Title: Differential Phagocytosis of Fibrillar and Soluble Oligomeric Aβ by Primary Human Microglia in Culture

Authors: *A. BAHRAMI, C. SWOPE, E. TAEFI, M. FLANAGAN, T. GEFEN, M.-M. MESULAM, C. GEULA;
Mesulam Ctr. for Cognitive Neurol. and Alzheimer's Dis., Northwestern Univ. Feinberg Sch. of Med., Chicago, IL

Abstract: The amyloid-β (Aβ) peptide accumulates in plaques in the brains of patients with Alzheimer's disease (AD) and contributes to disease pathogenesis. Aβ forms aggregates that assume various conformations based on size and arrangement of oligomers. Large aggregates of Aβ can form fibrils, with abnormal β-pleated sheet conformation, that deposit in compact, neuritic plaques, and have been shown to exert toxic effects on neurons. Smaller soluble Aβ oligomers disperse across various brain compartments and are proposed to cause synaptotoxicity. One mechanism of Aβ clearance from the brain involves phagocytosis and degradation by microglia, the resident macrophages of the central nervous system. While it is known that microglia phagocytose Aβ, it is not known whether they phagocytose fibrillar and soluble oligomeric Aβ with the same level of efficiency. Furthermore, the ability of cultured primary human microglia to phagocytose each Aβ conformation has not been investigated. In this study we investigated phagocytosis of fibrillar and soluble oligomeric Aβ by cultured primary human microglia. Microglia were isolated and cultured from postmortem human brains using protocols in routine use at our laboratory. Cells were seeded in multi-chamber slides and treated with 0, 2.5, 5 and 10 µg/100µL of fibrillar or soluble oligomeric Aβ conjugated to the 5-FAM fluorescent tag suspended in sterile BSA/RPMI (1mg/mL). The optical density of 5-FAM fluorescence in individual microglia was determined in triplicate experiments as a measure of Aβ phagocytosis. Both fibrillar and soluble oligomeric Aβ were phagocytosed by microglia in a dose-dependent manner. However, soluble Aβ oligomers were phagocytosed more efficiently than fibrillar Aβ. At every dose, optical density of 5-FAM soluble oligomeric Aβ was significantly greater than the control condition ($p<0.001$), while this difference reached significance only at the highest dose of fibrillar Aβ ($p<0.001$). Furthermore, at 5 and 10 µg/100µL concentrations, optical density of 5-FAM soluble Aβ oligomers were significantly

greater than fibrillar Aβ. 5-FAM fibrillar Aβ was often observed in clumps extracellularly, and apposed to microglia membranes. These findings indicate that human microglia phagocytose soluble Aβ oligomers much more readily when compared with fibrillar Aβ. Continuous interaction of extracellularly accumulating fibrillar Aβ with receptors on microglia membranes is likely to contribute to the inflammatory activation of microglia observed in AD.

Title: Strategies for studying the role of TREM2 in microglial phagocytosis using iPSC-derived "brain-in-a-dish" cell models

Authors: C. MUNN, M. K. LIVINGSTON, M. E. GOEDLAND, S. BURTON, S. HILCOVE, *C. B. CARLSON, W. W. POON, D. RAJESH;
FUJIFILM CDI, Madison, WI

Abstract: Microglia are immune cells that ordinarily maintain homeostasis in the brain; however, microglial dysfunction has been implicated in many neurodegenerative disorders, including Alzheimer's Disease (AD). Triggering Receptor Expressed on Myeloid Cells 2 (TREM2) has been identified as a novel potential therapeutic target for AD as it has been reported to regulate and alter the phagocytic function of microglia. Due to the limited availability of primary microglia, human induced pluripotent stem cell (iPSC)-derived microglia fill the critical gap for large-scale drug discovery applications. The present study focuses on the quantification of functional differences associated with TREM2 expression in an isogenic cellular system to identify the key regulators of phagocytic function of microglia. Cryopreserved iPSC-derived microglia from either an apparently healthy normal (AHN) donor or isogenic, gene-edited TREM2 knockout (KO) lines [both heterozygous (HZ) and homozygous (HO)] revealed altered kinetics of phagocytosis with bacterial particles and fibrillated amyloid beta. All three microglia lines were used to screen 32 different media conditions which identified two essential growth factors required for sustaining survival and amyloid beta phagocytosis. When grown in tri-culture with AHN iPSC-derived astrocytes and iPSC-derived neurons (both GABAergic and glutamatergic), microglia exhibited enhanced phagocytosis in tri-culture compared to mono-culture. These functional studies also illustrated that the consequences of TREM2 expression on phagocytic activity were dependent on the type of substrate, its concentration, and the media conditions used in the assay. These data underscore the power of

using iPSC-derived microglia to explore the role of TREM2 in neurodegenerative diseases and highlight the range of phenotypes observed with such “brain-in-a-dish” cell models.

Title: The dark microglial subset displays ultrastructural and metabolic alterations in an aged mouse model of beta-amyloid pathology

Authors: *M.-K. ST-PIERRE[1], M. CARRIER[1], F. GONZALEZ IBANEZ[1], E. SIMONCICOVA[2], M.-J. WALLMAN[3], L. VALLIÈRES[4], M. PARENT[3], M.-E. TREMBLAY[2]; [1]Univ. Laval, Quebec, QC, Canada; [2]Div. of Med. sciences, Univ. of Victoria, Victoria, BC, Canada; [3]Psychiatry and Neurosci., [4]Neurosciences, Laval Univ., Quebec, QC, Canada

Abstract: Recent technical advances helped to reveal the considerable heterogeneity of microglia, the resident immune cells of the central nervous system. One of these microglial subsets, the dark microglia (DM), was characterized by ultrastructural signs of cellular stress such as dilated endoplasmic reticulum (ER), altered mitochondria and loss of heterochromatin pattern. These dark cells were previously identified in middle-age wild-type (WT) controls as well as near amyloid beta plaques in age-matched APP-PS1 mice, a mouse model of amyloid beta deposition. However, their ultrastructural features and interactions with hallmarks of amyloid deposition (plaques, dystrophic neurites) were not yet investigated in aging. Using high-magnification chip mapping by scanning electron microscopy, we first analyzed the density of both typical and DM in the dorsal hippocampus CA1 (strata *lacunosum-moleculare* and *radiatum*) of 20-month-old male WT *versus* APP-PS1 mice. The density of DM per mm^2 profoundly increased in the APP-PS1 mice compared to WT controls, comprising nearly 20% of all microglial cells present in the *stratum lacunosum-moleculare*. We found DM interacting more with dystrophic neurites, while contacting less healthy synaptic elements, myelinated axons and brain vasculature compared to typical microglia. Moreover, DM possessed more dilated ER and

Golgi apparatus, as well as more mitochondrial alterations, alongside a cytoplasmic accumulation of glycogen granules. The present study further highlights the close interactions between DM and amyloid beta deposition hallmarks, suggesting a specialized involvement, whether beneficial or detrimental, compared to typical microglia in this context. Further investigations into the prevalence and parenchymal interactions of DM with Alzheimer's disease hallmarks will be performed in *post-mortem* brain samples from Alzheimer's patients and aged-matched controls. Studying DM close interactions with disease hallmarks could help us find new therapeutic targets modulating these cells in a context-dependent manner.

Abstract: Exposure to hypobaric hypoxia during extended stays at high altitude (HA) is known to cause maladaptive changes to brain physiology and function. HA compromises tissue oxygenation, which has serious implications for overall health and cognitive performance often lasting long after return to normoxic conditions. Previously, our mouse models have revealed enhanced angiogenesis and BBB leakage, increased microglial phagocytosis, and deficits in

hippocampal mediated behavior following HA. In our model, HA exposure is achieved by placing ~7 week old mice in a hypobaric chamber to a simulated altitude of 5000 m (10-11% O2, ~60% SpO2), with chronic exposures ranging 3-12 weeks. Here we assess the role of inflammation and neurovascular adaptive responses to HA. We identify significant increases in neurovascular structure through microCT imaging, with changes in average vessel diameter and tortuosity, along with region specific changes in BBB dysfunction. We also measured distinct regional differences in microglia movement dynamics through ex vivo 2-photon imaging of Cx3Cr1-GFP mice, showing an increase in process tip speed in response to laser ablation of microvasculature. These changes may be associated with variations in inflammatory cytokines (IL-6, TNFα) and increased expression of SDF-1α (involved in angiogenesis and microglia chemotaxis) in peripheral blood serum and brain homogenate samples. Increased levels of AQP-4 and cerebral arteriole pulsatility after HA corresponds to our EEG findings of decreased slow wave sleep and increased time awake, suggesting an impact of HA on glymphatics function. In summary, HA exposure significantly impacts neurovasculature and microglia interactions, leading to cognitive impairment with possible effects on glymphatic function. This is a serious health concern for those living and working at HA, and a potential risk factor for the development of neurodegenerative diseases.

Title: Sensory deprivation impacts microglia morphology and perineuronal net integrity in a manner that varies from that of chronic LPS challenge in early development

Authors: *A. BARRIENTOS[1], S. MROZIUK[2], A. LAHIJANI[3], J. C. BRUMBERG[2]; [1]Psychology, CUNY The Grad. Ctr., New York, NY; [2]Psychology, CUNY Queens Col., Flushing, NY; [3]New York Inst. of Technol., Old Westbury, NY

Abstract: Microglia are an integral part of the cellular constituents of the central nervous system with an indispensable role in the development and refinement of neuronal circuits during development. To date, limited studies focused on how microglia interact with the perineuronal

net (PNN), a neuron-associated form of the extracellular matrix in the developing brain. Using the barrel cortex as a model system, we examined how peripheral manipulations through chronic lipopolysaccharide (LPS) or minocycline administration alone or in conjunction with sensory deprivation impact microglia in the primary somatosensory cortex (S1). We also examined how microglia's reactive state as characterized by their morphology correlate to changes to the PNN in S1. C57BL/6 mouse litters were randomly assigned to be given intraperitoneal injections of saline, minocycline (a microglia inhibitor) or LPS (an inflammatory agent). A separate cohort of litters underwent sensory deprivation through whisker trimming in addition to receiving saline, minocycline or LPS. Pups received their assigned treatment from post-natal day 1 (P1) until P30. Microglia morphology, density and PNN density and integrity were examined using immunohistochemical (IBA1 was used to visualize microglia) and histochemical staining (WFA was used to visualize PNNs) and stereology. We tested the following hypotheses: (1) trimming coupled with LPS injection will interact synergistically resulting in fewer PNNs, and (2) minocycline will prevent microglia from becoming reactive and little to no impact will be observed to the PNN. We found that microglia morphology is impacted in a treatment-specific manner. Minocycline results in hyper ramification of microglial processes, while LPS resulted in smaller microglia somas and retracted processes. Sensory deprivation tapers these effects. LPS in conjunction with sensory deprivation results in a reduction of PNN density and diminished staining intensity. Female mice had fewer PNNs in S1 following sensory deprivation relative to males. Sensory deprived mice had reduced surface area of WFA+ somas relative to controls and those of minocycline and LPS-treated mice. A regression analysis shows that microglia density as well as specific morphological features correlated with fewer PNNs following sensory deprivation. Both minocycline and LPS treatment disrupt this relationship. Taken together, these studies suggest that sensory deprivation may render the developing brain more vulnerable to factors that influence microglia activity which may be related to PNN maturation.

Title: Apoe genotype and sex modulate lipid droplet accumulation in microglia

Authors: *T. IIDA, C. J. PIKE;
Leonard Davis Sch. of Gerontology, USC, Los Angeles, CA

Abstract: *APOE* genotype and sex modulate lipid droplet accumulation in microglia
T. Iida, C.J. Pike
Microglia are key immunomodulators of Alzheimer's disease (AD) pathogenesis. Biological sex and apolipoprotein E (*APOE*) genotype are significant regulators of not only AD risk, but also microglial phenotypes including those implicated in AD. Sex and *APOE* genotype also affect lipid profile and metabolism. Indeed, as high plasma lipid levels are associated with AD progression, higher plasma neutral lipids in *APOE4* carriers may contribute to *APOE4*-associated AD risk. Recently, accumulation of neutral lipids in the form of lipid droplets (LDs) has been observed within microglia in aging and AD brains and associated with impaired microglial function and altered transcriptomic profile. These findings suggest the modulation of microglial lipid metabolism may be highly relevant to understanding AD pathogenesis and developing interventions. Unknown is how *APOE* genotype and biological sex affect LD accumulation in microglia and the functional consequences of these relationships. To investigate these issues, we utilized primary microglia cultures generated from young adult (age 3-4 months) male and female mice homozygous for knock-in of human *APOE3* or *APOE4*. Since lipid metabolism varies among different sex and *APOE* genotypes, first we examined LD accumulation using the neutral lipid stain BODIPY under basal conditions and following stimulation with palmitic acid (PA) or lipopolysaccharide (LPS). Next, because LDs act as a form of energy storage and can have a protective role during cellular stress, we measured LD content and cell survival under starving stress conditions. Third, as lipid metabolism is strongly correlated with amyloid β (Aβ) clearance, we evaluated the relationship between LD content and clearance of oligomeric A β under basal conditions and following stimulation with PA or LPS. A range of individual and interactive outcomes were obtained across *APOE* genotypes and sex with a common theme of increased LD levels and poorer functional outcomes with *APOE4* and female sex. These findings provide new insight into the roles of *APOE* genotype and biological sex in AD risk with respect to regulation of microglial lipid metabolism and function.

Title: Estrogen deficiency in mice sensitizes hippocampal microglia to an immune challenge and alters behaviors

Authors: *K. SANCHEZ, S. L. WU, R. KAKKAR, J. S. DARLING, C. S. HARPER, R. CHEN, L. K. FONKEN;
The Univ. of Texas at Austin, Austin, TX

Abstract: Estrogen deficiency in women is linked to a heightened susceptibility to the development of mood disorders; indeed, oophorectomized women are 36% more likely to suffer from depression. Estrogens may exert neuroprotective effects by acting on microglia, the primary immune cell in the brain, and inhibiting neuroinflammation. Our objective was to determine the microglia-specific mechanisms through which estrogen deficiency alters neuroinflammatory responses, increasing susceptibility to behavioral deficits in a rodent model. C57BL/6 mice underwent either a bilateral ovariectomy or sham operation and received estradiol replacement or vehicle of sesame oil every four days to mimic their estrous cycle. After one month, mice were injected with saline or lipopolysaccharide (LPS) to stimulate an immune response. Our results indicate that ovariectomized mice tended to have greater anxiety-like behaviors and displayed exaggerated sickness anhedonia that was rescued by estradiol replacement. Iba1 immunoreactivity and microglia density in the hippocampus were elevated in estrogen-deficient mice; however, soma-specific features suggestive of microglia activation were not altered by estrogens. This was accompanied by exacerbated expression of the pro-inflammatory cytokine *Il6* after an immune challenge that was blocked by estradiol replacement. Moreover, *Cx3cr1* and *Trem2* (microglial receptors that maintain quiescence and limit activation) were downregulated at baseline in estrogen-deficient mice, indicating that estrogen loss may sensitize microglia to immune stimuli. Collectively, these results suggest that lack of estrogens may regulate microglia to confer exaggerated neuroimmune responses, thereby raising vulnerability to social- and anxiety-related behavioral changes. Since most women undergo permanent loss of ovarian function at some point in their lives, it is essential to uncover the neuroimmune mechanisms by which declining estrogen levels impact behavior.

Title: Microglial 3D reconstruction indicates subtle shifts in morphology following repeated binge ethanol exposure in female adolescent rats

Authors: *J. MELBOURNE[1], K. NIXON[2];
[1]Pharmacol. & Toxicology, Univ. of Texas At Austin, Austin, TX; [2]Pharmacol. & Toxicology, The Univ. of Texas at Austin, Austin, TX

Abstract: Adolescence is a critical developmental window during which time the brain is particularly sensitive to alcohol (EtOH) insult. EtOH exposure damages the adolescent brain and leads to activation of the neuroimmune system, including microglia. Microglia play critical roles in brain homeostasis, ongoing developmental processes such as synaptic refinement, myelination, and neurogenesis, as well as response to tissue injury. Microglia also exhibit innate immune memory such that ongoing functionality is impacted by prior stimuli, and our *ex vivo* studies indicate that ethanol induces a "primed" microglial state. While the literature suggests that females may be more sensitive to the neurotoxic effects of ethanol, most research has been carried out in males. Here, female adolescent rats (PND 30) were exposed to either a single or double ethanol binge, and alterations to microglial morphology were quantified. Rats in the single binge group (CE) were gavaged with isocaloric control diet every 8 h for 2 days (modified Majchrowicz model), allowed to recover for 7 days, and then gavaged with 25% (w/v) ethanol diet for a further 2 days. The double binge group (EE) received ethanol diet in both binges, and the remaining group control diet (CC), throughout. Tail bloods were collected immediately following each binge, with mean blood ethanol concentrations of 316.9 ± 13.0 mg/dl that did not differ significantly between groups. Following the last gavage rats were transcardially perfused with phosphate buffered saline and brains post-fixed in paraformaldehyde, sectioned at 4μm on a vibrating microtome, and fluorescence immunohistochemistry performed for microglia-specific marker, IBA1. Images from the dorsal dentate gyrus (molecular layer) and peri-/entorhinal cortices were acquired with a laser scanning confocal microscope (Olympus FV3000), and 3D reconstructed and analyzed using Imaris (Bitplane). Analyses included individual microglial volumetric and branching measurements. Results demonstrated an exposure-dependent decrease in microglial sphericity and a trend towards increase in total branch length and points with repeated ethanol exposure, though shifts in morphology were subtle. These results indicate subtle morphological changes to microglia following binge exposure in female adolescent rats, specifically hyper-ramification, and suggest a cumulative effect of repeated binge exposure consistent with priming. Alterations to microglial functionality may contribute to developmental perturbations following binge ethanol exposure in adolescents.

Abstract: Microglia play an important role in the maintenance of homeostasis in the CNS, and microglial dysregulation has been associated with the development and maintenance of chronic pain. However, the relevant molecular pathways remain poorly defined. In this study, we used a high-resolution mass spectrometry-based proteomic approach to globally profile histone protein modifications in microglia isolated from control and neuropathic pain mice. We identified several novel histone modifications including significantly decreased histone 3 lysine 27 mono-methylation and lysine 56 tri-methylation, as well as histone 3 tyrosine nitration associated with pain. Treatment of cultured microglia with an inhibitor of lysine demethylase 7A which is responsible for the demethylation of histone 3 lysine 27 mono-methylation significantly elevated its levels. Treatment of mice with neuropathic pain with the same inhibitor of lysine demethylase 7A markedly alleviated experimental pain in the mice. The identification of specific chromatin marks in microglia associated with chronic pain may yield critical insight into the contribution of glial cells to the development and maintenance of pain, and open new avenues for the development of novel therapeutics for effective management of chronic pain.

Abstract: Spinal cord injury (SCI) is a devastating condition affecting 17,500 people per year with no FDA approved treatments. In the USA, nearly 253,000 people suffer from disabilities related to SCI, with annual medical costs exceeding $9.7 billion. SCI pathophysiology is a complex phenomenon and involves a multitude of orchestrated cellular players including blood derived macrophages and resident microglia. These immune cells serve multiple functions such as phagocytosis of cellular debris, inflammation involvement, generation of reactive oxygen/nitrogen species, and secretion of growth factors. It has been suggested that promoting the anti-inflammatory (pro-healing) macrophage/microglia phenotype within the post-injured microenvironment may be beneficial for mitigating tissue degeneration and improving functional recovery. Previous findings in wound healing research have shown that lipid nanoparticles containing galactose-alpha-1,3-galactose (α-gal) antigen can recruit and activate blood-derived macrophages to the injection site via the complement pathway. Recruited macrophages produced VEGF and dermal wounds demonstrated faster, scar-less healing. In this work, we use human microglia HMC3 cells as a model to determine whether a-gal based nanoparticles can similarly transform quiescent microglia towards a pro-healing phenotype. Early results indicates that α-gal nanoparticles (when activated with serum) increase CD68 expression in resting HMC3 cells. Morphological analysis of these cells show greater elongation and larger total cell area vs controls. a-gal treated HMC3 cells further increased CD206 and arginase expression. Functionally, the α-gal exposed cells produced less pro-inflammatory cytokines (TNF-α and IL-6) compared to cells incubated with IFN-γ. The cumulative results suggest that like their blood derived macrophage counterparts, CNS microglia exposed to activated α-gal nanoparticles may induce activation to a pro-healing state. These implications may justify using a-gal nanoparticles as a therapeutic for SCI.

Abstract: Patients with severe COVID-19 illness may become critically ill with the development of acute respiratory distress syndrome (ARDS). The aim of this study was to investigate the involvement of the nervous system in the regulation of immune responses, and how chronic airway inflammation may be altered by the application of the $TRPV_1$ receptor agonist capsaicin. We used the ARDS model induced by lungs hyperventilation with poly-I:C 15 mg/kg in 6 month-old male Wistar rats. After anesthesia and subdiaphragmatic vagotomy single-unit activity was recorded in the cervical vagus nerve of mechanically ventilated animals. The first three groups were mechanically ventilated with a high tidal volume of 35 ml/kg –Vt35 (hyperventilation) for 4 hours. Group I: rats were administered poly I:C by intratracheal injection before hyperventilation; capsaicin 20 μg/kg was injected in a venous catheter near the right atrium after two hours of hyperventilation. Group II: hyperventilation with poly I:C. Group III: only hyperventilation. Group IV: control group was mechanically ventilated with a fixed tidal volume of 10 ml/kg and for 4 hours. All rats were sacrificed after the experiment and lungs were preserved for immune and histology study. Primary afferents were classified into “regular” and “irregular” according to the pattern of their activity. The control group with constant normoventilation showed a constant frequency of spike discharges (3.48 ± 0.91) during the experiment. The activities of nerve fibers for Group I, II and III at control conditions before hyperventilation were 1.7 ± 0.6 (n = 20), 0.41 ± 0.17 (n = 16) and 8.34 ± 2.15 (n = 20) imp/sec respectively. Hyperventilation resulted in significant growth spike discharges frequency in all primary afferents for Group I, II, and III compared to control: to 6.68 ± 1.73, 3.35 ± 0.87 and 19.42 ± 3.99 imp/sec ($p < 0.05$). And not recovered to control values after a stop of hyperventilation and were for Group I, II and III: 6.12 ± 1.49, 2.42 ± 0.71 and 20.47 ± 5.12 imp/sec respectively ($p < 0.05$). Capsaicin (2 μM/kg) evoked action potential discharge of 100% (11/11) of tested vagal afferents with irregular activity, and only one (1/9) afferent with regular activity was activated by capsaicin 20 μg/kg during hyperventilation. Our data have shown that long-time lungs hyperventilation is the main excitatory factor for primary afferents. Capsaicin (20 μM/kg) evoked action potential discharge of 55% (11/20) of vagal afferents but does not have a noticeable effect on the excitability of nerve fibers during hyperventilation.

