W. BRYNER, J. SIMPKINS, P. D. CHANTLER;
West Virginia Univ., Morgantown, WV

Abstract: Chronic stress is a powerful risk factor in the development and progression of countless diseases including dementia. Past work in our lab has shown that chronic stress induces cerebrovascular dysfunction and recently, impaired cerebrovascular hemodynamics has been identified as a preclinical marker of dementia pathology. Despite this, the compound impact of chronic stress on cerebrovascular function in an Alzheimer's disease model has yet to be explored. Here, we utilized a triple transgenic mouse model of Alzheimer's disease (3xTg AD) combined with our unpredicted chronic mild stress paradigm (UCMS), to examine middle cerebral artery (MCA) function and to test the hypothesis that chronic stress can accelerate vascular AD pathology. A subset of mice was euthanized immediately following 8 weeks of chronic stress while another subset of mice was euthanized 3 months post chronic stress. Following euthanasia, the MCA's were removed and positioned in a pressurized myobath. The MCA was exposed to increasing concentrations of acetylcholine (ACh; 10-9M to 10-4M), phenylephrine (PE; 10-9M to 10-4M), and sodium nitroprusside (SNP; 10-9M to 10-4M). Immediately following chronic stress exposure, MCA dilation to ACh in AD mice were impaired compared to wildtype control mice (6.2±1.9μm to 19.2±0.7μm, respectively; $p<0.05$). Wildtype mice that underwent UCMS showed similar response to ACh compared to AD control mice (7±2μm to 6.2±1.9μm, respectively). The combination of AD and UCMS resulted in further impaired MCA dilation to ACh compared to either AD control and wildtype UCMS mice (3±1.5μm vs 7±2μm, and 6.2±1.9μm, respectively; $p<0.05$). No differences were found between groups in the PE or SNP response. Interestingly, in the mice euthanized at 9 months of age, these trends persisted. Overall, these data suggest that AD induces similar cerebrovascular dysfunction as compared to chronic stress, with combination of these compounding the cerebrovascular dysfunction and accelerate vascular AD pathology, irrespective of age of euthanasia.

Title: Valosin-containing protein and the regulation of TDP-43 aggregation in neurodegeneration and myopathy

Authors: *E. LYNCH, S. PITTMAN, J. DAW, C. C. WEIHL;
Neurol., Washington Univ. Sch. of Med., Saint Louis, MO

Abstract: TDP-43 is a ubiquitously expressed RNA-binding protein commonly found aggregated in many neurodegenerative diseases and myopathies. TDP-43 is primarily localized in the nucleus but under conditions of cell stress will relocate to the cytoplasm as a component of stress granules. Under disease conditions aggregated TDP-43 remains in the cytoplasm and forms amyloid-like oligomers. These oligomers may initiate self-templated aggregate conversion of soluble TDP-43, leading to propagation and accumulation of phosphorylated insoluble aggregates. Dominant mutations in valosin-containing protein (VCP) cause several diseases which involve TDP-43 aggregation including frontotemporal dementia, inclusion body myopathy, and amyotrophic lateral sclerosis. In some cases such as multisystem proteinopathy (MSP), patients may have TDP-43 aggregation in both skeletal muscle and neurons. In these patients, the onset of myopathy often happens years earlier than the onset of dementia. Studies have shown that misfolded TDP-43 is capable of cell-to-cell transmission through neuronal networks, but it is unknown whether TDP-43 oligomers can spread from skeletal muscle to the central nervous system. We have two research goals: 1) to study TDP-43 aggregation in skeletal muscle to determine whether it is capable of self-templated conversion and spreading and 2) to investigate how mutations in *VCP* contribute to this process. Induced pluripotent stem cells (iPSCs) from VCP patients were differentiated into skeletal myocytes and analyzed for insoluble TDP-43 by fractionation western blot. We found that the VCP patient lines had increased insoluble TDP-43 compared to isogenic controls and this was further increased when treated with arsenite to induce cell stress. In addition, C2C12 mouse myoblasts which were treated with arsenite followed by a VCP inhibitor had a persistence of insoluble TDP-43 compared to arsenite-only controls. Together, these results suggest that mutations in *VCP* may facilitate TDP-43 aggregation as previously suggested, or lead to decreased clearance. A TDP-43 fluorescence resonance energy transfer (FRET) sensor line will be used to determine whether the muscle-derived TDP-43 aggregates are capable of seeding further aggregation. In addition, we used a tetracycline-activated expression system to generate a transgenic mouse line which expresses human TDP-43 with a mutated nuclear localization signal in skeletal muscle (rtTA-CKM x tetO-hTDP-43_{NLSm}). We plan to use these mice to further study mechanisms of TDP-43 aggregation in skeletal muscle and whether it is capable of propagation.

Title: Increased Accumulation of Synaptic Proteins in Microglia Suggests Enhanced Synaptic Pruning in Frontotemporal Lobar Degeneration with TDP-43 Proteinopathy

Authors: *I. A. AYALA, C. SPENCER, M. E. FLANAGAN, T. D. GEFEN, M. MESULAM, C. GEULA;
Northwestern Univ., Chicago, IL

Abstract: Frontotemporal lobar degeneration (FTLD) is characterized by degeneration of the frontal and temporal lobes and abnormalities in behavior and/or language. Synaptic loss is among the first changes associated with cognitive decline in aging and Alzheimer's disease (AD). Aberrant synaptic pruning by microglia may contribute to loss of synapses in AD. We have observed decreased cortical levels of synaptic proteins in FTLD with TDP-43 pathology (FTLD-TDP). In this study we investigated accumulation of synaptic proteins in microglia as a surrogate marker for potential increased synaptic pruning in behavioral variant frontotemporal dementia with TDP-43 pathology. Tissue from middle frontal gyrus of seven participants was used (Control, n=3, FTLD-TDP, n=4). Paraffin-embedded sections underwent double immunofluorescent processing to concurrently visualize microglia and synaptic proteins. Specific antibodies to the presynaptic protein synaptophysin, the postsynaptic protein PSD-95, and the dendritic spine protein spinophilin were used to visualize immunoreactivity for each synaptic protein. Antibodies to Iba1 or HLA-DR were used to visualize microglia. Reagents were chosen to fulfill the requirement of double immunofluorescent staining that the two antibodies are raised in different species. Modified unbiased stereological methods were used for quantitative analysis. Counts were obtained from three types of synaptic staining in microglia: 1) microglia with no synaptic proteins, 2) microglia with punctate synaptic proteins, and 3) microglia with large aggregates of synaptic proteins. The three patterns were observed in all cases and synaptic proteins. Significantly larger numbers of microglia displayed aggregates of PSD-95 than punctate staining in FTLD-TDP participants ($p<0.05$), whereas there were no significant differences between these two patterns in control participants ($p>0.05$). Furthermore, the percentage of total microglia that contained aggregates of synaptophysin was significantly

larger in FTLD-TDP when compared with controls ($p<0.03$). The number of microglia containing aggregates of spinophilin was significantly higher than microglia containing punctate staining in both FTLD-TDP and controls ($p<0.02$). These results point to accumulation of synaptic proteins in microglia, with larger aggregates predominating for some synaptic proteins in FTLD-TDP. One potential interpretation of these results is increased synaptic pruning. Mechanistic studies in animal models are required to determine whether aberrant synaptic pruning is indeed a feature of TDP-43 proteinopathies.

Abstract: Leukodystrophies constitute a group of genetically heterogeneous inherited diseases that affect myelin sheath production and/or function in the central nervous system (CNS). RNA polymerase (Pol) III-related leukodystrophy, an autosomal recessive disorder, is the second most prevalent leukodystrophy and was identified when five initially distinct syndromes with overlapping clinical and radiological features were found to have a common molecular basis. Patients are diagnosed between birth and adolescence with neurological and non-neurological deficits and are classified according to distinct brain MRI features and confirmed by sequencing. RNA polymerase (Pol) Pol III-related leukodystrophies involve mutations primarily in *Polr3a* and *Polr3b*, which encode the two largest subunits and form the catalytic core of the enzyme. Pol III synthesizes abundant short non-coding RNAs that have essential functions in protein synthesis, secretion and other processes. Despite the ubiquitous functions of these RNAs, the basis of this neural sensitivity and the mechanisms of disease pathogenesis remain unknown. We show that conditional knock-in of pathogenic *Polr3a* mutations in the Olig2 lineage in mice

results in growth, neurobehavioral and hypomyelination phenotypes in multiple regions of the cerebrum and spinal cord reflecting a subset of clinical features found in patients. In contrast, the gross motor defects and cerebellar hypomyelination that are common features of severely affected patients are absent in the mice, suggesting a relatively mild form of the disease in this conditional model. Our results show that disease pathogenesis in the mice involves defects that reduce both the number of mature myelinating oligodendrocytes and the ability of these cells to produce a myelin sheath of normal thickness. Our findings uncover a critical role for Olig2 expressing cells in disease pathogenesis, specifically in the development and/or survival of oligodendrocytes as well as their function in myelination.

Title: Functional consequences of novel mutations in the PANK2 gene identified in a large Dominican Republic cohort with pantothenate kinase associated neurodegeneration (PKAN)

Authors: I. OJUKWU[1], C. MUNIZ[2], S. BASER[3], C. BASS[4], M. SANTANA[5], *F. MIDDLETON[2];
[1]Syracuse Univ., Syracuse, NY; [2]SUNY Upstate Med. Univ., Syracuse, NY; [3]Allegheny Hlth. Network, Pittsburgh, PA; [4]Mind R&T, Murrysville, PA; [5]Hosp. Infantil Dr. Robert Reid Cabral, Santo Domingo, Dominican Republic

Abstract: Pantothenate Kinase Associated Neurodegeneration (PKAN) is an autosomal recessive genetic disorder caused by mutations in the gene encoding PANK2 (Pantothenate Kinase 2) an enzyme essential for vitamin B5 metabolism highly expressed in the basal ganglia. PKAN typically begins in late childhood causing dystonia, bradykinesia, dysarthria, tremors, and muscle wasting, although the pattern and severity vary between subjects. While rare globally (affecting 1 in 1,000,000 people worldwide) PKAN is common in the southwestern Dominican Republic (DR), where it affects more than 1 in 1,000 persons and where we have done extensive studies to gain insight into disease mechanisms and symptom heterogeneity. Comprehensive genotyping and whole exome analyses indicate that most affected DR subjects are homozygous for a Y227C mutation in the PANK2 protein unique to the DR. However, we also recently identified a novel R532W mutation in PANK2 protein transmitted in a bilineal compound

heterozygous fashion to 3 affected siblings. Whole exome sequencing and genotypic data analysis failed to reveal any other mutations in PANK2 or genes associated with other movement disorders, including NBIA, dystonia, Parkinson's disease, Huntington's disease or Wilson's disease. We hypothesized that both the Y227C and R532W mutations have reduced phosphorylation activity and disrupted protein-protein interactions that lead to neurodegeneration. To test this, we first performed in silico modeling of the potential effects of each mutation on protein conformation. This consistently predicted deleterious effects of the Y227C mutation in chain C of the PANK2 protein homotetramer due to conformational changes and disrupted binding interactions, but less consistent predictions regarding the effects of the R532W mutation. Consequently, we generated expression vectors for the wildtype (WT) human PANK2 gene as well as two single-mutant (Y227C and R532W) forms of the gene, to express His-tagged versions of each full-length protein. Expressed proteins were affinity purified and used for biochemical studies to monitor rates of end product formation by reverse-phase LC-MS. We also visualized the potential differences in enzyme activity and compared the cellular localization of the WT and mutant enzymes using Click-It Chemistry and immunofluorescent microscopy. Co-immunoprecipitation and MS analysis are currently in progress to reveal potential differences in protein-protein binding partners. Finally, cellular viability and transcriptional responses are being compared to gain additional insight into the impact of these specific mutations compared with others in the PKAN literature.

Title: Cerebellar mGluR1 receptors are required for caffeine-induced attacks of dyskinesia in Episodic Ataxia Type 2

Authors: *H. SNELL[1], A. VITENZON[2], K. KHODAKHAH[3];
[1]Albert Einstein Col. of Med. Dominick P. Purpura Dept. of Neurosci., Bronx, NY; [2]Albert Einstein Col. of Medicince, Bronx, NY; [3]Dept Neurosci., Albert Einstein Col. Med., Bronx, NY

Abstract: Episodic Ataxia type 2 (EA2), is caused by mutations in the CACNA1A gene, which encodes the pore forming subunit of the P/Q type voltage gated calcium channel. These

mutations result in a loss-of-function of the P/Q type calcium channel, which leads to baseline ataxia, and attacks of dyskinesia, that can last a few hours to a few days. These attacks are brought on by consumption of caffeine, ethanol, and physical or emotional stress. Using the *tottering* mouse, a well characterized mouse model of EA2, we have previously established that stress induces attacks by activation of cerebellar α1 adrenergic receptors. Activation of these receptors leads to an increase in casein kinase 2 (CK2) mediated phosphorylation of the calmodulin associated with SK channels, which decreases SK channel activity, causing an increase in Purkinje cell irregularity and attacks of dyskinesia. Because caffeine can increase NE levels and change the expression of α1 adrenergic receptors, we explored whether it also induced attacks by the same mechanism. We found that caffeine increased phosphorylated calmodulin in the cerebellum, suggesting that caffeine may also induce attacks via a CK2 dependent signaling pathways. Similar to stress, both caffeine-induced attacks and Purkinje cell firing irregularity were prevented by shRNA knock down, or block, of CK2. Block of α1 adrenergic receptors, however, failed to prevent caffeine induced attacks. Since at the concentrations that it causes attacks in EA2 caffeine is known to block A1 adenosine receptors, we explored a potential role for this pathway. We found that block of A1 adenosine receptors alone, induced attacks of dyskinesia and increased Purkinje cell firing irregularity to a similar extent as caffeine, suggesting caffeine indeed induces attacks through this mechanism. Block of A1 adenosine receptors increases the release of neurotransmitters such as glutamate, thus we hypothesized that activation of mGluR1 receptors on Purkinje cells led to the increased irregularity and attacks of dyskinesia in EA2. We found activating mGluR1 receptors induced attacks of dyskinesia, and the block of mGluR1 receptors significantly decreased the percent of caffeine-induced attacks. Finally, we discovered a novel direct interaction between mGluR1 and CK2, and the inhibition of mGluR1 prior to initiation of attack prevented the caffeine-induced increase in phosphorylated calmodulin. Given the success of pharmacological block of CK2 to prevent stress and caffeine induced attacks, we believe these data establish the ground-work for the development of therapeutics for the treatment of caffeine and stress induced attacks in EA2 patients.

Title: Endogenous tagging of RAN peptides in Fragile X-associated Tremor/Ataxia Syndrome.

Authors: *G. SKARIAH, C. J. MALTBY, A. KRANS, P. K. TODD;
Neurol., Univ. of Michigan, Ann Arbor, MI

Abstract: Fragile X-associated Tremor/Ataxia Syndrome (FXTAS) is caused by the expansion of a CGG trinucleotide repeat to a pre-mutation range (55-200 repeats) in the 5'UTR of the FMR1 gene. CGG repeat expansions in FXTAS support translation of homopolymeric proteins through a process known as CGG Repeat-associated non-AUG Translation (CGG RAN). Generation of the most abundant CGG RAN product, a polyglycine containing protein called FMRpolyG, elicits toxicity in human cells, Drosophila and transgenic mouse models of FXTAS. Accurate detection, tracking and quantification of RAN translation products from endogenous gene loci would markedly expand our ability to determine how they elicit dysfunction and to confirm selective inhibition of their production as a first step towards therapy. Unfortunately, currently available antibodies that readily detect heterologous expression of these proteins are not reliably effective at staining the endogenous untagged RAN products in a fashion that readily allows for their quantification. To address this, we designed specific CRISPR-Cas9 guides to incorporate either a luminescence based HiBiT-LgBiT tag or a split mNeonGreen21-10/11 (mNG2) fluorescent tag in the FMR1 locus in FXTAS patient derived induced pluripotent stem cells (iPSCs). I tested the CRISPR reagents in HEK cells by tagging the endogenous FMR1 locus in the FMRpolyG frame. We observed a modest increase in HiBiT signal in the setting of a normal repeat in HEK cells suggesting very low endogenous expression of FMRpolyG. Plasmid-based overexpression studies in HEK cells confirmed that the HiBiT tag expresses even in the context of expanded CGG and C9 repeats. In addition, we have successfully incorporated FLAG tags in the same locus to facilitate immunoprecipitation of the FMRpolyG RAN peptide. We are now optimizing the mNG2 system in FXTAS and iPSC lines to detect FMRpolyG in human patient neurons. Once established, we will validate these tools using a series of recently identified RAN translation specific modifiers.

Title: Spherical Nucleic Acids Targeting FXN Induce Frataxin Expression in Models of Friedreich's Ataxia

Authors: *G. T. CORBETT[1], U. A. BARAY[1], S. ANANTATMULA[1], A. K. LAGRIMAS[1], N. CRAMB[1], H. GURLER-MAIN[1], G. BALANGUE[1], A. EINHORN[1], S. MIX[1], E. W. BUSS[1], L. R. MOORE[1], A. SCHOOK[1], C. R. MURATORE[2], L. P. KELLY[1], W. L. DANIEL[1], M.

SCHROFF[1], B. R. ANDERSON[1];
[1]Exicure, Chicago, IL; [2]Ann Romney Ctr. For Neurologic Dis., Boston, MA

Abstract: Friedreich's Ataxia is a progressive neurodegenerative disorder caused by mutations in the *FXN* gene. Expanded intronic GAA repeats in *FXN* result in downregulation of frataxin protein, mitochondrial dysfunction, and neurodegeneration. Currently, there are no approved therapies to slow or prevent progression of FA. Spherical nucleic acids (SNA^{TM}) are nanostructures comprised of densely packed oligonucleotides radially arranged around a nanoparticle core. Compared to their linear counterparts, SNA show increased cellular uptake and persistence in the CNS. In this study, we designed and assessed several mono-targeting and multi-targeting FXN-SNA that exert two mechanisms of action for upregulation of *FXN* mRNA: i) transcript stabilization and ii) FXN natural antisense transcript (FXN_{NAT}) degradation. FXN-SNA were assessed for efficacy in FA patient fibroblasts and in induced neurons (iNs) generated from FA patient-derived induced pluripotent stem cells. In the absence of transfection agents, FXN-SNA exhibited strong FXN mRNA upregulation in patient cells. Importantly, FXN-SNA dose-dependently increased endogenous frataxin protein in the cytoplasm and mitochondria, and improved mitochondrial function in phenotypically-mature FA iNs. Several lead FXN-SNA were administered into the intra-cisterna magna space of mice expressing GAA-expanded human *FXN* in the absence of murine *Fxn* (*Fxn*^{null}::YG8s(GAA)$_{>800}$ mice). Fourteen days after dosing, brain, spinal cord and dorsal root ganglia (DRG) tissues were assessed for target engagement. FXN-SNA dose-dependently increased *FXN* mRNA and frataxin protein expression in the brain, spinal cord and DRG of humanized FA mice. Among the tested CNS regions, the strongest upregulation was observed in the cerebellum, a region critically affected in FA, where we observed up to 3-fold increases in frataxin protein versus vehicle. FXN-SNA also induced over a 2-fold increase in frataxin protein in dorsal root ganglia, another region greatly impacted in FA. Critically, we observed improvements in succinate dehydrogenase activity in these regions, a marker for mitochondrial function. All tested FXN-SNA were well-tolerated, as clinical and anatomic pathology assessments revealed no drug-related adverse events. In conclusion, we developed several FXN-SNA that exploit endogenous cellular machinery to upregulate FXN mRNA and protein via degradation of FXN_{NAT} and/or extension of *FXN* mRNA half-life. These findings support the continued development of FXN-SNA for potential treatment of FA and warrant exploration of SNAs for various other neurological diseases.

Title: Dopamine Transporter Deficiency Syndrome mouse model shows reduced hyperactive phenotype in response to amphetamine and alhpa-methyl-para-tyrosine

Authors: *E. RUSSO[1], A. REZAYOF[1,2], P. BEEREPOOT[1], M. MILENKOVIC[1], D. E. WATKINS-CHOW[3], A. RAMSEY[1], A. SALAHPOUR[1];

Abstract: Genetic mutations that result in misfolded proteins are a cause of a number of human diseases, one of which is Dopamine Transporter Deficiency Syndrome (DTDS). Autosomal recessive loss of function mutations in the dopamine transporter (DAT) lead to its retention and degradation in the endoplasmic reticulum (ER), ultimately resulting in low levels of functional DAT. A complex motor disorder arises, and patients diagnosed with DTDS display a classical clinical phenotype of initial hyperactivity that progresses over time to parkinsonism-dystonia. To gain additional information on the pathophysiology of this disease and to investigate potential pharmacotherapies we have created a new line of transgenic knock-in mice carrying one particular DTDS disease-causing DAT mutation. This mouse (mA313V) models the human DTDS mutation hA313V. Herein is a report on the initial behavioral and neurochemical characterization of the A313V mice as well as on promising drug treatments for the management of classic DTDS symptoms. A313V mice have approximately 5-fold less mature DAT in comparison to wildtype (WT) littermates and a consequent increase in locomotor activity as measured by the open field test. This hyperactivity can be reduced upon treatment of amphetamine and alpha-methyl-para-tyrosine (aMPT)

Title: Novel ataxia phenotype due to spontaneous Myo5a mutation detected by whole genome sequencing

Authors: *A. M. TELENSON[1,2], R. R. HSIEH[1,2], A. H. VO[1,3], M. HADHAZY[1,2], L. PESCE[1], M. J. PUCKELWARTZ[1,2], E. M. MCNALLY[1,2];

Abstract: Spontaneous mutations in mice contribute to understanding the genetic mechanisms of neurodegenerative diseases. A genetic backcross strategy was undertaken to assess the "Superhealing" MRL (Murphy Roths Large) strain for its ability to ameliorate the muscular dystrophy phenotype caused by the loss of the dystrophin associated protein gamma-sarcoglycan (*Sgcg*). In this context, during the fifth-generation backcross, a new spontaneous mutation was discovered and associated with a Novel Ataxic Phenotype (NAP). Breeding studies confirmed autosomal recessive inheritance, and genotyping confirmed the ataxic phenotype was separable from the *Sgcg* locus and thus the muscular dystrophy process. NAP mice first displayed ataxia by postnatal day 11, followed by defects in coordination, an abnormal righting reflex and hindlimb collapse. NAP mice exhibited rapid progression with severe motor deficits and lethality between days 21-25. Using Whole Genome Sequencing (WGS) on heterozygous parents, two affected offspring and an unaffected mouse from each of the original breeding lines, we applied systematic filtering of novel variants to uncover a single nucleotide polymorphism (SNP) in the 5' donor splice site of exon 14 of 41 in the *Myo5a* gene. *Myo5a* encodes an unconventional, processive actin-based myosin whose C-terminal tail engages with intracellular cargo. Autosomal recessive mutations in human *MYO5A* cause Griscelli Syndrome, a rare disorder associated with abnormal pigmentation, hypotonia and severe developmental delay. The splicing defect responsible for the findings in NAP mice show exon 14 exclusion, a significant reduction in *Myo5a* mRNA and a complete loss of myosin Va protein. *Myo5a* is highly expressed throughout the brain and in melanocytes, the latter contributing to coat color defects. Further neurological defects are being characterized, including the role of myosin Va in myelination and intracellular transport. Because the phenotype arose on the MRL background, we conclude that the Superhealing MRL background is insufficient to prevent the neuropathology in NAP mice.

Title: Slc39a14 knockout mice with increased blood and brain manganese levels and dystonia-parkinsonism exhibit increased TSPO levels in the cerebellum and brainstem indicative of active neurodegeneration

Authors: *A. N. RODICHKIN, J. L. MCGLOTHAN DZIEDZIC, T. R. GUILARTE;
Envrn. Hlth. Sci., Robert Stempel Col. of Publ. Hlth. & Social Work Florida Intl. Univ., Miami, FL

Abstract: In the last decade there has been an increasing number of reports describing individuals with inherited autosomal recessive mutations of the manganese (Mn) transporter gene *SLC39A14*. These individuals expressing the mutations have high concentrations of Mn in blood and brain and display childhood-onset dystonia-parkinsonism. Previously, we have reported that *Slc39a14*-knockout (KO) male and female young adult mice (postnatal day 60, PN60) exhibit increases in blood and brain Mn as well as dystonia-parkinsonism similar to the human cases. We have also reported that assessment of the *Slc39a14*-KO mice in nigrostriatal dopaminergic system showed no changes in striatal dopamine and metabolite concentrations or neurodegeneration of dopaminergic neurons of the substantia nigra pars compacta relative to wildtype (WT) mice. On the other hand, *Slc39a14*-KO mice have a marked inhibition of potassium-stimulated dopamine release in the striatum. To continue to characterize the pathophysiological changes in male and female PN60 *Slc39a14*-KO mice, we took a broad screening approach to assess ongoing neurodegeneration using quantitative Translocator protein 18 kDa (TSPO) autoradiography. TSPO is a well-validated quantitative biomarker of neuroinflammation resulting from brain injury and neurodegeneration that allows an unbiased screening approach to determine brain regions undergoing active degeneration. We used the TSPO specific radioligand [^{3}H]-DPA-713 to measure TSPO levels in multiple brain regions from wildtype (WT) and *Slc39a14*-KO male and female PN60 mice. Our results indicate no significant changes in [^{3}H]-DPA-713 specific binding to TSPO in several forebrain regions including cerebral cortex, striatum, globus pallidus, septal nucleus, hippocampus, amygdala, hypothalamus, and thalamus. However, we unexpectedly found significant increases in [^{3}H]-DPA-713 specific binding to TSPO in the cerebellum (male= 27.7%, female=16.7%), deep cerebellar nuclei (male=31.0%, female=21.1%), brainstem (male=29.1%, female=24.8%), and the facial motor nucleus of the brainstem (male=31.8%, female=22.2%) in *Slc39a14*-KO PN60 mice relative to WT. These results describe for the first-time active neurodegeneration in the cerebellum and brainstem of *Slc39a14*-KO mice, an observation that is consistent with the known role of these brain structures in the postural and gait instability in dystonia-parkinsonism.

Title: Wdr45 function and contribution to bpan

Authors: *B. L. MEYERINK, Z. C. STRICKLAND, J. J. BRUDVIG, J. M. WEIMER, L.-J. PILAZ;
Pediatrics and Rare Dis., Sanford Res., Sioux Falls, SD

Abstract: Mutations in the X-linked gene *WDR45* cause the rare disease Beta Propeller-protein Associated Neurodegeneration (BPAN) which leads to global developmental delay, intellectual disability, seizures, and premature death. *WDR45* encodes for a protein typically associated with autophagy regulators, though the protein's function and how its absence in BPAN patients leads to the disease is largely unknown. To explore protein function, we used a bait-BioID system to label protein interactors with WDR45 in neuroblastoma cells. We found a strong association of WDR45 with proteins involved in endomembrane-associated protein transport, RNA processing, and mitochondrial proteins important for metabolism of lipids and maintaining mitochondrial membrane potential. Defects in these pathways are known to occur in other neurodegenerative diseases such as Alzheimer's Disease, Parkinson's Disease, and Huntington's disease. To study WDR45's role in these pathways we have used iGONAD to make a mouse model with a genetically encoded epitope tag on endogenous WDR45 allowing specific detection of this molecule. This model will be used to explore WDR45's role in the pathways elucidated in the BioID screen and determine the expression pattern of WDR45 in the brain. We have also created a model introducing a patient-analogous premature stop codon early in the *WDR45* gene, ablating protein expression and more faithfully recapitulating the human disease phenotype in the mouse with early death occurring in homozygous mutant animals. We are characterizing this mouse line along with a previously generated BPAN model which has shown no altered survival phenotype in homozygous mutant animals. Our analysis focuses on early markers of neurodegeneration to characterize disease onset and progression. Knowledge of the neurodegenerative progression in these animals and causative mechanisms are key insights allowing for a more informed approach to therapeutic development. These findings reveal previously unexplored functions of WDR45 and potential causatives factors of BPAN pathology which may additionally give relevant insight to more common, phenotypically similar neurodegenerative diseases.

Title: Developing Adenoviral Vectors to target Distinct Cerebellar Cell Types

Authors: *E. KUL, S. PHILLIPS, P. VALINO-RAMOS, S. M. YOUNG, JR;
Dept. of Anat. and Cell Biol., Univ. of Iowa, Iowa City, IA

Abstract: Recombinant viral vectors have become integral tools for basic *in vivo* research applications. Helper-dependent adenoviral (HdAd) vectors are safe viral vectors with a large packaging capacity of ~36 kb of DNA and mediate long-term expression without toxicity. This carrying capacity of HdAd enables basic research and clinical fields requiring the delivery of large genes or multiple transgenes, which cannot be packaged into other widely used viral vectors, such as Adeno-associated virus (AAV). Genetic disorders involving the cerebellum, such as spinocerebellar ataxia type-6 (SCA6), ataxia-telangiectasia (A-T) and episodic ataxia type-2 (EA2) are caused by mutations in large genes and result in severe motor phenotypes in the affected individuals. Disfunction and degeneration of the Purkinje cell that is a key cell type of the cerebellum, is commonly observed in these disorders. Thus, successful delivery of large transgene constructs to Purkinje cells is essential in developing gene therapy approaches for these cerebellar disorders. Currently, the HdAd serotype 5 vectors are the most common adenoviral vector used in basic and clinical applications. However, HdAd type 5 vectors do not transduce Purkinje cells. To overcome the current limitations, we have been in the process of developing chimeric adenoviral vectors with altered viral tropisms. Here, we evaluate our vectors in the mouse cerebellum against molecular markers of distinct cerebellar cell types by colocalization studies. Furthermore, we discuss differential transduction patterns of each chimeric vector with a primary focus on the Purkinje cell.

Title: Astrocyte-specific expression of triple mutant TDP-43 causes changes in memory and anxiety-like behavior

Authors: *S. MCGRIFF, M. GITCHO;
Delaware State Univ., Dover, DE

Abstract: TDP-43 is the major pathological protein in motor neuron disease, frontotemporal dementia and is also found in ~50% of those with Alzheimer's disease. Alexander disease is a developmental leukodystrophy and mutations in GFAP segregate with disease. In Alexander disease, pathological inclusions containing phosphorylated TDP-43 were discovered. Astrocyte pathology, though rare is present in all TDP-43 proteinopathies. We have developed a new mouse model to selectively drive human TDP-43 with three ALS familial mutations (3XTDP43) specifically in astrocytes (GFAP-tTA). Methods: Utilizing the tetracycline inducible system, we examined 12-month-old mice for behavior (rotarod, light/dark box, and Barnes maze), pathology, biochemistry, proteomics, and exon array. Our study seeks to understand the correlation between astrocyte driven pathological TDP-43 functional alters memory and anxiety-like behavior. Results show pathological changes in astrocytes with a decrease in glial fibrillary acidic protein (GFAP) expression. We further show changes in memory and anxiety-like behavior with little motor deficits. Therefore, astrocyte driven TDP-43 pathology and the development of functional changes associated with memory and anxiety may provide a better understanding of pathways associated with neurodegeneration in TDP-43 proteinopathies.

Title: Astrocyte-specific expression of tdp-43 during development causes blindness in 12-month-old mice

Authors: *W. SMITH, S. AREZOUMANDAN, M. GITCHO;
Delaware State Univ. Dept. of Biol. Sci., Dover, DE

Abstract: Transactive response DNA binding protein 43 (TDP-43) is the major pathological protein in motor neuron disease. In some models of TDP-43 overexpression, mice do not survive when the transgene is on throughout normal development. We utilized an inducible model with mutations in the nuclear localization signal that drives expression of TDP-43 in the cytoplasm (TDP-43ΔNLS) specifically in astrocytes. For this study, the transgene was turned on throughout their development (tet-off system). Methods: behavior, histology, biochemistry, and functional magnetic resonance imaging (fMRI) were evaluated 12 months of age. Results: At 12 months of age, the mice lost their ability to see, and the lens of the eyes became opaque and there was a complete disorganization of the photoreceptors. In addition, we used functional magnetic resonance imaging to evaluate the visual pathway of the mice in the 4 months of age. Our preliminary data indicate that astrocyte expression of TDP-43ΔNLS throughout their development causes changes in vision. These findings suggest that the mislocalization and alteration of expression in astrocytes of TDP-43 affects visual development in the mice.

Title: Selective Vulnerability of Tripartite Synapses in Amyotrophic Lateral Sclerosis

Authors: *C. BONTHRON[1], M. J. BROADHEAD[1], J. WADDINGTON[1], M. LOPEZ[1], F. ZHU[2], S. G. N. GRANT[2], C. SMITH[2], G. MILES[1];

[1]Sch. Of Psychology and Neurosci., Univ. of St Andrews, St Andrews, United Kingdom; [2]Ctr. for Clin. Brain Sci., Edinburgh Univ., Edinburgh, United Kingdom

Abstract: Amyotrophic lateral sclerosis (ALS) is a fatal neurodegenerative disorder affecting the cortex, brainstem and spinal cord, resulting in progressive muscle paralysis. ALS has been described as a synaptopathy, with evidence of central and peripheral synaptic changes in animal models and patient post-mortem tissue. Astrocytes are key regulators of synaptic function and envelop synaptic terminals, forming 'tripartite synapses'. With growing evidence that astrocytes significantly contribute to ALS pathogenesis, here we aimed to investigate tripartite synapses in the context of disease. To do this, we performed high resolution quantitative microscopy of tripartite synapses in lumbar spinal cord sections obtained from $SOD1^{G93A}$ x PSD95-eGFP (Postsynaptic Density Protein 95) mice at several time points of disease progression, from presymptomatic stages through to the emergence of motor deficits (8 weeks [W], 12W, 16W). Tripartite synapses were visualised using PSD95-eGFP labelling in combination with immunohistochemical markers for presynaptic terminals (VGLUT2) and astrocyte contacts (EAAT2 and p-Ezrin). Stitched high magnification imaging of spinal hemisections allowed for the production of 'tripartite spinal maps', whereby Rexed laminae could be delineated allowing for region-specific analysis of millions of synapses from ALS mice. Analysis was conducted by multiple researchers blinded to animal genotype throughout. Overall, we observed progressive synaptic loss in 16W (early symptomatic) $SOD1^{G93A}$ mice. Interestingly, analysis of non-tripartite and tripartite synapses revealed selective decreases in **tripartite synapse density only**, when using either astrocytic marker (EAAT2: N=5, P<0.0001; p-Ezrin: N=4, P=0.0004). This loss of tripartite synapses was observed widely throughout spinal laminae. Furthermore, we observed the same selective vulnerability of tripartite synapses in human post-mortem tissue from ALS patients (N=6 control, N=9 ALS, P=0.011). These data suggest a selective vulnerability of tripartite synapses in ALS, providing further insight into previously reported synaptic loss which did not assess astrocytic components, and supporting a toxic role of astrocytic synaptic contacts in disease.

Title: When ALS processes are halted. motor neurons that resistant to pathological TDP-43 can mediate motor recovery.

Authors: *S. HUR[1], M. DOMINIQUE[1], M. FARAG[1], J. Q. TROJANOWSKI[2,1], K. J. SPILLER[3], V. M. LEE[1,2];
[1]Ctr. for Neurodegenerative Dis. Res. (CNDR), [2]Dept Pathol & Lab. Med., Univ. of Pennsylvania Sch. of Med., Philadelphia, PA; [3]Janssen R&D, LLC, Spring house, PA

Abstract: In intermediate disease stages, surviving motor neurons (MNs) can partially compensate for the initial loss of the most vulnerable MNs in amyotrophic lateral sclerosis (ALS) patients, but studying the nature of this compensation has been difficult. However, using transgenic mice with inducible *Tar-DNA binding protein-43* (TDP-43)-triggered ALS disease, we can now 1) identify the MNs that the mediate motor recovery after the first wave of fast-fatigable (FF)-type motor units are lost, and 2) determine how these MNs change over the course of continued disease. We have previously shown that slow motor units are disease-resistant in rNLS8 mice[1] and can recover from ALS-like disease when the hTDP-43ΔNLS transgene is turned off. In the present study, we use a viral tracing strategy to show that the disease resistant MNs sprout to innervate vacated motor end-plates of adjacent muscle fibers. Moreover, we find that these newly reinnervated motor units are resistant to axonal dieback during a second epoch of human *Tar-DNA binding protein-43* (hTDP-43)-triggered disease in a fast-type skeletal muscle (tibialis anterior, TA). We demonstrate that when the TA muscle is re-innervated by FF fibers (after a nerve crush experiment) there is no change in the ALS-like disease progression, but when SK3 positive slower MNs reinnervate TA (via cross-reinnervation surgery), these connections are now disease resistant. After a TDP-43-triggered loss and subsequent reinnervation, the resilience of the new connections is remarkable considering that these motor units have had to greatly expand their motor field and are now connecting to the muscle fibers that were initially the most disease-vulnerable. These results are particularly exciting given recent advances in ALS clinical programs aimed at targeting genetic drivers of disease. Taken together, these early results in a mouse model of TDP-43 proteinopathy offer hope that in the future, if the disease progression could be halted in ALS patients, those patients would likely regain some degree of their lost motor function over time.

Title: Tdp-43 triple mutation mouse model of als

Authors: *M. DOPLER, K. COX, S. AREZOUMANDAN, M. GITCHO;
Delaware State Univ., Dover, DE

Abstract: Amyotrophic Lateral Sclerosis (ALS) is characterized by the death of the upper and lower motor neurons. Symptoms include slurring of speech, difficult swallowing, progressive muscle weakness, and eventually paralysis. After diagnosis, the average lifespan is ~5 years, most commonly due to respiratory failure or pneumonia. There is currently no treatments for the disease. Over 95% of all ALS cases present hyper-ubiquitinated and phosphorylated transactive response DNA binding protein 43 (TDP-43) positive aggregates as part of the hallmark pathology. Replicating these hallmarks in a mammalian model is crucial in order to develop effective treatments. We have developed a new model of TDP-43 overexpression that contain three familial mutations (3XTDP43). When overexpressed in HEK293T and SHSY-5Y cells there are distinct changes in solubility producing phosphorylated TDP-43 aggregation. This leads us to developed a mouse that selectively expresses 3XTDP43 in the brain and spinal cord utilizing the neurofilament heavy promoter expressing tetracycline-controlled transactivator protein (NEFH-tTA). This mouse model demonstrates significant age-dependent motor deficits and mice only survive about 2 months of age. In addition, there are increases in neuroinflammation and phosphorylated TDP-43 pathology reminiscent of the human disease. This new mouse model may provide a better understanding of pathways associated ALS and other TDP-43 proteinopathies.

Title: Tdp-43 proteinopathy causes global dysregulation of neuronal protein synthesis in-vivo

Authors: *N. PENA, D. ZARNESCU, S. MACKLIN, C. CHELLMAN;
Univ. of Arizona, Tucson, AZ

Abstract: TAR DNA-binding protein 43 (TDP-43) is a DNA/RNA binding protein whose cytoplasmic aggregation is a pathological hallmark of amyotrophic lateral sclerosis (ALS). How disease-associated TDP-43 aggregates may exert toxicity within motor neurons, which rapidly deteriorate in ALS patients, is not fully understood. Given the important role TDP-43 plays in RNA metabolism and local translation within nerve cells, we investigated alterations in protein synthesis in *Drosophila* models of ALS based on wild-type or mutant TDP-43 overexpression in motor neurons. We found that global translation in neuronal cell bodies was reduced in the ALS fly models compared to controls, as indicated by puromycin labeling of nascent peptides. Additionally, genetic enhancement of translation initiation via 4EBP RNAi or S6K OE can rescue locomotor phenotypes induced by TDP-43 proteinopathy. Consistent with these results, wild-type animals show increased vulnerability to pharmacological inhibition of cap-dependent translation, which suggests a preexisting translational impairment in the *Drosophila* ALS models. When using fluorescent noncanonical amino acid tagging (FUNCAT) to label peptides in motor neurons, we also observe a reduction in newly synthesized proteins at the neuromuscular junction (NMJ) in flies overexpressing TDP-43. Finally, preliminary data suggest that both 4EBP RNAi and S6K OE can increase adult lifespan in the context of TDP-43 proteinopathy. Taken together, our data point toward compartment specific, cap-dependent protein synthesis impairment as a key process disrupted by TDP-43 pathology in-vivo.

Title: Tdp-43 proteinopathy causes differential expression of retrotransposons in a tdp43- q331k mouse model

Authors: *S. KORADA[1], O. TAM[2], M. HAMMELL[2], D. WILLBOLD[3], J. DUBNAU[4], R. SHER[1];

Spring Harbor, NY; [3]Heinrich Heine Univ., Dusseldorf, Germany; [4]Stony Brook Sch. of Med., Stonybrook University, NY

Abstract: Pathological cytoplasmic aggregation of TAR-DNA binding protein (TDP-43) is seen in 97% of ALS cases, 40% of FTD cases and many AD patients. TDP-43 is an RNA and DNA binding protein that has two RNA recognition motifs and an inherently disordered C- terminal domain that makes the protein prone to aggregation. TDP-43 is involved in many aspects of RNA metabolism such as transcriptional repression, translational regulation and mRNA splicing. TDP-43 has also been shown to regulate the expression of retrotransposable elements (RTEs). TDP-43 dysfunction, due to either over-expression, knock out, or the spontaneous proteinopathy seen in patients, result in elevated expression of RTEs. Studies in Drosophila in particular have demonstrated that the degenerative effects of TDP-43 are mediated by RTE toxicity to neurons and glia. The RTE phenomenology observed in Drosophila has also been observed in human subjects. Post- mortem RNA sequencing from ALS subjects, and analysis of chromatin silencing marks from FTD have revealed increased expression of human RTEs and endogenous retroviruses (ERVs), including HERV-K and LINE1. These changes in RTE expression are correlated with the degree of TDP-43 proteinopathy. While this phenomenology of RTE/ERV expression has been widely observed, and shown to provide a causal impact in Drosophila, there are as yet no mammalian model studies of the link between TDP-43 pathology, RTE expression, and toxicity. In this study, we tested the hypothesis that the TDP43-pathology impacts RTE expression in rodents. We used a mouse model with moderate levels of expression of the TDP-43 Q331K. We employed RNA-Seq analysis of total RNA from the motor cortex of transgenic mice overexpressing human TDP-43 Q331K, WT TDP-43, and their non- transgenic littermates. We found that expression of the Q331K transgene leads to derepression of several families of RTEs and ERVs. This effect was not observed in the animals expressing the TDP-43 WT protein. To correlate these effects with TDP-43 proteinopathy, we used surface-based fluorescence intensity distribution analysis (sFIDA) to detect TDP-43 oligomers at the pre-fibril stage in different regions of the brain and spinal cord. The TDP43 Q331K mutant mice show significantly higher levels of TDP-43 oligomers in the motor cortex. We conclude that there is an age- specific differential expression of retrotransposable elements in the motor cortex of the TDP-43 Q331K mouse model, which correlates with the degree of proteinopathy. This study provides a platform to investigate the mechanisms by which RTEs may contribute to neurodegeneration in this mammalian model of TDP- 43 proteinopathy.

Title: Characterization of TDP-43ΔNLS mice: Behavior and Biomarker Analyses

Authors: H. FERNANDES, I. MORGANSTERN, J. BELTRAN, M. KWAN, J. SHEA, A. GHAVAMI, D. HAVAS, *T. HANANIA;
Psychogenics Inc, Paramus, NJ

Abstract: Amyotrophic Lateral Sclerosis (ALS) is a neurodegenerative disease characterized by progressive loss of both upper and lower motor neurons and associated function, producing muscle denervation, motor impairments and brain atrophy leading to eventual death. One feature thought to correlate with ALS-related pathology is the deposition of insoluble cytosolic inclusions of TAR-DNA binding protein (TDP-43) in affected tissues. To study the progression of ALS-related phenotypes and establish a model for testing novel therapeutic interventions, we systematically characterized TDP-43ΔNLS mice (Walker et al., 2015). These inducible rNLS8 mice were generated by crossing a line of transgenic mice expressing tTA under the control of the human neurofilament heavy chain (NEFH) promoter with tetO-hTDP-43ΔNLS mouse containing a defective nuclear localization motif (DNLS). Administration of doxycycline (Dox) in these animals suppresses expression of both total and phosphorylated form of hTDP-43ΔNLS, and rescues the disease phenotype. Following Dox cessation, TDP-43ΔNLS mice show body weight loss, increased tremors, hindlimb clasping, impaired gait and decrease in survival compared to tTA control mice. Electromyography assessment showed an increase in the latency of muscular contraction and a decrease in the response amplitudes of muscle contractions following motor nerve stimulation in TDP-43ΔNLS animals. Histological analysis revealed strong overexpression of TDP43 in perinuclear cytoplasmic inclusions along with deposition of pTDP43 aggregates in hippocampus, cerebral cortex, dorsal striatum and cerebellum of TDP-43ΔNLS mice. TDP pathologies were accompanied by increased expression of inflammatory marker transcripts in cortex, astrogliosis and microglial activation in affected brain regions of TDP-43ΔNLS mice compared to tTA controls. Similar type of pathologies were detected in the spinal cord but at lower level of severity than in the brain. Dramatic elevations in neurofilament light chain, a biomarker of neurodegeneration, were seen in both plasma and CSF of TDP-43ΔNLS animals 5 weeks following withdrawal of Dox. In summary, expression of hTDP-43ΔNLS in rNLS8 mice resulted in cytoplasmic inclusions in multiple brain regions and spinal cord, a loss of murine nuclear TDP-43, progressive loss of muscle strength and function, and motor impairments. Each of these impairments were observed early after Dox removal in both male and female mice suggesting that this mouse model of ALS provides an aggressive and clinically-relevant phenotype for testing novel therapeutic strategies.

Title: Neuronal cytoplasmic TDP-43 accumulation leads to spinal cord lipid cacostasis in the rNLS8 mouse model of amyotrophic lateral sclerosis

Authors: *E. JENSEN[1], E. MCGUIRK[4], L. GUO[2], T. TAKSIR[3], Y. REN[1], A. BIALAS[1], J. YU[1], S. RYAN[3], D. OFENGEIM[1], B. ZHANG[1], P. SARDI[1], J. DODGE[1];

Abstract: TAR DNA-binding protein 43 kDa (TDP-43) is a highly conserved and ubiquitously expressed predominantly nuclear RNA-binding protein that performs important functions in transcription, translation, pre-mRNA splicing, and RNA transport to impact the expression of thousands of genes. Intracellular aggregation and accumulation of TDP-43 is a neuropathological hallmark observed in 97% of patients with amyotrophic lateral sclerosis (ALS) and 50% of patients with frontotemporal dementia (FTD). These neurodegenerative diseases are devastating for patients and are a growing societal burden. Transformative therapies are currently unavailable to patients living with ALS and FTD; thus, a deeper more complete understanding of the underlying mechanisms that trigger TDP-43 dependent neurodegeneration is urgently needed. Previously, we showed that lipid cacostasis occurs in the spinal cords of ALS patients and $SOD1^{G93A}$ mice, a familial mouse model of ALS. Here, we determined if TDP-43 mediated neurodegeneration in rNLS8 mice, a mouse model of motor neuron disease, is also associated with spinal cord lipid cacostasis. We used LC-MS to investigate the lumbar spinal cords of rNLS8 mice for potential subcellular (cytoplasmic vs. nuclear) changes in lipids. Consistent with previous studies, we demonstrate that induction of cytoplasmic TDP-43 accumulation at 3 months of age resulted in significant motor impairment in nestlet building, rotarod, and wirehang starting at 1 week. The rNLS8 mice displayed rapid disease progression with a significant loss of total, fat, and muscle mass at 3 weeks and a median time to death of 7.6 weeks. Starting at 16 days after disease induction, we measured increased levels of the full-length protein, C-terminal fragments, and S409/410 phosphorylated isoforms of TDP-43 in the cytoplasmic fraction of the lumbar spinal cord and increases in neurofilament-heavy in the serum suggesting neuronal loss. Finally, using lipidomics, we observed significant subcellular dysregulation of lipids in the lumbar spinal cord. Altogether, these results confirm that cytoplasmic TDP-43 accumulation leads to rapid progressive motor neuron disease and implicate nuclear/cytoplasmic lipid cacostasis as an important mechanism in disease progression.

Title: Impact of limb phenotype on tongue denervation atrophy, dysphagia penetrance, and survival time in a mouse model of ALS

Authors: *R. THOMPSON[1], M. MUELLER[2], K. OSMAN[2], S. KINGTON[2], Z. STEPHENSON[2], A. HAMAD[2], F. BUNYAK[2], N. L. NICHOLS[3], T. E. LEVER[4];

Abstract: Introduction
Dysphagia in ALS is predominantly attributed to progressive tongue weakness and atrophy, ultimately rendering patients unable to eat/drink by mouth. Current treatments are symptom-based (e.g., diet modification, feeding tube) and do not target the underlying tongue denervation atrophy. To address this clinical need, we are studying the low copy number SOD1-G93A (LCN-SOD1) mouse model of ALS with dysphagia and limb phenotype variability resembling human ALS. Our main goal was to quantify the impact of limb phenotype on tongue denervation atrophy, dysphagia penetrance, and survival time in preparation for future treatment-based studies. Methods Two male LCN-SOD1 breeders and 125 transgenic and wild-type (WT) offspring underwent behavioral testing for heritability of limb phenotype. Fifty-two offspring (30 LCN-SOD1 and 22 WT, both sexes) were randomly selected for characterization of dysphagia penetrance (via videofluoroscopic swallow study; VFSS) and survival time at disease end-stage (15-20% body weight loss). From these, 16 mice (8 LCN-SOD1 and 8 WT) underwent postmortem histological analysis of the tongue (genioglossus) for microscopic evidence of denervation atrophy. Results Both male breeders displayed a mixed ALS phenotype (i.e., hindlimb *and* forelimb involvement) at disease end-stage and sired equal proportions of mixed vs. hindlimb phenotype offspring. Both LCN-SOD1 phenotypes had significant dysphagia compared to WT mice ($p < 0.05$): slower lick and swallow rates, longer inter-lick and inter-swallow intervals, and longer pharyngeal transit times. Dysphagia penetrance differed between phenotypes (mixed = 100%; hindlimb = 64%), yet survival times were similar. LCN-SOD1

mice, regardless of phenotype, had significantly smaller genioglossus myofibers and more centralized myonuclei compared to WT mice ($p < 0.05$). These biomarkers of denervation atrophy were significantly correlated with VFSS metrics (lick and swallow rates, $p < 0.05$) but not survival time. Conclusions Limb phenotype heritance was only chance level for LCN-SOD1 mice, whereas dysphagia penetrance was complete for mixed (100%) versus incomplete for hindlimb (64%) phenotype mice. Remarkably, both phenotypes had tongue denervation atrophy, even hindlimb phenotype mice without dysphagia. Unlike human ALS, LCN-SOD1 mice with dysphagia and tongue atrophy did not have shorter survival times, likely due to our humane end-point criterion. Nonetheless, this mouse model recapitulates key aspects of human ALS and therefore provides a translational platform to accelerate the discovery of targeted treatments for tongue denervation atrophy and dysphagia.

Title: Investigating caspase expression and cellular localization in human retinal vascular disease

Authors: *L. RUSS[1], C. K. COLON ORTIZ[2], A. M. POTENSKI[2], C. M. TROY[3];
[1]North Carolina State Univ., Raleigh, NC; [2]Columbia Univ., New York City, NY; [3]Dept Pathol & Neurol, Columbia Univ. Medl Ctr., New York, NY

Abstract: Neurovascular injury, characterized by the breakdown of the blood-retina barrier and inflammation, has been associated with neurodegeneration. One treatment of retinal neuroinflammation targets vascular endothelial growth factor (VEGF), an inflammatory cytokine that promotes neovascularization and angiogenesis. While anti-VEGF treatments prevent neovascularization and edema, they do not prevent neuronal loss and subsequent decline in vision. Caspases, proteases that are associated with cell death pathways, increase in CNS tissues because of hypoxia-ischemia influencing neuronal death, a hallmark of neurodegeneration. Studies in a mouse model of vascular disease have indicated that activation of caspase-9 induces retinal neuronal death, and its inhibition reduces inflammation and neuronal damage. This

project's objective is to evaluate how caspase-9 expression and cellular localization in anti-VEGF treated and untreated post-mortem human retinas compares to a mouse model of neurovascular injury, retinal vein occlusion. The neuroretina is part of the CNS therefore allowing retinal findings to translate to neurological disease of the brain. The analysis tested the hypothesis that caspase-9 and caspase-7 signaling in anti-VEGF treated post-mortem human retinas will mirror that of uninjured WT mice. We collected four anti-VEGF treated and non-treated human retinas with different vascular diseases, as well as control retinas without vascular disease and immunostained them for caspases-9 and -7 and for cellular markers for endothelial cells and glial cells. Confocal images were obtained and processed via ImageJ. Our results emphasize the importance of evaluating the translational significance of anti-VEGF treatments when developing potential therapeutics for retinal vascular diseases.

Title: Cochlear neurodegeneration in deafened rats involves an immune response not requiring complement

Authors: *B. M. GANSEMER, S. H. GREEN;
Dept. of Biol., Univ. of Iowa, Iowa City, IA

Abstract: Background: Spiral ganglion neurons (SGNs) transmit information about acoustic stimuli from cochlear hair cells, the auditory receptor cells, to the CNS. SGNs slowly degenerate after hair cell loss but the reason for this degeneration is unclear because neurotrophic support remains available. Our RNA-seq and histological studies show an immune response, including complement activation, in the spiral ganglion after hair cell loss. We assessed whether complement activation contributes to SGN death using a rat model in which complement component 3 (C3) was knocked out. We assessed SGN survival in hearing and deafened $C3^{+/+}$ and $C3^{-/-}$ rats. Additionally, we analyzed histologically infiltration and activation of immune cells in the spiral ganglion.
Methods: Male and female Sprague-Dawley rats were intraperitoneally injected with kanamycin once daily from postnatal day 8 (P8) through P16 to destroy hair cells. Cochleae were collected and spiral ganglia isolated at P32 or P60 for RNAseq (6-8 ganglia per replicate). The RNAseq

data were analyzed using available computational tools and software packages. For histological analyses, cochleae from hearing and deafened $C3^{+/+}$, $C3^{+/-}$, and $C3^{-/-}$ rats were collected at P70 and cryosectioned parallel to the midmodiolar plane at 25 μm thick. Sections were labeled with antibodies to identify neurons (Tuj1), macrophages (IBA1), activated macrophages (anti-CD68), or CD4 immunoreactive cells.
Results: Gene set enrichment analysis (GSEA) revealed that the largest functional category enriched after deafening contained genes associated with an immune response. More specifically, genes involved in the complement cascade, chemotaxis, and antigen presentation were upregulated after deafening. Histological analysis revealed infiltration of macrophages and increased expression of CD68, a marker of phagocytic activity and cell activation, in the deafened ganglia. Moreover, the immune response includes not only monocytes but also CD4+ lymphocytes. However, C3 knockout did not affect SGN survival, indicating that complement activation does not play a role in SGN death after deafening.
Conclusions: Many immune response genes, including complement system genes, are upregulated in the spiral ganglion after hair cell loss, consistent with infiltration and activation of monocytes and lymphocytes. However, SGN death and IBA1+ cell infiltration were similar in $C3^{+/+}$ and $C3^{-/-}$ rats, implying that complement activation does not play a role in SGN death. The data do suggest that adaptive, as well as innate, immune responses are involved.

Title: Lrp1 as a modulator of neurotoxic astrocyte activation after stroke and traumatic brain injury

Authors: S. N. AHMAD[1], ***N. L. SAYRE**[2];
[1]Univ. of Texas Health, San Antonio, San Antonio, TX; [2]Univ. of Texas Health, San Antonio and South Texas Veteran's Hlth. Care Syst., San Antonio, TX

Abstract: Changes in gene expression patterns of glial cells can predict brain age[1] suggesting that glial function is a major contributor to changes in cognition during aging. Moreover, a history of brain damage such as from ischemic stroke or traumatic brain injury (TBI) increase the

likelihood of developing dementia or cognitive decline. **Our goal is understand a potential mechanism which underlies age-associated changes in astrocyte physiology.** With aging, astrocytes undergo a series of gene expression changes, switching their neurotrophic role to a neurotoxic role[2]. Neurotoxic reactive astrocytes have disrupted ability to promote synaptic function and improve neuronal survival after stress[3] and are induced by microglial secretion of Interleukin-1α (IL1α), Tumor necrosis factor (TNF), and Complement component C1q[3]. We have discovered a potential astrocyte mediator, Low-density lipoprotein receptor related protein 1 (**LRP1**). Located on the plasma membrane, LRP1 uses receptor mediated endocytosis to escort proteins to the endocytic system for degradation, associates with signaling complexes, and is cleaved to regulate nuclear signaling[4]. We discovered that loss of LRP1 causes increased astrocyte sensitivity to TNFα. Others found that LRP1 regulates components of the complement system,[5] and interferes with IL1 receptor signaling[6], altogether suggesting LRP1 could directly affect astrocyte sensitivity to microglia signals that activate neurotoxic astrocytes. We used an inducible Connexin-30 Cre to knockout LRP1 in astrocytes of adult mice. Mice were subjected to middle cerebral artery occlusion (MCAO) or repetitive traumatic brain injury and were aged for up to a year after injury. We discovered astrocyte KO of LRP1 had *improved* long-term behavioral outcomes after MCAO yet were *worsened* after repetitive TBI. We also found decreased astrocyte gliosis after MCAO. We think that these differential outcomes could be due to differential neurotoxic astrocyte activation. To test this, we are performing protein and gene expression studies in astrocytes lacking LRP1, while simultaneously interrogating the effect of LRP1 on neurotoxic astrocyte activation *in vivo* and in aged mouse models.

Title: Transcriptome Alterations in Myotonic Dystrophy Frontal Cortex

Authors: *B. OTERO[1], K. POUKALOV[2], R. P. HILDEBRANDT[2], E. T. WANG[2];
[1]Univ. of Florida, Gainesville, FL; [2]UF Dept of Mol. Genet. and Microbiology, Gainesville, FL

Abstract: Myotonic dystrophy (dystrophia myotonica, DM) is caused by expanded CTG/CCTG microsatellite repeats, leading to multi-systemic symptoms in skeletal muscle, heart, gastrointestinal, endocrine, and central nervous systems (CNS), among others. For some patients, CNS issues can be as debilitating or more so than muscle symptoms; they include hypersomnolence, executive dysfunction, white matter atrophy, and neurofibrillary tangles. Although transcriptomes from DM type 1 (DM1) skeletal muscle have provided useful insights into pathomechanisms and biomarkers, limited studies of transcriptomes have been performed in the CNS. To elucidate underlying causes of CNS dysfunction in patients, we have generated and analyzed RNA-seq transcriptomes from the frontal cortex of 21 DM1 patients, 4 DM type 2 (DM2) patients, and 8 unaffected controls. One hundred and thirty high confidence splicing changes were identified, most occurring exclusively in the CNS and not in skeletal muscle or heart. Mis-spliced exons were found in neurotransmitter receptors, ion channels, and synaptic scaffolds, and we identified an alternative exon in GRIP1 that modulates association with kinesins. Splicing changes exhibited a gradient of severity correlating with CTG repeat length, as measured by optical mapping of individual DNA molecules. All individuals studied, including those with modest splicing defects, showed extreme somatic mosaicism, with a subset of alleles having >1000 CTGs. Analyses of gene expression changes showed up-regulation of genes transcribed in microglia and endothelial cells, suggesting neuroinflammation, and down-regulation of genes transcribed in neurons. Gene expression of RNAs encoding proteins detectable in cerebrospinal fluid were also found to correlate with mis-splicing, with implications for CNS biomarkers of disease severity. These findings provide a framework for future mechanistic and therapeutic studies of CNS issues in DM.

Title: Remyelinating Multiple Sclerosis: effects of TLR4 blocking aptamer ApTOLL in murine EAE

Authors: *B. FERNANDEZ GOMEZ[1], D. PIÑEIRO[2], M. HERNÁNDEZ[2], P. GÓMEZ-MARTÍN[1], F. DE CASTRO[1];
[1]Cajal Inst., Madrid, Spain; [2]AptaTargets S.L., Madrid, Spain

Abstract: Multiple sclerosis (MS) is a degenerative and autoimmune chronic disease of the central nervous system (CNS) that constitutes the second cause of neurological disability in young adults. MS is characterized by the death of oligodendrocytes and the subsequent loss of myelin in both, the white and the gray matters. The autoimmune component of MS causes inflammation, demyelination, and axon. The activation of Toll-like type 4 receptor (TLR4) acts as a potent proinflammatory signal. ApTOLL is an innovative molecule developed with aptamer technology. ApTOLL is known to antagonize TLR4, generating an anti-inflammatory effect in stroke. This single chain DNA aptamer represents a novel strategy for its nature and mechanism of action to treat diseases with an important inflammatory component, such as MS. Our current research shows the immunomodulatory plus remyelinating effect of four doses of ApTOLL in the Experimental autoimmune encephalomyelitis (EAE) model of MS. A single-dose treatment at the onset of symptoms significantly ameliorates the clinical score, as well as significantly positive effects were observed in myelin and neurofilaments *in vivo*. Furthermore, this molecule seems to have a direct effect on the biology of oligodendrocytes precursors cells (OPCs) by promoting their proliferation and differentiation towards myelinating phenotypes *in vitro*. ApTOLL by itself and/or this effect combined with other neuroprotectors could be a highly innovative strategy that would cover all aspects of the ideal therapy for MS.

Title: Neuroinflammatory responses to viral-like stimuli causes alpha-synuclein aggregation and tau hyperphosphorylation in vivo with long-term changes to synaptic and vesicular transport proteins.

Authors: *O. BREKK, R. THOMAS, **K. J. CONNOLLY**, C. CLOUSE, S. ROSENTHAL, Z. K. MACBAIN, A. PERUGINI, C. M. DOUALA, P. J. HALLETT, O. ISACSON;
McLean Hosp., Belmont, MA

Abstract: In animal models, pro-inflammatory drivers mimicking either bacterial (lipopolysaccharide; LPS) (Koprich et al., 2008) or viral (polyinosinic:polycytidylic acid; POLY(I:C)) (Deleidi et al., 2010) have been shown to sensitize dopaminergic neurons to subsequent noxious stimuli in "double-hit" models of Parkinson's Disease (PD) pathogenesis. These observations indicate that host defense mechanisms -- if not physiologically resolved, and potentially in combination with genetic or environmental risk factors -- can precipitate neurodegenerative events leading to disease. To investigate early brain changes associated with acute anti-viral inflammatory responses, we unilaterally delivered the synthetic dsRNA toll-like receptor 3 (TLR3) agonist POLY(I:C) to the hippocampus and substantia nigra of WT mice. We assessed pre-degenerative changes by histology and biochemical assays at days 2, 12, and 33 post-injection, with daily behavioral readouts of sickness behavior. The results demonstrated increased proteolytic cleavage of C3 with accumulation of C1q protein levels at the 2-day time-point, with alpha-synuclein aggregation and concurrent Tau hyperphosphorylation in the ventral midbrain and hippocampus of Poly(I:C)-injected mice. There were signs of increased ApoE levels at 2 days, but not at 12 and 33 days. From day 16 onwards, the animals exhibited increased sickness behaviors which persisted until the study endpoint. Markers of axonal integrity and synaptic proteins were also studied, and the results will be reported. Additionally, to study prolonged states of chronic inflammation, WT mice were injected intra-peritoneally with POLY(I:C) for 12 consecutive months (with the last Poly(I:C) injection being at 11 months). Preliminary data suggest there is a degenerative change of the dopaminergic neurons of the SNpc at the 12-month time-point with changes related to axonal integrity and anterograde synaptic transport, and some increase of synaptic structural proteins. These attempts to mirror viral infection-induced neuronal and synaptic changes, indicate that factors associated with degeneration in PD and related brain degenerative disorders, are found in the substantia nigra and hippocampus with intra-parenchymal and systemic TLR3 stimulation.

Title: Cerebral blood flow is reduced and brain R_2* is increased in the lipopolysaccharide (LPS) model of inflammation: An in-vivo 9.4T MRI study

Authors: *Q. SHAFQAT[1,2,3], Y. WU[1,2,3], A. HAMILTON[1,2,3], M. HASHEM[1,2,3], J. F. DUNN[1,2,3];
[1]Dept. of Radiology, Fac. of Medicine, Univ. of Calgary, Calgary, AB, Canada; [2]Hotchkiss Brain Institute, Fac. of Medicine, Univ. of Calgary, Calgary, AB, Canada; [3]Dept. of Clin. Neurosciences, Fac. of Medicine, Univ. of Calgary, Calgary, AB, Canada

Abstract: Inflammation is associated with a wide range of neurological disorders. It is likely that systemic inflammation can induce inflammation in the central nervous system. Reductions in cerebral blood flow (CBF) have been reported in animal models of inflammation and in multiple sclerosis, which has an inflammatory component. Reductions in CBF have also been linked to hypoxia (low oxygenation) and declines in cognitive and behavioral function. Therefore, it is important to study the link between CBF, hypoxia, behavior, and inflammation. Here, we investigated the relationship between CBF, relaxation rate (R_2*) which is a qualitative marker of deoxyhemoglobin (dHb), and behavior in a model of systemic inflammation induced by bacterial lipopolysaccharide (LPS).

Female C57BL/6 mice received 2 mg/kg LPS (n=11) or saline (n=10) via i.p. injection once a day for 3 consecutive days. Behavior was assessed at baseline (pre-treatment) and once daily post-treatment using the open-field (OF) test. Mice were imaged in-vivo with 9.4T MRI 3 hours post-treatment on Day 3 to measure CBF and R_2*. CBF and R_2* were quantified in 7 regions. A Student's *t*-test was used to compare between control and LPS treated groups with an FDR-correction (Benjamini-Hochberg) for multiple comparisons. Linear relationships were assessed with Pearson correlation.