Title: Activation of spinal GPR109A attenuates spinal neuroinflammation and chronic pain in a lupus mouse model

Authors: *H.-R. WENG[1], V. VIATCHENKO-KARPINSKI[2], L. KONG[3];
[1]Sch. of Med., Macon, GA; [2]Biomed. Sci., Mercer Univ., Macon, GA; [3]Mercer Univ. Sch. of Med., Macon, GA

Abstract: Many patients with systemic lupus erythematosus (SLE) live with chronic pain despite advances in medical management in reducing mortality related to SLE. Few animal studies have addressed mechanisms and treatment for chronic pain caused by SLE. In this study, we provide the first evidence for the analgesic effects of a GPR109A specific agonist (MK1903) and its action mechanisms in chronic pain in female MRL/lpr mice, an SLE mouse model. We show that MRL/lpr mice at age 11 to 16 weeks had a higher sensitivity to heat stimuli. This was accompanied with significant microglial activation, increases in p38 MAPK and glutamatergic synaptic activities in the spinal dorsal horn. We demonstrate that chronic pain in MRL/lpr mice was significantly attenuated by intrathecal injection of MK1903. Activation of GPR109A receptors attenuated glutamatergic synaptic activity via suppressing production of interleukin-18 (IL-18). We provide evidence that activation of GPR109A attenuated chronic pain in the SLE animal model via suppressing p38 MAPK activity and production of IL-18. Our study suggests that targeting GPR109A is a potent approach for reversing spinal neuroinflammation, abnormal excitatory synaptic activity, and management of chronic pain caused by SLE.

Title: Behavioural comparison of the UVB model of sterile inflammatory pain between Wistar rats and C57BL/J mice

Authors: *A. DAVID-PEREIRA, C. MILLUM, C. TAYLOR;
Transpharmation Ltd, Sandwich, United Kingdom

Abstract: Acute over-exposure of skin to ultraviolet (UV)-B radiation (as frequently occurs following sunburn) has emerged as a highly translatable pain model inducing both thermal and mechanical hyperalgesia in rats and humans (Bishop et al., 2007, 2009, 2010). This model is characterised by transient sensory alterations with peak effect between 24-48h post irradiation (Davies et al., 2011) that start to resolve 72h post exposure. The rat model developed by Bishop and colleagues closely mimics the hypersensitivity observed in the clinical setting and allows investigation of altered sensory and neurogenic effects in vivo. The aim of this study was to compare the effects of increasing intensities of UVB irradiation in thermal and mechanical hyperalgesia in Wistar rats and C57BL/J mice. Additionally, we tested the effect of acute oral treatment in thermal hyperalgesia and mechanical allodynia.
Studies were conducted in accordance with the UK Animals (Scientific Procedures) Act 1986. Under isofluorane anesthesia, the plantar area of adult male Wistar rats was exposed to 500, 750 and 1000mJ/cm^2 with UVB light (n=27); adult male C57BL/J mice were irradiated with 500, 1000 and 1250mJ/cm^2 (n=26). Mechanical allodynia and thermal hyperalgesia were measured using von Frey hairs and a hot plate, respectively. Hypersensitivity was measured before and on days 1, 2, 4 and 7 after UVB exposure. The effect of orally dosed naproxen (20mg/kg; n_{rats}=9) and indomethacin (10mg/kg; n_{mice}=9) as well as of the TRPV1 antagonist, SB366791 (0.5mg/kg; n_{rats}=9; n_{mice}=8), were assessed on day 2.
Overall, all the tested intensities were effective in reducing the mechanical and thermal thresholds of rats (mechanical $ANOVA_{RM}$, time: $F(20,398)=2.680$, $p<0.0001$; intensity: $F(5,398)=19.68$, $p<0.0001$; thermal $ANOVA_{RM}$, time: $F(4,206)=42.87$, $p<0.0001$; intensity: $F(2,206)=0.7771$, $p=0.4611$) and mice (mechanical $ANOVA_{RM}$, time: $F(4,243)=53.40$, $p<0.0001$; intensity: $F(2,243)=1.193$, $p=0.3050$; thermal $ANOVA_{RM}$, time: $F(4,282)=59.16$, $p<0.0001$; intensity: $F(2,282)=1.213$, $p=0.2990$), an effect that peaked 48h after the exposure to UVB and lasted until at least 4 days after UVB exposure. Post-hoc tests show that both pharmacological approaches significantly reversed mechanical allodynia in both rats and mice. However, only the TRPV1 antagonist, but not naproxen or indomethacin, was significantly effective in treating thermal hyperalgesia 48h after induction. These results point to a lack of efficacy of standard gold anti-inflammatory drugs in an important part of the profile of this particular model of sterile inflammatory pain and the need to develop targeted treatments for different pathologies.

Title: Longitudinal in vivo imaging and characterization of neuroinflammation after repetitive mild traumatic brain injury (mTBI) and its role in long-term pain.

Authors: *T. NGUYEN[1], A. COCHRAN[3], S. TALLEY[4], E. CAMPBELL[5], F. A. WHITE[2]; [2]Dept. of Anesthesia, [1]Indiana Univ. Sch. of Med., Fishers, IN; [3]Psychological Sci., Purdue Univ., West Lafayette, IN; [4]Integrative Cell Biol., Loyola Univ., Chicago, IL; [5]Cell Biology, Neurobio. and Anat., Loyola Univ. Chicago, Maywood, IL

Abstract: Repetitive mild traumatic brain injury (mTBI) constitutes a major global health problem with neuropathological/behavioral sequelae contributing to long-term post traumatic pain (pTP). The prolonged neuroinflammation observed with mTBI is still poorly understood. To better understand the sequela of neuroinflammation following mTBI, we are assessing the degree to which inflammasomes contribute to the pathological response. The downstream events of this activating complex is known to initiate auto-activation of caspase-1 and consequent maturation of caspase-1 target molecules such as interleukin (IL)-1β and IL-18. In this study, we assessed the longitudinal changes of inflammasome activation in real-time by performing in vivo bioluminescence imaging (IVIS) of caspase1-activated-luciferase reporter mice. These mice were subjected to skull thinning and three repetitive controlled cortical impact (CCI) injuries separated by one week. First, we found an overall significant increase in caspase-1 activation after each mTBI, and this inflammatory enhancement was sustained for at least one month after three injuries. Second, we found greater lipopolysaccharide (LPS) – induced caspase-1 activation in injured mice cortical slices ex vivo compared to sham control. Furthermore, we also observed significant increases in astrocytic and microglial activation in these mice up to at least one week after the third mTBI. Pain behavioral assessments shows robust decrease in pain threshold (i.e. increased pain sensitivity) through Von Frey testing after three mTBIs, and this enhancement in pain sensitivity was sustained for almost two months post injury. There are also significant differences in inflammasome activation based on gender following the injury paradigm. Males were observed to exhibit rapid onset of caspase-1 activation following the first injury and a return to baseline one month after third mTBI. Female mice, exhibit reduced levels of caspase-1 activation following the first and second trauma events. However, caspase-1 activation levels were greatly enhanced after third mTBI and remained elevated for at least one month. Taken together, caspase-1 luciferase reporter mice, provide a unique tool to monitor neural inflammatory changes over time following cranial trauma. Our preliminary observations provide insights into the gender-specific responses which accompany repetitive mTBI-induced neuroinflammation, and its associated pain behaviors. Overall, this study provides a significant step in advancing our understanding of the short-term and long-term trauma-associated inflammatory events, which may contribute to mTBI-associated pTP.

Title: The role of resolvins in chronic pain

Authors: *N. WONG[1,2], D. W. LAMBERT[1,2], F. M. BOISSONADE[1,2];
[1]Sch. of Clin. Dent., [2]The Neurosci. Inst., Univ. of Sheffield, Sheffield, United Kingdom

Abstract: A series of findings suggests that resolvins, a class of molecules derived from omega-3 fatty acids, are instrumental in the active process of terminating inflammation. Recent studies have also shown that resolvins can alleviate pain symptoms in pre-clinical models, demonstrating their therapeutic potential in chronic pain. Since resolvins are naturally occurring and are produced endogenously, they may cause fewer adverse side effects than other therapeutics. Thus, resolvins have potential as pain therapeutics, and may help to address the unmet clinical need for effective and safe pain medications. Therefore, this study aimed to explore the role of resolvins in chronic pain, and how they interact to reduce inflammation and pain.

Dental caries can lead to inflammation in the tooth pulp and spontaneous pain, but not all patients with carious teeth report symptoms of pain. By comparing resolvin receptor expression in human tooth pulp tissues from patients with and without pain via immunohistochemistry, we hope to identify resolvin receptors that may be relevant to pain.

The specificity of antibodies we used was first evaluated using human umbilical vein endothelial cells (HUVECs), which have been previously shown to express the resolvin receptors BLT1, GPR32, ChemR23, and ALX/FPR2. The presence of BLT1, GPR32, and ChemR23 transcripts in HUVECs was confirmed using qPCR, and clear, positive immunocytochemical labelling for these receptors was present in the cells. BLT1 protein expression was also identified in HUVECs by western blot. To further validate BLT1 antibody specificity, immunocytochemistry and western blot assays were repeated after knocking down BLT1 expression in HUVECs via siRNA transfection. A significant reduction in BLT1 expression was observed compared with cells transfected with negative control non-targeting siRNA and mock transfection control, showing that the antibody is specific to BLT1.

The correlation between resolvin receptor expression and inflammation and pain in human tooth pulp tissues was then explored. To date, we have identified expression of BLT1 and GPR32 in human tooth pulp tissues using immunohistochemistry, and examined BLT1 expression in detail. BLT1 was found in blood vessels and nerve fibres, and further studies were conducted to quantify BLT1 expression in different groups of tooth pulp tissues. BLT1 expression in tissues from the carious painful group (n=11) was found to be significantly higher ($p<0.05$) than that

from the carious non-painful group (n=11), indicating that BLT1 may have a role in inflammatory pain. Ongoing work is examining BLT1 labelling in blood vessels and nerve fibres in human tooth pulp tissues.

Title: Ketamine normalizes high-gamma power in the anterior cingulate cortex in a rat chronic pain model

Authors: *Q. ZHANG, I. FRIESNER, E. MARTINEZ, H. ZHOU, J. GOULD, A. LI, G. SUN, Z. CHEN, J. WANG;
NYU Sch. of Med., New York, NY

Abstract: Chronic pain alters cortical and subcortical plasticity, causing enhanced sensory and affective responses to peripheral nociceptive inputs. Previous studies have shown that ketamine had the potential to inhibit abnormally amplified affective responses of single neurons by suppressing hyperactivity in the anterior cingulate cortex (ACC). However, the mechanism of this enduring effect has yet to be understood at the network level. In this study, we recorded local field potentials from the ACC of freely moving rats. Animals were injected with complete Freund's adjuvant (CFA) to induce persistent inflammatory pain. Mechanical stimulations were administered to the hind paw before and after CFA administration. We found a significant increase in the high-gamma band (60-100 Hz) power in response to evoked pain after CFA treatment. Ketamine, however, reduced the high-gamma band power in response to evokedpain in CFA-treated rats. In addition, ketamine had a sustained effect on the high-gamma band power lasting up to five days after a single dose administration. These results demonstrate that ketamine has the potential to alter maladaptive neural responses in the ACC induced by chronic pain.

Title: Changes in the dendritic spine density of the cortical neurons triggered by inflammatory pain

Authors: *E. DIMITROV, A. PAPADOGIANIS;
RFUMS, North Chicago, IL

Abstract: Background: The medial prefrontal cortex (mPFC) plays a major role in cognitive processes. Pain-associated impairment of cognitive functions is well established phenomenon but interestingly, female rodents are less affected. One possible explanation for pain-associated cognitive impairment is that pain alters the neuronal plasticity in the mPFC, as expressed by changes in the synaptic density of cortical neurons. Here, we compared the effect of inflammatory pain on the dendritic spine density of cortical neurons in male and female mice. Methods: Injection of Complete Freund's Adjuvant (CFA) into the hind paw served as a model for inflammatory pain. The neuronal soma, dendrites and spines were developed following Golgi-Cox impregnation. Microscopic Z-stack images at 100X magnification were collected bilaterally from the mPFC and were analyzed by ImageJ software. First, the neurons were categorized as pyramidal or interneurons according to their distinguish shape, size and dendritic arbor. The dendritic spines were counted on sections from third and fourth order dendrites. The spines were placed into 5 groups: mushroom, stubby, thin, long or branched. The counts of one to five dendrites per neuron on three to five neurons per animal were averaged by two independent observers in blind manner. Results: The CFA injection into the hind paw decreased the thermal threshold in both male and female mice. However, the CFA injection increased the dendritic spine density of the pyramidal neurons only in male mice. The increase of spine density was equal across different spine types. The CFA injection also increased the dendritic spine density of the interneurons in the mPFC of male mice, again without significant difference between the density of specific spine types. The CFA injection did not change the dendritic spine density of the pyramidal neurons in the mPFC of female mice but the injection did increase the spine density of the interneuronal dendrites. Again, as in males, the increase was equally distributed among the different spine types. Conclusion: Very likely, the resilience of female rodents to some of the deleterious cognitive effects of inflammatory pain relies on the unaltered spine density of the mPFC pyramidal neurons.

Title: Sex-dependent effects of alcohol on inflammatory pain and limbic system neuroadaptations in the context of pain

Authors: *J. A. CUCINELLO-RAGLAND, L. C. GOLD, S. EDWARDS, K. N. EDWARDS; Dept. of Physiol., Louisiana State Univ. Hlth. Sci. Ctr., New Orleans, LA

Abstract: Although a high percentage of both chronic pain patients and high-risk alcohol drinkers consume alcohol to manage their pain, there is a significant gap in knowledge regarding the mechanisms underlying the anti-nociceptive effects of alcohol. Previous findings from our lab suggest that the anti-nociceptive efficacy of alcohol may change over time in the context of chronic pain. The goals of the current project were to determine the longitudinal effects of alcohol on chronic pain and identify neuroadaptations associated with alcohol-induced anti-nociception. We utilized the complete Freund's adjuvant (CFA) model of inflammatory pain in adult female and male Wistar rats. Both nociceptive and negative motivational aspects of pain were measured using electronic von Frey (mechanical nociception), thermal probe test (thermal nociception), and mechanical conflict avoidance task (pain avoidance-like behavior). All behavioral tests were conducted at baseline and 1 and 3 weeks following intra-plantar CFA or saline administration. At both time points post-CFA, animals were treated with each of 3 doses of alcohol (intraperitoneal; 0g/kg, 0.5g/kg, 1g/kg) over separate days in a Latin square design. Alcohol produced dose-dependent analgesia in females but only modest anti-hyperalgesia in males. Consistent with clinical findings, only males displayed increased pain avoidance-like behavior, and this was most effectively attenuated by alcohol 1 week post-CFA. Although alcohol continued to attenuate CFA-induced decreases in both thermal and mechanical nociceptive thresholds in males 1 and 3 weeks post-CFA, females appeared to develop tolerance to these effects 3 weeks post-CFA. A separate cohort of rats was generated using these parameters to determine alterations in endocannabinoid (eCB) and glucocorticoid system-related protein levels in limbic regions, including the basolateral amygdala (BLA), central amygdala (CeA), and cingulate cortex. Western blot analysis revealed that alcohol differentially affects BLA and cingulate levels of the eCB synthetic enzyme diacylglycerol lipase-α (DAGLα) only in females. Preliminary data also suggests that alcohol decreases CeA glucocorticoid receptor (GR) phosphorylation only in control females, but not their CFA-treated counterparts. These findings will help elucidate the mechanism of analgesic action of alcohol in the context of chronic inflammatory pain states across sexes.

Title: The impact of neural activity on immune cell profile in the mouse colon

Authors: *A. EPOUHE[1], B. M. DAVIS[2], K. M. ALBERS[3];
[1]Univ. of Pittsburgh Ctr. For Neurosci., Pittsburgh, PA; [2]Dept. of Neurobio., Univ. of Pittsburgh, Pittsburgh, PA; [3]Dept Neurobio., Univ. of Pittsburgh Dept. of Neurobio., Pittsburgh, PA

Abstract: The impact of neural activity on immune cell profile in the mouse colon
A.Y. Epouhe, B.M. Davis and K.M. Albers
Pain detecting sensory neurons are now recognized as contributors to the body's immune response under normal physiological and pathological conditions. In the colon, dysregulation of this communication is thought to contribute to the chronic and recurring inflammatory conditions of the gut evident in inflammatory bowel disorders (Crohn's and colitis). In this exploratory study we are using optogenetic strategies to probe how nerve activity impacts immune cell populations in the distal colon. Recent studies using pharmacological agonism and chemical ablation strategies have demonstrated the capacity of visceral nociceptors to sense bacteria and modulate the inflammatory response. These approaches provide new but limited insight into whether sensory afferents have a direct or indirect role in these processes. To address this issue, we are using mice that express the light-activated channelrhodopsin (ChR2) protein under control of the TRPV1 or MrgD promoter. Targeted optogenetic activation of sensory afferents that innervate the distal colon is done *in situ* using a fiberoptic probe inserted into the distal colon. Colon tissue is then isolated from stimulated mice and analyzed using immunolabeling of sectioned swiss roll and whole mount colon tissue to determine the relative number and location of MHCII+ antigen-presenting cells and CD3+ T cells in the colon tissue. Analysis of changes in muscle thickness and opposition of fibers to immune cells are also taken to assess signs of inflammation and association between neurons and immune cells. Comparison of two groups of mice is being done: Group 1 mice express ChR2 in TRPV1+ or MrgD+ neurons and receive optogenetic stimulation and Group 2 mice that express ChR2 in TRPV1+ or MrgD+ neurons but do not receive optogenetic stimulation. Mice utilized for these experiments were on a C57/Bl6 background and were between 8-24 weeks old. Both male and female mice were included for

analysis, but sex differences were not assessed. Mice were stimulated for two 30 min sessions, with 2 hour breaks, over with a final 2 hour break prior to tissue collection. Initial results indicate that light stimulation of TRPV1+ colon afferents decreases the number of MHCII+ cells in the lamina propria of the colon, based on level of analysis with little or no change in CD3+ cell number. This suggests that acute TRPV1 stimulation may lead to MHCII+ cell migration in the distal colon. These studies were supported by NIH grant 5R01AR069951 and R01DK122798.

Title: Quantitative sensory testing in hidradenitis suppurativa could provide insight into pain mechanisms

Authors: A. M. ALSOUHIBANI[1,3], J. R. BARRON[2], M. GUNTER[1], O. G. HOEKENDIJK[1], P. SPECK[2], E. F. COLE[2], L. A. V. ORENSTEIN[2], *D. E. HARPER[1];
[1]Dept. of Anesthesiol., [2]Dept. of Dermatol., Emory Univ., Atlanta, GA; [3]Physical Therapy, Qassim University, Col. of Med. Rehabil. Sci., Buraydah, Saudi Arabia

Abstract: Hidradenitis suppurativa (HS) is a chronic inflammatory skin disease that is characterized by recurrent nodules, abscesses, and scarring tunnels. Most people suffering from HS report moderate or worse pain, contributing to reduced quality of life. The aim of our study was to determine the primary mechanism underlying the pain in individuals with HS using quantitative sensory testing (QST).
QST was performed in individuals with HS using the standardized protocol by the German Research Network on Neuropathic Pain (DFNS). The skin locations tested by QST included: (1) the dorsal hand (control site), (2) an actively inflamed HS lesion, and, if present, (3)a non-inflamed HS lesion. The tests included were cold, warm, and mechanical detection thresholds (CDT, WDT and MDT); cold, heat, and mechanical pain thresholds (CPT, HPT and MPT); thermal sensory limen (TSL); paradoxical heat sensations (PHS); pressure pain thresholds (PPTs); dynamic mechanical allodynia (DMA); mechanical pain sensitivity (MPS); and windup ratio (WUR).
Seven individuals with HS (age=39.7±12.5 years; 5 women) diagnosed by a dermatologist participated in the study. A total of 10 skin locations were tested by QST - 5 draining tunnels (inflamed), 2 scarred nodules (non-inflamed), 1 inflammatory nodule, 1 non-inflamed tunnel, and 1 perilesional site(s). The frequency of participants who had abnormal QST values (defined as a value greater than 95% confidence interval of the reference data) at the control site are as

follows: Hyperalgesia (gain of function): WUR = 2/7 (29%), MPS = 4/7 (57%), DMA = 3/7 (43%), PPTs = 3/7 (43%); Hypoesthesia (loss of function): WDT = 1/7 (14%), CDT = 1/7 (14%). All other measures (i.e., MPT, TSL, CPT, HPT, PHS) were within normal range. One participant (14%) reported paradoxical sensations at an inflamed location (draining tunnel). Also, a high frequency of abnormalities in the thermal sensory limen (TSL), indicative of small fiber loss, were found: 5/6 (83%) at the inflamed location and 3/4 (75%) at the non-inflamed location. Preliminary results suggest that peripherally, at the affected skin, a neuropathic component could play a major role in the perception of pain. However, the pain experienced by a subset of individuals may involve more than the pathology at the skin lesion and could be characterized as nociplastic. Other aspects such as descending inhibitory pathways should be investigated in future studies.

Title: Unlocking the behavioral signatures of inflammatory pain at millisecond resolution with supervised and unsupervised feature extraction

Authors: A. JHUMKA[1], ***W. FOSTER**[1], N. MOSSAZGHI[2], E. A. YTTRI[2], I. ABDUS-SABOOR[1];
[1]Columbia Univ., New York, NY; [2]Carnegie Mellon Univ., Pittsburgh, PA

Abstract: Chronic pain accounts for up to 20% of physician visits and as many as two thirds of patients are unsatisfied with current treatments. While humans can describe their pain levels both qualitatively and quantitatively, studies on pain in rodents have long relied on assays providing incomplete behavioral information. Discovering effective analgesics therefore depends on our ability to provide more objective and comprehensive measurements of pain in laboratory animals. To that end, we combine automated paw tracking with two statistical software platforms

to extract pain-related behavioral features in mice. PAWS (Pain Assessment at Withdrawal Speeds), uses a univariate projection of hind paw center position over time to automatically quantify predefined behavioral features of the hind paw withdrawal response. BSOiD (Behavioral Segmentation of Open-field In DeepLabCut) is an unsupervised learning algorithm that reveals and classifies behavioral features which are not user-defined by performing novel expectation maximization fitting of Gaussian mixture models on t-Distributed Stochastic Neighbor Embedding (t-SNE). In combination, these approaches generate a complete and intuitive description of hind paw withdrawal behavior on a trial-by-trial basis. While we previously described the behavioral signatures of acute evoked pain with PAWS, the signatures of inflammatory pain remained elusive. Here, we use PAWS and BSOiD to determine the behavioral signatures of carrageenan induced inflammatory pain and subsequent treatment with a nonsteroidal anti-inflammatory drug (meloxicam) in n=10-20 male C57BL/6J mice. With PAWS, we find that carrageen elicits changes in behavior indicative of increased mechanical sensitivity and that subsequent treatment with meloxicam tempers this increase in a behavior-feature specific fashion. With BSOiD, we make a novel distinction between angled and flat hind paw guarding behavior, which are selectively upregulated during mechanical allodynia and mechanical hyperalgesia respectively. To date, this measurement is the only specific behavioral readout that distinguishes between mechanical allodynia and hyperalgesia. Thus, our methods provide a framework to rigorously assess pain-related behaviors, and pain sensation by proxy, in multitudes of experimental paradigms.