Compared to controls, LPS treated mice experienced significant reductions in CBF in the cortex ($p<0.001$), right and left hippocampus ($p<0.03$), right piriform cortex ($p<0.01$), and left piriform cortex ($p<0.001$). LPS also resulted in increases in R_2* in the cortex ($p<0.05$), right and left hippocampus ($p<0.05$), and right piriform cortex ($p<0.01$). R_2* increase is consistent with increase in tissue deoxyhemoglobin (dHb). Cortical CBF and R_2* were negatively correlated ($p<0.05$, $R= -0.54$). Locomotion declined significantly in the LPS group by Day 2 and 3 post-treatment ($p<0.001$). Locomotion on Day 2 positively correlated with CBF in the cortex and right piriform cortex ($p<0.01$, $R= 0.61$; $p<0.05$, $R= 0.49$, respectively), and negatively correlated with

R_2* in the cortex ($p<0.05$, $R= -0.541$).
We report regional reductions in CBF alongside increases in R_2*, which is consistent with elevated dHb. Cerebral hypoperfusion coupled with elevated dHb could be associated with abnormal oxygen delivery or increased oxygen extraction by inflamed tissues. Reductions in CBF and increases in brain R_2* also correlated with a decline in locomotion. These data support the concept that inflammation can cause hypoxia in the brain as well as a reduction in blood flow, which relate to behavioral impairment.

Title: Pharmacological inhibition of the inflammatory receptor CCR2 relieves the immediate deleterious consequences of status epilepticus

Authors: *N. VARVEL, C. ALEMAN-RUIZ, W. WANG, R. J. DINGLEDINE;
Emory Univ. Sch. of Med., Atlanta, GA

Abstract: Generalized status epilepticus (SE) triggers a robust neuroinflammatory response involving reactive astrocytosis, activation of brain-resident microglia, and brain infiltration of CCR2+ monocytes. Multiple lines of evidence indicate that quenching SE-induced neuroinflammation can alleviate the adverse consequences of SE, including neuronal damage and cognitive impairments. Our recent findings show that blocking monocyte brain entry after SE, via global *Ccr2* KO, rescues several SE-induced adverse effects including blood-brain barrier (BBB) erosion and neuronal damage while enhancing weight regain. The goals of the present study were to determine if CCR2 antagonism with a small molecule after SE blocks monocyte brain entry, dampens brain inflammation, and provides neuroprotection three days after SE. Eight- to ten-week-old male *Ccr2*$^{+/rfp}$ heterozygous mice maintained on the C57BL/6NCrl inbred genetic background were subject to intraperitoneal injection of kainic acid (KA), scored for seizure severity, weight recovery, nest building capability, and sacrificed three days post-SE. Surviving mice were randomized into CCR2 antagonist (n=19) and vehicle (n=20)

groups. The CCR2 antagonist, or vehicle, was administered 24- and 48- hours post-SE via oral gavage. Mice subject to the CCR2 antagonist displayed faster weight recovery between one- and three-days post-SE and enhanced ability to build a nest on the third day after SE when compared to their vehicle-treated controls. The mRNA levels of a panel of inflammatory mediators was depressed by a mean of 47%, and the glial markers were reduced by 30% in mice treated with the CCR2 antagonist compared to controls. CCR2 antagonism provided neuroprotection and astrocytosis was reduced in four brain regions, but the area covered by the macrophage marker, Iba1, was not significantly reduced by the CCR2 antagonist. Our findings further confirm that inflammatory processes are pathogenic after SE, provide proof-of-concept that CCR2 antagonism after SE can alleviate multiple adverse effects, and identify CCR2+ monocytes as a viable therapeutic target.

Title: Neuroprotective effects of Maqui Berry on blood-brain barrier damage in a model of Pentylenetetrazole-induced recurrent seizures in old rats.

Authors: *O. GARCÍA[1,2], A. VEGA[3], C. GARCÍA[4], D. A. MORENO[4], S. A. OROZCO[1]; [1]Unit of Med. Res. in Neurolog. Dis., Mexican Inst. of Social Security, Mexico, Mexico; [2]Dept. of Biochem., Natl. Polytechnic Inst., Mexico city, Mexico; [3]Dept. of Physiol., Natl. Autonomous Univ. of Mexico, Mexico City, Mexico, Mexico; [4]Dept. of Food Sci. and Technol., Univ. Campus of Espinardo Building 25, Murcia, Spain, Spain

Abstract: Rationale: The aging process progressively deteriorates health and quality of life, increasing susceptibility to seizures. Additionally, blood-brain barrier (BBB) dysfunction has been reported as a cause of the development of seizure activity. The Maqui Berry (MB), *Aristotelia chilensis*, contains flavonoids with strong antioxidant activity; the inhibition of oxidative stress has anticonvulsant effects. **Goal:** To assess the neuroprotective effect of MB administration on BBB damage and seizure susceptibility in old rats. **Methods:** Male *Sprague dawley* rats, 12 months of age, were administered 100 mg/kg of MB, orally, for 20 days before and during the evaluation of seizure susceptibility; a subthreshold dose of Pentylenetetrazol (PTZ) 55 mg/kg (i.p) was applied, volume of 1 ml/kg of body weight three times in 2-day intervals between each evaluation. The BBB proteins, iNOS, Cox-2 and Zo1, were evaluated by Western blot and immunofluorescence in cerebral capillaries, as well as the expression of gliosis

and neuronal survival in the ventral hippocampus using GFAP and Neun, respectively. **Results:** The MB group showed an increase in the latencies of generalized seizures, a higher expression of Zo1 proteins ($p < 0.001$), a lower expression of iNOS, Cox-2 in cerebral capillaries compared to the PTZ control group, a reduction in gliosis and greater neuronal survival in CA3 and GD. **Conclusion:** The antioxidant properties of MB protect the BBB and seizure susceptibility, which demonstrates its potential use as a neuroprotector in the adult brain.

Title: Nsc-derived ev treatment in late middle age improves cognitive and mood function with antioxidant, antiinflammatory and neurogenic effects

Authors: *R. UPADHYA, S. ATTALURI, A. VOGEL, M. KODALI, M. LEELAVATHI NARAYANA, B. SHUAI, A. K SHETTY;
Inst. For Regen Med, Texas A&M Univ. Coll Med., College Station, TX

Abstract: Age-related cognitive dysfunction is typically associated with increased oxidative stress, moderate chronic neuroinflammation, and substantially decreased hippocampal neurogenesis. In the current study, we examined the effectiveness of intranasal (IN) administration of EVs generated from the rat subventricular zone neural stem cells (SVZ-NSCs) for improving cognitive and memory function in a mouse model of aging. The EVs from the SVZ-NSC culture media were first purified by anion-exchange chromatography and then characterized using NanoSight and markers of EVs. The anti-inflammatory property of EVs employed in this study was validated through an LPS-stimulated in vitro macrophage assay. A small RNA-*seq* study also confirmed that the EVs were enriched with miRs capable of mediating anti-inflammatory and neurogenic properties. Mice were treated intranasally with SVZ-NSC-EVs once weekly for three weeks (50 billion per administration) or vehicle starting from 18.5 months of age. A month later, the animals were interrogated with a series of behavioral tests to assess cognitive and mood function, following which the brain tissues were examined for oxidative stress, neuroinflammation, and neurogenesis. Vehicle-treated aged animals exhibited cognitive impairment for discerning a minor change in the environment in an object location test and distinguishing similar but not identical experiences in a non-overlapping fashion in a pattern

separation test. These animals also exhibited spatial memory dysfunction in a water maze test and anhedonia in a sucrose preference test. Remarkably, aged animals receiving NSC-EVs showed improved cognitive and mood function in all tests performed in the study. Furthermore, NSC-EV treatment normalized elevated concentrations of oxidative stress markers malondialdehyde and protein carbonyls and the proinflammatory cytokine IL-1 beta. NSC-EV treatment also stimulated increased production of the anti-inflammatory protein IL-10 and the antioxidant superoxide dismutase. Additional characterization demonstrated modulation of neuroinflammation typified by reduced astrocyte hypertrophy and activated microglia, and enhanced hippocampal neurogenesis in NSC-EV-treated animals. Thus, intranasal administration of NSC-EVs in late middle age improves cognitive and mood function, associated with the modulation of oxidative stress, neuroinflammation, and neurogenesis in the hippocampus.

Title: Iduronate-2-sulfatase transport vehicle restores peripheral and central manifestations of MPS II disease in a mouse model of Hunter Syndrome

Authors: A. ARGUELLO, H. N. NGUYEN, E. R. THOMSEN, B. TSOGTBAATAR, M. FANG, S. S. DAVIS, I. A. LOPEZ, R. MEISNER, A. BHALLA, C. S. MAHON, M. S. KARIOLIS, A. G. HENRY, J. M. HARRIS, P. E. SANCHEZ, *K. SCEARCE-LEVIE; Denali Therapeut., South San Francisco, CA

Abstract: Mucopolysaccharidosis type II (MPS II) is a lysosomal storage disorder caused by deficiency of the iduronate-2-sulfatase (IDS) enzyme, resulting in cellular accumulation of glycosaminoglycans (GAGs) throughout the body. Treatment of MPS II remains a considerable challenge as current enzyme replacement therapies do not adequately control many aspects of the disease, including skeletal and neurological manifestations. We developed an IDS transport vehicle (ETV:IDS) that is engineered to bind to the transferrin receptor; this design facilitates receptor-mediated transcytosis of IDS across the blood-brain barrier and improves its distribution into the brain while maintaining distribution to peripheral tissues. We have leveraged the MPS II mouse model to discover clinically translatable biomarkers and assess target, pathway, and disease-relevant changes following ETV:IDS administration. Here we demonstrate that chronic systemic administration of ETV:IDS reduced levels of peripheral and central nervous system (CNS) GAGs, reduced CNS lysosomal lipids, and reduced microgliosis in the brain of MPS II

mice. Additionally, ETV:IDS rescued auricular and skeletal abnormalities when introduced in adult MPS II mice. These effects were accompanied by improvements in several neurobehavioral domains including motor skills, sensorimotor gating, and learning and memory. Using fluid-based biomarkers, we also observed increases in markers of neuroinflammation, neurodegeneration, and bone dysplasia in this mouse model, some of which were reduced following administration of ETV:IDS. Altogether, these results highlight the therapeutic potential of ETV:IDS for treating peripheral and central abnormalities in MPS II and supports the use of these clinically translatable biomarkers to monitor MPS II disease progression and treatment outcomes with therapies such as ETV:IDS. DNL310, an investigational ETV:IDS molecule, is currently in clinical trials as a potential treatment for patients with MPS II.

Title: Targeting regulatory T cells to treat nerve injury-induced dynamic mechanical allodynia

Authors: *R. HU[1], J. ZHANG[2], X. LIU[1], D. HUANG[3], Y. CAO[1];
[1]Dept. of Anesthesiol., St. Louis, MO; [2]Dept. of Anesthesiol., Guangzhou, China; [3]Dept. of Pain Mgmt., Changsha, China

Abstract: Abstract Dynamic mechanical allodynia, the pain evoked by light brushing or stroking of the skin, is one of the most disabling symptoms of neuropathic pain. Despite the recent progress in elucidating the underlying mechanisms, effective treatment of dynamic allodynia remains elusive. Previous studies indicate that the immunosuppressive regulatory T (Treg) cells modulate the magnitude of punctate mechanical allodynia resulting from sciatic nerve injury. However, whether enhancing Treg-mediated suppression attenuates dynamic allodynia is not known. Daily low-dose interleukin-2 (ld-IL2) treatment has been used in many preclinical and clinical studies to preferentially expand and activate the endogenous Treg cells in peripheral tissues. In the present study, we investigated whether ld-IL2 treatment and Treg cell transfer are effective for the prolonged punctate and dynamic allodynia resulting from unilateral spared nerve injury (SNI) in mice. Daily ld-IL2 treatment from 5 days before SNI to 21 days post-injury completely blocked the development of SNI-induced dynamic mechanical allodynia and reduced the magnitude of punctate allodynia in female Swiss Webster mice. Delaying the initiation of ld-IL2 treatment to 7
days post-injury significantly attenuated the morphine-resistant punctate and dynamic allodynia at 3-5 weeks post-SNI. Furthermore, adoptive transfer of Treg cells to male C57BL/6J mice 3 weeks post-SNI effectively reversed the persistent punctate and dynamic allodynia, supporting that the effect of ld-IL2 is mediated through endogenous Treg cells, and is likely independent of mouse strain and sex. Neither ld-IL2 treatment nor Treg transfer affected the basal responses to punctate or brush stimuli. To elucidate the site of action of ld-IL2, we examined the effects of

SNI and ld-IL2 on the distribution of CD3+ T cells, especially the Treg cells, in the sciatic nerves and the lumbar L4 dorsal root ganglia (DRG) of female DEREG transgenic mice that express EGFP in Treg cells. There were very few CD3+ or EGFP+ T cells in the dorsal horn of the spinal cord after SNI and/or ld-IL2. In contrast, ld-IL2 significantly increased the frequency of Treg cells among total CD3+ T cells in the injured sciatic nerves but not in the uninjured nerves or the DRG at 30 days post-SNI, suggesting the injured nerve as ld-IL2's site of action. Collectively, the present study identifies Treg cell as a promising target and ld-IL2 as a potential therapy for nerve injury-induced persistent punctate and dynamic mechanical allodynia that are highly debilitating and are largely unresponsive to available treatments.

Title: Target engagement of a SCO-spondin-derived peptide ensuring neuroprotection and synaptic transmission in the CNS

Authors: *S. LEMARCHANT[1], M. SOURIOUX[1], S. AGUÉRO[2], S. HUGUES[3], M. FARINELLI[3], N. CALLIZOT[4], J. LE DOUCE[1], N. DELÉTAGE[1], R. TERREUX[2], Y. GODFRIN[1];
[1]Axoltis Pharma, Lyon, France; [2]ECmo Team, Tissue Biol. and Therapeut. Engin. Laboratory, UMR 5305 CNRS UCBL, Lyon, France; [3]E-Phy-Science, Sophia-Antipolis, France; [4]Neuro-Sys, Gardanne, France

Abstract: Neurodegeneration and synaptopathy are common features of CNS diseases and injuries which disrupt neural circuits and the execution of motor and cognitive functions. The subcommissural (SCO)-spondin is a brain-specific glycoprotein that strongly contributes to neuronal development during embryogenesis. The aim of this study was to investigate the effect of a SCO-spondin-derived peptide (NX210c) on neuroprotection and synaptic transmission and to identify NX210c receptors mediating such properties. Cell culture, electrophysiology and *in silico* methods were used as target engagement assays in parallel. NX210c promoted neuronal survival and prevented neurite network retraction against glutamate (glu)-induced excitotoxicity on rat cortical neurons by activating the PI3K/mTOR pathway and by disrupting apoptosis. NX210c neuroprotective effect was abolished in presence of an anti-β_1-integrin antibody (cell

death: glu = 31%, glu/NX210c = 10%, glu/NX210c/antibody = 33%) or an inhibitor of Notch signaling pathway (cell death: glu = 31%, glu/NX210c = 9%, glu/NX210c/DAPT = 23%), suggesting that β_1-integrin and Notch may represent putative receptors of NX210c (Delétage *et al.*, 2021). NX210c increased field excitatory postsynaptic potentials (fEPSP) in the somatosensory cortex after stimulation of the ventrobasal thalamus compared to vehicle-perfused brain slices (normalized fEPSP slopes at 400 µA: vehicle = 88 µA vs NX210c =119 µA). Similarly, NX210c also increased fEPSP in the hippocampal CA1 stratum radiatum after stimulation of Schaffer collaterals and commissural pathway. Evoked isolated NMDA- and AMPA-receptor excitatory postsynaptic currents (EPSC) were significantly increased in hippocampal CA1 pyramidal neurons after stimulation of Schaffer collaterals when brain slices were perfused with NX210c (amplitude of NMDA EPSC: vehicle = 53 pA vs NX210c = 102 pA). Further patch clamp experiments showed that on contrary to GluN2B, GluN2A subunit of NMDA receptors triggered the increase of EPSC in presence of NX210c. According to the results obtained using cell cultures and electrophysiology, an *in silico* approach using SUMO® and Rosetta® docking methods confirmed the strong binding of NX210c to β_1-integrin, Notch1, GluN2A subunit of NMDA receptors, and GluA1, GluA2 and GluA3 subunits of AMPA receptors. Collectively, these results show that NX210c represents an innovative drug candidate with a unique multifunctional mechanism of action to treat CNS diseases and injuries; it triggers neuroprotection through its binding to β_1-integrin and Notch receptors, and synaptic transmission through its binding to specific glutamatergic receptors.

Abstract
A promising attempt to regenerate peripheral nerve involves the cell-based therapy that can differentiate to neurons and/or secrete trophic factors to promote nerve regeneration. Dental pulp stem cells (DPSCs) are derived from the neural crest, which also gives rise to peripheral neurons and glia. Their similarity with the neuronal cells such as the strong neuronal marker molecules and neurotransmitter receptor expression suggests that DPSCs can actively adopt in the neuronal environment and promote neural regeneration. Furthermore, DPSCs are relatively easy to obtain through a minimally invasive procedure in adults and children. We have recently demonstrated that the complement C5a system, which is an important mediator of inflammation and tissue regeneration, is activated after complement activation by lipoteichoic acid-treated pulp cells, governs the production of brain-derived nerve growth factor (BDNF). This BDNF secretion promotes neurite outgrowth towards the injury site. Here, we extend our observation to DPSCs and compare their neurogenic ability to bone marrow-derived mesenchymal stem cells (BM-MSCs). Our ELISA and immunostaining data demonstrate that C5a receptor (C5aR) blocking reduced BDNF production on DPSCs, while the treatment with C5aR agonist increased the BDNF expression suggesting C5aR`s positive regulatory role in the BDNF modulation on DPSCs. Importantly, DPSCs produced significantly higher levels of C5aR-mediated BDNF compared to BM-MSCs. This observation is consistent with our real-time qPCR data. Taken together, these data make DPSCs as an ideal stem cell source for neural regeneration.

Title: Investigating the regulation of T148 phosphorylation on alphaA-crystallin and its impact on interactions with apoptosis-related proteins

Authors: *Z. B. SLUZALA, P. E. FORT;
Ophthalmology and Visual Sci., Univ. of Michigan, Ann Arbor, MI

Abstract: Our lab has shown that the functional and biochemical properties of the molecular chaperone protein αA-crystallin are regulated by its phosphorylation on residue T148. We previously showed that its solubility, oligomeric structure, and chaperone and neuroprotective functions are all controlled by T148 phosphorylation. Mechanistically, while we have shown that αA-crystallin regulates Bax translocation by interacting with and sequestering it into the cytoplasm, αA-crystallin's interactome and its regulation by T148 phosphorylation were still unknown. In the present study, we set to identify the kinase responsible for T148 phosphorylation and characterize αA-crystallin's interactome and its regulation by T148 phosphorylation. Since we showed that αA-crystallin is highly induced in both retinal neurons and glia we performed this study in both differentiated R28 retinal neurons and MIO-M1 Müller glial cells. Cells were transfected with plasmids encoding either 3x-FLAG-tagged wild-type (WT) or 3x-FLAG-tagged T148C αA-crystallin and exposed to "diabetes-like" stress (2h incubation with 100ng/ml TNFα and 25mM glucose) which we previously showed induced phosphorylation. Kinase identification was performed using the chemoproteomic PhAXA assay which requires a chemical crosslinker to stabilize kinase/substrate interactions, after which kinase/substrate complexes are immunoprecipitated and analyzed via western blot (WB) or liquid chromatography with tandem mass-spectrometry (LC-MS/MS). Specific complexes were observed by WB in the T148C +crosslinker condition, and CK2, one of the top candidate kinase predicted by bioinformatics, was identified by LC-MS/MS. Confirming the specificity of the kinase interaction, it could be outcompeted by incubation with excess ATP. Regarding αA-crystallin interactome, LC-MS/MS analysis of the 3x-FLAG-tagged WT pulldowns revealed 43 proteins shown through KEGG pathway analysis to be apoptosis-related, including Bax. The current study for the first time supports the prediction that CK2 can phosphorylate αA-crystallin and that αA-crystallin's interactome includes multiple apoptosis regulatory proteins in retinal neurons, consistent with the strong neuroprotective role of αA-crystallin in these cells.

Title: Dual threats of CSPGs in multiple sclerosis through inhibiting oligodendrocyte repair and polarizing Th17 cells

Authors: *S. GHORBANIGAZAR[1], W. YONG[2];
[1]university of calgary, calgary, AB, Canada; [2]Hotckiss Brain Inst. and Dept. of Clin. Neurosci., university of Calgary, calgary, AB, Canada

Abstract: In multiple sclerosis (MS), oligodendrocytes and myelin are damaged by immune responses. Remyelination failure contributes to the axonal loss and progression of disability. The failed repair process could be the consequence of ongoing toxic neuroinflammation and to inhibitors in lesions. The extracellular matrix (ECM) molecules, including members of the chondroitin sulfate proteoglycan (CSPG) family, contribute to the altered microenvironment of MS lesions. CSPGs, particularly versican V1, have been described to directly inhibit the differentiation of oligodendrocyte precursor cells (OPCs) and to prevent remyelination. Herein, we examined ECM members for their expression in lesions of MS and experimental autoimmune encephalomyelitis (EAE), a model of MS, and addressed whether these ECM molecules alter immune responses that then affect tissue repair in MS lesions.
By immunofluorescence confocal microscopy, we found increased levels in spinal cord EAE lesions of versican V1, fibronectin, thrombospondin-1 and heparan sulfate proteoglycans (HSPGs), but not versican V2 or aggrecan. Versican V1 deposition was confirmed in active MS lesions. In culture, a mixed CSPG preparation and purified versican V1, but not other ECM molecules tested, shifted T cell differentiation toward Th17 cells, which were then inhibitory for OPC differentiation. CSPG-polarized Th17 cells also killed OPCs. To inhibit CSPG synthesis in vivo, EAE mice were injected with difluorosamine (peracetylated,4,4-difluoro-N-acetylglucosamine) starting at the peak of clinical disease severity. Difluorosamine-treated mice has reduced injury-enhanced versican content in spinal cord lesions correspondent with lower frequency of Th17 cells. To study the effect of difluorosamine on remyelination during EAE, NG2-Cre:Tau-mGFP mice were used with GFP expression localized to newly formed oligodendrocytes and myelin. Drug was initiated from peak clinical
severity. We found that difluorosamine reduced levels of versican V1 in well-formed EAE lesions resulting in higher number of new oligodendrocytes and myelin sheets around and within lesions. These results highlight lesion-elevated CSPGs, especially versican V1, in directly inhibiting OPCs and indirectly in shaping T cell responses which then impact remyelination outcomes. We propose CSPG-lowering drugs as dual pronged repair therapeutics that directly affect OPCs, and that indirectly antagonize Th17 roles in inflammation and oligodendrocyte injury.

Title: Srebp2 signaling is essential for emopamil binding protein inhibitor-induced oligodendrocyte precursor cell differentiation

Authors: *G. SHENG[1], C. ZHU[1], Y. HUANG[1], J. FARLEY[1], J. GANS[1], S. MADDEN[1], A. BYRNE[1], L. GUO[1], X. CHAMLING[2], D. ZACK[2], K. RADZWILL1[1], G. MERRIMAN[1], G. GAO[1], T. Abstract: Immunotherapies significantly reduce CNS lesion formation and relapse rate in Multiple Sclerosis (MS) patients; however, they largely fail to prevent the accumulation of permanent disability that arises from axonal and neuronal damage, particularly during the progressive phase of the disease. Thus, therapeutic strategies that stimulate remyelination to promote neuroprotection are being explored for the treatment of MS. Pharmacological enhancement of myelination through the maturation of endogenous oligodendrocyte precursor cells (OPC) is responsive to several stimuli, including compounds that induce the accumulation of intermediate sterols. Specifically, inhibition of sterol isomerase emopamil binding protein (EBP), which catalyzes the conversion of zymosterol and zymostenol to dehydrolathosterol and lathosterol in the cholesterol biosynthesis pathway, effectively promotes oligodendrocyte precursor cell differentiation and remyelination in preclinical models of MS. However, the mechanism underlying the effect of EBPi on OPC maturation remains unknown. Here, we treated rat OPCs with EBP inhibitors or
triiodothyronine (T3) for 72 hours and then performed RNA-Sequencing. Differential expression profiles were found for both EBPi and T3. Interestingly, a subset of genes regulated by sterol regulatory element binding protein 2 (SREBP2) were significantly upregulated by EBPi but not by T3. Similarly, in single-cell RNA sequencing of the human embryonic stem cell-derived OPCs we found that SREBP2 was also activated by the EBPi. Repeated experiments showed a consistent upregulation of the SREBP2 signaling pathway by EBPi. Lastly, we found that inactivating SREBP2 signaling using PF-429242, an inhibitor of site-1 protease (S1P) which cleaves the SREBP2 precursor into its mature form, prevented EBPi induced OPC differentiation and the expression of myelin-associated genes. These results suggest that activation of the SREBP2 signaling pathway plays a crtical role in EBPi induced OPC differentiation and myelin formation**.**

Title: Pericytes play a protective role during neuroinflammation

Authors: *D. ATAK, A. B. GÖKYÜZÜ, E. YILDIZ, E. ÖZKAN, M. YOUSEFI, A. B. KIZILIRMAK, Y. GÜRSOY-ÖZDEMIR, A. VURAL;
Koç Univ., Istanbul, Turkey

Abstract: Background: Pericytes play a key role in blood-brain-barrier (BBB) maturation and maintenance of immune homeostasis in the central nervous system (CNS). Ablation of pericytes in developing mice causes vascular abnormalities, BBB leakage and, increased infiltration of leukocytes to the CNS in later life both in steady-state and pathological conditions. However, the effect of pericyte ablation during neuroinflammation in the presence of a fully mature BBB is unknown. **Aim:** In this study, we first aimed to generate a tamoxifen-inducible pericyte ablation model in adult mice. Then, we investigated the effect of pericyte loss on neuroinflammation in an experimental allergic encephalomyelitis (EAE) model. **Methods:** PDGFRβ-PA2-CreER+/- mice (JAX Mice, 030201) were crossed with Rosa26-DTA176+/+ mice (JAX Mice, 010527). After genotyping, 9-10 weeks old PDGFRβ-Cre+/DTA176+ (Cre+) mice were injected with 0.1mg/g tamoxifen (TAM) for two, three, or five consecutive days to induce the expression of diphtheria toxin in PDGFRβ+ pericytes. PDGFRβ-Cre-/DTA176+ (Cre-) mice were used as

controls. After 15 days, animals were sacrificed to assess pericyte coverage and numbers, and PDGFRβ gene expression in the cortex and spinal cord. After analysis, 2X TAM injection model was selected for EAE studies. MOG35-55 (Hooke Labs, EK2110) was used to induce EAE 15 days after TAM injection. Cre- and wild-type C57BL/6 mice were used as controls. Weight change and clinical scores were monitored for 28 days. Analysis was done by repeated-measures 2-way ANOVA multiple comparison test. **Results:** There was a 75% (+-SEM=0.9192) decrease in pericyte coverage in the cortex ($p<0.01$) and a 40% (+-SEM=2.385) decrease in the spinal cord ($p<0.01$) after 2X TAM injection (n=7). Similarly, Pdgfrβ gene expression was decreased to 55% (+-SEM=2.230) in the cortex ($p=0.017$) and 59% (+-SEM=4.511) in the spinal cord ($p=0.048$). During EAE, pericyte-ablated mice (n=7) had a more severe clinical score after Day 20 ($p=0.0086$, 0.0036, 0.0054, 0.07,0.041). Pericyte ablated mice lost more weight than the wild type mice ($p=0.0020$, 0.0101, 0.0039, 0.0064, 0.0181, 0.0091, 0.0006 from Day16 to 28). In addition to the spinal cord lesions, inflammatory foci were also detected in the periventricular region in the brain of the pericyte ablated mice but not in control mice. **Comment:** We have generated and characterized a TAM inducible pericyte ablation model in adult mice that does not require injection of a toxin. By using this model, pericytes were shown to play an important role during the resolution of inflammation.

Title: Differential regulation of metabolic pathways in oligodendrocyte precursor cells in response to distinct stimuli

Authors: *J. LEE, M. KORNBERG;
Johns Hopkins Univ., Baltimore, MD

Abstract: Multiple sclerosis (MS) is an autoimmune neurodegenerative disease with features of demyelination by self-reactive T cells and limited remyelination as oligodendrocytes that produce myelin are damaged. In MS lesions, the differentiation of oligodendrocyte progenitor cells (OPC) to oligodendrocytes is blocked, resulting in a lack of mature oligodendrocytes to repair myelin. The mechanisms underlying this blockage of OPC differentiation are poorly understood. Therefore, it is critical to investigate the mechanisms of OPC differentiation to

promote remyelination and develop regenerative treatments to complement current therapies that target the immune system and rely on anti-inflammatory effects. Interestingly, inflammatory cytokines have also been shown to inhibit OPC differentiation and result in a different phenotype featuring characteristics similar to activated immune cells. The metabolic balance between glycolysis and oxidative phosphorylation critically regulates immune cell fate; further, a metabolic switch is observed in stem cells, which rely on a high glycolysis rate to preserve their self-renewal capacity. These findings reveal a new function of OPCs in inflammation and suggest the possibility of metabolic regulation of OPC fate, with metabolic reprogramming serving as a checkpoint between pro-inflammatory and remyelinating OPC phenotypes. In this study, we investigated the metabolic programming of OPCs in response to various factors. We exposed OPCs to distinct stimuli including proliferating (PDGF-aa), differentiation promoting (T3), and inflammatory (IFN-γ) signals. We then measured the extracellular acidification rate (ECAR) and oxygen consumption rate (OCR) to analyze real-time ATP production rate. OPCs treated with T3 had a decrease in overall ATP production when compared to cells treated with PDGF-aa. IFN-γ treatment also decreased overall ATP production, but with a higher dependency of oxidative phosphorylation for ATP production. We plan to evaluate glycolytic programming of OPCs in distinct contexts of inflammation or remyelination *in vivo*. Further on, we will perform untargeted metabolomics identify metabolic pathways and metabolites that regulate inflammatory vs. remyelinating OPC fates. We will correlate metabolomics analysis to existing RNA-seq.

Title: Integrin-αM/cd11b inhibits β-glucan elicited regeneration of mammalian optic nerve axons

Authors: *R. PASSINO[1], X.-F. ZHAO[1], C. JOHNSON[1], L. HUFFMAN[2], M. FINNERAN[2], R. KAWAGUCHI[3], D. H. GESCHWIND[3], R. J. GIGER[1];
[1]Cell and Developmental Biol., [2]Neurosci. Grad. Program, Univ. of Michigan, Ann Arbor, MI; [3]Dept. of Neurol., UCLA, Los Angeles, United States, CA

Abstract: The immune system and the nervous system are in constant dialogue, and this interaction is particularly intense following nervous system injury. Intra-ocular injection of polymeric β [1-3]-glucose (β-glucan) triggers a strong immune response in the eye. When combined with retro-orbital optic nerve crush injury (ONC), β-glucan promotes lengthy regeneration of severed retinal ganglion cell (RGC) axons. In marked contrast, intra-ocular lipopolysaccaride triggers an immune response that does not support RGC axon regeneration. For an in-depth analysis of the β-glucan triggered immune response, we micro-dissected retinas and optic nerves from mice 3 days after ONC and intra-ocular injection of β-glucan or saline (PBS). Innate immune cells were isolated by immunopanning and subjected to single cell RNA-sequencing. A comparative analysis revealed that the retinal/intra-ocular immune milieu in β-glucan treated mice is dominated by neutrophils, monocytes/macrophages, and few microglia. In the injured optic nerve, microglia greatly outnumber macrophages and seven different microglia subpopulations were identified. Pharmacological ablation of microglia with the CSF1R inhibitor PLX56622 attenuated β-glucan elicited optic nerve regeneration, suggesting that microglia are necessary for immune-mediated axon regeneration. Differential gene expression and pathway analysis of scRNA-seq data under regenerating and non-regenerating conditions identified complement activation as one of the top hits. The complement receptor 3 (CR3) is composed of two subunits CD11b/(integrin αM) and CD18/(integrin β2). Because Integrin αM directly binds to β-glucan, we subjected *Itgam*-/- mice to intra-ocular β-glucan injection and ONC. Surprisingly, optic nerves from *Itgam*-/- mice showed significant increased axon regeneration when compared to parallel processed WT nerves. Increased RGC regeneration in *Itgam*-/- mice was blocked when combined with PLX5622 treatment. The complement component C3 is strongly upregulated in the retina of β-glucan injected mice. However, the increased RGC regeneration observed in *Itgam*-/- mice is not due to disruption of the CR3 receptor, since *C3*-/- mice failed to mimic the RGC regeneration phenotype observed in *Itgam*-/- mice. Ongoing experiments are focused on exploring the mechanism(s) that underlie the increased RGC axon regeneration observed in *Itgam*-/- mice.

Title: The Regulatory Role of TAM Receptors in Experimental Autoimmune Encephalomyelitis

Authors: *A. MUNIE[1], B. SEGAL[2];
[1]The Univ. of Michigan, Ann Arbor, MI; [2]The Ohio State Univ., Columbus, OH

Abstract: Multiple Sclerosis (MS) is an inflammatory demyelinating disease of the central nervous system (CNS), believed to be autoimmune in etiology. Myeloid cells comprise the majority of inflammatory cells in MS lesions and may play both pathogenic and regulatory roles during disease evolution. Studies in experimental autoimmune encephalomyelitis (EAE), a murine model of MS, indicate that activation of TAM family of receptor tyrosine kinases (Tyro3, Axl, Mer) on myeloid cells curbs neuroinflammation and promotes neuroprotection, thereby improving clinical outcomes. However, the mechanism of action of TAM receptors in this context is not fully understood. We found that Axl and MerTK are upregulated on a subset of alternatively activated Arg-1+ macrophages and monocyte-derived dendritic cells, that accumulate in the brain and spinal cord from the peak to late stages of EAE. EAE typically presents as an ascending paralysis associated with spinal cord lesions. Treatment with a TAM antagonist (LDC1267) converted the clinical manifestation of EAE to an atypical from, characterized by ataxia and hindbrain lesions. Collectively, our data suggest that the dominant effect of TAM receptor signaling in CNS myeloid cells is to selectively protect the brain against inflammatory infiltration. These findings reflect the heterogeneity of neuroinflammatory pathways across CNS compartments, which might explain the diversity of MS with respect to clinical course and therapeutic responsiveness.

Col. of Wisconsin-Prevea Hlth., Green Bay, WI; [5]Dept. of Obstetrics & Gynecology, Univ. of Texas, Houston, TX

Abstract: Introduction: One structural hallmark of Fetal Alcohol Syndrome (FAS) is a massive loss of neurons and oligodendrocytes (OLs). Dysregulation of lipids in myelin leading to apoptosis of oligodendrocyte precursor cells (OPCs) and altered OL differentiation has been shown in FAS rodent models but there are significant gaps in our understanding of the FAS-specific mechanisms of OL lipid loss and enhanced dysmyelination in the human fetus. We recently demonstrated an EtOH-dependent decrease in myelin basic protein (MBP, a marker for mature OLs), increased markers for OPC, increased in caspase-3 activity, and increased TNF-α in the human fetal brain early in gestation. Free fatty acid (FFA) effects are mediated *via* specific G protein-coupled receptors (FFAR), influencing OL development and myelination. We hypothesize that FAS is associated with a deficiency in ω-3 FFA, and that OL-derived exosomes (OL-Es), which can be isolated from maternal serum, carry FFA biomarkers for FAS. **Methods**: Blood samples were collected from EtOH-exposed and control pregnant women, stratified by gestational age, gender, and race according to an IRB-approved protocol. OL-Es were isolated from 250 μL of maternal blood, using MBP. EtOH-associated dysmyelination was assessed. OL-E mRNA was assayed by ddPCR for OL markers and FFAR expression. OL-E MBP and FFAR protein levels were quantified by ELISA (normalized to CD81) and flow cytometry assays. **Results**: Downregulation of FFAR was greatest in EtOH-exposed cases (n=6). Statistically significant downregulation of the MBP mRNA and protein levels also was found in EtOH-exposed OL-Es, but not in non-pregnant women. **Conclusion**: Non-invasive assessment of fetal OL-E biomarkers in clinical studies offers an opportunity to confirm pre-clinical findings. Future studies should focus on the correlation between OL-E markers and clinical phenotype/outcomes in FAS offspring and could further lead to clinical trials of dietary corrections of lipid abnormalities (*e.g.*, dietary ω-3 supplementation), to reduce dysmyelination in at-risk fetuses and in children with FAS.

Title: Social Enrichment Ameliorates Chemotherapy Induced Peripheral Immune Cell Trafficking

Authors: W. H. WALKER, II[1], J. R. BUMGARNER[1], J. A. LIU[1], O. H. MELÉNDEZ-FERNÁNDEZ[1], J. C. WALTON[1], R. J. NELSON[1], A. C. DEVRIES[1,2,3];
[1]Neurosci., [2]Medicine, Div. of Oncology/Hematology, [3]WVU Cancer Inst., West Virginia Univ., Morgantown, WV

Abstract: Chemotherapy is a mainstay in cancer treatment. It is estimated that as many as 650,000 cancer patients receive chemotherapy in an outpatient setting each year. Although chemotherapy has greatly increased survival rates and has superior anti-tumor efficacy, it is not without some detrimental side effects. Patients receiving chemotherapy commonly display somatic symptoms such as nausea, vomiting, diarrhea, neutropenia, and others. Furthermore, patients receiving chemotherapy commonly demonstrate non-somatic symptoms such as fatigue, depression, anxiety, and impaired cognitive function. Notably, the amount of social support prior

to cancer treatment predicts the levels of cognitive dysfunction and depressive symptoms in cancer survivors. Previous work for our lab has demonstrated the ability of social enrichment to attenuate chemotherapy induced neuroinflammation and affective behavior via oxytocin signaling in mice. However, the precise mechanism of chemotherapy-induced neuroinflammation and subsequent attenuation by social enrichment remains unknown. We hypothesized that chemotherapy increases peripheral immune cell trafficking within the CNS leading to neuroinflammation. Female Balb/C mice were randomly assigned to treatment groups and placed into their assigned housing (single or triad housing). One week later, mice received their first injection of vehicle (0.9% saline) or chemotherapeutic cocktail (9 mg/kg doxorubicin and 90 mg/kg cyclophosphamide). Fourteen days later mice received their second injection of vehicle or chemotherapeutic cocktail. One week following the second injection, mice were euthanized via transcardial perfusion, brains were extracted, and immune cells were isolated using a Percoll gradient and quantified via flow cytometry. Similar to our previous experiments, we did not observe neither an expansion of the microglia population ($CD11b^{+}$, $CD45^{intermediate/low}$, $Ly6G^{-}$) nor increased activation of microglia ($MHCII^{+}$) measured by flow cytometry following chemotherapy administration. However, singly housed mice receiving chemotherapy increased monocyte ($CD11b^{+}$, $CD45^{high}$, $Ly6C^{+}$, $Ly6G^{-}$) and neutrophil ($CD11b^{+}$, $CD45^{high}$, $Ly6C^{-}$, $Ly6G^{+}$) trafficking. Notably, social enrichment attenuated the increased neutrophil trafficking and prevented increased monocyte trafficking. These data are the first to demonstrated altered immune cell trafficking within the CNS following chemotherapy administration and provide further support for the potential beneficial effects of social enrichment.

Title: Cell Cycle Inhibitor p21 Expression Decrease in PPMS Cerebral Organoids Leads to Exhaustion of The Progenitor Pool Independently of Apoptosis Pathway

Authors: T. EDWARDS, E. CHEN, *N. DAVIAUD, S. A. SADIQ;
Tisch Multiple Sclerosis Res. Ctr. of New York, New York, NY

Abstract: Multiple sclerosis (MS) is an auto-immune neurological disorder characterized by inflammation, demyelination, and neural degeneration. The origin and evolution of MS are still poorly understood because of lack of animal models and relative inaccessibility to human brain tissue. Cerebral organoids represent an interesting tool to study neurological disorders as they

recapitulate early human neurodevelopment, including the generation, proliferation and differentiation of neural progenitors into glial cell and neurons.The purpose of this work was to use patient with MS induced pluripotent stem cells derived cerebral organoids to study the genetic components of MS. This model was used to analyze the human neural stem cell population in control and MS organoids after 42 days in vitro.The cell cycle inhibitor p21 is essential for the maintenance of stem cell quiescence and self-renewal. Immunostainings showed a high expression of p21 in the ventricular zone of control organoids. This expression was highly reduced in PPMS organoids compared to control and other subtypes of MS. Further analysis of the stem cells revealed that this decrease of p21 was associated with a significant reduction of the expression of the stem cell marker SOX2 and of the proliferation marker Ki67 in PPMS organoids compared to control, indicating a smaller stem cell pool and a reduced proliferation rate respectively. To explore if p21 expression in organoids is involved in the DNA damage and apoptosis pathway, immunostainings for γH2AX, p53, and CC3 were performed. Low to no γH2AX-positive cells were found in control and PPMS organoids, indicating low DNA damage. No difference was observed between the two conditions. p53 was detected in the ventricular zone/subventricular zone in both control and PPMS organoids, but there was no difference in p53 expression between the two conditions. A few CC3+ cells were detected in organoids, particularly localized in the upper cortical layers, with low to no positive cells in the stem cell population. No difference in CC3 expression was detected in PPMS compared to control organoids, indicating that there were no or low involvement of the apoptosis pathway in MS samples. Our data indicates that the reduced p21 expression in PPMS is independent of the p53/apoptosis pathway and is related to cell cycle only, leading to an exhaustion of the progenitor pool. Patient derived cerebral organoids may be a viable human model to study MS pathogenesis.

Title: Tat and gp120 promote microglial activation that can be ameliorated by corticosterone in a dose- and time-dependent manner: Implications for neuroHIV-like behavior

Authors: *E. MOSS[1], C. WORTH[2], F. MAHDI[1], J. PAIRS[1];
[1]Biomolecular Sci., [2]Chem. and Biochem., The Univ. of Mississippi, Oxford, MS

Abstract: The immunological effects of human immunodeficiency virus (HIV) infection are appreciated, but less well understood are its effects on the central nervous system (CNS). Combinatorial antiretroviral therapies (cART) attenuate the effects of HIV peripherally; however, approximately half of all cART-treated people with HIV contend with neurocognitive and neuropsychiatric complications referred to as "neuroHIV." The mechanisms of neuroHIV are not known, but likely involve the presence of neurotoxic HIV proteins in the CNS. In particular, the HIV virotoxins, trans-activator of transcription (Tat) and glycoprotein 120 (gp120), promote neuroinflammation via the activation of microglia. In search of novel therapeutics, we and others have found steroids to ameliorate the direct effects HIV virotoxins. We hypothesized that Tat and gp120 would activate microglia in cell culture, increase anxiety-like behavior in mice, and that steroid-based interventions would ameliorate these effects. In a human microglial cell line (HMC3) exposure to Tat (50 ng/mL) or gp120 (500 pM) increased the proportion of cells with a phagocytic morphology and reduced the proportion of resting cells when observed 6 h or 24 h later (but not 2 h later). The stress hormone, corticosterone, attenuated these effects when administered at 100 nM (but not 32 or 320 nM). Notably, the pre-glucocorticoid neurosteroid, TH-DOC, also demonstrated some capacity to attenuate Tat- (but not gp120) mediated microglial activation. When assessed i*n vivo*, conditional expression of Tat in transgenic mice increased anxiety-like behavior in an open field and this was exacerbated by co-infusion of gp120 (100 pM, bilateral intracerebroventricular). Steroid-based therapeutics may offset neuroinflammatory drivers of CNS dysfunction. In particular, glucocorticoid receptors on microglia may mediate Tat- and gp120-related activation, whereas neurosteroid targets (such as $GABA_A$ receptors) may be more involved in Tat-related activation alone. These data support the notion that CNS exposure to Tat and gp120 can exert additivity to promote neuroHIV-like behavior.

Title: Neurosteroids influence HIV-1 Tat-mediated HPA dysregulation and anxiety-like behavior

Authors: *M. SALAHUDDIN[1], F. MAHDI[2], J. J. PARIS[3];
[1]BioMolecular Sci., [2]Univ. of Mississippi, Oxford, MS; [3]BioMolecular Sci., The Univ. of Mississippi, University, MS

Abstract: Background: Human immunodeficiency virus (HIV) is associated with comorbid affective and stress-sensitive neuropsychiatric disorders (collectively referred to as neuroHIV) that afflict ~50% of infected individuals. Moreover, approximately ~46% of HIV patients show dysfunction of the hypothalamic-pituitary-adrenal (HPA) stress axis, but the mechanisms are not known. One factor that may contribute to HPA dysfunction is actions of the neurotoxic HIV-1 regulatory protein, trans-activator of transcription (Tat). Our prior studies in male mice revealed HIV-1 Tat to promote psychomotor and anxiety-like behavior. These behavioral effects occurred concurrent with an elevation of basal corticosterone and adrenal insufficiency in response to natural stressor or pharmacological blockade of HPA feedback, recapitulating the clinical endophenotype. The HPA axis, which mediates the neuroendocrine response to stress is tightly regulated by the GABAergic signaling and deficits of GABAergic signaling may reciprocally contribute to neuroendocrine dysfunction, conferring vulnerability to stress-sensitive disorders. Given that neurosteroids are potent allosteric modulators of $GABA_A$ receptor, enhancing neurosteroidogenesis may ameliorate HPA-related dysfunction in the context of HIV. Hypothesis: We hypothesized that the central infusion of the 18 kDa translocator protein agonist, FGIN-1-27, will boost neurosteroidogenesis and curtail Tat-induced HPA activation and associated behavioral deficits. Methods: Transgenic mice that expressed the Tat_{1-86} protein [Tat(+)] or not [Tat(-)] were administered either vehicle or FGIN-1-27 (5 µg/µL) directly to the lateral ventricle via an ALZET osmotic minipump (7 days) and behaviorally-tested in an open field and light-dark transition task. Results: In male mice, FGIN-1-27 administration enhanced circulating corticosterone concurrent with a decrease in anxiety-like behavior demonstrated by reduced time spent in the light zone and an increased latency to enter the dark zone in the light-dark transition test in mice. These data provide proof-of-principle that enhancing neurosteroidogenesis in the central nervous system can influence the HPA axis and reduce anxiety-like behavior. Additional studies will further assess the capacity for FGIN-1-27 to ameliorate Tat-promoted HPA deficits and related affective dysfunction. Conclusion:Therapeutic strategies that promote neurosteroidogenesis may improve HIV-related stress-sensitive disorders.

Title: Hiv-1 tat influences morphine reward and voluntary oral morphine consumption among ovariectomized female mice

Authors: *A. QRAREYA[1], M. SALAHUDDIN[1], F. MAHDI[1], T. VUJANVIC[1], P. SERRANO[2], J. PARIS[1];
[1]Univ. of Mississippi, University, MS; [2]Hunter Col., New York, NY

Abstract: In the era of combinatorial antiretroviral therapy, people with human immunodeficiency virus (HIV) are still at risk for chronic pain (~25-90%). As a consequence, opioids are clinically prescribed to a greater degree in the HIV+ population (~21-53%). HIV-infected individuals may be more vulnerable to develop opioid tolerance and substance abuse exacerbates HIV-associated neurocognitive disorders. While the mechanisms that underlie HIV interactions with opioids are not well-understood, we and others have found the HIV-1 regulatory protein, trans-activator of transcription (Tat), to potentiate the rewarding properties of drugs of abuse in male mice. We hypothesized that Tat expression would potentiate morphine's rewarding and reinforcing effects in ovariectomized (OVX) female mice that conditionally-expressed Tat in a doxycycline-dependent manner. As expected, inducing Tat expression significantly potentiated morphine-conditioned place preference (CPP) among OVX female Tat-transgenic mice. However, when mice were allowed to voluntarily self-administer a control quinine solution (2 mg/kg, PO) or escalating doses of morphine (0.6, 1.2, 2 mg/kg, PO) for 14 days, Tat-exposed mice consumed significantly less morphine (mg/kg body weight) than did control mice. All mice self-administrated more morphine than quinine. Naloxone-induced withdrawal behavior confirmed that mice had reached morphine-dependence. In a follow-up experiment, mice were exposed to quinine or escalating doses of morphine for 21 days. All mice escalated morphine consumption to a greater degree than in the 14-day experiment; however, Tat-exposed mice continued to voluntarily self-administer less morphine than control mice. Together, data obtained in the CPP paradigm may indicate an increase in the rewarding valence of morphine among Tat-exposed females, thus requiring less self-administration in the voluntary oral consumption task order to achieve an optimal hedonic effect. Differences in the neurocircuitry of brain regions involved in drug of abuse reward and reinforcement will be sought. Thus, these data demonstrate that HIV-1 Tat protein enhances the rewarding properties of morphine while reducing the demonstration of reinforcing behavior.

Title: Fronto-cortical neurovascular damage induced by morphine and HIV-1 Tat resembles accelerated brain aging

Authors: *M. OHENE-NYAKO[1], Y. HAHN[2], S. R. NASS[3], P. E. KNAPP[4], K. F. HAUSER[5]; [2]Anat. & Neurobio., [3]Dept. of Pharmacol. and Toxicology, [4]Dept Anat & Neurobio., [5]Pharmacol. & Toxicology, [1]Virginia Commonwealth Univ., Richmond, VA

Abstract: Fronto-cortical neurovascular damage induced by morphine and HIV-1 Tat resembles accelerated brain aging.
Authors: Michael Ohene-Nyako, Yun K. Hahn, Sara R. Nass, Pamela E. Knapp, and Kurt F. Hauser Fronto-cortical neurodegeneration occurs in HIV-infected individuals. In age-associated neurocognitive disorders, such pathology indicates the presence of pathologic protein aggregates, small vessel disease, and neuroaxonal degeneration. Opiate abuse is prevalent in the HIV-infected population; however, it is unknown if the comorbidity converges to enhance fronto-cortical age-related pathologic changes. We evaluated (i) vascular integrity using levels of claudin-5 (cldn5) and albumin (Alb), (ii) pathologic protein aggregates, and (iii) neuroaxonal damage by examining hyperphosphorylated tau load (p-tau), beta-amyloid (Aβ) levels, oligodendroglial (OLG) numbers, and neurofilament light chain (NFL) levels in the prefrontal cortex (PFC) of control and inducible HIV-1 Tat transgenic male mice that received morphine (10–40 mg/kg, increasing by 10 mg/kg/b.i.d., s.c. weekly) for 6 weeks. Levels of cldn5, Alb, Aβ, and NFL were evaluated by immunoblotting. Sub-anatomical Cldn5 expression, Alb leakage, OLGs, and p-tau load were determined by immunofluorescence assays in the anterior cingulate (ACC) and primary motor (M1) cortices. Tat decreased cldn5 and increased Alb levels in the PFC. Morphine exacerbated the Tat effects on cldn5 and Alb. Tat, and to a lesser extent morphine exposure, increased levels of NFL, Aβ peptide, and oligomeric forms. Enhanced NFL and Aβ pathology were observed in the comorbid brain. Immunofluorescence findings revealed that Tat and morphine independently dysregulated cldn5 and enhanced Alb leakage in the ACC. Morphine, but not Tat, altered Cldn5 and Alb immunofluorescence in the M1 cortex. The proportion of ACC p-tau-immunoreactive cells was increased by Tat irrespective of morphine treatment, but the opposite was observed in the M1. Morphine decreased CC1-stained OLG numbers in the ACC irrespective of genotype. No OLG reductions were observed in the M1. Neuroaxonal injury and small vessel disease in the M1 and ACC are associated with motor and cognitive dysfunction in Alzheimer's disease. Thus, our results may predict an accelerated risk for developing similar age-associated disorders in opiate abusing, HIV-infected individuals.

Title: Contrasting effects of HIV-1 Tat and morphine on depressive-like behaviors are associated with inflammation and neurodegeneration within prefrontal cortico-amygdalar circuits

Authors: *S. R. NASS[1], M. OHENE-NYAKO[1], V. D. MCLANE[1], Y. K. HAHN[2], P. E. KNAPP[1,2,3], K. F. HAUSER[1,2,3];

Abstract: HIV-1 trans-activator of transcription (HIV-1 Tat) can be expressed in the CNS of persons infected with HIV (PWH) resulting in emotional deficits, despite antiretroviral therapy, and these deficits can be further exacerbated by opioid use. Within prefrontal cortico-amygdalar (PFC-amygdala) circuits, inflammation and neurodegeneration can lead to depression and anxiety. To explore HIV-1 Tat- and morphine-induced emotionality deficits, Tat(+) and Tat(-) male mice were exposed to HIV-1 Tat for 8 weeks and administered saline or ramping doses of morphine twice daily (s.c.) during the last 2 weeks of HIV-1 Tat exposure. Mice were behaviorally tested in a battery of depressive-like behaviors 4 h after morphine administration to limit opioid-induced locomotor effects. In the novelty suppressed feeding test, morphine increased eating behavior, whereas in the novelty induced hypophagia test, Tat decreased sucrose intake, indicating that morphine and Tat differentially alter anhedonia in response to palatable and non-palatable food stimuli. Mice were also test in assays of daily living to model apathy. In home cages, Tat also decreased nesting behavior, whereas morphine decreased burrowing. Together, these data suggest that HIV-1 Tat and morphine differentially induce depressive-like behavior. Although innate immune tolerance appeared to develop within the PFC, Tat(+) mice administered morphine exhibited increased depressive-like behavior that correlated positively with PFC levels of CXCL1 in the forced swim test; whereas previous data indicated increased mobility in the forced swim test after Tat exposure alone correlated negatively with PFC expression of CXCL1. Interestingly, in Tat(+) mice administered morphine increased levels of TNFα, IL-3, and IL-10 also positively correlated with increased response to food stimuli. Tat decreased dendritic spine density on pyramidal neurons in layer V of the anterior cingulate region of the prefrontal cortex and the basolateral amygdala (BLA), but not the medium spiny-

type neurons within the central nucleus of the amygdala (CEA). Tat also increased amyloid-β (Aβ) levels within the amygdala. Together, our findings suggest that HIV-1 Tat and morphine differentially induce depressive-like behavior and are associated with Tat-induced neuronal damage within the prefrontal-amygdalar circuits.

Title: Cxcr6 contributes to neuroinflammation by maintaining tissue resident memory cd8+ cells in the cns in a viral recovery model

Authors: *S. F. ROSEN, A. SOUNG, W. YANG, S. AI, M. KANMOGNE, V. DAVE, J. A. MAGEE, R. S. KLEIN;
Washington Univ. Sch. of Med., St Louis, MO

Abstract: $CD8^+$ T cells are key players in pathogen elimination and viral clearance after central nervous system (CNS) infection. However, antiviral T cells can persist in the CNS for years after recovery from neurotropic viral infections. While T cells are important initially for viral clearance, their persistence in the CNS can lead to chronic microglial activation and long-term cognitive sequelae and neuronal damage. Published data from our lab has shown that $CD8^+$ T cell derived IFN-γ signaling in microglia causes persistent microglial activation in the CNS, and contributes to learning and memory deficits after recovery from viral infection. However, the mechanism by which $CD8^+$ T cells persist within the CNS is not known. We show, for the first time, that the CXCL16/CXCR6 chemokine signaling pathway is necessary for the maintenance of T_RM T cells in the CNS after recovery from CNS West Nile Virus (WNV) infection. Using an unbiased single-cell RNA-sequencing (scRNA-seq) approach, we see that CXCL16 levels are elevated in activated microglia and CXCR6 levels are elevated in $CD8^+$ T cells in the cortex and hippocampus 25 days after WNV infection. Additionally, 52 days after viral recovery, CXCR6 KO mice have reduced numbers of T_RM $CD8^+$ and viral-specific T cells, as well as decreased microglial activation, in the cortex and hippocampus compared to WT mice. We further show that CXCR6 KO mice recover synapses in the CA3 region of the hippocampus, which are eliminated during acute infection, by 52 days after viral recovery. Here, we have identified an

underappreciated role of the CXCL16/CXCR6 pathway in the maintenance of T_RM cells in the CNS parenchyma. Targeting of this pathway may be a successful approach for the prevention of learning and memory deficits that persist after recovery from viral encephalitis.

Title: Chronic, low dose methamphetamine reveals sexual dimorphism in memory performance impaired by exposure to HIV-1 Tat protein

Authors: M. KAUL[1,2,3], R. MAUNG[1,2], D. OJEDA-JUÁREZ[1,2], P. SANCHEZ-PAVON[2], A. B. SANCHEZ[2,3], A. J. ROBERTS[4], &. TMARC GROUP[3];

Abstract: We investigated the effects of chronic, low-dose methamphetamine (METH) use in the context of HIV infection of the brain. Therefore, we subjected transgenic mice that express a tetracycline-inducible viral protein Tat in the brain (iTat mice) at 4 months of age to a 12-week METH regimen starting week 1 at 0.5 mg/kg s.c., 1 x day, step-wise increase by 0.5 mg/kg with each injection over 5 days (Mon-Fri), followed by 11 weeks of 1 x 2.5 mg/kg/day. During week 4, the mice received Doxycyclin (Dox, 100 mg/kg, i.p.) for induction of Tat expression. The mouse cohort included rtTA-positive TRE-Tat-negative control animals, which cannot express Tat upon Dox injection, and comprised about 50 % females and males. Four months after METH exposure, at 11-12 months of age, all iTat-tg mice underwent behavioral testing, including optomotor test of vision (OPT), locomotor activity (LM), novel object recognition (NO) and Barnes maze test (BM; 4 day acquisition + probe trial). Tat compromised performance in the NO and BM paradigms but the combination of METH and Tat resulted unexpectedly in a virtually

normal performance in the probe trial of the BM. However, the NO paradigm revealed a sexual dimorphism in that METH alone only compromised males, whereas females, in contrast to males, displayed no discrimination between familiar and novel object after exposure to Tat with or without METH. Thus, METH apparently compromises recognition but not spatial memory in a sex-dependent fashion.

Title: Hiv-1 nef expression in astrocytes of the nucleus accumbens increases cocaine-induced seeking behavior in rats

Authors: *J. PLA-TENORIO, M. ALVARADO-TORRES, G. RODRIGUEZ-TORRES, M. CRUZ-RENTAS, B. VELAZQUEZ-PEREZ, M. COLON-ROMERO, M. SEPULVEDA-ORENGO, R. J. NOEL, Jr.;
Ponce Hlth. Sci. Univ., Ponce, Puerto Rico

Abstract: Recreational use of cocaine increases the risk of acquiring HIV and exacerbates HIV-related disease by increasing replication and damage to the central nervous system (CNS). In addition to cellular injury, studies have shown that cocaine can also alter the brain's reward system and could work synergistically with viral proteins to promote neuronal injury. Production of HIV neurotoxins contributes to HAND even with cART-suppressed replication. When HIV replication is well-controlled, the neurotoxic HIV-1 Nef protein is more likely to cause pathology than other viral proteins because it is produced by astrocytes. In this study, we focus on determining the impact of HIV-1 Nef on cocaine-seeking behavior in rats. We hypothesize that Nef will increase sensitivity to cocaine leading to an enhanced drug seeking. Using Sprague Dawley (SD) rats, we infused a lentiviral vector expressing Nef from an astrocyte specific GFAP promoter into the nucleus accumbens (NAc), an important structure involved in the development of cocaine abuse. After recovery, we used an addiction paradigm where rats were exposed to 10 sessions of a short-access cocaine self-administration, followed by 14 sessions of extinction. After extinction, all rats underwent a cue-primed reinstatement followed by a session of cocaine-primed reinstatement three days later. Rats were then sacrificed for further molecular analysis by

immunofluorescence and western blot. Our preliminary data demonstrated that SD rats expressing Nef in the NAc had an increased sensitivity to cocaine during the self-administration sessions. In addition, the Nef group reinstated similarly to the control group during cue-primed reinstatement. However, during cocaine-primed reinstatement, the Nef group increased cocaine seeking compared to the control group. These data suggest that an enhanced cocaine seeking in Nef animals may be driven by a heightened sensitivity to cocaine. Moreover, future studies will focus on understanding the principal mechanisms involved in the co-exposure of HIV-1 Nef and cocaine-related extracellular glutamate regulation.

Title: Methamphetamine Augments HIV-1 gp120 Attenuation of Synaptic Transmission and Plasticity in Rat Hippocampal Slices

Authors: Y. ZHENG[1], B. C. REINER[2], J. LIU[1], ***H. XIONG**[1];
[1]Dept. of Pharmacol. and Exptl. Neurosci. Univ. of Nebraska Med. Ctr., Omaha, NE; [2]Ctr. for Neurobio. and Behavior, Univ. of Pennsylvania, Philadelphia, PA

Abstract: Methamphetamine (Meth) abuse and human immunodeficiency virus type 1(HIV-1) infection are two major public health issues worldwide. Being frequently comorbid with HIV-1 infection, Meth abuse exacerbates neurocognitive deficits in HIV-1-infected individuals even in the era of combined antiretroviral therapy. While a large body of research has studied the individual effects of Meth and HIV-1 envelope glycoprotein 120 (gp120) in the brain, far less has focused on their synergistic influence. Moreover, it is well-documented that the hippocampus is the primary site of spatial learning and long-term memory formation. Alteration of synaptic transmission and plasticity in the hippocampus is believed to impact cognitive function. To uncover the underlying mechanisms of the increased incidence and severity of HIV-1-associate neurocognitive disorders (HAND) in HIV-1-infected patients with Meth abuse, we investigated acute individual and combined effects of Meth and gp120 on synaptic transmission and plasticity in CA3 to CA1 synapses in rat hippocampus, a brain region known to be vulnerable to HIV-1 infection. Our results showed that localized application of Meth and gp120 each alone onto the

CA1 region of hippocampal slices reduced short-term dynamics of input-output responses and frequency facilitation, and attenuated long-term potentiation (LTP) induced by high frequency stimulation as well as theta burst stimulation. A synergistic augmentation on synaptic plasticity was observed when Meth and gp120 were applied in combination. Paired-pulse facilitation results exhibited an altered facilitation ratio, suggesting a presynaptic site of action. Further studies revealed an involvement of microglia NLRP3 inflammasome activation in Meth-induced augmentation of gp120-associated attenuation of LTP. Taken together, our results demonstrated Meth augments gp120-mediated attenuation of synaptic plasticity in the hippocampus. Since LTP is the accepted experimental analog of learning at the synaptic level, Meth augmentation of gp120 attenuation of LTP may underlie Meth exacerbation of HAND observed clinically.

Biomed. Sci., Univ. of North Dakota, Grand Forks, ND

Abstract: The crosstalk between peripheral infection-induced inflammation and the central nervous system is becoming increasingly evident. *Streptococcus pyogenes* (Group A Streptococcus, GAS) bacteria cause a spectrum of human diseases ranging from self-limiting pharyngitis and mild uncomplicated skin infections (impetigo, erysipelas, cellulitis) to highly morbid and rapidly invasive life-threatening infections such as streptococcal toxic shock syndrome and necrotizing fasciitis (NF). Polymorphisms in human leukocyte antigen class-II (HLA-II) alleles are linked with differential outcomes and severity of GAS infections. While post-streptococcal neurological and neuropsychiatric conditions are associated with autoimmune

response to host mimics of GAS proteins (molecular mimicry), it is not known whether invasive GAS NF can induce neuroinflammatory changes that may lead to behavioral and cognitive dysfunction. To study the consequences of peripheral GAS skin infection on the brain, we used a NF model with and without treatment with clindamycin (CLN), the standard antibiotic care, using HLA-II transgenic mice that mimic inflammatory responses and outcomes as seen in humans. Mice expressing HLA-II DR3 or DR4 alleles were divided into three groups: uninfected controls, GAS infected, and GAS infected with resolution by CLN treatment (10mg/kg/5 days). The groups were monitored for 15 days post-infection. Skin GAS burden and hippocampal mRNA levels of inflammatory markers S100A8/A9, IL-1β and IL-33, inflammasome-related Casp1 and NLRP6 were elevated in DR3 but not DR4 mice. The levels of these markers were significantly reduced following CLN treatment in DR3 mice. Although GAS was not detectable in the brain, astrocyte and microglia activation were evident from increased GFAP and Iba-1 mRNA levels and immunoreactivity in HLA-II DR3 mice. Collectively, our data suggest a skin-brain axis during GAS NF, and the proinflammatory "cytokine storm" implicated in the pathogenesis of invasive GAS infections may regulate neuroinflammatory changes and glial phenotype alterations in an HLA-II allele-specific manner. Further investigation is warranted for developing therapeutic strategies to attenuate long-lasting brain inflammation due to latent GAS infection in those who are genetically "at-risk" and prevent possible cognitive dysfunction as a sequela.

Title: Isoflurane exposure has no effect on behavioral outcomes following repeated diffuse brain injury in male and female mice

Authors: *L. B. TUCKER[1,2], A. H. FU[1,2], Y. KIM[1,2], J. T. MCCABE[1,2,3];
[1]Uniformed Servies Univ. of the Hlth. Sci., Bethesda, MD; [2]Pre-Clinical Behavior and Models Core, Bethesda, MD; [3]Ctr. for Neurosci. and Regenerative Med., Bethesda, MD

Abstract: Experimental brain injury is usually performed under anesthesia for humane reasons. However, questions arise regarding the clinical relevance of the employment of anesthesia, as well as concerns of neuroprotective properties of anesthetic agents such as isoflurane. The goal

of the current study was to determine the effects of isoflurane exposure on anxiety- and depressive-like behaviors following repeated diffuse brain injury in mice. Male and female mice were placed in restraint cones and randomly assigned to one of the following groups: 1) 4X (24-hr interval) traumatic brain injury (TBI; induced with the Closed-Head Impact Model of Engineered Rotational Acceleration (CHIMERA) device) with isoflurane (approximately 4 min/day), 2) 4X sham procedures with isoflurane (approximately 4 min/day), 3) 4X TBI with no isoflurane, and 4) 4X sham procedures with no isoflurane. Righting times were observed following injury procedures; almost all unanesthetized mice regained the righting reflex immediately following injury whereas mice that underwent anesthesia remained in a supine position for several minutes. For approximately seven weeks following TBI or sham procedures, mice were tested for anxiety-like behaviors in the open field test (OFT) and elevated plus maze (EPM), and for depressive-like behaviors in the three-chambered sociability test and tail suspension test (TST). The effects of TBI on anxiety-like behaviors were test and/or time-dependent; injured mice were more anxious (displayed more thigmotactic behavior) in the OFT than sham mice on Day 4 following the final injury, but spent more time in the open arms of the EPM than sham mice on Day 20 following injuries, suggesting reduced anxiety or increased risk-taking behaviors. TBI had no effect on social behaviors on Day 32 following injury, but there was an injury by sex interaction effect on immobility time in the TST on Day 40, with injured males having less immobility time than sham-treated males. Aside from time to regain the righting reflex, isoflurane exposure had no effect on any measured behaviors. Pathological analysis is on-going, but preliminary data suggest that this TBI model induces mild damage limited to white matter. Overall, these data suggest that brief durations of isoflurane exposure in a nonsurgical TBI model do not affect the functional consequences of mild, repeated TBI in mice.

Title: Early intervention with levetiracetam or brivaracetam prevent injury-induced changes in AMPA receptor expression after traumatic brain injury in rats

Authors: *D. LING[1], R. ZANCA[2], A. SANJANA[1], P. QUAN[1], A. MEJIA-BAUTISTA[1], T. RODRIGUEZ[2], J. H. GOODMAN[3], P. A. SERRANO[2];

Abstract: One of the pathologic sequels of traumatic brain injury (TBI) is the development of epilepsy. In the controlled cortical impact (CCI) model of TBI in rats, severe cortical trauma leads to posttraumatic epileptogenesis (PTE) characterized by evoked and spontaneous ictal-like discharges. We have found that timely, post-injury administration of the pyrrolidone antiseizure drugs (ASDs) levetiracetam (LEV) or brivaracetam (BRV) can prevent PTE after CCI injury. In this study, we examined the effects of post-injury administration of BRV and LEV on injury-induced changes of glutamatergic AMPA receptor subunit expression. Rats were subjected to severe CCI trauma (2.0 mm depth) at post-natal day 25 – 30. Randomly selected CCI-injured rats were given a single dose of LEV (150 mg/kg, IP) or BRV (21 mg/kg, IP) immediately after injury, while drug-control subjects received only the saline vehicle. Sham-injured control rats were not subjected to CCI injury. Three weeks after injury, rats were euthanized and their brains snap-frozen for western blot analysis. Hemispheres ipsilateral to the CCI site were evaluated for GluA1 and GluA2 levels. We found that the ratio of GluA1 to GluA2 levels in CCI-injured rats were significantly higher than those in sham-injured subjects ($p < 0.05$), which would be consistent with an increase in synaptic excitation due to a potential shift towards calcium-permeable AMPA receptor expression. Analysis of tissue from CCI-injured rats treated with LEV or BRV suggests that early intervention with these ASDs prevented the injury-induced change in the GluA1/GluA2 ratio. These findings may provide insights to the pathogenic mechanisms of TBI that give rise to neural circuit hyperexcitation and epileptogenesis, and to the antiepileptogenic mechanisms of LEV and BRV.

Title: Increased sensitivity to ketamine’s behavioral effects in mice exposed to mild blast induced traumatic brain injury.

Authors: *C. BROWNE[1], H. A. WULF[1], M. L. JACOBSON[1], M. OYOLA[2], T.-Y. J. WU[2], I. LUCKI[1];

Abstract: Neurobehavioral deficits emerge in approximately 50% of patients following a mild traumatic brain injury (TBI). These effects may persist for months following recovery from the initial trauma. Ketamine is used frequently in medicine for management of anesthesia, pain and psychiatric disorders. However, patients with a history of TBI may develop differential sensitivity to the neurological and behavioral effects of ketamine, complicated their treatment. Therefore, this series of studies examined male C57BL/6J mice exposed to a single blast overpressure, inducing a mild blast TBI (mbTBI), for indications of altered sensitivity to ketamine at varying times after injury. Dystaxia (altered gait), diminished sensorimotor gating (reduced prepulse inhibition) impaired working memory (step-down inhibitory avoidance), and behavioral performance in the forced swim test and the sucrose preference test were evaluated following intraperitoneal injections of R,S-ketamine hydrochloride in mbTBI and sham animals. Dynamic gait stability was compromised in mbTBI mice on day 7 and 35 post injury and further exacerbated following ketamine administration. On day 14 and 42 post injury, prepulse inhibition was robustly decreased by mbTBI, which ketamine further reduced. Ketamine-associated memory impairment was apparent selectively in mbTBI animals 1 and 24 h post shock (tested on day 15/16 post injury). Blast exposure increased immobility scores (day 28) and reduced sucrose consumption (Day 74), and these effects were reversed selectively by ketamine treatment. Together these data demonstrate enhanced sensitivity to ketamine over an extended period in mice following a TBI. The results endorse the potential of ketamine as a treatment for neuropsychiatric complications that emerge after TBI but urge caution in clinical practice for enhanced sensitivity to its side effects in this patient population.

Title: Development of a touchscreen device for assessing pig cognition

Authors: *C. VONDER HAAR[1], K. M. PECHACEK[1], S. K. WAMPLER[1], W. AO[1], M. GRACE[1], C. L. FLOYD[2];

Abstract: Porcine models of disease have become prominent for a number of disorders with relevance to cognition, including traumatic brain injury, Alzheimer's disease, Huntington's disease, and exposure to neurotoxins. Despite the importance of cognitive dysfunction for each of these cases, relatively few studies focus on assessment of behavioral outcomes, likely due to a lack of readily-available tools. To address this problem, we developed a touchscreen for assessing pig behaviors. A Raspberry Pi microcomputer was used to control a touchscreen. Custom programs were written in Python using the tkinter package for a graphical user interface. A peripheral printed circuit board provided interface with a 28-volt pellet dispenser (1 gram fruit-flavor sucrose). Two iterations of this device were tested: version 1.0 with a capacitive touchscreen and screen-adjacent pellet dispenser, and version 2.0 with a resistive touchscreen and remote pellet dispenser. All mechanical/electrical elements worked well and can be acquired or produced for a low cost. Pigs acquired a response to the touchscreen in the first session and took another 2-3 sessions to become accurate to smaller illuminated squares on the screen. Pigs then underwent testing on a delay discounting task and showed a robust aversive response to the delay. Ongoing experiments are assessing a complex discrimination task. Version 1.0 of the device worked reasonably well for training, but the capacitive touchscreen was not amenable to testing without an experimenter to wipe the screen down from saliva and ultimately failed due to a crack in the LCD display element. Version 2.0 uses a commercial-grade resistive touchscreen and testing is ongoing with this device. Ultimately, pigs were readily trained to the touchscreen and can rapidly be tested on cognitive assessments. Additional training sessions (AM/PM) may improve upon the speed of this process even further. On the physical side, some components require additional hardening against the strength of pigs and studies are ongoing to optimize the components so that the device may be brought to labs studying disorders with relevance to cognitive function.

Title: Discrepancies in chronic behavioral deficits and inflammatory responses between male and female rats following traumatic brain injury

Authors: *S. K. WAMPLER[1], K. M. PECHACEK[1], M. A. FRANKOT[2], C. VONDER HAAR[1];
[1]The Ohio State Univ., Columbus, OH; [2]West Virginia Univ., Morgantown, WV

Abstract: Traumatic brain injury (TBI) often results in chronic deficits in decision making and impulsivity. Neuroinflammation is a potential contributor to the development of such symptoms following brain injury. Our lab previously demonstrated that brain injury increased impulsivity and decreased optimal decision making in male rats. The current study compared long-term behavioral outcomes on tasks of impulsivity (five-choice serial reaction time task) and risky decision-making (rodent gambling task) in male rats versus female rats after TBI and compared that against histological measurements of glial inflammatory activity. After training, rats were given a bilateral frontal controlled cortical impact injury. After one week of recovery, rats were retested for 11-15 weeks and then perfused and immunohistochemistry stains performed for IBA-1 and GFAP. Both male and female rats had significant and chronic increases in impulsivity and reduced optimal decision-making, however the magnitude of this effect was less pronounced in female rats. Conversely, female rats displayed significant increases in IBA-1+ microglial cells in the perilesion area, while male rats did not. Female rats also had significantly increased GFAP+ astrocytic cells. These data suggest that the inflammatory response may not be as directly tied to the development of chronic behavioral deficits or that there are critical sex differences in inflammation which converge upon similar functional outcomes. It is important to continue to investigate the effects of TBI in females to determine effective treatment strategies for females as well as males.

Title: Cueing Risky Outcomes Impairs Decision-Making, Increases Impulsivity, and Augments Traumatic Brain Injury-Induced Deficits in Rats

Authors: *K. M. PECHACEK[1], C. A. FUERTES[2], S. K. WAMPLER[1], C. VONDER HAAR[1]; [1]The Ohio State Univ., Columbus, OH; [2]West Virginia Univ., Morgantown, WV

Abstract: Traumatic brain injury (TBI) is a leading cause of disability world-wide and results in the development of psychiatric symptoms including risky decision-making, impulsivity, and substance dependence. It is not well known how substance dependence develops after TBI, but dopamine dysfunction and behavioral impairments such as risky decision-making and impulsivity have important roles. Cues related to drug use can induce drug-seeking behavior and relapse, which are of relevance. The goal of this study was to assess the role of cues on decision-making and impulsivity, determine how these interact with post-TBI behaviors, and evaluate dopamine modulation via pharmacological challenges. Rats were trained on the rodent gambling task (RGT), an operant task that measures risky decision-making and impulsivity, or the cued version of this task (the cRGT). The RGT has four different choice options with varying corresponding probabilities of reinforcement or punishment, with two safe choices (lower magnitude of reinforcement, but more optimal) and two risky options (higher magnitude of reinforcement, but overall detrimental). In the cRGT, the cues increase in complexity and variability associated with the size of reinforcement and drive risky decision-making. After a behavioral baseline was established, rats received moderate-to-severe bilateral frontal controlled cortical impact injuries or sham procedures. Starting at 10 weeks post-injury, two acute dopaminergic drug challenges were given to probe potential dopamine system alterations: amphetamine (0.3, 1.0, 1.5 mg/kg) and methylphenidate (0.5, 2.0, 5.0 mg/kg). Prior to injury, cues increased impulsivity and changed the choice prolife on the RGT (*p's* < 0.001). Cues and TBI decreased optimal decision-making in an additive fashion (*p's*< 0.001). Additionally, cues increased impulsivity as an additive effect in sham but not TBI rats ($p < 0.001$; $p = 0.059$). For the dopaminergic manipulations, both amphetamine and methylphenidate did not affect optimal decision-making or impulsivity. Further research is needed to understand the biological mechanism by which cues exert their effects on decision-making and impulsivity.

Title: Early life stress effects on cognitive performance after a mild traumatic brain injury in adult male rats

Authors: *A. SALINAS GARCÍA, J. ZAMUDIO FLORES, J. MEJÍA OLIVA, N. LAJUD;
Ctr. de Investigación Biomédica de Michoacán, Inst. Mexicano de Seguridad Social, Morelia, Mexico

Abstract: Early life stress (ELS) increases the vulnerability to a pediatric traumatic brain injury (TBI). However, weather if this effect is maintained when the injury is performed in adults remains unknown. For this reason, we evaluated if exposure to ELS in the form of maternal separation affects cognitive performance after a mild and severe TBI in adults. A controlled cortical impact injury of mild (mTBI) and moderate (TBI) intensities (2.6 and 2.8 mm respectively at 4m / s) was performed in control and maternally separated (MS, 3 hours a day from postnatal day 1 to 21) adult rats (110 days of age). Cognitive performance was evaluated in the Morris water maze (MWM) from post-injury day 14 to 18 and a probe trial was assessed on post injury day 19. As expected, our results indicate that moderate TBI but not mTBI affects cognitive performance in the learning phase of the MWM; however, MS + mTBI rats showed a significant impairment in cognitive performance when compared to Shams. No differences were observed on the probe trial. In conclusion, our data indicate that MS increases cognitive deficits after a mTBI but not after a more severe injury. This results highlight the importance the interaction between early environment and the brain insults later on life and suggest a possible difference in adaptation depending on the severity of the second hit.

Title: Neurobehavioral and physiological effects of traumatic brain injury in spontaneously hypertensive rats

Authors: *R. REDDY, P. RENNERFELDT, E. H. MOSCHONAS, B. WEHRMEYER, T. RANELLONE, S. BALAJI, J. P. CHENG, A. E. KLINE, C. O. BONDI;
Phys Med. Rehab, Safar Ctr. for Resuscitation Res., Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Introduction. 2.8 million people sustain a traumatic brain injury (TBI) yearly, with many experiencing long-term disabilities often exacerbated by pre-existing comorbidities. In the USA, an estimated 50% of adults suffer from hypertension, which may lead to heart attacks, reduced blood flow to muscles, strokes, and premature death. There is a critical need to investigate TBI in hypertensive rats to better characterize neurological, physiological, and cognitive impairments, and to enhance translatability. This study explores the effects of TBI on Spontaneously Hypertensive Rats (SHR) via a battery of behavioral assays, such as motor coordination/balance, hippocampal-dependent learning, sustained attention, and anxiety-like symptoms. Hypothesis: Hypertension will exacerbate TBI-induced deficits. Methods. We conducted a pathophysiological study on SHR rats compared to normotensive Wistar Kyoto (WKY) rats. Rats were randomly assigned to receive either a cortical impact injury or a sham injury. Adult male SHR-TBI rats exhibit 10% higher heart rate and 30% higher mean arterial pressure than injured WKY counterparts. TBI and sham SHR rats underwent beam-walk tests (post-operative days 1-5) and water-maze (postoperative days 14-19) testing to assess motor coordination and spatial learning, respectively. Open field testing (OFT) and the shock probe defensive burying (SPDB) task were then performed to examine anxiety-like and active/passive coping behavior, respectively. To examine sustained attention and distractibility, a 3-choice serial reaction time task (3-CSRT) was utilized in a separate cohort of SHR rats. Before surgery, rats underwent 3-CSRT training for 3-5 weeks to a 2 s cue in operant chambers. Starting on post-op day 14, rats underwent 10 days of 3-CSRT re-testing. Results. Injured SHR rats display impaired beam-walking capability, as well as reduced learning compared to SHR shams ($p<0.05$). SHR TBI rats presented more immobility and anxiety-like behavior in comparison to SHR shams, seen as reduced center area exploration in OFT and less time approaching and burying the shock probe in SPDB ($p<0.05$). SHR TBI rats also displayed markedly reduced percent accuracy and increased omissions during 3-CSRT suggesting impairments in sustained attention ($p<0.05$). Conclusions. This array of behavioral paradigms show behavioral impairments that result from TBI in SHR rats, some more pronounced than TBI- impairments previously shown in adult male Sprague-Dawley rats. Significance. Understanding the impact that underlie conditions like hypertension can have on TBI pre-clinically is critical to developing clinically-relevant therapies.

Title: Instrumental learning and attentional set-shifting during adolescence: A comparison of two models of pediatric TBI

Authors: *S. BALAJI, P. RENNERFELDT, B. WEHRMEYER, E. H. MOSCHONAS, T. RANELLONE, J. P. CHENG, N. S. RACE, A. E. KLINE, C. O. BONDI;
Phys Med. Rehab, Safar Ctr. for Resuscitation Res., Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Traumatic brain injuries (TBIs) account for approximately 800,000 emergency department admissions of children in the U.S. yearly. Survivors have a higher risk of repeated mild insults or concussions, known as rmTBIs, which can lead to delayed learning and development as well as enhanced propensity for attentional and mood disorders. Preclinical models of attention after TBIs have not been cross-referenced across different injury types, leaving the possibility that injury modality differentially alters behavior. We thus aimed to compare behavioral assays of preclinical rodent models following rmTBIs (i.e., repeated concussions via closed-head injury, 1 mm depth at 4 m/s) versus a one-time controlled cortical impact (CCI) (i.e., focal injury, cortical deformation depth 2.2 mm at 4 m/s). In this study we evaluated goal-directed behavior, motivation, and attention in adolescent rats following either CCI (postnatal day, PND 17) or rmTBI (PND 17-19, 3x every 24 hrs) as pediatrics. Motivation-based behavior was measured through an instrumental learning task (ILT) requiring subjects to complete nose-pokes into illuminated holes to retrieve sucrose pellets over 12 training days during adolescence, commencing at two weeks post injury. Results were analyzed using repeated-measures ANOVAs, followed by Newman-Keuls post hoc tests. The ILT revealed no significant behavioral changes between CCI and rmTBI injuries. However, we found that adolescent rats in both TBI groups completed more total trials, made fewer task irrelevant pokes, had shorter cue-to-poke and poke-to-reward retrieval latencies compared to sham rats ($p's<0.05$), contrary to our hypothesis that TBI rats would underperform. The findings suggest divergent interpretations, such as enhanced motivation, yet reduced multi-tasking and exploratory behavior in adolescent rats after pediatric TBI. Behavioral flexibility was tested by a digging-based attentional set-shifting test (AST) with increasingly difficult contingencies for a food reward. No differences were found in trials to criterion or number of errors between CCI and rmTBI rats, or between TBI groups and Sham rats, likely due to a well-described cognitive rigidity exhibited by adolescents on AST. This study justifies evaluating CCI and rmTBI injury modalities in preclinical models for attention. Further research using clinically-relevant injury modalities to predict post-injury behavioral symptoms in survivors of childhood TBIs is therefore warranted.

Title: Nlrx1-cgas-sting-mediated neuroinflammation is triggered by mitochondrial dna and worsens outcome in a mouse model of traumatic brain injury

Authors: *L. FRITSCH[1], J. JU[2], E. GUDENSCHWAGER BASSO[2], E. SOLIMAN[2], S. PAUL[2], J. CHEN[2], E. KOWALSKI[2], T. TUHY[2], R. SOMAIYA[3], X. WANG[3], I. ALLEN[2], M. THEUS[2], A. M. PICKRELL[4];

Abstract: Traumatic brain injury (TBI) is a leading cause of death and disability, yet there are zero Food and Drug Administration (FDA) approved treatments. Injuries occur in two phases: primary mechanical damage due to the external force, and secondary cellular cascades such as neuroinflammation that contribute to exacerbated tissue damage. The inflammatory response to TBI is highly complex and poorly understood, but is of significant interest as a therapeutic target. Interferons, a type of inflammatory cytokine, have recently been shown to be upregulated in both mouse models of TBI and human TBI patients. The cyclic GMP-AMP Synthase-Stimulator of Interferon Genes (cGAS-STING) pathway is a key mediator of the interferon response to viral infection, but how it is activated and regulated in neurotrauma remains unclear. We provide evidence that STING is activated in a murine controlled cortical impact (CCI) model of TBI, and genetic knockout (KO) of endogenous STING or its upstream mediator, cGAS, results in reduced lesion size, cell death, and cytokine production 24 hours after injury. cGAS KO animals also show reduced motor deficits 4 days after injury, with smaller lesion size 14 days post-TBI. These data suggest that cGAS-STING activity after neurotrauma is detrimental to recovery, so we sought to clarify how it is activated in sterile injury. As a pattern recognition receptor, cGAS canonically binds cytosolic viral nucleic acids to promote STING activation. By isolating the cytosolic fraction of ipsilateral (damaged) cells from the injured cortex, we identified mitochondrial DNA (mtDNA) as being present and available for cGAS binding acutely following injury. Free nuclear DNA does not appear to be enriched in the cytosol after injury, suggesting that mtDNA is the most likely ligand for cGAS. To evaluate a possible mechanism of regulation, we investigated the effects of genetic KO of NLR family member X1 (NLRX1), a protein that has been shown to inhibit STING *in vitro*. NLRX1 KO mice showed significant increases in activated STING 3 days after injury, indicating that in the absence of NLRX1, STING is hyperactive in the injured cortex. Taken together, these data suggest that cGAS-STING signaling is aberrantly activated in brain injury by cytosolic mtDNA, and is regulated in

part by NLRX1. NLRX1-cGAS-STING signaling may therefore be a potential therapeutic target for reducing neuroinflammation after TBI.

Title: Therapeutic potential of humanin (HN) in TBI pathology

Authors: *P. THAPAK[1,3], Z. YING[1,3], G. ZHANG[2], X. YANG[2], F. GOMEZ-PINILLA[1,3]; [1]Departments of Neurosurg. and Integrative Biol. and Physiol., [2]Dept. of Integrative Biol. and Physiol., UCLA, Los Angeles, CA; [3]UCLA BIRC, Los Angeles, CA

Abstract: Background: Traumatic brain injury reduces the threshold for neurological and psychiatric disorders, and there are no therapeutic approaches.The pathology of TBI is highly complex involving inflammation, increased calcium influx, and alterations in mitochondrial activity leading to energy dysfunction and neuronal death. Humanin (HN) is a small peptide encoded by mitochondrial DNA. We have investigated the effects of HN on JAK/STAT since this pathway is engaged on cell survival via regulation of mitochondrial functions.**Methods:** Fluid percussion injury (FPI) was performed in C57BL/6J mice (n=7) and HN (40 µg/kg, i.p.) was administered after 1 and 6 hr post-TBI. Memory function in the Barnes maze was assessed one week post-TBI. Pro-inflammatory cytokines levels were assessed (cytokine array kit, Abcam, UK) in plasma and protein levels were measured in the hippocampus using quantitative western blots.**Results:** FPI reduced memory retention ($p<0.05$) compared to sham animals, and these effects were counteracted via HN treatment. Pro-inflammatory cytokines levels were elevated in the plasma of TBI mice. Protein levels of Gp130 ($p<0.05$), p-STAT3 ($p<0.01$) were increased whereas p-CREB ($p<0.01$) levels were reduced in the hippocampus of FPI mice. Interestingly, HN treatment counteracted the effects of FPI on pro-inflammatory cytokines levels in plasma and protein expression of Gp130, p-STAT3, and p-CREB.**Conclusion:** Our results show the powerful action of HN on molecular systems underlying neuronal function and

cognition, and suggest that HN treatment has neuroprotective potential against TBI-induced cognitive dysfunction.

Title: Sleep fragmentation enhances inflammation and compromises stress-responsive circuitry following traumatic brain injury

Authors: *Z. TAPP[1], J. KUMAR[2], S. CORNELIUS[2], A. OBERSTER[2], R. ATLURI[2], K. WITCHER[1], C. BRAY[3], J. VELASQUEZ[3], F. ZHAO[1], J. PENG[1], J. SHERIDAN[3,4], C. ASKWITH[1], J. GODBOUT[1,3], O. N. KOKIKO-COCHRAN[1,3];

Abstract: Traumatic brain injury (TBI) impairs the ability to restore homeostasis in response to stress, indicating hypothalamic-pituitary-adrenal (HPA)-axis dysfunction. Many stressors result in sleep disturbances, thus sleep fragmentation (SF) provides a common biological pathway through which to study the effects of stress after injury. We hypothesize SF stress engages the dysregulated HPA-axis after TBI and exacerbates post-injury neuroinflammation. To test this, adult male and female mice were given moderate lateral fluid percussion TBI or sham-injury and left undisturbed or exposed to daily, transient SF for 7- or 30-days post-injury (DPI). Sub-acutely after injury (7 DPI), post-injury SF increased cortical expression of interferon- and stress-associated genes characterized by inhibition of the upstream regulator NR3C1 that encodes glucocorticoid receptor. Moreover, post-injury SF uniquely increased neuronal activity in the hippocampus, a key regulator of HPA-axis reactivity. By 30 DPI, chronic post-injury SF enhanced cortical microgliosis and increased expression of pro-inflammatory glial signaling genes characterized by persistent inhibition of the NR3C1 upstream regulator. Within the

hippocampus, post-injury SF exaggerated microgliosis associated with decreased CA1 neuronal activity. Electrophysiological assessment revealed both TBI and SF induced deficits in Schaffer collateral long-term potentiation compared to controls. TBI increased neuronal activity in the bed nucleus of the stria terminalis associated with suppressed activity in the hypothalamic paraventricular nucleus with post-injury SF, indicating possible enhanced inhibitory tone of the HPA-axis with stress exposure after injury. Together these data demonstrate that post-injury SF engages stress-responsive brain regions and the dysfunctional HPA-axis to enhance neuroinflammation. Therefore, external stressors that disrupt sleep have an integral role in mediating outcome after brain injury.

Title: High Frequency stimulation acutely after injury to in vitro neuronal networks is neuroprotective

Authors: C. P. ROJVIRAT[1], T. D. NGUYEN[2], ***J. R. BERLIN**[3];
[1]Pharmacology, Physiol. and Neurosci., Rutgers-New Jersey Med. Sch., Newark, NJ; [2]Physics, The Col. of New Jersey, Ewing, NJ; [3]Rutgers, The State Univ. of NJ - Newark, Newark, NJ

Abstract: Mild traumatic brain injury (mTBI) accounts for majority of all TBI cases. Patients can suffer acute and persistent symptoms but, despite the prevalence of significant impairments, treatment options are limited, and interventions to prevent symptomology are lacking. One impediment towards improving this situation is our lack of understanding how and why brain networks change acutely after injury. The goal of this research was to understand acute injury-induced changes in *in vitro* neuronal networks and then apply neuroprotective interventions to mitigate those changes. To capture acute changes in neuronal network dynamics, Ca^{2+} fluorescence imaging was used to record activity from large numbers of cells during spontaneous and stimulated activity in cultures of rat neocortical neurons. Stimulated activity was initiated by

single-cell photolysis of caged-glutamate (photostimulation) to reveal functional connections, or links, between neurons. Experiments were performed in the presence of bicuculline to characterize the properties of excitatory neurotransmission. To mimic the effects of mTBI, neuronal networks, grown on 0.005in thick silicone membrane, were stretched at two different strain and strain rate levels, 45%, $20s^{-1}$ or 70%, $35s^{-1}$. Compared to non-injured controls, injured neurons showed a decrease in link stability, number of neurons responsive to photostimulation, and participation of neurons in and amplitude of spontaneous activity at both strain levels. In addition, network parameters after injury were characterized by increased variability when compared to non-injured controls. Thus, network activity was acutely depressed and highly variable after injury. Cell excitability, measured as the Ca^{2+} response to direct photostimulation, also decreased after injury in a strain-dependent manner. A number of purported neuroprotective interventions were assessed after injury, but only one, brief periods of high frequency electrical stimulation (HFS: 100 Hz field stimulation, 1 s duration, repeated 3 times), was shown to prevent injury-induced changes in network parameters, including variability, and could prevent injury-induced reductions in cell excitability. Preliminary results suggest HFS-induced neuroprotection may involve activation of GluN2B receptors, an NMDA receptor sub-type known to play a critical role in Ca^{2+}-dependent neuroplasticity. These results point to future experiments that will explore the mechanism of neuroprotection by high frequency stimulation.

Title: Injury induces lipid-droplet associated microglia with defective phagocytosis

Authors: *P. MANCHANDA[1], P. PRAKASH[1], E. ROGERS[2], Z. ZHANG[2], T. B. BEAUCLAIR[2], A. D. DUNHAM[1], R. SHI[2], G. CHOPRA[1];

Abstract: Traumatic Brain Injuries (TBI) are correlated with an elevated risk of developing Alzheimer's Disease (AD) and related dementias, known as post-TBI AD. Microglia, the resident immune cells of the brain, are professional phagocytes that are essential for clearing amyloid-beta (Aβ) aggregates; Aβ accumulation in the brain is related to the onset of neurodegenerative disorders, such as AD and post-TBI AD. Previous studies have indicated that microglia become dysfunctional and dystrophic in neurodegenerative and aged brains. Further studies indicate that microglia in the aged brain accumulate lipid droplets (LDs) and have a proinflammatory and defective phagocytic phenotype. Our recent work showed that Aβ exposure induces LDs in microglia in age and sex-dependent manner inducing phagocytic dysfunction using the AD mouse model (5xFAD). To determine phagocytic response, we developed and extensively characterized a pH-dependent fluorogenic human Aβ1-42 reporter (AβpH) that exhibits green fluorescence upon internalization into the acidic phagosomes of cells, allowing us to image glial uptake of AβpH in real-time in live animals. We asked if the LD associated microglia is also induced as a response to injury with similar phagocytic defect towards Aβ? To this end, we used a recently developed *in vitro* "TBI on a chip" model to induce impact injury to cells in addition to simultaneous electrophysiological and morphological observations during impact. We showed that impacted mouse microglial cells treated with Aβ have lower phagocytic capacity but increased inflammatory response with elevated production of nitric oxide, 7-days post-impact. Inflammation and phagocytosis assays were done following 1, 3- or 7-days post-impact by using AβpH. Further, using an established, clinical-relevant *in-vivo* blast TBI model, we discovered that microglia isolated from blasted mice brains accumulate more LDs compared to sham, and similar to LD accumulation seen in age-matched 5xFAD mice. These LD+ blasted microglial cells also showed phagocytic defect, similar to microglia from 5xFAD mice, suggesting a novel mechanism that may lead to post-TBI AD. Uncovering the pathophysiological mechanisms leading to dysregulated microglial phagocytosis in TBI will open new avenues for potential targets and therapeutics to combat neurodegeneration. Our work is especially relevant for military applications, as there is an alarming increase in post-TBI AD and related dementia among soldiers, imposing an enormous socioeconomic burden on military families, and society.

Title: Adapting the brain-on-a-chip system to evaluate whether reprogramming astrocytes hold the key to healing damaged neuronal networks

Authors: *D. LAM[1], C. BOGGURI[1], J. CADENA[2], A. LADD[2], A. SEBASTIAN[1], H. A. ENRIGHT[1], N. O. FISCHER[3];
[1]Physical Life Sci. Directorate, [2]Engin. Directorate, [3]Physical and Life Sci., Lawrence Livermore Natl. Lab., Livermore, CA

Abstract: Traumatic brain injury (TBI) is a global public health concern, with a high incidental rate in military personnel. To date, there are no effective treatments available for TBI. In the last 6 years, in vivo cellular reprogramming has been an attractive approach; reducing secondary injury and replacing lost neurons in mouse models of an acute brain injury (i.e., stab or stroke), Alzheimer's and Parkinson's disease. In vivo cellular reprogramming, either chemically or by adding a single gene to the targeted cell's genome, of astrocytes or microglia causes the innate cells to take on functional characteristics of the desired neuron. Advances in this technology is now selective: reprogramming reactive astrocytes or microglia into neurons, while not affecting the healthy cells has been successful. While the technology has shown to be effective in generating neurons within the damaged or diseased brain tissue, there is no information on whether these 'new' neurons can functionally integrate into existing neuronal networks (i.e., healthy, damaged or dysfunctional). Integration into existing neuronal networks is needed for healthy brain function. At Lawrence Livermore National Laboratory, we have recently developed a 3D human brain-on-a-chip (BOC) system that integrates a 3D biological system with a novel 3D multi-electrode array (3D MEA). Here, we adapt this system to contain human astrocytes to evaluate (using western blot and immunocytochemistry) the efficiency of chemically reprogramming oxygen-glucose deprivation (OGD)-induced activation of astrocytes into neurons. Using the 3D MEA, we will evaluate the ability of new neurons (from reprogrammed astrocytes) to restore neuronal networks disrupted by OGD, the secondary injury phase of TBI. This will address whether strategies that 'add' neurons to the TBI-injured brain (i.e., cellular reprogramming or stem cell transplant) are able to reverse or mitigate the effects of TBI or if additional approaches, (e.g., electrical neuromodulation) are required to support the integration of these neurons into existing networks.
This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344 through LDRD award 21-LW-014. (LLNL-ABS-824251)

Title: Btbi-on-a-chip: a novel, in vitro model for mechanistic investigations of blast injuries

Authors: *T. B. BEAUCLAIR[1], E. A. ROGERS[1], Z. ZHANG[2], A. THYEN[5], L. PRACHT[3], R. SHI[4];
[1]BME/BMS, [2]Purdue Univ. Interdisciplinary Life Sci., [3]Biol. Sci., [4]Depat. Basic Med. Sci., Purdue Univ., West Lafayette, IN; [5]Sch. of Med., Indiana Univ., Indianapolis, IN

Abstract: Every year, over 20,000 soldiers experience traumatic brain injuries (TBI), resulting in significant loss of income and quality of life. Further, up to 95% of these highly heterogeneous injuries are caused by explosive blasts, or bTBI. Unfortunately, there are no current treatments available and the underlying mechanisms remain elusive. However, oxidative stress is one vector thought to play a role. Recently, our laboratory successfully developed a novel approach for sub-cellular investigations of concussion injuries, utilizing neuronal networks on multielectrode arrays (MEAs), capable of providing simultaneous morphological and electrophysiological observations. By combining this unique method with our established in vivo bTBI device, we introduce “bTBI-on-a-chip,” a high resolution in vitro blast injury model with recording capabilities. The blast injury device consists of a pressure chamber and chute separated by a 0.25mm thick polyethylene terephthalate membrane. Upon ignition, nitrogen gas is delivered to the pressure chamber, rupturing the membrane, and generating a shockwave directed at the culture below. Cultures consist of primary murine cortices that have been mechanically disassociated, pooled, and seeded onto MEAs, allowed to mature for 7 days, and subsequently placed into a 75x125mm plastic membrane containing 50mL of culture media, secured via custom acrylic “lock bars” 54mm below the blast injury device. Pressure levels were determined in a series of optimization experiments: a pressure transducer with and without a sample present revealed a relatively consistent blast exposure of 120kPa, or levels comparable to those experienced by animals in our previously established in vivo model. Post-exposure, samples are returned to incubation for later analysis. The blast procedure can be completed in ~4min while maintaining temperature, pH, and osmolarity. Initial experiments have established a conservation of cellular adhesion at 24hrs post-injury application, with over 95% viability, as compared to age and procedurally matched control networks. Pilot studies utilizing standard immunocytochemical methods have demonstrated significant increases in acrolein-lysine adducts (a clinically established marker of oxidative stress) at 24 hours post-blast injury when compared to procedurally and age matched control networks. Further, increased process shearing has been shown using neurofilament staining. These preliminary results illustrate the effectiveness of our system and open the door for mechanistic studies into bTBI, while offering a semi-throughput device for investigating potential pharmaceutical interventions.

Title: Mitochondria fragmentation in microglia as a main contributor to secondary injury progression in a human 3D triculture brain model of traumatic brain injury

Authors: *V. LIAUDANSKAYA[1], Y. MILTON[1], A. SHEVZOV-ZEBRUN[1], V. K. ROSE[1], M. R. SHAPIRO[1], M. COE[1], A. BARREIRO[1], Y. ZHANG[1], A. J. SYMES[2], M. J. WHALEN[3], I. GEORGAKOUDI[1], T. J. NIELAND[1], D. L. KAPLAN[1];
[1]Tufts Univ., Medford, MA; [2]Pharmacol., USUHS, Bethesda, MD; [3]Pediatrics, Massachusetts Gen. Hosp., Charlestown, MA

Abstract: Therapies to reduce or prevent neurological sequelae of traumatic brain injuries (TBI) do not exist, in large part because of our limited understanding of secondary injury progression. Mitochondria malfunctioning and neuroinflammation have been linked to secondary injury propagation; however, the cascade of events preceding mitochondria disbalance and cell-specific contribution remains unknown. We aimed to evaluate the effect of mitochondria dysregulation on the pathobiology of secondary damage progression post-TBI on a cell-specific level using a physiologically relevant human cell triculture 3D in vitro neural tissue model. To establish the triculture system, human stem cell-derived neurons, primary astrocytes, and a microglial cell line were seeded in silk protein porous scaffolds and embedded in collagen gel. Live staining showed that the tricultures remained viable and without necrosis for at least 12 months. At 6 weeks post-seeding, tricultures reached a mature state and were used to study traumatic injury: neurons expressed maturation markers MAP2 and Syn1 and formed Tuj1-positive dense networks; astrocytes and microglia expressed cell-specific markers ALDH1A1 and TMEM119, respectively. Injuries were inflicted on the 3D tricultures using controlled cortical impact (CCI) (moderate injury: 6m/s speed, and 0.6mm penetration). At 24 hours after CCI, injury of tricultures resulted in 80% reduction of Tuj1 positive network ($n=12$, $p<0.001$), whereas di-cultures of neurons with astrocytes or microglia showed preservation of the network (80%, $n=12$, $p<0.001$). Neuronal network degeneration in tricultures was associated with increased mitochondrial fission and pro-inflammatory cytokine production. Treatment with an anti-mitochondrial fission inhibitor P110 (1μM) slowed secondary damage progression and neuroinflammatory response at 2 ($n=9$, $p<0.001$) and 14 ($n=4$, $p<0.05$) days after injury. Naïve

neurons treated with extracellular mitochondria isolated from astrocytes, conditioned with microglial extracellular mitochondria (primed with media from injured neurons) resulted in 50% of Tuj1 positive network loss ($n=8$, $p<0.05$), induced Drp1/Fis1 mitochondria fission ($p<0.05$), and cytokines release. However, when microglia were excluded from transfer experiments, the Tuj1 neuronal network remained intact. Using a novel physiologically relevant human 3D *in vitro* triculture model of brain injury we discovered that mitochondria fragmentation in microglia is driving secondary neurodegeneration after moderate type of brain injury. We thank the NIH (P41EB027062, S10OD021624) and the DoD (HU00012020015) for support.

Title: Detection of DNA damage response via novel genetic biodosimetry sensors permits the risk assessment of space radiation-induced neurodegeneration and cognitive decline

Authors: *E. KNOTT[1], M. WYNNE EL-SAADI[2], X. TIAN[3], J. CHANCELLOR[5], L. HARRISON[2], X. LU[4];
[1]Louisiana State Univ. Hlth. Scienc Pharmacoloy, Toxicology & Neurosci., Shreveport, LA; [2]LSU Health, Shreveport, Shreveport, LA; [4]Dept. of Pharmacology, Toxicology & Neurosci., [3]Louisiana State Univ. Hlth. Sci. Ctr., Shreveport, LA; [5]Physics and Astronomy, Louisiana State Univ., Baton Rouge, LA

Abstract: There is growing concern that exposure to galactic cosmic radiation (GCR) during long-term space exploration missions to Mars or other destinations may induce or accelerate the progression of cognitive decline and neurodegeneration. The ability of the scientific community to assess these risks has been limited by the lack of an *in vivo* tool with sufficient spatiotemporal resolution and sensitivity to observe neurons after space radiation exposure. To this end, we have developed a genetically-encoded *in vivo* biodosimetry sensor, Probe with a viRal proxy for the Instability of DNA surveillance/repair in somatic brain Mosaicism (PRISM), that combines the

transduction specificity of AAV(PHP.eB) with the instability of hypermutable mononucleotide repeat regions in order to observe neuronal DNA damage response (DDR). Using both cultured HEK293 cells and retro-orbitally injected C57BL/6J mice, we have demonstrated that PRISM reports both *in vitro* and *in vivo* genomic instability inflicted by chemical radiation mimics, including a frameshift mutagen and inducers of DNA double-strand breaks. The mechanism of action of the genetic sensors was further validated using a newly developed DNA Endonuclease T7E1 assay, capillary electrophoresis, and targeted next-generation sequencing (NGS) on an Illumina MiSeq. Furthermore, *in vivo*, DDR-induced expression of these membrane-tethered fluorescent sensors is driven by the transgenic expression of Cre recombinase under cell-type-specific promoters in pyramidal (CamkIIa-Cre) or dopaminergic (TH-Cre, Drd1-Cre, and Drd2-Cre) neurons. This will allow us to identify which neuronal cell types or brain regions associated with neurodegenerative disease are more susceptible to GCR, which may guide future therapeutic measures. Utilizing these sensors, we have demonstrated the ability to visualize single neurons with varying degrees of neurodegeneration, and are developing protocols to apply deep learning methods to achieve high-resolution scans of tissue-cleared (iDISCO) whole mouse brains and trace subcellular neurodegenerative changes. Our immediate future efforts to evaluate the onset and progression of neurodegeneration following GCR exposure will utilize these transgenic Cre-expressing mice, each administered 1×10^{11} genome copies of each biodosimetry sensor via retro-orbital injection, to implement a newly-developed method of recreating the radiation environment expected on spaceflight vehicles and extraterrestrial habitats. Ultimately, we are poised to determine how the space environment - as well as variables such as age and sex - affect brain genomic instability, structure, and function.

Title: D-serine produced by reactive glia mediates synaptic damage following traumatic brain injury

Authors: *D. ARIZANOVSKA[1], S. A. TAPANES[1], O. O. FOLORUNSO[2,3], S. E. BROWN[2], J. GRACIOLLI CORDEIRO[1], D. T. BALU[2,3], D. J. LIEBL[1];
[1]Neurosurg., Univ. of Miami Miller Sch. of Med., Miami, FL; [2]Translational Psychiatry, McLean Hosp., Belmont, MA; [3]Psychiatry, Harvard Med. Sch., Boston, MA

Abstract: Traumatic brain injury (TBI) is a major worldwide health concern, affecting an estimated 69 million people each year. A primary component of all TBI pathology is diffuse synaptic damage, observed in mild to severe TBI. However, few studies have examined the mechanisms that regulate synaptic damage within the complexity of the traumatically injured brain, where extrasynaptic N-Methyl-D-aspartate receptors (NMDARs) are thought to be important contributors. We recently showed that D-serine, the primary co-agonist for synaptic NMDARs physiologically produced by neurons, is synthesized by reactive hippocampal astrocytes following controlled cortical impact (CCI) and causes impairments in synaptic plasticity and memory. Here, we identify microglia as a novel cellular source of D-serine after injury and take advantage of genetically modified male mice to determine the role of glial D-serine in causing synaptic damage. Specifically, we employed a tamoxifen-inducible strategy to genetically eliminate serine racemase (SRR; the enzyme that converts L-serine to D-serine) or Slc1a4 (a D-serine transporter) specifically in astrocytes or microglia prior to CCI injury or sham control surgery. Evaluators were blinded to genotypes and conditions and all studies were performed in technical duplicate. Using Golgi analysis (n= 4, 3segments/cell, 3 cells/animal) to quantify dendritic spine density and morphology, we show that reactive glial D-serine contributes to synaptic damage in the CA1 region of the hippocampus; this is reflected in functional deficits on a contextual fear conditioning task (n = 10-12) 7 days after injury. To complement this genetic strategy, we pharmacologically blocked glial D-serine transporters or GluN2B-containing NMDARs after CCI and analyzed synaptic loss and memory. The neuroprotective effects of both strategies demonstrate that reactive astrocytes and microglia contribute to threshold levels of D-serine that hyper-activate extrasynaptic GluN2B-containing NMDARs, which are primed for activation due to excess extracellular glutamate. Furthermore, we examined 12 human TBI patient samples using Western blot and quantitative polymerase chain reactive (qPCR) and found that contused tissues express higher levels of SRR and Slc1a4 as compared to controls. Together, this illuminates a conserved mechanism of D-serine mediated damage in mouse and human injury and suggests a critical pathological pathway that may be targeted to protect synaptic function following TBI.

Title: Deficiency in the truncated BDNF receptor trkB.T1 confers neuroprotection after traumatic brain injury in male mice

Authors: *R. SHAHROR[1], J. HE[1], Z. ZHAO[1], S. G. DORSEY[2], A. I. FADEN[1], J. WU[1]; [1]Dept. of Anesthesiol. & Ctr. for Shock, Trauma and Anesthesiol. Res., Univ. of Maryland, Sch. of Med., Baltimore, MD; [2]Sch. of Nursing and Program in Neurosci., Univ. of Maryland Baltimore, Baltimore, MD

Abstract: TrkB.T1 is a truncated isoform of the BDNF receptor—tropomyosin related kinase B (trkB). It is known that trkB.T1 lacks the intracellular kinase domain of the full length receptor and is up-regulated in multiple neurological disorders. TrkB.T1 is the sole isoform of trkB receptors expressed on astrocytes. We have previously reported in mouse spinal cord injury that trkB.T1 is predominantly up-regulated in reactive astrocytes and deletion of trkB.T1 in astrocytes reduces hyperpathic responses and improves motor coordination. However, neither the cellular mechanisms nor critical role of trkB.T1 in the pathophysiology of traumatic brain injury (TBI) are studied. Here, we investigated the role of trkB.T1 in the pathobiology of TBI using a controlled cortical impact model in adult male trkB.T1-deficient (trkB.T1$^{-/-}$) mice. We observed a rapid and persistent up-regulation of trkB.T1 mRNA in the injured cortex and hippocampus after a moderate TBI. TrkB.T1 protein expression was elevated 2-3-folds at 7 days and sustained up to 6 weeks post-injury. These changes were associated with increased astrocytic GFAP expression. Flow cytometry demonstrated increased GFAP^{+} astrocytes and NOX2 expression in astrocytes from ipsilateral brain at 7 days post-injury which were significantly reduced in the absence of TrkB.T1. Furthermore, TBI in WT mice induced phosphorylation of Akt and its downstream target GSK-3β as well as ERK1/2 in both injured cortex and hippocampus at 6 weeks post-injury which were significantly enhanced in the trkB.T1$^{-/-}$ mice. In a battery of neurocognitive behavioral tests, WT/TBI mice displayed significant cognitive deficits as demonstrated by reduced time with novel object in novel object recognition test, and reduced time spent in platform quadrant in Morris water maze test. Search strategy analysis of these mice exhibited higher reliance on looping search strategies than spatial and systematic search strategies compared with WT/Sham group. In contrast, trkB.T1$^{-/-}$/TBI mice showed better performance in these tasks, indicating improved learning and memory. Assessment of depressive-like behaviors using the tail suspension and forced swim tests revealed significantly reduced immobility times in trkB.T1$^{-/-}$/TBI mice. Taken together, our data indicate an important role for trkB.T1 in regulating secondary injury-mediated functional damage post-TBI

Title: Impairment of autophagy in microglia/macrophage potentiates neuroinflammation after spinal cord injury

Authors: *Y. LI, Z. LEI, J. HE, R. RITZEL, H. LI, M. LIPINSKI, J. WU;
Dept. of Anesthesiol. & Ctr. for Shock, Trauma and Anesthesiol. Res. (STAR), Univ. of Maryland, Sch. of Med., Baltimore, MD

Abstract: Autophagy is a catabolic process that degrades cytoplasmic constituents and organelles in the lysosome, thus it serves an important role in cellular homeostasis and protection against neurodegeneration. We have previously reported that defects in autophagy contribute to neuronal cell damage and are part of the secondary injury mechanism in traumatic spinal cord injury (SCI). Recent data implicate autophagy in regulation of immune and inflammatory responses, with high levels of autophagy flux associated with anti-inflammatory, and low levels with pro-inflammatory phenotypes. To determine if autophagy may be involved in modulation of neuroinflammation after SCI, we assessed the levels of autophagy in resident microglia and infiltrating macrophages following moderate contusion SCI in male mice. Flow cytometry demonstrated temporal dysregulation of autophagic function in both microglia and infiltrating myeloid from injured spinal cord at 3d post-injury which was accompanied by increased proinflammatory cytokines. Immunohistochemistry in transgenic Cx3cr1-GFP mice confirmed accumulation of autophagosomes and inhibition of autophagy flux specifically in the activated microglia/macrophages. Beclin1 (becn1) is a core subunit of the phosphatidylinositol-3 kinase (PI3K) complex and an important component in autophagosome formation. Beclin1 heterozygous ($Becn1^{+/-}$) mice displays autophagy hypomorph. Nanostring analysis with the neuroinflammation panel demonstrated increased proinflammatory genes and decreased expression of molecules related to neuroprotection in the $Becn1^{+/-}$ mice compared to their wild type (WT) littermates at 3d post-injury. These findings were further validated by real-time qPCR, in which we observed significantly higher levels of proinflammatory cytokines. Western blot analysis showed higher protein expression levels for microglia/macrophage marker Iba-1 and autophagosome marker LC3 in $Becn1^{+/-}$ mice at 1d SCI, along with increased levels of the inflammasome marker NLRP3. Assessment of functional outcome through the Basso Mouse Scale for locomotion showed significantly worse impairments for $Becn1^{+/-}$ mice after SCI compared to WT mice. Furthermore, histology analysis for spared white matter and lesion volume at 6 weeks after SCI showed worsening tissue damage in $Becn1^{+/-}$ mice. Taken together, our data indicate that inhibition of autophagy in microglia/macrophage potentiates pro-inflammatory activation that is associated with poorer functional outcome. These findings

highlight the importance of autophagy in resident immune cells of CNS and further elucidates its role in secondary injury after SCI.

Title: Differential changes in plasma extracellular vesicles with age and biological sex after spinal cord injury

Authors: *N. Z. KHAN, R. M. RITZEL, S. A. ALLEN, Z. LI, Y. LI, A. I. FADEN, J. WU; Dept. of Anesthesiol. & Ctr. for Shock, Trauma and Anesthesiol. Res. (STAR), Univ. of Maryland Sch. of Med., Baltimore, MD

Abstract: Spinal cord injury (SCI) leads to secondary brain neuroinflammation and neurodegeneration that increases dementia risk. Preclinical studies support that cognitive behavioral deficits are exacerbated with age and worse in males. However, the mechanisms contributing to SCI-induced brain dysfunction are not well understood. Cell-to-cell signaling through extracellular vesicles (EVs) has emerged as a critical mediator of neuroinflammation, including at a distance through circulation. We have previously shown that SCI in young adult (YA, 3-month-old) male mice leads to robust changes in plasma EV count and microRNA (miR) content. Here, our goal was to investigate the impact of age, biological sex, and aging on EVs after SCI. YA or aged (18-month-old) mice received T10 midline moderate contusion injury. Total plasma EVs were isolated by ultracentrifugation. Particle count and size distribution were assessed by nanoparticle tracking analysis, while individual EV protein expression was quantified by Western blot. YA mice were subjected to SCI followed by 19 months post-injury. There was no difference in particle count or size in either sex of both sham and SCI groups. Interestingly, males had increased expression of tetraspanin EV markers CD63 and CD81 after SCI, suggesting a sex-dependent difference in circulating EV subpopulations. We then evaluated plasma EVs in aged male animals at early and late timepoints following SCI. In shams, plasma EVs from aged mice had decreased count and a smaller peak size relative to YA. At 2 months post-injury, there was no significant difference in particle count or size distribution between YA and aged mice. However, aged animals showed increased expression of CD63 and CD81 with

SCI. To identify changes in plasma EV miR cargo, we performed the Fireplex® assay in YA and aged mice at 1d post-injury. While miR-145-5p, miR-206, miR-214-3p, and miR-23a-3p increased with injury in both groups, miR expression did not significantly differ alone with age or within a specific injury group. Using the same assay, we found that SCI increased miR-451a, miR-486-5p, miR-15b-5p and decreased miR-206 expression in EVs derived from the injury site in both groups. Interestingly, miR-206 decreased in EVs at the injury site and increased in plasma EVs, suggesting that this miR is shuttled through EVs into circulation. miR-206 is highly expressed in astrocyte EVs, and increased plasma miR-206 is correlated clinically with transition from mild cognitive impairment to dementia. These studies are the first to describe changes in circulating EVs after chronic SCI and in aged animals and support a potential EV-mediated mechanism for SCI-induced brain changes.

Title: Age-related dysregulation of autophagy contributes to aggravated microglial dysfunction and long-term neurological outcome after traumatic brain injury

Authors: *R. RITZEL, Y. LI, J. HE, J. CARTER, N. KHAN, A. I. FADEN, J. WU;
Dept. of Anesthesiol. & Ctr. for Shock, Trauma and Anesthesiol. Resea, Univ. of Maryland, Sch. of Med., Baltimore, MD

Abstract: Elderly patients with traumatic brain injury (TBI) have higher mortality and poorer long-term outlook compared to younger individuals. This may contribute to the assumption that aggressive management of geriatric TBI is futile. The present study examined the long-term recovery potential and underlying mechanisms associated with advanced age in male C57BL/6 mice using a controlled cortical impact model. 18-month-old aged mice had a higher mortality rate compared to young (10-weeks-old) mice at 12 weeks post-injury. While aging alone had a significant impact on behavioral ability, the recovery slope in some, but not all, neurobehavioral tests was relatively similar between young and old mice. By 12 weeks, however, aged mice displayed significant cognitive deficits and depression. Histopathology revealed larger lesion volumes and increased microglia activation in aged TBI mice. Nanostring analysis identified

several age- and injury-specific genes that were differentially expressed in the injured brain, including those involved with the complement, phagocytosis, and autophagy pathways. Flow cytometry demonstrated temporal dysregulation of autophagic function in microglia from injured mice which was exacerbated with age and accompanied by increased neuroinflammation. Given the critical role for autophagy in promoting the cellular degradation of lipids, proteins, and damaged organelles we reasoned that a treatment employing an autophagic inducer such as trehalose may be a viable therapeutic strategy for old mice. Trehalose was administered in the drinking water (3%) starting at d1 post-injury up to 8 weeks. Aged male mice were randomly assigned to one of four groups based on surgery (sham or TBI) and treatment (trehalose or sucrose control). Behavioral testing was performed by an investigator blinded to each group. Old TBI mice treated with trehalose exhibited either delayed deficits or enhanced recovery in cognitive and motor tasks. Trehalose treatment modified expression of autophagy markers and reprogrammed the microglial response to chronic TBI. Taken together, our data indicate that microglia undergo chronic changes in autophagic regulation with both normal aging and TBI that is associated with poorer functional outcome. Boosting autophagy may be a promising therapeutic strategy for older TBI patients.

Title: Exploring the effects of unpredictable chronic mild stress on traumatic brain injury outcomes in drosophila melanogaster

Authors: *B. E. TOLAN, R. E. HARTMAN;
Loma Linda Univ., Loma Linda, CA

Abstract: Traumatic brain injury (TBI) is a leading cause of neurological deficits and mortality worldwide. The consequences of TBIs include sensorimotor, cognitive, and psychological deficits, all of which may be exacerbated by chronic stress from environmental stressors. Environmental stress and TBI are both associated with inflammation, and each has the potential to induce depression and/or impair performance on cognitive and sensorimotor tasks. However, the nature of the interaction between these two nervous system insults is currently unclear. Furthermore, there are currently no proven pharmaceutical strategies to either protect against or repair nervous system dysfunction initiated by chronic stress and/or TBI. A cost efficient and widely available solution may be found in dietary sources such as pomegranate juice. Abundant

in phytochemicals, polyphenols are the most common and considered the most bioactive. These compounds have anti-inflammatory and antioxidant properties. Pomegranate juice contains ellagitannin and punicalagin, which is hydrolyzed into ellagic acid (EA). Here we show that a high-throughput *Drosophila* model of TBI induced behavioral deficits and increased mortality. Using a well-characterized high-impact trauma device, TBIs were administered to young adult (7 day old) wild-type *Drosophila melanogaster* (*N* = 1600). Following the TBI, the flies were transferred to individually housed treatment vials of 10% pomegranate juice, 10% ellagic acid, 10% sucrose, 10% ellagic acid + sucrose, or standard fly media. At 24 hours and 9 days, flies were assessed for locomotor and behavioral deficits using Rapid Iterative Negative Geotaxis (RING) and Drosophila Activity Monitor (DAM). Lifespan was also assessed. Additionally, an Unpredictable Chronic Mild Stress (UCMS) protocol, in which the flies were exposed to mild stressors (cold temperature, housing vial agitation, and light:dark cycle disruption) presented in a semi-random order over the course of a week, was associated with decreased climbing performance and higher mortality. Interestingly, flies administered both TBIs and chronic stress demonstrated increased climbing performance compared to flies only administered TBIs. Finally, dietary supplementation with pomegranate juice and/or ellagic acid resulted in increased climbing performance in flies compared to a standard diet. These results suggest that while TBI and chronic stress may result in behavioral deficits such as decreased climbing performance as well as decreased lifespan, dietary supplementation with pomegranate polyphenol, particularly ellagic acid may reduce these negative effects.

Title: Hormetic effect of ellagic acid on longevity after traumatic brain injury

Authors: *M. M. MENDOZA[1], E. Y. CHU[2], R. E. HARTMAN[1];
[1]Sch. of Behavioral Hlth., Loma Linda Univ., Loma Linda, CA; [2]Western Univ. of Hlth. Sci., Pomona, CA

Abstract: Polyphenols (e.g., ellagic acid) are produced by plants to protect against environmental insults such as insects / animals, ultraviolet light, extreme temperatures, etc. Despite a wealth of data demonstrating that dietary consumption of polyphenols generally confers health benefits, polyphenols often have a bitter taste and mild cytotoxic properties. Therefore, hormesis, in which mild systemic stressors can activate endogenous anti-oxidant and anti-inflammatory pathways, may explain at least some of their beneficial effects. However, this

would imply that a high enough dose will ultimately become detrimental. Although our group has demonstrated neuroprotective effects of ellagic acid and related compounds in flies, mice, and humans, we have never systematically determined minimal, optimal, and maximum dosages. Here we show in a high-throughput *Drosophila* model of traumatic brain injury (TBI) that high doses of ellagic acid may indeed have negative consequences, and that these effects manifest in a sex- and injury-dependent fashion. High doses in females, for example, reduced lifespan but did not further exacerbate the reduction in lifespan associated with a blunt-force traumatic injury. High doses in males, however, had little effect on control fly lifespan, but significantly exacerbated the negative effects of injury on lifespan. These results suggest that the often-reported benefits of consuming dietary polyphenols may be at least partially explained by hormetic processes. If so, these data further accentuate the importance of determining optimal dose in all future experimental explorations of polyphenol efficacy. “More is better” may not be the best approach to dietary supplementation. These results also suggest that other sources of environmental stress may interact with polyphenol consumption. Future studies are planned to determine the biochemical pathways activated and/or inhibited at low and high doses.

Title: Assessing the Efficacy of a Dietary Polyphenol Treatment on Space-Like Radiation Exposure in a Fruit Fly Model of Traumatic Brain Injury

Authors: *T. TOGASHI[1], A. D. TROFIMOVA[2], W. HARDEMAN[3], V. WATTS[3], G. A. NELSON[3], R. E. HARTMAN[4];
[1]Loma Linda Univ., Redlands, CA; [2]Psychology, [4]Psychol, [3]Loma Linda Univ., Loma Linda, CA

Abstract: PhD/ Principal Investigator: Richard E. Hartman/ Co-Investigator: Tori Togashi
Astronauts traveling outside the Earth’s magnetosphere on deep-space missions will be exposed to proton irradiation from the sun and galactic cosmic rays. Additionally, the tight quarters, low gravity, demanding work environment, and lack of comprehensive emergency medical care will increase both the risks and consequences of sustaining a traumatic brain injury (TBI) during the mission. Proton irradiation and TBI each have the potential to impair performance on cognitive and sensorimotor tasks, but the nature of the interaction between these two nervous system insults is currently unclear. Furthermore, there are currently no proven pharmaceutical strategies to either protect against or repair nervous system damage initiated by irradiation and/or TBI. Here we show that a high-throughput *Drosophila* model of TBI induced climbing deficits,

hypoactivity, and reduced lifespan. Exposure to low doses of proton irradiation did not have significant effects on these parameters, but patterns of behavioral deficits after radiation exposure regardless of injury status were apparent. Additionally, dietary supplementation with ellagic acid (a polyphenol found in pomegranates) significantly increased lifespan regardless of TBI or irradiation status.
These results suggest that exposure to even low levels of proton irradiation during deep-space missions (e.g., to Mars) may exacerbate the effects of nervous system insults such as TBI. We have previously shown that dietary polyphenols can increase the nervous system's resilience to irradiation (in mice) and injury (in mice and humans), and the current data demonstrate a significant increase in longevity. Thus, prophylactically supplementing the astronauts' diet with polyphenols may help to ameliorate some of the negative effects associated with their increased risks of TBI and exposure to proton irradiation.
More importantly, these findings generally demonstrate that this high-throughput fruit fly model of TBI, in combination with exposure to varying degrees of proton radiation, can be a useful, highly replicable, and inexpensive platform with which to study the viability of multiple strategies for attenuating the effects of nervous system injury.

Abstract: Traumatic brain injury (TBI) is a major contributor to neurological deficits and mortality. After the initial injury, secondary immune signaling pathway activities lead to chronic neuroinflammation and significant neurodegeneration. Low levels of chronic inflammation are observed in the aged population and may exacerbate TBI outcomes. Because *Drosophila* lack a conserved adaptive immune system, genetically modified flies uniquely facilitate isolated

observation of innate immune system activity following TBI. Release of damage associated molecular patterns (DAMPs) from degenerating axons can activate innate immune receptor signaling, triggering inflammation after mammalian TBI. To address whether DAMPs trigger the immune response that follows TBI in *Drosophila*, young and aged flies expressing membrane-bound green fluorescent protein in dopaminergic projection neurons were injured using a modified High Impact Trauma (HIT) device (Katzenberger, et al., 2013). We hypothesized that axonal degeneration will occur following TBI and that advanced age will exacerbate degeneration in this population of neurons, which are vulnerable to oxidative stress. Young and aged injured flies exhibited temporary incapacitation and abnormal wing positioning. After injury, flies were placed in an activity monitor to measure climbing, or their brains were dissected at 60m, 24h, and 7d post-injury. Interestingly, we found that climbing behavior was only decreased in injured young flies. Z-stacks of dissected brains were captured, and axon length and surface area were measured. This preliminary study provides a foundation for high throughput studies aimed at elucidating the contribution of the innate immune system to neurodegeneration after TBI.

Title: Nitric oxide synthase levels transiently decrease after TBI in aged Drosophila

Authors: M. L. MCDOLE[1], T. M. MACKEY[2], L. M. BUHLMAN[2], A. N. JUBA[3], T. C. THOMAS[5], M. J. CASTRO[4], *T. B. JONES[3];
[1]Arizona Col. of Osteo. Med., [2]Biomed. Sci., [4]Anat., [3]Midwestern Univ., Glendale, AZ; [5]Dept. of Child Hlth., Univ. of Arizona Col. of Med. Phoenix, Phoenix, AZ

Abstract: The degree to which secondary injury contributes to neurodegeneration after traumatic brain injury (TBI) is becoming more apparent, and aged populations have poorer outcomes. Immune signaling can contribute to secondary damage by inducing chronic upregulation of proinflammatory mediators and oxidative stress. Nitric oxide synthase (NOS), a key inflammatory mediator, is upregulated after human TBI and may contribute to disease progression by catalyzing production of peroxynitrite, a potent reactive oxygen species.

Mammals express inducible, neuronal, and endothelial NOS isoforms, which participate in processes that include inflammation, neurotransmission, and platelet aggregation. The *Drosophila melanogaster NOS* ortholog *dNOS* is expressed throughout development and adulthood and is thought to perform the functions of all three mammalian isoforms. We hypothesized that injured flies would have increased dNOS and climbing ability would decrease. Using flies harboring a GFP reporter under the control of *dNOS* expression, we measured relative dNOS levels and motor function immediately and chronically following TBI using a modified high impact trauma (HIT) device in young and aged flies (Katzenberger *et al.*, 2013). *Drosophila* brains were dissected or climbing behavior was assessed in injured *NOS-GAL4>UA2xEGFP* flies at 30 minutes, 1 hour, 24 hours, or 7 days post-injury. Brains were fixed, z-stacks captured, and GFP intensity and area of expression were analyzed. Number of climbing attempts was transiently decreased in injured young flies, while average height climbed was transiently decrease in aged flies. Interestingly, NOS expression was decreased in injured aged flies at 30 minutes post injury and recovered by day 7. These results suggest that our injury protocol did not induce an inflammatory response or that dNOS does not play a role in inflammation in adult *Drosophila*. Observations of decreased dNOS expression may reflect changes in pathways involved in neurotransmission or synapse formation. Future studies will evaluate whether dNOS levels increase after a more severe injury and whether increases correlate with more severe climbing deficits and brain nitrosylation.

Title: Effectiveness of Beta-Hydroxybutyrate Isomers at Ameliorate Symptoms Following Traumatic Brain Injury in a Drosophila melanogaster model

Authors: *K. MOONEY[1,4], D. C. LEE[2], G. R. TANNER[3,4], J. BALSBAUGH[3], H. VAN PELT[3], K. GAVILANES[3], Y. THELUSMA[3], J. MOONEY[3];
[1]Univ. of Connecticut, Danbury, CT; [2]Univ. of Connecticut, Tolland, CT; [3]Univ. of Connecticut, Storrs, CT; [4]The Connecticut Inst. for Brain and Cognitive Sci., Storrs, CT

Abstract: Traumatic Brain Injury (TBI) events—which are increasing in both concern and incidence in contact sports—are defined as brain injuries sustained from a blow or force to the

head that disrupts normal brain function. Following TBI, individuals may experience headaches, confusion and disorientation, and difficulty speaking. Multiple TBI events may lead to Chronic Traumatic Encephalopathy (CTE), a progressive neurodegenerative condition characterized by impaired judgment and learning and memory, and personality changes including anxiety, depression, and hyper-aggressive behavior. Progressively more young athletes in contact sports are experiencing repeated TBI, making research into TBI and CTE critical. The ketogenic diet (KD) is a low-carbohydrate, adequate-protein, and high-fat diet that has been used effectively in the clinic to treat neurological disorders such as intractable pediatric epilepsy. We have shown that directly supplementing standard high-carbohydrate *Drosophila melanogaster* diets with ketone bodies (KBs; specifically, beta-hydroxybutyrate, BHB) increases lifespan and decreases male-on-male aggression following TBI events. Our results have suggested that different enantiomeric forms of exogenous BHB may vary in their effectiveness at reducing aggression and increasing lifespan. Compared with a control diet (CD) alone, dietary supplementation with either pure R-BHB (the main endogenous form), or a BHB racemic mixture, both significantly decrease number of post-TBI aggressive events in male-male pairs; racemic and pure-S-BHB lengthen latency to the first aggressive event.The mechanism by which BHB supplementation ameliorates elevated aggression and increases lifespan following TBI is poorly understood. BHB's primary metabolic function is mitochondrial ATP production under conditions of low circulating glucose levels leading to elevated brain-wide ATP/ADP ratios. However, BHB can also act as a GPCR ligand, a gene-expression regulator (via histone deacetylase inhibition), and a sirtuin protein activator (via increased cytoplasmic [NAD+]). Sir2 activation promotes cell survival through a variety of mechanisms, including activation of autophagy proteins (e.g. autophagy-related protein 8a; Atg8a) which can mediate clearance of damaged cellular components. We hypothesize that BHB works to decrease neuronal cell death following TBI by improving neuronal metabolic stability and by activating and upregulating levels of Sir2 and Atg8a. Future experiments will include confirming reduced neuronal cell death and determining NAD+/NADH ratios in whole brains from TBI-subjected flies receiving exogenous BHB.