Title: Inference of a common cause for body ownership takes trial-to-trial sensory uncertainty into account

Authors: *M. CHANCEL[1], H. H. EHRSSON[1], W. MA[2];
[1]Karolinska Inst., Stockholm, Sweden; [2]Ctr. for Neural Sci. and Dept. of Psychology, New York Univ., New York, NY

Abstract: How do we perceive the fundamental distinction between the physical self and the external world, and how do we come to sense that an object in view, for example, a hand, is part of our own body or not? Over the past two decades, many studies have investigated the contributions of vision, touch, and proprioception to the sense of body ownership, i.e., the multisensory perception of limbs and body parts as our own. However, the processes involved in subjectively experienced body ownership have only been qualitatively described, and the computational principles that determine such sensations remain unclear. To address this issue, we developed a detection-like psychophysics task based on the classic rubber hand illusion paradigm where participants were asked to report whether the rubber hand felt like their own (the illusion) or not. We manipulated illusion strength by varying the asynchrony of visual and tactile stimuli delivered to the rubber hand and the hidden real hand under different levels of visual noise. We found that (1) the probability of the emergence of the rubber hand illusion increased with the addition of visual noise and was well predicted by a causal inference model involving the observer computing the probability of the visual and tactile signals coming from a common source; (2) the causal inference model outperformed a non-Bayesian model involving the observer not taking into account sensory uncertainty; and (3) by comparing the casual inference of ownership and visuotactile synchrony detection, we found that the prior probability of inferring a common cause for the two types of multisensory precepts was correlated but greater for ownership, which suggests that individual differences in rubber hand illusion can be explained at the computational level as differences in how priors are used in the multisensory integration process. Collectively, these results demonstrate that the sense of body ownership is determined by Bayesian causal inference, which implies that the same statistical principles determine the perception of the bodily self and the external world.

Title: Body ownership and the neural processes of memory encoding and reinstatement

Authors: *H. M. IRIYE[1], H. H. EHRSSON[2];
[1]Karolinska Inst., Solna, Sweden; [2]Neurosci., Stockholm, Sweden

Abstract: Memories are inextricably tied to having a body. Yet, we are just beginning to understand how the fundamental perception of one's body as one's own (i.e. body ownership)

influences neural processes during encoding and retrieval. Here, we investigated how body ownership influences patterns of neural activity associated with memory formation and reactivation during retrieval. We immersed participants (N = 27) within pre-recorded videos viewed through virtual reality glasses, which depicted realistic, everyday events that included a natural first-person view of a mannequin's reclining body which was aligned with the location of the participants' real bodies during fMRI scanning. We manipulated feelings of body ownership over the mannequin using a perceptual full-body illusion. Participants saw an object touch the mannequin and simultaneously felt touches on the corresponding location of their real body, which created an illusory sense of ownership over the mannequin. As a control condition, we disrupted the illusion by delivering seen and felt touches in an alternating pattern in half of the videos. The experimenter was blind to the condition assigned to each video. 1 week later, participants retrieved memories for the videos during fMRI scanning. Participants answered cued recall questions concerning specific event details at the end of each session to assess memory accuracy. Preliminary results suggest that patterns of activity during encoding in lateral frontal, medial and lateral temporal, posterior parietal, and visual cortices were able to differentiate between memories encoded with differing levels of body ownership. Further, by correlating patterns of activity at encoding and retrieval, we found that forming memories with intact compared to disrupted body ownership increased reinstatement of that event during retrieval in the hippocampus based on both the strength of perceived ownership over the mannequin during encoding and the accuracy with which event details were retrieved. Our findings have the potential to provide new insights into how to optimize memory for past events and preserve the ability to vividly relive the past in the context of both healthy ageing and clinical disorders (e.g., Alzheimers Disease).

Title: The neural substrates of body ownership and agency and their interaction during voluntary action

Authors: *Z. ABDULKARIM[1], A. GUTERSTAM SHAHIM[1], Z. HAYATOU[2], H. EHRSSON[1];
[1]Karolinska Insitutet, Stockholm, Sweden; [2]Univ. Paris-Saclay, Paris, France

Abstract: Background: The sense of body ownership and the sense of agency are two central concepts of bodily self-consciousness. Multiple neuroimaging studies have investigated the neural correlates of the senses of body ownership and agency in isolation, while few have investigated their relationship during voluntary movement. In this study we investigated the neural correlates of body ownership and the sense of agency as well as their interaction.
Methods: By eliciting the moving rubber hand illusion in 29 healthy volunteers while manipulating the synchrony of the finger movements of the rubber hand and the real hand, the movement type (active or passive movements) and the placement of the rubber hand (anatomically congruent or incongruent) during functional magnetic resonance imaging, we isolated activations reflecting the sense of body ownership and agency, respectively, as well as their interaction. This 2x2x2 factorial design allowed us to effectively control for confounds while designing contrasts that isolate the phenomena of interest. The statistical analysis was done using SPM12, and the main results are reported after family-wise error (FWE) correction with the alfa-level set at 0.05.
Results: We found that perceived ownership of the hand was associated with activity in premotor, posterior parietal and cerebellar regions whereas the sense of agency over the hand was related to activity in the superior temporal cortex and dorsal premotor cortex. Importantly, agency over a hand that felt like part of one's own body was associated with stronger activation in the somatosensory cortex than agency over a hand that felt like an external object, whereas activation in the visual association cortex was observed for the inverse relationship. We further noted that activations in previously identified agency regions such as the left insular cortex and right temporoparietal junction (angular gyrus) reflect the synchrony or asynchrony of the visuo-proprioceptive stimuli rather than the sense of agency.
Conclusions: These results identify the neural bases for the sense of agency and the sense of body ownership during voluntary movement, as well their interaction, and further suggest that the sense of agency over one's own bodily movements should be distinguished from agency over external events that are indirectly caused by one's actions.

Title: Body ownership manipulation through a Multisensory platform combining virtual reality and nerve stimulation

Authors: *G. PREATONI[1], F. DELL'EVA[1], A. PEDROCCHI[2], S. RASPOPOVIC[3];
[1]ETH Zurich, Zurich, Switzerland; [2]NEARLAN, Politecnico di Milano, Milan, Italy; [3]Dept. of Hlth. Sci. and Technol., ETH Zürich, Zuerich Eth-Zentrum, Switzerland

Abstract: We experience the environment through multiple senses, which often provide us with redundant information. Our brain uses this redundancy to merge the incoming information in an unambiguous perception. This process, known as multisensory integration, is fundamental to develop a comprehensive representation of what we consider our *self*. Even if these mechanisms are automatic, several neurological diseases cause changes in this coherent representation and lead patients to distorted perceptions of their body. Fortunately, this representation is malleable and can be manipulated. Evidence for this comes from the Full Body Illusion (FBI), where subjects develop ownership over a mannequin thanks to spatio-temporal congruent stimulation of the real and fake body. Numerous studies have replicated this illusion. However, the vast heterogeneity in the measurement approaches make it difficult to compare the results and shed light on the validity of the metrics. Moreover, the functional benefits of such approaches for rehabilitation purposes are not yet clear. In this project, we developed a multisensory platform combining two technologies that allow an unseen precision in the generation of the illusion: visual feedback through Virtual Reality (VR) and touch through Transcutaneous Electrical Nerve Stimulation (TENS). The subject is immersed in a realistic environment, where visual and tactile stimuli are synchronized in a millisecond precision. Unlike previous approaches, not only the platform allows to obtain high temporal precision, but also to stimulate multiple body parts and to perform any movement concomitantly. Importantly, we applied a multifaceted evaluation approach combining variate, objective and subjective measurements (e.g., proprioceptive drift, peri-personal space, questionnaires) to calculate the strength of the illusion. To validate our multimodal approach, we perform experiments recreating the FBI and using the same platform in a different scenario to understand the functional benefits of the visuo-tactile stimulation. The system is being tested in healthy subjects and patients affected by diabetic neuropathy. Our preliminary results show that the platform outdoes classical approaches and give indications on the validity of the measurements, confirming the inability of subjective reports to measure the illusion. Our platform stands as a new approach to perform body illusions with a highly reproducible and controlled method. Finally, the ability to stimulate distal areas with TENS and to adapt to the subject movements will allow it to be a new actor in the rehabilitation field to provide sensory, motor and cognitive benefits.

Title: Task-specific cortical organization of multisensory spatial representation

Authors: *G. BERTONATI[1,2], M. AMADEO[1], C. CAMPUS[1], M. GORI[1];
[1]Inst. Italiano di Tecnologia, Genova, Italy; [2]Univ. degli studi di Genova, Genova, Italy

Abstract: For a long period, primary sensory cortices were thought to process unisensory information only. However, more recent literature highlighted a multisensory nature of primary sensory areas, suggesting that the design principle of the cortical architecture is task-specific rather than modality-specific. In agreement with this idea, early strong involvement of visual occipital areas has been shown for complex spatial representations, independently of the sensory modality involved. Given these assumptions, we hypothesized that in the processing of multisensory spatial information, visual occipital areas are recruited differently according to the nature of the spatial tasks. To explore this hypothesis, we tested healthy participants in an electrophysiological study involving two different spatial tasks. In a spatial bisection task, three audiovisual (AV) stimuli (S1, S2 and S3) were consecutively played at three different spatial positions and participants evaluated whether S2 was spatially farther from S1 or S3. In a spatial localization task, one AV stimulus (S2) was played in a specific spatial location and participants identified whether it was positioned on the left or the right of the setup's center. It is important to note that the AV stimulus to localize (S2) was identical between the spatial bisection and the spatial localization tasks (in terms of spatial position and sensory modalities), and that the only difference between the two was the experimental question. While participants performed the tasks, we measured their Event-Related Potentials (ERPs), focusing on responses in an early time window (50-90ms) known to be involved in the earliest stages of multisensory integration. As expected, in both tasks, S2 elicited an occipital and a temporal activation contralateral to its spatial position. Nevertheless, while the two tasks shared a similar activation to AV stimuli at temporal sites (taken as control areas), the occipital response during the spatial bisection task was significantly stronger than during the spatial localization task. As predicted, we revealed that the nature of the spatial task modulated the occipital activation to multisensory stimuli. Thus, the early recruitment of occipital areas might play a more important role in scaffolding the multisensory processing for constructing complex spatial representations, as in the spatial bisection task, while it might be less substantial in a simpler spatial localization task. Our study allows to further understanding the multisensory brain's supra-modal architecture and provides insights on how primary sensory areas encode task specificity.

Title: Cortical Depth-dependent Multisensory and Attentional Influences on Peripheral Sound Processing

Authors: *I. ZULFIQAR[1], E. FORMISANO[1], S. KASHYAP[2], P. DE WEERD[1], M. MOEREL[1];
[1]Dept. of Cognitive Neurosci., Maastricht Univ., Maastricht, Netherlands; [2]Techna Inst., University Health Network, ON, Canada

Abstract: Recent evidence supports the existence of multisensory processing in early auditory regions of the cortex[1,2,3]. To study the source of these multisensory modulations, we investigated visual influences on the auditory cortex in a cortical depth-dependent manner using high resolution functional MRI at 7 Tesla. Specifically, given the reciprocal connectivity between early visual cortex representing the periphery and auditory cortex[4,5], we set out to explore audiovisual integration of peripherally presented stimuli. For 10 subjects, we collected anatomical data at 0.6 mm isotropic and functional data at 0.8 mm isotropic resolution. In a blocked design, the participants were presented with unisensory stimuli and audiovisual stimuli [auditory (noise) and visual (grating, spanning 5 - 8^{o}); temporally modulating at 3 Hz; located at 5^{o} in the right azimuthal plane]. Attention was directed either towards the auditory stimulus, or away from both stimuli towards the fixation cross. Our preliminary results showed multisensory enhancement in a cortical network comprising early sensory sites (auditory and visual cortex), insula, and ventrolateral prefrontal cortex. Multisensory enhancement was present in the primary auditory cortex and increased along the auditory cortical hierarchy irrespective of attention. These findings confirm that the primary auditory cortex is not uniquely unisensory. Additionally, we observed a task-dependent attentional modulation of multisensory enhancement in the deep layers of the auditory belt. This suggests a top-down origin of attention that stems from long-range cortico-cortical feedback, which may originate from the visual cortex or higher-order association areas. Our finding contrasts the existing empirical observation of context-dependent feedback being most prominent in superficial layers due to a short-range cortical influence[3]. This difference in observations between studies indicates that the multisensory effects may critically depend upon the stimulus characteristics (location, salience, etc.), and tasks. Future analyses will include cortical depth-dependent connectivity analysis which may help discriminate between the frontal regions and visual cortex as sources of the observed context-dependent multisensory

enhancement in deep layers of the auditory belt, and a multivariate analysis to increase sensitivity of our analysis by examining distributed multisensory effects.

Title: Integration of global and local features in stereognosis

Authors: *E. BERGER-WOLF, N. SHELCHKOVA, D. SHEETS, E. OKOROKOVA, A. R. SOBINOV, C. M. GREENSPON, S. J. BENSMAIA;
Univ. of Chicago, Chicago, IL

Abstract: When we grasp an object, we experience a vivid sense of its three-dimensional shape, a sensory ability termed stereognosis. At each point of contact with the object, tactile signals convey information about its local contours, for example, a curved surface or an edge. The global shape of the object is computed based on proprioceptive signals about the conformation of the hand. These two streams of information — cutaneous and proprioceptive — are then integrated to give rise to stereognosis, a process about which virtually nothing is known. In the present study, we sought to characterize how the local features and global shapes of objects interact at a perceptual level. To this end, human participants were asked to rate the dissimilarity of pairs of objects that differed in their local features, their global shape, or both. We found that the perceived dissimilarity of an object that varied in both local features and global shape could not be straightforwardly predicted from the dissimilarity of objects that varied only in one or the other. We explore the implications of our findings for the neural mechanisms of stereognosis.

Title: Task-relevance reverses the effect of efference copy based predictions during multisensory path-integration

Authors: *L. ROSENBLUM[1], A. KREß[1], B. ARIKAN[2], B. STRAUBE[3], F. BREMMER[1]; [1]Dept. Neurophysics, Philipps-University Marburg, Marburg, Germany; [2]Dep. of Psychology, Justus Liebig Univ. Giessen, Giessen, Germany; [3]Translational Neuroimaging Marburg, Dept. of Psychiatry and Psychotherapy, Philipps-Universität Marburg, Marburg, Germany

Abstract: Successful navigation requires an accurate estimate of one's own movement through space. Information about self-motion parameters like travelled distance (path integration) is provided by various sensory modalities. Two important sources of information are retinal optic flow in the visual, and tactile flow across the skin in the tactile domain. To control our own movements, we must also distinguish self-generated from externally induced motion signals. The predictive coding framework suggests that the sensory representation resulting from one's own motion can be attenuated. In a previous fMRI study we tested this idea in a visual-auditory path integration task. We observed both supramodal BOLD suppression as well as modality-specific enhancement in sensory areas for active distance reproduction (Krala et al., JoV, 2019). In line with previous literature, we have proposed that for successful distance reproduction, task-relevance and prediction interacted synergistically, leading to enhanced instead of suppressed neural activation in early sensory cortices. To probe this hypothesis, task-relevance was manipulated in the current study. We explored the role of visual and tactile flow in the processing of self-motion information in a multisensory path integration task. In one block of trials, subjects' task was to replicate (Active/Reproduction = ACT/R) a previously observed distance of passive self-displacement (Passive/Reproduction = PAS/R). In another block, subjects first travelled a self-chosen distance (Active/Self = ACT/S) which was then played back to them (Passive/Self = PAS/S). Stimuli were presented in each unimodal and a bimodal condition: Visual self-motion was simulated as forward motion across a 2D ground plane of random dots. Tactile self-motion stimuli were delivered by air flow across the subjects' forehead. Cues from both modalities were combined congruently in the bimodal condition. In line with our previous study, preliminary results show higher BOLD activation of primary sensory cortices for visual (V1) and tactile (SI) self-motion cues for ACT/R as compared to PAS/R trials in all three modalities. As hypothesized, BOLD activation in these areas was suppressed for ACT/S as compared to ACT/R, which confirms that the effect of one's own action - and hence prediction - on sensory processing is strictly dependent on the respective behavioral task and its relevance.

Remarkably, for PAS/S compared to ACT/S we found stronger activation of primary sensory areas and higher-order sensory areas (e.g. insula) indicating that task-relevance can reverse the suppressing impact of prediction on sensory processing in a path integration task.

Title: Sensory-motor plasticity in the representation of self induced by robotic telepresence

Authors: *J. VENTRE-DOMINEY, D. FARIZON, P. F. DOMINEY;
INSERM, Dijon, France

Abstract: The current research investigates the plasticity of the representation of self. The integrated perception of self is constructed through the multi-modal integration of sensorimotor signals including visual, proprioceptive, and tactile. The perception of self is plastic, and can be modified by substituting perceptual inputs. This has been classically revealed in the rubber hand illusion (Botvinick and Cohen 1998). A crucial aspect of this effect is the synchrony between visual and tactile stimulation. Interestingly this illusion can be extended to the whole body. We previously characterized a form of rubber hand extended to the whole body, using a form of motor synchrony (Ventre-Dominey, Gibert et al. 2019). In the current research we extend this and demonstrate the plasticity of the representation of self which can be evoked via tactile stimulation Using a simple neuroscience-inspired procedure to beam human subjects into robots, we previously demonstrated by visuo-motor manipulations that embodiment into a robot can enhance the acceptability and closeness felt towards the robot. In that study, the feelings of likeability and closeness toward the robot were significantly related to the sense of agency, independently of the sensations of enfacement and location. Here, using the same paradigm we investigated the effect of a purely sensory manipulation on the sense of robotic embodiment associated to social cognition. Wearing a head-mounted display, participants saw the visual scene captured from the robot eyes. By positioning a mirror in front of the robot, subjects saw themselves as a robot. Tactile stimulation was provided by stroking synchronously or not with a paintbrush the same location of the subject and robot faces. In contrast to the previous motor induction of embodiment which particularly affected agency, tactile induction yields more generalized effects on the perception of ownership, location and agency. Interestingly, the links

between positive social feelings towards the robot and the strength of the embodiment sensations were not observed. We conclude that the embodiment into a robot is not sufficient in itself to induce changes in social cognition and that the intentional motor signal constitutes an essential cue to link embodiment and social features.

Abstract: Maternal stress before, during and after pregnancy have profound effects on the development and life-long function of the infant's stress response systems such as the Hypothalamic Pituitary Adrenal axis (HPA) and the Autonomic Nervous System (ANS). We hypothesized that prenatal stress (PS)-induced programming of HPA and ANS is reflected in epigenetic and biophysical biomarkers, which can be employed for early detection and follow up of affected children. In this presentation we will show results aimed to find non-invasive epigenetic biomarkers of PS in the newborn salivary DNA. Pregnant women were screened for stress exposure using Cohen Perceived Stress Scale (PSS-10) and were classified into stressed (SG, PSS-10 ≥ 19, n= 79) and control group (CG, PSS-10 <19, n=85) matched 1:1 for parity, maternal age and gestational age. Prenatal Distress Questionnaire (PDQ) was also administered to assess specific pregnancy worries. Maternal and fetal ECGs were recorded to derive coupling between maternal and fetal heart rates resulting in a Fetal Stress Index (FSI). Upon delivery,

maternal hair strands were collected for cortisol measurements and newborn's saliva samples were collected. DNA was extracted from saliva samples (n=114) and DNA methylation was measured using EPIC Bead-Chip array (850k CpG sites). To identify associations between PSS/PDQ/FSI/Cortisol and methylation, linear regression models adjusting for confounders (sex, gestational age, smoking, autoimmune disease, gestational diabetes, Illumina plate factor and surrogate variables (SVA)) were run using limma package in R. The top hits were consistent with the basic model adjusted for sex, gestational age, Illumina plate factor and SVAs. We found epigenome-wide significant associations for 6 CpG sites in association with stress phenotypes (PDQ and cortisol) at FDR < 5%. Annotated genes to the CpGs were found to be enriched for development and growth in hippocampus signalling pathway, organelle biosynthesis, and metabolism of proteins, cell proliferation and bone development. We report novel associations between DNA methylation and maternal stress phenotypes. We observe that the several associations are related to neurobiological disorders such as autism, schizophrenia, neural tube defects and atrophy. Since this is a longitudinal study, we are assessing the neurodevelopmental outcome of the two years old infants and we will assess the differential methylation in saliva samples at that age. Detecting differences in methylation between the two ages will give a window of opportunity for early interventions.

Title: Differential DNA methylation targets exons and CpG shores in the ventral dentate gyrus following early life adversity in mice

Authors: *E. BRINDLEY[1], A. NABILA[1], F. TAKI[1], S. ODELL[1], L. J. ZALLAR[1], M. SKELLY[1], J. GAL TOTH[1], R. J. CHEN[1], A. ALONSO[1], K. E. PLEIL[2], M. TOTH[3]; [2]Dept. of Pharmacol., [1]Weill Cornell Med., New York, NY; [3]Weill Cornell Med. Col., New York, NY

Abstract: Early life adversity (ELA) is known to cause psychopathological consequences later in life, such as anxiety in humans and anxiety-like behavior in rodent models. The adult behavioral manifestations of ELA suggest persistent epigenetic changes established during early

life in neurons implicated in anxiety-related behavior, including ventral dentate granule cells (vDGCs). Previous work identified small genomic regions containing clusters of differentially methylated CpG sites established during development. Here, we investigate how ELA during fetal development disrupts DNA methylation patterns in vDGCs by two ELA conditions resulting in innate anxiety-like behaviour in offspring: Maternal anxiety (MA), wildtype offspring of 5HT-1A deficient dams and Maternal LPS (ML), offspring of LPS injected dams. Using reduced-representation bisulfite sequencing, we observe differentially methylated CpG sites clustering to 5364 small genomic regions following ELA. These differentially methylated regions (ELA-DMRs) were defined as 2CpG sites with >5% methylation change within 1kb, present in MA and ML ELA conditions with at least 1 bp overlap. ELA-DMRs were enriched in exonic regions and CpG shores, and less prominently in islands. Further, exonic localization of ELA-DMRs indicates preferential targeting of evolutionarily conserved sequences by ELA. At the CpG level, there was a close to 50:50 split between hypomethylation and hypermethylation. Single cell RNA sequencing of vDGCs from MA mice, revealed 124 differentially expressed genes with respect to control. 63 of these 124 genes contained one or more ELA-DMRs, suggesting a correlation between DNA methylation and gene expression. Functions related to synaptic transmission were overrepresented in this subcategory and 94% were downregulated in ELA with respect to control. Many of the differentially expressed genes that did not contain DMRs were related to potassium channels and 80% were upregulated in ELA with respect to control. Decreased expression of synaptic genes and increased expression of potassium channels are consistent with preliminary electrophysiological experiments indicating a reduction in excitability of vDGCs.

Title: Mitigating the epigenetic consequences of early life stress with a behavioral intervention

Authors: *T. CAMPBELL[1], K. DONOGHUE[1], N. COLLINS[1], S. FERN[1], H. DUFFY[1], T. L. ROTH[2];
[2]Psychology, [1]Univ. of Delaware, Newark, DE

Abstract: Aversive caregiving in early life is a risk factor for aberrant brain and behavioral development throughout the lifespan. This outcome is related to aberrant epigenetic regulation of the *Bdnf* gene. The *Bdnf* gene encodes for brain-derived neurotrophic factor (BDNF), a neurotrophin involved in neural plasticity, learning, and memory. Disruptions in caregiver-infant interactions lead to increased methylation and decreased expression of the *Bdnf* gene. One way to mitigate this effect is hypothesized to be through aerobic exercise. Exercise increases BDNF at the protein and gene expression levels, making it an exciting target for therapeutic interventions. To our knowledge, exercise has never been studied as a therapeutic intervention in preclinical rodent models of early life caregiver maltreatment. To that end, the current study is investigating the effect of an adult voluntary wheel running intervention on *Bdnf* aberrant methylation and expression in the prefrontal cortex of rats who experienced aversive caregiving in infancy. We are using a rodent model (Long Evans rats) wherein rat pups experience intermittent caregiver-induced stress from postnatal days 1-7 and are given voluntary access to a running wheel (except in the control condition) from postnatal days 70-90 as a young adulthood treatment intervention. This study presents novel findings on the mechanisms underlying neural plasticity in the prefrontal cortex in an early life stress context. Current results suggest that early life stress and exercise affect *Bdnf* gene methylation and expression in an exon and sex specific manner. Future work will continue to probe sex differences in wheel running behavior and epigenetic activity.

Title: Neuronal transcriptomic and epigenomic signatures of early-life adversity and exercise underlie modulations to cognitive function

Authors: *N. E. NELSON[1], B. GOMRINGER[2], S. D. A. VALIENTES[3], P. ABDOLI[2], A. BAYAT[3], C. MANDIA[4], A. S. IVY[3];

Abstract: Introduction: Adverse childhood experiences such as neglect, abuse, and chronic stressors resulting from the COVID-19 pandemic, are increasingly recognized as having long-term impacts on pediatric cognitive health. There is an immediate need for interventions to offset the negative consequences of early-life adversity (ELA) on later-life cognition. Rodent models can be used to identify targetable mechanisms to offset the cognitive consequences of ELA. We developed a mouse model of early-life exercise (ELE) and discovered that ELE has lasting effects on hippocampal memory and synaptic plasticity (Ivy et al, *Sci Rep* 2020). We aim to identify memory-associated gene expression programs and their epigenetic regulators resulting from ELA and ELE, and apply ELE as a *post-hoc* strategy to gain mechanistic insights for therapeutic intervention after ELA. We hypothesize *that juvenile exercise introduced after ELA can prevent the negative consequences of ELA on hippocampal memory in adulthood*. Methods: We crossed Emx1$^{IRES\ cre}$ females with males harboring the NuTRAP cassette, a *loxP*-flanked Gt(ROSA)26Sor$^{tm1(CAG-birA,-mCherry/Rangap1,-EGFP/Rpl10a)Evdr}$ transgene, to generate the Emx-NuTRAP mouse. This allows for paired transcriptome and epigenome sequencing specifically from hippocampal neurons. During postnatal days (P) 2-9 Emx-NuTRAP mice are placed in limited bedding and nesting (LBN) cages to model ELA (Rice et al, *Endocrinology* 2008). ELE is then introduced during P21-41 to a subset of LBN mice. During young adulthood (P60+), mice underwent a battery of behavior tasks: 1) spatial y-maze, 2) object location memory task, 3) open field exploration (OFE), and 4) elevated plus maze (EPM). Middle-aged mice (8-10 month) will also be tested in the objects in updated locations (OUL) task (Wright et al, *Curr Protoc Neurosci* 2020). Once ELA-induced memory impairments are identified, RNA-Seq, ATAC-Seq, and CUT&Tag-Seq will be performed from isolated hippocampal neurons to evaluate molecular targets of memory reconsolidation after ELA and/or ELE. Results: Mouse running distances in the ELE paradigm were not significantly impacted by prior ELA exposure. ELA, with or without ELE, does not provoke differences in anxiety compared to controls in the OFE and EPM tasks, and all mice regardless of early-life exposure had similar performance in hippocampal short -and long-term memory tasks. Conclusion: We have established working models of LBN and ELE paradigms using Emx-NuTRAP mice. With pending OUL memory tasks and sequencing, we aim to identify exact memory impairments after ELA, and whether ELE can offset the consequences of ELA on memory function in middle-age.

Abstract: Early life stress (ELS) is a well-known risk factor for the development of several psychiatric diseases, including depression. Many studies on this topic have focused on cognition-related brain regions and behavior, so mechanisms underlying the impact of ELS on reward-related regions, such as the nucleus accumbens (NAc), and related reward-seeking and motivated behaviors are lacking. To begin to fill this gap, here we used the limited bedding and nesting model of ELS (LBN), which involves rearing pups in a limited resources environment, to study the impact of ELS on motivated behaviors for a natural reward, as well as on molecular mechanisms in the NAc.

Using Qiagen Ingenuity Pathway Analyses (IPA) we identified a sex difference in several predicted upstream regulators in a previously published NAc RNAseq dataset performed on LBN and control Long-Evans rats (group N's = 4-6), including BDNF and CREB1. Notably, CREB1 was significantly enriched as an upstream regulator in LBN females but not males. Additionally, IPA identified CREB signaling as a significantly enriched pathway in stressed females. Targets of this upstream regulator also differed between sexes. In females, CREB1 is a predicted regulator of 24 differentially expressed genes (DEG), of which 10 are activated and 14 are inhibited. In males, CREB1 is a predicted regulator of 6 DEGs, where 5 are activated and 1 is inhibited.

A genome-wide screen of histone posttranslational modifications (PTM) revealed differing patterns of LBN-driven PTMs in the NAc of males and females (group N's = 4-5). LBN increased the expression of 3 histone marks in males and decreased the expression of 1 histone mark in females. Acetylation of two of these marks (H4k12ac and Hk23ac) has been shown to be in part driven by CREB-binding protein (CBP). Additionally, previous work shows that acetylation of these histone marks in reward-related regions is altered by social defeat and chronic unpredictable stress in rats. This suggests CREB signaling and CBP-driven histone acetylation may be a driving force of stress phenotypes. Preliminary data from an ongoing study shows that LBN reduces motivation for a palatable food reward (sucrose pellets) in a progressive ratio operant tasks in non-food deprived adult male and female rats (group N's = 4-7; $p=0.025$). In upcoming studies we will assess the role epigenetic modifications, such as CBP-driven histone acetylation, may be playing in this LBN-driven depression-like phenotype.

Title: Sensitization of microcircuits by early-life stress in the nucleus accumbens

Authors: *J.-A. BALOUEK, C. A. MCLAIN, R. L. RASHFORD, T. ISLAM, C. J. PEÑA; Princeton Univ., Princeton, NJ

Abstract: In humans, early-life stress (ELS) heightens the risk of developing psychiatric disorders such as anxiety and depression. There is evidence that experiencing trauma early in life sensitizes individuals to future experiences of stress. However, little is known about the level at which this sensitization might be occurring in the brain. We hypothesized that ELS-induced stress sensitization may be evident at the level of neuronal microcircuits, such that cells activated by ELS might be more reactive to adult stress. We studied this by using a transgenic mouse line to tag and track experience-activated cells. We found that after going through an early-life stress paradigm, mice with an ELS history had an increased neuronal activation in the nucleus accumbens (NAc). We then postulated that the reactivation of ELS-responsive microcircuits in the NAc is a necessary component of the sensitized behavioral response to additional stress. To test this hypothesis, we performed stereotaxic surgery to target viral over-expression of *hM4Di*, an inhibitory Designer Receptors Exclusively Activated by Designer Drugs (DREADD), in the NAc of male and female pups at 7 days old. This allowed for optimal expression of DREADD in experience-responsive cells in the NAc of mice during an ELS-specific time-sensitive period. During adult chronic social defeat stress (CSDS), we inhibited experience-responsive microcircuits with olanzapine, a ligand specific to inhibitory DREADDs, and studied the effect on subsequent depression- and anxiety-like behavior, in both male and female mice. We found interactions between inhibition of early-life-responsive cells and response to adult stress, which suggests that inhibitory DREADDs were expressed in distinct microcircuits in the NAc, responsive to either ELS or reward, and inhibition of these neuronal ensembles during CSDS reduced or enhanced the stress experience, respectively.

Title: Type 1 corticotropin releasing factor receptor differentially modulates neurotransmitter levels in Nucleus Accumbens of juvenile versus adult rats

Authors: *J. ZEGERS[1], J. A. NOVOA[3], F. CALDERON[2], C. BLANLOT[2], H. E. YARUR[1], C. BASTIAS[2], K. GYSLING[4];

Catolica De Chile, Santiago, Chile

Abstract: Juvenile rats exposed to social isolation have shown an increase of anxiety-like behavior and significant changes in Nucleus Accumbens (Nac) dopamine (DA) activity in their adulthood. Brain response to stress is mediated in part by the corticotropin releasing factor (CRF) system, composed by CRF and its two major receptors CRF-R1 and CRF-R2. In Nac shell, CRF induces anxiety-like behavior and changes in local DA balance. Nevertheless, the role of CRF receptors in controlling Nac neurotransmission is not fully understood. Previous results of our laboratory showed that the infusion of a CRF-R1 antagonist (CP-154,526) in Nac of juvenile rats increased DA levels in response to a depolarizing stimulus and decreased basal glutamate (Glut) levels. Nevertheless, the effect of CRF-R1 antagonism is not totally understood in adult rats. To evaluate the effect of a CRF-R1 antagonist (CP-154,526) we performed *in vivo* microdialysis in Nac of adult rats. We observed the opposite in Nac of adult rats compared to juvenile rats. The infusion of a CRF-R1 antagonist in Nac of adult rats decreased DA levels in response to a depolarizing stimulus and increased Glut levels in response to a depolarizing stimulus. Interestingly, we observed similar effects in Nac synaptosomes using an *ex vivo* approach. Furthermore, our results suggest that CRF-R1 controls glutamate levels through PKC signaling in Nac terminals. We propose that the function of Nac CRF-R1 receptors will be differentially modulated depending on the stage of life. Funded by FONDECYT grant N° 1191274

Title: Single-cell transcriptomics of hypothalamic CRH-expressing neurons informs mechanisms by which early-life adversity sculpts enduring stress-responses.

Authors: *A. K. SHORT[1,2], C. WILCOX-THAI[3], A. L. PHAM[1], Y. CHEN[4], M. BIRNIE[1,2], J. L. BOLTON[2,1], A. MORTAZAVI[3], T. Z. BARAM[1,2];

Abstract: Mental and cognitive health, as well as vulnerability to neuropsychiatric disorders, involve the interplay of genes with the environment, particularly during sensitive developmental periods. Early-life stress / adversity (ELA) promotes vulnerabilities to stress-related affective disorders, yet it is unknown how a transient ELA dictates life-long neuroendocrine and behavioral reactions to stress. The population of hypothalamic corticotropin-releasing hormone (CRH)-expressing neurons that regulate stress-responses is a promising candidate to mediate the enduring influences of ELA on stress-related behavioral and hormonal responses via enduring transcriptional and epigenetic mechanisms. Capitalizing on a well-characterized model of ELA, we examined here the resulting change in gene expression profiles in stress-sensitive CRH-neurons in the hypothalamic paraventricular nucleus (PVN) of male mice. Given the known heterogeneity of these neuronal populations, we employed single-cell RNA sequencing (RNA-seq) approaches. In pups, ELA-provoked changes clustered around expression of genes involved in neuronal differentiation, synapse formation, altered energy metabolism and cellular responses to stress and injury. The use of single-cell transcriptomics demonstrated that ELA-induced transcriptional changes took place in specific subtypes of CRH-cells, and primarily in select populations of glutamatergic CRH cells. Importantly, ELA-induced transcriptional reprogramming of hypothalamic CRH-expressing neurons heralded significant, enduring disruptions of both hormonal and behavioral responses to stress throughout life.

Title: Examining the synergistic effect of stress during puberty and pregnancy-related hormones on the PVN transcriptome

Authors: *K. N. GAUTIER[1], P. J. KANE[2], T. L. BALE[2], K. E. MORRISON[1];
[1]West Virginia Univ., Morgantown, WV; [2]Pharmacol., Univ. of Maryland Baltimore, Baltimore, MD

Abstract: Women who undergo adverse childhood experiences are at risk for developing lasting biological changes, including affective disturbances and stress dysregulation. Although we know this connection exists, the mechanisms underlying this relationship are unclear. We have previously shown that pubertal adversity is associated with a blunted glucocorticoid response within the hypothalamic-pituitary-adrenal (HPA) axis in both peripartum humans and mice. In mice, we have examined puberty-stress reprogramming in the paraventricular nucleus (PVN) of the hypothalamus, the brain region that initiates the HPA axis response. We found that pubertal stress led to an upregulation of immediate early genes (IEGs) in the PVN of adult, pregnant mice. IEGs are stimulus-dependent transcription factors that have many important downstream targets. Separately, we have shown that the pregnancy-associated hormone allopregnanolone is both necessary and sufficient to produce the blunted stress response phenotype in both pubertally-stressed adult female and male mice. Here, we assessed allopregnanolone as the potential mechanism underlying IEG expression changes associated with pubertal stress exposure. We hypothesized that administration of allopregnanolone would increase IEG expression in the PVN of pubertally stressed mice but not controls. Male and female mice underwent 14 days of chronic variable stress (CVS) beginning on postnatal (PN) day 21 using our previously established paradigm. CVS consisted of two stressors (tactile, olfactory, or auditory) per day. Control animals did not experience CVS. In adulthood (12 weeks old), all animals were given either allopregnanolone or vehicle (25% w/v HPβCD) treatment via two separate subcutaneous injections: 3 mg/kg of allopregnanolone 20 hours and 1 mg/kg 2 hours before brain collection. PVN micropunches were obtained from brains, RNA was isolated, and gene expression was measured using quantitative real-time PCR. If allopregnanolone is linked to increased IEG expression in the PVN, we expect to see that exogenous allopregnanolone increased each IEG of interest only in mice that experienced pubertal stress. Ongoing studies will address this question in a site-specific manner by delivering allopregnanolone directly into the PVN. These studies will further delineate the functional role for the increased IEGs in the pubertal stress-associated blunted HPA axis phenotype. Results from these studies will provide

novel insight into the mechanisms underlying female-relevant risk factors for stress dysregulation, a central endophenotype of affective disorders.

Title: The impact of stress during puberty on the transcriptional state of the developing hypothalamus

Authors: *J. M. MENDOZA, K. N. GAUTIER, G. C. PIFER, R. B. GANDEE, S. L. HIGLEY, B. M. KAREM, C. A. KING, **K. E. MORRISON**;
Psychology, West Virginia Univ., Morgantown, WV

Abstract: Stress is a common occurrence, but excessive adversity during puberty can lead to negative outcomes in the brain. We have previously shown that stress during puberty leads to dysregulation of the hypothalamic-pituitary-adrenal (HPA) axis stress response, a key endophenotype of affective disorders, specifically during the peripartum window in both humans and mice. Using this translationally-relevant mouse model, we have additionally shown alterations to the transcriptome of the paraventricular nucleus of the hypothalamus (PVN), which initiates the HPA axis stress response. Specifically, pubertal stress resulted in an increase in six immediate early genes (IEGs) in the PVN of adult, pregnant mice in comparison to non-stressed pregnant mice, but in baseline conditions. IEG expression is canonically stimulus-dependent as they function to quickly produce necessary downstream signals. This baseline expression only in pubertally stressed females suggests potential aberrant transcription within the PVN. While these changes have been measured in adulthood, the exact timeframe for when the IEG transcriptional changes occur between the end of stress (early adolescence) and pregnancy in adulthood is unknown. We examined the developmental trajectory of IEG expression in the PVN immediately after pubertal stress. Male and female mice were exposed to chronic variable stress, or not, from PN 21-34. Twenty-four hours following the end of stress (PN35), brains were collected at baseline from non-stimulated animals. The PVN was collected by micropunch, RNA was isolated, and quantitative real-time PCR was performed to quantify relevant IEGs. If pubertal stress produces immediate reprogramming of the PVN, we expect to see increased IEG expression in pubertally stressed mice at PN 35 compared to controls. Alternatively, a lack of transcriptional changes immediately after stress will illustrate that pubertal stress has latent

effects only seen later in development or in combination with other dynamic life events, such as pregnancy. Ongoing studies will examine multiple time points following pubertal stress. Understanding the altered trajectory of the transcriptome in pubertally stressed mice will uncover whether pubertal stress leaves an immediate mark on the brain and will allow for potential opportunities for prevention of the adult phenotype. This translationally-relevant mouse model provides the opportunity to understand the molecular underpinnings of risk for stress dysregulation, a central endophenotype of affective disorders.

Title: The Impact of Pubertal Stress on Maternal Memory Formation

Authors: *G. C. PIFER, R. B. GANDEE, B. M. KAREM, K. E. MORRISON;
West Virginia Univ., Morgantown, WV

Abstract: Stress early in life has been shown to have a negative impact on adaptive and efficacious parenting in humans. Previous studies have established that induced maternal behavior by exposure in virgin mice is enduring. We have previously shown that stress during puberty, an important period of brain development characterized by high neural plasticity, alters the hypothalamic-pituitary-adrenal (HPA) stress axis response in adult females only during pregnancy and postpartum. Specifically, pubertal adversity led to a blunted HPA response during pregnancy, which was associated with increased postnatal depression scores in humans. It is possible that pubertal stress creates a disorganization of maternal responsiveness and an increased vulnerability to affective disorders. We have not found major disruptions in pup retrieval behavior in pubertally stressed dams. However, in a maternal separation test during which dams were separated from pups by a mesh barrier, we observed that pubertally stressed dams were less likely to spend time at the barrier. The current study aims to build on these bodies of research by testing whether or not stress during puberty had an impact on the formation of maternal memory. We hypothesized that virgin females who experienced pubertal stress would have a deficit in the ability to form maternal memory in adulthood. Maternal memory is operationally defined as continued maternal responding toward pups during behavioral testing over time. Females were exposed to chronic variable stress (CVS) from postnatal day (PN) 21-

34, during which they received one stressor (olfactory, tactile, or auditory) per day for two hours each day. In adulthood (PN70), virgin females were tested for the ability to form maternal memory. This test was composed of two brief periods of exposure to unfamiliar pups, and then a subsequent pup retrieval task in a t-maze. The t-maze was repeated two weeks later with complete separation of females and pups in the interim. Brains were collected at PN84. Ongoing studies will examine a potential role for the medial preoptic area and paraventricular nucleus of the hypothalamus in any pubertal stress-induced alterations to the formation of maternal memory. The medial preoptic area is largely responsible for regulating maternal behavior, while the paraventricular nucleus initiates the HPA axis stress response. Therefore, stress during puberty could have a lifelong impact on continual parental responding and stimulation, which is supported by maternal memory. These results will provide novel insight into the impact of adversity during puberty on lifelong risk for altered maternal behavior.

Title: Psychosocial stress and obesogenic diet synergize to alter behavior and modulate FKBP5 methylation

Authors: *T. SIMON[1], P. ONTIVEROS-ANGEL[1], J. VEGA-TORRES[1], V. WILLIAMS[1], C. VILLALOBOS[1], F. SHARAFEDDIN[1], M. POMPILUS[4], M. FEBO[5], C. VIET[2], I. DELA PENA[3], J. FIGUEROA[1];
[1]Basic Sci., [2]Dent., [3]Pharmaceut. Sci., Loma Linda Univ., Loma Linda, CA; [4]Psychiatry, [5]Psychiatry Dept., Univ. of Florida, Gainesville, FL

Abstract: Background: Obesity and psychosocial stress are becoming more prevalent throughout the world and have been exacerbated by the Coronavirus 2019 outbreak. These environmental factors can shape neurodevelopmental trajectories, orienting neural circuits towards altered stress reactivity and emotional dysregulation. Adolescents that consume obesogenic diets enriched with saturated fats and carbohydrates are more susceptible to

dysregulated stress responses and behaviors. A pivotal biomarker associated with stress reactivity is *FKBP5*, which is a gene that encodes for the chaperone FK506 binding protein 51. This study investigated the potential involvement of *FKBP5* gene regulation in the neuropathological signatures associated with obesity and psychosocial stress. **Methods:** Adolescent Lewis rats (n = 56) were fed a Western-like diet (*WD*, 41% kcal from fat) or control diet (*CD*, 13% kcal from fat) beginning at postnatal day (PND) 21 and then subdivided into exposed and unexposed groups. The exposed groups endured a psychosocial stress model (PSS) that includes 30 consecutive days of social instability (PND 60 - 90) and two predator exposures (at PND 60 and 70). All groups underwent a battery of behavioral tests. Brain tissue was harvested at PND 107 and prepared for *FKBP5* gene methylation analyses, diffusion tensor imaging (DTI), neurohistology, and stress biomarker measurements.**Results:** Behavioral results reflected deficits in sociability and fear extinction along with an increase in anxiety-like behavior and food consumption in PSS/WD rats. DTI findings indicated a decrease in fractional anisotropy in the arcuate nucleus of the hypothalamus of rats exposed to PSS. We also found that PSS and the WD synergized to reduce *FKBP5* methylation in the hippocampus (approximately 8% hypomethylation upstream of the promoter and in multiple intronic and exonic regions). RNAscope confirmed altered *FKBP5* mRNA expression in the hippocampus of exposed to PSS/WD. We found higher fecal corticosterone levels in PSS/WD rats, supporting the observed *FKBP5* upregulation.**Conclusions:** Long-term consumption of an obesogenic diet during adolescence negatively affects behavior, stress responsiveness and increases the amount of *FKBP5* expression in the hippocampus. *FKBP5* hypomethylation may contribute to the amplified stress reactivity and obesity-related behaviors seen in those who have experienced childhood trauma. These results deepen our understanding of potential mechanisms linking early exposure to trauma and obesity.

Title: Role of C. elegans RAPGEF in Synapse Development at Neuromuscular Junction

Authors: *R. E. LAMB, S. J. CHERRA, III;
Neurosci., Univ. of Kentucky, Lexington, KY

Abstract: Guanine Exchange Factors (GEFs) are a family of proteins that activate GTPase signaling cascades. They accelerate the rate of GDP dissociation and subsequent GTP binding. The RAPGEF subfamily of GEFs are associated with multiple neurological disorders such as schizophrenia and myoclonic epilepsy. In murine models, disruption of RAPGEF6 function resulted in reduced anxiety behaviors, increased long term potentiation, but no changes in gross brain morphology. Although these studies suggest that RAPGEFs modulate synaptic function, the exact mechanism is currently unknown. To determine how RAPGEFs regulate synapses, we used the *Caenorhabditis elegans* neuromuscular junction. PXF-1 is the only *C. elegans* RAPGEF orthologue. We hypothesized that PXF-1 contributes to neural circuit function by promoting synapse development at the neuromuscular junction. To determine how PXF-1 modulates neural circuit function, we used aldicarb, an acetylcholinesterase inhibitor, to measure changes in motor circuit activity. Treatment with aldicarb induces paralysis that directly correlates with levels of cholinergic activity. We found that two independent mutant alleles of *pxf-1* caused the animals to become resistant to aldicarb in comparison to wild type animals. We then used fluorescently tagged synaptic proteins to investigate whether *pxf-1* mutants displayed alterations in synapse number or morphology. We detected no differences in the number of cholinergic synapses between wild type and *pxf-1* mutant animals, suggesting that PXF-1 does not regulate synapse formation. We then measured the area of presynaptic terminals in developing animals. We found that *pxf-1* mutant animals displayed a decrease in the size of puncta labeled by fluorescent synaptic vesicle and active zone proteins. To reveal the expression pattern of PXF-1, we used CRISPR/Cas9 genome editing to create a PXF-1::3xFLAG knock-in animal. In the nervous system, we detected PXF-1 in cell bodies of neurons and in processes near synapses. Based on our findings, PXF-1 may function in motor neurons to coordinate synaptic development and promote the function of neuromuscular junctions. Overall, our work provides a new insight into how RAPGEFs regulate nervous system function and how disruption of RAPGEF function may contribute to the development of certain neurological disorders.