Title: Pupillary Light Reflex changes show promise as an objective biomarker in the acute phase of concussion

Authors: *T. R. ZUIDEMA[1], L. M. FERRIS[2], N. L. PORT[1];
[1]Sch. of Optometry, Indiana Univ. - Bloomington, Bloomington, IN; [2]Dept. of the Air Force, San Antonio, TX

Abstract: Purpose: Concussion awareness is improving, and eye care providers are increasingly involved in concussion management. Photophobia is a common symptom of concussion, yet no objective visual biomarkers of concussion currently exist. Pupillary light reflex (PLR) dysfunction has been demonstrated in chronic traumatic brain injury and is increasingly used to detect neurological dysfunction. However, to date, no studies have published results on the potential of PLR as an objective biomarker for acute concussions. In this matched cohort pilot study, we analyzed pupillary light reflexes across three stimulus intensities and investigated whether PLR changes are detectable in the acute and/or recovery phase of concussion.
Methods: Acute concussion (≤ 72 hrs) and recovery (2 wks, 8 wks, 6-18 months) data was collected on a total of n = 39 Division I NCAA collegiate athletes n = 19 concussed and n = 20 age, sex, and sport-matched controls. At each visit automated PLR measurements were collected with an SR Eyelink 1000 eye tracker and custom software. Descriptive statistics including mean, variance, and effect size with Cohen's d were performed. Finally, an ANOVA was conducted to determine the effect of injury group and stimulus intensities on outcomes.
Results: Concussed athletes consistently demonstrated diminished PLR function relative to controls. There was an effect of stimulus intensity for three of the six PLR variables. The ANOVAs revealed significant effects of concussion injury for three variables: peak constriction diameter (davg=0.57, p=0.003), peak constriction velocity (davg=0.36, p=0.041), and peak constriction latency (e.g., time to peak constriction) (davg=0.81, p=0.000).
Conclusion: Automated pupillometry evaluating the PLR shows promise as an objective biomarker for assessing acute concussion status in collegiate athletes. Consistent with existing literature, maximum constriction velocity, constriction amplitude, and constriction latency were depressed in concussed athletes relative to their matched, healthy, teammates. These findings highlight the pathophysiological relationship between vision and concussion. Further study is warranted investigating the potential use of automated pupillometry for acute concussion assessment and management.

Abstract: The Epilepsy Bioinformatics Study for Antiepileptogenic Therapy (EpiBioS4Rx) is an ongoing, international, multicenter Center without Walls investigating translational biomarkers of epileptogenesis in traumatic brain injury (TBI) patients and a preclinical model of induced TBI. Prior literature has shown that injury characteristics such as lesion type, location, and extent are correlated with increased risk of posttraumatic epilepsy (PTE). In a recent study (Tubi et al. 2018), temporal lobe trauma was found to be associated with higher rates of early seizures and subsequent PTE. Therefore, assessment and evaluation of lesion phenotypes at the time of injury is critical to facilitate optimal patient care and prognosis. However, there is no automated lesion segmentation toolbox optimized for TBI. The goal of this work is to generate gold-standard lesion segmentations that will be used as ground-truths for a machine learning-based lesion segmentation software. EpiBioS4Rx has enrolled 218 patients with moderate-to-severe TBI at 14 hospitals in the US, Australia, and Russia under local IRB approval. Enrollment criteria include frontal and/or temporal hemorrhagic contusion and Glasgow Coma Scale score between 3-13 without continuous sedation at the time of enrollment. Multimodal magnetic resonance imaging (MRI) is acquired at day 14 +/- 4 days after injury. Hemorrhagic contusions and surrounding edematous tissue were labeled on T2-weighted-Fluid-Attenuated Inversion Recovery (T2-FLAIR) MRI using ITK-SNAP. At the time of submission, segmentations for 67 patients had been reviewed by neuroradiologic experts. Binarized segmentation masks were coregistered with T2-FLAIR images into MNI space and visualized using MRICron. Voxelwise overlap of registered lesion masks for 67 patients is shown in **Fig.1**. Maximum overlap in a given voxel was 22, indicating that the regions most common (e.g. ventromedial prefrontal cortex, rostral middle temporal cortex, rostral superior temporal cortex) amongst the heterogeneous cohort were involved in 32.8% of patient injuries. Existing lesion segmentation toolboxes are optimized for white matter hyperintensities (e.g. multiple sclerosis lesions) and tumors. Brain deformations caused by trauma pose difficulties for existing registration and tissue classification algorithms that cause these methods to fail on TBI cases. This preliminary work provides data to fill the critical need for validated lesion masks that can be used to train machine-learning systems for automated lesion classification. Automated Injury phenotyping will ultimately expedite injury-related biomarker identification for PTE.

Title: Cortical and Subcortical MRI Gray Matter Abnormalities Associated with Depth Electrode-Recorded Ictal EEG Onset Patterns in Human Temporal Lobe Epilepsy

Authors: *C. OWENS-WALTON[1], H. ZHENG[1], S. I. THOMOPOLOUS[1], I. FRIED[2], N. SALAMON[3], J. P. ENGEL, Jr.[4], P. M. THOMPSON[1], R. STABA[4];
[1]Keck Sch. of Med., USC, Los Angeles, CA; [2]Dept. of Neurosurg., UCLA, University of California, Los Angeles, CA; [3]Dept. of Radiology, [4]Dept. of Neurol., UCLA, Los Angeles, CA

Abstract: Introduction: Direct brain recordings and experimental models of temporal lobe epilepsy (TLE) indicate that different ictal EEG seizure onset patterns are generated by different neuronal mechanisms; however, the structural abnormalities associated with these seizures are unclear. Here we sought to determine whether different seizure onset patterns are associated with unique or shared spatial distributions of MRI gray matter abnormalities.
Methods: Subjects in this research included patients with medication-resistant, focal temporal lobe seizures who had invasive EEG tests as part of their presurgical diagnostic evaluation. Depth ictal EEGs were reviewed, and patients grouped according to their predominant pattern as follows: hypersynchronous (HYP; n=17), low voltage fast (LVF; n=57), and rhythmic spiking (RS; n=29) patterns. We evaluated regional cortical thickness and subcortical volumes between patients and age- and sex-matched control groups (n=114) using mass univariate general linear models, with a Benjamini-Hochberg false discovery rate (FDR) correction used to adjust *p*-values, and a significance threshold of *p*-FDR of < 0.05.
Results: HYP participants displayed reduced bilateral entorhinal, bilateral fusiform, left postcentral, left precentral, left supramarginal, right inferior temporal, right lingual and right paracentral cortical thicknesses compared to Controls. LVF participants displayed reduced left entorhinal, paracentral, bilateral precentral and left temporal pole cortical thicknesses compared to Controls. These subjects also had greater left *pars triangularis*, right supramarginal, left transverse temporal and right rostral middle frontal cortical thicknesses compared to Controls. RS participants displayed reduced thickness of the left precentral cortex compared to Controls.

HYP participants displayed no significant differences in subcortical volumes compared to Controls. By contrast, LVF and RS groups had reduced left thalamus and putamen (LVF only), right amygdala and nucleus accumbens, and bilateral hippocampus volumes compared to Controls.
Conclusions: In complicated cases of TLE, MRI abnormalities to subcortical structures areas may indicate a more extensive, structural network supporting the onset and spread of LVF and RS seizures than HYP seizures. Results are consistent with the hypothesis that thalamus and mesial temporal limbic structures are important hubs in TLE, representing an anatomical link between temporal and extra-temporal cortical nodes of the network generating these seizures.

Title: Diffusion Kurtosis Imaging of Optic Radiation Damage in Glaucoma

Authors: C. PARRA[1], J. BANG[1], R. W. CHAN[1], J. M. AU[1], E. FIEREMANS[2], G. WOLLSTEIN[1], J. S. SCHUMAN[1], *K. C. CHAN[1];

Abstract: Glaucoma is a neurodegenerative disease and is the leading cause of irreversible blindness worldwide. Currently, intraocular pressure is the only clinically modifiable risk factor for glaucoma. Characterization of other factors such as brain involvements may allow improved treatment options including neurotherapeutics. In this study, 8 early glaucoma (66.1±7.7 years old; 5 males), 19 advanced glaucoma (65.3±7.9 years old; 10 males), and 9 healthy control subjects (63.1.1±8.1 years old; 7 males) underwent diffusion-weighted magnetic resonance

imaging (DWI) at 3 Tesla using diffusion-weighting factors (b values) of 250, 1000, and 2000 s/mm^2 at 4, 20, and 60 diffusion directions, respectively covering the whole brain. Parametric maps of the conventional diffusion tensor imaging (DTI), the high-order diffusion kurtosis imaging (DKI), and the DKI-extended white matter tract integrity (WMTI) model estimates were computed from DWI using open-source DESIGNER software. These maps were then compared between subject groups via semi-automatic Tract-Based Spatial Statistics and regions-of-interest analyses of the optic radiation using ANOVA followed by post-hoc Tukey tests and trend analyses (Fig. 1). DTI revealed fractional anisotropy (FA) reduction in the optic radiation bilaterally in glaucoma. For DKI and WMTI, radial kurtosis (RK) and axonal water fraction (AWF) were reduced in the right optic radiation of advanced glaucoma to similar spatial extents, whereas intra-axonal space diffusivity (IAS_Da) showed a more localized reduction in the right optic radiation. Our findings suggest that DTI, DKI, and WMTI estimates may be feasible biomarkers to quantify and better understand trans-neuronal visual system damages in glaucoma. While FA in conventional DTI appears more sensitive to glaucomatous brain damages bilaterally, RK in DKI and AWF or IAS_Da in WMTI may reflect more specific characterizations of local white matter changes with relevance to glial and axonal integrity, respectively.

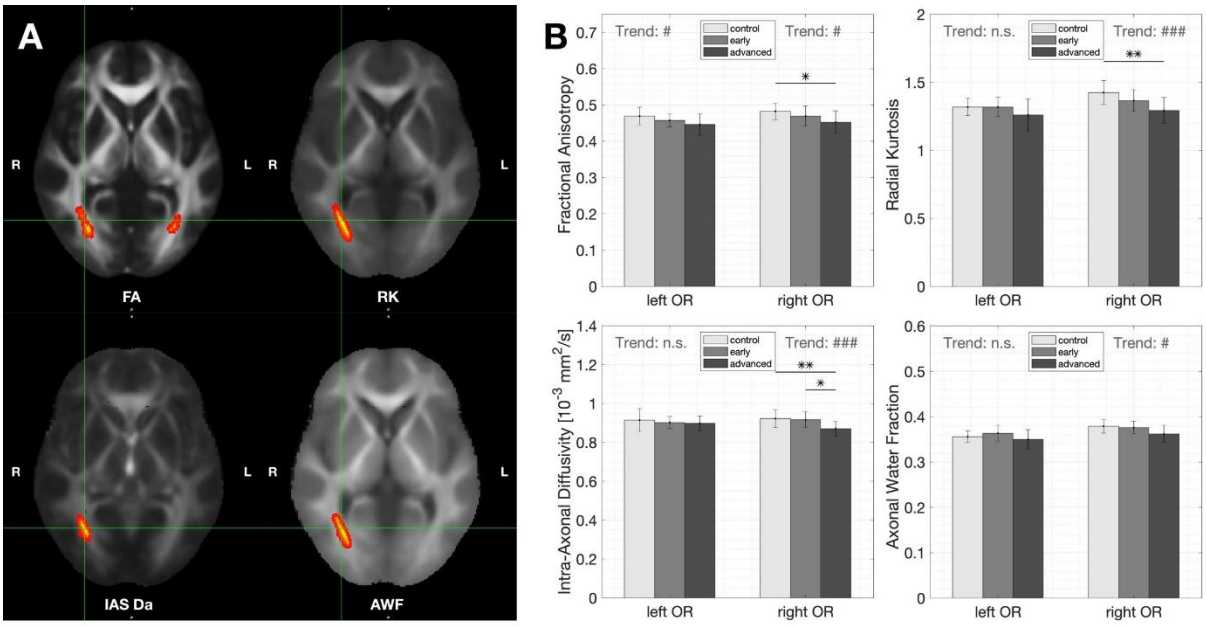

Figure 1: Tract-Based Spatial Statistics (TBSS) and Region-of-Interest (ROI) Statistical Analyses for the Optic Radiation (OR). **(A)** TBSS analysis for diffusion parametric maps including fractional anisotropy (FA) [derived from diffusion tensor imaging (DTI)], radial kurtosis (RK) [derived from diffusion kurtosis imaging (DKI)], and intra-axonal space diffusivity (IAS_Da) and axonal water fraction (AWF) [estimated from extended kurtosis analyses]. Colored overlays represent statistically significant differences for healthy control > advanced glaucoma (threshold-free cluster enhancement-corrected, p<0.05) in the OR of each diffusion parametric map. **(B)** ROI analyses pertinent to each map in Fig. 1A showed significant group differences (*: p < 0.05, **: p < 0.01) or significant linear trends (#: p < 0.05, ##: p < 0.01, ###: p < 0.001; n.s.: not significant) in the left or right OR between healthy control, early glaucoma, and advanced glaucoma subjects, consistent with the laterality and significance of the TBSS counterparts.

Title: Bedside PET imager: potential for research and point-of-care imaging

Authors: *J. BREFCZYNSKI-LEWIS[1], A. STOLIN[1], N. SIVA[1], C. GLOVER[1], S. RAJAGOPALAN[1], K. NOTT[1], S. CHANDI[1], T. WUEST[1], J. W. LEWIS[2], G. MORANO[1], S. MAJEWSKI[3];
[2]Dept Neurobio. & Anat., [1]West Virginia Univ., Morgantown, WV; [3]Univ. of California Davis, Davis, CA

Abstract: Hospital and research PET are typically done at specialized facilities with a body-dedicated PET imager that require a supine position. Multiple head-dedicated PET brain imagers have been developed in recent years, but none have allowed patients or research subjects to remain in their own bed or chairs, or stand upright. We have developed a brain dedicated PET system that is self-contained with a rolling cart and arm that supports the imager in multiple positions. We tested the imager on both phantom (NEMA and Hoffman brain) and in human participants. Methods. 16 Hamamatsu TOF-capable modules were connected in a ring formation, with a diameter of 26.7cm, with the aim of accommodating most human heads, including the tubing for brain injury patients. Both NEMA NU-4 and Hoffman brain phantoms were tested using standard quality control testing parameters (Stolin et al. 2019). The imager was then placed in a custom constructed encasement that supported the imager at multiple head angles. The encasement was attached to an overhead height-adjustable arm that was connected to a cart that housed the computer with imaging processing unit. Four clinical PET-scan scheduled participants were seated comfortably, upright on a chair. They were given 1-2 millicuries of fluorodeoxyglucose and were then scanned by the Bedside PET scanner for 5 minutes of the first scan after receiving 10% of the injection. After uptake of the full clinical dose (90min) the patients receive another 5-minute scan. Results. NEMA NU-4 “rat” phantom tests revealed a spatial resolution of 2.3 mm at 5 mm from the center of the scanner, with a peak sensitivity of 1.28% and temporal TOF resolution of 462 ps. Image quality of the Hoffman brain revealed clear delineation of sulci and brain structures. For the patient imaging, brain images were collected, but image quality was affected by random/scatter from the whole body dose as well as

motion artifact. Conclusion and future directions. The bedside PET imaging system reveals that a workable imager can be made from commercially available PET modules. Image quality using phantoms was promising, but logistics to prevent head motion and to reduced body radiation interference with image quality. Head stabilizer options and lead shielding options will be explored. Bedside PET scanning would allow greater access of brain imaging to critical care patients who are at risk of stroke in supine position or due to transport to brain imaging facilities. It would also reduce contamination time needed for infectious patients and allow for smaller clinic imaging. As there is no need for specialized room shielding, research use in behavioral laboratories is facilitated.

Title: Electroencephalogram data-driven machine learning for traumatic brain injury and stroke classification

Authors: *M. CAIOLA[1], N. VIVALDI[2], M. YE[1];
[1]FDA, Silver Spring, MD; [2]Mathworks, Natick, MA

Abstract: Background: Traumatic brain injury (TBI) presents a significant challenge affecting an estimated 2.5 million people annually. Current clinical scores can classify TBI by severity but not with enough sensitivity to detect mild TBI or monitor progression. Therefore, ongoing efforts seek alternative clinical assessment tools for TBI. EEG has advantages of being non-invasive, easy-to-use, portable, and cost effective. However, when applied to TBI research, EEG yields mixed results in the literature with some studies showing significant differences in EEG-based power spectra data between mild TBI and normal groups, while others report no such distinction. Due to the inherent complexity of TBI, including the absence of consensus on biomarkers, underlying relationships between data, and patient-to-patient variability, big data analytics have the potential to make determinations about population characteristics that would otherwise be too difficult/impossible to manually identify. By comparing EEGs recorded between normal, TBI, and stroke patients, we can show unique and novel differences between the different disease brain states. Methods: We evaluated the performance of commonly used supervised machine learning algorithms in the classification of patients with TBI history (N=142) from those with stroke history (N=165) and normal EEG (N=105). Support vector machine (SVM) and K-nearest

neighbors (KNN) models were generated with a diverse feature set (selected using various feature section techniques) from Temple EEG Corpus for three-class classification of TBI, stroke and normal subjects. This was then followed by a deep-learning Convolutional Neural Net (CNN) approach using the same pool of populations but nearly 10 times the EEG samples. Results: Accuracies of 0.85 and 0.71 were reached in Cross Validation (CV) and Independent Validation (IV) respectively. Overall, linear discriminant analysis (LDA) feature selection and SVM models consistently performed well in both CV and IV. Compared to normal control, both TBI and stroke patients showed an overall reduction in coherence and relative power spectral density in delta frequency, and an increase in higher frequencies. But stroke patients showed a greater degree of change and had additional global decrease in theta power. Our study suggests that EEG data-driven machine learning can be a useful tool for TBI classification and can potentially provide specificity to separate different neurological conditions.

Title: The role of epidermal cells in Drosophila melanogaster nociception

Authors: *S. S. MALI[1], J. YOSHINO[2], C. R. WILLIAMS[2], J. Z. PARRISH[2], D. M. BAUTISTA[1,2];

Abstract: For an organism to survive, it needs to rapidly detect harmful stimuli in the environment and respond appropriately. Our studies, and others, have shown that epithelial cells, our first point of contact with the environment, work in concert with sensory neurons to mediate responses to noxious stimuli. We find that epidermal cells in Drosophila melanogaster larvae are physically and functionally coupled to somatosensory neurons, exhibit heterogeneity in their sensitivity to mechanical and thermal stimuli, and activation of epidermal cells modulates behavioral responses to noxious stimuli. Ultrastructural imaging studies show that epidermal cells in Drosophila larvae ensheath nociceptive class IV dendrite arborization (c4da) neurons, and that this anatomical coupling modulates nociception. Optogenetic stimulation of epidermal cells evokes calcium transients in somatosensory neurons and elicits a stereotyped nocifensive behavioral response. Using single cell calcium imaging and electrophysiology, we have found

that epidermal cells are intrinsically mechano- and thermosensitive. RNA-sequencing analysis demonstrates that Drosophila epidermal cells express a repertoire of sensory channels, and thus, we have set out to identify key signaling molecules for sensory transduction in epidermal cells. This work will further our understanding of a highly evolutionarily conserved sensory system and offer new cellular and molecular targets for the urgent unmet need of pain therapeutics.

Title: The effect of TEA, 4-AP and in combination on primary sensory neurons in marine crustacean model

Authors: *H. TANNER[1], R. L. COOPER[2];
[1]Eastern Kentucky Univ., RICHMOND, KY; [2]Dept Biol, Univ. of Kentucky Dept. of Biol., Lexington, KY

Abstract: The channels for transmitting electrical activity along neurons is similar from squid to humans with sodium currents accounting for the upstroke of an action potential and potassium channels for the rapid and delayed ionic flux for the repolarization. Pharmacological agents tetraethylammonium chloride (TEA) and 4-aminopyridine (4-AP) block different subsets of voltage gated potassium (K+) channels. The chordotonal organs in crab limbs are a model of proprioceptive sensation and have rapidly- and slowly-adapting sensory neurons. Since 4-AP is used clinically for amyotrophic lateral sclerosis (ALS) treatments, a better understanding of its action on proprioceptive models can aid in understanding the potential effects for mammalian systems. To assess the action of these blockers on the function of proprioceptive sensory neurons, the neurons were evoked by movements associated with the joint while applying these compounds individually as well as in combination. Both 4-AP and TEA decreased activity individually, as well as when combined together. Full function was not returned in most preparations after the 4-AP and TEA were washed out both individually and in combined settings. Thus, the potassium channels are sensitive to both blockers in this marine crustacean model.

Title: Ionotropic Receptor-dependent cool cells control the transition of temperature preference in Drosophila larvae

Authors: J. TYRRELL, J. WILBOURNE, A. OMELCHENKO, J. YOON, *L. NI;
Virginia Tech., Blacksburg, VA

Abstract: Temperature sensation guides animals to avoid temperature extremes and to seek their optimal temperatures. The larval stage of Drosophila development has a dramatic effect on temperature preference. While early-stage Drosophila larvae pursue a warm temperature, late-stage larvae seek a significantly lower temperature. Previous studies suggest that this transition depends on multiple rhodopsins at the late larval stage. Here, we show that early-stage larvae, in which dorsal organ cool cells (DOCCs) are functionally blocked, exhibit similar cool preference to that of wild type late-stage larvae. The molecular thermoreceptors in DOCCs are formed by three members of the Ionotropic Receptor (IR) family, IR21a, IR93a, and IR25a. Early-stage larvae of each Ir mutant pursue a cool temperature, similar to that of wild type late-stage larvae. At the late larval stage, DOCCs express decreased IR proteins and exhibit reduced cool responses. Importantly, late-stage larvae that overexpress IR21a, IR93a, and IR25a in DOCCs exhibit similar warm preference to that of wild type early-stage larvae. These data suggest that IR21a, IR93a, and IR25a in DOCCs navigate early-stage larvae to avoid cool temperatures and the reduction of these IR proteins in DOCCs results in animals remaining in cool regions during the late larval stage. Together with previous studies, we conclude that multiple temperature-sensing systems are regulated for the transition of temperature preference in fruit fly larvae.

Abstract: Two PIEZO mechanosensitive cation channels, PIEZO1 and PIEZO2, have been identified in mammals, where they are involved in numerous sensory processes. While structurally similar, PIEZO channels are expressed in distinct tissues and exhibit unique properties. How different PIEZOs transduce force, how their transduction mechanism varies, and how their unique properties match the functional needs of the distinct tissues where they are expressed remains unknown. The nematode Caenorhabditis elegans has a single PIEZO ortholog (pezo-1) predicted to have twelve isoforms. While all isoforms share many transmembrane domains, they differ in the number shared, particularly in those underlying the differences between PIEZO1 and PIEZO2 in mammals. Here we use translational and transcriptional reporters to show that long pezo-1 isoforms are selectively expressed in mesodermally derived tissues (such as muscle and glands). We show that pharyngeal muscles, glands, and valve all rely on long pezo-1 isoforms to respond appropriately to the presence of food. We found that gland cell activation is modulated by food presence and density. However, RNAi against long isoforms of pezo-1 resulted in gland cells with reduced activity that did not significantly respond to food. The number of pezo-1 isoforms in C. elegans, their differential pattern of expression, and their role in experimentally tractable processes make this an attractive system to investigate the molecular basis for functional differences between members of the PIEZO family of mechanoreceptors.

Title: Ionotropic Receptor-dependent dorsal organ warm cells mediate warm sensing in Drosophila larvae

Authors: *A. OMELCHENKO, J. TYRRELL, L. NI;
Sch. of Neurosci., Virginia Tech., Blacksburg, VA

Abstract: Temperature sensation is critical for animals to avoid thermal extremes, seek optimal temperatures, and regulate body temperature. It is particularly important for small animals, such as fruit flies, which rely on the ambient temperatures for homeostasis. Though dorsal organ cool cells (DOCCs) and their function in cool sensing have been extensively studied in fly larvae, the cellular and molecular aspects of warm sensing are largely unknown. Here, we identified two warm-activated neurons in the vicinity of DOCCs, named dorsal organ warm cells (DOWCs), that are critical for choosing optimal temperatures within a specific temperature range. Three members of the Ionotropic Receptor (IR) family, IR25a, IR93a, and IR92a, in DOWCs are required for the warm responsiveness of DOWCs and the thermotactic behavior. This study identified a new set of neurons that depend on IRs to respond to warm stimuli and control larval warm sensing in innocuous temperatures. Interestingly, the previously identified ammonia receptor IR92a is a component of the warm receptor, suggesting that a tuning IR can pair with different sets of IR coreceptors for distinctive functions.

Title: Transient and steady-state spiking response of the Drosophila noxious cold-sensing neurons

Authors: *A. SAKURAI, N. MAKSYMCHUK, D. N. COX, G. S. CYMBALYUK;
Neurosci. Inst., Georgia State Univ., Atlanta, GA

Abstract: Temperature is one of the most critical environmental factors that affect the life of insects. The ability to sense temperature and take appropriate action is crucial to their survival. This study investigated the mechanisms of cold temperature coding by the *Drosophila* larva Class III (CIII) neurons by applying electrophysiological and computational neuroscience methods.

Electrophysiological recordings revealed that, to a fast temperature drop, most CIII neurons responded by a peak of spiking rate followed by spike frequency adaptation at the steady cold temperature interval of stimulation. In contrast, most CIII neurons responded with a gradual increase of spiking rate to a slow temperature decrease. On average, the steady-state spiking rate increased at lower temperatures. Fitting the spiking rate at different temperatures with the Boltzmann's function revealed high variability in temperature of half-maximal activation. Cell-to-cell variation was also seen in the pattern of spiking activity: all CIII neurons showed tonic spiking activity during the cold stimulation, while about 50% of them, depending on the stimulus intensity, exhibited bursting activity. Bursting activity more often appeared within 20 seconds after the onset of the fast cold stimulus, whereas at slow temperature decrease, bursting occurs at lower rates and broadly distributes across the whole temperature range. There was a significant positive correlation between the burst frequency and the rate of change in temperature.

Based on transcriptomic data from *Drosophila* CIII neurons, we developed a computational model implementing basic TRP current kinetics with temperature-dependent activation and Ca^{2+}-dependent inactivation. The model suggested that the kinetics of a TRP current may contribute to mechanisms underlying the phasic-tonic responses of CIII neurons and coding the rate of temperature change and cold temperature value. The model also exhibited both cold-evoked activity regimes, tonic spiking, and bursting. These regimes were determined by the kinetics of TRP current and parameters of pattern-generating subsystems of the model, including Ca^{2+} activated K^{+} currents and voltage-gated Ca^{2+} channels.

Together the results indicate that the steady temperature value was encoded by the tonic spiking activity, whereas accumulation of bursting activity at the time of a rapid temperature drop suggests that CIII neurons may encode the rate of temperature decrease by bursting activity.

Title: Role of Cystic Fibrosis Transmembrane conductance Regulator in chloride homeostasis in swine sensory neurons

Authors: N. HENAO-ROMERO, J. P. IANOWSKI, ***V. A. CAMPANUCCI**;
Anatomy, Physiol. & Pharmacol. (APP), Univ. of Saskatchewan, Saskatoon, SK, Canada

Abstract: Cystic Fibrosis (CF) is a common fatal disorder associated with mutations of recessive inheritance in the gene that encodes for the cystic fibrosis transmembrane regulator (CFTR) protein. Although traditionally considered a deadly pediatric disease due to respiratory failure and gastrointestinal (GI) complications, current advances in treatment and management have increased the average life expectancy of CF patients in Canada to 51 years of age. Therefore, now adult CF patients are exposed to previously unknown chronic complications of the CF pathology, such a peripheral neuropathy. In addition, considerable evidence shows that CFTR is not only expressed in epithelial cells as initially thought, but it is also widely expressed in the nervous system. However, the role of CFTR in neurons and its potential contribution to the CF pathology remains to be explored. In the current study, we investigated the cellular effects of lack of CFTR function in dorsal root ganglia (DRG) neurons. We quantified chloride levels in DRG primary cultures from wild-type (WT) and CFTR -/- swine using a chloride sensitive dye (i.e., MQAE) and perforated patch-clamp electrophysiology. In addition, we used the CFTR inhibitor 172 (CFTR (inh)-172) and current-clamp electrophysiology to investigate the effect of pharmacological inhibition of CFTR, versus the lack of its expression, in DRG neuron function. Our findings indicate that DRG neurons from CFTR -/- swine had a lower intracellular chloride concentration than WT neurons. We also observed that pharmacological inhibition of CFTR for 48 hr had no effect on DRG neuronal excitability or on the GABA-mediated modulation of action potential firing in DRG neurons. Taken together, our data suggest that CFTR contributes to chloride homeostasis in DRG neurons, possibly acting in combination with the Na-K-Cl co-transporter (NKCC1), which drives chloride influx. Thus, our data show for the first time that lack of CFTR function may alter DRG neuron function and contribute to the development of peripheral neuropathy in CF patients.

Title: Identifying somatostatin interneuron subsets by combining intersectional genetics, retrograde labeling, and immunohistochemistry

Authors: *R. HOSTETLER, H. HU, A. AGMON;
Dept of Neurosci., West Virginia Univ., Morgantown, WV

Abstract: Somatostatin (SOM) inhibitory interneurons are the second largest inhibitory subtype in the neocortex, but their considerable diversity has hampered attempts to understand their role in cortical circuits underlying sensory, motor and cognitive functions. Subsets of SOM cells differ in their layer-specific axonal projections, marker protein expression, and electrophysiological properties, but most previous studies used transgenic approaches which target all SOM cells indiscriminately. There is therefore an acute need for well-validated tools to identify and target distinct subsets of SOM cells. To address this need we used intersectional genetics, and validated this approach with retrograde labeling from layer 1 (L1), immunohistochemical staining in fixed tissue, and ex-vivo electrophysiological recordings (see companion poster).We crossed the SOM-Flp mouse line with lines expressing Cre recombinase driven by SOM subset-specific promoters: nicotinic receptor alpha 2 subunit (Chrna2)-Cre, calretinin (CR)-Cre and prodynorphin (pDyn)-Cre, and with a dual reporter (RC::FLTG) which expresses GFP in Cre+/Flp+ cells and tdTomato in Cre-/Flp+ cells. L1-projecting cells were retrogradely labeled by placing a Fast Blue (FB) dyed filter paper on the pial surface of the somatosensory cortex followed by 24 hour survival. Fixed brain sections were then stained with antibodies to determine expression of the marker proteins CR, calbindin (CB) and neuropeptide Y (NPY). GFP and tdTomato-expressing cells within the FB-labeled region were counted by layer and scored as FB+ or FB- and as antibody+ or antibody-. Male and female mice (age 6-24 weeks) were used, N=3 per genotype.The majority of SOM cells in L2/3 and L5 were FB+ (i.e. L1-targeting), while the majority in layers L4 and L6 were FB-. The vast majority of Chrna2-Cre cells were in L5 and most were FB+, CB+, CR- and NPY-. The majority of CR-Cre cells were in L2/3 and L5, were FB+, and were CR+, CB+ and NPY+. The majority of pDyn-Cre cells were in L4 and L5 and were FB- in L4, but ~50% were FB+ in L5. Most FB- pDyn-Cre cells were CB-,

NPY-, and CR-, while most FB+ pDyn-Cre cells were CB+, and some were CR+ and NPY+. We conclude that CR-Cre and Chrna2-Cre SOM cells represent two distinct, non overlapping L1-projecting SOM subsets in L5. PDyn-Cre SOM cells contain at least two distinct, non overlapping groups, cells that are L1-projecting, CB+ and occasionally CR+, and cells that are non L1-projecting and are CB- and CR-. The former group likely includes the CR-Cre subset, and the latter most likely corresponds to the previously described X94 subset.

Title: Electrophysiological characterization of three non-overlapping layer 5 SOM interneuron subtypes

Authors: H. HU, R. HOSTETLER, ***A. AGMON**;
Neurosci., West Virginia Univ., Morgantown, WV

Abstract: Somatostatin-containing (SOM) neurons are the second largest group of inhibitory neocortical interneurons; however efforts to decipher their roles in cortical circuits underlying sensory, motor and cognitive functions have been hampered by their considerable diversity. SOM interneurons vary in their layer-specific axonal projections, electrophysiological fingerprints, and marker protein expression (e.g. cell-surface receptors and neuropeptides). Especially diverse is the SOM population in layer 5, which consists of both layer 1-targeting and layer 4-targeting SOM cells. Previous studies from our lab and others have examined SOM interneuron diversity using transgenic mouse lines with subset-specific expression of GFP, and more recently by intersectional genetics; however most studies to-date have used mouse Cre lines which target all SOM interneurons indiscriminately, leading to confusing and at times contradictory results. Thus, well-validated genetic tools to identify and target the major SOM interneuron subsets in-vivo and ex-vivo are acutely needed. Here we used triple-transgenic mouse lines to target 3 major non-overlapping layer 5 SOM subsets for electrophysiological recordings, and show that the three subsets can be reliably identified by their electrophysiological parameters and firing patterns. We crossed SOM-Flp mice with mice expressing Cre driven by promoters for the marker proteins calretinin (CR), Chrna2 and prodynorphin (pDyn). Further crossing with the RC::FLTG reporter resulted in GFP in Cre-expressing SOM cells and tdTomato in all other SOM cells. For validation, we also crossed

Chrna2-Cre and pDyn-Cre mice with X94 and X98 mice in which GFP is expressed, respectively, in subsets of layer 4-targeting and layer 1-targeting SOM cells. We then conducted single and dual ex-vivo whole-cell recordings from GFP and/or td-Tomato-expressing neurons, in 1-3 months old male and female mice. We found that Chrna2-Cre, CR-Cre and X94 SOM cells in layer 5 have largely non-overlapping and highly distinct electrophysiological fingerprints which should allow their reliable identification even without fluorescent protein expression. These subsets are also distinct in their axonal projection targets and marker protein expression, as shown in the companion poster. PDyn-Cre cells are a superset which contains the X94 subset. Beyond mere subtype characterization, this intersectional approach can be used to express inhibitory and excitatory opsins or calcium and voltage reporters in distinct subsets of SOM interneurons, enabling investigations of their roles in sensory perception, behavior and learning.

Title: Sensory and action-related responses of VIP interneurons in mouse whisker S1 during goal-directed behavior

Authors: *D. L. RAMAMURTHY, A. CHEN, P. C. HUANG, P. BHARGHAVAN, G. KRISHNA, K. CASALE, D. E. FELDMAN;
Helen Wills Neurosci. Inst. and MCB Dept., UC Berkeley, Berkeley, CA

Abstract: Vasoactive intestinal peptide-expressing (VIP) interneurons have emerged as an important GABAergic cell type for regulating cortical activity via disinhibition of pyramidal (PYR) cells. In primary somatosensory cortex (S1), VIP neurons respond to motor and neuromodulatory signals during active whisking and locomotion to promote PYR cell firing, but the function of VIP cells in sensory processing of whisker tactile stimuli is not well understood. VIP neurons respond to passive whisker deflections, but their stimulus selectivity and activation by other behaviorally relevant signals like reinforcement is unknown. Therefore, we developed a Go/NoGo whisker detection task with a post-stimulus delay period that separates sensory-driven activity from action- or reward-related neural signals during goal-directed behavior. Vip-cre; Ai162 (TIGRE2.0-GCaMP6s) mice were trained to lick to deflection of a randomly chosen whisker (Go trials) to receive a reward, but not lick on trials in which no whisker was deflected

(NoGo trials, which were neither rewarded nor punished). We used 2-photon calcium imaging to measure activity of L2/3 VIP neurons to goal-relevant whisker stimuli, licks, and rewards in behaving mice. ~70% of imaged VIP cells showed significant whisker responses. VIP cells exhibited whisker receptive fields. ~65% of whisker-responsive cells had a single best whisker (BW) that evoked a significantly stronger response than the next-best whisker (which evoked ~60% of BW response). Whisker tuning of VIP cells was slightly broader than for PYR cells. VIP cells showed an intermixed tuning organization in which only ~40% of VIP cells in a given anatomical whisker column were tuned for the columnar whisker. This is similar to the salt-and-pepper organization observed for PYR cells. In addition, most VIP cells (~60%) showed strong lick-evoked activity, which was on average ~40% of the magnitude of the best whisker-evoked response). On average, reward delivery on hit trials did not elevate VIP cell activity over that seen on false alarm trials, or during spontaneous licking. Thus, VIP interneurons in S1 represent both sensory and motor (lick) events during goal-directed behavior. Our results suggest that VIP interneurons contribute to stimulus feature selectivity in S1, in addition to their known role in mediating motor influences.

Title: Layer-specific regulation of SST inhibition in mouse barrel cortex during whisker-dependent sensory learning

Authors: *E. PARK, D. A. KULJIS, A. L. BARTH;
Biol. Sci. Dept., Carnegie Mellon Univ., PITTSBURGH, PA

Abstract: Somatostatin (SST)-expressing GABAergic neurons comprise a major class of inhibitory interneurons in the cerebral cortex. Previous studies have suggested that inhibition from SST neurons may be regulated during sensory experiences and learning. However, whether changes in SST neurons are state-dependent or manifested as changes in synaptic weights, as well as the cellular target of these changes, remain unclear. Here we investigated whether SST output onto pyramidal (PYR) neurons in the primary somatosensory cortex was altered during sensory association training, using analysis of SST-IPSCs in acute brain slices from trained animals. Because downregulation of SST interneurons is hypothesized to be critical for gating

synaptic plasticity, we hypothesize that reduction in SST-neuronal output might facilitate the potentiation of excitatory synapses that has been detected in previous studies. We found that SST-neuronal output is reduced on layer 2/3 PYR neurons but not on layer 5 PYR neurons after sensory association training. Furthermore, the reduction of SST input was not apparent when the water reward was decoupled from the whisker stimulation. Our results suggest that the depression of SST output onto PYR neurons is a layer-specific modification selectively engaged during reinforcement learning but not sensory exposure.

Title: Cortical Feedback Activity Under Anesthesia is Pathway Dependent

Authors: *K. ARULJOTHI[1], A. LAM[2], E. ZAGHA[1];
[1]Dept. of Psychology, [2]Biomed. Sci., Univ. of California Riverside, Riverside, CA

Abstract: 'Top-down processing' refers to the use of prior knowledge and internal context to bias sensation, perception, and action. Studies of cortical anatomy and physiology support that top-down processing is mediated, in part, by cortical feedback pathways, which connect higher order to lower order cortical regions. Given the importance of top-down processing during wakefulness, a long standing assumption with some experimental evidence is that cortical feedback is not active under anesthesia. In this study, we measure the spontaneous activity of two cortical feedback pathways during slow wave anesthesia. We demonstrate that under anesthesia the retrosplenial cortex to primary visual cortex feedback pathway is not active, yet the whisker motor cortex to whisker primary somatosensory cortex feedback pathway is active. These findings suggest that the functions of cortical feedback are not limited to wakefulness. Ongoing studies are attempting to determine the mechanisms underlying these activity differences.

Title: Short-term dynamics of long-range corticocortical synapses revealed by selective optical stimulation

Authors: *L. E. MARTINETTI[1], K. E. BONEKAMP[2], D. M. AUTIO[2], S. R. CRANDALL[2]; [1]Dept. of Physiol., Michigan State Univ. Neurosci. Program, Lansing, MI; [2]Dept. of Physiol., Michigan State Univ., East Lansing, MI

Abstract: Synapses are continually regulated by their own activity. In the neocortex, direct interactions between cortical areas play a central role in cognitive function, but the dynamic regulation of these long-range corticocortical synapses by activity and their impact on a postsynaptic target neuron is unclear. Here, we use an optogenetic strategy to study the connections between mouse somatosensory and motor cortex. We found that short-term synaptic facilitation was strong in both corticocortical synapses, resulting in far more sustained responses than local intra-cortical and thalamocortical connections. This facilitation was dependent on the presynaptic calcium sensor synaptotagmin-7 and altered by several optogenetic approaches. Recordings revealed that during repetitive activation, the short-term dynamics of corticocortical synapses enhanced the excitability of layer 2/3 pyramidal neurons, increasing the probability of spiking with activity. Furthermore, the properties of the connections linking primary with secondary somatosensory cortex resemble those between somatosensory-motor areas. These results reveal a synaptic mechanism by which corticocortical projections may mediate specific changes in cellular excitability over relatively extended periods.

Title: Structured dynamics of the whisker map in layer 2/3 of somatosensory cortex in awake, behaving mice

Authors: *H. WANG, D. E. FELDMAN;
Helen Wills Neurosci. Inst., Univ. of California, Berkeley, Berkeley, CA

Abstract: In sensory cortex, single neurons exhibit spontaneous tuning instability that appears locally random yet remains bounded within mean sensory map topography. How tuning instability is organized within maps is unknown. We used 2-photon Ca^{2+} imaging to characterize spontaneous tuning dynamics in L2/3 pyramidal (PYR) cells in whisker somatosensory cortex (S1) of mice performing a whisker-attentive behavioral task. Neurons were sharply tuned for one or a few whiskers, and cells tuned to different whiskers were intermixed in a salt-and-pepper fashion. In each column, ~50% of cells were tuned for the columnar whisker (CW) and 50% for nearby non-columnar (non-CW) whiskers. To assess tuning stability, we imaged longitudinally in Drd3-Cre/TIGRE2.0-GCaMP6s mice, which stably express Ca^{2+} sensor in L2/3 PYR cells, over 4 sessions 4-7 days apart (total of 2-3 weeks of imaging). Whisker tuning was highly dynamic, with 29%, 36%, and 43% of neurons significantly changing whisker tuning over 1, 2, and 3-session intervals. In addition, many neurons lost and gained sensory responsiveness across days. Tuning instability was structured within the map: CW-tuned neurons exhibited relatively stable tuning, while 48% of non-CW tuned neurons changed whisker tuning over 3 sessions. The most sharply tuned neurons also tended to maintain constant tuning. Tuning dynamics persisted when whiskers were chronically paralyzed with Botox, suggesting that active whisker experience does not drive tuning dynamics. Thus, the whisker map in L2/3 combines a stable columnar core and a highly dynamic, non-columnar surround. This organization may explain how S1 cortex balances flexibility and stability of neural codes and selects optimal representations to perceive the complex environment.

Title: Bitter Taste Avoidance is Dependent on Olfactory Cues

Authors: *S. SCOTT, B. T. STONE, J.-Y. LIN, D. B. KATZ;
Brandeis Univ., Waltham, MA

Abstract: Consuming beneficial substances while rejecting unsafe ones is an evolutionarily-critical task. Both chemosensory systems, olfaction and gustation, work in a highly-integrated manor to guide this behavior. In the lab, these sensory systems are often disambiguated with specific experimental assays, such as the Brief Access Task (BAT), which quantifies a taste's hedonic value while controlling for other sensory variables like smell. It records licking behavior in response to blind, randomized presentations of nonvolatile and purportedly-odorless tastant solutions, which should prevent the animal from identifying the presented solutions prior to tasting. However, previous results found that rats avoid quinine (QHCl) at much higher rates than other presented tastants ($F(4, 79) = 53.9$, $p<.05$), suggesting they may identify tastants prior to licking. We hypothesize that rats either employ a chemosensory tag to mark lick spouts as they drink, or they are perceiving the olfactory characteristics of our nonvolatile and supposedly odorless tastants. To investigate, we randomly alternated delivery of vials of sucrose and QHCl differing number of times per vial, with and without a fan blowing. If avoidance behavior is cued by a pheromonal marker, avoidance would increase over the duration of a testing session as the tag was built up whereas if rats can simply smell the odorless tastants, avoidance should be reduced in fan-on trials. Our task-manipulation experiment demonstrates that avoidance does not scale with the number of times a vial has previously been presented during a testing session ($t(6) = 1.12$, $p>.05$). We show a significant difference in avoidance with and without a fan present ($F(1, 3) = 4.6$, $p < 0.05$)—indicating that QHCl avoidance behavior is likely due to rats perceiving olfactory characteristics of the QHCl solution. In conclusion, we demonstrate that male Long Evans rats can perceive olfactory elements of the commonly-used quinine-hydrochloride tastant solution and use those elements to guide decisions to avoid sampling behavior in a Brief Access Task.

Title: Strong Aversive Conditioning Triggers a Long-Lasting Generalized Aversion

Authors: *R. RAMOS[1], C.-H. WU[2], G. TURRIGIANO[3];
[1]Brandeis Univ. Grad. Neurosci. Program, Waltham, MA; [2]Biol., [3]Dept of Biol., Brandeis Univ., Waltham, MA

Abstract: All learning is a balance between the specific details of a memory and what can be generalized in future scenarios. While some degree of generalization can endow an animal with cognitive flexibility, persistent over-generalization is associated with pathological conditions, such as post-traumatic stress disorder. Currently, what the different forms of synaptic plasticity are that work to shape this balance and how they do so remains incompletely understood. Our previous experiments demonstrated that following Conditioned Taste Aversion (CTA) learning, a robust form of associative learning dependent on Hebbian mechanisms, animals formed a generalized aversion that, over the course of many hours, became specific to the conditioned tastant through synaptic downscaling of excitatory synapses onto the conditioning-active ensemble. Here, we characterize a different behavioral phenotype: a long-duration generalized aversion persisting at least two-weeks post-conditioning. Following just a single strong CTA conditioning event (0.30M LiCl), animals form a generalized aversion that can be measured at 3, 7, 10- and 14-days post-conditioning. Repeated exposure to the generalized tastant results in extinction of the generalized aversion. Interestingly, this generalized aversion and its attenuation do not impact the acquisition and maintenance of a specific taste aversion to the conditioned tastant, suggesting distinct mechanisms or sites of plasticity. We hypothesize that this persistent generalized state arises from experience-dependent gating of homeostatic plasticity. Currently, electrophysiological experiments are underway to record from the conditioning-active neural ensemble in the gustatory cortex of animals during the formation and reversal of the persistent long-lasting generalized aversion.

Title: Assessment of critical taste response to monosodium glutamate (umami)

Authors: *L. LIN[1], J.-Y. LIN[2], D. B. KATZ[3];
[1]Brandeis Univ. Undergraduate Neurosci. Program, WALTHAM, MA; [3]Dept Psychol, [2]Brandeis Univ., Waltham, MA

Abstract: Monosodium glutamate (MSG) is a naturally occurring amino acid. While often used to enhance food's flavor, the subjective taste experience of MSG has left the taste field wondering whether it should be considered as one of the core tastes or merely as a mixture (of sweet and salt). While past research has touched on this subject, until recently this question was out of reach. As shown in the research from our lab (and others), taste identity information is reflected/coded in the neural activity of the gustatory cortex (GC; the cortical region of the central gustatory pathway). To gain a better understanding of MSG processing, we therefore looked at the evoked GC identity response to MSG and compare it to other basic tastes or taste mixtures. In this study we used female Long-Evans rats unilaterally implanted with a multi-channel electrode to GC. In each 60-min testing session, the water-deprived rats actively sampled (i.e., lick) different tastes while GC neuronal activity was recorded. Using a taste battery of MSG (0.1M), sucrose (0.1M), NaCl (0.1M) and a mixture of sucrose and NaCl, we assessed the similarity of the MSG neural response to sweet and salty tastes. Our results show that, in single unit analysis, we found that neurons that responded to MSG also responded to sucrose or/and NaCl. In the populational analysis involving a Receiver Operating Characteristic (ROC) with the mean firing rate from each GC neuron as the dimensions, we found that the evoked GC ensemble activity of MSG is more similar to NaCl and mixtures than that of sucrose. This pattern of results suggests that in GC, the evoked response of MSG resembles salt-like stimuli. However, this does not exclude "a sucrose component" in MSG. Future research will seek to investigate whether the removal of the salt-component of MSG (by amiloride, a sodium blocker) will shift the GC response toward sucrose-like activity so that we can gain insight into how the interaction between salt and sweet elements modulates cortical MSG processing.

Title: Regulation of licking responses by amygdala somatostatin expressing neurons that project to the nucleus of solitary tract

Authors: *J. J. BARTONJO[1], S. ST. JOHN[2], R. F. LUNDY[1];
[1]Anatom. Sci. & Neurobio., Univ. of Louisville, Louisville, KY; [2]Psychology, Rollins Col., Winter Park, FL

Abstract: Neural processing in the nucleus of the solitary tract (NST) is critical for concentration-dependent intake of normally preferred and avoided taste stimuli (e.g., hedonic responding); and is influenced by descending input from numerous forebrain regions. In one region, the central nucleus of the amygdala (CeA), a subpopulation of neurons that project to the NST expresses the neuropeptide somatostatin (Sst). The present study investigated whether this CeA/Sst-to-NST pathway contributes to concentration-dependent intake of sucrose and quinine hydrochloride (QHCl) solutions. We used virus-based optogenetic tools and laser light illumination to manipulate the activity of CeA/Sst neurons that project to the NST. During brief-access lick trials (5s) and light-induced inhibition of CeA/Sst-to-NST neurons, mice licked significantly more to our three highest concentrations of QHCl compared to control mice, while sucrose intake was unaffected. Interestingly, light-induced activation of this descending pathway did not influence licking of either sucrose or QHCl. These findings suggest that the CeA/Sst-to-NST pathway must be active for normal affective responding to an exemplary aversive taste stimulus.

Title: Extrasynaptic $GABA_A$ receptors in the gustatory cortex and taste-dependent impulsive behavior

Authors: *P. YEVOO, A. FONTANINI, A. MAFFEI;
Dept. of Neurobio. & Behavior, SUNY Stony Brook, Stony Brook, NY

Abstract: Impulsivity is a preexisting trait in most people. It can be advantageous; however, when excessive, it becomes maladaptive. Heightened impulsivity is a predictor and/or consequence of many neuropsychiatric conditions, including eating disorders. Binge eating is a dysfunctional pattern of feeding behavior that consists of consuming palatable foods rich in sweets and fats. It is the most prevalent disorder in the United States and a major driving cause of severe obesity - a condition that affects roughly 40% of adults and 18% of children and adolescents.
Studies show that the insular cortex's (IC) circuitry may be altered in binge eating disorders. The IC has been associated with impulsive actions and classified as a neurobiological gate to develop impulsivity-related disorders. The anterior IC – also known as the gustatory cortex (GC) – is also

involved in the processing of taste, the expectation of reward, and decision-making regarding food consumption. Here, we test the hypothesis that altered levels of tonic GABAergic inhibition in GC play a central role in mediating taste-dependent impulsive choices. Using the neurosteroid allopregnanolone, we investigate the contribution of tonic inhibition to GC circuit excitability and impulsive behavior (IB).
Neurosteroid-sensitive extrasynaptic $GABA_AR$s contain the δ subunit. To determine their expression in GC, we examined the patterns of expression of δ-$GABA_AR$s using immunohistochemistry and showed that these receptors are localized in GC. To examine the receptor's functionality, we utilized patch-clamp recordings from neurons in acute slices to test the magnitude of tonic inhibitory currents and found an increase in tonic currents following neurosteroid application. We then assessed the effect of local neurosteroid infusion on IB. We used the Go/No-Go task to measure impulsivity for food by evaluating the ability to inhibit licking to sucrose during the No-Go cue and Brief Access Test to examine changes in taste responsiveness. Our data show that infusions of neurosteroids modulate licking behavior and may alter taste sensitivity, supporting the hypothesis that GC plays a central role in controlling ingestive behaviors and that tonic inhibition is a likely mechanism for the control of licking to predictive cues.
This work provides novel insights into differences in neural network physiological properties underlying taste-dependent IB. A more precise understanding of the mechanisms underlying deficits of inhibitory control will provide novel biomarkers for the diagnosis, treatment, and prevention of impulsivity-related neuropsychiatric disorders improving the lives of patients and their families.

Title: A critical period for the development and expression of taste preference

Authors: *H. C. SCHIFF[1], J. F. KOGAN[1], M. ISAAC[1], A. FONTANINI[2], A. MAFFEI[3]; [1]Stony Brook University, Neurobio. & Behavior, Stony Brook, NY; [2]Dept. of Neurobio. & Behavior, SUNY Stony Brook, Stony Brook, NY; [3]Neurobio. and Behavior, SUNY-Stony Brook, Stony Brook, NY

Abstract: Taste preferences are critical for survival as they direct consumption towards the most nourishing food and away from dangerous substances. As animals transition from relying on their mother's milk to foraging for food, they experience an abundance of new tastes and acquire relevant information associated with consuming them. Although evidence from humans suggests that these early life experiences shape taste preferences, studies have not examined whether cortical regions processing gustatory information show plasticity in critical periods or remain plastic throughout life. Here we report, in mice, that taste experience at the time of weaning, but not in adulthood, affects preference for sweet tastes later in life. Using a brief access test, we determined that sucrose preference is enhanced following exposure to a variety of tastes at weaning compared to naïve mice exposed only to water and chow. The same exposure at 8 weeks of age did not affect sucrose preference. The change in sucrose preference did not depend on familiarity with sucrose. Within the gustatory cortex (GC), early exposure to tastants accelerated the association of parvalbumin (PV^+) neurons with perineuronal nets (PNNs) and increased the frequency of spontaneous inhibitory postsynaptic currents (sIPSCs) onto excitatory neurons. Degrading PNNs with intra-GC infusions of chondroitinase ABC restored sensitivity to taste exposure in adults. Calcium imaging of GC PV^+ neurons is currently underway to examine their response to sucrose following exposure. These results point to the presence of a critical period when experience during the postnatal period induces long-term changes in taste preference and a central role for PV^+ neurons and their association with PNNs in the experience-dependent modulation of taste preference.

Title: The contribution of the lateral hypothalamus to cortical palatability coding and behavior

Authors: *K. MAIGLER[1], D. B. KATZ[2];
[2]Dept Psychol, [1]Brandeis Univ., Waltham, MA

Abstract: Both the lateral hypothalamus (LH) and primary taste cortex (GC) are emphatically involved in the modulation of feeding behavior, but there is currently no evidence for how they interact with each other. GC ensembles enter a state that reflects the hedonic value of the taste

(palatability) as part of the taste-evoked response; this transition both predicts and drives consumption behaviors. LH also encodes palatability as part of the taste-evoked response with dynamics that dovetail nicely with those observed in GC. Both experimental and theoretical work on metastable dynamics provide reasons to suspect that regions reciprocally connected to GC almost certainly contribute to the computation of palatability (and the eventual emission of a consumption decision). LH is one such reciprocally connected region. Here, we began an investigation into the cooperation between LH and GC related to the palatability calculation. Using multi-site *in vivo* electrophysiological recordings and optogenetics in behaving rats we demonstrate functional connectivity between LH and GC for the first time. In experiments utilizing four of the basic tastes that range in palatability, we show optogenetic inhibition of GC-projecting LH terminals for 2.5 seconds in half of our trials reduces the correlation to palatability in laser-on trials exclusively within the palatability epoch (700-1000ms post taste delivery). We go on to recapitulate our Li et al., 2013 finding that there are two types of taste responses in LH with opposing correlations to palatability. Then using dual-site electrophysiology we find change points related to LH palatability-related firing onset couples with ensemble dynamics in GC. In a subset of experiments, electromyography was used to identify taste-reactive behavior and suggest LH ensembles also couple with the onset of behavior. Therefore, we suggest a role for LH-GC cooperation in the palatability calculation and the transition to the decision state and behavioral output.

Title: Illness alters the functional code of gustatory cortex neurons

Authors: *B. T. STONE[1], A. MAHMOOD[2], J.-Y. LIN[1], D. B. KATZ[3];
[2]Neurosci., [3]Dept Psychol, [1]Brandeis Univ., Waltham, MA

Abstract: An animal's reactions to sensory input are influenced by external (e.g. environmental context) and internal (e.g. health-related) variables. These contextual variables shape the perception of a stimulus, thereby guiding decision making. For instance, systemic illness, such as that induced by the intake of mild toxins (e.g. lithium chloride; LiCl), affects an animal's feeding behavior, likely because of modified taste perception: sickness is thought to change taste

palatability, making even normally preferred substances aversive. The specific impact of an ill state can be long-lasting, permanently changing the processing of a stimulus with which subsequent (or even in certain circumstances contemporaneous) illness has been associated. This coupling between malaise and taste makes it reasonable to propose that illness may manifest, at least in part, as network phenomena involving brain regions which carry out behavior- and learning-related taste responses. However, research on the effects of systemic illness on neural correlates of taste processing are lacking. Using extracellular (single-neuron and local field potentials; LFPs) recordings of gustatory cortical responses to passive taste delivery under two conditions (LiCl-induced sickness and healthy), I demonstrate evidence that sickness alters the network state (reflected in changes in 7-12Hz power) at a latency of 12 min post-injection—the same time point at which concomitant illness-related behaviors emerge. Furthermore, in comparison to a healthy state, illness reduces the neural correlates of palatability (indicated via spearman rank correlations and linear discriminant analyses)-a feature which may elucidate the function that an animal's welfare has on the establishment and maintenance of reward valuation and associative effects of stimuli.

Title: Cortical Taste Processing Changes With Taste Experience Across Trials and Days

Authors: *D. SVEDBERG, E. BARASH, D. B. KATZ;
Brandeis Univ., Waltham, MA

Abstract: Laboratory rodents are typically raised in highly taste-impoverished environments, and much of the corpus of taste research has operated under the assumption that taste perception is innate—that the first exposure to a taste is processed "normally." Behavioral phenomena such as taste neophobia, however, suggest that taste perception may change as animals grow familiar to taste stimuli, at least on the time scale of days. Here, we investigate whether taste responses in gustatory cortical (GC) ensembles change with familiarization to novel tastes within a single session, and whether any such changes depend on familiarization at longer time scales. We

observe that the normal coding of taste quality and the temporal structure of taste responses evolve across the initial exposures to taste stimuli. This rapid evolution of ensemble activity in GC indicates that experience is required-that taste processing is not inherent. Specifically, our analyses show rapid enhancement of taste-identity coding following the first 5 taste exposures, as well as that the last of 3 normal epochs in the taste response—which is responsible for determining hedonic value of taste (palatability)—is significantly delayed or absent in the first presentations of a novel taste, consistent with recent behavioral analyses of taste neophobia. We then go on to show that home-cage pre-exposure to sucrose eliminates this quick response-evolution to just the pre-exposed taste, but not naive tastes, suggesting that taste-novelty related changes in processing are taste-specific. These experiments add to a growing literature showing that exposure to even simple sensory stimuli can be a “learning” experience, and demonstrate that this learning process occurs across multiple time scales. As such, they reveal the danger of studying taste perception with a "taste-naïve" subject.

Title: Cortical plasticity underlying gustatory perceptual learning in behaving mice.

Authors: *J. KOGAN, A. FONTANINI;
Neurobio. and Behavior, Stony Brook Univ., Stony Brook, NY

Abstract: To adapt and survive, animals must learn to discriminate partially overlapping sensory stimuli predicting different outcomes. This phenomenon, known as perceptual learning (PL), has been well described in the visual, auditory, somatosensory and olfactory systems. However, very little is known about gustatory PL and the associated patterns of plasticity. Here we present results addressing this significant gap in the literature. The experiments are based on a newly designed taste PL paradigm for mice, which relies on a two alternative forced choice task. The task consists of a taste sampling period at a central spout, a delay period with no access to spouts, and a decision period with access to two lateral spouts. Mice first learn a simple sucrose vs NaCl discrimination, in which sucrose presentation at the central spout is associated with reward at one lateral spout and NaCl with reward at the other. Once they reach criterion, they are tested with a battery of taste mixtures to establish a pre-learning psychometric performance curve. Next, they

are trained to discriminate between increasingly similar pairs of sucrose/NaCl mixtures. After reaching criteria on one pair (>85% correct trials, 3 consecutive days), they advance to the next. The pairs are 75/25 vs 25/75, 65/35 vs 35/65 and 60/40 vs 40/60 (%sucrose/%NaCl). After reaching criteria on the 60/40 vs 40/60 discrimination, mice are tested again with the battery of mixtures to establish a post-learning psychometric curve. Data from n=6 mice show that the post-learning curve has a steeper slope than pre-learning, indicating that the mice are better able to discriminate between the taste mixtures after extensive training. To record neural activity across sessions as mice learn, we use chronic widefield and 2photon calcium imaging. Imaging is conducted in PV-tdTomato mice to record simultaneously from pyramidal and PV+ interneurons. Activity is recorded during all psychometric testing sessions, as well as the first and last sessions of 60/40 vs 40/60 learning. We observe increased numbers of neurons discriminating the 60/40 vs 40/60 mixtures, improved population decoding of mixture identity and increased slope of neurometric curves after learning. These changes are observed both in the sampling and delay periods, consistent with the importance of GC activity during both periods in gustatory PL. These experiments further elucidate the neural basis of PL and overall provide novel information about taste processing in excitatory and inhibitory GC circuits.

Title: The synaptic organization of the associative and sensorimotor basal ganglia output

Authors: *G. SITZIA[1], S. BARISELLI[2], D. M. LOVINGER[3];
[1]NIH/ Karolinska Institutet Individual Grad. Partnership, Washington, DC; [2]NIAAA, NIH, Bethesda, MD; [3]Chief, Lab. Integrative Neurosci, Natl. Inst. on Alcohol Abuse and Alcoholism Rockville Office, Rockville, MD

Abstract: Parallel cortico-basal ganglia-thalamo-cortical loops contribute to associative, sensorimotor and emotional behaviors. Glutamatergic inputs from associative and sensorimotor cortices segregate respectively onto the dorsal medial striatum (DMS) and dorsal lateral striatum (DLS). This topographic logic is maintained in the BG output projections to thalamic, brainstem and midbrain areas. The substantia nigra pars reticulata (SNr) is the main BG output in mice. The SNr integrates inputs from striatal 'direct pathway' spiny projection neurons (dSPNs) and 'indirect pathway' inputs from the subthalamic nucleus (STN) and globus pallidus (GPe). The

intrinsic electrophysiological properties, molecular identities and output projections of SNr neurons vary across the medio-lateral axis. Furthermore, medial SNr neurons (^{m}SNr) are innervated by the DMS, and lateral SNr neurons (^{L}SNr) are innervated by the DLS. We hypothesized that this medio-lateral gradient in SNr neuron properties might also underlie differences in the synaptic integration of direct and indirect pathway inputs. We used optogenetic-assisted circuit mapping combined with whole-cell electrophysiology to label SNr neuronal subpopulations as part of associative (DMS-targeted) or sensorimotor (DLS-targeted) BG loops. We found that the direct pathway DMS-^{m}SNr and DLS-^{L}SNr synapses have similar strengths. Further, ^{m}SNr neurons had lower frequency and smaller amplitude of spontaneous GABAergic IPSCs compared to ^{L}SNr neurons. Next, we studied indirect pathway STN-^{m}SNr and STN-^{L}SNr synapses. We found that the STN targets ^{m}SNr and ^{L}SNr neurons with similar probability. Surprisingly, STN-^{m}SNr synapses were comparatively weaker than STN-^{l}SNr synapses. These results reveal a synaptic basis for a differential control of associative and sensorimotor basal ganglia output neurons by the indirect pathway.

Title: Deep brain stimulation of hyperdirect axon collaterals

Authors: *C. S. BINGHAM, C. C. MCINTYRE;
Duke Univ., Durham, NC

Abstract: Various mechanisms of subthalamic deep brain stimulation have been proposed over the last quarter century, many recent iterations of which focus on the tendency for extracellular electrical stimulation to preferentially activate large axons of prominent basal ganglia white matter pathways. Despite numerous empirical studies of subthalamic deep brain stimulation and anatomical descriptions of the basal ganglia, an adequate understanding of the role that important pathways, such as the hyperdirect pathway, play in mechanisms of DBS remains elusive. Recent revelations in basal ganglia white matter anatomy and advances in computing have made model-based examination of the motor hyperdirect pathway under STN-DBS possible. As such, this study presents a new model of the human motor hyperdirect pathway, anatomically contextualized within the CIT168 head, and computes estimates of pathway behavior under

cathodal, anodal, and bipolar current-controlled stimulation. The chief results show that while very large diameter fibers are likely to be directly recruited in the internal capsule at very low amplitudes, a realistic mixture of fiber diameters results in a strong spatial and temporal smearing both within the STN and in the primary motor cortex. Anodal stimulation increases activation thresholds but also increases the likelihood of activation within the terminal collaterals over the corticofugal fibers, resulting in longer latencies at the cortex. Bipolar stimulation dramatically increases activation thresholds but provides for much greater selectivity for collaterals over corticofugal fibers in the internal capsule. Lastly, relative to anatomically detailed collateral arbors, simple and unbranched collaterals only slightly underpredict both recruitment thresholds and the likelihood of preferential collateral activation with large diameter fibers at low-range amplitudes, but the ability to describe spatiotemporal patterns within the terminal region is greatly enhanced when anatomical realism is properly represented.

Title: Potentiation of fast Kv4.3 currents after dopamine neuron-specific KChIP4a knockout strengthens inhibitory signaling in silico

Authors: *C. J. KNOWLTON[1], K. M. COSTA[2,3], C. C. CANAVIER[1], J. ROEPER[3]; [1]LSU Health, New Orleans, New Orleans, LA; [2]NIH, Baltimore, MD; [3]Goethe University, Frankfurt, Franfurt, Germany

Abstract: Inhibitory inputs to dopamine neurons (DA) in the midbrain are believed to drive extinction learning by evoking pauses in firing in the absence of expected reward. Within the VTA, subpopulations are characterized by dramatically different responses to hyperpolarization applied in vitro, suggesting that these intrinsic subthreshold differences may play a role in integration of inhibitory inputs. DA neurons that project to the core/medial shell are characterized by both a minimal sag potential and a prolonged (1+ s) ramp-like delay after the offset of a hyperpolarizing step, whereas lateral shell and dorsal striatum-projecting cells are characterized by both significant sag potentials and a short (< 500 ms) ramp-like delay followed by a rebound “burst” or phasic increase in firing rate. In vitro experiments have shown that the longer, ramp-like delays are due to the slower inactivation of Kv4.3-mediated K channels. We have recently discovered that this slower inactivation is driven by selective expression of the KChIP4a slice variant, an auxiliary subunit of the Kv4.3 channel complex. Somewhat counterintuitively, suppression of the slower KChIP4a subunit in a dopamine neuron-specific knockout was found to significantly increase the rate of extinction learning in mice, which implies enhanced negative reward prediction error (RPE) signals. Based on the biophysical characteristics of heterologously expressed KChiP4a-Kv4.3 channels, we integrated these channels into our recently developed single compartment in silico models of core-projecting ("atypical") VTA DA neurons. In addition, we simulated an in vivo-like balanced excitation-inhibition (E-I) state and applied phasic bouts of increased inhibition to simulate repeated

negative RPE trials. The in vivo simulations showed that the removal of the KChIP4a splice variant - resulting in higher conductance of faster inactivating A-type K currents, significantly increased the pauses that follow phasic inhibition, thereby providing a candidate mechanism for the enhanced extinction learning in the dopamine-selective KChIP4a knockout mice. Currently, we are expanding these cell models to include realistic morphologies as well as biophysical properties of native A-type K channels from wildtype and dopamine-specific Kchip4a-KO mice.