Title: Establishing the cohort of early active zone proteins and their role in synaptic strength and maturation at the Drosophila neuromuscular junction

Authors: *E. J. GUSS, P. PUJOLS VÁZQUEZ, Y. AKBERGENOVA, J. LITTLETON;
Dept. of Biol. and Dept. of Brain and Cognitive Sci., MIT, Cambridge, MA

Abstract: Dysfunction in glutamatergic synaptic signaling can result in defects in learning and memory and contributes to neurodevelopmental disorders like intellectual disability and autism. Critical to normal formation of glutamatergic synapses is the development of active zones (AZs), specialized structures which cluster voltage-gated calcium (Ca^{2+}) channels (VGCCs), synaptic vesicles and the fusion machinery to ensure rapid Ca^{2+}-dependent vesicle fusion. Despite their importance, the molecular mechanisms that control AZ development and maturation at early stages of synaptogenesis are poorly understood. The *Drosophila melanogaster* larval neuromuscular junction (NMJ) provides an excellent genetically tractable system for understanding glutamatergic AZ development. Previous work in *Drosophila* determined that the AZ proteins Syd-1, Unc-13b and Liprin-alpha arrive early in AZ development, while the ELKS/CAST homolog Brp, Unc-13a, RIM Binding Protein and Ca^{2+} channels (Cacophony) arrive later in AZ development. Work in our lab has established that both developmental time and delivery of late AZ components correlate with release probability (P_r) and synaptic strength. In contrast, the full cohort of early AZ proteins is unknown, as well as how delivery of early AZ material correlates with synaptic strength and P_r. We are currently testing how manipulations of early AZ proteins alter structural and functional AZ maturation, as well as how they contribute to synaptic strength. Structural maturation is assessed by imaging and analyzing delivery of critical presynaptic proteins such as Cacophony and SNAREs, as well as formation of Glutamate receptor “rings,” a postsynaptic feature of maturing AZs. To identify novel early AZ seeding factors, we are also conducting CRISPR-based screens in single neurons, focusing on the role of lipid kinases and phosphatases as potential drivers of early AZ seeding. Together, these studies should provide important insights into early molecular events in AZ formation and their subsequent role in establishing synaptic strength at individual release sites.

Title: Effect of Thrombospondin on NMJ Structure and Locomotion of Drosophila melanogaster

Authors: G. C. WOODS[1], K. COREY[1], S. M. LEE[1], I. MAXWELL[1], E. LOWENSTEIN[3], A. WOOTEN[3], L. ROTELLO[2], A. OSGOOD[4], D. MENDOZA ORTIZ[5], *N. A. VELAZQUEZ ULLOA[1];

Abstract: Thrombospondin (TSP) is an extracellular matrix glycoprotein that plays a role in synaptogenesis at glutamatergic synapses in the mammalian brain. While there are 5 TSP genes in humans, there is a single homologous gene in *Drosophila melanogaster* (D-TSP) and there is conservation in the protein domains involved in TSP's function in synaptogenesis. It has not been investigated if D-TSP plays a role in synaptogenesis in *D. melanogaster*. Here we determined if D-TSP modulates synaptogenesis and locomotor behavior in the *D. melanogaster* third instar larval NMJ. We hypothesized that D-TSP would be necessary for normal NMJ formation and locomotor behavior. We used the GAL4-UAS system to knockdown D-TSP in neurons with two different RNAi lines and quantified features of the NMJ structure and locomotor behavior in larvae with normal or decreased D-TSP expression. All data come from at least two independent experiments and include the parental control lines and the experimental cross. Both RNAi experiments showed no significant survival differences between the parental lines and the cross. We took images of NMJs from muscle 4 of segments A2-4 in female third instar larvae from both RNAi crosses. In experiments with one of the RNAi lines, we manually counted the number of boutons, number of branches, number of branch points, and number of islands of each NMJ, and generated a complexity index comprising the number of branches, number of branch points, and number of islands. Our preliminary results suggest an increase in NMJ complexity when D-TSP is knocked down in neurons. We also calculated the polygon area for each NMJ, and found no differences in the D-TSP knockdowns. We are currently normalizing our morphological data by muscle area, and we are completing similar anatomical analyses with the second RNAi line. To investigate locomotor behavior, we took videos of male and female larvae moving in a gridded arena, and we performed a zones analysis that measures how far larvae moved from their point of origin. We did not determine sex differences in locomotor behavior. Larvae with the knockdown of D-TSP in both crosses with the RNAi lines show no changes in zones occupancy. We are in the process of validating the knockdowns of D-TSP by RT-qPCR. Next, we will explore a clumping phenotype seen in some NMJs, and measure other anatomical features. We will also quantify additional movement patterns, such as curvature, distance, and velocity, and we will analyze additional behaviors, such as head-turning and body contractions.

Title: Temporal regulation of nicotinic acetylcholine receptor subunits supports central cholinergic synapse development in Drosophila

Authors: *J. ROSENTHAL[1,2], J. YIN[3], A. GRIGSBY-BROWN[4], J. LEI[4], A. SATHYAMURTHY[5], J. SHORT[4], C. LONG[4], E. SPILLMAN[6], C. SHENG[7], Q. Abstract: The construction and maturation of the postsynaptic apparatus are crucial for synapse and dendrite development. The fundamental mechanisms underlying these processes are most often studied in glutamatergic central synapses in vertebrates. Whether the same principles apply to excitatory cholinergic synapses, such as those found in the insect central nervous system, is not known. To address this question, we investigated a group of projection neurons in the *Drosophila* larval visual system, the ventral lateral neurons (LNvs), and identified *Dα1* and *Dα6* as the main functional nicotinic acetylcholine receptor (nAchR) subunits in the larval LNvs. Using morphological analyses and calcium imaging studies, we demonstrated critical roles of these two subunits in supporting dendrite morphogenesis and synaptic transmission. Furthermore, our developmental expression profiling and endogenous tagging approaches identified distinct transcriptional controls over the two subunits resulting in the up-regulation of *Dα1, which is suppressed by elevated presynaptic activity*, and down-regulation of *Dα6* during larval development. Additional functional analyses of synapse formation and dendrite dynamics further revealed a close association between the temporal regulation of these two nAchR subunits and their sequential requirements during cholinergic synapse maturation. Finally, preliminary screens have identified candidate regulatory factors coordinating expression and postsynaptic activity of nAchRs, including transcription factors and molecular chaperones. Together, our studies identify temporal control of nAchR subunits as a core regulatory element for the development and plasticity of central cholinergic synapses, which likely involves both transcriptional and post-translational processes.

Title: Role of the cellular determinant Numb in NMJ size and function

Authors: T. SUKHANOVA[1], N. PRITCHETT[2], K. M. RENKEMEYER[2], B. A. BERKE[3], *H. KESHISHIAN[1];

Abstract: Drosophila motoneurons regulate synaptic plasticity using retrograde transsynaptic TGF-beta growth factor signaling. These signals can locally influence different levels of plasticity at distinct presynaptic branches of the same motoneuron. Potentially, asymmetrically localized molecular determinants might mediate this example of local branch plasticity. We examined Numb expression and function at the Drosophila larval NMJ. In 3rd instar larvae we observe Numb immunolabeling at synaptic boutons throughout the bodywall muscle fibers (mfs). The labeling was validated as Numb-specific by driving a presynaptic Numb RNAi knockdown to reduce levels of the antigen. Numb immunolabeling was observed in wild type larvae at type Ib and Is synaptic boutons. Numb loss of function phenotypes were tested using multiple presynaptic Numb-RNAi constructs. A significant reduction in bouton number was found at larval NMJs, scored at mfs 7&6, when compared to the control drivers (63.1 +/- 6.5 boutons, control Gal4 driver; 44.8 boutons +/- 2.6, Gal4-driven Numb RNAi knockdown, n=18 larvae). This is consistent with Numb's involvement in the presynaptic growth of the NMJ. An induced Geneswitch (GS) RNAi knockdown of presynaptic Numb partially suppressed activity-dependent plasticity in hyperactive K-channel (eag Sh) mutants (95.6 +/- 2.6 boutons, GS-uninduced Numb RNAi control; 75.7 +/- 4.7 boutons, GS-induced Numb knockdown, n=20 larvae). Electrophysiological studies point to a corresponding reduction of NMJ quantal content, consistent with the reduced bouton number. Ongoing studies will test genetic interactions with components of the TGF-beta signaling pathway. We hypothesize that Numb exerts a permissive role regulating NMJ size and plasticity, and could, through a localization to specific neural branches, influence presynaptic plasticity in a branch-specific fashion.

Title: Postsynaptic neurotransmitter receptors regulate presynaptic neurotransmitter stability at the neuromuscular junction

Authors: *S. GODAVARTHI[1,2], N. C. SPITZER[1,2];
[1]Neurobio., Univ. of California San Diego, La Jolla, CA; [2]Kavli Inst. for Brain & Mind, Univ. of California San Diego, San Diego, CA

Abstract: The *Xenopus* neuromuscular junction (NMJ) is a well-studied cholinergic synapse that exhibits activity-dependent switching of the canonical presynaptic motor neuron (MN) neurotransmitter acetylcholine to glutamate, GABA, or glycine. These transmitter switches are accompanied by selection of the complementary postsynaptic receptors in myocytes, thus ensuring continued synaptic function and homeostatic plasticity. This raises a fundamental question: *Do postsynaptic receptors in myocytes influence expression of the cognate neurotransmitter in presynaptic neurons?* Although several membrane-permeant and secreted retrograde factors have been identified, it is not known if postsynaptic transmitter receptors participate in retrograde signaling. Using the *Xenopus* NMJ as a model system, we find that sparse *ectopic expression* of functional GABA receptors ($GABA_AR\alpha\beta\gamma$) in myocytes during development leads to expression of GABA in presynaptic cholinergic MNs. GABA expression is seen both in the local axon terminals innervating the $GABA_AR\alpha\beta\gamma$-expressing myocytes, and in cell bodies located in the spinal cord. Co-expression of the MN markers Hb1 and ChAT confirms that these cholinergic-GABAergic- neurons are indeed MNs. Further, the appearance of the GABA synthetic enzyme GAD67 and vesicular GABA transporter in these MNs suggests that MNs are capable of synthesizing and packaging GABA. Misexpression of a single $GABA_AR\alpha$ subunit, resulting in a non-functional GABAR that is not trafficked to the postsynaptic membrane, does not produce these changes. Using a GABA-insensitive mutant $GABA_AR\alpha\beta_{E179Q}\gamma$, we find that $GABA_AR$ channel activity is not necessary for presynaptic expression of GABA. Electrophysiological recordings from $GABA_AR\alpha\beta\gamma$ myocytes reveal that these NMJs exhibit GABAergic miniature endplate potentials (mEPPs) along with cholinergic mEPPs, showing that they use GABA functionally. Because these MNs normally express GABA transiently at earlier stages of development, exogenous $GABA_AR\alpha\beta\gamma$ seem likely to be stabilizing GABA expression. Loss-of-function studies blocking the endogenous acetylcholine receptors result in loss of ChAT in presynaptic MNs, recapitulating the role of receptor in stabilizing presynaptic NT expression. Our work indicates that postsynaptic receptors are not silent responders to changes in presynaptic neurotransmitter identity but actively shape presynaptic neurotransmitter stability. Such *receptor-mediated retrograde signalling* at the

synapse may be an acknowledgment signal for maintaining transmitter identity under normal conditions and play a role in synaptic remodelling and in neurological disorders.

Title: Tmem184b regulates neuronal excitability and locomotion in Drosophila larvae

Authors: *T. CHO[1], E. BEIGAITė[2], N. KLEIN[1], S. T. SWEENEY[2], M. BHATTACHARYA[1]; [1]Univ. of Arizona, Tuscon, AZ; [2]Univ. of York, York, United Kingdom

Abstract: The enigmatic Tmem184b seven-pass membrane protein was identified as a regulator of neuronal survival after injury and loss causes aberrant neuromuscular architecture. The mechanism through which Tmem184b affects neuromuscular synapses is currently unclear. Here we show that the *Drosophila* ortholog of human Tmem184b, Tmep, promotes efficient locomotion in *Drosophila* larvae. Tmep is expressed broadly, localizes to endosomes and is required for full viability. *Tmep* mutant larvae crawl less readily than controls, with stronger deficits in females. Using RNAi knockdown, we show that Tmep is required in motor neurons for proper larval locomotion. In recordings from body wall muscles, Tmep mutants show substantial hyperexcitability, with many post-synaptic potentials fired in response to a single stimulation. Neuromuscular junctions in Tmep mutants show modest structural deficits and endosomal aberrations. Locomotor defects can be rescued by knock-down of endoplasmic reticulum calcium channels, suggesting that excess cytosolic calcium may drive behavioral deficiencies. Our ongoing analysis of *Tmep* mutants aims characterise a novel link between endosomal function, calcium regulation and neuronal survival in the nervous system.

Title: Transcriptional control of synapse elimination by a homeodomain transcription

Authors: *K. ALEXANDER[1], C. LAMBERT[1], M. DOITSIDOU[2], C. BENARD[3,1], A. WALKER[4], M. FRANCIS[1];
[1]Neurobio., Univ. of Massachusetts Med. Sch., Worcester, MA; [2]Integrative Physiol., Univ. of Edinburgh, Edinburgh, United Kingdom; [3]Univ. du Québec à Montréal,, Montréal, QC, Canada; [4]Mol. Med., Univ. of Massachusetts Med. Schoool, Worcester, MA

Abstract: Developmental remodeling of synaptic connectivity is an important process in the establishment of adult neural circuit organization. Central to this process is the elimination or pruning of juvenile synaptic connections. Defects in synapse elimination have been linked with several neuropsychiatric disorders, yet we have an incomplete understanding of the molecular mechanisms involved. I am investigating synaptic remodeling using the motor circuit of the nematode *Caenorhabditis elegans* as a model. A subset of GABAergic motor neurons, the dorsal D-class (DD) neurons, undergo an interesting form of remodeling where the axonal and dendritic domains switch during circuit development. This process requires eliminating juvenile synaptic connections and forming new synaptic contacts to establish the adult circuit. To identify key genes involved in synapse elimination, I carried out a forward genetic screen for mutants that fail to properly eliminate their juvenile synapses (visualized as clusters of GFP-tagged cholinergic receptors). From this screen, I isolated a mutation in the homeodomain transcription factor *dve-1*. In *dve-1* mutants, juvenile acetylcholine receptor clusters are not eliminated and instead persist into adulthood. Interestingly, the relocation of presynaptic components proceeds normally in *dve-1* mutants, such that, following remodeling, newly formed vesicle clusters identifying synaptic outputs of the mature circuit are interleaved with juvenile receptor clusters that would normally be eliminated. DVE-1 localizes to GABAergic motor neuron nuclei during remodeling, consistent with cell-autonomous DVE-1 transcriptional regulation of remodeling. To identify DVE-1 transcriptional targets that may be important for synapse elimination, we performed RNA-seq and identified several interesting candidates downregulated in juvenile *dve-1* mutants compared to wild type. Our findings begin to uncover a previously unknown transcriptional network for the control of developmental synapse elimination. We expect that our ongoing studies of transcriptional control of synapse elimination by DVE-1 will illuminate conserved genetic mechanisms controlling synapse removal during circuit development.

Title: The RNA-binding protein Musashi specifies synapse number and localization for individual axon branches via regulation of poly(A) tailing

Authors: *M. LANDÍNEZ-MACÍAS[1], W. QI[2], A. BRATUS-NEUENSCHWANDER[2], M. MUELLER[3], O. URWYLER[1];
[1]Dept. of Mol. Life Sci., [2]Functional Genomics Ctr. Zurich, [3]Univ. of Zurich, Zurich, Switzerland

Abstract: Central nervous system (CNS) circuit development critically relies on the correct specification of subcellular locations for synaptogenesis. Mutations in genes controlling synapse formation and organization are associated with neurodevelopmental and psychiatric disorders. Yet, our understanding of how synapse locations in neuronal processes are determined is very limited *in vivo*. Using single-cell labeling of mechanosensory neurons (MSN) in the *Drosophila* CNS, we here find that the evolutionary-conserved RNA-binding protein Musashi is required for determination of branch-specific numbers and subcellular locations of synapses. Remarkably, loss of Musashi leads to distinct synaptogenesis defects in individual CNS collateral branches of the same MSN axon. Musashi has additional functions in other CNS circuits. In olfactory receptor neurons, Musashi controls synaptic connectivity. Animals lacking *musashi* have mistargeting of olfactory receptor axons to a wrong glomerulus. We identify a type IIa receptor protein tyrosine phosphatase (Ptp69D), which localizes to future synaptic regions in developing axons, as a Musashi target. Loss of *ptp69D* causes similar synapse-patterning and synaptic connectivity defects as loss of *musashi*, and a genetic interaction between *musashi* and *ptp69D* supports their involvement in the same pathway. An RNA-editing approach ("TRIBE") reveals that Musashi binds to the 3'-untranslated region of *ptp69D* mRNA. Furthermore, a single-molecule sequencing approach shows that Musashi enhances *ptp69D* mRNA poly(A) tailing. Finally, *ptp69D* mRNA and protein levels are reduced in animals lacking *musashi*. We rationalize that *ptp69D* mRNAs with long poly (A) tails are more stable and translated more efficiently, and that loss of these mRNA molecules in *musashi* mutants reduces Ptp69D protein levels, thereby causing local synaptogenesis and synaptic connectivity defects. Together, our data reveal novel roles for Musashi in CNS wiring, and provide an entry point to the

understanding of how post-transcriptional mechanisms direct the establishment of axon branch-specific synaptogenesis.

Title: Axonal CB1 receptors mediate inhibitory bouton formation via cAMP increase and PKA

Authors: J. LIANG, ***C. J. WIERENGA**;
Utrecht Univ., Utrecht, Netherlands

Abstract: Experience-dependent formation and removal of synapses are essential throughout life. For instance, GABAergic synapses are removed to facilitate learning, and strong excitatory activity is accompanied by formation of inhibitory synapses to maintain coordination between excitation and inhibition. We recently discovered that active dendrites trigger the growth of inhibitory synapses via CB1 receptor-mediated endocannabinoid signaling, but the underlying mechanism remained unclear. Using two-photon microscopy to monitor the formation of individual inhibitory boutons in hippocampal organotypic slices from mice (both sexes), we found that CB1 receptor activation mediated the formation of inhibitory boutons and promoted their subsequent stabilization. Inhibitory bouton formation did not require neuronal activity and was independent of $G_{i/o}$ protein signaling, but was directly induced by elevating cAMP levels using forskolin and by activating G_s proteins using DREADDs. Blocking PKA activity prevented CB1 receptor-mediated inhibitory bouton formation. Our findings reveal that axonal CB1 receptors signal via unconventional downstream pathways and that inhibitory bouton formation is triggered by an increase in axonal cAMP levels. Our results demonstrate an unexpected role for axonal CB1 receptors in axon-specific, and context-dependent, inhibitory synapse formation.

Title: Examination of synaptic PSD-95 levels in the hippocampus of mature and developing NMDA receptor GluN2 chimera transgenic mice

Authors: *G. A. WILD[1], R. E. KEITH[2], T. C. DUMAS[1];
[1]Psychology, [2]George Mason Univ., Fairfax, VA

Abstract: In the hippocampus, N-methyl-D-aspartate receptors (NMDARs) are made up of two GluN1 subunits and two auxiliary GluN2 subunits (from GluN2A-D) and play central roles in synaptic plasticity and memory formation. During development, NMDAR composition shifts as expression of GluN2A increases in forebrain regions and synaptic content of GluN2A overtakes GluN2B. Previous research has shown that NMDAR integration into synapses is developmentally regulated by specific anchoring proteins in the postsynaptic density, including SAP102 and PSD95. In correlation to the auxiliary subunit shift, SAP102 is at its highest expression early in development, and decreases with age, whereas PSD95 is low at postnatal stages and increases during the course of the GluN2B to GluN2A switch. Knockdown of PSD95 prevents the GluN2B to GluN2A shift. However, the switch of subunits cannot be based solely on the change in PSD95 levels, as the scaffolding protein has been found to bind well to both GluN2A and GluN2B. Previous immunohistochemical research from our lab revealed increased expression of PSD95 in the hippocampus of young adult transgenic mice expressing GluN2 chimeras. PSD95 levels were increased in area CA1 and the dentate gyrus in “ABc” mice that express the N-terminus and transmembrane domains of GluN2A fused to the C-terminus of GluN2B. “BAc” mice, expressing N-terminus and transmembrane domains of GluN2B fused to the C-terminus of GluN2A, had PSD95 levels that were similar to wildtypes. Therefore, we sought to confirm the effect these GluN2 chimeras on PSD95 expression with more sensitive Western blots and extend the research to developmental animals. Preliminary results from young adult animals (P30-P60) demonstrate no differences in PSD95 levels between the different transgenic lines. Juvenile samples taken before and after the third postnatal week (P17-P19 and P22-P24) from both genotype lines are being quantified to determine any such differences. These findings will clarify any bidirectional interactions between NMDA receptors and PSD95 at hippocampal synapses yield greater insight into the complexity of synaptic maturation in the hippocampus.

Title: Axonal inputs into mouse hippocampal area CA2 from the Dentate Gyrus

Authors: S. CHONG[1], D. RADZICKI[2], *S. M. DUDEK[1];
[1]Natl. Inst. of Env. Hlth. Sci., NIH, Research Triangle Park, NC; [2]Neurobio. Lab., NIEHS/NIH, Research Triangle Park, NC

Abstract: Hippocampal area CA2 is a molecularly and functionally distinct region of the hippocampus that had been classically defined as the area with large pyramidal neurons lacking input from the dentate gyrus and the thorny excrescences (TEs) characteristic of CA3 neurons. A modern definition of CA2, however, makes use of the expression of a number of genes that distinguish it from its neighboring CA3 and CA1 (RGS14 or PCP4, for example). Using this definition, it is evident that the axons originating from DG granule cells (DGGCs), forming what are known as mossy fiber (MF) synapses and contained in the *stratum lucidum* (SL), extend well into area CA2 to form excitatory synapses on the pyramidal neurons there. What is less known is how the presynaptic MF boutons (MFBs) and postsynaptic CA2 spines of these MF-CA2 synapses differ in comparison to the more highly characterized MF-CA3 synapses. Here we have implemented viral tracing, immunofluorescence, and confocal microscopy to compare the fine morphology of MFBs along the CA3-CA2 axis. Small-volume, targeted intracranial injections of AAV viruses into the dorsal hippocampus of wild-type C57 mice were used to express red or green fluorophores to label the pre- and postsynaptic elements of these synapses.Similar to previous findings, we observed many large ($\geq$ 6 μm^3) MFBs as well as the corresponding complex spines (thorny excrescences; TEs) on the CA3 apical dendrites, characteristic of the synaptic glomeruli typical of MF synapses. Previous work by Kohara, et al. demonstrated significant differences in pre- and postsynaptic complexity in the more distal regions of SL (i.e, smaller MFBs and lack of TEs in CA2). Similarly, we found fewer large MFBs in CA2. However, we found evidence of TEs in the SL of CA2, though much fewer in number than in CA3. Our observations indicate that TEs alone may not be suitable as a distinguishing feature differentiating CA3 from CA2 neurons. Additionally, we replicated Kohara's finding that dorsal DGGCs send long-range, longitudinal projections to the 'intermediate' CA2 but not to the corresponding CA3, suggesting that the axons are traversing through CA2 longitudinally. Within 100 μm of the distal-most SL, there was no significant difference in total MFB density in intermediate CA2 (0.0052 ± 0.0011 MFBs/μm^2) and dorsal CA2 (0.0042 ± 0.0012 MFBs/μm^2) in six sections from n= 3 mice (two tailed paired t-test: *p=0.57*). Ongoing 3D reconstruction and quantification of MFBs will help us to better understand potential differences in MF synaptic morphology along transverse and septotemporal axes and provide a basis for future functional studies.

Abstract: Leucine rich repeat transmembrane neuronal proteins (LRRTMs) are a family of postsynaptic synapse organizing proteins that mediate excitatory synapse development through binding to presynaptic neurexins. LRRTM1 and LRRTM2 are highly expressed in the hippocampal CA1 and dentate gyrus regions However, their *in vivo* functions are poorly understood. To determine their role in synapse development and plasticity, we ablated *Lrrtm1/Lrrtm2* either globally from birth or locally in the CA1 and the dentate gyrus. We assessed the contribution of LRRTM1 and LRRTM2 to synapse numbers, synaptic composition and synaptic morphology using immunocytochemistry of brain sections, golgi staining and transmission electron microscopy. Loss of LRRTM1 and LRRTM2 from birth led to a marked reduction (by ~24%) of excitatory presynaptic inputs, assessed by vesicular glutamate transporter 1 (VGLUT1) puncta staining, to the CA1 dendritic compartments. In accord, ultrastructure studies showed that loss of LRRTM1 and LRRTM2 from birth reduced asymmetric synapse numbers by 27% when compared to wildtype controls. In contrast, VGLUT1 puncta density and synapse numbers were not altered in mature mice in which LRRTM1 and LRRTM2 were acutely deleted. Next, we assessed the role of LRRTM1 and LRRTM2 in synaptic function and plasticity using slice electrophysiology assays. We found that miniature excitatory postsynaptic current was significantly reduced (by ~30-35%) in both the developing and mature deletion models.

These deficits were accompanied by impaired long-term-potentiation and deficits in contextual fear memory. Our results suggest that LRRTM1 and LRRTM2 regulate excitatory synapse development, plasticity and behavior in a development-stage and context-dependent manner.

Title: Loss of core PCP protein Vangl2 affects the morphofunctional development of the hippocampal mossy fiber synapse, resulting in working memory impairments

Authors: *N. DEPRET[1], M. GLEIZES[1], M. MOREAU[1], G. BARTHET[2], S. DOS-SANTOS CARVALHO[1], A. QUIEDEVILLE[1], B. J.-A. ROBERT[3], S. AL ABED[1], C. MULLE[2], A. DESMEDT[1], C. RACCA[4], A. For Neurosci., Bordeaux, France; [3]Neurocentre Magendie, Bordeaux, France; [4]Newcastle Univ., Newcastle-upon-Tyne, United Kingdom

Abstract: Deciphering how neurons acquire complex morphologies during development and how they modulate their core synaptic complexes to adapt to the environment during life and aging, is key to our understanding of how the nervous system is built and functions. A key brain structure in cognitive processes is the hippocampus, which is known for its role in episodic memory and context discrimination. The hippocampus is a highly connected region where we find a distinctive complex synaptic connection formed postnatally between the dentate gyrus (DG) and the CA3 sub-regions: the mossy fiber bouton / thorny excrescence synapse (MFB/TE). The morphogenesis of these large synapses critically depends on cytoskeleton remodelling, and variations of their morphology and size can impact their functional properties and alter behavioural processes. Amongst many regulators of cytoskeleton dynamics, the Wnt/PCP pathway is a conserved signalling pathway known to shape tissues during development via the

regulation of adhesion complexes and cytoskeleton. The PCP pathway plays a known role in prenatal brain development but its role in post-natal brain morphogenesis remains unclear. Here, we investigated the role of the core PCP protein Vangl2 in the post-natal development of the MFB/TE synapse, using a conditional *vangl2* knock-out (Vangl2f/f::EMX1-cre mice, henceforth called EMX1-Vangl2$^{-/-}$) mice. We show that Vangl2 is enriched postnatally in the DG and the CA3, during the period of development of the MFB/TE synapse. Using confocal and electron microscopy and 3D reconstruction, we show that the early loss of Vangl2 affects the size and complexity of the MFB/TE synapse in young mice and alter their structural plasticity in adults. Using electrophysiology, we also show that the basal properties of the MFB/TE synapses are altered by the early loss of Vangl2. Finally we show that the early deletion of *vangl2* impairs the performance of the adult animals in complex memory tasks. Altogether, our results shed a new light on the role of Vangl2-dependent PCP pathway in the brain, and more specifically provide evidence for the control and/or maintenance of circuits crucial for specific properties and components of relational/declarative memory.

Title: Impact of mossy cell ablation on adult hippocampal neurogenesis

Authors: *C. R. BUTLER[1], G. L. WESTBROOK[2], E. SCHNELL[3];
[1]Oregon Hlth. & Sci. Univ., Portland, OR; [2]Vollum Inst., Portland, OR; [3]Portland VA Med. Ctr., Portland, OR

Abstract: The neurogenic niche of the hippocampus allows for the incorporation of new dentate granule cells (DGCs) into the hippocampal circuit even in adulthood, and the proper integration of these new DGCs is critical for learning and memory. Disruption of adult-born DGC

proliferation and integration has been observed in animal models of traumatic brain injury, epilepsy, and stroke, often associated with hippocampal circuit changes such as hilar mossy cell loss. We hypothesized that hilar mossy cells contribute to early survival and integration of adult-born DGCs, and that the loss of mossy cells in disease could contribute to aberrant neurogenesis and integration of these new neurons. To test this idea, we selectively ablated hilar mossy cells via virus-mediated apoptosis in Crlr-Cre mice, and examined the proliferation, survival, and dendritic arborization and spine development of adult-born DGCs using BrdU and retroviral labeling. The removal of mossy cell inputs within the dentate gyrus did not impact proliferation or survival of adult-born DGCs. Ablation of mossy cells did accelerate dendritic outgrowth of adult-born DGCs, but did not affect the morphology of DGCs after maturation. Interestingly, despite the loss of axonal projections from mossy cells in the inner molecular layer, the dendritic spine density of 21 day-old DGCs was equivalent in the inner molecular layer and outer molecular layer with or without mossy cell innervation. Preliminary data suggests this may reflect reorganized excitatory inputs from the medial entorhinal cortex. Our results demonstrate that removal of hilar mossy cells accelerates outgrowth of adult-born DGCs, and that glutamatergic inputs in the molecular layer appear to compensate for the loss of mossy cell inputs. In ongoing work, we are examining the mechanisms linking mossy cell innervation to functional neurogenesis. Overall, our work suggests that loss of mossy cell inputs may drive reorganization of excitatory input within the dentate gyrus.

Title: Cyclic adenosine monophosphate signaling-mediated phosphorylation of diacylglycerol lipase-alpha regulates interaction with ankyrin-g and dendritic spine morphology

Authors: *S. YOON, K. MYCZEK, P. PENZES;
Dept Physio, Northwestern UniversityNothwestern Univ. Feinberg Sch. Med., Chicago, IL

Abstract: Diacylglycerol lipase α (DAGLα), a key biosynthetic enzyme for endogenous cannabinoid signaling, has emerged as a risk gene for several psychiatric disorders. However, its role in the regulation of dendritic spine plasticity is unclear. We found that DAGLα modulated dendritic spine size and density, but with different effects of changes in protein level and enzymatic activity, suggesting a 2-arachidonoylglycerol (2-AG)-dependent or independent

mechanism. The 2-AG-independent effect was mediated by the interaction of DAGLα with ankyrin-G, a multifunctional scaffold protein associated with psychiatric disorders. Using super-resolution microscopy, we observed coexistence in distinct nanodomains that correlated with spine size. In situ proximity ligation assay combined with structured illumination microscopy showed that upon forskolin treatment, DAGLα phosphorylation enhanced interaction with ankyrin-G in the spine, resulting in increased spine size and decreased DAGLα surface diffusion. Ankyrin-G conditional knockout mice showed a significant decrease in DAGLα-positive neurons in the forebrain. In mice, ankyrin-G was required for forskolin-dependent reversal of depression-related behavior. These data reveal novel synaptic signaling mechanisms and potential therapeutic approaches.

Campus Querétaro, Querétaro México, Mexico; [4]CUSUR, Ciudad Guzmán, Jalisco, México. Univ. de Guadalajara, Ciudad Guzmán Jalisco, Mexico

Abstract: Low-protein diet intake during pregnancy switch fatty acids concentration in breastmilk during lactation, these could be associated to alterations in the Nervous System in the postnatal stage in offspring. It is unknown about the effect of deficient protein intake during pregnancy on modifications of polyunsaturated fatty acids in breastmilk and changes of synaptogenesis in the hippocampus during neurodevelopmental in the neonatal stage. We analyzed if hypoprotein diet intake during pregnancy affects the percentage of polyunsaturated fatty acids in breastmilk and we studied in offspring synaptophysin area percentage in CA1 and dentate gyrus of the hippocampus. It was a longitudinal study in females rats exposed to a

hypoprotein isocaloric diet, during pregnancy and lactation 10 days. We used a control diet 18% protein and an experimental diet 6% protein. Were evaluated the feeding behavior and concentration of lipids and glucose in serum, fatty acids in breastmilk were determined by gas chromatography, and the synaptophysin area in pyramidal, oriens, and radiatum stratum of CA1 and granular, molecular, and lacunose molecular layer of the dentate gyrus of the hippocampus of the offspring by immunohistochemistry. We analyzed intragroup and intergroup. We showed that breastmilk from mothers exposed to hypoprotein diet was lower than control females (38%), fat content (50% lower) ($p<0.05$); polyunsaturated fatty acids were less (24%) linolenic acid concentration decreased 45% ($p<0.05$), and arachidonic and eicosanoic acid (100%) compared to breastmilk of mothers exposed to control diet ($p<0.05$). The synaptophysin area percentage in pyramidal and oriens stratum of CA1 in male offspring of mothers exposed to the hypoprotein diet decrease by 98% ($p <0.001$). Body weight decreased (5%) and concentration of high-density lipoproteins in serum in mother during lactation with hypoprotein diet. The glucose in serum decreased by 40-45% in the offspring of mothers exposed to a hypoprotein diet. These results suggest that hypoproteic diet intake during pregnancy and early lactation decrease the proportion of eicosanoic and arachidonic acid in breast milk, as well as the synaptophysin area percentage in pyramidal and oriens stratum of CA1 of male offspring in the neonatal stage, these results suggest that synaptogenesis has been altered in hippocampus in P10 neonates affecting the hippocampal network performance. Title: Potential role of serotype and perineuronal nets in the preferential expression of adeno-associated virus-packaged genetic cargo in hippocampal CA2 neurons

Authors: *G. M. ALEXANDER, K. E. CARSTENS, B. GLOSS, S. R. LILLEY, B. S. SLAY, N. P. MARTIN, S. M. DUDEK;
Neurobio. Lab., Natl. Inst. of Envrn. Hlth. Sci., Research Triangle Park, NC

Abstract: A common approach to studying hippocampal circuits is through viral delivery of genetic material that encodes effector molecules and fluorophores. This is often accomplished through direct injection of adeno-associated viral (AAV) particles into the hippocampus, or via the bloodstream for some serotypes. In previous studies and in our own experiments, we have observed preferential expression of AAV-delivered cargo in CA2 compared to CA1 and CA3, even when not targeted to CA2. This curious observation led us to ask why CA2 neurons are preferentially targeted by AAVs. Because different AAV serotypes target different receptors, one possible mechanism by which differential AAV expression occurs is that CA2 neurons may preferentially express a receptor for specific serotypes of AAVs. Thus, we predicted that preferential expression of AAVs by CA2 neurons would vary with different serotypes, which target different receptors. Alternatively, we hypothesized that the preferential targeting of AAVs to CA2 is mediated by the dense expression of a specialized extracellular matrix, perineuronal nets (PNNs), which uniquely surround excitatory CA2 pyramidal neurons in addition to specific populations of inhibitory neurons throughout the brain.
To test the hypothesis that AAV expression in CA2 is dependent upon serotype, we injected AAVs of various serotypes, each coding for enhanced green fluorescent protein (eGFP) under the control of the human synapsin (hSyn) promotor, into the hippocampus of C57Bl/6 mice. Thus far, we have found that for each of multiple AAV serotypes injected intra-hippocampally, CA2 neurons preferentially express eGFP relative to CA1 and CA3 neurons. In addition, we found that eGFP was preferentially expressed in CA2 neurons after intravenous injection of the PHP.B serotype, which is known to cross the blood-brain barrier. To address the role of PNNs in AAV infection, we generated a conditional aggrecan gene (*ACAN*) knock-out (KO) mouse. Aggrecan is a primary component of PNNs detected around CA2 neurons as well as a class of interneurons. By pairing this “floxed” *ACAN* strain with our CA2-targeted *Amigo2* cre strain or parvalbumin (PV) neuron-targeted cre strain, we successfully deleted WFA-labeled PNNs from CA2 pyramidal neurons or from PV neurons, respectively. We injected CA2 *ACAN* KO mice with PHP.B-hSyn-eGFP intravenously and found that despite the absence of PNNs, CA2 neurons continued to express eGFP. These data do not support the hypotheses that preferential expression of AAVs by CA2 varies according to AAV serotype or that PNNs (or at least *ACAN*), is required for preferential expression in CA2 and point toward an alternative mechanism.

Title: Prrt2 is a driver of neuropsychiatric phenotypes in 16p11.2 microduplication mice

Authors: *M. FORREST[1], M. DOS SANTOS[1], N. PIGUEL[1], Y.-Z. WANG[2], N. HAWKINS[3], V. BAGCHI[1], L. DIONISIO[1], S. YOON[1], M. MARTIN-DE-SAAVEDRA[1], R. GAO[1], M. S. LEDOUX[4], J. A. KEARNEY[3], J. N. SAVAS[2], P. PENZES[1];
[1]Physiol., [2]Neurol., [3]Pharmacol., Northwestern Univ., Chicago, IL; [4]Neurol., Univ. of Tennessee Hlth. Sci. Ctr., Memphis, TN

Abstract: Copy number variants (CNVs) are a major class of genetic risk variants for neuropsychiatric disorders (NPDs), but the biological pathways involved in mediating risk are often unknown. The 16p11.2 microduplication (16p11.2$^{dup/+}$) is a highly pleiotropic CNV conferring risk of autism spectrum disorder, schizophrenia, intellectual disability, and epilepsy. Here, we use the 16p11.2$^{dup/+}$ mouse model to investigate the molecular, cellular and circuit basis for this shared NPD risk, and assess the contribution of individual genes to disease phenotypes. Using quantitative proteomics, we profiled neocortical membranes of 16p11.2$^{dup/+}$ mice to gain insight into pathophysiology. Membrane proteomics revealed an upregulation of synaptic proteins and a disruption of proteins associated to multiple NPDs. In particular, we identified a highly enriched network of synaptic and epilepsy-associated proteins in the mouse neocortex suggesting an alteration of cortical circuitry. Phenotypic characterization of 16p11.2$^{dup/+}$ mice uncovered cellular and circuit alterations including increased synaptic connectivity, hypersynchronous cortical circuitry, and increased seizure susceptibility. We hypothesized that a regulator of the proteomic changes in 16p11.2$^{dup/+}$ mice would have an important impact on pathophysiology. Using human co-expression data and interactome analysis, we find that PRRT2, a protein encoded within the microduplication, is a central hub in the dysregulated synaptic/epilepsy associated protein network. To evaluate the role of PRRT2 on disease phenotypes, we crossed 16p11.2$^{dup/+}$ mice with Prrt2$^{+/-}$ mice to correct PRRT2 copy number at the genomic level. Genetic correction of *Prrt2* reversed key neuropsychiatric associated with the 16p11.2 microduplication. Together, our work suggests that *Prrt2* is a major driver of disease biology in the 16p11.2 microduplication and that increased cortical connectivity and synchrony may be predisposing risk factors for diverse neuropsychiatric phenotypes.

Abstract: The 16p11.2 locus is a highly penetrant copy number variant (CNV) strongly linked to autism spectrum disorders and schizophrenia (SCZ). Whereas deletion at the 16p11.2 locus is a risk factor for numerous neurodevelopmental disorders, only duplications are linked to schizophrenia. There appears therefore, to be a unique role of 16p11.2 duplication in schizophrenia risk, suggesting a distinct etiological effect of 16p11.2 duplication. Using iPSC-derived induced cortical neurons from CRISPR-Cas9 isogenic 16p11.2 duplication lines and SCZ patient lines, penetrant 16p11.2 duplication phenotypes that may contribute to SCZ susceptibility were identified. Transcriptomic analyses identified deficits in neurite outgrowth, calcium handling and cell-cell junction gene expression. Consistent with this, iPSC from both isogenic and patient lines showed robust alterations in dendritic length, synaptic puncta and calcium handling. Moreover, these deficits converged on a penetrant alteration in network activity, revealed by network calcium imaging. Interestingly, network dynamics deficits were unchanged in the presence of iPSC-derived inhibitory neurons, supporting 16p11.2 duplication as a causative factor in excitatory cortical neuronal network dysfunction. These factors may contribute to excitatory neuron dysfunction in 16p11.2 duplication carriers early in development and promote cortical dysfunction and, thus, SCZ risk.

Abstract: Synaptic development, which is highly influenced by neuronal activity, is a critical step during brain maturation that is required for the formation of functional neural circuits. This process is believed to be impaired in many neurodevelopmental disorders (NDDs), but it has been challenging to pinpoint when and where activity-dependent synaptic development is affected by the genetic and environmental factors in NDDs. Thus, there is an urgent need to design new tools and approaches to systematically monitor and examine activity-dependent synaptic development throughout the whole brain. To meet this challenge, we have constructed, for the first time, a longitudinal map of the developing mouse brain undergoing activity-dependent functional maturation during the early postnatal period. We generated a reporter mouse, Npas4-Cre, based on the activation of an immediate early gene (IEG) Npas4, which is selectively and robustly induced by neuronal activity and functionally important for synapse development. Crossing with a Cre-dependent reporter mouse, Ai75, neurons undergoing activity-dependent synaptic development, by activating Npas4 expression, are permanently labeled with nuclear-localized tdTomato (red). Combined with tissue clearing, whole-brain imaging, and computationally registering labeled neurons onto the newly developed developing mouse reference brains, we were able to monitor the sequence of synaptic maturation on the whole brain level. We observed a distinct sequence of brain regions undergoing synaptic maturation. For example, the neurons of sensory and motor-related regions (piriform cortex, somatosensory cortex, striatum et al.) are labeled earlier than regions associated with cognitive function (hippocampus). Using this approach, we were able to identify brain regions in which activity-dependent synaptic maturation was affected by developmental interventions that either enhanced (environmental enrichment, EE) or impaired brain development (NDDs). In addition to characterizing the synaptic development sequence, this approach allows us to carry out a multifaceted, detailed investigation of specific neuronal populations within developing neural circuits to uncover the underlying cellular and molecular mechanisms. We employed electrophysiology as well as transcriptomic experiments to identify molecular players important for synaptic development and behavior improvement in EE. The multipronged approach, enabled by the Npas4-Cre reporter mouse, has proven to be particularly powerful to identify targeting

regions and study genetic pathways impacted by developmental intervention, such as NDD mouse models.

Title: Emergence of synaptic modules during early cortical development

Authors: *L. ZHOU[1], A. BHADURI[2], Q. BI[1], S. WANG[1], A. KRIEGSTEIN[1];
[1]UCSF, san francisco, CA; [2]UCLA, Los Angeles, CA

Abstract: Normal brain development requires electrical activity triggered by long-range inputs or local circuits, but little is known about the emergence of local cortical circuits during human brain development. We explore the physiological and morphological features of early intracortical connectivity in the developing human cortex during the second trimester, at the beginning of synaptogenesis. Single-cell Patch-seq demonstrates that electrophysiologically immature and morphologically simple cells in the cortical plate and marginal zone express genes for synaptic components. *Ex vivo* rabies tracing reveals the emergence of local synaptic modules in the cortical plate and subplate composed of immature excitatory neurons including migrating cells. Activity-dependent and independent spontaneous patterns of calcium activity can be observed in the synaptic modules. Furthermore, serotonin signaling regulates the formation of local synaptic modules through the activation of 5-HT2A receptors. Understanding the development of early intracortical circuits may shed light on the etiology of neurodevelopmental disorders and can inform *in vitro* models of human brain development.

Title: Development of GABAergic and glutamatergic synapses in the motor cortex

Authors: W. MATYSIK[1], J. KAPUR[2], J. BURNSED[1];
[1]Pediatrics, [2]Dept Neurol., Univ. of Virginia, Charlottesville, VA

Abstract: Synaptic development occurs when a synapse is formed between two neuron forms: presynaptic and postsynaptic terminals. There are no previous studies of the development of excitatory and inhibitory synapses in the motor cortex, which is considered a central region required for skilled voluntary movements, control, learning, and memory. The aim of our study was to compare synaptic development in brains of c57/Bl6 mice, between postnatal day (p)10 (neonatal) and p30 (young adults). We used immunohistochemistry for pre and postsynaptic markers such as glutamate receptor 1 (GluA1) and 2 (GluA2), vesicular glutamate transporter 1 (vGluT1), PDS-95, Bassoon, GABA (A) γ2, synaptophysin, and GAD65 to quantify and localize GABAergic and glutamatergic synapses. We used Western blot assays to quantify differences in protein production of synapses markers in the motor cortex. Lastly, we used the patch-clamp method to fill layer II/III neurons in the motor cortex with biocytin and then stained the slices with Streptavidin-AlexaFluor488 to assess the growth and length of dendrites. Western blot data shows that there was less production of pre and postsynaptic receptors in p10. The ratio of p10 to p30 for synaptophysin was 0.73 ± 0.03 (p=0.001), vGluT1 was 0.677 ± 0.02 (p=0.01). GluA2 and PSD-95 were not significantly different based on preliminary data. We observed an increase in pre and postsynaptic GABA and glutamate markers from p10 to p30 by a combination of immunohistochemical markers. We observed differences in the distribution within layers of the motor cortex with the use of GluA1 and GluA2 markers. We have also seen more intense staining in adults compared to neonates by looking at GluA2 and synaptophysin staining. These findings show differences in synaptic maturation in the motor cortex between neonatal and young adult mice under normal developmental conditions. Ongoing work focuses on evaluating surface expression of proteins and assessing the length and number of dendrites from p10 and p30 in layer II/III neurons in the motor cortex.