Title: Regulation of striatal circuit formation by the nuclear-localized protein Zswim6

Authors: *N. T. HENDERSON[1], K. CHOI[1], D. TISCHFIELD[1], S. A. ANDERSON[2], M. V. FUCCILLO[1];
[1]Univ. of Pennsylvania, Philadelphia, PA; [2]Psychiatry, Children's Hosp. of Philadelphia/Upenn Sch. Med., Philadelphia, PA

Abstract: The striatum integrates synaptic inputs from multiple brain regions and is crucial for many motor and cognitive processes. Despite these central functions and its association with brain disease, relatively little is known about the genetic and molecular mechanisms governing striatal circuit development and maintenance. Zswim6 (Zs6) is a striatally expressed gene that is implicated in Schizophrenia, intellectual disability, and educational attainment. The function of Zs6 is unknown, but the presence of SWIM and sin3-like domains suggest a role in gene regulation. Previous work in Zs6 constitutive knockout (KO) mice revealed defects in dendrite and synaptic morphology in striatal spiny projection neurons (SPNs), and behavioral deficits consistent with striatal dysfunction. To further assess the function of Zs6 in the development of striatal circuits, we utilized conditional Zs6 KO (cKO) mice together with acute slice synaptic physiology, morphological analyses and cell culture. Conditional deletion of Zs6 in SPNs did not affect cell morphology, but impacted specific aspects of synaptic function. Zs6 deletion in either direct pathway or indirect pathway SPNs (dSPNs or iSPNs, respectively) caused an increase in paired-pulse ratio (PPR), suggesting decreased synaptic release probability. These findings suggest that Zs6 plays a role in regulating synaptic function in SPNs. Given the presence of SWIM and sin3-like domains, which are found commonly found in chromatin remodeling proteins, we tested the hypothesis that Zs6 functions as a transcriptional regulator. Utilizing primary neuron cultures, we expressed FLAG-tagged Zs6 to determine its subcellular

localization and biochemical interactions. In line with a role for Zs6 in gene regulation, we found that Zs6 localized almost exclusively to the nucleus in primary neurons. Additionally, Zs6 biochemically associated with chromatin when expressed in HEK293T cells. Together, our findings suggest that Zs6 may influence the development or maintenance of synaptic inputs to SPNs via transcriptional regulation. Future experiments will entail direct assessment of this hypothesis using RNA-seq and ChIP-seq to determine the role of Zs6 in transcriptional regulation, in addition to further electrophysiological analysis of the effects of Zs6 deletion at the synaptic and circuit levels. Together, these experiments will provide insights into the mechanisms by which Zs6 regulates striatal circuit function.

Title: Functional dissection of ipsilateral versus contralateral projections from the pedunculopontine tegmental nucleus to dopaminergic neurons

Authors: *D. PENNY[1], C. HOFFMAN[1], I. KHETARPAL[1], M. NEELALA[1], E. FARRELL[1], M. HORN[1], J. CLARK[2], L. MUZYKA[1], J. VALADEZ[1], C. WILLIAMS[2], G. M. BEAUDOIN, III[3]; [1]Biol. and Neurosci., [2]Biol. and Chem., [3]Biol., Trinity Univ., San Antonio, TX

Abstract: Dopamine plays an important role in communication between neurons, notably in the nigrostriatal dopaminergic pathway. This pathway is involved in motivation and reward-seeking behavior and is activated by stimulatory inputs. Our research is studying the synapses between the midbrain regions pedunculopontine tegmental nucleus (PPN) and substantia nigra pars compacta (SNc). The PPN is composed of three main phenotypes of neurons, cholinergic, GABAergic, and glutamatergic. Previous research has shown that PPN fibers contain more projections to the SNc and exert stronger activity in the nigrostriatal dopaminergic pathway. While many brain nuclei confine their outputs either ipsilaterally or contralaterally, the PPN appears to project to both. These two projections from PPN have not been extensively studied electrophysiologically due to a lack of tools. To further understand the strength of this synapse, unilateral and bilateral injections in the PPN are performed to determine ipsilateral and

contralateral communication from PPN to SNc. To test the strength of this synapse, we are utilizing optogenetics, a method that allows us to selectively stimulate PPN neurons and record responses to SNc dopamine neurons. To determine if SNc dopaminergic neurons receive ipsilateral and contralateral input from the PPN, we are using opsins activated by two different wavelengths, channelrhodopsin-2 and ChrimsonR. We have optimized a virus encoding the red-shifted opsin, ChrimsonR, tagged with green fluorescent protein for these experiments. To better characterize these PPN projections, we are investigating the neurotransmitter type and receptor types from each projection using pharmacology to block specific classes of receptors. Injection site images of both bright-field, yellow fluorescent protein (YFP), and red fluorescent protein (RFP) were obtained to ensure the injection sites were properly hit. Our results, obtained through immunohistochemistry and confocal microscopy, confirm previous studies demonstrating PPN projects ipsilaterally and contralaterally to the SNc and subthalamic nucleus (STN). These results will further delineate the neural circuit between PPN and SNc.

Title: Visuomotor adaptation promotes spindle clustering and fast spindle-SO coupling locally, over the contralateral motor network

Authors: *A. SOLANO[1], L. A. RIQUELME[1], D. PEREZ-CHADA[2], V. DELLA-MAGGIORE[1];
[1]IFIBIO Houssay, Sch. of Medicine, UBA, Buenos Aires, Argentina; [2]Intrnl. Med., Pulmonary and Sleep Service, Austral Univ. Hosp., Pilar, Buenos Aires, Argentina

Abstract: The last decade has seen remarkable progress in the identification of the neural signatures of sleep-dependent consolidation. Yet, most advances have emerged from the field of declarative memory, possibly due to the substantial evidence suggesting that only hippocampal dependent learning benefit from sleep. Overnight reactivation of hippocampal memories appears to depend on the precise synchrony between slow oscillations (SO) and sleep spindles

(Muehlroth et al., 2019). Here, we sought to examine whether this coupling is also critical for the consolidation of human motor memories. With the objective of identifying the neural signatures supporting sleep stabilization of visuomotor adaptation (VMA) memories in humans, a set of subjects (n = 10) was exposed to a VMA session and a control (CTL) session without visual perturbation. Subjects went to bed 10 min after each training session, and EEG recordings were obtained throughout a whole night of sleep. We found that VMA increased the overall density of fast (≥12 Hz) but not slow (<12Hz) sleep spindles during NREM3 ($\chi^2(1)=12.97$; $p<0.001$). This modulation was manifested locally, over the hemisphere contralateral to the trained hand. Motor learning also increased the proportion of spindles clustered into trains (inter-spindle intervals <= 6 secs), a phenomenon that has recently been linked to memory reactivation (Antony et al., 2018; Boutin & Doyon, 2020). This effect was observed during NREM3 only, over the contralateral hemisphere to the trained hand ($\chi^2(1)=6.63$; $p=0.01$), and the inter-hemispheric modulation correlated significantly with memory retention overnight ($R=0.74$, $p=0.02$). To explore the potential relevance of spindle clustering in sleep-dependent plasticity (Antony et al., 2019), we quantified the impact of VMA on spindle duration and amplitude. We found that motor learning increased these intrinsic parameters (RM-correlation; Duration: $Rrm = 0.75$, $p < 0.001$; Amplitude: $Rrm = 0.76$, $p < 0.001$), a finding consistent with the potential role of spindles as a window of opportunity for memory reactivation and plasticty (Klinzing et al., 2019; Ngo et al., 2020). Finally, although VMA did not affect the density of SOs ($t(9)=-1.07$; $p>0.05$), it substantially enhanced the number of fast spindles locked to the active phase of SOs ($\chi^2(1)=5.82$, $p=0.02$). The fact that only coupled spindles of the contralateral hemisphere predicted long-term memory overnight, points to the spindle-SO association as a fundamental signature of motor memory consolidation. Our work provides evidence in favor of a common mechanism at the basis of the stabilization of declarative and non-declarative memories.

Title: Unveiling the contribution of the hippocampus to motor learning

Authors: *G. GRIFFA, F. JACOBACCI, V. DELLA MAGGIORE;
IFIBIO Houssay, Sch. of Medicine, UBA, Buenos Aires, Argentina

Abstract: The hippocampus has been long associated with the codification of declarative memories. Recently, however, a few studies carried out in human and non-human animals have linked it to the consolidation of non-declarative memories (Dohring et al., 2017; Sawangjit et al., 2018; Schapiro et al., 2018). For example, we have shown that improvements in performance observed during the quiet rest periods of learning a novel motor sequence (MSL) are associated with an increment in hippocampal activity (Jacobacci et al., 2020), and microstructural plasticity (Sagi et. al, 2012) 30 min post learning, reflected as a reduction in mean diffusivity (MD). Some current theories may explain the role of the hippocampus in the encoding of both declarative and non-declarative memories. Buzsaki and Tingley (2018) proposed that it may act as a sequence generator, connecting encoded items of different modalities in space/time. Another -non exclusive- view posits that it may be involved in associating nearby stimuli in a sequence explicitly, during early stages of learning (Krakauer et al., 2019). Here, we carried out two MRI studies to test these hypotheses. To address the former, subjects (n = 18) learned a visuomotor adaptation task (VMA) that involves no sequencing. Like MSL, learning this task depends on an initial explicit component (Taylor et al., 2014). Thus, to address the second hypothesis, a different set of subjects (n = 20) learned an implicit version of the VMA task (IVMA; Hyosub et al., 2019). In both experiments, 3 Diffusion Weighted Image acquisitions were obtained before, 30 minutes and 24 hours after training, and Diffusion Tensor Imaging was applied to quantify microstructural changes based on MD. As in our previous study (Jacobacci et. al., 2020), we found that training on either VMA or IVMA decreased MD in the left hippocampus 30 minutes post-learning (SwE, $p<0.05$ FWE-corrected), and that this reduction predicted overnight memory retention. Yet, microstructural changes induced by VMA returned to baseline values by 24 hs, whereas those induced by IVMA were longer lasting (SwE, $p<0.016$ FWE-corrected). This difference may stem from the supremacy of the implicit component leading to stronger retention (Scott et al., 2020) and plasticity. Our results do not support a role of the hippocampus in sequence generation or explicit processing. We instead propose that, during learning, the hippocampus may act as a short-term memory buffer transiently reactivating information necessary to predict actions/items in upcoming iterations, regardless of data structure -sequential or not-, the learned material -words or actions-, and the nature of the task -implicit or explicit-.

Abstract: Motor sequence learning (MSL) refers to the acquisition of a new sequential motor program. We have recently shown that improvements in performance during the quiet rest periods interspersed with practice of a novel sequence (micro-offline gains, Bonstrup et. al., 2019) are associated with increased activity in the hippocampus during early learning, and microstructural changes in mean diffusivity 30 min post-training. In the present work we aimed to characterize how learning-related changes in the hippocampus impacted on its cortical connectivity. To this aim we collected resting-state functional magnetic resonance imaging data from 21 subjects before, 30 min and 24 h after training on a five item (MSL) or an active control task involving no learning. To identify the learning-specific effects on network connectivity and topology, we performed a network analysis using three different approaches: a global analysis, a connectome-wide analysis comprising edge- and node-level analyses, and a multivariate analysis with machine learning techniques. At a global level, we found that network modularity increased 30 minutes after performing the MSL task (permutation test, $p = 0.005$), and this increase was followed by a return of modularity to its baseline state 24 hours post learning. Interestingly, this increase in modularity was associated with the amount of total learning during MSL ($r= 0.48, p<0.05$). At the edge-level, MSL drove connectivity changes in a network mainly composed of connections between cortical and subcortical regions. Importantly, the anterior portion of the left hippocampus yielded the highest degree in this network, and its connections were all restricted to a group of bilateral somatomotor network regions. At the nodal level, we found a decrease in the intermodular connectivity of a right hemisphere post-central sulcus somatomotor region 30 minutes after MSL training (Wilcoxon Signed Rank test $p = 0.014$), which returned to baseline levels at 24 hours. Finally, a feature selection and supervised classification showed that four somatomotor-hippocampal connections serve to discriminate an MSL pre-learning network state from a post-learning network state with an accuracy of 80.95%; again, the anterior region of the left hippocampus was the region with higher degree in this connectivity pattern. Altogether, our results deepen in the rapid functional network reorganization induced by MSL, highlighting

the critical role of hippocampal-somatomotor connections, the increase in network segregation, and the decrease in between-modules connectivity of a post-central sulcus somatomotor region.

Title: Anodal (excitatory) HD-tDCS dissociates a lateralized role of the posterior parietal cortex in both early and late phases of learning

Authors: *B. DEXHEIMER[1], C. W. SANDBERG[2], K. SELBY[1], S. JAYASINGHE[3], S. S. KANTAK[4], R. L. SAINBURG[1,3];
[1]Kinesiology, [2]Communication Sci. & Disorders, Penn State Univ., State College, PA; [3]Neurol., Penn State Col. of Med., Hershey, PA; [4]Moss Rehabil. Hosp., Elkins Park, PA

Abstract: The functional neuroanatomy underlying motor learning remains poorly understood, and this research is further complicated by differing neural processes that may contribute to the many aspects of motor learning, including different task types (adaptation vs. skill learning), different types of learning (implicit vs. explicit), and different phases of learning (early vs. late). We have previously studied motor learning through the investigation of adaptation to visuomotor rotation (VMR). This research has demonstrated that focal lesions to the left, but not right, posterior parietal cortex (PPC) prevent adaptation to VMR, regardless of the arm used for the task. While these findings suggest a lateralized role of the left PPC for adaptation, it's contribution to fast and/or slow components of learning are not well understood. Kumar et al. (2020) recently utilized high-definition transcranial direct current stimulation (HD-tDCS) to show that left, but not right, PPC inhibition disrupts adaptation to VMR, primarily in the late phase of learning. This suggests that excitatory HD-tDCS to the left PPC may enhance VMR adaptation, specifically slow learning processes, thus demonstrating potential as an effective technique within stroke rehabilitation. However, it is also plausible that left PPC excitation has no impact on motor learning. To investigate this, we tested participants on a VMR task in a 2D virtual environment, while applying either anodal HD-tDCS or sham stimulation to their left PPC. Participants performed baseline reaches to eight virtual targets, followed by the introduction of a 30-degree VMR, then a period of de-adaptation (VMR removed). Performance

was quantified by initial direction error, reflecting feedforward mechanisms, along with deviation from linearity and final position error, which reflect both feedforward and feedback control mechanisms.Our preliminary results (12 participants) indicate that anodal HD-tDCS leads to lower initial direction error overall ($p = .028$), and lower error variability ($p = .005$). In terms of deviation from linearity, there was no difference between the groups in the early phase of learning ($p > .999$), but a significant difference in the late phase ($p < .0001$), with the HD-tDCS group performing straighter reaches. Interestingly, for final position error, there was an overall non-significant trend towards higher error for the HD-tDCS group ($p = .088$). These findings indicate a potentially lateralized role of the left PPC in adaptation to VMR across both the early (primarily fast) and late (primarily slow) phases of learning.

Title: Changes in resting state functional connectivity associated with dynamic adaptation of the wrist and alternate motor control strategies

Authors: *A. FARRENS[1], F. SERGI[2];
[2]Biomed. Engin., [1]Univ. of Delaware, Newark, DE

Abstract: Dynamic adaptation is an error-driven process of adjusting our planned motor actions to changes in task dynamics. Adapted motor plans are consolidated into motor memories that contribute to better performance on re-exposure to the same dynamic condition. In parallel, dynamic perturbations can be compensated for by alternate motor control processes, such as co-contraction, that contribute to error reduction. Whether these motor control strategies share the same neural resources for memory formation is unclear. To address this, we used an fMRI-compatible wrist robot, the MR-SoftWrist, to identify neural processes specific to dynamic adaptation and subsequent motor memory formation. Using the MR-SoftWrist, 30 healthy young adults performed a wrist pointing task in a zero force condition (control condition), and in a lateral force condition (dynamic condition) during fMRI to localize task-related brain networks. Resting state fMRI scans were acquired immediately pre- and post-performance of both tasks to quantify changes in resting state functional connectivity (rsFC) within these networks. We

assessed behavioral retention of training 24 hours later. A variance decomposition analysis was used to isolate behavior associated with adaptation versus alternate error reduction strategies. Immediately after the lateral force task, rsFC significantly changed in two brain networks: rsFC increased within the cortico-thalamic-cerebellar (CTC) network of the trained wrist and decreased interhemispherically within the cortical sensorimotor networks. Linear regression analysis returned significant associations between rsFC measured within the sensorimotor network and day 1 measures of error reduction, while changes within the CTC network were associated with behavioral measures of adaptation and retention, indicative of memory formation. Variance decomposition analysis indicated that increases within the CTC network were associated with adaptation, while decreases in interhemispheric sensorimotor rsFC were associated with alternate error reduction processes.

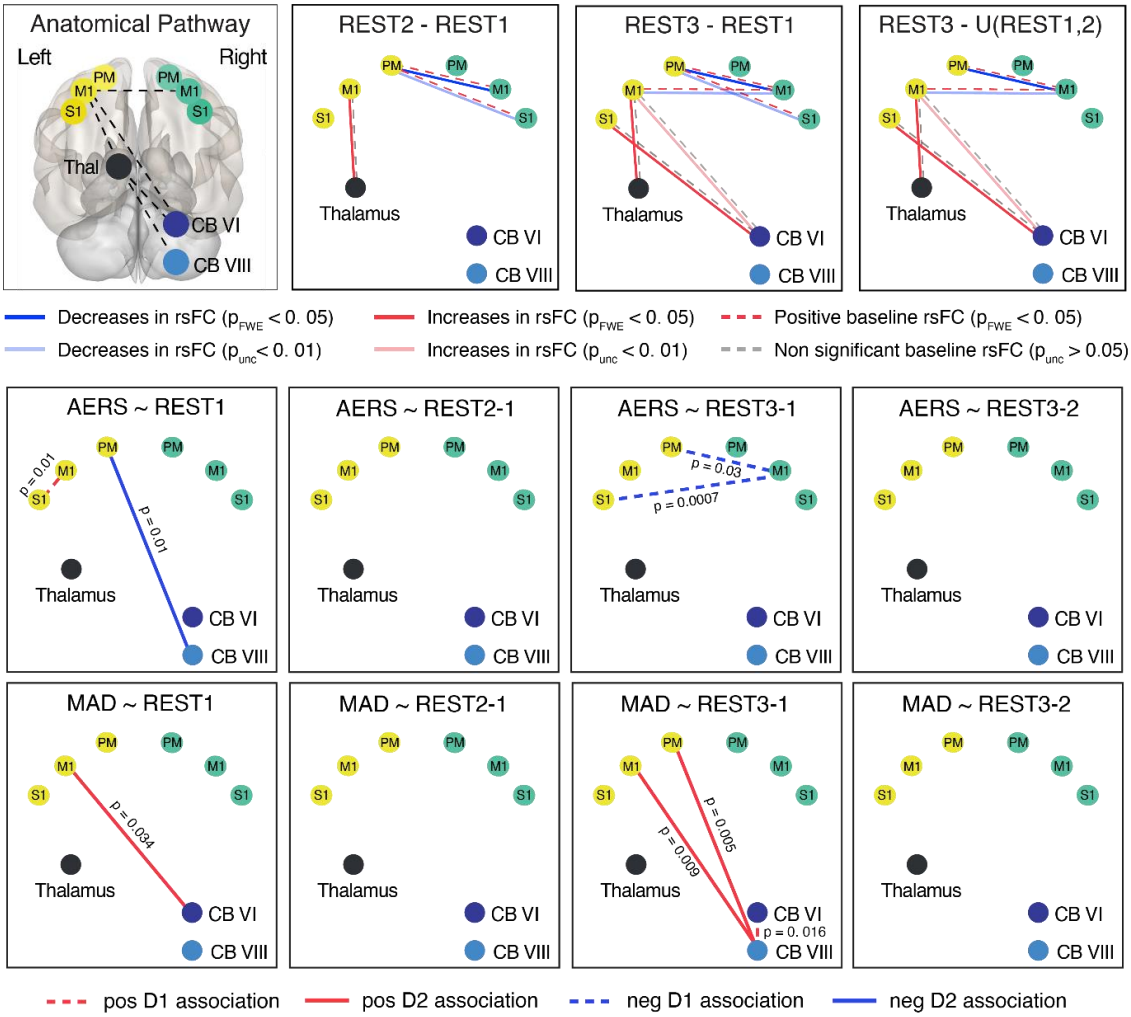

Figure 1. Top: Changes in rsFC from baseline (REST 1) immediately following the motor task performed in the zero-force condition (REST 2), and the dynamic perturbation task performed in the lateral force condition (REST 3). Mixed model analysis showed significant decreases in interhemispheric rsFC within the sensorimotor network following both tasks, and significant increases in the cortico-thalamic-cerebellar network following the dynamic perturbation task. **Bottom**: Results of a linear regression analysis between changes in rsFC to behavioral metrics of alternate error reduction strategies (AERS) or adaptation specific processes (MAD). RsFC measured within the sensorimotor network was associated with alternate motor control strategies contributing to task performance on day 1, while increases within the cortico-thalamic-cerebellar network were associated with adaptation specific motor memory formation.

Title: Interference underlies the attenuation observed during relearning of a sensorimotor perturbation

Authors: *G. AVRAHAM, M. MALAVIYA, R. IVRY;
Univ. of California, Berkeley, Berkeley, CA

Abstract: Savings describes the benefits in performance resulting from the recall of a previously learned behavior. In sensorimotor adaptation, savings is tested by presenting the same perturbation over two learning blocks separated by washout. Savings, manifest as faster relearning, has been attributed to a recall of an explicit strategy (Haith et al. 2015, Morehead et al. 2015). We have recently shown that implicit adaptation does not contribute to savings, and is actually attenuated upon relearning (Avraham et al. 2021). To understand this attenuation, it is important to note that, due to the removal of the perturbation, participants are exposed to an opposite error during washout. A persistent trace of this experience may produce interference during relearning. To test this hypothesis, we used a visuomotor task that isolates implicit adaptation. While reaching to a target, the cursor followed an invariant path with an angular offset from the target. Despite instructions to ignore the cursor, participants show implicit adaptation to this clamped feedback, with the hand path shifting in a direction away from the target (and cursor). For one group (Active Washout), washout was induced by an initial exposure to an opposite clamped feedback followed by an extended period of veridical feedback. For another group (Passive Washout), all feedback was eliminated during washout; here participants exhibited a gradual, often incomplete decay back towards baseline. The Active group showed marked attenuation, with a ~30% decrease in aftereffect in the second learning block. In contrast, the Passive group did not show any sign of attenuation. Importantly, the absence of attenuation was not due to incomplete washout: There was no correlation between the hand angle measured during late washout and a measure of attenuation ($r=0.03$, $p=0.831$). These results suggest that attenuation requires experience with an error signal inconsistent with that experienced during learning. We next tested if prolonged exposure to veridical feedback prior to initial learning would produce attenuation. A new group (Prolonged Baseline) received veridical feedback for same number of trials as an Active group experienced in the initial learning and washout blocks. The learning of the Prolonged group was not attenuated; it was comparable to the initial learning

of the Active group. Thus, veridical feedback, even in the same experimental context as subsequent perturbed feedback, is not a source of interference. Overall, the results support the hypothesis that implicit adaptation is subject to interference effects between different errors experienced in a changing environment.

Title: Reinforcement feedback changes Beta and Gamma neural oscillations during visuomotor learning

Authors: *C. HILL[1], D. E. WADDELL[2], A. J. DEL ARCO[3,4];
[1]Northern Illinois Univ., Dekalb, IL; [2]Biomed. Engin., Univ. of Mississippi, University, MS;
[3]Health, Exercise Sci. and Recreation Mgmt. (HESRM), The Univ. of Mississippi, Oxford, MS;
[4]Neurobio. and Anatom. Sci., Univ. of Mississippi Med. Ctr., Jackson, MS

Abstract: Reinforcement feedback (i.e. reward and punishment) have dissociable effects on the learning of visuomotor adaptation tasks and differently affect the associated EEG activity (i.e. event-related potentials). Beta (β) and Gamma (γ) neural oscillations contribute to task learning and are sensitive to reinforcement feedback. However, it is currently unclear whether reinforcement feedback changes Beta and Gamma oscillatory activity during motor learning. . Participants were randomly placed into one of three groups [Reward (n=14), Punishment (n=14), Control (n=14)] and performed 280 trials of a visuomotor rotation task [Baseline (80 trials), Adaptation (200 trials)] with a Wacom pen and tablet. Adaptation (learning phase), featured an incongruent position between the cursor and the target, with the cursor trajectory rotated 30-degrees counterclockwise to the target, requiring participants to adapt their movement to hit the target. During Adaptation, after each trial, feedback was provided based on error magnitude in the form of a positive number (Reward), negative number (Punishment) or two vertical lines (Control). Positive and negative numbers represented a monetary gain and loss, respectively. EEG was recorded in during the Adaptation condition from 28 electrodes to measure spectral power of β (13-30Hz) and γ (30-50Hz) frequency bands after feedback presentation. Learning was quantified by calculating the average change in angular error (ΔΘ) trial to trial during Adaptation. We found that all feedback groups displayed similar reductions in error trial to trial throughout the learning phase ($F(2,39)=1.21$, $p=0.31$, ANOVA), suggesting reinforcement feedback does not alter task learning [Reward= -0.078ΔΘ, Punishment= -0.096ΔΘ, Control= -0.123ΔΘ]. Reward, but not Punishment, demonstrated an increased spectral power in β

(F(2,36)=3.87, p=0.03, ANOVA) compared to Control during Adaptation. Moreover, both Reward and Punishment demonstrated a decreased spectral power in γ (F(2,36)=5.19, p=0.011, ANOVA) compared to Control (p=0.014 and p=0.033 respectively). These results suggest that cortical β and γ oscillations reflect the saliency of reinforcement feedback and may operate as a marker of different error monitoring processes utilized during the task.

Title: Relating Resting-State EEG Frontoparietal Coherence with Visuospatial and Motor Skill Performance

Authors: P. WANG[1], K. R. LOHSE[3], A. PATHANIA[4], N. K. HAIKALIS[1], S. Y. SCHAEFER[2]; [1]Biomed. Engin., [2]SBHSE, Arizona State Univ., Tempe, AZ; [3]Physical Therapy, Washington Univ. in St. Louis, St. Louis, MO; [4]Hlth. and Kinesiology, Univ. of Utah, Salt Lake City, UT

Abstract: Visuospatial ability may explain individual variabilities in the extent of motor skill learning. Recent research suggested that better visuospatial scores correlate with more retention. Neuroimaging evidence suggests that the frontoparietal structures underlie both visuospatial performance and visuomotor learning. Furthermore, neuropsychological findings suggest that right frontoparietal networks specifically may be critical for this relationship, as many visuospatial processes are specialized to the right parietal cortex. Thus, this proof-of-concept study aims to test whether frontoparietal functional connectivity at rest, measured by resting-state EEG coherence, is related to both visuospatial performance and early motor skill acquisition. A retrospective dataset of 21 participants was analyzed, with 2-min eyes-closed resting state EEG, Visuospatial/Constructional Index score from the Repeatable Battery for the Assessment of Neuropsychological Status (RBANS) and five trials of motor practice on a functional motor task. Right frontoparietal coherence in the alpha band (8-12Hz) was computed with imaginary coherence (IC) between electrodes F4 and P4. ICs from the left (F3-P3) and midline (Fz-Pz) electrodes were also included as negative controls. Results indicated that F4-P4 alpha IC was highly correlated with the RBANS Visuospatial Constructional Index (r = 0.55, p = .035), while left and midline alpha ICs were not (all ps > .140). This study extends previous structural findings and indicated that frontoparietal functional connectivity, especially in the right

hemisphere, may underlie visuospatial function. However, this study did not find a correlation between right frontoparietal alpha IC with motor skill acquisition ($p = .474$), measured as within-session rate of improvement. This null finding is likely due to the limited dose of motor practice (only 5 trials) in the retrospective dataset, which was not inherently designed to investigate motor skill acquisition per se. Further studies are needed to use a larger training dose to accurately evaluate motor skill acquisition and its relationship with right frontoparietal coherence. However, this study supports that right frontoparietal IC is positively related with visuospatial function. This finding has implications for developing right frontoparietal alpha IC-based neurofeedback applications for cognitive training in and of itself, or to benefit slow- or non-learners in motor rehabilitation.

Title: Distinct patterns of cortical manifold expansion and contraction underlie human sensorimotor adaptation

Authors: *D. J. GALE[1], C. ARESHENKOFF[2], J. Y. NASHED[1], D. STANDAGE[1], R. D. MARKELLO[3], J. FLANAGAN[1], J. P. GALLIVAN[1];
[1]Ctr. for Neurosci. Studies, [2]Dept. of Psychology, Queen's Univ., Kingston, ON, Canada; [3]McConnell Brain Imaging Ctr., Montreal Neurolog. Institute, McGill Univ., Montreal, QC, Canada

Abstract: Previous studies have implicated a widely distributed network of cortical regions in sensorimotor adaptation that span motor, sensory, and cognitive networks. This work shows that the recruitment of these regions can vary throughout different stages of adaptation. However, the nature of interactions between these regions during learning, particularly within the context of cortical functional organization, remain poorly understood. To probe the network processes that underlie sensorimotor learning, we capitalized on recent connectivity gradient approaches that examine the low-dimensional structure of brain-wide patterns of connectivity. In two identical fMRI sessions, scans were collected while subjects (N = 32) adapted to an instantaneous 45-degree rotation applied to the cursor, following Baseline trials, during an 8-target center-out

movement task performed with the right hand. We characterized cortical functional connectivity patterns by a low-dimensional manifold, in which the top three principal components consisted of sensorimotor, visual, and frontoparietal gradients. Adaptation-related changes in functional integration and segregation were identified by manifold contraction and expansion, respectively, during the Early and Late adaptation phases. Relative to Baseline, Early adaptation was marked by manifold contraction in several motor (e.g., dorsal premotor cortex), parietal (e.g., intraparietal sulcus), and higher-order association (e.g., posterior cingulate cortex) regions in the contralateral (left) hemisphere. These regions also remained contracted during Late adaptation—wherein learning was largely complete—but were additionally accompanied by expansion of bilateral visual areas along the manifold (e.g., areas V3 and V4, lateral occipital cortex). We further demonstrate that the extent of manifold contraction of sensorimotor regions is related to individual differences in learning, such that greater contraction of sensorimotor regions is associated with lower overall error during Early adaptation. Together, these findings suggest that sensorimotor adaptation is characterized by the increased integration of contralateral sensorimotor regions within the cortical manifold, as well as the later segregation of visual areas from this same manifold, at a time when the contribution of visual feedback to performance is likely diminished.

Title: The effect of multiple concussions on rule-based and basic visuomotor performance in humans.

Authors: S. ENTEZAMI[1], M. DALECKI[2], N. SMEHA[1], J. A. BROWN[3], A. CAVALIERE[1], J. M. HURTUBISE[4], A. K. MACPHERSON[1], *L. E. SERGIO[1];

Abstract: Sustaining a concussion can affect many aspects of daily life, including basic and complex motor performance. While long-term effects of any concussion are increasingly documented, less is known about the effect of multiple concussions on skilled motor behavior. Recent rodent models of repeated concussion have noted increases in reactive oxidative species production, excessive excitatory amino acids and nitric oxide, and intracellular Ca2+ accumulation, all leading to Blood-Brain Barrier dysfunction and consequent pathology development. While our previous work in humans has consistently shown a decline in rule-based visuomotor performance (i.e., cognitive-motor integration,CMI) in those with a history of concussion (vs. no history), we have not specifically examined the effects of more than one concussion on behaviour. Here we characterize the cognitive-motor integration performance of individuals as a function of concussion number.
We tested 199 asymptomatic individuals ages 9-53 years old (mean 18.71, 29.2% female) with a history of 1-10 concussions (mean 1.67). To assess CMI performance, participants were tested on 2 visuomotor tasks where reach and gaze were spatially dissociated using two linked touchscreens: 1) a standard condition requiring direct interaction with visual targets, and 2) a dissociated non-standard conditions requiring CMI (visual feedback reversal and motion/viewed targets in different planes). Based on the literature, we hypothesized that those with 2 or more concussions would experience significantly greater neuropathological effects on the brain networks required for rule-based visuomotor performance, relative to those with just 1. We predicted that this would translate to a significant worsening of behavioral performance in these individuals. An exploratory aspect of the study was how age, athletic experience, and sex would affect the concussion/performance relationship. We observed significant differences in both basic visuomotor ($p<0.05$) and CMI ($p<0.01$) performance, but paradoxically those in the 2+ concussion group performed *better*. We found significant correlations between both age (positive) and sport experience (negative), and visuomotor/CMI performance ($p<0.01$,both). We also observed these correlations for concussion group inclusion($p<0.01$). Thus, these data suggest that such factors have a greater impact on performance. Conclusions: Our predictions were not supported. Rather, because our sample was fairly young, these data emphasize the clinical importance of accounting for developmental age and sport experience when assessing the effects of multiple concussion on visuomotor skill.

Title: Changes in large scale brain organization during long term sequence learning

Authors: *I. PAPPAS[1], A. TAMBINI[2], J. MILLER[3], A. KIYONAGA[4], M. DESPOSITO[5]; [1]Stevens Neuroimaging and Informatics Inst., USC, Los Angeles, CA; [2]Dept. of Neurobio. and Behavior, Univ. of California, Irvine, Irvine, CA; [3]Helen Wills Neurosci. Inst., UC Berkeley, Berkeley, CA; [4]Dept. of Cognitive Sci., UCSD, San Diego, CA; [5]Helen Wills Neurosci. Inst., Univ. of California Berkeley, Berkeley, CA

Abstract: During learning, distributed brain systems change their functional interactions in order to satisfy the demands of mastering the task at hand. Over the course of learning, human fMRI studies have shown that the brain shifts to a more differentiated state in which brain systems work autonomously (Bassett et al., 2015; Finc et al., 2020). However, these studies have used relatively simple tasks, sampled over modest learning windows, which may incompletely capture long-term changes in large-scale network configuration. Here, we asked how large-scale brain organization would be impacted by intensive task-learning over a protracted training period. To answer this question, we scanned individuals repeatedly across three months, densely sampling the learning process while acquiring structured sequence knowledge in the context of a serial reaction time (SRT) task. In this task, novel images were embedded in probabilistic temporal sequences of four stimuli. Robust sequence learning was observed behaviorally via reduced response time for intact sequences across sessions. To quantify changes in the brain's large-scale organization, we evaluated functional connectivity based on the brain's "background" fluctuations i.e., correlated fluctuations that were slower than the transit trial evoked activation. We then assessed that background connectivity using modularity, a graph-theoretic quantity measuring the integrity of whole-brain differentiated communities. High modularity implies more segregation between communities. Using linear mixed modeling we found that modularity consistently increased in participants as a function of time, indicating that a more differentiated network organization developed across task acquisition. However, this effect emerged later in training, suggesting that modularity increased gradually with learning. We also examined modularity in a second learning phase, when a set of novel images were introduced into the SRT task to reset the learning process. Some subjects showed a dip in modularity at the start of the second phase, which then recovered and increased again across learning, while other subjects showed a continuous increase in modularity. This individual variability may reflect different levels of adaptation to the new cognitive demands. In conclusion, over the course of 3 months, we found evidence for changes in large-scale organization in which brain systems became more autonomous, which may enable automaticity in executing well-learned tasks. In the future we want to examine whether these changes in modularity are driven by changes in large-scale interactions between specific learning systems.

Title: Bimanual control policies that confer coupling between the limbs are dependent on the inertial symmetry of a given task.

Authors: *J. YUK[1], A. PRZYBYLA[2], R. L. SAINBURG[1];
[1]Dept. of Kinesiology, Penn State Univ., University Park, PA; [2]Dept. of Kinesiology, Univ. of North Georgia, Physical Therapy, Dahlonega, GA

Abstract: Prior research on bimanual arm movements has shown that coordination depends on establishing a specific control policy or synergy in which potential errors arising from one hand can be efficiently compensated by the other. These control policies have been shown to recruit both feedforward and feedback mechanisms, which can yield remarkably symmetric temporal and spatial coupling between arms when required movements are mirror imaged and unperturbed. Coupling of bimanual movements through such control policies has been shown to be maximized when the task is shared between the arms (shared cursor condition), as compared to when the task is independent (independent cursor for each hand). Previous research has indicated that interlimb differences in coordination during reaching movements are associated with dominant arm advantage for coordinating intersegmental inertial dynamics. We now ask whether bilateral control policies associated with shared, as compared with independent task conditions reduce movement asymmetries through coupling of interlimb commands and feedback mediated actions. We designed a task with either symmetric or asymmetric intersegmental inertial requirements. We hypothesized that bimanual control policies established during the shared (single cursor) condition should reduce interlimb trajectory asymmetries, as compared with those during the non-shared condition (independent cursors). We found a strong spatial correlation and temporal synchrony of both arms when the two arms reached with symmetrical inertial conditions, but poor correlations and asynchronous actions when reaching with asymmetrical inertial conditions. This pattern was not affected by cursor condition (shared or independent), as we predicted. We conclude that bimanual control policies that confer interlimb coupling during bimanual tasks are dependent on the biomechanical symmetry of the task, and thus are not general in nature. Therefore, this type of bimanual coupling should be limited in the application to most common tasks, which do not involve mechanically symmetric actions.

Title: Mouse motor cortex activity during the dexterous high-speed oromanual movements of food-handling

Authors: *J. M. BARRETT, A. FORREST, F. HAUSMANN, N. LONGO, M. E. MARTIN, W. MWANIKI, M. G. RAINERI TAPIES, M. TORRES, G. M. SHEPHERD;
Feinberg Sch. of Med., Northwestern Univ., Chicago, IL

Abstract: The coordinated use of the hands and mouth to manipulate and consume food items is an ethologically relevant forelimb behavior exhibited by mice. Prominent features of this behavior include rapid cycling between a passive ‘holding’ mode and an active ‘oromanual’ mode, and ultra-fast ‘regrip’ maneuvers (Barrett et al, 2020). To explore the neural basis for this skillful behavior, we recorded from motor and somatosensory cortical regions during food handling.

High-speed (1000 fps) video was recorded while head-fixed adult mice of either sex handled and ate food items such as sunflower seeds and grain pellets. Kinematics were analyzed using DeepLabCut tracking. Recordings of single- and multi-unit spiking activity were made using 32-channel linear multielectrode arrays placed in forelimb motor cortex (fl-M1), forelimb somatosensory cortex (fl-S1), or tongue-jaw motor cortex (tj-M1; Mayrhofr et al.,2019).

In all three recorded regions, array-average firing rates were higher during the oromanual phase than during holding. However, the pattern of activity in each region was distinct. fl-M1 firing peaked around the transition into oromanual, then decayed slightly but remained elevated above baseline as handling continued. By contrast, fl-S1 and tj-M1 were both tonically active throughout the oromanual phase.

Array-average firing rates may mask neuron-to-neuron variation in patterns of food-handling-related activity. To investigate these, we clustered neural responses using non-negative matrix factorization (NNMF; Lee & Seung, 1999; Xu et al. 2020). In all three regions NNMF revealed two main clusters: one peaking in activity around the transition into the oromanual phase; and the other active later in the oromanual phase and peaking around regrips. Relatively more of the former type of response was seen in fl-M1, whereas fl-S1 and tj-M1 had proportionally more of the latter.

Our findings show that activity in sensorimotor cortex correlates with kinematic features of ongoing food-handling behavior, with patterns of activity that vary as a function of cortical area and between neurons within a given area. These results support the use of food-handling as a paradigm for studying neural mechanisms of complex, innate, dexterous behavior in the mouse.

Title: Interactions between discrete and rhythmic movements in bimanual upper-limb control

Authors: R. ANGEL, *S.-W. PARK;
The Univ. of Texas at San Antonio, San Antonio, TX

Abstract: Many motor tasks in everyday life, such as driving and cooking, involve a combination of discrete and rhythmic movements. Although an increasing number of studies have identified discrete and rhythmic movements as dynamic primitives in complex motor control, specifying conditions in which rhythmic movements facilitate discrete movements and vice versa remains unknown. The present study measures the change of kinematics when ongoing rhythmic movement in one arm is perturbed by rhythmic or discrete initiation of the other arm.Thirteen healthy young adults participated in the study after giving a written informed consent approved by the Institutional Review Board. The participants performed bimanual forearm rotation on the horizontal plane. In one condition (DISCRETE), their non-dominant arm initiated a point-to-point reaching while their dominant arm moved rhythmically at a specific tempo (0.75 Hz). In the other condition (RHYTHMIC), their non-dominant arm initiated a rhythmic movement while their dominant arm performed the same rhythmic movement as in the first condition. For both conditions, timing of the imperative visual cues for initiation was randomized. The elbow angle profile from the two forearm rotations was recorded by absolute encoders so that the veridical elbow angle was displayed on a monitor in real time. The task consists of two phases: Familiarization and test. In the familiarization phase, the participants practiced moving their forearm at a specific speed (180 deg/s) for the discrete movement and at a specific tempo (0.75 Hz) for the rhythmic movement unimanually and then bimanually. In the test phase, approximately 100 trials for the DISCRETE condition (50 inward and 50 outward movements) and 100 trials for the RHYTHMIC condition were performed for each participant. We analyzed the magnitude and direction of the perturbation in the ongoing rhythmic movement in the dominant arm as calculating the root-mean-squared error between the desired and actual profile of instantaneous phase in the dominant arm at the initiation of the non-dominant arm.

Results showed that, when a rhythmic movement is initiated, the amount of perturbation in the ongoing rhythmic arm depended on the phase relationship between the two arms. When a discrete movement is initiated, the amount of perturbation in the ongoing rhythmic arm depended on the phase of the ongoing arm at the initiation of the discrete movement. Interestingly, this was independent from the direction of the initiation of the discrete arm. The results suggest that the underlying neural mechanism in discrete movement is different from that in rhythmic movement.

Title: The effects of bimanual coordination constraints on postural control

Authors: *J. M. HONDZINSKI[1], M. DAVIS[2], Y. WANG[2], R. CASTRO, Jr.[2], R. HUA[2,3], D. M. KENNEDY[2];
[1]Sch. of Kinesiology, Louisiana State Univ., Baton Rouge, LA; [2]Dept. of Hlth. and Kinesiology, [3]J. Mike Walker '66 Dept. of Mechanical Engin., Texas A&M Univ., College Station, TX

Abstract: Many activities of daily living require individuals to coordinate actions with their upper limbs while standing. A coalition of bimanual coordination constraints have been identified that influence the impact of one limb on the contralateral limb, including cortical and subcortical neural crosstalk. However, it is unclear if these bimanual constraints also impact balance. Therefore, the current experiment was designed to determine the effects of bimanual coordination constraints on postural control. Eleven right limb dominant participants (mean age = 20.9, 6 Female, 5 male) were required to rhythmically produce patterns of isometric force by abducting their index fingers in a 1:1, 1:2, and 2:1 coordination pattern while standing on a force plate. Lissajous displays and a goal template were used to guide performance. The template illustrated the specific pattern of force requirements needed to produce the coordination patterns. Participants performed 20, 35 second trials in 2 blocks for each coordination pattern at 10% maximum voluntary contraction (MVC). Results indicated the participants could quickly and effectively perform the bimanual coordination patterns within the allotted trials. As expected, bimanual performance was more accurate and stable for 1:1 compared to 1:2 and 2:1 patterns. When comparing the 1:2 and 2:1 tasks, the results indicated that the dominant limb influenced the non-dominant limb regardless of which limb was performing the faster frequency; however, the non-dominant limb only influenced the dominant limb when assigned the faster frequency.

This influence is also reflected in the harmonicity values with decreased harmonicity for the left limb in the 1:2 task and for both the left and right limb in the 2:1 task. A decrease in harmonicity indicates an increase in adjustments, hesitations, and/or perturbations. Similarly, the postural sway data indicated that participants were more stable during the 1:1 task than the 1:2 and 2:1 tasks. When performing the 1:2 and 2:1 bimanual coordination tasks greater medial-lateral sway displacement was observed than for the 1:1 task. However, no differences were observed in the anterior-postural direction during the bimanual tasks. These results are consistent with previous investigations indicating the neural crosstalk can influence bimanual coordination by stabilizing 1:1 coordination and interfering with other frequency patterns. Interestingly, it appears that the motor, perceptual, and/or cognitive constraints associated with bimanual coordination can also influence postural control.

Title: Deficits in performance on a mechanically coupled bilateral task in chronic stroke survivors with mild unilateral paresis

Authors: *S. A. L. JAYASINGHE[1], C. MAENZA[1,2], D. GOOD[1], R. L. SAINBURG[2,1]; [1]Neurol., Pennsylvania State Univ. Col. of Med., Hershey, PA; [2]Kinesiology, Pennsylvania State Univ., State College, PA

Abstract: Most upper extremity mediated activities of daily living require coordinated interaction between the arms, such as when buttoning a shirt or cutting a slice of bread. Previous work using bilateral reaching tasks performed either synchronously or asynchronously have provided evidence of bilateral coordination deficits in stroke survivors. However, these approaches have typically used movements that do not reflect the distribution of functions that occur in everyday tasks, nor have they addressed the natural type of mechanical coupling that occurs between the arms in such tasks. We now present a virtual reality-based task that incorporates mechanical coupling, requiring that one hand stabilize against a spring load that varies with the displacement of the other arm. We examined differences in performance between the ipsilesional and contralesional hands in these two aspects of control in 15 unilateral chronic stroke survivors with mild contralesional impairment. We also examined differences between

hands in 7 age-matched typical adult controls. All participants were right-handed. The hands were connected by a spring, and participants had to maintain the position of one hand while using the other hand to perform a rapid out-and-back movement. We present two primary performance measures to reflect the positional stability of the stabilizing hand (acceleration and maximum distance moved) and accuracy and coordination of the reaching hand (initial direction error and linearity). For reaching performance, we found that performance was more erroneous in our stroke group than in the control group. We found a main effect of group for linearity ($F(1,20)=6.57$, $p=.019$), and post hoc analysis revealed significant differences between hands in stroke survivors ($p=.047$). We found a main effect of group for initial direction error as well ($F(1,20)=4.36$, $p=.0498$). For stabilizing performance, we found a significant interaction between hand and group for acceleration ($F(1,20)=6.75$, $p=.017$), such that the dominant right hand of controls accelerated more than the nondominant left hand. While the spring forces imposed by motion of the reaching hand produced interaction effects with regards to acceleration, these effects were not significant for distance. Our findings suggest that when remediating bilateral movements in stroke, using the ipsilesional arm for manipulation while using the contralesional arm for stabilizing might be an effective strategy. However, more research is necessary to determine whether this strategy can be effective when it is opposite to the pattern used premorbidly, due to handedness.

Title: Repeated locomotor adaptation and de-adaptation facilitate retention of motor learning during walking in individuals post-stroke

Authors: *S. PARK[1,2], S. YAN[1,2], W. DEE[1], R. REED[1], E. ROTH[1,2], W. RYMER[1,2], W. MING[1,2,3];
[1]Shirley Ryan AbilityLab, Chicago, IL; [2]Northwestern Univ., Chicago, IL; [3]Univ. of Illinois Chicago, Chicago, IL

Abstract: Gait restoration has been one of the important parts of stroke rehabilitation. Inducing continuous adaptation to new walking patterns has been widely used for rehabilitation of gait after stroke. However, walking is already a complex task and the adaptation to novel walking

patterns with no/minimal rest during a single session may be too physically demanding to efficiently promote the locomotor learning. Here, we test whether the spaced-out adaptation (i.e., repeated adaptation and de-adaptation) to novel walking patterns elicited by external perturbation induces better retention of the adapted locomotion in stroke survivors, compared with the effect of the continuous adaptation. Fifteen individuals post-stroke (58.5±6.0 years, 6 women) participated in two experimental sessions consisting of 1) treadmill walking inducing spaced or continuous adaptation to externally perturbed walking patterns and 2) overground walking. During the treadmill walking, we applied the laterally pulling force to the pelvis toward the non-paretic side during the stance phase of the paretic leg to disturb mediolateral weight shifts toward the paretic side. Both spaced and continuous condition elicited improved weight shift toward the paretic side and enhanced muscle activation of hip abductor and adductors immediately after the removal of the pelvis perturbation ($P<0.05$). Only the spaced condition retained these improved weight shift and enhanced muscle activation later after the perturbation release and even exhibited increased overground walking speed after the treadmill walking ($P<0.04$). We provide new evidence that spaced adaptation to novel locomotor patterns reinforces retention of the adapted locomotion and its generalization to the other context, compared with the effect of the continuous adaptation.

Title: Feasibility of a virtual reality based upper extremity rehabilitation platform

Authors: *A. BRUNFELDT[1], P. LUM[2], B. BREGMAN[1], A. W. DROMERICK[3]; [1]Georgetown Univ., Washington, DC; [2]The Catholic Univ. of America, Washington, DC; [3]Natl. Rehab Hosp, Washington, DC

Abstract: Translational researchers are intensely focused on developing safe and effective therapies for people with motor impairments. Recent advances in upper extremity stroke rehabilitation have failed to show sustained improvements. This is likely due to therapies either costing substantial time and money, or they lack resemblance to activities of daily living. To

improve health outcomes for patients, we need ecologically valid movement tasks capable of increasing patients' use of their paretic limb. Here we developed a virtual reality (VR) reaching task using commercially available equipment to systematically alter bilateral coordination to favor the use of one limb over the other.
We conducted a feasibility study in healthy, right-handed volunteers where they performed a bimanual reaching task in a 3-dimensional VR environment. They controlled a shared cursor, located at the midpoint between the hands, and reached to targets located at 80% of full arm extension. Participants completed a total 480 reaches divided into 5, 96 trial blocks. In the first, third, and fifth blocks, participants reached normally. In the second and fourth blocks they reached with a wrist weight applied to one limb. We used surface EMG to approximate muscle activity in the anterior deltoid and biceps brachii, bilaterally. Relative contribution (RC) was calculated as the right hand displacement divided by the sum of right and left hand displacements. The root mean square (RMS) of surface EMG was used to calculate muscle contribution (MC), computed as RMS in the right muscle divided by the sum of RMS in both muscles (per pair).
We found that during the first baseline block, participants reached with an equal contribution from both arms (RC = 50%). RC increased by 0.91% and MC decreased by 5.6% relative to baseline when the weight was applied to the left arm; RC decreased by 0.94% and MC increased by 6.7% when the weight was applied to the right arm. These data suggest participants alter coordination in an attempt to minimize muscle output asymmetry between limbs. Our task can be paired with assistive devices that normalize muscle output asymmetries between the upper extremities in hemiplegic stroke patients. This may form the basis for low cost, at-home technologies for stroke rehabilitation.

Title: The flexibility vs persistence of visual-motor control policies (synergies) for coordinating bilateral arm movements

Authors: *N. M. KITCHEN[1,2], R. L. SAINBURG[2,1], A. PRZYBYLA[3];
[1]Dept. of Neurology, Col. of Med., Penn State Univ., Hershey, PA; [2]Dept. of Kinesiology, Penn State Univ., State College, PA; [3]Dept. of Kinesiology, Univ. of North Georgia, Physical Therapy, Dahlonega, GA

Abstract: Prior research on bimanual arm movements has shown that coordination depends on establishing a specific control policy or synergy in which potential errors arising from one hand can be efficiently compensated by the other. These control policies have been shown to recruit both feedforward and feedback mechanisms, which results in remarkably symmetric temporal and spatial coupling between arms when required movements are mirror imaged and unperturbed. In contrast, when the required movements of the two arms differ, decoupling can be remarkably difficult and lead to bilateral interference. Thus, previous evidence suggests that bimanual control policies can either facilitate or degrade coordination, depending on task demands. Here, we address the flexibility vs persistence of visual-motor control policies for coordinating bilateral movements. Participants performed a series of bimanual reaching movements to transport a single, shared cursor from a start position to a target along the mid-sagittal axis. On different blocks of trials, the gain contribution of either hand to the cursors horizontal position (i.e. perpendicular to start-target axis) was covertly manipulated to be either equal (2:2 ratio) or asymmetric (3.8:0.2 ratio) between hands. We predicted that an inflexible bimanual control policy would be unaffected by asymmetric gains such that covariance would be maintained between the hands, while a compliant policy should adjust to the asymmetric gain conditions, reducing covariance. We found a significant change in the regression slope for the asymmetric gain conditions, consistent with a compliant bimanual control policy. However, this effect was significant only at movement end and was incomplete, maintaining some covariance under conditions where it was of no benefit to task accuracy. Furthermore, these changes in control policy appeared implicit because modifications of gain were covert, and participants did not report awareness of the gain manipulation following the experiment. Thus, visual-motor control policies for coordinating bilateral movements respond flexibly to task demands but this adaptability is limited by persistence of bimanual coupling.

Title: Human-human connected dyads learning a visuomotor rotation in a movement tracking task

Authors: *A. GENDY[1], J. L. PATTON[2], M. DEMASI[1];
[1]Univ. of Illinois, Chicago, Chicago, IL; [2]Sensory Motor Performance Prog, Rehab Inst. Chicago, Chicago, IL

Abstract: Dyads are 2 humans coupled to collaborate to perform a task together. Several studies have shown that mechanical haptic interactions lead to the dyad outperforming the solo task. These achievements are hypothesized to be the result of haptic communication, triggering the creation of internal forward models. The dyad acquires and exploits additional information about itself, improving performance. Here we show a novel Pantograph device used in a pilot study to further study this learning process. Like other studies, seated subjects practiced a pursuit task for 40 minutes holding the pantograph handles with visual feedback from a flatscreen superimposed above their arms. We hypothesized that Novice-Novice interaction enhances learning speed more than Expert-Novice, since it requires mutual negotiation. We found this was unsupported (learning time constants 5.53 ± 2.79 for Novice-Novice and 8.45 ± 3.78 for Expert-Novice, p = .075). This study demonstrates how a simple device built in-house for haptic interaction between humans can further reveal the characteristics of collaborative learning processes.

Abstract: Microelectrode arrays are standard tools for conducting chronic electrophysiological experiments, allowing researchers to simultaneously record from large numbers of neurons. Specifically, Utah electrode arrays (UEAs) have been utilized by scientists in many species, including rodents, rhesus macaques, marmosets, and human participants. The field of clinical human brain-computer interfaces currently hinges on using the UEA as several research groups

have FDA clearance through the investigational device exemption pathway. Despite its widespread usage in systems neuroscience, few studies have comprehensively evaluated the reliability and signal quality of the Utah array over long periods of time in a large dataset. We collected and analyzed over 6000 recorded datasets from various cortical areas spanning almost a decade of experiments. The scale of this dataset allowed us to evaluate the average life of these arrays, based primarily on the signal-to-noise ratio of each electrode over time. Using implants in multiple motor-related cortices, we found that the average lifespan of available recordings from UEAs was over one and a half years, although we provide several examples of these UEAs lasting over 1000 days and one up to 9 years; human implants were also shown to last longer than non-human primate implants. We also found that electrode length did not affect longevity and quality, but iridium oxide metallization on the electrode tip exhibited superior longevity and quality as compared to platinum metallization.

Title: Temporal network dynamics of cortical neurons reveal single-trial task information in the progression of pairwise correlations

Authors: *M. SUNDIANG, N. G. HATSOPOULOS, J. N. MACLEAN;
Univ. of Chicago, Chicago, IL

Abstract: Neural dynamics in primary motor cortical (MI) populations underlie skillful, voluntary movements. Linking these population dynamics to individual neurons is key to understanding how MI drives complex behaviors. To do so we summarize pairwise correlations between neurons by representing population dynamics as a functional network (FN). Typically FNs are generated on a trial by trial basis. However since movement is inherently a dynamic process, here we capture the temporal progression of these pairwise correlations within small epochs of time throughout the trial in order to accurately relate single-trial population dynamics to behavior. We constructed FNs by measuring the estimated mutual information between spike trains in macaque MI within a sliding window across single-trials in a center-out reaching task. To examine the temporal progression of the networks over the course of a single trial, temporal FNs were projected into a low-dimensional space using UMAP. This low-dimensional

embedding revealed that the dynamically evolving trajectories of the single-trial temporal FNs in this space are separated and carry information about the instructed reach. Additionally, we measured the network similarity (graph alignment score, GAS) between all pairs of FNs and show that the similarity of these temporal FNs depend on the similarity of the reach, and become maximally dissimilar when we compare opposite reach directions. To determine how discriminable the instructed reach is using single-trial FNs, we measured the fraction of k-nearest-neighbors in the high-dimensional space belonging to the same reach direction using a precision-at-k (p@k) metric. We observe a significant increase p@k of FNs constructed from the data compared to FNs constructed from rate-matched Poisson neurons indicating additional information beyond firing rates alone, again, highlighting the importance of pairwise correlations in decoding behavior. These results demonstrate that FNs carry behaviorally relevant information and that they are dynamic over time which argues for a temporal network perspective to link neural dynamics and network structure to complex behavior.

Title: Characterizing neuromechanical strategies used by marmosets during foraging and prey capture

Authors: *J. WALKER[1], J. N. MACLEAN[3], N. G. HATSOPOULOS[2];
[1]Organismal Biol. and Anat., [2]Univ. of Chicago, Chicago, IL; [3]Neurobio., The Univ. of Chicago, Chicago, IL

Abstract: Understanding the cortical contribution to motor control will benefit from investigations of motor cortical neural dynamics during complex naturalistic behaviors (Saxena & Cunningham 2019; Gao & Ganguly 2015; Gao et al. 2017; Musall et al. 2018). Foraging and prey capture are ideal behaviors to study as they are ethologically relevant and provide natural extensions of standard experimental tasks used to study motor control and learning (Borghuis & Leonardo 2015; Hein et al 2020; Yoo et al. 2020). Here we apply a voluntary behavioral training approach to allow common marmosets (Callithrix jacchus) daily sessions of foraging (mealworms) and prey capture (moths and crickets) over the course of multiple months. We use markerless motion capture to reconstruct the kinematics of the marmoset's visuo-manual

behavior and wireless multi-electrode array recordings to simultaneously sample sensorimotor neocortical populations from premotor cortex, primary motor cortex and primary sensory cortical areas. We present preliminary estimates of kinematic distributions and sensorimotor delays characterizing marmoset foraging and prey capture toward a description of neuromechanical strategies employed during these naturalistic visuo-manual behaviors.

Title: Dissociating intrinsic and input-driven neural dynamics underlying behavior

Authors: *P. VAHIDI, O. G. SANI, M. M. SHANECHI;
Electrical and Computer Engin., USC, Los Angeles, CA

Abstract: To understand the neural population dynamics underlying behaviors, it is crucial to study the source from which these dynamics emanate. Neural dynamics observed in a brain region could either be largely due to the intrinsic dynamics of the recurrent networks within that region, or reflect the dynamics of the inputs to that region. These inputs could be excitations from other brain regions or even from sensory stimuli. Since inputs themselves could be temporally structured, a major challenge is faced when building models of neural dynamics: these models may misinterpret input dynamics as intrinsic dynamics emanating from the recurrent networks within the brain region. As a result, researchers may be limited in what conclusions they can make from these models and may need to design careful experiments — for example by only using external sensory inputs that are not temporally structured. Further, whether input-driven or intrinsic, neural population dynamics relate to a diversity of behaviors and functions that happen simultaneously; thus, it is critical to dissociate those dynamics that are relevant to a particular measured behavior of interest (e.g. limb movement kinematics) so that they are not masked or confounded by other dynamics. Recently, we developed a new method called preferential subspace identification (PSID) that dissociated behaviorally relevant neural dynamics but without explicit modeling of inputs (Sani et al, Nat Neurosci, 2021). Here, we develop a new modeling approach termed input-PSID (IPSID), that addresses both challenges simultaneously. Our new approach enables dissociation of intrinsic neural dynamics from the

dynamics of measured inputs (e.g. sensory task instructions), and hence avoids learning models that are confounded by sensory input dynamics. IPSID also models the effect of input on neural activity and prioritizes the learning of behaviorally relevant neural dynamics, whether input-driven or not, such that they are not masked by other neural dynamics. We first demonstrate in numerical simulations that IPSID correctly dissociates intrinsic dynamics from input dynamics. We next apply IPSID to neural activity recorded from monkeys during behavioral tasks. We find that IPSID learns distinct neural dynamics and intrinsic modes of activity that are not confounded by sensory input dynamics. Moreover, models learned by IPSID more accurately explain behaviorally relevant neural dynamics compared with prior modeling approaches. IPSID uniquely enables the dissociation of input dynamics from intrinsic behaviorally relevant neural dynamics to study the neural basis of behavior.

Title: Learning behaviorally relevant dynamics in population spiking activity with Poisson preferential subspace identification (Poisson-PSID)

Authors: *L. L. OGANESIAN, O. G. SANI, M. M. SHANECHI;
Electrical Engin., USC, Los Angeles, CA

Abstract: Population spiking activity consists of a large number of binary time-series happening at fast millisecond time-scales and indicating the presence or absence of action potential events. This activity can simultaneously represent a mixture of numerous cognitive processes and behaviors, leading to two challenges when modeling the neural encoding of behavior. First, encoding models need to describe the temporal structure of both behavioral and spiking activity, the latter being a collection of binary time-series. Second, encoding models need to dissociate the behaviorally relevant information in spiking activity, defined as all the information related to a particular measured behavior of interest, from other information. Algorithms that learn state-space models with linear-nonlinear Poisson observations for population spiking activity do not address the second challenge because they are unsupervised with respect to behavior. We recently developed the preferential subspace identification (PSID) algorithm that solves both

challenges for continuous neural observations, such as field potentials or binned spike counts (Sani et al, Nat Neurosci, 2021). However, dissociating behaviorally relevant dynamics while taking into account the discrete binary nature and fast timescale of spiking activity introduces the new challenge of finding shared subspaces between hybrid continuous and discrete signals. Here we introduce a new learning algorithm termed Poisson-PSID that addresses this new challenge by jointly modeling both continuous behavioral and discrete population spiking activity in terms of low-dimensional latent states, while dissociating and prioritizing behaviorally relevant spiking dynamics. We show that Poisson-PSID can successfully learn low-dimensional models of spiking dynamics that preserve behaviorally relevant information and decode behavior more accurately. This new Poisson-PSID algorithm can be used to uncover low-dimensional behaviorally relevant manifolds in population spiking activity, helping reveal the neural basis of diverse behaviors across brain regions and enabling better brain-machine interfaces.

Title: Nonlinear modeling of behaviorally relevant neural dynamics using recurrent neural networks

Authors: *O. G. SANI[1], B. PESARAN[4], M. M. SHANECHI[1,2,3];
[1]Electrical and Computer Engin., [2]Neurosci. Grad. Program, [3]Biomed. Engin., USC, Los Angeles, CA; [4]Ctr. for Neural Sci., New York Univ., New York, NY

Abstract: Neural activity exhibits diverse dynamics that simultaneously relate to multiple brain functions and behaviors. Thus, a significant challenge when studying the neural basis of a specific measured behavior is that the dynamics related to that behavior may be masked or confounded by all the other neural dynamics that coexist. Recently, we developed a method termed preferential subspace identification (PSID) that addresses this challenge (Sani et al, Nat Neurosci, 2021) by modeling behavior and neural activity jointly while prioritizing the learning of their shared dynamics. While PSID addresses the challenge of learning behaviorally relevant neural dynamics within a linear modeling framework, studies suggest that neural dynamics, including potentially behaviorally relevant dynamics, could be nonlinear. Here, we develop a

new method using recurrent neural networks (RNN) that learns nonlinear dynamical models with low-dimensional latent states that can predict behavior and neural activity, while prioritizing preservation of shared dynamics and states between behavior and neural activity. As a result, this method also enables nonlinear dimension reduction for neural activity in a way that preserves behaviorally relevant neural dynamics. We validate the method in numerical simulations and then use it to explore nonlinearities in behaviorally relevant neural dynamics in multiple experiments that record neural activity in monkeys performing different behavioral tasks. We find that this nonlinear method extracts low-dimensional latent states from neural activity that more accurately predict behavior compared to linear PSID and nonlinear dynamic modeling approaches that do not prioritize behaviorally relevant information. Further, using the new method, we find that across multiple experiments, similar model parameters are consistently the most important in capturing the nonlinear behaviorally relevant neural dynamics. Finally, we demonstrate that models learned by the new method achieve better neural decoding of behavior compared with other methods while still being fully causal and real-time. Overall, the novel method introduced here enables flexible nonlinear dynamical modeling and dimension reduction of neural population activity while preserving behaviorally relevant information and enabling causal real-time behavior decoding.

Title: Efficient learning of low dimensional latent dynamics in multiscale spiking and field potential population activity

Authors: *P. AHMADIPOUR, O. G. SANI, Y. YANG, M. M. SHANECHI;
Electrical and Computer Engin., USC, LOS ANGELES, CA

Abstract: Learning low-dimensional latent state representations in spike and field potential activity together can reveal the relationships between population dynamics across different spatiotemporal scales and how they explain behavior. But because spikes are discrete-valued action potential events with millisecond time-scales while field potentials are continuous-valued with slower time-scales, their simultaneous multiscale modeling had remained elusive. We

recently resolved this challenge by developing a multiscale expectation maximization (multiscale EM) algorithm that maximizes the joint likelihood of these signals iteratively, and discovers a multiscale low-dimensional dynamical mode that is shared in spike-field activity and best explains naturalistic movements (Abbaspourazad et al, Nature Communications, 2021). However, in some applications -- for example when tracking adaptation and plasticity in basic science studies or during real-time learning in brain-machine interfaces --, a desirable feature for a learning algorithm is computational efficiency. Consequently, it is critical to develop multiscale learning methods that are more computationally efficient than the multiscale EM, which is iterative. Here, we develop a multiscale subspace identification (multiscale SID) algorithm that enables computationally efficient multiscale learning and dimensionality reduction for simultaneous spike-field activity. We demonstrate that the new multiscale SID accurately learns dynamical models of spike-field signals, extracts multiscale low-dimensional dynamics/modes in these signals, and decodes behavior. Further, it correctly aggregates information from spikes and field potentials, leading to better identification of multiscale dynamics/modes and decoding of behavior compared to using a single scale. Most critically, multiscale SID achieves the above precise learning, dimensionality reduction, and decoding with much lower computational cost compared with multiscale EM while having better or similar accuracy. Overall, multiscale SID is beneficial both for studying multiscale neural dynamics and for brain-machine interfaces, especially when efficient and real-time tracking is important such as in learning and adaptation experiments or in brain-machine interfaces.

Title: Cortical motor maps depending on learning- and contexts

Authors: *K. TAMURA, H. THIALLIER, S. CROCHET, C. C. H. PETERSEN;
École Polytechnique Fédérale de Lausanne (EPFL), Lausanne, Switzerland

Abstract: Cortex contributes to motor control, but cortical motor maps remain relatively poorly-defined. Here, we have begun to investigate whether cortical motor maps can change depending on learning and context. To quantitatively map causal behavioral impact, we optogenetically stimulate the dorsal cortex of head-fixed mice by focal laser pulses, and analyze the evoked orofacial movements by high-speed video filming. In naïve Thy1-ChR2 mice, stimulation in different coordinates evokes movements in different facial parts such as whiskers, jaw, nose and eyelids. Movements of the jaw are robustly evoked, but tongue protrusions are less apparent. Next, the mice are water-restricted and encounter a task in which they are sometimes unpredictably rewarded by voluntarily licking a spout. We perform optogenetic stimulation during inter-trial-intervals, and we do not reward the licks following the optogenetic stimulation. Unexpectedly, optogenetic stimulation now appears to evoke rhythmic protrusion of the tongue. The corresponding tongue motor map appears to show a focal spot in the area where jaw movements are also evoked, suggesting overlap of tongue and jaw primary motor cortex (tjM1). We next perform the motor mapping in the same mice after they have learned to lick the reward spout in response to a brief deflection of a single whisker. As a result, the tongue motor map appears to extend more posteriorly from tjM1 to somatosensory cortices. These results suggest that cortical motor maps are plastic and adapt depending on task demand and context. To further analyze the dynamics of cortical motor maps and the underlying circuit mechanisms, we are now studying layer-specific ChR2 mice during context-discrimination tasks combined with wide-field calcium imaging.

Title: Isolation of learned skills in motor cortex in a context-switching task

Authors: E. M. TRAUTMANN[1], N. J. MARSHALL[2], H. CHEN[4], E. ALIYARI[5], E. AMEMATSRO[5], D. M. WOLPERT[3], M. N. SHADLEN[6], M. M. CHURCHLAND[2]; [1]Zuckerman Inst., Columbia Neurosciences, New York, NY; [2]Neurosci., [3]Columbia Univ., New York, NY; [4]Columbia, New York, NY; [5]Columbia, NEW YORK, NY; [6]Neurosci., Howard Hughes Med. Inst. - Columbia Univ., New York, NY

Abstract: The brain can acquire a vast repertoire of motor skills, each requiring its own sensorimotor transformations. The motor cortex (M1) performs computations to control muscle activity, including error correcting responses. Are these computations skill-specific, or do they lie downstream of the library of motor skills? Put differently, if two skills require identical patterns of muscle activity, does M1 use different strategies or a unified strategy? In support of a unified strategy, pro- and anti-reaches are generated by similar M1-activity patterns. Yet this case is ambiguous — the sensory-motor transformations could be accomplished well before the reach. We thus sought to compare two skills that required different sensorimotor mappings throughout the movement, yet produced the same muscle activity. We trained a monkey to follow a scrolling path with a cursor using isometric forces. We employed two 'skill contexts', in which the cursor either moved up or down with increasing force. The same forces were generated in both contexts, driven by paths with inverted shapes. Using primate Neuropixels, we recorded large populations of neurons from M1 and dorsal premotor cortex. Most neurons' activity was strongly context dependent. A context-independent (force-predictive) neural dimension captured a modest fraction of the population variance. In most dimensions, activity was unrelated to force and was strongly context-dependent. We hypothesized that context-dependent activity enables transformation of the same visual error into different motor corrections. We introduced visual cursor perturbations, and found two dimensions that captured perturbation specific responses. In the first, transient activity reflected the sign of the visual perturbation. In the second, activity was more sustained and reflected the sign of the motor response. We speculate that this can occur because cortical dynamics allow activity in the 'visual' dimension to impact activity in the 'motor' dimension. Such dynamics have to be context-dependent, because the sign of the sensory-motor transformation reverses between contexts. This is consistent with the fact that cortical activity was strongly context dependent when the perturbation was delivered, allowing different local dynamics to implement the visual-to-motor transformation. These results suggest that neural activity driving feedback control in motor cortex is skill-specific. Initially this strategy seems implausible: it requires unique patterns of activity for every skill that maintain the necessary low trajectory tangling. Yet this is sensible given recent findings that M1 activity is surprisingly high dimensional.

Abstract: What does the motor cortex contribute to behavioral decisions, performance and subcortical dynamics? Motor cortex and the basal ganglia may work together to plan movements, potentially through the generation of motor plans and control of kinematic parameters, respectively. This hypothesis has clear and testable predictions about the contribution of motor cortex to striatal dynamics and animal behavior. We sought to study movement kinematics during spontaneous and goal-directed behavior before and in the days immediately following bilateral lesions of the caudal forelimb area (CFA). This behavioral monitoring was paired with recordings from MSN and FSI neural populations in striatum. Mice were trained on a basic or reaction time-based reaching task. In both tasks, movement kinematics were severely impaired following ablation and began to recover towards baseline performance after 6-8 days.
Reaction time drastically increased and then return to pre-ablation levels. Concurrent recordings in striatum revealed a selective loss of tuning to movement onset and kinematics in both MSN and FSI populations, with severely altered response arising only after behavioral recovery.
Additionally, we found that while locomotion was largely intact after lesions, however when faced with a decision (e.g. to turn left or right) the animal paused in place for several tens of seconds in a fashion similar to freezing of gait seen in Parkinson's disease.
Finally, we contrasted these result to lesion of posterior parietal cortex, which did not induce widespread changes in striatal activity or behavior and served as a control against generalized brain dysfunction following lesion.
Our results help to understand how neural populations orchestrate both goal-directed and spontaneous, naturalistic behavior. As striatal tuning to movement kinematics is lost even after reaching behavior recovers, these results argue strongly that cortex selects actions, changing between motor states, and drives the movement-related dynamics in striatal neurons.

Title: Movement-specific spatial recruitment patterns in the primary motor cortex

Authors: *W. LIANG[1], K. BALASUBRAMANIAN[1], V. PAPADOURAKIS[2], N. G. HATSOPOULOS[1];
[2]Organismal Biol. and Anat., [1]Univ. of Chicago, Chicago, IL

Abstract: The primary motor cortex (M1) is known to have a coarse spatial organization where representations of different body parts form clusters on the cortical sheet. However, it is largely unknown if there exists any spatiotemporal organization that is behaviorally relevant. Our previous work found that amplitude attenuation of the local field potential (LFP) in the beta band (13-35Hz) propagates along a stereotyped rostro-caudal axis and signals the initiation of movement but does not provide movement-specific information [1]. To characterize potential M1 spatiotemporal patterns that might be important during movement execution, this study investigated the high gamma band (200Hz - 400Hz) of the LFP given its similar directional tuning properties to multi-unit activity as well as its established utility in movement decoding for brain-machine interfaces [2]. Neural recordings were collected from two male rhesus macaques - each with implants in M1 consisting of two 64-electrode arrays, when they performed reach tasks with their right upper limbs constrained by a 2D exoskeletal robot. Given that single-trial high gamma amplitude envelopes were quite variable, we first denoised the single-trial envelopes using a contractive autoencoder [3], then smoothed and normalized the amplitude between 0 to 1 for each trial. The high gamma amplitude envelopes from different electrode locations tended to amplify around movement initiation at slightly different times; to quantify this difference, we computed the time at which the envelope on each electrode crossed a unified threshold. We then performed planar regression of the threshold-crossing times to characterize the spatiotemporal patterns, and computed the propagation orientation for each trial. We found that for both monkeys there existed salient propagating orientations for each array. Furthermore, for both monkeys, the exact orientation of this propagating pattern varied according to reach directions, indicating that the spatio-temporal patterns might encode movement-specific information. Next, we plan to explore whether and how these patterns might aid in the execution of movements. [1] Balasubramanian et al(2020). Title: Vocal specific premotor neurons in the mouse brainstem

Authors: *J. PARK[1], F. WANG[3,2];
[1]Dept. of Biomed. Engin., [2]Dept. of Neurobio., Duke Univ., Durham, NC; [3]Dept. of Brain and Cognitive Sciences, McGovern Inst. for Brain Res., MIT, Cambridge, MA

Abstract: Vocalization is a critical orofacial behavior for communication in many species. How the brain precisely controls the activity of distinct muscles to produce vocalization is largely unknown. The brainstem contains many orofacial-pharyngeal motoneurons and their premotor neurons. Due to technical challenges, previously vocalization-specific premotor neurons in the brainstem have not been clearly identified, and thus target-specific functional manipulation has not been possible. Here, we map premotor neurons of laryngeal muscles, and identify a vocal-specific premotor population in the brainstem of adult mice. Utilizing a three-step monosynaptic rabies virus transsynaptic tracing approach, we found that the laryngeal premotor neurons were distributed in the brainstem with three major clusters in: the Retroambiguus Nucleus (RAm), the PreBotzinger Complex, and the Nucleus Tractus Solitarius. Furthermore, c-fos, an immediate early gene is strongly induced in the RAm area by vocalizing behaviors. We therefore employed an activity-dependent tagging technique, called Capturing Activated Neuronal Ensemble (CANE) to tag vocalization-activated c-fos-positive RAm neurons (RAm^{VOC} neurons hereafter), whose location overlaps with that observed for laryngeal premotor neurons in the RAm. Tracing axonal projections in the brainstem co-stained with a motoneuron marker, ChAT revealed that the RAm^{VOC} neurons were indeed premotor neurons extensively innervating laryngeal motoneurons. We next expressed tetanus light chain in RAm^{VOC} neurons using CANE. Interestingly, bilateral inhibition of the RAm^{VOC} neurons completely abolished vocalizations,

including both ultrasonic vocalizations and audible stress-response squeaks. Taken together, RAm^{VOC} neurons are premotor neurons essential for vocalization.

Title: Investigating genetic regulation of cortical vocal motor circuits in mice

Authors: *L. C. KUPER[1], L. BOYD[2], E. D. JARVIS[2,3];
[1]Lab. of Neurogenetics of Language, The Rockefeller Univ., NY, NY; [2]Lab. of Neurogenetics of Language, The Rockefeller Univ., New York, NY; [3]Howard Hughes Med. Insitutute, Chevy Chase, MD

Abstract: Vocal learning is the ability to learn and modify vocalizations, which is an essential trait for spoken language in humans. Vocal learning in humans as well as in songbirds is thought to be facilitated by a direct projection between primary motor cortex (MOP) and neurons in the brainstem involved in speech. Mice also show rudimentary signs of vocal learning circuitry and behavior, as they are able to modulate their high-frequency vocalizations and they possess a direct, but sparse corticomotoneuronal projection. Little is known about the evolution of these projections from MOP to brainstem, specifically the genetic pathways involved in the development of these circuits. Comparative genetic studies between human and songbird vocal areas have found a number of convergently expressed genes, including axonal guidance genes. Through manipulation of these genes in mouse MOP, we can elucidate how axon guidance cues regulate projections from MOP to brainstem related to vocalization. We generated transgenic mice with knockdown of PlxnA1 and Slit1 in layer 5 neurons of putative mouse laryngeal motor cortex, to mimic expression in vocal learners. Preliminary experiments suggest that these mice have greater axonal connectivity from layer 5 neurons to the vocal motor neurons of the brainstem, nucleus ambiguous. These studies contribute to a greater understanding of the mechanisms and evolution of vocal learning in advanced vocal learners.

Abstract: Bats exhibit several traits associated with human communication that are rare among mammals, such as complex social communication and potentially vocal learning. Here, we investigate the cortical representation of the bat larynx as a model for the motor control of complex vocal behaviors. We applied ICMS in anesthetized Egyptian fruit bats to evoke muscle contractions and determine which areas of the neocortex control muscles of the larynx involved in social vocalization. We tested for the presence of a larynx representation in M1, S1, and adjacent cortex by recording EMG activity from the cricothyroid muscle during motor stimulation. In order to correct for EMG artifacts introduced by the ICMS signal itself, we varied ICMS circuitry (e.g. return lead placement, current sense resistor) to minimize contamination and reduce the need for “blanking” techniques, which can lead to signal loss. These corrections reduced the artifact by ~90% and increased the EMG signal-to-noise ratio, providing a robust laryngeal signal. Here we report that muscles of the larynx in a single case study were activated by ICMS at two rostromedial sites in M1. Cricothyroid activation occurred with distinct latencies for the two sites (20 vs 190 ms). Ongoing experiments will continue to survey a large region of cortex while also focusing on denser mapping of this putative larynx region, with the goal of understanding whether latency differences reflect modules within M1 or distinct cortical fields, perhaps with different roles in the control of vocal behavior. A more complete understanding of

the motor cortical representation in bats, including that of a potential laryngeal representation, could help test hypotheses about the neural mechanisms that support vocal communication.

Title: Stimulation of Mouse Primary Motor Cortex Activates Intrinsic and Extrinsic Vocal Muscles

Authors: *C. D. M. VARGAS[1], E. N. WAIDMANN[1], E. D. JARVIS[1,2];
[1]The Rockefeller Univ., New York, NY; [2]Howard Hughes Med. Inst., Chevy Chase, MD

Abstract: Vocalizations are a dynamic and complex behavior that can be innate or learned. Vocal learners, animals that learn to imitate or modify vocalizations, use top-down input from the forebrain to provide fine motor control over vocal musculature. These forebrain circuits coordinate sub-cortical networks during and after learning to precisely execute these learned behaviors. Currently, we do not have genetically tractable mammalian models for speech and vocal learning. However, behavioral and anatomical findings from our lab and others' show that the ultrasonic song system of mice exhibits some rudimentary features of vocal systems found in advanced vocal learners, including multisyllabic structure that varies with social context, and a sparse but direct input to laryngeal motor neurons in the brainstem from a small pool of neurons in the primary motor cortex (M1). This population of laryngeal-projecting M1 neurons were termed the laryngeal motor cortex (LMC). Work from others has also shown that the orofacial motor cortex (OFC), located anterolaterally in the motor cortex, is involved in controlling vocal behavior by influencing the digastric muscle. Using intracortical microstimulation with paired electromyography (ICMS/EMG), we tested whether electrically exciting the previously identified LMC and OFC regions could influence vocal muscles. We recorded EMGs from the cricothyroid muscle, an intrinsic laryngeal muscle, and the digastric muscle, related to jaw opening. Our results confirm previous studies showing that stimulating the OFC can induce digastric muscle contractions. In addition, we found that stimulating the LMC induces muscle contractions in the larynx. By measuring the latency of the muscle response after ICMS, we find

that both regions have very short response times. The OFC in particular produced consistently faster responses (5-10 ms) than the LMC (10-20 ms). The latencies from the OFC are in line with those found in monosynaptic circuits, suggesting this region may be more involved in fine motor control of vocal behaviors than had been previously considered. We suggest that the mouse LMC could be the precursor of human dorsal LMC (dLMC), and the mouse OFC the precursor of human ventral LMC (vLMC). Overall, these results represent the first time that stimulation of the primary motor cortex in a mammal, other than humans, has resulted in laryngeal muscle contractions.

Title: Characterization of Pre-motor Region Contributions to the Productions of Call

Authors: *D. BROWN[1], A. SRINIVASAN[1], P. M. TOSTADO[2], J. I. CHAVEZ[1], D. H. NGUYEN[1], A. KADWORY[1], E. M. ARNEODO[1], T. GENTNER[3], V. GILJA[4];

Abstract: Songbirds are a powerful model for studying the acquisition and production of complex learned vocal behavior. Zebra Finches in particular have been heavily studied for their stereotyped motif which is a major component of their song. However, the syllables of the motif are only a small portion of the zebra finch's vocal repertoire. The majority of their vocal behavior consists of vocalizations collectively referred to as 'calls'. Calls refer to all vocalizations that are not the introductory note or part of the stereotyped motif; some are learned and others are not. While previous work has found that neural activity in pre-motor nuclei (i.e. HVC and RA) encodes information regarding which syllable the bird will sing, few studies focus on elucidating what activity, if any, relates to call production. Here we report novel spectral features of neural activity that correlate with call identity in a premotor nuclei. We applied

unsupervised dimensionality reduction techniques to map spectrograms of manually segmented Calls to a lower dimensional representation. The spectrograms of the calls were then manually clustered and annotated based upon this representation. The neural activity recorded during each call was then analyzed using methods previously used to study motif syllable production (Brown et al. 2021). We report finding phase preference to motor onset of calls similar to that reported to syllable production in HVC of songbirds. Specifically, we find statistically significant Inter-Trial Phase Coherence (ITPC) in Local Field Potentials (LFP) across multiple types of calls in frequencies ranging from 2-50 Hz. Our results give preliminary evidence that the pre-motor nuclei of the song system play a role in the production of vocal units other than the syllables of the stereotyped motif. These results elucidate the relationship between pre-motor nuclei in the song system to call production and help clarify the function of these nuclei in regards to the generation of vocal behavior.

Title: Information processing by neuronal networks in singing and sleeping zebra finches.

Authors: *W. G. GONZALEZ, F. LANFRANCHI, C. LOIS;
Caltech, Pasadena, CA

Abstract: How is information processed by neurons during performances of a complex motor behavior and how does sleep affect maintenance of such behavior? To address these questions we simultaneously recorded the activity from neurons in multiple brain areas of zebra finches. Songbirds are a well-established animal model of vocal learning but few studies have studied the mechanism by which information transfer across brain areas controls singing behavior. Using

high density extracellular probes (Neuropixels) we recorded the activity from hundreds of neurons across two premotor nuclei (HVC and RA) as well as from auditory brain areas in singing and sleeping zebra finches. Neurons in these brain areas are known to control singing behavior and have been proposed to replay the song during sleep. By monitoring the online and offline communication between neurons across these brain areas we identify mechanisms by which premotor neurons control, monitor, and rehearse a complex learned behavior. During performance of the song, slow oscillation (1 - 5 Hz) in HVC and RA mark the start and end of a song while packets of high frequency oscillations (20-100 Hz) relay song specific information. Production of an abnormal song is preceded by an increase in synchronous activity in HVC and RA. Simultaneous bilateral recordings during sleep identifies offline periods during which partial representations of the song are asynchronously reactivated across hemispheres. These results highlight a hierarchical organization of neuronal activity during performance of a complex motor behavior and identify the presence of mechanism that asynchronously modulate neuronal activity across hemispheres during sleep.

Title: Experimental method for longitudinal investigations of behavioral adaptations in individualized orofacial movements of rats using XROMM

Authors: *K. TAKAHASHI[1], C. HAXTON[1], T. E. LEVER[2], B. SAGL[3], L. AVIVI-ARBER[4], S. FELS[5], I. STAVNESS[6];
[1]Organismal Biol. and Anat., Univ. of Chicago, Chicago, IL; [2]Otolaryngology - Head and Neck Surgery, Univ. of Missouri Columbia, Columbia, MO; [3]Ctr. of Clin. Research, Univ. Univ. of Vienna, Vienna, Austria; [4]Univ. of Toronto Dent., Toronto, ON, Canada; [5]Electrical and Computer Engin., Univ. of British Columbia, Vancouver, BC, Canada; [6]Computer Sci., Univ. of Saskatchewan, Saskatoon, SK, Canada

Abstract: It has been shown in rat models that intraoral manipulations (e.g., tooth extraction or dental implants) induce neuroplasticity in the orofacial sensorimotor cortex and corresponding

morphological and histochemical changes in cranial muscle tissue, and that neurological disease models (e.g., Parkinson's) exhibit oropharyngeal dysfunction. However, data is lacking relative to high fidelity kinematic and behavioral changes in orofacial functions over time. Moreover, a major challenge of using rats for long-term kinematic studies is that their musculoskeletal system grows over time. Here, we describe our initial efforts in establishing robust methodology for conducting chronic orofacial kinematic studies in rats. We combined a high-speed biplane x-ray reconstruction of moving morphology (XROMM) system to capture radiopaque marker movements over time, obtained in-vivo CT scans to capture skeletal morphological changes over time, and combined these two data sources to produce high throughput orofacial kinematics through an individually customizable simulation model. To achieve this, we implanted radiopaque tantalum markers within the cranium, right and left hemimandibles, and the tongue of 4 adult rats (3 females and 1 male) that were at least 12-week old and weighed >250 grams. To dampen growth, animals underwent caloric restriction to reduce the number of the CT scans. XROMM sessions took place twice a week for at least a month to ensure at least 5 mins of self-feeding was recorded for each animal while eating radiopaque kibble. XROMM videos were sampled at 400 FPS and digitized by XMALab. X-ray (90 kV and 25/20 mA) was emitted only when animals were engaged in feeding to minimize the risk of radiation-induced symptoms. In-vivo CT was obtained every 3-4 weeks to capture morphological changes over time. The ArtiSynth modeling toolkit was used to develop a rat orofacial simulation model to compute the joint angle and 3D translation of each hemimandible and tongue movements from the marker locations in the cranium coordinate system. Results showed that right/left hemimandible movements were somewhat independent, but all animals showed the highest normalized standard deviation of translation movements along the anterior-posterior axis. Additionally, two animals exhibited significant differences in gape duration across days despite constant kibble consistency. Once optimized, we envision our new experimental workflow from marker implant surgery to kinematic analysis will open a gateway for longitudinal high throughput studies of orofacial function in rats while controlling for individual morphological changes due to skeletal growth.

Title: Short term behavioral adaptations in gape cycle patterns due to tooth extraction

Authors: *C. HAXTON[1], K. TAKAHASHI[1], N. SHIRAISHI[2], T. E. LEVER[3], L. AVIVI-ARBER[4], A. ZIMMERMAN[4], N. KATARIA[4], B. SAGL[5], C. ROSS[1], M. INOUE[6]; [1]Organismal Biol. and Anat., Univ. of Chicago, Chicago, IL; [2]Div. of Advanced Prosthetic Dent., Tohoku Univ., Sendai, Japan; [3]Otolaryngology - Head and Neck Surgery, Univ. of Missouri Columbia, Columbia, MO; [4]Univ. of Toronto Dent., Toronto, ON, Canada; [5]Univ. Clin. Dent., Med. Univ. of Vienna, Vienna, Austria; [6]Niigata Univ., Niigata, Japan

Abstract: It has been shown in rodents that intraoral manipulations (i.e., tooth extraction or dental implants) induce neuroplasticity in the orofacial sensorimotor cortex as well as morphological and histochemical changes in cranial muscle tissue. However, little is known about how fast and what kind of behavioral changes may occur. To answer these questions, we implanted radiopaque markers (0.5mm diameter) within the cranium, right and left hemimandibles, and tongue of two adult female rats that were at least 8 weeks old and weighed 200 grams. We used a high-speed biplane x-ray reconstruction of moving morphology (XROMM) system to capture marker movements, which were projected onto a cranium coordinate based on in-vivo CT images of the skull markers. This produced 3D movements of the hemimandibles and tongue relative to the cranium. Next, the three right maxillary molars were luxated under aseptic conditions, consistent with our previously published protocols. XROMM data during unconstrained feeding of radiopaque kibble were collected at 250 FPS prior to molar extraction, serving as a baseline, as well as 1, 2, 3, 4, 7, & 14 days post-extraction to characterize fast behavioral adaptations for chewing and swallowing. XROMM data were digitized by XMALab and the hemimandible movements, gape angle, and 3D translations were computed. There are two well-defined jaw gape cycles: rhythmic chewing (RC) and swallowing (S). For cycle type assignment, each video was examined to check if a gape cycle in a feeding sequence was rhythmic, then further checked for swallowing. Cycles containing swallowing events were labeled as S, and those with only rhythmic chewing were labeled as RC. We then analyzed how RC and S cycle frequency changed across days. During the pre-tooth extraction period, median gape frequencies were significantly higher ($p<0.05$) for RC cycle (7.14 Hz) than S cycle (6.02 Hz). Both RC and S cycles were significantly slower on Day 1 (RC: 5.99 Hz vs S: 3.72 Hz) and the variance increased significantly compared to baseline (RC: 2.65 times vs S: 2.45 times). From Day 2 to Day 7, both RC and S cycle frequencies became faster; however, RC cycle variance decreased, while S did not change ($p>0.05$) after Day 3. Our results show that, in addition to the previously reported slow adaptations in the central and peripheral nervous systems, molar tooth extraction induces rapid behavioral changes with different RC and S gape cycle statistics. Our findings suggest there may be corresponding fast neural adaptations and tissue regeneration taking place that have not been rigorously investigated. Furthermore, dental integrity may be more important for swallowing than generally thought.

Title: Specializations of tongue motor cortex for lingual echolocation in the Egyptian fruit bat (Rousettus aegyptiacus)

Authors: *A. C. HALLEY[1], M. M. YARTSEV[2], L. A. KRUBITZER[3];
[1]Univ. of California, Davis, Davis, CA; [2]Bioengineering, Univ. of California Berkeley, Berkeley, CA; [3]UC Davis, Davis, CA

Abstract: The Egyptian fruit bat (*Rousettus aegyptiacus*) is one of the only megabats to echolocate, and is rare among bats in its use of tongue-clicks to generate active sonar. Remarkably, *Rousettus* produces directional sonar without moving its head or jaw, instead altering the frequency and direction of sonar clicks by manipulating its tongue. In recent mapping studies using intracortical microstimulation (ICMS), we found that representations of the tongue are enlarged in motor regions of the neocortex in *Rousettus*. However, little is known about how the precise tongue movements involved in echolocation are generated in the neocortex. To better characterize this specialized motor behavior, we used long-train ICMS to elicit movements from areas of the neocortex involved in tongue movement (e.g. M1, S1). We found that movements of tongue subregions (e.g. distal vs. proximal) as well as distinct movements types (e.g. extension) are represented regularly across areas of cortex involved in generating movement. This kind of discrete representation of tongue subregions and movement types in the neocortex is rare among mammals, and suggests that motor systems in *Rousettus* have evolved for specialized tongue control in order to produce their novel form of lingual echolocation.

Title: Discrimination of different levels of finger extension from the electroencephalogram

Authors: M. BATES, C. HADDIX, *S. SUNDERAM;
Biomed. Engin., Univ. of Kentucky, Lexington, KY

Abstract: Assistive technologies such as brain-computer interfaces (BCIs) offer individuals with central or peripheral neural injuries the means to interact with external devices. However, the reliance on EEG for convenient access to the brain limits the ability to accurately quantify control signals associated with fine motor control, especially in victims of stroke, who may have cortical lesions. Here we test the feasibility of modeling gradations in motor effort associated with a finger extension task using EEG measurements. Following an IRB-approved protocol, we acquired scalp EEG in three healthy human subjects. Instructions were given to extend their fingers outward to one of three levels in response to a visual cue: Low, Medium, and High, as well as a fourth control condition, 'No-Go', in which no movement is expected. The subject's hand movement and muscle activity (extensor digitorum communis) were monitored using a commercial motion capture glove and bipolar EMG, respectively. The glove recorded each phalange's position in Cartesian space, which allowed us to track extension of each digit relative to the wrist. We focused on the index, middle, and ring finger alone since they are similar in length to minimize error, and averaged the smoothed measurements from these three fingers to produce a scalar displacement in degrees. EEG was simultaneously recorded over 32 scalp locations and the mean-squared power in a moving window estimated in the 8 - 30 Hz band during each cue relative to a reference period before cue onset. A quadratic discriminant classifier was constructed from training samples of this feature and the accuracy of prediction of test samples was assessed using a four-fold cross-validation scheme. The mean classification accuracy was 57% over the four levels of extension, much greater than the chance level of 25%. Confusion between low and medium extension was the major source of error. By comparison, using a similar approach, measures of EMG power and finger displacement gave mean accuracies of 53% and 47%, respectively, an indication that variability in the subject's performance of the task may have contributed at least in part to the error. Our findings show that the EEG can predict effort associated with gradations in finger extension. This offers BCIs a measure of fine control for interactive rehabilitation protocols. Future work will focus on closing

the loop using these distinguishable signals to provide real-time feedback, which can be incorporated into existing regimens to promote functional recovery.

Title: Quicker Proficiency in Imagined Cursor Tasks with Tripolar Concentric Ring Electrodes

Authors: *W. G. BESIO[1,2], P. G. ADEGBOYEGA[1];
[1]Electrical, Computer, and Biomed. Engin., Univ. of Rhode Island, Kingston, RI; [2]CREmedical Corp., East Greenwich, RI

Abstract: Brain-computer interfaces (BCIs) allow the translation of brain signals into device control signals. Tripolar concentric ring electrodes (TCREs) for electroencephalography (tEEG) were first reported by Besio (2006). The tEEG has significantly higher spatial resolution and signal to noise ratio (SNR) than EEG. The tEEG was also shown to have significantly less mutual information than EEG. The tEEG has previously been shown to improve BCI accuracy in offline classification and for real-time center-out cursor control compared to EEG. We have also shown that the outer ring of the TCRE produces an equivalent signal to EEG (eEEG) and TCREs can therefore record EEG and tEEG from the same sensor concurrently. In this study we compared whether naïve BCI users could become proficient with less runs using either tEEG or EEG.
We evaluated how quickly naïve BCI users could achieve proficiency with conventional EEG or tEEG recorded from TCREs. The study was approved by the URI IRB. We tested 12 healthy BCI naive subjects, randomly assigned, six each, to standard EEG or tEEG, with their goal to, "hit", sixty percent of the targets in a single "run" of an imagined movement cursor task. The TCREs were placed at CP3, C3, C1, Cz, C2, C4, CP4, of the 10-20 International Electrode positions, as well as a conventional disc electrode on each mastoid process as the ground and reference. The skin to electrode impedances were kept below 10 kΩ. Each participant completed a short training/ calibration session in the form of a stimulus presentation to obtain data for the individual classifiers. Participants were asked to remain still and imagine motor imagery tasks as arrows pointing left or right appeared on a monitor directly in front of them. Offline r^2 analysis using BCI2000 was performed to determine the locations and frequencies used for the real-time

classifiers. Participants were blinded to the type of electrodes signals they were using. Five out of six participants in the EEG group were unable to reach sixty-percent proficiency, even after 14 runs. Conversely, five of six tEEG participants reached sixty-percent proficiency, and the sixth reached fifty-five percent proficiency, higher than most of the EEG participants. The results show that significantly more participants were able to reach >= to sixty-percent proficiency within less runs using tEEG compared to EEG. There was a significant difference in the number of proficient participants (Mann Whitney unpaired test with correction $p = 0.017$). Once a participant reached sixty-percent proficiency they did not perform any further runs. The tEEG participants likely would have had even higher hits if they continued beyond reaching sixty-percent.

Title: Non-invasive hands-free control of a robotic arm

Authors: *D. E. G. SHEETS, B. A. HASSE, D. M. GIN, Y. FAHMY, A. J. FUGLEVAND; Physiol. and Neurosci., Univ. of Arizona, Tucson, AZ

Abstract: Simple tasks such as using a computer, feeding oneself, personal hygiene, and grabbing objects are impossible for high level tetraplegics without assistance. Most of these individuals, however, retain the ability to voluntarily move their head, eyes, and tongue and can speak. It seems reasonable to hypothesize that signals derived non-invasively from these actions could be used to accurately control movements of a robotic limb or a paralyzed upper limb using functional electrical stimulation. The goal of this project, therefore, was to evaluate various hands-free methods to position the endpoint of a robotic arm to different locations. Healthy adult human subjects participated in each of five experimental sessions for this study. In four of the sessions, subjects used one of four input modalities (head, tongue, eyes, and for comparison, movements of their own hand) to move the tip of a robot arm to different targets. Within each session, two types of continuous control were enacted: position and velocity. In position control, the position of the input device was mapped to the position of an effector - like the position of a computer mouse dictating cursor position on a screen. In velocity control, the position of the

input device controlled the velocity of the effector - like a gas pedal in a car. In a fifth session, subjects used discrete voice commands to control movements of the robotic arm. When using the head, tongue, or hand, signals from small 6 degree-of-freedom movement sensors attached to those body parts were used as inputs to the robot arm. For the eyes, measured pupil movements were used to estimate gaze location that served as the input to the robot arm. Eye movements were only used in the context of position control. Once instrumented and having practiced, subjects performed a set of 72 trials, involving 6 reaches to 12 different targets for each control system. Physical targets were wooden rings mounted on supports of different heights. For a successful reach, the tip of a pointer attached to the robot arm needed to be situated and held for 1 s within a virtual 5-cm diameter sphere centered in the middle of the wooden ring. Movement time, path length, and throughput were calculated for each reach. Overall, head control was just as effective in controlling robot-arm reaches as that using the hand. Position control outperformed velocity control in all modalities except for that involving the tongue. These findings provide critical insight into the utility of various non-invasive methods to control an assistive robot arm and should improve the ability individuals with high level paralysis to interact with their environment.

Title: Steerable localized electrical stimulation using high density subdermal electrode arrays in rodents

Authors: V. JAIN, ***M. FORSSELL**, D. TANSEL, C. GOSWAMI, G. FEDDER, P. GROVER, M. CHAMANZAR;
Electrical and Computer Engin., Carnegie Mellon Univ., Pittsburgh, PA

Abstract: Objective: Transcranial stimulation using large current-injection electrodes has shown effects in improving learning,memory, movement disorders, pain, etc. The large size of electrodes results in a diffuse electric field in the brain, preventing targeted localized neural stimulation. Recent efforts in using high-density transcranial direct current stimulation (HD-TDCS) have resulted in improved outcomes and reduced side-effects. However, typical HD-TDCS uses electrode distances of several cm in humans and above 5 mm in rodents. Increased

electrode density can improve the field focus and enable beam steering to actively target different regions within the brain.
Methods: Here, we discuss a method for high resolution steerable electrical stimulation using a 6x4 array of high-density electrodes (0.4 mm diameter electrodes in a 1 mm grid) implemented using flexible PCB technology. The electrode grid is placed directly over the skull of C57BL6 mice (n=7, aged 4 to 6 weeks). Multiple current-injection patterns are generated by selectively activating subsets of electrodes. The current is injected via 2x2 active electrodes, positioned in one of three locations, located mediolaterally at -2,0, and +2 mm from Bregma. The spatial extent of the electric field within the tissue is affected by changing the distance between the active electrodes and four return electrodes (one at each corner) from 1 to 3 mm. Evoked responses are measured using electromyography (EMG) of limbs and video recording of whisker movements. For EMG, selectivity is assessed by measuring the amplitude of the motor evoked potential (MEP) in the different muscles. Intracortical microstimulation (ICMS) using implanted metal electrodes is used as a ground truth to validate the response to electrical stimulation.
Results: The results from the current study showed preferential contralateral response by steering active electrodes on either side of the skull as evidenced by higher MEP amplitude and whisker movement on the contralateral side. An equal bilateral response was observed when the active electrodes were centered on Bregma. Selectivity can be enhanced by tuning the pattern with more focused current fields, at the cost of higher current injection. Interestingly, whisker movement changes from contralateral to ipsilateral when the more focused patterns are used.
Conclusion: Focusing of transcranial currents using high density electrode arrays allows selective motor responses in mice. High density arrays enable adjusting the location of the stimulation as well as the extent of the stimulated region. This could potentially open new avenues for BCI applications.

Title: Validation of an electrical head phantom model for EEG motion artifacts susceptibility

Authors: M. NONTE[1], J. C. BRADFORD[2], A. MCGOUGH[1], ***W. HAIRSTON**[3];
[1]DCS Corp., Alexandria, VA; [2]Army Res. Lab., Aberdeen Proving Ground, MD; [3]US Army Res. Lab., Aberdeen Proving Ground, MD

Abstract: In recent years there have been many new approaches developed to improve the convenience and quality of data extracted from EEG collected in real-world environments. These range from new materials for “dry” or quick-application sensors to multi-layer sensing, or post-collection de-noising techniques. In most cases these target the removal of noise from motion or other non-brain sources. However, a continual challenge is that it is extremely difficult to prove or validate the efficacy of these approaches, given the lack of a true ground-truth comparative signal (we don’t know what the original true signal looks like). One method to address this problem is the use of an EEG “phantom” which provides a known-quantity signal propagated through a simulated conductive head and scalp to use in comparing new methods. Previous efforts have suggested use of ballistics gelatin as a substrate, but it’s performance as a surrogate has not been fully validated. Here we describe the process of validating a phantom head formulation for re-creating motion artifact susceptibility associated with EEG electrodes or similar DAQ components. EEG data were collected from human volunteers walking on a treadmill simultaneous with optical motion capture (MoCap) while wearing a Biosemi 64 channel cap. Phantom head models with 0.5cm scalp thickness over an ABS inner continuous hollow skull were fabricated based on designs from Open EEG Phantom (https://osf.io/qrka2/) using ballistics gelatin (BG) (200g/L) or agarose (20 g/L, 0.0125% NaCl) outer layers. Phantoms were affixed to a 6dof Heaxpod to re-create each human’s motion based on profiles from that individual’s MoCap while wearing the identical Biosemi cap. RMS amplitude of the signal for different walking speeds was then compared against human data for both materials. Results show that BG does not re-create average artifact amplitude or the step-to-step variability of human data. Data collected on an agarose phantom more accurately recreates mean power and variability across gait cycles of human subject movement much better, supporting use as a phantom skin material. Notably within-subject, cross-trial variance remains substantially higher for native human data, likely reflecting physical components not re-created in the phantom (e.g. hair, jerk movements).

Abstract: There is an evolving interest in capturing Electroencephalogram (EEG) in ecologically valid environments: while subjects are moving or are performing tasks in the field. This introduces large-amplitude nonstationary noise into an already small, nonstationary signal. Given we are attempting to measure an unknown, nonstationary signal with unknown noise, fully understanding this noise to create an appropriate filter is an arduous task. Recent work has focused on making better electrodes or other data acquisition (DAQ) devices, but validating the signal efficacy of new sensors or DAQ techniques is difficult with only human subject comparisons, which are variable and inconsistent over time. Instead an alternate approach is to use a "phantom" device to provide a consistent testbed and ground truth signal for analysis. Some research groups have developed gel-based phantom heads for independently testing and removing this noise; these can reproduce properties of the skin-electrode interface relevant to noise and can reproduce limited realistic human movement. These phantoms lack several important physical features (e.g. hair) that introduce inter-subject variability and require better range of motion to fully recreate human movement.
Here we introduce a method for examining and evaluating EEG and other biosignal capture equipment using a live human as the testbed, providing the realism of skin, hair, or motion, but with a known-quantity ground truth signal. We use a voltage-controlled transcranial electrical stimulator (tES) attenuated to appropriate biosignal level to inject a test signal on the scalp of a human volunteer. By evaluating that signal, we are able to analyze time synchrony of various devices as well as noise inherent in the systems' sensing. This has the advantage of capturing the natural human-to-human variance in signal quality as well as the naturally evolving interface with human skin that is otherwise difficult to replicate. For this proof-of-concept, we compare two EEG systems (g.tec and OpenBCI) and two electrode types (traditional gel/AgCL and g.tec gold metal pin), as well as a Bioharness monitoring system through a short series of artefact-generating movements. We are able to accurately extract the original signal, better synchronize the systems, and determine the noise profile of each system. Future protocols could include miniaturized signal generators integrated with biocapture systems to better understand the noise associated with sensing in real-world environments.

Title: Determining neural correlates of proprioception in order to improve robotic-assisted movement training (RAMT)

Authors: *C. M. CHAISSON[1,4], D. J. REINKENSMEYER[1,2,3], T. FAKE[4], J. HILL[5,4], T. M. VAUGHAN[4], D. GUPTA[4,5];

Abstract: Robot-assisted movement training (RAMT) is increasingly popular in neurorehabilitation. However, its current benefits are limited and highly variable. Better RAMT protocols are needed. A recent study of hand function in people with stroke showed large finger proprioceptive error measured before RAMT predicted minimal benefit of subsequent RAMT (NNR 2017). Anatomical damage to the somatosensory network was better explained as treatment-related hand function gains than damage to the motor network (Neurology 2019). Better understanding of the neural correlates of proprioceptive error could lead to more effective RAMT protocols, such as protocols that blend RAMT with brain-computer interface training of those correlates. The previous study used a novel crisscross paradigm with a customized robotic exoskeleton. We add a concurrent EEG recording to this paradigm and describe our preliminary observation. Data was collected from five healthy people (4m/1f, 22-66yrs) with informed consent (all experiments approved by the Stratton IRB). The exoskeleton performed passive movements of the right index and middle fingers in a pre-programmed crisscross protocol. The fingers moved continuously between full extension and 60 deg flexion. 80-100 crossover trials with randomized inter-trial intervals were collected with vision occluded. The task was to press a button with the left index finger when the right index and middle fingers crossed over each other. Scalp EEG (32 channels) was recorded with reference to the right mastoid and digitized (256-Hz) (NCAN BCI2000 software; gUSB amplifiers (g.tec GmbH, Austria)). A MEMS inertial sensor measured the button press movement and robot position sensors recorded finger metacarpophalangeal (MCP) joint trajectories. Proprioception error was calculated as the difference in degrees of MCP joint rotation of the two fingers at the time of button press. Errors were categorized as small (<6deg) and large (>6deg). EEG was pre-processed and denoised with xDawn. Focusing on the sensorimotor electrodes contralateral to the robotically driven hand (C5 and C3), evoked responses for trials with small and large errors were averaged in the -2s to -1s window. Preliminary results (one subject) show the mean C3 and C5 ERP response was significantly more negative for the large error. Furthermore, a 32-channel logistic regression classification with a 10-fold stratified cross-validation showed error-related EEG feature classification, with precision more than chance level. This preliminary ERP outcome suggests the possibility of extracting a neural feature related to finger proprioceptive error with this paradigm.

Title: Improving the performance of brain-computer interface-based color vision assessment using data interpolation methods

Authors: *H. HABIBZADEH[1,2], K. J. LONG[2], A. E. ATKINS[3,2], T. M. VAUGHAN[2], J. R. WOLPAW[2], D.-S. ZOIS[1,2], J. J. S. NORTON[2,1];

Abstract: We have developed a BCI-based system for color-vision assessment that requires no behavioral responses. This system uses steady-state visual evoked potentials (SSVEPs) to identify metamers—light sources with different spectral distributions that appear to be the same color. Precise evaluation of the identified metamers requires dense sampling of the color space; each sample is obtained by adjusting the stimulus color and obtaining the SSVEP. Thus, dense sampling is time and labor intensive and may tire the participant.
One alternative to dense sampling of the color space is interpolation. Our metamer identification problem can be posed as a two-dimensional search problem; the system searches for the combination of a dichromatic (red+green) test source that appears identical to a monochromatic (amber) reference source of a fixed luminance. To evaluate the effectiveness of interpolation, we compared 5 interpolation methods to the dense sampling.
In a study with 5 healthy participants (1 male; ages 21-67) with normal color vision, we recorded EEG from 16 locations using BCI2000. Each participant completed 4 identical sessions of data collection. Each session included 168 trials; each trial sampled a different location in the dichromatic color space. During each trial, the participant looked at a stimulus that alternated between the two sources at 10 Hz. We used canonical correlation analysis (CCA) to extract SSVEPs. The Stratton IRB approved this study.
We averaged the CCA coefficients from all 4 sessions to obtain the ground truth for each

participant. We then computed the ratio of the interpolation error to the measurement error for each interpolation method. The number and order of interpolated values were picked randomly (we used 750 random selections). The average error ratio for the Gaussian interpolation was 1.52±0.50, lower than 1.55±0.59 for B-spline ($p=0.094$), 1.69±0.24 for linear ($p<0.001$), 2.18±0.30 for cubic ($p<0.001$), and 2.71±0.58 ($p<0.001$) for nearest-neighbor interpolation. On average, Gaussian interpolation had the smallest error. Additionally, for 2 participants, the error ratio of the Gaussian interpolation was <1 when <40 values were interpolated, indicating that the interpolation error was less than the measurement error.
In sum, these results suggest that interpolation is an effective alternative to densely sampling data for identifying metamers using SSVEPs. This should enhance our new system's value for evaluating people (e.g., children) in whom lengthy data collection is not practical.

Title: A BCI-based system for automatically assessing color vision

Authors: J. J. S. NORTON[1,2], **A. E. ATKINS**[3,1], H. HABIBZADEH[2,1], K. J. LONG[1], J. S. CARP[1], T. M. VAUGHAN[1], J. R. WOLPAW[1];

Abstract: We describe a brain-computer interface(BCI)-based system for automatically assessing color vision that uses steady-state visual evoked potentials (SSVEPs) to identify *metamers*—light sources with different spectral distributions that appear to be the same color. Metamer identification is an established method for assessing color vision. It normally requires participation by the person under study. Recent research in our lab shows that a stimulus alternating between two metameric light sources—an amber monochromatic *reference source* and a red+green dichromatic *test source*—minimizes SSVEP size. Thus, by fixing the setting of the reference source and adjusting the settings of the test source, it is possible to identify metamers using SSVEPs, without the person's participation.

Here, we show that this BCI can identify metamers automatically. The system uses gradient descent to solve metamer identification as an optimization problem. First, the settings of the monochromatic source are fixed, and those of the dichromatic source are set to an initial estimate of the metamer. Then, SSVEPs elicited at nearby settings of the dichromatic source are measured. Based on these sizes, the system calculates a gradient and updates the dichromatic source settings of the initial estimate. The process repeats until the differences in sizes of the SSVEPs elicited near the new estimate of the metamer are below a criterion. The settings of the dichromatic source when the process stops define the metamer.
We tested our system by comparing its metamers to those identified behaviorally in 3 people with normal color vision (all experiments approved by the Stratton VA IRB). Each method matched the color of the dichromatic test source to the color of the monochromatic reference source at a luminance of 600 D/A units. The new system recorded EEG signals from 16 electrodes, elicited SSVEPs by alternating between the two sources at 10 Hz, and measured SSVEPs using canonical correlation analysis. Each person completed three runs with different initial settings of the dichromatic source (e.g., red,green=[0,0;100,0;0,100]). Averaged across participants the settings of the dichromatic source that were behaviorally- (red 149±14, green 49±1) and SSVEP-identified (red 124±7, green 63±11) as a metamer of the monochromatic source were similar. These results are an initial proof of concept that the new automated system can identify metamers.
An SSVEP-based BCI that can automatically assess color vision without active participation has numerous clinical, research, and industrial applications. Future work (e.g., optimizing search parameters) should further improve the new system.

Computer Engin., Univ. at Albany, State Univ. of New York, Albany, NY; [3]Dept. of Neurosciences, Union Col., Schenectady, NY

Abstract: Color vision deficiencies (CVDs) affect >20% of people; they may impair school or work performance (*Jadhav et al. (2017)*). Our recent research (*Norton et al., under review*) shows that steady-state visual evoked potentials (SSVEPs) can be used to identify *metamers*—light sources with different spectral distributions that appear to be the same color, and that there are clear differences between the metamers of people with and without CVDs. Unlike other CVD detection methods, this method does not require participation; thus it may be useful in small children or those with cognitive deficits. This new method uses a stimulus alternating between a dichromatic test source and a fixed monochromatic reference source to elicit SSVEPs. Previously, we used a grid search of dichromatic source settings to find those that elicited the smallest SSVEP (i.e., the metamer of the reference source). This search sampled 72 dichromatic source settings, limiting the precision of metamer identification. More dense sampling of the grid requires a single much longer session (which may be impractical), or multiple sessions (which may introduce noise). Here, we compare two methods for sampling a dense grid (168 settings); one uses data from 1 session, the other uses data from 4 sessions over 4 days. Four healthy participants with normal color vision (1 male, age 21-67) completed 4 sessions. The Stratton IRB approved the study. Each session included: 4 runs, 42 trials/run, 7 s/trial. 16-channel EEG activity was recorded from the occipital region. SSVEPs were elicited by alternating between the monochromatic and dichromatic light sources at 10 Hz, and measured by canonical correlation analysis. We compared the two dense-sampling methods using universal kriging with an exponential trend model (*Murphy et al., PyKrige (2021)*). The average sum of absolute errors (defined as sum of the absolute differences between the interpolated and sampled canonical correlation coefficients) was 40.8±16.4 and 45.5±21.1 for the first and second sampling methods, respectively. There was a large effect size (*Cohen's d = 0.84*), but no significant difference (Student's paired t-test, $n = 4$, $p = 0.19$) between the two methods. 3 of 4 participants had more spatially continuous dense grids when data was collected in one session. The results suggest that constructing dense grids from data collected in one session reduces absolute error, and thus improves metamer detection. Alternatively, or in addition, interpolation might be used to improve the resolution of data obtained with a relatively coarse grid (*see adjacent Habibzadeh et al. abstract*).

Abstract: Epidural electrocorticographic (ECoG) electrodes serve as a minimally invasive tool to record cortical surface potentials (CSPs). The use of ECoG affords real-time, high-fidelity, chronic recording of CSPs at a high spatiotemporal resolution. In addition to lower frequency rhythms seen in EEG, ECoG is able to transduce high-frequency gamma band cortical activity (30-175 Hz). In a brain-computer interface (BCI), ECoG electrodes record modulation in brain activity. These electrophysiological features are decoded in real-time by a computer, with the output used to control an external device, such as a computer cursor.
In this work, four Rhesus macaques were trained to perform a two-dimensional cursor control task in virtual reality using a joystick. The primates had 32-channel platinum epidural ECoG arrays surgically implanted bilaterally over somatomotor cortex. They were then able to perform the cursor task via the BCI-control paradigm by modulating power across multiple frequency bands between 8 and 175 Hz. Baseline recordings from each BCI session were collected over six months of task performance. We hypothesized that chronic BCI-driven modulation in cortical power is associated with changes in resting-state magnitude-squared coherence of those CSPs that are decoded features in the BCI model. Here we show a rapid increase and a gradual return to baseline of task-free somatomotor CSP coherence over the time course of the BCI study period.

Title: Improved Mirror-Therapy: Reanimation of Fine Motor Function Using Low-Cost Transcutaneous Electrical Nerve Stimulation Driven by Synchronized Bilateral Movements

Authors: *M. TROUT[1], T. S. DAVIS[2], J. A. GEORGE[1];
[1]Electrical Engin., [2]Dept. of Neurosurg., Univ. of Utah, Salt Lake City, UT

Abstract: The long-term goal of this research is to develop a highly-specific and noninvasive reanimation system for the hand that can rehabilitate fine motor function for hemiparetic patients. Stroke is a leading cause of disability, and after a stroke, roughly 80% of patients experience weakness and lack of coordination on one side of the body known as hemiparesis. Mirror-therapy is a common rehabilitation intervention that uses a mirror to create illusory visual feedback of a paretic hand moving based on synchronized movements of the contralateral hand. Here, we introduce a system that leverages transcutaneous electrical nerve stimulation (TENS) of the arm nerves to reanimate a paretic hand in synchrony with the contralateral hand, thereby providing true visual feedback, as well proprioceptive and cutaneous feedback, to further engage neuroplasticity.

We developed a low-cost (~$60), high-voltage (+/- 300 V) Arduino-based stimulator capable of delivering arbitrary stimulation waveforms with up to 16 mA on three independent channels. Consistent with prior work, we found that TENS of the median, ulnar and radial nerves (applied to specific locations on the inner, upper arm) was able to produce repeatable, isolated finger flexion and extension across all digits, as well as functional combination movements (i.e., grasps).

A simple PID controller was used to drive TENS in order to match the grip forces exerted on bilateral load cells. A healthy participant was recruited to validate the preliminary efficacy of this system by relaxing one of their hands around a load cell to emulate a paretic hand and using their other hand to repeatedly squeeze a second load cell ten times. The stimulation-driven grasps yield 10.0 ± 1.32 N maximum contraction force without becoming uncomfortable, which was 29 ± 2.93% of the maximum-voluntary-contraction force from the contralateral hand. When working within the useable range of stimulation-driven forces (i.e., < 10 N), controlled stimulation matched the grip force between the two hands with 75.4 ± 0.97% accuracy (RMSE = 2.28 ± 0.22 N). For each grasp, there was a 113.6 ± 0.5 ms delay of stimulation-driven force onset and a 22.6 ± 3.71% difference in peak contraction force (7.47 ± 0.23 N in the “paretic” hand vs. 9.17 ± 0.65 N in the contralateral hand).

Further investigations will extend this work to acute and chronic stroke patients and measure short-term assistive benefits (e.g., grip force with and without stimulation), as well as long-term rehabilitative benefits (e.g., grip strength and hand dexterity before and after stimulation).

Title: Error detection during the control of two finger-groups with invasive brain-machine interfaces

Authors: M. BENYAMINI[1], ***D. M. WALLACE**[2], S. R. NASON[3], M. S. WILSEY[3], P. G. PATIL[3], C. A. CHESTEK[3], M. ZACKSENHOUSE[1];
[1]Mechanical Engin., Technion - Israel Inst. of Technol., Haifa, Israel; [2]Robotics Inst., [3]Biomed. Engin., Univ. of Michigan, Ann Arbor, Ann Arbor, MI

Abstract: Summary: Brain-machine interfaces (BMIs) are prone to prediction errors. We have previously developed a method for detecting erroneous movements based on spike trains recorded by invasive BMIs and evaluated its performance offline with non-human primates performing virtual single finger movements (Benyamini et al., NER 2019). Here we extend this method to a more complex task involving simultaneous and independent movements of two finger-groups (index and middle-ring-small [MRS] fingers) and evaluate its performance both off and online.
Methods: We implanted one nonhuman primate with a Utah microelectrode array in the hand area of primary motor cortex. Following online brain-control of the virtual fingers using a Kalman filter (Nason et al., bioRxiv 2020), we trained step-wise linear discriminate analysis (SWLDA) classifiers to detect erroneous movements using thresholding events from 96 M1 electrodes in 50 ms bins. Short movement segments that were consistently toward or away from the target were labeled accordingly, while segments with inconsistent movement direction were not included in training. The effect of the number of bins in each segment was assessed by evaluating the true positive rate (TPR, i.e., the rate at which segments away from the target are correctly classified as such) and false positive rate (FPR, i.e., the rate at which segments toward the target are mistakenly classified as away from the target). Classification rates were improved by accounting for the decoded direction of the movement (extension or flexion), so two classifiers were trained for each finger-group resulting in 4 classifiers in total.
Receiver operating curves (ROCs), which quantify the tradeoff between TPR and FPR, were estimated for each classifier. We determined both the optimal performance, which minimizes total error rate, and the performance when, for practical operation, the FPR was restricted to 5%.
Results: Offline analysis revealed that best performance was achieved with 5 bins per segment (i.e., 250 ms windows). Optimal TPR and FPR were 82% and 34.3% for the MRS group and 68.4% and 46.5% for the index finger. Restricting FPR to 5% during validation resulted in a TPR

and FPR of 42% and 4.5% for the MRS group and 23% and 8% for the index finger. Real-time performance is under evaluation.
Conclusions: Erroneous movement segments can be distinguished from correct movements based on the neural activity in M1. This suggests that the neural activity encodes information related to error processing and can be used to improve invasive BMIs.

Title: A pulse-interval modulation communication scheme for low-power, wireless brain machine interfaces

Authors: *J. T. COSTELLO[1], S. R. NASON[2], J. LEE[1], H. AN[1], M. J. MENDER[2], H. TEMMAR[2], D. M. WALLACE[3], J. LIM[1], M. S. WILLSEY[4], P. G. PATIL[4], H.-S. KIM[1], D. BLAAUW[1], C. A. CHESTEK[2];
[1]Electrical and Computer Engin., [2]Biomed. Engin., [3]Robotics Grad. Program, [4]Neurosurg., Univ. of Michigan, Ann Arbor, Ann Arbor, MI

Abstract: Brain-machine interfaces (BMIs) have the potential to restore motor function but are currently limited by electrode count and long-term recording stability. These challenges may be solved through the use of free-floating “motes” which wirelessly transmit recorded neural signals. In particular, motes that are powered by and transmit data through infrared light can be scaled to sub-250 um dimensions for high-density recording, a similar density to existing arrays. However, a key challenge with implanted wireless devices is minimizing power usage to stay within safe tissue irradiation limits.
Here, we evaluate a novel pulse-interval modulation (PIM) communication scheme that reduces mote power usage to stay within limits. It has previously been shown that recording power can be reduced by sampling at only 2000 Hz and using the 300-1000 Hz spiking band power (SBP)

as a neural feature. With the PIM scheme, data packets contain each mote's ID and encode SBP by the rate at which packets are transmitted (Lim...Blaauw, VLSI 2021). Then, a receiver can resolve packet collisions through the use of temporal and spatial filters matched to each mote's ID. Individual mote power usage and signal fidelity can be adjusted by changing the average packet rate. Due to asynchronous transmission times, PIM-based motes can use clock speeds less than 10 kHz, unlike synchronized schemes that require clock speed (and power) to scale with the number of motes. Furthermore, PIM removes the need for a power-demanding analog-to-digital converter.

To test PIM's ability to efficiently communicate SBP, we simulated the communication scheme in a real-time BMI. Two Rhesus macaque monkeys, previously implanted with 96-channel Utah microelectrode arrays in primary motor cortex, were trained to control a virtual hand using the BMI. In this system, Kalman filter decoders predicted finger velocity from SBP or simulated PIM-SBP. At a rate of 100 packets/s, equivalent to 1.3 Kbps using a 12-bit mote ID, PIM-SBP decoders performed as well as standard SBP decoders (target acquisition times of 1.26 and 1.36 sec, respectively). This suggests that BMI performance can be maintained with significantly lower bit rates than transmitting the full 30 kHz signal (480 Kbps/channel) or SBP signal (32 Kbps/channel). Using this scheme, data from 1000 channels could be transmitted using 1.3 Mbps, and initial simulations of 1000 motes suggest that despite packet collisions, SBP data can be recovered through the use of matched filters on the receiver.

These results suggest that PIM-based communication can significantly reduce power usage of wireless motes to enable higher channel counts for high-performance BMIs.

Abstract: Brain Computer Interfaces (BCIs) have the potential to restore lost upper limb function by translating neural signals into the motion of an external device. Despite successful demonstrations, there remain challenges to real-world BCI control of complex tasks, including signal instability. Additionally, continuous, high-dimensional neural input is required to perform functional upper limb tasks which operate in a high dimensional action space. Recently, we demonstrated that stable "plug-and-play" control of a 2D cursor is possible by leveraging the stability of electrocorticography (ECoG) with long-term closed-loop decoder adaptation. Here, we aim to increase the control dimension of the action space by using multiple stable and stacked discrete signals with the goal of continuous, real-time control of a 6-dof robotic arm. A subject with severe spastic tetraparesis was implanted with a 128-channel chronic ECoG array over sensory and motor cortices. To initialize discrete control commands, the subject was instructed to imagine movements related to distinct body parts (right hand, head, left hand, feet, tongue, and lips). A multilayer perceptron was used to classify discrete actions from the extracted neural features (delta (0.5-4 Hz), beta (12-30 Hz), and high-gamma (70-150 Hz) power). The discrete actions were mapped to Cartesian directions to control the translation of a robotic arm end-effector. Continuous motion was achieved by imposing virtual mass-damper dynamics with the decoded discrete state acting as an input. This produces smooth motion with the ability to move in off-axis trajectories. To enable robotic grasping, the same set of imagined movements was mapped to an alternate set of robot actions that control the gripper opening and wrist orientation. An additional imagined movement (both hands) acts as a clicker, allowing the subject to switch between the translation and grasp modes and increasing the dimension of control. Using this framework, the subject was able to successfully control the robotic arm to reach to and grasp objects on a table. These results suggest that robust discrete commands decoded from ECoG signals can be used as the input to be a "universal joystick" for neuroprosthetic control which can be mapped to different action spaces, providing a framework for the development of long-term control of devices which operate in high-dimensional spaces.

Title: High-velocity prosthetic finger movements in real-time brain-machine interfaces using artificial neural networks

Authors: *M. S. WILLSEY[1], S. R. NASON[1], S. R. ENSEL[4], H. TEMMAR[1], M. J. MENDER[1], J. T. COSTELLO[1], P. G. PATIL[2], C. A. CHESTEK[3];

Abstract: Brain-machine interfaces (BMIs) that control prostheses may help restore motor movements to patients with injuries causing motor paralysis. The algorithm converting recorded neural activity into motor movements for the prostheses, the decoder, is critically important to its speed and efficiency. Herein, we introduce a novel feed-forward neural network velocity decoder (NN) to control finger prostheses using neural activity recorded from intracortical Utah arrays. An intention based retraining step, similar to that used in the recalibrated feedback intention–trained (ReFIT) Kalman filter, was used to produce an improved decoder, the ReFIT NN (RN). Utah arrays were implanted in motor cortex of two male rhesus macaques, trained to perform a two-dimensional finger task. Using a low power proxy for spiking rate, spike-band power (SBP), a five-layer neural network decoder (NN) was trained based on the relationship between finger velocities and SBP. NN was then used to decode finger trials and further refined by the ReFIT re-training step. Over multiple days of testing in both animals, the NN and RN are compared using an adaption to Fitt's law bit rate, a measure of throughput, without online hyperparameter tuning. The NN and RN decoders are then compared to our previously published ReFIT Kalman filter for fingers (RK; Nason et al. 2020). In both animals, when comparing RN vs NN, the intention based retraining step substantially improved the throughput – 42% in Monkey N ($P < 10^{-5}$) and 20% in Monkey W ($P < 10^{-5}$). Comparing RN with RK also revealed performance gains of 62% in Monkey N ($P < 10^{-5}$). RN was found to operate with higher decoding velocities than RK, and these higher velocities are thought to account for the improved performance. An offline analysis accounting for differences in decoder gain also confirmed that the neural network algorithm was better able to model higher velocities than the Kalman filter. Using an architecture loosely inspired by biological motor pathways, this novel neural network decoder can be refined with an intention-based retraining step and substantially outperforms our previously published RK with more natural-appearing finger movements.

Title: Improving reaching with functional electrical stimulation by incorporating stiffness modulation

Authors: *T. JOHNSON[1], D. M. TAYLOR[2,1];
[1]Case Western Reserve Univ., Cleveland, OH; [2]Neurosciences, Cleveland Clin., Cleveland, OH

Abstract: Objective: Intracortical recordings have now been combined with functional electrical stimulation (FES) of arm/hand muscles to demonstrate restoration of upper-limb function after spinal cord injury. However, for each desired limb position decoded from the brain, there are multiple combinations of muscle stimulation levels that can produce that position. The objective of this simulation study is to use a virtual arm model to explore how modulating the amount of coactivation of antagonist muscles can impact reaching performance and energy usage during FES. Stiffening the limb by cocontracting antagonist muscles makes the limb more resistant to perturbation. Minimizing cocontraction saves energy and reduces fatigue. Approach: Prior demonstrations of reaching via FES used a fixed empirically-derived lookup table for each joint that defined the muscle stimulation levels that would position the limb at the desired joint angle decoded from the brain at each timestep. This study expands on that previous work by using simulations to: A) test the feasibility of controlling arm reaching using a suite of lookup tables with varying levels of cocontraction instead of a single fixed lookup table for each joint, B) optimize a simple function for automatically switching between these different cocontraction tables using only the desired kinematic information already being decoded from the brain, and C) compare energy savings and movement performance when using the optimized function to automatically modulate cocontraction during reaching versus using the best fixed level of cocontraction. Main Results: Our data suggests energy usage and/or movement performance can be significantly improved by dynamically modulating limb stiffness using our multi-table method and a simple function that determines cocontraction level based on decoded endpoint speed and its derivative. Specifically, reducing cocontraction during acceleration and increasing cocontraction during deceleration enabled one to reduce the baseline level of cocontraction and energy usage while still maintaining good movement performance. Significance: By demonstrating how modulating cocontraction can reduce energy usage while maintaining or even improving movement performance, this study makes brain-controlled FES a more viable option for restoration of reaching after paralysis.

Title: Decoding Recordings of Extracellular Activity from Longitudinal Intrafasicular Electrodes to Control a Prosthetic Hand

Authors: *T. R. BENIGNI[1], J. J. ABBAS[2], R. JUNG[1];
[1]Biomed. Engin., Florida Intl. Univ., Miami, FL; [2]Ctr. for Adaptive Neural Systems, Arizona State Univ., Tempe, AZ

Abstract: Motorized prosthesis users typically control their prosthesis with signals derived from muscles in the residual limb. Neural recordings from longitudinal intrafascicular electrodes (LIFEs) have been used to control a single degree of freedom prosthesis using a Schmitt trigger and leaky integrator to provide some level of control. With the introduction of multi-degree of freedom prostheses with options for grasp patterns and improved capabilities for graded control, advanced algorithms will be required to simultaneously decode multiple graded motor intent signals in order to detect the class of the action (e.g. grasp type) and the degree of the action (e.g. grasp force). We have developed a Python-based algorithm suitable for real-time decoding of motor intent recorded from small groups of axons. To assess the quality of the decoding algorithm, we used our published software platform to simulate neural motor signals recorded with LIFE electrodes. The simulator utilizes motor intent signals to drive a mixed pool of simulated motoneurons with various spike shapes, recruitment characteristics, and firing frequencies. Each electrode records a weighted sum of a subset of simulated motoneuron activity patterns allowing the simulated electrodes to be influenced by multiple motor pools (Abdelhani et al. 2014). Three different motor intent signals commonly used to control a prosthesis were used to generate simulated extracellular recordings to assess the decoding algorithm's performance: a grip and hold (saturating line function), a grip, hold and drop (square pulse), and a low force open/close (cosine wave function). Recordings were generated with a sampling rate of 24 kHz and a good quality extracellular SNR of 5 dB. The decoding algorithm used small windows of the simulated neural recording (50 ms) and then filtered, rectified, and normalized each window, to extract signal features (mean absolute value) related to the motor intent. Control signals for prosthetic hands need to have an overall latency of less than 100 ms and have a high enough quality to transmit the user's intent. Results demonstrated that the decoder can process

each window at <2ms and match the underlying intent with an average normalized root mean square error of less than 16%. This indicates that the decoded signals could be suitable for the control of a prosthetic hand. We plan to investigate if this approach, when applied to multiple channels of LIFE recordings from antagonist motor pools, could be used to control a multi-degree of freedom prosthesis.