Title: Comprehensive meta-analysis reveals a general cross-species timescale for neocortical synaptic development

Authors: *H.-J. BOELE[1], C. JUNG[1], L. A. LYNCH[1], D. PACUKU[1], M. TESTERMAN[2], S. GUARIGLIA[1], J. VERPEUT[4], **S. S.-H. WANG**[3];
[1]Princeton Neurosci. Inst., Princeton, NJ; [2]Lewis Sci. Library, [3]Princeton Neurosci. Inst., Princeton Univ., Princeton, NJ; [4]Psychology, Arizona State Univ., Phoenix, AZ

Abstract: Neocortical synaptic connections proliferate and are eliminated during development, a process that has been studied extensively over four decades. To place this work into a single scheme, we performed a meta-analysis on 16,000 data points extracted from 150 studies spanning 12 animal species, according to PRISMA guidelines and using SciBERT natural language processing to screen relevant literature. In altricial animals, synapse density started to increase soon after birth and peaked at around 1 gestational period postnatally, a pattern that persisted across neural subtypes, synapse type and location, and cortical layer. Brain regional differences were seen in humans and macaques. Synapse density declined over the next 4-5 gestational periods, with the exception of the human prefrontal cortex, which peaked at 10-15 gestational periods. Although evidence is still limited, autistic brains deviated from the overall pattern, with generally less spine pruning leading to higher synapse densities during adulthood. This first meta-analysis of synapse maturation will provide a scalable framework for understanding the mechanisms influencing brain development and a resource for identifying atypical neurodevelopment. (All data will be open-source, all data will be available online in a ShinyR dashboard.)

Title: Developmental activation of pyramidal neurons differentially regulates cytoarchitecture and excitatory-inhibitory balance across distinct regions of the neocortex

Authors: *E. L. CRESPO[1], E. C. IKEFUAMA[2], N. J. COON[3], A. M. VAN LOO[4], G. FOLKERT[3], U. HOCHGESCHWENDER[5];

Abstract: Many psychiatric disorders are thought to have neurodevelopmental origins, stemming from malformation of neural circuits in early development. Early disruptions to cortical activity may underlie the later manifestation of behavioral changes typical of disorders such as autism. We carried out unbiased testing of the role of developmental over-excitation in altering adult behavior and circuit dynamics. We took advantage of Bioluminescent Optogenetics (BL-OG), where light stimulation of an optogenetic element is achieved either through bioluminescence emitted from a tethered luciferase upon application of a chemical substrate or through application of physical light via fiber optics. Mice conditionally expressing LMO3, a fusion of sbGLuc and VChR1, were crossed with Emx1-Cre transgenic mice, thus limiting expression of LMO3 to cortical pyramidal neurons. By delivering the luciferin CTZ intraperitoneally during post-natal days 4-14, over-excitation was induced chemogenetically in the cortical pyramidal neurons of developing mouse pups. During adulthood, mice were tested behaviorally, assessed for electrophysiological changes in circuit dynamics by standard optogenetic interrogation, and probed for changes in interneuron numbers. While Emx1-positive neurons were hyperexcited during postnatal development across the cortex, behavioral, electrophysiological, and morphological effects manifested differently in distinct areas.

Title: Conserved molecular signatures for probing subclass-specific circuit motifs in the adult neocortex

Authors: *A. J. MOUSSA, J. C. WESTER;
Neurosci., The Ohio State Univ., Columbus, OH

Abstract: A prevailing challenge in neurobiology is understanding how diverse neuronal cell types integrate into circuits with emergent functions. We mined the Allen Institute for Brain Science's single-cell RNA-sequencing database of adult mouse cortical neurons to identify subclass-specific molecular signatures of circuit architecture across the cortex. We analyzed differential expression (DE) of cellular adhesion molecules (CAMs) and their regulatory genes among major subclasses of GABAergic (inhibitory) and glutamatergic (excitatory) neurons in two brain regions: the anterior lateral motor cortex (ALM) and the primary visual cortex (VISp). We hypothesized that differential expression of CAMs among major neuronal subclasses is conserved between these two functionally distinct cortices. We used the R package Seurat to determine differential gene expression and filtered the results using the gene ontology (GO) software PANTHER 16.0 to classify DE genes by selected terms: "Cell-Cell Adhesion", "Regulation of Cell-Cell Adhesion", and "Regulation of Trans-Synaptic Signaling." Downstream bioinformatic analysis was conducted to identify unique and conserved DE patterns among subclasses both within and between ALM and VISp. Our analysis indicates that both glutamatergic and GABAergic subclasses display region-independent conservation of gene expression associated with synaptic connectivity, suggesting cell type-specific wiring principles. Thus, subclass identity likely plays a greater role than cortical region in determining local circuit architecture. Finally, we used ClinVar Miner to focus on genes associated with neurological disorders identified through clinical testing. ClinVar review uncovered that 14% of the DE CAM-related genes are relevant to neurological disorders, with many defining conserved regulatory relationships across subclasses and cortices in both glutamatergic and GABAergic neurons. These findings thereby associate disease-relevant genes with specific neuron subclasses to provide candidate mechanisms, targeted to these subclasses, for investigating aberrant circuit architecture in future studies.

Title: Emergence of coordinated network activity in the developing mouse parietal cortex.

Authors: *L. MA[1,2], J. HOFFMAN[4], J. N. GELINAS[2,1,3];
[1]Biomed. Engin., Columbia Univ., New York, NY; [2]Inst. for Genomic Med., [3]Neurol., Columbia Univ. Med. Ctr., New York, NY; [4]Univ. of Alberta, Edmondon, AB, Canada

Abstract: Mature rodent parietal cortex (PPC) connects with a multitude of cortical regions and subcortical structures, playing an essential role in brain functions such as association and navigation. Such complex functions require intercortical communication, which is often facilitated by neural oscillations. However, precisely coordinated oscillatory activity enabling cognition is not an innate property of the underlying neural networks. To investigate how such patterns emerge, we performed *in vivo* electrophysiology on mouse pups between postnatal day 5 and postnatal day 14. Using flexible, conformable, and high-density electrode arrays with high spatiotemporal resolution and large cortical coverage, we recorded local field potentials (LFP) and action potentials from dorsal cortical brain regions of mouse pups as they cycle through normal sleep states. We identified electrodes recording from primary sensory (S1), primary visual (V1), and parietal cortex using vesicular glutamate transporter 2 (VGluT2) immunohistochemistry. Although spindle burst oscillations are a dominant pattern in early development of S1 and V1, there was a paucity of such activity in PPC. Independent PPC oscillatory activity could be acquired starting in the second postnatal week, with distinct frequency and waveform characteristics. We also found evidence of intercortical comodulation of oscillatory activity during this epoch. These results suggest that PPC neural activity is developmentally regulated, with a maturation pattern distinct from neighboring primary sensorimotor cortices and potentially linked to emergence of higher cognitive processes.

Title: Networks and function of somatostatin-expressing interneurons across primary sensory areas of the mouse neocortex during early postnatal development

Authors: *F. GHEZZI, L. J. BARUCHIN, N. T. HA, S. J. B. BUTT;
Dept. of Physiology, Anat. and Genet., Univ. of Oxford, Oxford, United Kingdom

Abstract: GABAergic interneurons (INs) play an essential role during the development of mammalian neocortical network. Somatostatin-expressing (SST+) INs are optimally suited to provide the main source of GABAergic signalling during postnatal development as they integrate early into the cortical network. In mouse primary somatosensory barrel cortex (S1BF), layer (L)5b SST+ INs establish a transient, translaminar, reciprocal circuit with L4 spiny stellate neurons during the critical period for plasticity (postnatal day (P)5-8). This network plays a role in timing the emergence of sensory-driven, feed-forward inhibitory architecture in L4. However, whether this transient network represents a common strategy employed by other brain areas during early postnatal development remains to be investigated. Through *in vitro* electrophysiology and circuit mapping techniques, we studied GABAergic networks of the mouse primary visual cortex (V1) during the first 3 weeks of development. Our results show that the transient L5b-L4 circuit found in S1BF is not present in V1 through postnatal life, rather thalamocortical-recipient L4 pyramidal neurons receive local GABAergic input from within L4. Furthermore, SST+ INs in infragranular layers form a distinct translaminar network with L2/3 pyramidal neurons during the first postnatal week of development. We next explored the contribution of these INs to emergent somatosensory and visual perception *in vivo*. We expressed Channelrhodospin-2 in either *SST* or *Nkx2-1* Cre driver lines and used optogenetic spike-tagging to identify the contribution of SST+ INs and parvalbumin-expressing (PV+) INs to both spontaneous activity and sensory-evoked cortical responses. Our results reveal that SST+ interneurons are engaged by sensory stimuli prior to the onset of active perception in both sensory areas. However, the layer location of sensory-responsive SST+ INs differs between S1BF and V1, in line with our *in vitro* circuit mapping. As such we demonstrate that local GABAergic networks readily differ across primary sensory areas from early development postnatal life. This suggests that genetic mutations that cause an impact on the network integration of GABAergic interneuron will result in circuit dysfunction in an area-dependent manner with selective consequences for emergent function. In conclusion, our study highlights that general principles for synaptic integration and circuit formation cannot be extrapolated across cortical areas with consequences for our understanding of neurodevelopmental psychiatric disorders.

Title: Whole Brain Mapping of Developmental Neural Activity in Oxytocin Receptor Deficient Mice

Authors: *K. NEWMASTER[1], Y. KIM[2];
[1]Pennstate Col. of Med., Middletown, PA; [2]Col. of Medicine, Penn State Univ., Hershey, PA

Abstract: Neural activity during early postnatal development plays an important role in establishing neuronal wiring patterns. Oxytocin regulates neuronal activity and maturation via the oxytocin receptor (OTR). In our previous mapping of OTR expressing cells across the whole mouse brain during postnatal development, we found that OTR has specific spatiotemporal expression patterns, and it is expressed in both glutamatergic and GABAergic cell types. However, it remains unclear how oxytocin signaling in different cell types is affecting neural activity in the developing brain. Here we investigate neural activity throughout the entire mouse brain on postnatal day (p)7 and p14 in cell type specific OTR knockout (KO) mice which were generated using either Gad2-Cre or vGlut2-Cre to mediate conditional OTR KO. To visualize neural activity in developing brains, we used IDisco to label the immediate early gene, cFos a protein marker for neural activity. These brains were imaged using light sheet fluorescent microscopy and detected signals were quantified with age matched reference brains. cFos quantification in normal mice revealed significant activation of the cortical subplate (SP) and paraventricular thalamus (PVT) at p7, while regions involved in reward processing and stress such as the ventral tegmental area (VTA) show increased cFos-positive cells at p14. Interestingly, lack of OTR in glutamatergic cells lead to a decreased cFos levels (20%) in the PVT, VTA, and other reward related regions at p14. In contrast, lack of OTR in GABAergic cells increaser p14 cFos levels in stress related regions such as the central amygdala (CEA) and bed nucleus stria terminalis (BST) (20%). These patterns suggest that Oxytocin modulates the development of reward and aversion processing during the second postnatal week.

Abstract: Immature neural circuits are characterized by spontaneously occurring synchronized network events that involve large neuronal populations. Within the first postnatal month in rodents, there is a transition to desynchronized and continuous activity. What are the cellular dynamics and intrinsic biophysical mechanisms underlying neuronal synchrony in the intact developing brain? To address this question, we use two-photon Ca^{2+} imaging to analyze neuronal network activity in the developing mouse hippocampal area CA1 at single-cellular resolution *in vivo*. Strikingly, we find an intermediate network bursting period in the second postnatal week, i.e. after the developmental emergence of effective synaptic inhibition. At this time, pyramidal neurons fire in an almost random manner, and pairwise neuronal correlations are low. We reveal that enhanced network synchrony reflects an increased functional coupling of the activity of individual neurons to that of the local population. Dynamic systems modeling identifies network bi-stability as a potential regime underlying network burstiness at this age. We further show that network bursts depend on proper input timing and strength, pointing to the emergence of the network's capability of input selectivity. We thus propose that CA1 network bursts underlie extensive input-discrimination learning prior to the onset of environmental exploration.

Title: Effects of prenatal stress in a genetic mouse model of autism

Authors: K. M. HARPER, J. A. JIMENEZ, M. J. ZYLKA, *S. S. MOY;
Univ. of North Carolina at Chapel Hill Sch. of Med., Chapel Hill, NC

Abstract: Autism spectrum disorders have complex etiology, which likely includes interactions between multiple genes and/or environmental factors. *CHD8* is a high confidence autism gene, but ASD-like phenotypes in *Chd8* heterozygous (HET) or mutant mouse models have varied greatly and are often mild. This study investigated whether prenatal exposure to maternal stress would increase the emergence and severity of behavioral phenotypes in *Chd8* HET mice. Subjects were offspring of C57BL/6J wild-type dams bred to *Chd8* HET males. Dams in the stress condition underwent a series of behavioral tests, including acoustic startle and conditioned fear, across gestational days 10 to 15. Control dams received only routine husbandry care. Offspring were weaned at 22 days in age and evaluated for ASD-like and other phenotypes, starting at 4 weeks in age. The testing battery included assays for anxiety-like and depression-like behavior, activity, social approach, olfaction, and conditioned fear. Preliminary results indicate significant effects of both prenatal stress and genotype in a subset of tests, with different behavioral profiles observed in males and females. Overall, this study extends the characterization of the *Chd8* HET mouse as a gene x environment model for ASD-like phenotypes.

Abstract: Prenatal stress is critical in neurodevelopment and increases risk for autism spectrum disorder (ASD), particularly in those genetically susceptible to stress. In animal models, we demonstrated that aberrant social behavior was observed in offspring of heterozygous serotonin

transporter knock-out (SERT-het) mice exposed to stress during pregnancy, and restricted social interaction was associated with epigenetic changes in the embryonic brains. Two independent clinical studies have shown that the higher incidence of ASD in prenatally stress-exposed mothers is associated with maternal presence of the SERT short-allele (deletion in promoter region). Recently, we have reported differential expression (DE) of microRNAs (miRNAs) in blood samples of prenatally stress-exposed mothers carrying short allele who have children with ASD, which may serve as a potential blood biomarker of the gene x environment (G x E) interaction in ASD. To further investigate the role of miRNAs as a potential biomarker during pregnancy in this G x E interaction model, we profiled the miRNA expression in blood from dams in the mouse model of SERT-het/stress dams at embryonic day 21 (E21) and postnatal day 60 (PD60) and compared with that of wild-type mice at the same time window. More than three thousand mature miRNAs were examined, and the ANOVA analysis detected several DE miRNAs. However, there was no common DE miRNAs between E21 and PD60, which suggested a transition in miRNA profiles in SERT-het/stress dams after delivery. One of upregulated miRNAs (miR-149-3p) at PD60 and two of upregulated miRNAs (miR-328-5p and miR-762) at E21 were also found in the DE miRNAs of human samples from our previous study. These miRNAs could be biomarker candidates for G x E interactions in ASD, and are highly dynamic over time. Our study provides evidence for epigenetic alterations associated with the gene x environmental interaction which we hope will lead to better understanding of the causes and treatments of ASD, resulting from prenatal stress exposure in genetically stress susceptible individuals.

Title: Increased oxidative injury and blood brain barrier disruption in the brain of two murine models of autism spectrum disorder.

Authors: *E. GOZAL[1], R. JAGADAPILLAI[1], T. CHU[1], J. CAI[1], Z. LI[2], G. N. BARNES[3]; [1]Dept of Pediatrics PRI, Univ. of Louisville, Louisville, KY; [2]Neurol., Vanderbilt Univ., Nashville, TN; [3]Dept Neurol, Univ. of Louisville Sch. of Med., Louisville, KY

Abstract: Immune dysregulation, oxidative stress and neuroinflammation with glial activation have been proposed to play a role in the pathogenesis of Autism Spectrum Disorder (ASD). A study of post-mortem human ASD brains showed altered expression of genes associated with blood brain barrier (BBB) integrity and increased neuroinflammation. However, few studies exist of the involvement and the mechanisms of BBB disruption in autism animal models, such as BTBR or neuropilin-2 (NRP2)/Semaphorin 3F (Sema 3F) KO mice. BTBR mice, an inbred mouse model of ASD, exhibit a neuroinflammatory profile that correlates with some of their repetitive behavior, characteristic of ASD. We have previously described a neuropilin-2 (NRP2) knockout as a novel murine genetic model of autism and epilepsy. GABAergic interneurons-selective deletion of the NRP2 ligand, Sema 3F, is associated with decreased interneurons numbers, ASD behavioral symptoms, and showed microglial activation and increased inflammatory and oxidative markers in several brain regions that could contribute to BBB dysfunction. As neuroinflammation is common to both BTBR and Sema3F KO ASD models, we investigated whether both models exhibit oxidative markers and BBB disruption and could provide reliable models to study how these characteristics may lead to the disease in humans.BTBR, C57BL/6 control mice, Sema 3F KO and WT mice were sacrificed and perfused for histological analysis. DHE staining showed increased superoxide formation in the cortex, hippocampus and amygdala of BTBR and of Sema 3F KO mice, compared to their respective controls, attesting to increased oxidative stress in various ASD mice brain areas relevant to autism. Immunostaining for albumin showed that while perfusion removed most of the vascular albumin from control mice tissue, significant albumin remained in the tissue of Sema 3F KO and BTBR mice, suggesting vascular leakage. Intracardiac administration of fluorescently labeled Dextran tetramethylrodamine 10kD to BTBR or C57BL/6 mice, prior to sacrifice, showed some extravasation in the cortex of BTBR, but not of C57BL/6, confirming our data. Additionally, zonula occludens protein 1 (ZO1), a tight junction protein significantly decreased in BTBR mice brains. In conclusion, 2 different murine ASD models, the inbred BTBR polygenic model and the monogenic Sema3F KO, share enhanced neuroinflammation, oxidative injury and BBB disruption markers, also reported in humans, and that could directly contribute to autistic behavior impairment.

Title: Taok2 mediates er-microtubule tethering during neuronal development

Authors: *S. BYEON[1], S. YADAV[2];
[1]Univ. of Washington Grad. Program In Neurosci., Seattle, WA; [2]Pharmacol., Univ. of Washington, Seattle, WA

Abstract: The autism risk gene *TAOK2* encodes a serine/threonine kinase important for several aspects of neurodevelopment including axon elongation, dendritic branching, and spine formation. We have recently discovered that TAOK2 is an endoplasmic reticulum (ER) membrane localized protein kinase that tethers the ER membranes to microtubules. Despite its importance in neuronal development and the strong association of TAOK2 mutations with neurodevelopmental disorders, the molecular function of TAOK2 in neuronal development is not well understood. To explore how TAOK2 contributes to neurodevelopment, we generated a human TAOK2 knockout induced pluripotent stem (iPS) cell line, which was differentiated into neural progenitor cells and excitatory forebrain neurons. We found that TAOK2 KO iPS derived neural progenitor cells exhibit defects in ER-microtubule tethering compared to control. Further, we characterized the impact of autism associated *TAOK2* mutations on neurodevelopment. Using in vitro kinase assays, we found that *TAOK2* mutations differentially affect its catalytic activity and ER localization. Using time lapse confocal microscopy we found that disease mutants perturbed ER dynamics within the neurites and dendritic spines of neurons. Our results suggest that through regulation of ER-MT tethering, TAOK2 mediates dendritic growth and spine formation in excitatory neurons.

Abstract: Evidence demonstrates a role for the gut microbiome in Autism Spectrum Disorder (ASD), with signaling via microbial metabolites such as Short chain fatty acids (SCFAs) including acetate as a potential mechanism. In order to investigate microbiome and metabolite effects in a model for ASD we utilized a gene x microbiome paradigm in which we combined antibiotic (Abx) depletion of the microbiome with acetate replenishment in the Shank3 deletion (Shank3KO) model for ASD. In addition, to assess the clinical relevance of findings from the mouse model, targeted serum SCFA metabolomic analysis in Phelan McDermid (PMS) patients, who are hemizygous for the Shank3 gene, was conducted. Shank3KO mice and wild-type (Wt) littermates were divided into control, Abx depletion, acetate replenishment and acetate + Abx groups at weaning. On postnatal day 60, animals were subjected to behavioral testing using three-chambered social interaction. Caecal content was collected for 16S sequencing, metagenomic analysis and metabolomic profiling. Medial prefrontal cortex (mPFC) taken for gene expression profiling and western blot analysis. Serum from male and female PMS patients and their control counterparts was collected for targeted SCFA analysis. Analysis of mouse microbiome contents revealed a Shank3KO gene effect leading to decreased microbiome diversity, altered Bacteroidetes to Firmicutes ratios, and reduced levels of Lactobacillus genus bacteria. Metagenomic profiling revealed altered microbial functional output including fatty acid metabolism, this was confirmed by metabolomic analysis as reduced levels of SCFAs including acetate, effects that were exacerbated by Abx treatment. Behaviorally, control KO mice demonstrated decreased social interaction, a deficit exacerbated by microbiome depletion. RNA-sequencing showed marked changes in gene expression related to epigenetic regulation and synaptic plasticity in Abx+KO mice compared to Wt. Treatment of KO animals with acetate or Abx + acetate reversed the social deficits reported accompanied by changes to acetylation of specific histone marks. Human PMS patients were found to have sex-specific alterations in SCFA levels including acetate, which correlated with clinical behavioral measures. Our rodent data identified an altered gut microbiome and acetate levels in the Shank3KO model which can be targeted to reverse core social deficits possibly via epigenetic mechanisms. Clinical data corroborate findings of altered gut derived metabolites in PMS and add sex differences as a variable for further investigation.

Abstract: Autism spectrum disorders (ASDs) are a group of neurodevelopmental disorders associated with deficits in social behavior, communication, and repetitive, restrictive behaviors. Despite advances in our ability to identify a growing number of ASD-associated risk genes, we lack pharmacological interventions targeting the core deficits in ASD, due in large part to our limited understanding of the underlying neurodevelopment mechanisms. In this study, we capitalize on the transparency and tractability of zebrafish as a vertebrate system to investigate the effects of loss of function of 10 high confidence ASD genes in parallel. Using CRISPR/Cas9 technology, we generated zebrafish mutants carrying frameshift mutations in the orthologs of 10 ASD risk genes. First, to investigate the effects of gene disruption on simple behaviors, we performed high-throughput behavior-based assays analyzing sensory processing and rest-wake behaviors. We identified unique and overlapping phenotypes across ASD risk gene mutants. Second, to identify brain activity phenotypes, we performed whole-brain activity mapping using immunohistochemistry to label active (pERK) and all (tERK) neurons. We found that zebrafish mutants display alterations in baseline brain activity. Third, to identify potential pharmacological suppressors, we screened over 750 FDA-approved compounds to identify their effects on behavior in wild-type fish. By comparing the fingerprints of these drugs in wild-type fish to the behavioral profiles of ASD risk gene mutants, we aim to identify compounds that rescue mutant behavioral phenotypes. Together, this research leverages the zebrafish system to identify mechanisms by which ASD risk gene disruption alters basic neurodevelopmental circuits and aims to identify potential drug candidates for further investigation.