Title: Restoration of complex movements in paralyzed upper limbs

Authors: *B. A. HASSE, D. E. G. SHEETS, N. L. HOLLY, K. M. GOTHARD, A. J. FUGLEVAND;
Physiol. and Neurosci., Univ. of Arizona, Tucson, AZ

Abstract: Functional electrical stimulation (FES) artificially activates muscles to help restore function in paralyzed limbs. The use of FES to enable reaching and grasping in tetraplegics has been limited to a small set of preprogrammed movements due to the difficulty in identifying stimulus patterns needed to elicit more complex behaviors. To overcome this limitation, we used machine learning to predict patterns of activity across multiple muscles associated with complex upper limb movements. Those patterns were then used as FES templates to evoke desired arm movements in temporarily paralyzed (anesthetized) monkeys. Twenty-nine arm muscles in each of three male rhesus macaques were surgically implanted with recording/stimulating electrodes. Electromyographic (EMG) and kinematic data, recorded while the monkeys tracked complex trajectories, were used to train artificial neural networks (ANNs). Trained ANNs were then used to predict EMG signals associated with a new set of complex movements. Predicted patterns of muscle activity were transformed into stimulus pulse trains that were subsequently delivered to intramuscular electrodes to evoke arm movements in the monkeys while under general anesthesia. Predicted EMG signals were based on training data obtained from the same monkey (*'self'*) or from a different monkey (*'other'*). The accuracies of *self*-predicted EMG for muscles actively involved in moving the hand through space were quite good with R^2 values often > 0.8. As expected, *other*-predicted EMG signals for such muscles were not quite as good but still reasonable with $R^2 \sim 0.60$. When predicted (*self* and *other*) or *actual* EMG signals were used as

stimulation templates, the average R^2 values for evoked compared to desired kinematics were not significantly different from one another (all ~ 0.33). However, all of these were significantly greater than that associated with evoked movements in which the stimulus patterns were randomly shuffled among all muscles. These results indicate that the sources of EMG templates are not crucial, and that errors are primarily related to how such templates are transformed into muscle active states. Regardless, these findings demonstrate that machine learning can be used to identify patterns of muscle stimulation needed to evoke complex, large scale movements in paralyzed upper limbs that approximate desired trajectories. The errors, however, can be significant - inclusion of real-time feedback would seem to be one way to improve control over these otherwise open-loop movements.

Title: Mirror Training Improves Offline-Decode Performance for Multi-DOF Myoelectric Prosthetic Control

Authors: *T. N. TULLY, C. J. THOMSON, G. A. CLARK, J. A. GEORGE;
Univ. of Utah, Salt lake City, UT

Abstract: Transradial prostheses can provide intuitive control by training an algorithm to correlate electromyographic signals from the residual forearm muscles to intended movements of the amputated hand. One training paradigm, “mimicked training”, relies on amputees mimicking a virtual hand with their missing hand such that the corresponding muscle activations are correlated to the preprogrammed kinematics. A second training paradigm, “mirrored training”, relies on unilateral amputees mirroring their contralateral hand with their missing hand such that the muscle activations are correlated to the kinematics of the contralateral hand (determined via motion capture). Our prior work with intact participants demonstrated that mirrored training captures kinematics more closely related to the target (i.e., missing) hand. This abstract extends this work to assess the impact on prosthetic control. Seven participants mimicked a virtual bionic

hand with their dominant hand and contralateral hand simultaneously while we recorded the kinematics of both hands with a low-cost infrared camera. We compared the performance of a modified Kalman filter (MKF), shallow convolutional neural network (CNN) and a deep CNN for both training paradigms. We also compared the performance of these 3 algorithms when the training dataset was small (5 movements per digit) versus large (50 movements per digit). Performance was measured as the Root Mean Squared Error of algorithm predictions relative to the ground-truth kinematics of the dominant hand. The larger training dataset significantly improved the performance of both CNNs under both training paradigms (p's < 0.0042, individual t-tests with Dunn-Sidak correction for multiple comparisons), whereas there was the larger dataset did not improve the MKF under either training paradigm. For the large dataset, mirrored training significantly improved the shallow CNN and deep CNN (p's < 0.0042. For the small dataset, mirrored training significantly improved the shallow CNN ($p < 0.0042$) and trended towards improving the deep CNN ($p = 0.0278$). Further investigations will explore a larger demographic of intact subjects, examine real-time performance, and compare these training paradigms and algorithms with amputee participants on activities of daily living.

Title: Object property recognition during closed-loop control of a prosthetic hand with elicited tactile feedback through transcutaneous nerve stimulation

Authors: *L. VARGAS[1], H. HUANG[1], Y. ZHU[2], X. HU[3];
[1]NCSU/UNC Joint Dept. of Biomed. Engin., North Carolina State Univ. and Univ. of North Carolina-Chapel Hill, Raleigh, NC; [2]Dept. of Mechanical Engin., North Carolina State Univ., Raleigh, NC; [3]NCSU/UNC Joint Dept. of Biomed. Engin., Univ. of North Carolina at Chapel Hill, Chapel Hill, NC

Abstract: Although many prosthetic devices have evolved to replicate the motions of the human hand, these systems often lack tactile feedback to the users. This study aimed to evaluate if non-invasive somatotopic feedback elicited through transcutaneous nerve stimulation could help

participants to discern different object properties (shape and size), while a prosthetic hand was controlled using different myoelectric control strategies (position and velocity control). Using a 2x8 electrode array placed on the upper arm, fingertip tactile sensations were elicited through stimulation of the median and ulnar nerves. Evoked percepts were intensity-modulated to resemble the changes in fingertip forces from a prosthetic's index and middle fingers. Myoelectric signals of the finger flexor and extensor muscles were used to control the position or velocity of the prosthetic finger joint. Object shape recognition involved the stimulation of two distinct electrodes pairs each corresponding to discrete fingers. Object size was distinguished based on the time to contact and/or the level of muscle activity during position control. The results showed a significant improvement of the object recognition accuracy with evoked tactile feedback. Our results demonstrated the efficacy of our nerve stimulation approach and its robustness across control strategies. Overall, the outcomes promote our understanding on the role of sensory feedback during human-machine interactions, potentially improving user experience and confidence when using myoelectric prosthetic hands.

Abstract: Intracortical brain-computer interfaces (iBCIs) use signals recorded directly from the brain to help individuals with paralysis to control assistive devices such as computer cursors or robotic arms. Robotic exoskeletons, which are typically made out of rigid materials combined with motors and gears, have limitations as iBCI effectors due to their relative complexity, bulkiness, and cost. Recently, advances in soft robotic technology have enabled the development of soft exoskeletal wearables that have shown promise as assistive and rehabilitative tools for individuals with motor impairment. In this study, we paired our iBCI neural recording and decoding system with a soft robotic glove (SRG) and explored the effects of proprioceptive feedback during SRG-activated hand movement on neural activity in the human motor cortex. Data were collected from participant T11, a 36-year-old, right-handed man with a spinal cord injury (C4 AIS-B). T11 had two 96-electrode arrays (BlackRock Microsystems) implanted in his left precentral gyrus (PCG) as part of the BrainGate Clinical Trial. Neural data were recorded while T11 was asked to attempt functional hand movements (power grip, pinch grip, open hand) while the quality of sensory feedback was varied. An SRG moved either his own hand or a mannequin hand into the corresponding grip postures. Moveable barriers were used to either obstruct or expose visual feedback of the moving hand. T11 was also asked to perform trials where he passively observed the moving hand without attempting the grips. Threshold-crossing rates were used to assess neural activity across 192 channels and construct neural decoders to assess discriminability between different hand movements. The recorded neural population responded to all volitional and feedback conditions, including conditions where the participant experienced visual feedback or proprioceptive feedback alone. Neural responses during attempted hand movement were more robust than during passive observation, and visual feedback evoked greater neural modulation than proprioceptive feedback. Neural decoders were able to reliably discriminate between grip types when calibrated on attempted movement data and could also decode passively-watched hand movements but with less accuracy. The type of feedback did not significantly affect decoding of grip type during attempted movement trials, however, suggesting that the introduction of proprioceptive feedback produced when operating an SRG would not negatively impact decoding in a PCG-based iBCI. Further work is needed to verify these results in individuals with different degrees of upper-limb sensorimotor impairment.

Title: Interaction of effector and direction encoding in motor cortex of a person with tetraplegia during a bimanual task

Authors: *T. HOSMAN[1,2,4], C. E. VARGAS-IRWIN[3,2,4], A. KAPITONAVA[5], L. R. HOCHBERG[4,5,1,2,6], J. D. SIMERAL[4,1,2];

Abstract: Intracortical brain computer interfaces (iBCIs) have consistently enabled individuals with paralysis to control a computer cursor or a robotic arm and hand. Simultaneous decoding of bilateral movements would offer additional degrees of freedom to interact and communicate through iBCI assistive technologies, such as two-handed typing, tablet control using gestures of each hand, or twisting open a jar. Here, we report intracortical neural encoding in human motor cortex during bilateral movements when the effector (right or left thumb) and movement direction (upper, lower, left, or right targets) are cued separately.

At the time of this study, the participant, T11, was a 36 year-old male with C4 ASI-B spinal cord injury who had two 96-channel microelectrode arrays implanted in the left precentral gyrus. In an instructed delay task, T11 attempted to move a single cursor from the center to one of four cardinal targets with his left, right, or both thumbs. The upcoming target direction and effector instructions were presented sequentially. Center-out cursor movements were controlled by the computer and analyses were performed offline with two types of features derived from neural activity: binned spiking (threshold crossings at 3.5 RMS) and spike-power band LFPs (250-5000 Hz). Significance was assessed using the Kruskal-Wallis test (p<0.01).

For cue order direction then effector choice, we found that, on average, 50% of 384 features deviated from baseline values (i.e. were considered responsive) when direction cues were

presented without effector context and 29% of features then displayed significantly different values for different targets (i.e. were direction selective). Next, when the effector was presented, 52% of features were responsive and 8% selective between left and right movement trials. Interestingly, during unimanual ipsilateral left/right movement trials ~75% of the selective feature responses changed after the effector cue presentation suggestive of a body-midline representation. No equivalent change in response was found during contralateral or bimanual left/right movements nor for any effector during up/down movements. We additionally performed ensemble analyses to test for a communication subspace where movement and effector information is combined. Finally, we applied the same techniques to a similar partially cued grasp task. While this study was performed with a single participant with tetraplegia, these results suggest that the effector context is important for understanding and decoding bimanual movements for iBCIs.

Title: Internal Model with Interaction Gain and Feedback Contribution Successfully Interprets Weight Distribution According to the Asymmetry in Plantar Pressure

Authors: *D. DOLLAHON, H. PARK;
Electrical and Computer Engin., Texas A&M Univ., College Station, TX

Abstract: The variety and steadily increasing quantity of cases where patients have motor impairments is prompting the development of new rehabilitative techniques. Sensory intervention is promising as motion dependent sensory feedback plays a critical role in reorganizing the nervous system and recovering motor function. To maximize the efficacy of existing rehabilitative techniques and promote the development of new approaches, a full understanding of how the human sensorimotor system responds to the given sensory intervention is essential. The leading method for understanding the sensory intervention is through the analysis based on an internal model, which analytically describes the operation of the sensorimotor system based on known neural pathways. However, currently available internal models do not yet provide sufficient details to quantitively characterize the sensorimotor loop operation, and therefore are not actively used by clinicians. The objective of this experiment was to develop a new internal model which can quantitatively describe the change in motor output in response to the sensory intervention. To accomplish this goal, we added “interaction gain” and

"feedback contribution" to the internal model and identified those values based on the relationship between the change in plantar pressure (sensory intervention) and weight distribution (motor output). Those values are defined respectively as the level of interaction the sensorimotor system has with the associated stimulus and as the amount of feedback control that affects the associated motor output. A balancing task was chosen to demonstrate the new internal model. Subjects stood on rubber mats of varying surface areas on top of a pressure pad, to change the plantar pressure. Data was collected for both blindfolded and unblindfolded cases, and both cases where the subjects were instructed to balance normally and where subjects were instructed to distribute weight to equalize plantar pressure. From these results we determined that (1) tactile feedback contribution was significant for the cases where the subject was instructed to match the perceived plantar pressure; (2) tactile feedback contribution was larger for trials where visual feedback was restricted; (3) visual feedback contribution increased when subjects focused on matching tactile pressure. Based on the results, we conclude that the new internal model with interaction gain and feedback contribution will discover how the motor output changes based on sensory intervention.

Title: Methods to test lower limb position sense using a split belt treadmill

Authors: *J. WOOD, H. E. KIM, S. M. MORTON;
Univ. of Delaware, Newark, DE

Abstract: Human locomotion is highly adaptable, allowing us to move across a range of different environments and surfaces. To safely walk under these varied conditions, it is necessary to have accurate estimates of lower limb location which often rely less on visual feedback, making our position sense estimates all the more important. However, it is unclear how accurate lower limb position sense estimates are and whether perceptions shift during gait adaptation. Locomotor adaptation is frequently studied using the split-belt treadmill, in which the two treadmill belts, and therefore the two legs, are driven at different speeds, such that participants are forced to walk with a significant degree of interlimb asymmetry. The most consistent sensory change observed after adapting in this paradigm is the sense of limb speed (Jensen et al., 1998,

Leech et al., 2018). Yet, other, perhaps equally important percepts such as limb position sense, i.e., one foot's position relative to the other, have received less attention. Therefore, the objective of the current study was to assess the accuracy of relative foot positions measured in a locomotor-relevant task to provide a basis for future assessments of proprioceptive shifts caused by locomotor adaptation. We modified the approach used by Vasquez et al. (2015). We employed a two-alternative forced choice task using the method of constant stimuli with 9 target positions (0, ±10, ±20, ±30, ±40 mm) representing the difference between the two legs along the sagittal plane. Individuals stood on a treadmill with vision of their legs occluded. For each trial, the treadmill slowly moved the test limb to a random start position drawn from a normal distribution centered on zero (to prevent the limb always moving in the same direction) then to the target location. Each target was visited 15 times. Participants were asked if they felt the left or the right limb was more forward. We calculated the probability of the participant responding 'left' at each target location and fit a psychometric function to each individual's data. We used the mean and standard deviation of the psychometric fits as our measures of bias and precision of limb position sense, respectively. We found that, on average, participants in our sample perceived their test limb to be slightly behind their reference limb, and their position was accurate to < 1 cm. We conclude that this method can be used to determine perceptual shifts induced by split-belt treadmill adaptation.

Title: Responses to visual perturbations during walking in children with and without cerebral palsy.

Authors: *A. SANSARE[1], M. ARCODIA[2], S. C. K. LEE[1], J. J. JEKA[3], H. REIMANN[2];
[1]Dept of Physical Therapy, [2]Kinesiology and Applied Physiol., [3]Kinesiology & Applied Physiol., Univ. of Delaware, Newark, DE

Abstract: Children with cerebral palsy (CP) tend to rely on vision more than other sensory modes to control their balance in standing and during single plane lower extremity movement. However, it is not known whether this also applies to walking, an activity where the threat to balance is generally higher. The aim of this pilot study is to assess how children with CP use visual information for sensorimotor feedback during walking, compared to children with typical

development (TD). We perturb balance during treadmill walking by visual fall stimuli in the frontal plane using a virtual reality projection. Our hypothesis, based on previous studies on older adults, is that children with CP will demonstrate a magnified and delayed response to visual perturbations. Additionally, unlike neurotypical adults who show stance foot ankle roll as an immediate response to visual perturbations, followed by a step placement response, we hypothesize that children with CP would show a lack of ankle roll but a larger step placement response to the visual perturbations. Twelve children (6 with CP, age 18 ± 2.9, 2 female; 6 age- and sex-matched controls with TD, age 18 ± 3.1) participated in the study. They walked on a self-paced treadmill inside a virtual reality environment that induced a visual fall stimulus in the frontal plane every 10-12 steps. Each trial lasted two minutes and was repeated ten times, with intermittent rest breaks. Participants in both CP and TD group reacted to the perturbation by moving their center of mass away from the fall stimulus. Participants with CP showed a delayed and magnified shift in the center of mass trajectory compared to their age-matched TD peers. While the participants with TD inverted their ankle immediately following a visual fall stimulus, the participants with CP did not show this response, as indicated by no change in their subtalar joint angles and peroneal muscle electromyography recording. Instead, they employed a magnified step placement strategy, showing a higher peak step placement change compared to the TD group. Overall, a magnified and delayed response to visual perturbations was seen in participants with CP compared to their age and sex matched peers. These results suggest that children with CP show a greater reliance on visual feedback over other sensory modalities, potentially to compensate for impaired proprioceptive abilities seen in CP. While most assessments as well as treatments for balance rehabilitation in CP address motor deficits, our findings highlight the importance of considering sensory regulation of walking balance in rehabilitation protocols.

Title: Purkinje cell modulations of vestibular neurons and its role for balance

Authors: *F. AUER, K. NARDONE, D. SCHOPPIK;
Otolaryngology and Neurosci. & Physiol., New York Univ. Langone Med. Ctr., New York, NY

Abstract: The cerebellum is important to adjust and maintain balance. Consequently, lesions in the vestibular cerebellum lead to postural instabilities. While it is known that Purkinje cells (PC)

of the cerebellum directly target neurons in the vestibular nuclei, it is unclear how these vestibular neurons are modulated by PCs in the context of balance and posture. Zebrafish are an exceptional model system to address this question. Our lab has done much work to characterize the vestibular circuitry of larval zebrafish and develop tools to measure vestibular function and postural control. Here we report a set of chemogenetic manipulations to directly activate or lesion PCs and the resulting effect on postural control, as well as calcium imaging to further dissect this circuit. After PC lesion, fish adopt asymmetric postures in the pitch axis. Specifically, we observed PC lesioned fish spent more time at eccentric nose-up postures than control siblings. Further, we observed asymmetric implementation of postural adjustments. We used a generative model of swimming to show that changes to these corrective postural adjustments can account for the nose-up postures we observe. To investigate PC modulations, we are using a vestibular pitch stimulus combined with calcium imaging in vestibular nucleus neurons. We give a nose-up stimulus or a nose-down stimulus. The majority of cells have a preferred stimulus direction, either nose-up or nose-down. After lesion of PCs, we observe systematic changes in the calcium responses of putatively PC-targeted neurons in the vestibular nucleus. Nose-down responses increased in magnitude after lesion, indicating direct Purkinje cell input, whereas nose-up responses decreased in magnitude, suggesting indirect input via contralateral, inhibitory neurons. Together, we find an asymmetric effect of PC lesions on behavior as well as on downstream targets, likely explained by an asymmetry in targeting of nose-up versus nose-down preferring cells.

Title: The Role of Cognitive Impairment on Dual-Task Gait Performance

Authors: *D. GHIDELLA, T. PHAM, Z. TUTTLE, V. KRISHNAN, Y.-H. CHO;
California State University, Long Beach, Long Beach, CA

Abstract: More than 33% of older adults age 65 and older fall each year, with fall risk increasing each year (Gillespie et al., 2009). Falls often occur when dual-task (DT) walking (walking while performing a cognitive task) where DT gait cost (difference between walking with and without performing a cognitive task) was reported to be positively associated with future falls (Muir-Hunter & Wittwer, 2016). Previous studies have used postural stability and walking speed as measures of DT gait cost (Yogev-Seligman et al., 2008). However, it is uncertain whether other gait parameters may be linked with future fall risk (Muir-Hunter &

Witterwer, 2016). Our study will bridge the gap within the literature by investigating the roles of various levels of cognition on DT cost of multiple gait parameters. We hypothesized that cognitively healthy older adults will have better gait performance than the mildly and severely impaired group. Sixty-four older adults (M_{age} = 76.2 ± 8.23) participated in the study. Global cognition was assessed using Montreal Cognitive Assessment (MoCA). Older adults were categorized as cognitively healthy (N = 27), mildly impaired (N = 25), severely impaired (N = 12) if their MoCA score was ≥ 26, between 22 - 25, and ≤ 21, respectively. Gait parameters included velocity step length, stride length, cycle, and cycle time coefficient of variation (CV) and were measured using Zeno walkway system. DT gait cost was computed from single-task (ST; walking alone) and dual-task (walking while performing Stroop) conditions with this formula: [((DT - ST) / ST) * 100]. One-
way MANOVA was conducted to examine the role of level of cognitive impairment on the combined DT cost of the gait parameters. Differences among the groups on the DT gait cost were statistically significant, Wilks' Λ = .71, $F(10, 114) = 2.11$, p=.029. Follow up univariate analysis showed that the cognitively healthy older adults had less difficulty in walking during DT than the severely impaired older adults on velocity [F(2, 1376.28) = 6.312, p =.003)], step length [F(2, 354.48) = 3.318, p=0.43)], stride length [F(2, 363.47) = 3.369, p=.041)], cycle time F(2, 1074.38) = 3.1456, p = .0380], and cycle time CV [F(2, 153208.94) = 3.492, p = .037)]. The results indicate that older adults with severe cognitive impairment exhibited greater deficits in their gait than their cognitively healthy peers when dual-tasking. To the best of our knowledge, this study is one of the few to examine the association between different levels of cognition with various gait parameters among older adults. These findings can be extended by implementing different fall prevention programs according to older adults' level of cognitive impairment.

Title: Healthy aging modifies head kinematics during continuous gaze stabilization exercises

Authors: *W. H. SOUZA[1], O. ZOBEIRI[1], J. MILLAR[2], M. C. SCHUBERT[3], K. E. CULLEN[1]; [1]Dept. of Biomed. Engin., [2]Dept. of Physical Med. and Rehabil., [3]Dept. of Otolaryngology, The Johns Hopkins Univ., Baltimore, MD

Abstract: The vestibular system is essential to maintain gaze, gait and postural control. Gaze stability exercises are prescribed for patients with vestibular hypofunction and often for patients with subjective reports of dizziness, yet normal vestibular function. Recent evidence shows that head kinematics during continuous gaze stabilization exercises can differentiate individuals with vestibular hypofunction from healthy controls, suggesting these exercises may provide a reliable proxy of functional vestibular performance. It is unknown, however, the extent to which such difference in kinematic behavior is attributed to aging. Furthermore, given the high prevalence of dizziness and falls in healthy elderly, we sought to examine differences in head kinematics during yaw (horizontal) and pitch (vertical) head motion in young vs. older adults. Herein, we assess the effects of aging on head kinematics during continuous gaze stabilization exercises in adults with no vestibular impairment as per video head impulse testing. Twenty healthy participants (55% female) composed two groups: young (n = 10, 24 ± 2.7 years) and older (n = 10, 66 ± 5.4 years). Each performed six 30-second gaze stabilization exercises with continuous head motion in pitch (3) and yaw (3) axes while standing. Participants were asked to constantly look at a target – a 1-inch letter "x" placed at eye level on the wall (1m and 2m), or hand-held at arm's length. Motion signals were recorded with a 6-dimensional motion sensor (3-axis linear acceleration and 3-axis gyroscope) placed on the back of the participants' heads. We examined head range of motion and cycle duration. Range of motion was significantly reduced ($p < 0.05$ – 0.01) in older vs. younger participants in pitch axis only (1m-wall pitch, 1m-wall yaw and hand-held pitch and yaw exercises). Cycle duration was equivalent between groups. Our results showed that, while head rotation cycles are similar in time between groups, older adults deploy smaller amplitude motion to maintain gaze stability during pitch rotations – an adaptation implemented over gaze fixation on near, not far targets. This behavior suggests that healthy aging leads to slower head velocities as a strategy to ensure effective proximal gaze stability in pitch head rotation, even when vestibular function is effective. Moreover, head kinematic measurements during continuous gaze stabilization exercises reveal adaptations relative to older age, which should be accounted for by clinicians prescribing and interpreting this type of exercise.

Title: Neural pathways underlying thalamic deep brain stimulation-induced gait ataxia in Essential Tremor

Authors: M. BLUMENFELD[1], A. BRINDA[1], D. MARTICORENA[1], R. BUTLER[1], C. SPENCER[1], J. D. KRIEG[1], L. K. WILMERDING[1], T. PALNITKAR[2], R. PATRIAT[2], N. HAREL[2], L. SCHROCK[3], S. E. COOPER[3], J. Y. MATSUMOTO[3], *M. D. JOHNSON[1]; [1]Biomed. Engin., [2]CMRR, [3]Neurol., Univ. of Minnesota, Minneapolis, MN

Abstract: Background: Deep brain stimulation (DBS) in the region of the ventral intermediate nucleus (Vim) of the thalamus can be highly effective for treating tremor in individuals with Essential Tremor (ET). However, a side effect of DBS that can limit the ability to achieve full tremor control is gait ataxia.
Objective: In this study, high-field (7T) MRI-based patient-specific computational models of DBS were used to assess the relationship between induction of gait ataxia and activation of 12 different neural pathways in and around the motor thalamus.
Methods: Two ET patients (one with bilateral and one with unilateral Vim-DBS implants) performed trials of tandem gait during DBS across multiple electrode configurations and stimulation amplitudes. Trials were clinically evaluated as “ataxic” or “non-ataxic” based on the Brief Ataxic Rating Scale (BARS). For each implanted DBS lead, modeled tractographic pathways included the motor cortex (MC) to external Vim (VimE), MC to internal Vim (VimI), medial lemniscus (ML), MC to anterior ventral lateral thalamus (VLa), somatosensory cortex (SSC) to ventral posterior thalamus (VPL), superior cerebellar peduncle (SCP) to the reticular nucleus of thalamus, SCP to VimI, SCP to VimE, lenticular fasciculus (LF), thalamic fasciculus (TF), internal capsule, and zona incerta. These biophysical axon models were coupled with patient-specific finite element tissue models to estimate the percent activation of each of the twelve neural pathways for stimulation settings that were either ataxic or non-ataxic.
Results: While some differences in pathway activation between ataxic and non-ataxic gait were observed (increased ML and SSC-VPL activation and decreased LF and TF activation for ataxic settings), these differences were not statistically significant ($p>0.05$).
Significance: This preliminary data suggests that activation of a single neural pathway may not be solely responsible for production of gait ataxia as a side effect of Vim-DBS. Development of an objective measure of gait ataxia, such as using markerless pose estimation, may help further understand the relationship between pathway activation and gait ataxia.

Title: Clustering and Prediction of Disease Trajectory in Adrenomyeloneuropathy

Authors: *B. R. TURK[1], Y. FAN[2], A. SMITH FINE[1], J. KELLER[1], M. UNBERATH[2], A. FATEMI[1];
[1]Kennedy Krieger Institute, Johns Hopkins Univ., Baltimore, MD; [2]Whiting Sch. of Engineering, Johns Hopkins Univ., Baltimore, MD

Abstract: BACKGROUND
Adrenomyeloneuropathy (AMN) is the slow progressive phenotype of X-linked Adrenoleukodystrophy (ALD). Dying-back axonopathy of the spinal cord and peripheral neuropathy underlie the neurological impairment in AMN, commonly presenting with sensory-motor deficits, ataxia, and pain. Rate of disease progression is variable in both men and heterozygous females with AMN.
AIM
This study aimed to A) explore the structure of AMN disease trajectories using unsupervised clustering methods, in order to determine whether labels for progression could be generated i.e. progressor vs non-progressor, and B) train a neural network to predict those individual patient labels.
METHOD
Longitudinal quantitative sensorimotor, gait measurement and clinical neurological data were gathered from 61 male and 87 female AMN from a clinical trial at the Kennedy Krieger Institute in 2007-2012 [NCT00545597]. An unsupervised pipeline was designed: I) Multi-cluster feature selection (MCFS) algorithm was applied to mean delta 1- and 2-year data-sets. II) binary K-means clustering was performed. III) Logistic regression for each variable, and variable domain (sensory, motor, mixed) was performed. Cluster difference between means were tested. The unsupervised pipeline was used to generate a binary pseudo-ground truth of AMN progression, which was then used to train a supervised Bayesian neural network (BNN) to predict disease progression. Leave-out-out cross-validation was used. In every fold, the unsupervised cluster was re-run, and then used to optimize BNN network parameters using cross-entropy between the network's class prediction and the unsupervised cluster assignment.
RESULTS
Generated clusters showed significant differences in gait measurements: trajectory, velocity, stride Length, cadence as well as hip strength, knee and ankle spasticity. There was no significantly different distribution of men and women, or between motor or sensory domain for

binary clustering. Interestingly, there was no correlation between EDSS (dropped from clustering) and trajectory clusters for 1 and 2 years. Cluster 1 with higher (more severe) mean trajectories was labelled ‘fast progressor/progressor’, and cluster 2 ‘slow progressor/non-progressor’. The BNN demonstrated an area under the ROC curve (AUC) of 0.904 for 1 year disease trajectory, and an AUC of 0.716 for 2-year disease trajectory.

CONCLUSION

We demonstrate that unsupervised clustering of AMN disease trajectory can be used to generate labels for progression, and that using those labels, a supervised neural network is able to confidently predict 1- and 2-year AMN disease progression.

Title: Prenatal alcohol exposure alters power in translational neurophysiological signal during rodent touchscreen tasks

Authors: *S. OLGUIN[1], V. LICHERI[1], J. F. CAVANAGH[2], J. L. BRIGMAN[1,3];
[2]Dept. of Psychology, [1]Univ. of New Mexico, Albuquerque, NM; [3]New Mexico Alcohol Res. Ctr., Albuquerque, NM

Abstract: Although it is well established that alcohol consumption during pregnancy leads to long lasting difficulties in offspring, Fetal Alcohol Spectrum Disorders (FASD) remain the most common neurodevelopmental syndrome. Poor reporting of alcohol consumption throughout gestation and underdiagnoses of FASD requires novel diagnostic tools and improved behavioral measures between clinical and preclinical models to increase translation between species. The National Institutes of Mental Health (NIMH) has promoted the Research Domain Criteria (RDoC) initiative, which emphasizes the quantification of behavior more likely to reflect a specific neurophysiological circuit. Two RDoC domains that are negatively impacted in individuals with FASD are cognitive control utilizing 5-Choice Continuous Performance Task (5C-CPT) and reward learning via probabilistic learning task (PLT). Additionally, we tested physical effort using progressive ratio breakpoint (PRBP). These tasks can be integrated with

electroencephalography (EEG) recordings in humans and dura-resting EEG-like recordings in rodents. Here, we incorporated touchscreen analogs of these tasks with EEG-like recordings in a rodent prenatal alcohol exposure (PAE) model. Mice were obtained from the NMARC where PAE is established via a drinking-in-the-dark model (10% EtOH with 0.066% saccharine for 4hrs/day throughout gestation; BAC: ~90mg/dL; controls=0.066% sweetened water, "SAC"). Beginning at 8-10 weeks, mice trained to touch white square target stimuli of the 5C-CPT. Once responding rapidly and accurately mice underwent stereotactic surgery and fitted with dura-resting skull screws targeting medial prefrontal, parietal, and motor cortices, with a ground over the cerebellum. After recovery and reminder to criterion, non-target trials (5 stimuli presented; withholding of response rewarded) were added at a 2:1 ratio for 5 days, then recorded at a 5:1 ratio for 12 days. Animals were then recorded for 1 day on the PRBP, wherein animals had to touch a single stimuli for progressively more responses to receive reward. Lastly, animals were recorded for 5 days on PLT wherein the probability of reward differed for the target and non-target image. We found that PAE impaired the ability to withhold responding to non-targets during 5C-CPT and altered breakpoint on the PRBP. Importantly, when PAE animals displayed deficits in behavior, this tracked with alterations in power in relevant *a priori* regions of interest in the EEG-like signal. These results utilizing dura-resting recording suggests that alterations in cortical activity in readily available EEG systems can be used as a potential biomarker of PAE.

Title: Focal repetitive electrical stimulation as an therapeutic intervention in a model of intermittent access to alcohol consumption in wistar rats

Authors: *A. LOPEZ-CASTRO, D. ANGELES-VALDEZ, J. ROJAS-PILONI, E. GARZA-VILLARREAL;
Univ. Nacional Autonoma De Mexico, Queretaro, Mexico

Abstract: About 3 millions of people died worldwide in 2018 due to Alcohol Use Disorder (AUD) which is defined as: excessive alcohol use that affects physical and mental health. Neuromodulation interventions, such as Deep Brain Stimulation (DBS) and repeated transcranial magnetic stimulation (rTMS), are proposed as possible new complementary therapies to treat AUD. However, information about mechanism of action, optimal brain targets and types of stimulation protocols remain insufficient. This study aimed to explore the effect of high-frequency electrical stimulation on the prelimbic cortex in subjects who developed chronic

voluntary alcohol consumption. Method: The two-bottle choice intermittent access AUD preclinical model (IA2BC) at 20% concentration is used in young adult wistar rats (P45) for 20 sessions and we will divide them based on the subjects of the groups, in high consumers and low consumers by means of the hierarchical cluster analysis. Subsequently, a high frequency stimulation protocol (20 Hz) is replicated for 10 consecutive days at 100 pulses (duration = 0.2μs intensity = 400μA) in eight randomized subjects, who were separated into: 1) an active stimulation group and 2) a group of simulated stimulation (sham). Results: Our results indicate that two subjects who received active stimulation and one with sham stimulation reduced their alcohol. consumption. Discussion: The two subject who reduced consumption where heavy alcohol users, the result of active stimulation could correspond to that of Henricks., et al (2019) who found that high-frequency electrical stimulation only modified high consumptions. And for the rat with sham stimulation that decreased consumption, it could be due to local morphological changes in the implantation area.

Title: Frontocortical dependent behavioral deficits in rats exposed to binge levels of ethanol in adolescence are rescued following voluntary wheel running exercise

Authors: *M. J. FECIK, P. T. NUNES, L. M. SAVAGE, Ph.D.;
Psychology-Behavioral Neurosci., Binghamton Univ. Dept. of Psychology, Binghamton, NY

Abstract: Exposure to binge levels of ethanol in adolescence alters the typical trajectory of this development and contributes to a number of neural and behavioral deficits that persist into adulthood, including damage to the basal forebrain cholinergic system, which is involved in modulating attention, arousal, and learning. The nucleus basalis magnocellularis (NbM) sends cholinergic projections to the entirety of the cortical mantle, including the medial prefrontal cortex (mPFC) and orbitofrontal cortex (OFC). One of the interventions thought to reverse some of the impairments seen in rats exposed to adolescent intermittent ethanol (AIE) is voluntary wheel running exercise (VEx). The current study looked to see if exposure to binge levels of ethanol during adolescence led to selective frontocortical behavioral deficits and whether or not these deficits could be rescued by VEx. 31 Long Evans rats of both sexes were assigned to either

an AIE group which received intragastric gavages of 20% ethanol dosed at 5mg/kg on a two day on-two day off schedule from PD 25-55, or a control group that received gavages of water on the same schedule. Rats from both the AIE and control group were further divided into a VEx group that was given free access to a running wheel attached to their cage from PD 70-100, or a stationary control group that stayed in their regular home cages during this time. Following their respective treatments, rats were tested on spontaneous alternation behavior using a plus shaped maze as well as attention set shifting behavior and a delayed non-matching to position task in an operant conditioning chamber. Our results show that AIE rats were impaired on reversal learning, an OFC dependent measure of behavioral flexibility, and that rats exposed to VEx performed significantly better than stationary controls on this task. We did not detect an AIE or VEx difference on either spontaneous alternation or delayed non-matching to position. These results form the basis for an ongoing project that will investigate these deficits with a larger sample size, as well as ACh efflux into the OFC and mPFC as measured by in vivo microdialysis and acetylcholinesterase fiber density in these regions.

Title: Oxytocin Attenuates Stress-Induced Reinstatement of Alcohol-Seeking Behavior in Rats

Authors: *H. S. BALLAS, S. WILFUR, K.-C. LEONG;
Dept. of Psychology, Trinity Univ., San Antonio, TX

Abstract: The National Institute of Health estimates that nearly 15 million people in the United States alone suffer from Alcohol Use Disorder (AUD). Stress responsivity often plays a major role in such alcohol-dependent behavior, and can trigger a relapse in addiction and usage. Therefore, it is important to investigate potential pharmacological interventions that may alleviate stress response during the addiction cycle. Previous studies have demonstrated that the neuropeptide oxytocin produces anxiolytic effects in mammals. The purpose of the present study was to investigate the effect of oxytocin on stress-induced alcohol relapse, and identify a neural structure mediating this effect, through the use of an ethanol self-administration and yohimbine-induced reinstatement paradigm. In Experiment 1 adult male Sprague-Dawley rats were first trained to self-administer ethanol through an FR1, and then FR3 schedule of reinforcement. An extinction period was then enacted in which a lever press no longer resulted in ethanol delivery. Stress-induced reinstatement of ethanol-seeking behavior was then induced by the anxiogenic drug yohimbine. Rats received either concurrent systemic administration of oxytocin (1 mg/kg;

i.p.) and yohimbine (2 mg/kg; i.p.) or yohimbine alone. While yohimbine administration resulted in reinstatement of ethanol-seeking behavior, concurrent administration of yohimbine and oxytocin attenuated this effect, suggesting that oxytocin may disrupt stress-induced ethanol-seeking behavior. The central amygdala (CeA) is a structure driving emotional responses and robustly expresses oxytocin receptors. In Experiment 2, animals received concurrent intra-CeA infusion of oxytocin (0.5µg/0.5 µL; intra-CeA) and systemic injection of yohimbine (2 mg/kg; i.p.) in an identical behavioral paradigm as Experiment 1. Intra-CeA oxytocin similarly attenuated yohimbine-induced reinstatement of ethanol-seeking behavior. These results demonstrate that oxytocin has the potential to attenuate stress-induced relapse into ethanol-seeking behavior, and that this mechanism is occurring specifically within the central amygdala.

Title: Profiles of impulsivity and compulsive drinking and their associations with negative emotionality, alcohol consumption, and alcohol-related problems.

Authors: *T. GUNAWAN[1], U. ZIAUSYTE[2], J. W. LUK[2], J. K. MORRIS[1], M. L. SCHWANDT[2], V. A. RAMCHANDANI[1], N. DIAZGRANADOS[2], D. GOLDMAN[3]; [1]Lab. on Human Psychopharmacology, [2]Office of the Clin. Director, NIH/NIAAA, Bethesda, MD; [3]Lab. on Neurogenetics, NIH/NIAAA, Rockville, MD

Abstract: RATIONALE: Alcohol use disorder (AUD) is conceptualized as a transition from reward-driven, impulsive drinking to habit-driven, compulsive drinking. This leads to the possibility that distinct phenotypic clusters, or profiles, can be identified based on levels of trait impulsivity and compulsive drinking. The present study uses latent profile analysis (LPA) to identify such distinct phenotypic profiles and examine their relationships with negative emotionality, alcohol consumption, and alcohol-related problems. **METHODS:** Participants (*N* = 440; 40.5% female, 45.7% White) enrolled in the NIAAA natural history protocol approved by the IRB were diagnosed via SCID interview. 53.9% of the sample had a current AUD diagnosis and 40.0% were seeking treatment. Subscales of trait impulsivity (UPPS-P Impulsivity Scale), impaired control over drinking (Impaired Control Scale), and compulsive drinking (Obsessive-Compulsive Drinking Scale) were used as indicators in the LPA to identify distinct classes,

which were then used to examine associations with negative emotionality (anxiety, stress, depression), alcohol consumption (Timeline Followback), and alcohol-related problems (Alcohol Use Disorders Identification Test; AUDIT). Sex, age, race, income, education, treatment status, family history, and age of first drink were included as covariates. **RESULTS:** A four-profile solution provided the best fit to the data. Drinkers in profile 1 (n = 171; 39.0%) exhibited lowest impulsivity and compulsive drinking scores, profile 2 (n = 69; 15.6%) had moderate impulsivity but lower compulsive drinking scores, profile 3 (122; 27.8%) showed moderate impulsivity and compulsive drinking scores, and profile 4 (n = 78; 17.6%) displayed highest impulsivity and compulsive drinking scores. Negative emotionality scores were lowest among profile 1 and highest among profile 4. Profiles 2 and 3 exhibited similar levels of negative emotionality. Drinking days, heavy drinking days, and average drinks per day significantly increased across profiles, with profile 1 exhibiting the lowest alcohol consumption, and profile 4 exhibiting the highest. AUDIT scores followed the same pattern of effects. **CONCLUSIONS:** Our findings indicate 4 distinct profiles of drinkers based on their levels of trait impulsivity and compulsive drinking. These results are consistent with the conceptualization of AUD as a transition from reward-driven drinking to habit-driven drinking. These profiles may capture individuals at distinct stages of this transition. Future research is needed to examine the trajectory of these individuals across these profiles.

Title: The relationship of adolescent alcohol exposure with extinction learning and prefrontal parvalbumbin expressing neurons

Authors: *A. LENSING, R. BOERGER, S. GILBERT, H. LIN, C. PICKENS;
Kansas State Univ., Manhattan, KS

Abstract: There is an established link between adolescent alcohol consumption and various long-term behavioral changes. Our lab has previously found an association between adolescent alcohol consumption and operant extinction performance in adulthood, as rats that consumed more alcohol during adolescence showed faster extinction rates during reinforcer devaluation tests (Fisher et al., 2017). Since these studies were not specifically designed to test operant extinction learning, we conducted experiments to replicate this effect and determine a potential

underlying neural mechanism. Adolescent male and female rats received chronic intermittent access to alcohol (n = 23) or water-only (n = 19) access for 6 weeks (from postnatal day 26-66). Ten days after completion of the CIA paradigm, rats began behavioral training. The rats received 2 once-daily sessions of cued instrumental training, in which a lever-light compound was presented during 40-sec trial and lever-presses could earn 2 food pellets/trial on an intermittent reinforcement schedule. Then, rats underwent extinction training in which no food was earned. At the end of the study, parvalbumin-positive (PV+) neurons were assessed in medial prefrontal cortex subregions in both sexes. We found that rats with prior alcohol access exhibited faster instrumental extinction than rats only given water. There were no differences in PV+ expression between the groups given alcohol or water-only in the anterior cingulate cortex (ACC), prelimbic cortex (PL), or infralimbic cortex (IL). However, there was a significant interaction of sex and the level of alcohol consumption in the PL and ACC PV+ levels in rats with prior alcohol access. Within the alcohol exposed group, males had a positive correlation between PL PV+ neurons and the level of alcohol consumption while females had a weak negative correlation. In contrast, there was a negative correlation between ACC PV+ neurons and alcohol consumption levels in females while males had a weak positive correlation. These findings suggest that PV+ neurons are not the underlying neural mechanism between prior adolescent alcohol consumption and changes in the rate of operant extinction learning. However, these findings also suggest that there is an association between PV+ neurons and adolescent alcohol consumption (possibly due to pre-existing differences in PV+ neuron levels), with sex differences. Future research is needed to determine the nature of this relationship.

Title: Sex difference and recognition impairments during social memory task in young adults following adolescent intermittent ethanol exposure

Authors: *J. P. MATO, P. T. NUNES, A. BLACKWELL, N. L. REITZ, B. KIPP, A. J. STANWISE, B. M. HITCHCOCK, J. N. MELITA, L. SAVAGE;
Psychology, State Univ. of New York, Binghamton, Binghamton, NY

Abstract: Adolescent binge drinking is known to be associated with cognitive impairments and with changes in brain structure and connectivity. Previous studies using a model of adolescent intermittent ethanol exposure (AIE) have shown a normal spatial working memory and stable activity-dependent dorsal hippocampal acetylcholine (ACh) efflux in early adulthood following AIE. However, other studies have shown that affective behaviors are altered by AIE in early adulthood. Given that ventral hippocampus (vHPC) regulates emotional and motivated behaviors, including social memory, we investigate whether male and female rats exposed to binge-like levels of ethanol (postnatal days (PD) 25 to 55) show disruption in social memory two months after AIE (PD120). Analysis of social interaction revealed a significant effect of sex: Male rats spent more time interacting with juveniles than female rats during both the acquisition phase and the recognition phase. A significant effect of recognition (more time spent with novel juvenile over familiar juvenile) was found and planned contrasts revealed that control male and control female rats (water-gavage treatment) spent more time interacting with a novel juvenile rat than with a familiar juvenile, recognizing the familiar rat. In contrast, AIE male and AIE female rats spent similar amounts of time interacting with novel or familiar juvenile rats, demonstrating impairment in social memory. To further understand the behavioral effects of AIE and whether the cholinergic response in the vHPC is associated with the disruption of social memory, social recognition task was adapted to microdialysis procedures. Acetylcholine samples were extracted via microdialysis during social recognition tasks and vHPC ACh will be analyzed via High Performance Liquid Chromatography. Also, protein levels of nicotinic and muscarine receptors, and vesicular acetylcholine transporter (VChAT) will be analyzed in brain regions involved with social memory, such as vHPC and amygdala.

Title: Male, but not female, Val68Met BDNF mice exhibit social anxiety, prefer alcohol over social interaction, and are resistant to the anxiolytic effects of alcohol

Authors: *J. J. MOFFAT[1], S. A. SAKHAI[2], D. RON[3];
[2]Neurol., [1]Univ. of California, San Francisco, San Francisco, CA; [3]Dept. of Neurol., UCSF, San Francisco, CA

Abstract: The BDNF Val66Met polymorphism, which results in impaired activity-dependent BDNF release, is prevalent in humans and associated with multiple psychiatric disorders. We previously developed an animal model of this polymorphism and showed that mice carrying the mutation (Met68BDNF mice) exhibit excessive and compulsive alcohol drinking behaviors, compared to Val68BDNF mice (1). In this study we examined behavioral deficits in Met68BDNF mice that may be linked to excessive alcohol use. We first hypothesized that Met68BDNF mice may exhibit anxiety-like behavior and consume excessive alcohol as a means of self-medication. We found that male Met68BDNF mice display distinct social anxiety-like behavior in a three-chamber social novelty paradigm, while female Met68BDNF mice and wild type Val68BDNF mice of both sexes do not. We further showed that male Met68BDNF exhibit a greater preference for alcohol compared with social interaction in a real-time place preference test. We then examined the hypothesis that Met68BDNF mice consume more alcohol than Val68BDNF mice because of an impaired response to the anxiolytic actions of alcohol. To do so, mice were systemically administered with alcohol (1.25 g/kg) or saline and anxiety-like behavior was tested using an elevated plus maze. We found that male Met68BDNF mice are less sensitive to the anxiolytic effects of alcohol compared with Val68BDNF mice. The ventral hippocampus (vHC) is a brain region linked to social anxiety-like behavior and alcohol dependence in rodents. We hypothesized that overexpressing Val68BDNF in the vHC of male Met68BDNF mice may be sufficient to improve social anxiety-like behavior and increase sensitivity to the anxiolytic effects of alcohol. Indeed, we found that overexpression of wild type Val68BDNF in the vHC of male Met68BDNF mice ameliorates social anxiety-like behavior rescues a social aversion phenotype in a social-alcohol conditioned place preference/aversion test. Overexpressing Val68BDNF in the vHC also restored the anxiolytic effect of alcohol in male Met68BDNF mice. Taken together, these data suggest that the BDNF Val68Met polymorphism causes social anxiety-like behavior in male mice and engenders a resistance to the anxiolytic effects of alcohol. These phenotypes, in turn, are likely to influence the excessive and compulsive alcohol consumption observed in these animals. 1. Warnault et al. Biological Psychiatry. 2016.

Title: Neuromolecular and behavioral effects of ethanol deprivation in Drosophila

Authors: *K. MCCULLAR[1], N. D'SILVA[2], A. CONARD[3], T. BLACKWATER[1], R. AZANCHI[1], U. HEBERLEIN[5], E. LARSCHAN[4], K. KAUN[4];

Abstract: Alcohol use disorder (AUD) is a complex and relapsing disorder that is characterized, in part, by periods of abstinence followed by a loss of control in limiting alcohol intake. The behaviors associated with cessation of alcohol after repeated exposures, and the underlying molecular changes have yet to be fully elucidated. Using a *Drosophila melanogaster* model, we sought to explore the effects of alcohol use and subsequent deprivation on spontaneous behavior, and the underlying neuromolecular mechanisms. We present a novel repeated intermittent ethanol exposure paradigm in *Drosophila*, and quantified behavior using the machine vision software ctrax and behavior annotator JAABA. We found that multiple days of ethanol exposure followed by ethanol deprivation resulted generally in an increase in social behaviors and a decrease in locomotor behaviors. The resulting behavioral shifts were then compared to those listed in the Browsable Atlas of Behavior-Anatomy Maps to identify brain regions associated with identified behaviors. We performed RNASeq of whole head samples to identify gene expression changes correlated with the behavioral effects. This three-pronged approach allowed us to establish a framework to measure and compare behavioral, circuit, and gene expression changes. We found that the observed locomotor and social behavioral shifts were associated with a wide range of brain regions. These marked changes in behavior were also correlated largely with changes in expression of genes associated with sensory responses and neural plasticity. Interestingly, changes in social behavior persisted longer than changes in locomotor behavior and mapped to the greater mushroom body (MB) region, and areas of the brain associated with sensory responses including the anterior ventrolateral protocerebrum (AVLP), lateral horn (LH), antennal lobe (AL), prow, lobula, superior intermediate protocerebrum (SIP), flange and subesophageal zone (SEZ). These persistent behavioral responses were correlated with changes in gene expression associated with Immune Deficiency (Imd) and Toll signaling pathways, suggesting that alcohol deprivation induces changes in innate immune responses, consequently altering behavioral responses. By locally manipulating gene expression in brain regions of interest, the molecular mechanisms underlying the observable behavioral shifts associated with ethanol deprivation can be causally understood.

Title: The effect of acute stressors on heroin seeking after punishment-imposed abstinence in male rats.

Authors: *J. CHARLES[1], C. BORGES[1], U. SHALEV[2];
[2]Dept. of Psychology, [1]Concordia Univ., Montreal, QC, Canada

Abstract: Stress is a major trigger of relapse in addicts following a period of abstinence. Recently, we found that acute food-deprivation stress increases heroin seeking in rats using a punishment-imposed abstinence model. Currently, it is not known whether the effect of food deprivation on heroin seeking generalizes to other stressors following punishment-imposed abstinence. Furthermore, correlations between drug use and individual differences in traits such as exploratory drive, anxiety, reward-seeking, and pain-sensitivity have been found. In the current study, adult male Long Evans rats underwent the following pre-screening procedures: sucrose preference test (SP; a measure of reward seeking), elevated-plus maze (EPM; a measure of anxiety-like behaviour), open field test (OF; a measure of exploratory behaviour), and tail-flick test (TF; a measure of pain sensitivity). Following pre-screenings, rats were trained to self-administer heroin under a seek-take chain for 14 days. Completed seeking links were subsequently punished on 30% of trials. Next, rats were exposed to a stressor, electrical footshock, and a heroin-seeking test. A second heroin-seeking test was subsequently run after 24 hr food-deprivation stress. Exposure to footshock stress resulted in a statistically significant increase in heroin seeking. Interestingly, food-deprivation stress did not. High- and low-responders identified through median split were statistically significantly different in both the footshock- and food-deprivation-induced relapse tests. We found statistically significant differences between high- and low-responders in the stress-induced relapse tests in the following parameters: time spent freezing in the EPM (footshock), distance travelled in the OF (footshock), time in center in the OF (footshock), and fecal boli in the OF (footshock and food-deprivation). Only fecal boli in the OF significantly predicted responding during the heroin-seeking test following both footshock and food-deprivation.

Title: Glucagon-like peptide-1 receptor agonist reduces cue- and drug-induced fentanyl seeking in rats

Authors: *L. A. URBANIK[1,2], N. ACHARYA[1], P. S. GRIGSON[1];
[1]Dept Neural and Behavioral Sci., [2]Pennsylvania State Univ. Col. of Med., Hershey, PA

Abstract: Opioid Use Disorder (OUD) is a crisis in the United States today. It is a chronic relapsing disorder that has negative impacts on the individual, the family, and the community at large. In 2019, the United States recorded over 70,630 drug overdose deaths. Opioid overdose deaths accounted for nearly 70% of these deaths. According to the National Institute on Drugs of Abuse, opioid related deaths rose from 21,088 in 2010 to 49,860 in 2019. Further, the rise in opioid related deaths coincides with a significant rise in the use of the 150 times more potent synthetic opioid, fentanyl, where in 2019, there were 36,359 fentanyl overdose deaths. Since 2020, the United States has been facing yet another surge in opioid related deaths during the COVID-19 pandemic. Monthly drug overdose deaths have increased in nearly every state and, from February to May, saw an increase of over 9,000 deaths, an increase of nearly 50%. Furthermore, this overdose trend has spared no demographic and costs the nation an estimated $51.2 billion annually. Thus, it is imperative to better understand the underlying mechanisms of OUD, in order to identify potential targets for treatment. Using animal models, studies have shown that rats readily self-administer heroin and, following an extinction period, reinstate drug-seeking behavior when presented with cues for drug, the drug itself, or stress. We have shown that treatment with the glucagon-like peptide-1 receptor (GLP-1R) agonist, liraglutide, can reduce heroin seeking behavior in rats. Therefore, using our rodent model, we established a fentanyl self-administration paradigm, to test whether treatment with the GLP-1 receptor agonist also can reduce fentanyl seeking in fentanyl experienced rats. The results of the study show that rats readily self-administer fentanyl (0.5 ug/kg) intravenously with evidence of individual differences whereby some rats (High Takers) self-administer more fentanyl than others (Low Takers). As with other drugs of abuse, following a period of extinction, rats readily reinstate fentanyl seeking when challenged with cue, fentanyl and stress. Here, treatment with the GLP-1 receptor agonist, liraglutide (0.3 mg/kg sc), was found to attenuate both cue-induced fentanyl seeking and drug-induced reinstatement of fentanyl seeking at the same efficacy as the currently approved opioid agonist, buprenorphine. Taken together, these data suggest that a known satiety signal, GLP-1, may serve as an effective non-opioid alternative for the treatment of OUD without the risk of opioid dependence or precipitated withdrawal.

Title: Sex-dependent effect of chronic intermittent ethanol vapor exposure on oxycodone self-administration in C57BL/6J mice

Authors: *Y. CHEN, A. BOISVERT, A. KIMBROUGH;
Basic Med. Sci., Purdue Univ., West Lafayette, IN

Abstract: While substance use disorder (SUD) is well studied, most preclinical research focuses on investigating the use of a single drug in isolation, whereas polysubstance use disorder is widespread in the real world. One potential mechanism for co-abuse of multiple drugs is self-medication with one drug to alleviate the withdrawal symptoms of another. We sought to design a preclinical model of self-medication of oxycodone during withdrawal from alcohol. We hypothesized that withdrawal from alcohol dependence would modulate oxycodone intake. Male (n=42) and female (n=42) C57BL/6J mice were used in this study. Mice were split into two groups, alcohol dependent oxycodone self-administration (CIE+O; n=16/sex) and oxycodone self-administration (O only; n=16/sex). The CIE+O group was made alcohol-dependent through chronic intermittent ethanol vapor (CIE) exposure. During the CIE weeks, mice were exposed to 16 hours of alcohol vapor per day, 5 days a week. Following the CIE weeks, the mice received a one week break. After three weeks of CIE exposure (week 6), the mice underwent intravenous catheterization (IV) surgery to insert catheters into their right jugular vein. The mice then received a fourth week of CIE exposure and then the following week were tested for IV self-administration of oxycodone (0.25 mg/kg/infusion) for 4 hours per day for 5 days. During this week, the O only group also self-administered oxycodone daily. Both O only and CIE+O mice then paused oxycodone self-administration while the CIE+O group received the fifth week of CIE. Following this week of CIE, both O only and CIE+O mice resumed oxycodone self-administration for 4 days. Brains were collected 24 hours after the last self-administration session for further examination.A significant increase in self-administration of oxycodone was found in the last three sessions in the male CIE+O mice compared to O only mice. However, female CIE+O mice did not show the same increase in oxycodone self-administration compared to O only mice. These data suggest that we can model the use of oxycodone to self-medicate alcohol withdrawal in mice. Additionally, males appear to be more sensitive to modulation of oxycodone intake by alcohol withdrawal; however, this may be due to a ceiling effect in the

female mice. Further testing will be necessary to determine the specific mechanisms behind the sex differences. We are currently examining neural activity patterns across the brain in each group to explore potential treatment or sex effects.

Title: Infralimbic pyramidal neuron activity after an unreinforced lever press is necessary for encoding extinction of heroin seeking in rats

Authors: *M. S. MCGREGOR[1], K. E. NETT[1], A. R. ZIMBELMAN[2], R. T. LALUMIERE[1,2,3]; [1]Interdisciplinary Grad. Program in Neurosci., [2]Dept. of Psychological and Brain Sci., [3]Iowa Neurosci. Inst., Univ. of Iowa, Iowa City, IA

Abstract: The medial prefrontal cortex (mPFC) has been implicated in the regulation of heroin-seeking behavior. Our laboratory has previously published data indicating that activity in the infralimbic (IL) portion of the mPFC following an unreinforced lever press is critical for encoding the extinction of cocaine seeking. For heroin seeking, however, evidence on the role of the IL has been mixed. Some work suggests that the IL suppresses cued reinstatement to heroin seeking. Yet other evidence suggests that the IL promotes reinstatement of heroin seeking in some situations. Thus, it is unclear whether the extinction process itself recruits the same mechanisms for cocaine and heroin seeking. To determine whether IL activity is similarly necessary for extinction of heroin seeking, we employed an activity-controlled optogenetic approach to inhibit IL pyramidal neurons for 20 s immediately after unreinforced lever presses during extinction training. Male and female Sprague-Dawley rats received bilateral injections of AAV-CaMKII-eNpHR3.0 into the IL and bilateral optical fibers above the IL. Rats then underwent 12 d of 6 h operant heroin self-administration training, where active lever presses produced a .075 mg/kg heroin infusion, light/tone cues, and lever retraction. These experiments utilized an availability window design, where the active lever was only available for 90 s windows throughout a session. Then, rats proceeded with 5 d of 2 h extinction sessions, where active lever presses only produced lever retraction and 20 s of laser illumination to the IL to inhibit pyramidal neurons during the period immediately following an unreinforced lever press. This was followed by 7 d of unmanipulated extinction sessions, where lever presses resulted only

in lever retraction, which served as an index of retention of extinction learning. Preliminary results indicate that inhibiting IL activity for 20 s after an unreinforced lever press increases lever pressing in male rats during the initial 5 d of extinction training, suggesting impaired encoding of the extinction learning. Moreover, rats that received inhibition also had impaired retention of extinction learning, as indicated by higher levels of lever pressing during the 7 d of unmanipulated extinction sessions. Ongoing work is examining whether this is also the case in female rats. Nonetheless, this finding indicates that IL activity in the 20 s following an unreinforced lever press is critical for encoding the lever press-no reward contingency that facilitates extinction of heroin seeking, suggesting that IL activity is similarly important for encoding extinction of both cocaine and heroin seeking.

Title: Effects of repeated fentanyl treatment on the locomotor activity of adolescent and adult rats

Authors: D. Y. LOPEZ SANCHEZ, J. W. RIOS, H. A. DIAZ, J. A. TAYLOR, D. J. GONZALEZ, *C. A. CRAWFORD;
California State Univ., San Bernardino, CA

Abstract: Opioid misuse has reached epidemic proportions in the United States, primarily as a result of the increased availability of synthetic prescription opioids like fentanyl. Despite the growing problem of fentanyl abuse, few preclinical investigations have assessed the addictive properties of this compound. The goal of the current study was to assess the abuse liability of fentanyl using a multi-trial behavioral sensitization paradigm. In this experiment, adolescent and adult male and female Sprague-Dawley rats (*n*=9-10) were given daily injections of saline or fentanyl (100 or 200 µg/kg, sc) for seven consecutive days. Immediately after injections, rats were placed in locomotor activity chambers for 60 min. After a 2 or 10 day abstinence period, all rats were injected with fentanyl (100 µg/kg, sc) and locomotor activity was measured for 120 min. On the first pretreatment day, fentanyl (100 and 200 µg/kg) reduced the locomotor activity of adolescent and adult male and female rats. However, by pretreatment day seven, the suppressive effects of fentanyl were no longer apparent and all rats treated with 100 µg/kg

fentanyl exhibited more locomotor activity than rats treated with saline. On both test days, fentanyl (100 and 200 µg/kg) pretreatment resulted in more locomotor activity than saline pretreatment, but some sex- and age-dependent differences were apparent. After two abstinence days, adolescent female rats were more active than adolescent male rats. Adult rats did not exhibit any sex differences, but adults pretreated with 200 µg/kg fentanyl were more active than adults pretreated with 100 µg/kg fentanyl. After ten abstinence days, pretreatment with 200 µg/kg fentanyl caused more locomotor activity in male and female adolescent rats than 100 µg/kg fentanyl. Interestingly, adolescent rats showed an increased sensitivity to fentanyl after ten abstinence days, while adult rats had similar levels of locomotor activity on both test days. In summary, our results suggest that both adolescent and adult rats showed a progressively enhanced locomotor response after repeated fentanyl exposure. Moreover, adolescent rats were more sensitive to fentanyl after a 10 day, as compared to a two day, abstinence period.

Title: Interactions between fentanyl and 2,5-dimethoxy-4-methylamphetamine (DOM), a direct-acting 5-HT_{2A} receptor agonist, in rhesus monkeys responding under a food versus drug choice procedure

Authors: *D. R. MAGUIRE, C. P. FRANCE;
Univ. of Texas Hlth. Sci. Ctr. San Antonio, San Antonio, TX

Abstract: Direct-acting 5-HT_{2A} receptor agonists such as DOM enhance antinociceptive effects of opioids suggesting a 5-HT_{2A} receptor agonist could be combined with an opioid to improve treatment of pain. However, it is unclear whether 5-HT_{2A} receptor agonists also enhance adverse effects of opioids, including reinforcing effects that contribute to abuse. This study examined whether DOM alters the reinforcing effects of fentanyl in rhesus monkeys (n=6) responding under a food versus drug choice procedure. Responding on one lever delivered sucrose pellets and responding on the other lever delivered intravenous infusions. Sessions comprised 4 blocks, each with 2 forced trials, during which only one option was available, followed by 6 choice trials, during which both options were available. The unit dose of fentanyl (0.0001-0.0032

mg/kg/infusion) increased across blocks each session. In the first experiment, sessions were preceded by intravenous administration of DOM (0032-0.32 mg/kg), naltrexone (0.032 mg/kg), or heroin (0.1 mg/kg). Then, fentanyl was available for self-administration in combination with DOM in unit dose ratios (fentanyl to DOM) of 1:3 or 1:10. Fentanyl increased choice of infusions from less than 10% of trials with the two smallest unit doses to over 80% of trials with the two larger unit doses. Naltrexone decreased choice of fentanyl, shifting the dose-effect curve rightward, and heroin increased choice of the two smallest unit doses of fentanyl. When administered before the session, DOM reduced choice of fentanyl as well as the number of trials completed. However, DOM did not alter choice or the number of trials completed when available in combination with fentanyl. Attenuation of fentanyl choice by naltrexone and enhancement of fentanyl choice by heroin demonstrate sensitivity of responding to modulation by other drugs. DOM did not appear to enhance the reinforcing effects of fentanyl whether given as a pretreatment or made available in combination with fentanyl. Although pretreatment with DOM decreased choice of fentanyl, it did so at doses that reduced trials completed, suggesting effects of DOM might have been due, at least in part, to generalized rate-decreasing effects. Taken together with previous studies, these results suggest that DOM enhances some (antinociceptive) but not other (reinforcing) effects of opioids and that combining a direct-acting 5-HT_{2A} receptor agonist with an opioid to treat pain would not increase potential for abuse.

Title: Ventral Tegmental Area Glutamate Neurons Contribute to Cue-Induced Oxycodone Seeking Behavior

Authors: *D. MCGOVERN[1], D. H. ROOT[1], A. M. POLTER[2], E. PREVOST[1], A. LY[1], D. MULCAHY[1];
[1]Univ. of Colorado Boulder, Boulder, CO; [2]Dept. of Pharmacol. and Physiol., George Washington Univ., Washington, DC

Abstract: Ventral tegmental area (VTA) GABA neurons regulate dopamine neuron activity via a local projection modulated by the mu-opioid receptor. A subset of neurons within the VTA, defined by the presence of the vesicular glutamate transporter (VGluT2), also regulate dopamine

neuron activity via a local projection but their role in drug-seeking behavior is unknown. We first identified that select subsets of VTA VGluT2+ neurons express the mu opioid receptor. Further, optogenetic activation of local projections from VTA VGluT2 neurons results in mu-opioid receptor sensitive currents. These data led us to hypothesize that VTA VGluT2 neurons participate in opioid-seeking behavior. To test this hypothesis, we leveraged an oral oxycodone self-administration paradigm to determine the functional role of VGluT2+ VTA neurons in both oxycodone self-administration and cue-induced drug-seeking during reinstatement. Male and female VGluT2::Cre mice were surgically injected with a FLEX-GFP (control) or FLEX-hM4Di AAV in the medial ventral tegmental area prior to oxycodone self-administration. After four weeks mice learned to operantly self-administer escalating doses of oxycodone solution by nose-poking an illuminated port that also resulted in a tone-light off cue. Nose pokes into the inactive port were recorded but had no programmed consequence. At the highest dose (1 mg/mL) mice were given an IP injection of behaviorally-subthreshold clozapine to activate the hM4Di DREADD and silence VTA glutamate neuron activity in the experimental group. Mice self-administered for three additional days at this dose following hM4Di activation before transitioning to extinction. During the extinction phase mice were placed in the same operant box for one hour with illuminated nose ports, however no behavioral action produced either the drug paired cue or the availability of oxycodone. Following two consecutive sessions of active pokes below extinction criterion, mice were tested for cued reinstatement in the presence of hM4Di activation or control conditions (GFP). Chemogenetic inactivation of VTA VGluT2+ neurons did not significantly modify drug consumption at the highest oxycodone dose, however silencing these neurons during cued reinstatement significantly reduced cue-induced oxycodone seeking compared to GFP control mice. This work establishes a functional role for VTA glutamate neurons in prescription opioid cued reinstatement behavior.

Title: Attenuation of cue-induced heroin-seeking by the atypical antidepressant mirtazapine

Authors: *A. L. PERSONS, T. C. NAPIER;
Rush Univ., Chicago, IL

Abstract: Opioid use disorders (OUD) and associated mortality have emerged in recent years as a significant public health problem in many countries. Opioids activate *mu*-opioid receptors, and currently available pharmacotherapies for OUD all target this receptor as a full agonist (methadone), a partial agonist (buprenorphine), or an antagonist (naltrexone). These medications promote recovery, but relapse to drug-taking remains high. The addiction profile of opioids reflects imbalances in downstream transmitters, including dopamine and serotonin (5-HT). The 5-HT_{2A} and 5-HT_{2C} receptors (R) bidirectionally regulate dopamine release. The atypical antidepressant mirtazapine has multiple sites of action, including agonism at 5-HT_{2A}R and inverse agonism at the 5-HT_{2C}R. This favorable 5-$HT_{2A/2C}$R profile suggests it may be efficacious for OUD therapy. We previously demonstrated that mirtazapine reduces stimulant-induced behaviors in rats (Herrold *et al*, 2009; Voigt *et al*, 2011; Voigt & Napier, 2011), including drug-seeking behavior in rats that self-administered methamphetamine (Graves & Napier, 2011) and opioid-induced place preference (Graves *et al*, 2012). Here, we hypothesized that mirtazapine will attenuate cue-induced heroin-seeking behavior. Young adult male Sprague-Dawley rats were trained to nose-poke for heroin (0.075mg/kg per 1mL infusion) on a fixed ratio-1 schedule of reinforcement for 10 days (6h/day). One day after heroin self-administration (SA), a baseline cue reactivity test (CR, 20min) was conducted. Thereafter, rats were subjected to an intermittent SA /CR cycle in which rats self-administered heroin for two days, followed by a CR test the following day; this cycle was repeated until each rat was tested for CR in the presence of vehicle (1mL/kg, ip), mirtazapine (1mg/kg, ip) or mirtazapine (5mg/kg, ip) injected 30min prior to the test. A one-way repeated measures ANOVA with *post hoc* Newman-Keuls was used to analyze the number of active nose-pokes during the CR session. Mirtazapine at 1mg/kg had no effect on heroin-seeking. In contrast, 5mg/kg mirtazapine significantly decreased heroin-seeking ($p<0.05$). These positive outcomes suggest that mirtazapine has the potential to be repurposed for relapse reduction during abstinence therapy of OUD.

Title: Neuronal activity during acute food deprivation-induced heroin seeking test, after punishment-imposed abstinence, in male rats.

Authors: *C. BORGES, E. AH YEN, J. CHARLES, B. GIULIANO, U. SHALEV;
Dept. of Psychology, Concordia Univ., Montreal, QC, Canada

Abstract: Punishment-imposed abstinence in animal procedures models self-imposed abstinence due to negative consequences of drug-use in addicts. Understanding the mechanisms that underlie self-imposed abstinence due to negative consequences is crucial to better understand human abstinence. Stress is one of the key triggers in human relapse. Environmental stressors such as food deprivation are recurrent in addicts who chose to allocate their money towards drugs over food. Caloric restriction is suggested to be positively correlated with increase cravings and subsequent relapse in humans abstaining from cigarettes and alcohol. Thus, the goal of this study is to identify the brain areas that are involved in food deprivation-induced relapse to heroin seeking after punishment-imposed abstinence. Rats (N=30) underwent heroin self-administration training (SA, 0.1 mg/kg/infusion) for 2 weeks using the seek-take chain (completing a VI60 schedule of reinforcement on the seek lever allowed access the drug-paired lever - take lever, under FR1). Next, rats were exposed to 4 days of punishment-imposed abstinence, in which 30% of the completed seek links resulted in a mild footshock instead of access to the take lever. The footshock (0.5 s) gradually increased at 0.1 mA/day from 0.2 to 0.4 mA and remained fixed at 0.4 mA for one more day. For heroin-seeking tests, rats were assigned to 24 h food deprivation (FD) or Sated groups and tested under extinction conditions (1 h). The following groups were used: 1. Rats only exposed to SA (Baseline, N=6), 2. Rats exposed to SA and punishment (N=4), 3. Rats exposed to SA, punishment and FD/sated conditions without test (FD: N=3, Sated: N=3) and 4. Rats exposed to SA, punishment, FD/Sated conditions and heroin-seeking test (FD: N=7, Sated: N=7). All brains were collected after the test session or at the same time of the day. Fos expression is currently assessed through immunohistochemistry, while focusing on brain areas related to stress (central nucleus of the amygdala (CeA), basolateral amygdala (BLA), bed nucleus of the stria terminalis (BNST)), reward (prefrontal cortex (PFC), ventral tegmental area (VTA), nucleus accumbens (NAc)), feeding and conflict (paraventricular nucleus of the thalamus (PVT), ventral hippocampus (vHPC)).

Title: Withdrawal from oxycodone self-administration increases cocaine intake

Authors: *S. KHATRI[1], H. ULANGKAYA[3], W. STOOPS[2], C. GIPSON-REICHARDT[1]; [1]Family and Community Med., [2]3.Department of Behavioral Science, Psychiatry and

Psychology, Ctr. on Drug and Alcohol Res., Univ. of Kentucky, Lexington, KY; [3]Barrett Honors Col., Arizona State Univ., Tempe, AZ

Abstract: Opioid use disorder (OUD) is a leading public health crisis in the United States. Individuals with OUD frequently use other substances concurrently, including cocaine. Opioid withdrawal has been linked to increased cocaine use motivation, although the neurobiology underlying this pattern of co-use is as of yet unknown. Thus, the aim of this study is to develop a preclinical opioid and cocaine co-use model in rats to further evaluate underlying mechanisms. Male and female Long Evans rats underwent sequential self-administration (SA) of the μ opioid agonist, oxycodone (0.03 mg/kg/infusion; FR-1), followed by cocaine SA (0.25 mg/kg/infusion; FR-1) sessions beginning in acute oxycodone withdrawal (16 hrs after the final oxycodone session) in an A-B-A-B design. Rats underwent a minimum of 10 oxycodone SA ("A") sessions prior to the first cocaine SA ("B") phase, followed by oxycodone SA ("A") and a day of cocaine SA ("B", test day). Somatic signs of opioid withdrawal were measured prior to initiating the first cocaine session and during each switch from oxycodone to cocaine SA. Control rats self-administered food followed by cocaine. Rats readily discriminated between the active (food/oxycodone) and inactive levers. Further, the average number of cocaine infusions and consumption on test day was higher in the oxycodone compared to food SA group, and there was an increasing trend in the total number of oxycodone infusions with switch back to oxycodone after cocaine SA. No sex specific differences were observed in cocaine intake. Somatic signs (e.g., foot licks, grooming, among others) were increased at 16 to 20hrs of oxycodone withdrawal that were attenuated by subsequent cocaine SA. These results suggest that oxycodone withdrawal increases cocaine SA. In all, this study establishes the first model of this pattern of polysubstance use which can be further used to study underlying neurobiology.

Title: The effect of first-time heroin exposure on c-Fos signaling in rodentsThe effect of first-time heroin exposure on c-Fos signaling in rodents

Authors: *B. EVANS, S. BALLARD, K. NEWMASTER, Y. KIM, S. GRIGSON;
Penn State Col. of Med. Neurosci. Grad. Program, Hershey, PA

Abstract: While we are familiar with brain areas and pathways implicated in opioid use disorder (OUD), we do not have a full understanding of the neural circuits activated upon first drug exposure. In order to identify areas of the brain most activated by the first exposure to opioids, transgenic c-Fos-GFP mice were injected interperitoneally (ip) with saline or 10mg/kg heroin and returned to their home cages. Two hours later, the mice were transcardially perfused with 1x phosphate buffered saline (PBS) followed by 4% paraformaldehyde (PFA) in PBS. Brains were removed and post-fixed in 4% PFA at 4℃. They were placed in 1% agarose mold in order to be prepared for two photon microscopy imaging. The results showed a trending increase in c-Fos activation following exposure to heroin. Specifically, we observed c-Fos activation differences in the Nucleus Accumbens (NAc), Lateral Hypothalamus (LH), Orbitofrontal Cortex (OFC), Basolateral Amygdala (BLA), Habenula, Nucleus Tractus Solitarus (NTS), Parabrachial Nucleus (PBN), Periaqueductal Gray (PAG), Cingulate Cortex (CC), and Locus Coeruleus (LC). We looked at these brain regions in particular, because they are known to be associated with reward, satiety, or aversion. We also examined c-Fos based cortex activation in rats by utilizing a tissue clearing and 3D immunolabeling method combined with light sheet microscopy. Naïve male Sprague Dawley rats were injected with glucagon-like peptide-1 receptor agonist (GLP-1RA), 0.3mg/kg liraglutide, or saline 6 hours before injection with 10mg/kg heroin. Two hours after heroin injection, the rats were transcardially perfused with 1x phosphate buffered saline with sodium azide (PBS/NaN_3) followed by 4% paraformaldehyde (PFA) in PBS. Brains were removed, post-fixed as described, delipidated, immunolabeled with c-Fos, and cleared for light sheet microscopy imaging. Here, treatment with the GLP-1RA reduced heroin-induced c-Fos activation in the cortex in rats - providing a mechanism by which such treatment also reduces heroin intake, cue-induced seeking, and drug-induced reinstatement.

Title: Characterizing supraspinal pain-relevant glutamatergic afferents to the Ventral Tegmental Area.

Authors: *C. MANNING[1], J. A. KAUER[2];
[1]Stanford Univ., West Menlo Park, CA; [2]Dept. of Psychiatry, Stanford Univ., Stanford, CA

Abstract: Many ventral tegmental area dopamine neurons (VTA_{DA}) exhibit reduced firing rates in response to injury or noxious events (Ungless et al, 2004, Science 303: 2040; Huang et al, 2019, Mol.Brain 12:89), and disinhibition of VTA_{DA} neurons results in analgesia, indicating that VTA firing contributes to behavioral responses to noxious or aversive events. However, VTA_{DA} synaptic physiology in response to injury has not been extensively characterized. The VTA is innervated by regions implicated in the control of pain, including the periaqueductal grey (PAG), anterior cortex, and lateral habenula -- all of which send glutamatergic afferents to VTA_{DA}. To characterize these circuits after injury we isolated specific glutamatergic afferents to identified dopaminergic neurons (PITX3-GFP), and compared their function in saline- and carrageenan-treated mice. To achieve afferent-type specificity, we injected AAV-DJ-hSyn-ChR2-eYFP at p21, and 3 weeks later recorded optically-evoked EPSCs. We pursued the PAG-VTA_{DA} afferent, as PAG has a known role in opioid analgesia and its excitatory afferents to the VTA can drive aversion. Paired pulse ratios in response to various interstimulus intervals (50ms, 100ms, 500ms, 1000ms) were unchanged between inflammatory injury and saline-treated animals (N=20 cells, 11 animals, p=0.11). Furthermore, no differences were seen between groups comparing the first to the tenth EPSC in an optically evoked train of 10 stimuli at 1, 5, 10, or 20Hz under either basal or inflammation states (N=16 cells/ 11 animals, p=0.18). Our data suggest that probability of release at excitatory PAG terminals does not change in our inflammation model. We have begun to characterize postsynaptic responses of the PAG-VTA_{DA} synapses. Intriguingly, many of these VTA_{DA} neurons displayed excitatory currents at -70 mV that were not blocked by NBQX (10uM), as well as excitatory currents at +40 not blocked by d-AP5 (50uM). We therefore tested the GluA2-lacking AMPAR antagonist, NASPM, as well as the NR2C/D receptor antagonist, UBP141. Many optically evoked PAG-VTA_{DA} EPSCs were decreased by UBP141(24uM) and NASPM (20uM), indicating the presence of both NR2C/D NMDARs and GluA2-lacking AMPA receptors at these synapses. We are currently testing whether acute inflammation alters AMPA/NMDA ratios as well as sensitivity to NASPM and UBP141. Our data show that presynaptic function in PAG-VTA_{DA} synapses appears unchanged 24 hours after carrageenan injection, and preliminary results suggest no difference in overall AMPA/NMDA ratios following inflammatory injury. Potential avenues for future study include excitatory PAG afferents on VTA GABAergic neurons.

Title: Chronic morphine increases expression of the neuropeptide NMS in ventral tegmental area dopamine neurons

Authors: *C. M. RIVERA-QUILES, S. C. SIMMONS, A. L. GARRISON, N. M. CAMACHO-FONTÁNEZ, M. S. MAZEI-ROBISON;
Michigan State Univ., East Lansing, MI

Abstract: Although opioid dependence and addiction continue to constitute a major health and economic burden, our limited understanding of the underlying neurobiology limits better diagnostics and interventions. Dysregulation of the mesocorticolimbic reward circuit is acknowledged to contribute to various aspects of drug addiction, with alteration in the activity and output of dopamine (DA) neurons in the ventral tegmental area (VTA) known to contribute to the rewarding aspects of drug use. However, the molecular mechanisms underlying these changes in VTA DA function remain relatively unexplored. Thus, we used translating ribosome affinity purification (TRAP) to identify gene expression changes in mice that specifically occur in VTA DA neurons following chronic morphine exposure. We have validated gene expression changes via qPCR and intriguingly, we find that expression of a number of neuropeptides not traditionally described in the VTA are robustly induced by morphine exposure. Neuromedin S (NMS) was of particular interest as it was enriched in VTA DA neurons and its expression was robustly increased following chronic morphine exposure. It is known that the primary receptor with which NMS interacts, neuromedin U receptor 2 (NMUR2), is expressed within the target regions of VTA DA neurons, such as the nucleus accumbens (NAc). However, whether all VTA DA neurons express NMS, and their potential functional impact has yet to be determined. Thus, we have begun to characterize the expression and functional impact of VTA DA neurons that co-express NMS using NMS-Cre mice and Cre-dependent viral vectors. We have found that a subset of VTA DA neurons express NMS (<5%) and that these neurons exhibit diverse projection targets. Using DREADDs, we have found that acute activation of VTA-NMS neurons does not affect general locomotor activity or elicit conditioned place preference or aversion. We are now assessing whether activation of VTA-NMS neurons alters morphine-elicited behaviors (conditioned place preference, locomotor sensitization). Together, these studies are expected to set the stage for future work investigating the role of specific VTA-DA^{NMS} circuits, their activity during behavior, and their potential as targets for therapeutic intervention.

Title: Subtype specific changes in the intrinsic electrophysiological properties of mouse hypocretin/orexin (H/O) neurons following exposure to chronic morphine

Authors: *E. BERRY[1], S. JAVED[1], R. MCGREGOR[2], C. WALLER[1], C. HOLLANDER[1], M. ISHIBASHI[3], J. M. SIEGEL[2], C. S. LEONARD[1];
[1]Dept. of Physiol., New York Med. Col., Valhalla, NY; [2]Dept Psychiat, Univ. California Los Angeles, North Hills, CA; [3]Dept. of Neurophysiol., Hamamatsu Univ. Sch. of Med., Hamamatsu, Japan

Abstract: Hypothalamic H/O neurons exhibit structural and functional plasticity in their regulation of arousal, feeding, and reward. Indeed, human heroin addicts have H/O somata that are ~20% smaller and 50% more numerous than those in control subjects (Thannickal et al. 2018). Our NEURON simulations of this size change in simplified H/O-neurons (soma + 5 dendrites) indicate that the resulting altered passive properties increase their excitability. We therefore investigated the impact of chronic morphine on H/O-EGFP neurons by whole-cell recordings in acute brain slices from male mice (9-18 w) treated with a single daily injection (s.c.) of either morphine (50 mg/kg) or saline for 14 days. With investigators blind to the treatment, we confirmed that somatic cross-sectional area of H/O-EGFP neurons was ~17% smaller in morphine (n=4, ~100 neurons/mouse) vs. saline (n = 4, ~90 neurons/mouse; $p < 0.05$) treated mice. We next distinguished D- and H-type H/O-EGFP neurons by their membrane responses which are dominated by A-type K^+ currents in H-cells (Schöne et al. 2011). Morphine treatment did not alter the proportion of D- or H- type neurons (saline n = 18 D /13 H cells; morphine n = 17 D /14 H cells) or alter their spontaneous firing, sEPSC amplitudes, input resistance or cell capacitance, although there was a trend toward increased capacitance and decreased sEPSC amplitudes for H cells ($p = 0.07$). However, morphine treatment selectively altered spiking in H cells, for which rheobase was increased by ~43%, action potential amplitude was decreased by ~10% and the peak afterhyperpolarization was ~3 mV less negative (t-test, $p < 0.05$) compared to H-cells from saline treated mice. Repetitive firing in response to 2s constant current pulses was also selectively decreased with the F-I curve down-shifted following morphine treatment in H- but not D- cells. Moreover, firing patterns for H-, but not D-cells shifted from one of continuous firing toward more clustered and reluctant firing during the current pulse. Since structural plasticity is reversed after four weeks of withdrawal (Thannickal et al. 2018), we are testing whether these changes in H-cell excitability are also reversed

following withdrawal. In summary, our data indicate that in addition to inducing structural plasticity in H/O neurons, chronic morphine induces an intrinsic plasticity of H-type neurons which decreases their excitability. This implies that H- and D-type H/O neurons differentially participate in brain reward pathways and addiction, and raises the possibility that selective impairment of information outflow from H-cells may contribute to the hypodopaminergic state associated with chronic opiate use.

Title: μ-opioid receptor signaling bias alters opioid-induced dopamine release in the mesolimbic circuit

Authors: *S. W. GOODING[1], C. CHAU[2], E. LEWIS[3], J. L. WHISTLER[3];
[1]Neurosci. Grad. Group, [3]Ctr. for Neurosci., [2]Univ. of California Davis, Davis, CA

Abstract: Disinhibition of midbrain dopamine neurons is a well-studied action of opioids in the brain. The μ-opioid receptor (MOR), an inhibitory GPCR found on GABAergic terminals in the ventral tegmental area (VTA), reduces tonic GABA release when bound by agonists. MOR signaling to G-protein is titrated by arrestin-3 in the presence of endogenous MOR agonists. In contrast, most clinical opioids, such as morphine, produce G-protein signaling with little arrestin-3 engagement and are therefore “biased” for G-protein compared to endogenous ligands. We have previously shown that both analgesia and reward (CPP) by morphine are potentiated in knock-in mice (RMOR) with a MOR that effectively recruits arrestin-3 when activated by morphine. Furthermore, RMOR mice are resistant to development of analgesic tolerance and physical dependence following repeated morphine administration. This suggests that balanced signaling at the MOR is effective in combating both short and long-term homeostatic responses to MOR signaling such as receptor desensitization and upregulation of cAMP.We hypothesized that signaling bias at the MOR would affect the opioid-sensitive mesolimbic circuit and modulate downstream dopamine release. Using the fluorescent sensor dLight1.3b we recorded dopamine release in medial or lateral shell of the nucleus accumbens during intravenous opioid

administration in both WT and RMOR mice. Our data show differences in morphine-induced dopamine release between the two genotypes indicating that signaling bias produces circuit-level effects that are measurable downstream of the VTA. We further explore this hypothesis with methadone, a clinically important MOR agonist that recruits arrestin-3, to further implicate signaling bias at the MOR as a key presynaptic modulator of striatal dopamine release.

Title: Neuron-glial co-cultures exhibit differential molecular and functional signatures following sub-chronic exposure to low and high doses of fentanyl

Authors: D. LAM, A. SEBASTIAN, C. BOGGURI, S. K. G. PETERS, M. E. MENDEZ, N. R. HUM, C. A. VALDEZ, N. O. FISCHER, G. G. LOOTS, *H. A. ENRIGHT;
Lawrence Livermore Natl. Lab., Livermore, CA

Abstract: Fentanyl is one of the most frequently used synthetic opioids in medicine where it has established itself as an analgesic for patients undergoing surgery, and in the proper management of chronic pain. Unfortunately, due to its euphoric side effects, illicit use has been dramatically increasing, contributing to a steep rise in lethal drug overdoses. Fentanyl, like morphine, binds to mu-opioid receptors (MOR) in many brain regions, and this binding event can lead to addiction, tolerance, impairment of cognitive functions, and inhibit nociception, arousal, and respiration. Much research has focused on opioid receptor tolerance and the effector mechanisms at a cellular level, but how fentanyl affects the neural activity at a system level is poorly understood. Using a neuron-glial brain-on-a-chip system developed by our lab, we examined the neuroadaptive molecular and functional neural network changes following sub-chronic exposure to fentanyl. Primary rat co-cultures, containing cortical neurons, astrocytes and oligodendrocyte precursor cells, were seeded on a multi-electrode array (MEA) or 96-well tissue culture plate (for serial endpoint bulk RNA sequencing and imaging analyses). Once networks matured (28 days *in vitro*), co-cultures were treated with a low (0.01 μM) or high (10 μM) dose of fentanyl, and electrophysiology was monitored daily for 5 days. Sub-chronic fentanyl exposure resulted in a decline in neural (i.e., spiking) and network (i.e., bursting) activity, with diminished activity sustained for 5 days at the high dose condition. For the low dose condition, a decline at 24 hours relative to vehicle control was observed. Cultures treated with the mu-opioid receptor (MOR)

antagonist CTOP, in the presence of fentanyl, revealed that diminished activity was MOR-dependent in the low-dose condition but MOR-independent in the high-dose condition. The MOR-dependent and independent effect induced by low and high doses, respectively, paralleled pre-and postsynaptic gene expression changes predominantly observed in the low-dose condition, while other biological processes (e.g., neurotransmitter synthesis, growth factor expression and cytokine signaling) were found altered in cultures exposed to the high dose. Collectively, the findings of this study suggest that neuroadaptive changes to neural network activity at a systems level *in vitro* is dependent on the concentration of fentanyl, where at a low dose, fentanyl exposure primarily influences neuronal activity while at a high dose both neurons and glial cells are affected.

Title: Calcium-permeable AMPA receptors are upregulated in the rat nucleus accumbens during incubation of oxycodone craving

Authors: *K. A. ENGELN[1], E.-K. HWANG[2], M. E. WOLF[2];
[1]Oregon Hlth. and Sci. Univ. Sch. of Med., Portland, OR; [2]Behavioral Neurosci., Oregon Hlth. & Sci. Univ., Portland, OR

Abstract: The prescription opioid oxycodone is a widely prescribed and highly effective treatment for pain, but its addicting properties and severe withdrawal symptoms have contributed significantly to the opioid epidemic. Avoiding relapse to oxycodone during abstinence is a major challenge for recovering oxycodone users in part because cues associated with previous oxycodone intake can elicit cravings that often lead to relapse even after prolonged periods of abstinence. Identifying synaptic mechanisms underlying heightened cue-induced cravings during abstinence is critical for developing appropriate treatments for opioid use disorder. Cue-induced opioid cravings that persist throughout abstinence can be studied in rats using the incubation of drug craving model, in which cue-induced drug seeking progressively increases during withdrawal from drug self-administration. Studies of incubation of stimulant craving (cocaine,

meth) have demonstrated that upregulation of Ca^{2+}-permeable AMPA receptors (CP-AMPAR) in the nucleus accumbens (NAc) core mediates expression of incubation in late withdrawal. Here we determined whether upregulation of CP-AMPAR also occurs in parallel with incubation of oxycodone craving. Male and female Long Evans adult rats underwent 10 days of extended access oxycodone or saline self-administration (6h/d for 10 d; 0.1mg/kg/infusion; infusion paired with light cue). Rats received a 30 min test for cue-induced drug seeking on withdrawal day 1 (WD1) during which responding in the previously active nose poke hole delivered the cue in the absence of drug, and another 'seeking test' on either WD15 or WD30. Two to 12 days after the WD15 seeking test, whole cell recordings of medium spiny neurons in the NAc core were performed. The contribution of CP-AMPAR to the excitatory postsynaptic current was measured in oxycodone and saline groups using the rectification index (RI). Rats showed significant increases in cue-induced responding on WD15 vs WD1, indicating expression of incubation of craving (the WD30 study is in progress). There were no observed sex differences in drug intake or incubation. Compared to saline cells, oxycodone cells showed an elevated RI, indicating upregulation of CP-AMPAR in the NAc core between WD15 and WD30. These results suggest that CP-AMPAR upregulation is a form of plasticity common to protracted withdrawal from stimulants and the opioid oxycodone. Thus, preventing or reversing CP-AMPAR upregulation in the NAc during withdrawal may be a potential strategy for preventing cravings and relapse to multiple different classes of addicting drugs.

Title: Opioid Biosensors for Pharmacokinetics: Organelles to Whole Animals

Authors: *A. K. MUTHUSAMY[1], C. H. KIM[2], A. V. SHIVANGE[2], P. M. BORDEN[3], A. L. NICHOLS[2], H. EBISU[2], A. KORANNE[2], T. M. CHIN[2], S. GRANT[1], K. BERA[2], A. KAMAJAYA[2], J. S. MARVIN[3], B. N. COHEN[2], D. A. DOUGHERTY[1], Y. OKA[2], L. L. LOOGER[3], H. A. LESTER[2];
[1]Chem. and Chem. Engin., [2]Biol. and Biol. Engin., Caltech, Pasadena, CA; [3]Janelia Res. Campus, Ashburn, VA

Abstract: The chronic effects of exogenous opioids originate in part from intracellular interactions. In addition to plasma membrane (PM) activation, some opioids bind to their receptors in the endoplasmic reticulum (ER) to facilitate trafficking via pharmacological chaperoning and in Golgi/endosomes to effect signaling. At the whole animal scale, physiological and genomic variance and drug delivery mode lead to varied pharmacokinetics, complicating behavioral analyses. To provide a basis for cellular and circuit mechanisms of opioid action, we optically measure pharmacokinetics across these spatial scales. We developed a new class of genetically encoded biosensors, "intensity-based opioid-sensing fluorescent reporters", or "iOpioidSnFRs" to detect fentanyl, methadone, and naltrexone among other drugs. We adapted a biosensor scaffold based on OpuBC, a choline-binding periplasmic binding protein, and circularly permuted GFP. We screened 16 biosensor mutants against 40+ opioids representing μ, δ, and κ ligands to discover initial hits. Through directed evolution, we converted OpuBC variants to opioid binding proteins. Isothermal titration calorimetry and stopped-flow kinetics fleshed out a biophysical model for the new biosensors. These biosensors fulfill key criteria: (1) sensitivity across the pharmacologically relevant concentration range, (2) selectivity against endogenous ligands and other drugs, (3) sufficient reporter kinetics, and (4) photostability during all desired experiments. Results: (A) We established culture assays for organellar pharmacokinetics. Biosensors were directed to the PM, cytoplasm, ER, and Golgi using address sequences. Transfected HeLa cells and transduced primary neurons were imaged under perfusion across a range of [opioid]. Opioids permeated the ER nearly as well as they access the PM, indicating that ample drug is available for chaperoning. Furthermore, methadone accumulated in the Golgi ~4-fold relative to the extracellular solution, supporting the receptor activation observed in that compartment. (B) We recorded cytoplasm-directed iFentanylSnFR in freely behaving mice via fiber photometry. AAV9-hSyn-iFentanylSnFR was injected in the VTA and used to detect fentanyl after IP injection. These measurements are synchronized with annotated video to provide a dose-dependent behavioral time course. This method addresses: (1) whether animals self-administer to optimize a certain [opioid] vs. time waveform and (2) the *individualized* behavioral hallmarks at the heights and troughs of [opioid], where we expect possible euphoria and onset of withdrawal respectively.

Title: Evaluation of morphine withdrawal-induced anhedonia in male and female rats

Authors: *A. C. HARRIS[1], P. MUELKEN[1], J. R. SMETHELLS[1], S. X. LIU[2], A. RAMAKRISHNAN[3], L. SHEN[3], P. TRAN[4], M. G. LESAGE[1], J. C. GEWIRTZ[2];

Abstract: Understanding mechanisms underlying individual differences in susceptibility to opioid addiction is essential to developing more effective, individualized treatments. A major challenge in studying such mechanisms in preclinical models is the lack of a reliable behavioral predictor of future opioid self-administration. We recently reported that elevations in intracranial-self stimulation (ICSS) thresholds (anhedonia-like behavior) during withdrawal from acute morphine in male rats was negatively correlated with a wide range of measures of subsequent i.v. morphine self-administration. These findings implicate withdrawal-induced anhedonia (WIA) as a reliable prospective behavioral marker of individual differences in opioid addiction vulnerability. The goal of this study was to characterize WIA under a more clinically relevant morphine dosing regimen involving multiple spontaneous withdrawal episodes rather than a single spontaneous withdrawal episode, and to provide the first characterization of WIA in females. Repeated daily injections of morphine (5.6 mg/kg, s.c) produced a progressive increase in ICSS thresholds (i.e., WIA) measured 23 hr after each injection in both sexes, whereas repeated saline injections did not affect ICSS thresholds in either sex. There was no significant sex difference in the magnitude of WIA. The degree of WIA showed considerable individual variability (e.g., range of ICSS thresholds during final 3 test sessions (% baseline) = 100.3%-139.3%) - sufficent to allow for evaluation of the relationship between individual differences in magnitude of WIA and gene expression in future studies. Consequently, we are now combining this behavioral measure with next-generation sequencing (NGS) techniques to characterize alterations in the transcriptome and epigenome in the medial prefrontal cortex (mPFC) of rats tested for WIA. Based on our recent study using a similar morphine dosing regimen without WIA testing, we expect to observe significant up-regulation of genes relevant to synaptic signaling and neuroplasticity in the mPFC of both sexes. These findings establish a protocol for evaluating individual differences in the early stages, and escalating severity, of the anhedonic component of opioid withdrawal in both sexes. Integration of these behavioral data with NGS outcomes promises to yield novel molecular targets underlying individual differences in vulnerability to opioid addiction.

Title: Novel role for reverse transcriptase in Aplysia synaptic facilitation

Authors: *A. R. GOLD[1], D. L. GLANZMAN[2,3];
[1]Psychology - Behavioral Neurosci., [2]Integrative Biol. and Physiology, and Neurobio., UCLA, Los Angeles, CA; [3]Integrative Ctr. for Learning and Memory, BRI, Los Angeles, CA

Abstract: Most research on learning and memory focuses on changes in synaptic strength as a mnemonic mechanism; however a growing body of evidence has emerged in recent years that indicates that nuclear mechanisms play a central role in memory storage. Studies investigating nuclear phenomena associated with memory have focused primarily on epigenetic changes, for example, DNA (de)methylation and/or histone post-translational modification patterns; but retrotransposon activity has also been implicated in memory storage. Many transposable elements (TEs) operate through an RNA intermediate; these TEs therefore require the enzyme reverse transcriptase, the sequence for which is embedded in the transposon genetic sequence itself. To investigate the potential role of TEs in long-term memory in *Aplysia*, we tested whether reverse transcriptase activity was required for long-term facilitation (LTF) in *Aplysia* sensorimotor cocultures. As shown previously, exposing *Aplysia* sensorimotor cocultures to five spaced bouts of serotonin (5HT) induces facilitation of the *in vitro* sensorimotor synapse that persists for 24-72 h. This form of synaptic facilitation represents the cellular analog of long-term sensitization of the defensive withdrawal reflex in the intact animal. By contrast, a single pulse of 5HT induces short-term facilitation (STF) of the *in vitro* sensorimotor synapse, which lasts for < 30 min and corresponds to short-term sensitization of the withdrawal reflex. We found that the reverse transcriptase inhibitor lamivudine blocked 5HT-induced LTF in *Aplysia* sensorimotor cocultures. Unexpectedly, lamivudine also partially blocked STF of *in vitro* synapses produced by a single pulse of 5HT. Lamivudine by itself did not affect the strength of sensorimotor synapses, thereby indicating that the lamivudine-induced blockade of 5HT-induced plasticity was not due to detrimental or nonspecific effects of the drug on the neurons' health. Our data reveal novel roles for reverse transcriptase in both LTF and STF in *Aplysia*. They indicate that genetic rearrangement may occur during long-term memory in *Aplysia*. In addition, the effect of lamivudine on STF suggests an intriguing potential role for reverse transcriptase in short-term memory.

Title: Effect of type 1 diabetes on capillary obstructions and cognitive function in mice

Authors: *S. SHARMA, K. A. TENNANT, C. BROWN;
Univ. of Victoria, Victoria, BC, Canada

Abstract: Introduction Recent work from our lab has shown that the brain capillaries routinely get clogged by cells and debris even under healthy conditions. The present study was undertaken to determine how experimentally induced type 1 diabetes affects this phenomenon, and whether obstructions contribute to cognitive decline. **Methods** C57BL/6 male and female mice were injected with streptozotocin to induce type 1 diabetes. These mice were implanted with cranial windows and cortical volumes were repeatedly imaged from 3-9 weeks after induction of diabetes. To model susceptibilities to short or long lived obstructions, we injected (i.v.) 5µm diameter fluorescent microspheres in diabetic and control mice at 30 minutes and 3 days before euthanasia. The density of microsphere obstructed capillaries was quantified across 15 different brain regions. To determine the impact of diabetes on cognitive and sensorimotor activity, mice were subjected to a battery of behavioural tests. **Results** 2-photon imaging indicated that diabetic mice have higher rates of capillary stalling in somatosensory cortex that became more pronounced with duration of diabetes. The majority of stalls in diabetic mice were associated with Rhod6G labelled cells, suggesting that leukocytes play a key role. Increased stalling also led to greater pruning of cortical capillaries. Consistent with these observations, our fluorescent microsphere obstruction assay yielded significantly higher levels of short and long lived capillary obstructions in both male and female diabetic mice, including those treated with insulin. Behaviourally, diabetic mice were not different from controls in tests of anxiety or ambulatory activity (open field or elevated plus maze), nor did they show any differences in visual function. However, diabetic mice were significantly impaired in learning/memory tests such as the novel object recognition, water maze learning or reversal learning. **Conclusions** These studies suggests that diabetes is associated with greater risk for capillary obstructions in the brain as well as learning/memory deficits. Our future aims will provide a mechanistic understanding of how diabetes elevates one’s susceptibility to capillary obstructions and cognitive decline, and whether manipulating certain immune signalling pathways can alleviate these impairments.

Title: Disruption of memory allocation by stress: a role for parvalbumin interneurons and endocannabinoid signaling

Authors: *S. L. LESUIS[1], B. J. WALTERS[2], M. N. HILL[3], P. W. FRANKLAND[1], S. A. JOSSELYN[1];
[1]Neurosci. and Mental Hlth., The Hosp. for Sick Children, Toronto, ON, Canada; [2]Neurosci. and Mental Hlth., Univ. of Toronto Mississauga, Mississauga, ON, Canada; [3]Hotchkiss Brain Inst., Univ. of Calgary, Calgary, AB, Canada

Abstract: AIMS: The ability to remember which cues in a particular environment predict threat, and which do not, is imperative for survival. Overgeneralization of threatening cues, such that also neutral cues are perceived as threatening, may result in excessive anxiety-like behavior, and is a core symptom in many anxiety-related disorders and PTSD. Stress may promote such overgeneralization of memory, and hence may instigate or amplify anxiety-disorders. The overarching objective of these studies is to decipher the key pathways that underlie stress-induced memory generalization at the level of behavior, network dynamics and the cellular level, with a focus on inhibitory interneuron signaling.
METHODS: Mice were exposed to corticosterone injections or acute restraint stress, and the specificity of memory during fear conditioning and reward learning was assessed. Using *in vivo* fiber photometry, opto- and chemogenetics and iDISCO we establish the underlying cell types and networks mediating these effects.
RESULTS: After stress, mice show stronger memory generalization, both for memory with a positive and negative valence. In parallel, the lateral amygdala ensembles encoding for these memories are enlarged, and these enlarged ensembles were responsible for the generalized expression of the memories. Stress suppresses the activity of parvalbumin $(PV)^+$-interneurons, and indeed the effects of stress on memory generalization and ensemble size could be prevented by activation of PV^+-interneurons, while inhibition of PV^+-interneurons mimicked the effects of stress. We next show that endocannabinoid signaling within the lateral amygdala, which is directly modulated by stress, underlies the stress effects on interneurons and memory generalization.
CONCLUSIONS: Stress results in generalized memory expression, and disrupted memory allocation, which is prevented by modulating PV^+-interneuron activity. We propose that endocannabinoid signaling mediates these effects. Understanding these neurobiological

mechanisms of stress-induced memory generalization may be a first step towards the development of novel treatment strategies for anxiety-related pathologies.

Title: C57bl/6 substrain differences in conditioned fear and hippocampal transcriptome

Authors: L. R. GOLDBERG, A. SEBASTIAN, I. ALBERT, ***T. GOULD**;
The Pennsylvania State Univ., University Park, PA

Abstract: Accumulating evidence supports significant phenotypic and genomic differences between the closely related C57BL/6 (B6) substrains, C57BL/6J (B6J) and C57BL/6N (B6N). Inconsistent differences in conditioned fear between B6J and B6N have been reported. These inconsistences may be due to B6N substrain selection (B6NJ vs B6NCrl) or fear conditioning paradigm characteristics. Here, we aimed to determine if B6J and B6NJ substrains differed in contextual fear conditioning and learning-induced hippocampal transcriptome. Male B6J and B6NJ (PND60, n=8 per group) were fear conditioned with 1 pairing, 2 pairings, or 4 pairings of footshock and auditory cue, and then were tested for hippocampus-dependent contextual fear learning or hippocampus-independent cued fear learning. A 2-way ANOVA of Strain and number of Pairings for contextual fear learning revealed a significant effect of Strain ($F_{1,41}$=48.83, $p<0.001$), a significant effect of Pairings ($F_{2,41}$=4.99, $p<0.05$), but no interaction of Strain and Pairings. For all number of Pairings, B6NJ showed enhanced contextual freezing compared to B6J. A 2-way ANOVA of Strain and number of Pairings for cued fear learning revealed a significant effect of Strain ($F_{1,41}$=5.46, $p<0.05$), but no significant effect of Pairings or interaction of Strain and Pairings. For all number of Pairings, B6NJ showed enhanced cued freezing compared to B6J. To investigate baseline and learning-induced changes in hippocampal transcriptome that may underlie the observed behavioral differences between B6J and B6NJ, dorsal (DH) and ventral hippocampi (VH) were dissected for RNAsequencing. Samples were collected from B6J and B6NJ male mice from three groups (n=6 per group): direct from home cage, 30 minutes after 2-pairings of shock and cue, 30 minutes after 2 exposures to cue alone. Preliminary analyses of B6J and B6NJ home cage transcript level expression identified 336 DH and 153 VH differentially expressed transcripts. Enrichment analyses using Enrichr identified 7

enriched GO Biological Processes (adjusted p-value <0.05), including regulation of synapse maturation, glutamatergic synaptic transmission, and regulation of nervous system development. Continued analyses include learning-induced differential transcriptome expression between B6J and B6NJ in both hippocampal regions. Together, these behavioral and transcriptomic findings confirm differences in conditioned fear between the commonly used B6 substrains, B6J and B6NJ, and begin to uncover the underlying hippocampal transcriptome differences.

Abstract: Protein translation is a critical component of brain function, and aberrant translational processes have been implicated in psychiatric disease. Transfer (t)RNAs, non-coding clover-leaf shaped RNAs that are key players in ribosomal protein synthesis, are barely explored in brain. Nsun2, a mammalian tRNA cytosine methyltransferase, is expressed at high levels in brain and

has been linked to neurodevelopmental defects in humans and mice. Previous work has shown that loss of tRNA cytosine methylation produces deficits in protein synthesis in non-neuronal cells, but the role of tRNA methylation in adult neuronal function has not been explored. We used conditional ablation and transgene-derived overexpression of Nsun2 in the mouse prefrontal cortex (PFC) to manipulate tRNA methylation levels postnatally. We used targeted RNA bisulfite sequencing and tRNA sequencing to assess tRNA methylation/expression, LS-MS/MS to measure protein expression, electrophysiological recordings to assess synaptic transmission, and behavioral testing for complex behaviors including cognition, behavioral despair, and addiction-related behaviors. Results showed that complex behaviors relating to emotion, cognition, and addiction are highly sensitive to bi-directional changes in Nsun2 in prefrontal cortex (PFC) neurons. Further, Nsun2-deficient cortex showed a selective deficit in multiple glycine tRNAs which resulted in codon-specific shifts in the proteomic landscape, with decreases in glycine-rich neuronal proteins that were associated with impaired neurotransmission and altered behavioral phenotypes. Overall, we found that tRNA methylation is a critical process for regulating synaptic plasticity and behavior through proteomic changes in the mature cortex. Additionally, this data suggests that there is another mechanism, aside from glycinergic receptors, by which glycine could critically regulate brain function and complex behaviors, suggesting potential for novel therapeutic avenues in psychiatry.

Title: Tet2 demethylation of DNA after learning destabilizes memory

Authors: *M. M. CARON, M. M. BISHOP, S. M. STRUGAR, B. G. MALACHOWSKY, K. E. ZENGELER, C. P. GETTENS, H. P. SMITH, A. J. KENNEDY;
Bates Col., Lewiston, ME

Abstract: Active DNA methylation in neurons that encode experience is required for long-term memory formation. TET enzymes oxidize and lead to the removal of DNA cytosine methylation.

Here we demonstrate that the conditional knockout of Tet2 in glutamatergic neurons induces enhanced long-term memory retention in mice. We found enhanced DNA methylation patterns in the promoter of experience-regulated genes due to Tet2 deletion in these neurons, which corresponded with altered gene expression. Additionally, we demonstrate that deleting Tet2 from recently activated neurons, induced by learning, selectively enhanced the recall of individual memories. These data suggest that Tet2 is a negative regulator of memory retention in neurons following learning and a target for memory enhancement.

Title: Regulation of gene expression in neurons by bivalent chromatin marks

Authors: *C. GREER[1], A. DUNCAN[2], J. WRIGHT[2], J. WEISS[1], R. J. COLBRAN[2], G. KAAS[1];
[1]Pharmacol., [2]Dept Molec Physiol & Biophysics, Vanderbilt Univ., Nashville, TN

Abstract: We recently reported that two isoforms of the Ten-eleven translocation 1 (*Tet1*) gene are transcribed in the mouse brain.[1] The longer isoform facilitates, and the shorter isoform suppresses, long-term memory formation in adult male mice. The longer isoform is less abundant, but strongly influences neuronal gene transcription and other functions. To identify mechanisms regulating *Tet1* expression, we examined the post-translational chromatin marks surrounding the two *Tet1* gene promoters from publicly-available cell-type specific chromatin immunoprecipitation sequencing data. The long isoform promoter region is co-enriched with both active (Histone 3 lysine 4 trimethylation, H3K4me3) and suppressive (Histone 3 lysine 27 trimethylation, H3K27me3) marks in neurons. The enzymes regulating these two marks are known to be important for long-term memory formation. While both the short and long promoters had H3K4me3 marks in neurons and non-neurons, only the neuronal long promoter also had H3K27me3 marks. Dually edited genomic loci with active and suppressive marks are known as bivalent chromatin in embryonic stem cells. They usually resolve themselves to either solely active or suppressive monovalent marks in differentiated cells, and have not been

previously characterized in mature neurons. However, surprisingly, an examination of bivalent chromatin derived from hippocampal neurons of adult mice revealed that hundreds of gene promoters exist in this cell-type specific bivalent state. In addition, many of these same promoters were found to be bivalently marked in neurons from the anterior cingulate cortex. Many of the neuronal bivalent genes encode transcription factors and cell-surface receptors that are involved in regulating cell proliferation, developmental pathways, and signal transduction. Specific examples include the autism-associated gene Reelin (*Reln*), and *Erbb4*, which is a schizophrenia risk gene associated with memory formation. Enhancer of zeste homolog 2 (EZH2) generates H3K27 methylation marks, and we find that EZH2 inhibitors elicited derepression of bivalently marked genes in neuronal, but not in glial cultures. Collectively, our data suggests that neurons utilize bivalent chromatin to sustain tight control over transcriptional levels for critically important genes.

Title: Paired genomic and epigenetic sequencing reveals neuronal signatures of early-life exercise

Abstract: Aerobic exercise is a potent environmental signal that is associated with improved hippocampal memory. Studies in rodents have shown that neurobiological mechanisms activated by exercise include epigenetic modifications, which act to influence expression of memory-

associated genes. Less is known regarding the effects of early-life exercise on adolescent gene expression and epigenetic regulation that may influence long-term improvements in neuronal function. Traditional *in vivo* approaches to next-generation sequencing for answering these questions use heterogeneous cell populations from whole tissue homogenates. In order to evaluate neuron-specific epigenetic and transcriptional changes resulting from early-life exercise, we developed a line of transgenic mice expressing the NuTRAP cassette under the neuron specific Emx1 promoter (named Emx-NuTRAP mouse). This approach allows for simultaneous isolation of both nuclei and translating ribosomal mRNA from a primarily neuronal population. We employ a new technique that combines the nuclear isolation using Isolation of Nuclei TAgged in Specific Cell Types (INTACT) and Translating Ribosomal Affinity Purification (TRAP) methods in order to couple neuron-specific epigenetic modifications and gene expression programs driven by early-life exercise. Data from RNA-seq and CUT&RUN-seq were paired to evaluate histone modifications influencing gene expression after exercise. We also performed separate INTACT and TRAP isolations from a second group of exercised and sedentary Emx-NuTRAP mice, and show similar patterns of gene expression and histone modification occupancy. Finally, as traditional approaches sequence from opposite hemispheres in order to obtain transcriptomic and epigenomic data, we take a bioinformatics approach to determine if hemispheric differences in gene expression and histone modifications in hippocampal neurons. Our data reveal a transcriptional and epigenetic signature of early-life exercise exposure, and discovers candidate gene-histone modification interactions for further investigation. Importantly, our novel approach of combined INTACT/TRAP methods from the same cell suspension allows for simultaneous transcriptomic and epigenomic sequencing in a cell-type specific manner.

Title: Neuroprotective Role of Integrin Linked Kinase in Prenatal Brain Development

Authors: B. LITTLE[1], N. SUD[1], M. ESCOBAR[2], *D. BHATTACHARYA[1];
[1]Lake Erie Col. of Osteo. Med., Erie, PA; [2]Oakland Univ., Rochester, MI

Abstract: Integrin Linked Kinase (ILK) is a synaptic scaffolding protein that plays an important role in learning and memory and glutamatergic synapse development. We previously reported using fetal alcohol spectrum disorder (FASD) rat model, the moderate alcohol exposure results in the deficits in hippocampal dependent contextual memory and synaptic plasticity in the offspring that correlate to the impaired function of ILK. ILK can be activated through stimulation of Brain Derived Neurotrophic Factor (BDNF) receptor, Tyrosine kinase B (TrkB). We have evidence to suggest that administration of 7,8 dihydroxyflavone (7,8-DHF), potent TrkB agonist attenuates spatial memory deficits in the same FASD rat model. Chronic administration of 7,8 DHF during preadolescence (P15-30) resulted in increased general activity and exploration in a Y-maze task, thus reducing some aspects of the spatial deficits otherwise observed in FASD rats. However, it is not yet tested if ILK activity is essential during brain development to counter the teratogenic effect of alcohol. Here, we evaluated the effect of intraperitoneal injection of ILK inhibitor, QLT0267 (Inh) or control saline (con) in time pregnant rats (injected on alternate days during gestation) on the spatial memory development in the offspring. Administration of QLT0267 (5mg/kg) during gestation significantly reduced the percentage dwell time in the offspring using a novel arm exploration protocol in a Y-maze compared to the control rat offspring. A Mann-Whitney test indicated the percentage dwell time was greater in con (N=11) as compared to inh (N=10) offsprings (U=23, p=0.02). This suggests that ILK activity impairment during brain development by prenatal alcohol exposure may result in deficits of spatial memory function in the offspring. There is no significant change in hippocampal ILK protein expression. ILK inhibition during early brain development has significantly reduced the (N-Methyl-D-aspartic acid) NMDA receptor subunits, NR2B (con=5, inh=4, t=2.712, df=7, p=0.03) and NR1 expression (con=5, inh=4, t=3.969, df=7, p=0.005) in the hippocampal protein lysates. However, no significant changes are observed in the expression of other glutamate receptor subunits including (α-amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid) AMPA receptors. This study concludes that ILK activity deficits dysregulated hippocampal NMDA receptor expression impairing spatial learning and memory in rats exposed to prenatal inhibition. Therefore, prenatal alcohol mediated impairment of ILK activity during development is one of many mechanisms contributing to hippocampal learning and memory deficits.

Title: Neural circuitry for infant attachment: mother enhances hippocampal activity during early life

Authors: *R. M. ZANCA[1,2], W. SONG[3], M. OPENDAK[1,2], N. NAEEM[3], N. GRAF[3], A. I. BLOMKVIST[4], P. A. SERRANO[5], D. A. WILSON[1,2], R. M. SULLIVAN[1,2];
[1]Child and Adolescent Psychiatry, NYU Langone Hlth., New York, NY; [2]Emotional Brain Inst., Nathan Kline Inst., Orangeburg, NY; [3]New York Univ., New York, NY; [4]Psychology, Stockholm Univ., Solna, Sweden; [5]Dept of Psychology, Hunter Col. and City Univ. of New York, New York, NY

Abstract: The infant attachment literature suggests that the child's attachment quality to the caregiver promotes a healthy foundation for neurobehavioral developments. Yet our understanding of the neurobiology of this relationship remains elusive. Within this relationship, one infant behavior reliably associated with the attachment figure is proximity seeking, with strangers much less likely to evoke approach. For our approach, we used infant rats because similarly to children, attachment is learned and once learned, evokes prosocial behaviors towards the attachment figure. While children rely on all sensory systems to identify the attachment figure, rat pups primarily use the mother's odor, which pups rapidly learn. Since the rat maternal odor is diet-dependent, we produced a "stranger" mother by feeding it a different diet, which pups had not learned to identify as the maternal odor. Here we define neurobehavioral responses to the mother vs. a stranger mother focusing on the hippocampus and cortex. We used 12 to 18-day old infant rat pups, an age range of robust attachment. Pups' behavior were recorded during a 1hr session with either a anesthetized mother or an anesthetized stranger mother (different maternal odor) or a no odor control (pup placed in empty arena). Sessions were videotaped and scored offline for behavioral assessment. Two measures of dorsal hippocampal activity were used, autoradiography (14C 2-DG) and western blot for synaptic D1 dopaminergic receptors (D1R) since previous has highlighted maternal control of infant rats' amygdala dopamine. Cortical and hippocampal local field potential (LFP) oscillations were also measured. Results indicate that pups spent more time with the mother and exhibited significantly more prosocial behaviors vs. the stranger. Neural markers showed greater hippocampal activity (2-DG), and increased synaptic D1R expression to the mother vs. the stranger. LFP recordings show divergent LFP responses to the mother and stranger. These results begin to better define specialized attachment circuitry within two divergent social context.

Title: Spatial disorientation and Alzheimer's disease: the relationship between task-induced activation profiles in the brain's navigational system and reorientation deficits in the 3xTg-AD mouse model of tau and amyloid beta aggregation

Authors: *J. R. DIXON, A. C. STIMMELL, S. C. MOSELEY, A. A. WILBER;
Dept. of Psychology, Florida State Univ., Tallahassee, FL

Abstract: Impaired navigation is one of the first symptoms of Alzheimer's disease (AD). Understanding the brain changes associated with this early impairment is critical for the development of earlier AD diagnosis methods and treatments. Previously, we found that 6-month female 3xTg-AD mice are impaired at using distal cues to get re-oriented in space (spatial reorientation task; Stimmell et al., 2019), and subsequently, that the pTau density profile across a parietal-hippocampal network was a strong predictor of this impairment (Stimmell et al., 2021). Thus, in 6-month female 3xTg-AD mice and age matched controls, we assessed the c-Fos activation profile across the parietal-hippocampal network induced by the spatial reorientation task. Specifically, we used c-Fos immunohistochemical staining to assess the c-Fos positive cell density in seven regions: the parietal cortex (PC), the dorsal and ventral CA1 field of the hippocampus, the dorsal and ventral subiculum (Sub), and the dorsal and ventral areas of the retrosplenial cortex (RSC). We found that, as in our previous work, female 6-month 3xTg-AD mice, which accumulate tau and amyloid beta (Aβ), are impaired at the spatial reorientation task (Stimmell et al., 2019). Further, task-induced c-Fos density was higher in the PC but not the remaining 6 regions, suggesting that there may be hyperactivation of the parietal cortex of 3xTg-AD mice. This is consistent with some studies that have reported hyperactivation of the default mode network in individuals with preclinical AD (Sperling et al., 2009) and of the cortex of AD mice in response to Aβ oligomers (Keskin et al., 2017). Surprisingly, the strongest correlations between task induced c-Fos activation and spatial reorientation performance were with the CA1 and RSC and the weakest correlations were with the ventral Sub and PC. Taken together, this suggests that network level dysfunction is driving the hyperactivation in PC and that other components of this network are more closely tied to spatial reorientation performance. Finally, the direction of the strongest correlations was negative, meaning that the higher the density of activation in the RSC and the CA1 region of the hippocampus, the worse spatial learning and memory (i.e., more active RSC and CA1 cells were associated with worse performance). This suggests that, at early time points prior to significant tau and Aβ accumulation (e.g., pre-plaque), hyperactivity in the parietal-hippocampal network may be reflective of pathophysiology of AD.

Title: Sleep Reverses Spatial Reorientation Impairments in a Mouse Model of Alzheimer's Disease

Authors: *A. C. STIMMELL, J. R. DIXON, S. C. MOSELEY, A. A. WILBER;
Florida State Univ., Tallahassee, FL

Abstract: In early Alzheimer's disease (AD), getting lost is one of the first cognitive impairments to emerge. The precise cause of this impairment is unclear. Previously, we demonstrated that impaired spatial navigation may result from a failure to use distal cues to get oriented in space (spatial reorientation task; Stimmell et al., 2019). This impaired use of distal cues for spatial reorientation in 3xTg-AD mice, which accumulate both amyloid beta (Aβ) and tau, emerges early in disease progression before the onset of plaques and tangles, suggesting the impairments we observed in mice may be informative about those observed in early AD in humans (Henderson et al., 1989; Weintraub & Salmon, 2012; Allison et al., 2016). Only 6-month female 3xTg-AD (not 3-month female) mice were impaired on the spatial reorientation task. In addition, we have also shown that the profile of phosphorylated tau positive cell density across brain regions associated with spatial navigation is highly predictive of spatial learning and memory performance in 6-month female 3xTg-AD mice (Stimmell et al., 2021). The search for treatments of AD is ongoing and some treatments are aimed at prolonging quality of life or staving off early symptoms of AD. One such approach is modifying sleep. Poor sleep quality, short sleep duration, and disrupted slow wave sleep are all associated with increased Aβ, poor cognition, and risk of AD (Nebel et al., 2018). Decreased sleep is associated with an increase in the release of tau and phosphorylated forms of tau seen in the earliest stages of AD, as well as decreased clearance of tau (Lucey 2020). Sleeping is also associated with Aβ and tau clearance (Lucey 2020; Nebel et al., 2018; Tononi & Cirelli 2014; Toro et al., 2019). Thus, we set out to test the hypothesis that sleep could ameliorate impairments we observed in 6-month female 3xTg-AD mice. We assessed spatial reorientation performance either with or without pre- and post-task sleep sessions. We replicated our previously observed spatial reorientation impairment in no-sleep mice; while sleep mice did not differ from age-matched controls. Thus, sleep modification may ameliorate cognitive dysfunction in AD.

Title: Rescuing impaired cortical-hippocampal interactions during sleep in a mouse model of Alzheimer's disease

Authors: S. D. BENTHEM[1], I. SKELIN[3], S. MOSELEY[1], J. DIXON[1], A. STIMMELL[1], A. A. WILBER[2];
[1]Psychology, [2]Florida State Univ., Tallahassee, FL; [3]Neurosci., Univ. of Lethbridge, Lethbridge, AB, Canada

Abstract: In preclinical Alzheimer's disease (AD), spatial learning and memory is impaired (Allison et al., 2016). We reported similar navigational impairments in 6-month 3xTg-AD female mice on a virtual task that requires learning and memory for using landmarks to get oriented in space (Benthem et al., 2020). Memory replay during sleep is critical for learning related plasticity (Ego-Stengel & Wilson, 2009; Jadhav et al, 2012; Maingret et al, 2016), and hippocampal-cortical dysfunction is a potential mechanism for memory impairments in individuals with AD (Gennaro et al, 2017; Khan et al, 2014).We found that early in disease progression deficits in hippocampal-parietal cortex (PC) coordination during sleep coincided with navigation impairments on the virtual maze (Benthem et al, 2020). Gamma-stimulation (40Hz) has been shown to clear AD pathology in mice (Iaccarino et al, 2016; Martorell et al, 2019), and improve functional connectivity in preclinical AD patients (He et al, 2021). Thus, we assessed hippocampal-PC coordination in 6-month female 3xTg-AD/PV^{cre} (4xTg) mice that were learning the same *spatial reorientation task*. Mice were implanted with a 16 tetrode recording array targeting PC and hippocampus and an optical fiber aimed at HPC. Then daily recording sessions of rest-task-rest commenced as mice learned to locate the unmarked reward zone. During the same surgery a cre-dependent AAV was used to express channel rhodopsin 2 in the parvalbumin+ interneurons in the hippocampus. This allowed for daily stimulation sessions, with either 40Hz entrainment in hippocampus or SHAM stimulation. We assessed sleep quality metrics, multi-unit activity patterns, cortical spindles, and delta waves (DW) in PC and markers of memory replay in the hippocampus (SWRs) during SWS. We found no difference in any sleep

quality metrics. We also found no difference in number or rate of DW or SWRs. However, in SHAM stimulated mice were SWR-DW cross-correlations were significantly reduced, similar to our previous findings in 3xTg-AD mice (Benthem et al, 2020). In the 40Hz stimulated mice, this functional connectivity was rescued. Furthermore, the 40Hz stimulated mice showed improved performance on the virtual reorientation task compared to the SHAM stimulated mice. Thus, 40Hz stimulation of hippocampus may rescue functional connectivity impairments in the hippocampal-PC network and spatial navigation.

Title: Effects of medial entorhinal cortex lesions in rats on the Traveling Salesman Problem

Authors: L. OLIVAS[1], D. ABOUCHEDID[1], *R. BLASER[1], J. B. HALES[2];
[2]Psychological Sci., [1]Univ. of San Diego, San Diego, CA

Abstract: Although highly controlled behavioral tasks are valuable for isolating and targeting specific processes, they risk producing too narrow an understanding of behavior in natural contexts. The Traveling Salesperson Problem (TSP) is a spatial navigational task that differs from simple spatial memory tasks; rather than examining an animal's ability to perform a precise behavior, it explores foraging behaviors in a naturalistic setting. While foraging is a spontaneous behavior, it is also complex, in that it involves decision-making, attention, spatial processing and navigation, course planning, and memory. Experiments using simple, highly-controlled conditions have indicated that the medial entorhinal cortex (MEC) plays an important role in spatial processing and spatial memory in ways that are similar to, and yet distinct from, those of the hippocampus. Therefore, comparing the effects of MEC lesions to those of hippocampal lesions on rats' performance in the TSP task may help clarify the relative contributions of these different anatomical brain areas to spatial navigation under more ecologically relevant conditions. Previous research from our lab found that rats with hippocampal lesions were impaired on their performance of the TSP task in comparison to sham controls, particularly on measures of spatial memory, such as making more errors by revisiting targets and making fewer

consecutive retrievals prior to the first revisiting error. In our currently study, we found that MEC lesions also impaired performance on the TSP, although to a more limited degree than hippocampal lesions. Like rats with hippocampal lesions, those with MEC lesions showed more revisit errors and longer travel distances than those with sham lesions. Experimental rats also showed a greater tendency to circle the perimeter of the arena, possibly as a strategy to cope with reduced spatial working memory.

Title: Neural activity in entorhinal cortex-led processing loops evoked by exposure to a known or new environment

Authors: *C. H. GODFREY, E. M. BUNCICK-ROAKES, K. M. GEISINGER, J. L. REGAN, G. M. GRAVEEL, M. C. ZRULL;
Appalachian State Univ., Boone, NC

Abstract: Perception of the environment happens in less than a moment and permits movement through a space, navigation to or around objects, and reaching a goal location. Using adolescent Long-Evans rats (n=20), we examined two processing loops, one led by superficial medial entorhinal cortex (MEC) thought to process information about the global scene and path navigation and the other led by superficial lateral EC (LEC) that may process information regarding objects and their locations. Structures in each loop were explored using an environmental enrichment paradigm (EE) and by assessing c-FOS expression in neural regions in each loop following exposure to an environment with objects in animals with and without a history in the environment (EE+EE, No+EE groups, respectively). Control groups with and without EE history did not have a final EE experience (EE+No, No+No), and EE+EE and EE+No groups experienced 18 periodic EE sessions through adolescence. Counts of active, c-FOS+, neurons were made with digital microscopy, and data were standardized to No+No counts. Regardless of processing loop or region, there were no differences between control groups. In the MEC-led, “global scene/navigation” processing loop, more neurons were activated in superficial MEC (MEC)and proximal CA1 of No+EE (+200%, +390%, $p<.01$) and both No+EE and EE+EE (+350%, +690%, $p<.01$) than in controls; however, in distal subiculum and deep MEC enhanced activation was similar for No+EE and EE+EE groups (+375%, +140%, $p<.01$). In the LEC-led, “object/object location” processing loop, more neurons were activated in superficial LEC of both No+EE and EE+EE (+60%, $p<.02$) and in distal CA1 of No+EE (+355,

p<.01) and both No+EE and EE+EE (+600%, p<.01) than in controls; however, in proximal subiculum and deep LEC enhanced activation was similar for both No+EE and EE+EE groups (+325%, +55%, p<.01). Differences in evoked activity between EE+EE and No+EE groups in superficial MEC but not in superficial LEC support the idea of MEC processing global scenes and LEC processing local cues with similar activity patterns in both proximal and distal CA1 across EE+EE and No+EE groups suggesting subsequent integration of global and local information into a more complete representation of a space. The data suggest subiculum, in both loops, likely modifies information as well as simply acting as a relay back to deep MEC and LEC. While our results show support for differences and similarities in processing global and local cues though MEC/LEC to hippocampus loops, they also point to the need for further research using various methodologies.

Title: Evoked activity in superficial entorhinal cortex after exposure to an environment with or without objects

Authors: H. B. WOLFE, K. M. GEISINGER, E. A. GIBSON, J. L. REGAN, ***M. C. ZRULL**; Appalachian State Univ., Boone, NC

Abstract: The entorhinal cortex (EC) leads, and ends, two neural processing loops through the hippocampal formation (HF). In part, activity across two loops, one beginning with medial EC (MEC) and the other with lateral EC (LEC), contributes to neural representations of an animal's environment as a whole (e.g., MEC led loop) and the location of items within that environment (e.g., LEC led loop). In this initial study, we used c-FOS to examine neural activation in Layers 2 and 3 of MEC and LEC, which receive input derived from a range of brain regions and relay input to the HF, evoked by exposure to enriched environments (EEs) with or without a variety of moveable objects. Subjects were 15, adolescent Long-Evans hooded rats. After weaning, the animals were housed in groups in standard shoebox cages and handled daily. At 49 days old and prior to sacrifice, 5 rats spent 1.5 h in an enclosure with ramps and platforms (NoObj group), 5 rats spent 1.5 h in an EE but with a number of objects (YesObj group), and 5 rats spent 1.5.h in a standard shoebox cage in a quiet and dark room (control). Brains were processed to visualize c-FOS+ neurons, and cell counts were made using digital microscopy and stereological technique. All data were standardized to the control group cell counts. Enhanced neural activity was

observed across Layers 2 and 3 of MEC and LEC of both NoObj and YesObj groups in comparison to controls (all $p<.01$). For LEC Layer 2, NoObj and YesObj groups did not differ in c-FOS+ neuron counts; however, 147% more activated neurons were observed in LEC Layer 3 of NoObj than YesObj brains ($p<.037$). Both Layer 2 and 3 of MEC in NoObj brains exhibited enhanced evoked activity relative to YesObj brains (+133%, $p<.017$ and +827%, $p<.001$, respectively). These results were somewhat unexpected. MEC layers were expected to be activated similarly across NoObj and YesObj groups due to responsivity to spatial cues of the overall environment (i.e., the global scene). However, more neural activity was elicited in three of four EC layers by exposure to an environment devoid of moveable objects than a setting with various objects (i.e., NoObj vs. YesObj groups). In contrast, and more expectable, more c-FOS+ neurons were found in MEC than LEC (+46%) of the NoObj group, and within the YesObj group more activated neurons were in LEC than in MEC (+71%). These latter results align with suggestions that while MEC responds to the global nature of an environment, the LEC responds to both the space of an environment and the location of various objects within that space. That said, our data seem to suggest the EC may be more responsive to the global nature of an environment than local cues within that space.

Title: Fluoxetine as a novel treatment to attenuate cisplatin-induced cognitive impairment

Authors: X. DELGADO, D. RAYMOND, C. RECHSTEINER, N. MARION, V. STEIGAUF, J. BARFOOT, W. DYER, A. RIEHL, *A. LACROSSE;
Northern Michigan Univ. Departments of Biol. and Psychology, Marquette, MI

Abstract: The American Cancer Society estimates that there are 4,950 new cancer cases each day in the US, and ¾ of that population may suffer cognitive decline because of treatments that were necessary to save their lives. Cisplatin, a chemotherapeutic agent, initiates cell death through various methods that include mtDNA damage during cell replication and produces damaging pro-inflammatory cytokines. Unfortunately, the damage caused by cisplatin treatment is not selective to only cancer cells but also damages healthy cells. This can result in long-term chemotherapy-induced cognitive decline (CICD). Fluoxetine (FLX) is a selective serotonin reuptake inhibitor widely used in patients with anxiety and mood disorders. Published studies report that FLX could sensitize cancer cells to chemotherapy treatment and assist in attenuating

CICD. We hypothesize that the combined therapy of Cisplatin and FLX will increase the sensitivity of cancer cells to Cisplatin and protect against CICD. Methods include both *in vitro* and *in vivo* studies. To assess the ability of FLX to sensitize cancer cells to Cisplatin, we used established cancer cell lines and various doses of FLX or Cisplatin to determine the dose that achieved 50% cell death. Optimal doses were combined, and cytotoxicity was measured. To determine whether FLX treatment could reduce CICD, we used C57 mice and a delayed non-match-to-sample (DNMS) or delayed-match-to-sample (DMS) operant tasks to assess learning and cognitive flexibility. Treatment cohorts included saline/saline, cisplatin/saline, FLX/saline, and FLX/Cisplatin. The treatment regimen included two 5-day cycles of Cisplatin treatment with 5 days rest in between. FLX or saline was administered for the entire 15 days. Mice were then trained to lever press for reinforcement under either DMS or DNMS conditions. Following successful acquisition of the task, reinforcement conditions were reversed. Results indicate that FLX sensitizes cancer cells to cisplatin treatment *in vitro*, and *in vivo* cisplatin induces CICD that FLX is able to attenuate. Combined treatment of FLX and Cisplatin may reduce undesirable side effects by using a lower chemotherapeutic dose to achieve the same rate of cancer cell death, and FLX may help protect healthy cells from chemotherapy-induced toxicity. This research will ultimately provide scientists and medical professionals with new information on why patients may experience alterations in their cognitive function and potentially offer a new treatment option to improve the overall quality of life. Further studies are necessary to explore the underlying neuronal changes that occur with cisplatin treatment and how FLX attenuates CICD.