Abstract: Introduction: Deletions and duplications of the chromosome 16p11.2 locus are associated with autism spectrum disorders, schizophrenia, cognitive and language deficits. Diffusion tensor imaging (DTI) studies have reported increases and decreases in fractional anisotropy (FA) in 16p11.2 deletion (16pDel) and 16p11.2 duplication (16pDup) respectively, with respect to healthy controls (HC) in deep white matter (WM) [1]. Here we analyzed data from five independent cohorts worldwide and reported WM alterations in the largest diffusion MRI (dMRI) study of 16p11.2 CNV carriers to date. We used advanced dMRI models that are highly sensitive to axonal density (AD), to avoid established biases of the DTI model. Methods: We measured axonal density with Diffusion Kurtosis (DKI), Mean Apparent Propagator (MAP) and Neurite Orientation Dispersion and Density Imaging (NODDI). We analyzed 19 WM regions of interest using the ENIGMA-DTI protocol [2]. Differences between 16pDel or 16pDup and HC were investigated using multiple linear regression with an HC4 method to account for heteroscedasticity [3]. dMRI measures were harmonized across sites using ComBat [4]. We used the following model and calculated the effect sizes of group differences: DTI-ROI-measure =

ß$_1$Diagnosis + ß^{2}Sex + ß$_3$Age + ß$_4$Age^2 + ß$_5$Mean-ROIs. Demographics: 70 individuals with a 16pDel (mean age: 14.0±7.3, 45M/25F); 63 individuals with a 16pDup (mean age: age 27.9±13.9, 40M/23F); 233 healthy controls (mean age: 28.8.0±15.5, 119M/114F).
Results: Higher AD was found in 16pDel in the cingulum, tapetum, and corona radiata and corpus callosum body, and lower AD in the superior longitudinal fasciculus. In 16pDup, lower AD was found in the cingulum, uncinate, and external capsule, and higher AD in the superior fronto-occipital fasciculus (Figure 1). Conclusions: AD is affected in both 16p11.2 CNV syndromes. Differences in AD between 16p11.2 CNV and HC were similar across dMRI measures, including mirror effects in the hippocampal cingulum (CGH).

Title: Electrophysiological Biomarkers of Sleep and Cognition in Children with Neurodevelopmental Disorders

Authors: *V. SARAVANAPANDIAN[1], D. NADKARNI[2], S. S. JESTE[3];
[1]Psychiatry, UCLA, Los Angeles, CA; [2]Pediatric Neurol., Children's Hosp. Med. Ctr. of Akron, Akron, OH; [3]A7-469, UCLA Semel Inst. of Biobehavioral Sci., Los Angeles, CA

Abstract: Despite the high prevalence of sleep disturbances and cognitive deficits in children with neurodevelopmental disorders (NDDs), very few studies have examined the correlation between altered sleep physiology and cognition in NDDs. This study explores the relationship between abnormal sleep physiology and neurodevelopmental phenotype in children with 15q 11.2-13.1 duplications (Dup15q syndrome), a genetic disorder highly penetrant for intellectual disability, autism, hypotonia, and epilepsy. Genes in the 15q region, particularly UBE3A and a cluster of $GABA_A$ receptor genes, are critical for neural development, disrupting synaptic protein synthesis and degradation as well as inhibitory neurotransmission. Children with Dup15q syndrome have abnormal sleep physiology including reduced sleep spindles, reduced slow wave sleep (SWS), and increased beta band oscillations (12-30 Hz). Considering the role of GABAergic neurotransmission in the generation of beta oscillations and in healthy NREM sleep physiology, these EEG signatures we see in Dup15q syndrome, together, likely reflect aberrant GABAergic neurotransmission. We analyzed 7 hours of overnight sleep EEG recording from a cohort of children with Dup15q syndrome (n=23, mean age: 5.9 years). We computed beta power in sleep, spindle density and %SWS, and investigated the relationship between these sleep metrics to quantitative measures of cognition, adaptive skills and sleep behavior. While we found no significant correlations with spindle density, we found that %SWS correlated with verbal cognition (R^2=0.32, p=0.04) and daytime sleepiness (R^2=0.36, p=0.04), and beta power correlated with daytime sleepiness (R^2=0.43, p=0.02). A better understanding of the relationship between impaired sleep and cognition in this condition will provide further understanding into the pathophysiology associated with the syndrome and offer insights into potential treatments that target sleep, and ultimately, improve cognitive and developmental outcomes in children with Dup15q syndrome.

Title: High-throughput identification of de novo regulatory mutations contributing to autism and intellectual disability

Authors: *I. ANTONY, E. M. A. LEWIS, T. TURNER, K. KROLL;
Washington Univ. in St. Louis, St. Louis, MO

Abstract: Autism spectrum disorder (ASD) impacts 1:54 American children and 1:160 children worldwide. Due to its high societal and individual costs, autism research must be prioritized in the global health sphere. A largely unexplored area is how mutations in regions of the genome that do not encode proteins play a role in disease pathology. Although genome-wide association studies have identified hundreds of single nucleotide variants (SNVs) associated with ASD, it is difficult to identify which SNVs functionally contribute to disease. We hypothesize that many noncoding ASD risk variants are in enhancer elements and alter expression of genes under their control by disrupting transcription factor binding. To test this model, we analyzed *de novo* SNVs in 2,671 individuals with autism and their unaffected siblings. We prioritized putative causal mutations by integrating SNVs identified in individuals with autism with functional genomic data from fetal brain tissue and induced pluripotent stem cell (iPSC)-derived neurons. These datasets included chromatin enrichment for the histone modification H3K27ac, which marks active enhancers, and accessible chromatin, as defined by ATAC-seq. When compared to sibling controls, autistic probands are over-represented for both SNVs found in regions with H3K27 acetylation and for SNVs found in known enhancers. Critically, the greatest over-representation of SNVs in ASD probands occurs in syndromic ASD genes identified by the SFARI Gene database, hinting that many of these SNVs contribute directly to ASD. Our preliminary data thus supports a model in which functional *de novo* noncoding variants perturb enhancer activity and thereby alter transcriptional regulation of genes with statistical enrichment for protein-coding de novo variants. To test this model, we are designing a Massively Parallel Reporter Assay (MPRA)

to define quantitative effects of these putative ASD risk alleles on enhancer activity and downstream gene expression. This high-throughput approach will identify noncoding SNVs that lead to autism, advancing our understanding of how altered gene regulation disrupts neurodevelopmental gene regulatory networks in ASD. We also expect our experimental approach to be applicable to identifying and characterizing noncoding mutations that contribute to other human diseases and disorders.

Abstract: The association of HIV, mood disorders, and neurotransmitter metabolism in HIV-infected individuals under effective ART. Ross.H. Luu[1], Serena Spudich[2], and Eliseo.A. Eugenin[1] [1]University of Texas Medical Branch (UTMB), Department of Neuroscience, Cell Biology and Anatomy, University of Texas Medical Branch, Galveston, TX, USA.[2]Yale School of Medicine, Department of Neurology, Yale University, New Haven, CT, USA.**Disclosures**R.H. Luu: None. E.A. Eugenin: None.**Abstract**Cocaine dysregulates brain activity and promotes extensive neurotransmitter activity changes resulting in compromised judgment and higher risks of contracting sexually transmitted diseases, including HIV. In this work, we examined the short term effects of cocaine abuse in neurotransmitters in HIV-infected individuals, including neurotransmitter metabolism and associated transcription regulation. Here, we determine that cocaine had acute transcriptional effects on HIV replication and long-term HIV replication has profound alterations in neurotransmitter metabolism even in the absence of HIV replication and transcription of key nuclear genes. We used HPLC to determine the presence and metabolism of dopamine, serotonin, and noradrenergic pathways in the serum of HIV-infected individuals under ART for extended periods. Mood disorders further compromised the metabolism of these catecholamine pathways suggesting profound effects on synaptic dysregulation even in viral replication. We determine that cocaine, a drug that further

compromises neurotransmitter metabolism, acutely increased viral replication, suggesting an intersection between HIV, long-term infection, ART, depression, and viral reactivation.

Title: Glycine Transporter 1 expression in the basal ganglia

Authors: *R. PEREZ[1], M. MIRANDA[2];
[1]Univ. of Texas At El Paso, El Paso, TX; [2]Univ. of Texas at El Paso, EL PASO, TX

Abstract: Glycine is an inhibitory neurotransmitter that participates in the regulation of many sensory and motor functions. It is cleared from the synaptic cleft by two different plasma membrane transporters, glycine transporter 1 (GlyT1) and glycine transporter 2 (GlyT2). These transporters share similarities in the localization within the central nervous system (CNS) but the organization and localization of the cells expressing them still require further investigation. GlyT2 is known as a neuronal marker and functions to recycle glycine into presynaptic neurons. On the other hand, GlyT1 is recognized as a glial marker and is important for fast transport of glycine from the synaptic cleft and termination of neurotransmission. A few studies have focused on the study of GlyT1 due to the historical concept of being expressed only in glial cells. Therefore, the objective of our study will be to identify the cells expressing GlyT1 in the mouse forebrain and midbrain using traditional IHC and transgenic technology. To date, our results in tissue sections suggest the presence of cell bodies labeled with Neuronal Nuclei antibody (Ab) in the subthalamic nuclei (STN) and substantia nigra (SN) and plasma membrane GlyT1. Staining with glial GFAP has shown poor colocalization of GlyT1 in astrocytes. Furthermore, to confirm these data, a knock-in mouse was generated to label GlyT1-positive cells with the reporter td-Tomato. Preliminary results have shown tdTomato expression in neuronal cell bodies labeled also with NeuN and GlyT1 antibodies in the STN and SN. Additional characterization of these neurons will be further analyzed by intracranial delivery of adeno-associated viral particles

(AAV's) and expression of the reporter in glial or neuronal cells. Altogether, these data suggest that GlyT1 can be expressed in neurons but their localization and function are yet unknown.

Title: 5ht-type-2a receptor abnormalities in a mouse model of nmda receptor hypofunction relevant to schizophrenia

Authors: M. SINGH[1], K. NAKAO[1], J. J. HABLITZ[3], K. NAKAZAWA[2];
[1]Neurosci., [2]Southern Res., Birmingham, AL; [3]Dept. of Neurobio., Univ. of Alabama At Birmingham, Birmingham, AL

Abstract: Schizophrenia (SCZ) is a severe psychiatric disorder characterized by positive, negative and cognitive symptoms. Theories regarding etiology of SCZ have focused on the role of cortical dysfunction. Accumulating evidence suggests N-methyl-D-aspartate receptor (NMDAR) hypofunction in cortical interneurons in SCZ. We generated a conditional transgenic mouse, in which the Grin1 gene is disrupted from PV interneurons. *In vivo* local field potential (LFP) recording from auditory cortex of Grin1 mutant showed robust N1-like spontaneous LFP spikes during inter-stimulus intervals (ISIs) in response to periodic 40-Hz click train stimuli, suggesting induced-cortical hyperexcitability. *In vivo* microdialysis revealed increase of 5HT in auditory cortex of Grin1 mutant mice after acoustic stimulation. Slice electrophysiology recording of cortical pyramidal neurons (PyN) from Grin1 mutant mice conditioned with acoustic stimulation showed increased action potential firing (AP frequency), suggesting neuronal hyper excitability, control mice had no effect. TCB2, specific agonist of 5-HT2a receptor, mimicked acoustic effect in Grin1 mutant mice, indicating a role of 5-HT2a receptor in PyN hyperexcitability. Gαq-protein inhibitor YM254890 and GIRK channel activator ML297 completely reversed PyN excitability induced by acoustic stimulation. These results suggest that 5-HT receptors contribute to PyN excitation by activating Gα-protein pathway, subsequently inhibiting GIRK channel that causes increased neuronal firing. Increase in basal AP frequency of PyN in the Grin1 mutant mice was observe. Bicuculline, a GABAA receptor inhibitor, significantly increased AP frequency in control PyN after acoustic stimulation, no effect was observed in Grin1 mutant mice, suggesting chronic disinhibition caused increased excitability. Previous studies have shown that 5-HT2a receptors are involved in GABA release. Our

investigation revealed that TCB2 induced increase of sIPSC was abolished in Ppp1r2-Grin1 KO mice. Application of TCB2 increased sIPSC in floxed controls but not in Grin1 mutant mice. BIM-46187, a Gαq G protein inhibitor completely abolished the effect of TCB2 in control mice, indicating that activation of 5-HT2a receptor exerts its effect on presynaptic GABA release by activating Gαq protein pathway that is defected in Grin1 mutant. Present study provides an insight into the cause of PyN hyperexcitability after Grin1 deletion from PV interneurons, that is largely contributed by chronic disinhibition and impaired 5-HT2a receptor function in Grin1 mutant mice.

Title: Mdma stimulates rhoa activity and neurotransmitter transporter internalization through the trace amine-associated receptor, TAAR1, in serotonin neurons

Authors: *S. M. UNDERHILL, S. G. AMARA;
Natl. Inst. of Mental Hlth., Bethesda, MD

Abstract: The use of 3,4-methylenedioxymethamphetamine (MDMA) has recently gained interest as a therapeutic tool for the treatment of post-traumatic stress disorder (PTSD). However, the mechanism of action of this drug has not yet been fully elucidated. Here we demonstrate that MDMA acts by targeting the intracellular trace amine associated receptor 1 (TAAR1), an intracellular G-protein coupled receptor (GPCR) found throughout the brain. In previous studies, we have shown that the closely related compound, amphetamine (AMPH), enters neurons through the dopamine and norepinephrine transporters (DAT and NET) and activates TAAR1 which increases the activity of RhoA, a small GTPase that increases internalization of the DAT, NET and the neuronal glutamate transporter, EAAT3, resulting in an increase in extracellular DA, NE and glutamate concentrations. In this study, we show that MDMA enters serotonin neurons through the 5-HT transporter (SERT) and activates similar signaling cascades. Serotonin (5-HT) neurons in culture were identified by immunocytochemistry and functional SERT activity was confirmed by citalopram sensitive ^{3}H-5-HT uptake. Pre-treatment of these cultures for thirty minutes with 1 μM MDMA resulted in a decrease of SERT transport activity. This loss of function was blocked by an inhibitor of RhoA, indicating a similar biochemical cascade of that which we observed for DAT and NET in

response to AMPH. We confirmed that MDMA-induced loss of SERT function was due to trafficking of the SERT out of the plasma membrane by total internal reflection fluorescence (TIRF) microscopy in HEK293 cells. EAAT3 in these cells was also internalized in response to MDMA. In HEK293 cells in which the TAAR1 gene was deleted by CRISPR-Cas9, MDMA treatment did not lead to internalization of either transporter. MDMA-induced SERT and EAAT3 trafficking was examined in acute brain slices from wildtype or TAAR1 knockout mice brains. Slices containing the Raphe nucleus were treated with either vehicle control or MDMA (1 μM) and subsequently treated with a cell-impermeable biotin reagent that would label all surface proteins. By western blot analysis, we observed internalization of SERT and EAAT3 in response to the MDMA treatment. However, neither transporter exhibited any change in cell-surface expression in response to MDMA in the TAAR1 knockout tissue. These data indicate that pharmacological agents can regulate TAAR1 signaling in serotonergic neurons that may affect both serotonin and glutamatergic tone, indicating potential mechanisms to target for the development of novel drugs to treat PTSD.

Title: G protein βγ subunits interact with the serotonin transporter to evoke serotonin efflux

Authors: N. AWADALLAH[1], J. PINO[2], L. GONZALEZ[1], ***G. TORRES**[1];
[1]CUNY Sch. of Med., New York, NY; [2]Univ. of Atacama, Copiapo, Chile

Abstract: Extracellular serotonin (5HT) levels in brain are primarily regulated via the reuptake of 5HT through the serotonin transporter (SERT). SERT is a dynamic 12 transmembrane domain protein that regulates that reuptake of 5HT from the extracellular space in a Na^+/Cl^- dependent manner. Selective serotonin reuptake inhibitors (SSRIs) such as fluoxetine, used in the treatment of psychiatric ailments, selectively bind to SERT and prevent the reuptake of 5HT. Highly potent and addictive drugs of abuse such as amphetamine and its analogues are known to switch the functional role of SERT and produce an efflux of 5HT rather than reuptake. However, the precise mechanism of this phenomenon is still unknown. Our group has shown that βγ subunits of G Proteins bind to the carboxy terminus of the dopamine transporter (DAT) and that activation βγ subunits results in DAT-mediated dopamine efflux, similarly to the action of amphetamine. Here, we show parallels between the dopamine and 5HT systems using CHO cells

and, *ex vivo* acute brain slices. First, Gβγ and SERT are co-immunoprecipitated together in both CHO cells and in hippocampal and prefrontal cortex rodent brain tissue. Pharmacological work shows that incubation in both AMPH and mSIRK, a known and Gβγ activator, significantly increase 5HT efflux and is further potentiated when the two are combined. Further, activation of Gβγ via mSIRK significantly increases 5HT efflux in hippocampal and prefrontal cortex acute brain slices as measured by high performance liquid chromatography (HPLC). Gallein, a Gβγ inhibitor, attenuates this response back to basal levels. Together, these results indicate that Gβγ binds SERT and that activation of Gβγ promotes 5HT efflux. Overall, further characterizing this mechanism may aid in establishing more specific pharmacotherapies for 5HT-related disorders.

Title: Novel optical reporter reveals compartmentalized trafficking of the dopamine transporter in neurons

Authors: *J. SAENZ, X. ZHOU, D. J. BARKER, E. DICICCO-BLOOM, P.-Y. PAN; Rutgers Univ., Piscataway, NJ

Abstract: The dopamine transporter (DAT) is a major gateway for DA uptake and termination of dopaminergic signaling in the brain. DAT trafficking is a highly regulated process and is implicated in a multitude of human conditions, such as cocaine addiction. While much of our understanding on constitutive and regulated DAT trafficking came from studies of heterologous cells, it remains unclear if central DA neurons, especially their dendrites and axons, share the same rules. We have now engineered a novel pH-sensitive reporter for DAT by conjugating pHluorin to the second exofacial loop of human DAT. We show that DAT-pHluorin is a superior tool to study DAT trafficking in neurons as it exhibits DA uptake, cocaine sensitivity as well as PI3K/PKC regulated DAT recycling similar to the endogenous protein. Unlike the homogenous expression of DAT in heterologous cells, midbrain neurons exhibit compartmentalized DAT expression. While dendrites and soma contain a higher fraction of recycling/degradative DAT in the acidic compartment, axons express most of the DAT on the plasma membrane. Large axonal varicosities may be active sites of DAT turnover, as a higher fraction of acidic DAT was found

in these structures compared to the axonal shaft. Furthermore, our data suggests that a 24-hour cocaine treatment induces a redistribution of the intracellular recycling DAT in the soma and dendrites to the surface of neurites. Thus, our study using the newly engineered DAT optical reporter reveals, for the first time, compartmentalized DAT trafficking rules in neurons.

Title: Gaba and glutamate are depolarising during early development of the hypothalamic arcuate nucleus in japanese quail (coturnix japonica).

Authors: *A. JOHNSTON, S. MEDDLE;
Univ. Edinburgh, Edinburgh, United Kingdom

Abstract: The regulation of feeding is a complex interaction between central and peripheral signalling governed centrally by the melanocortin system comprising specific neuronal populations and circuits in the hypothalamus and brainstem. Little is known about the central mechanisms regulating the development of appetite in birds in early life. Using whole cell patch clamp electrophysiology in Japanese quail brain slices containing the hypothalamic arcuate nucleus (ARC), we investigated the effects of GABA and glutamate from embryonic day 10 to post hatch day 5. The exogenous application of GABA caused a membrane depolarisation between embryonic day 14 and day 2 after hatch, when there is a depolarising to hyperpolarising shift in the response of ARC neurones to exogenous GABA. During the GABA-mediated depolarisation both spontaneous synaptic activity and action potential firing was reduced. By contrast, exogenous glutamate always depolarised ARC neurones and increased action potential firing at all developmental stages. The GABA-induced depolarisation was abolished by the specific $GABA_A$ receptor antagonist bicuculline. It was also absent in brain slices pre-incubated with verapamil and bumetanide, suggesting there is an influx of Ca^{2+} ions through L-type voltage-gated calcium channels during the $GABA_A$ receptor-mediated depolarisation. This depolarising action of exogenous GABA is correlated with the expression of the developmentally regulated NKCC1 Cl^- ion importer during avian brain development. We conclude that GABA is functionally inhibitory in the avian hypothalamic feeding circuits, but the inhibition is associated with a depolarisation during embryonic development. Glutamate is excitatory at all stages of

development to become the dominant excitatory neurotransmitter. Our data is in agreement with studies that identify GABA as predominantly depolarizing at the cellular level over a limited period of time and, at the same time, inhibitory at the network level during mammalian brain development. All work was performed under UK Home Office licence, ARRIVE guidelines and local ethical review. Research supported by BBSRC (BB/5015760/1).

Abstract: Absence Seizures (ASs) are genetic generalized non-convulsive paroxysms due to alterations in GABA neurotransmission. Administration of drugs that boost GABA levels elicits ASs in normal individuals while exacerbates them in Absence Epilepsy (AE) patients. Extrasynaptic GABA-A receptors ($GABA_A$Rs) tonic inhibition is increased in the thalamus of AE animal models, indicating that an increase, rather than a decrease, of $GABA_A$R inhibition, contributes to the pathophysiology of ASs. Extrasynaptic $GABA_A$Rs are activated by ambient GABA and the level of GABA is controlled by GABA transporters (GATs). An increase in tonic $GABA_A$R inhibition is necessary and sufficient for the appearance of experimental ASs. In different genetic animal models of AE, the increased tonic $GABA_A$R inhibition results from a malfunction in the GABA transporters type 1 (GAT1). Strikingly, no genetic abnormalities of the GAT1 gene have been identified in absence epilepsy animal models. In consideration of this, here we have investigated the nature of GAT1 malfunction in the polygenic rat model GAERS (Genetic Absence Epilepsy Rat from Strasbourg) and the monogenic mice model Stargazer (*stg*) to evaluate differences in GABA uptake in AE animals and to test whether the thalamic GAT1

malfunction resulted from a failure of trafficking to the outer astrocytic membrane or a misplaced localization concerning the synaptic or extrasynaptic space. We also assessed GAT3 function/localization for comparison.Our data show a decrease in total GABA uptake due to a smaller GAT1 mediated uptake in the motor cortex, somatosensory cortex, visual cortex, thalamus, and hippocampus of GAERS and stg, compared to their respective controls. The observed decrease in GAT1 uptake is not due to a trafficking failure and is not observed in the early stages of life before ictogenesis.

Title: Adenosine/a2a receptor retrograde signaling mediates presynaptic hippocampal ltp and facilitates epileptic seizures

Authors: *K. NASRALLAH[1], C. BERTHOUX[1], R. LUJAN[2], M. GULFO[1], P. E. CASTILLO[3]; [1]Albert Einstein Col. of Med., Bronx, NY; [2]Univ. de Castilla-La Mancha, Albacete, Spain; [3]Albert Einstein Coll Med., Bronx, NY

Abstract: The dentate gyrus (DG) of the hippocampus contains two types of excitatory neurons, granule cells (GCs) and mossy cells (MCs), which are reciprocally connected, thereby forming an associative circuit that has been implicated in DG-dependent memory and temporal lobe epilepsy. MCs can powerfully influence GC activity. Remarkably, a single MC contacts about 30,000 GCs. MC-GC synapses express a robust form of presynaptic long-term potentiation (MC-GC LTP) that increases DG output and may contribute to memory formation and epileptogenesis. We recently found that initial epileptic seizures trigger broad MC-GC LTP *in vivo*, which promotes further seizures. It is therefore crucial to understand the molecular processes underlying MC-GC synaptic strengthening. MC-GC LTP requires both *post*synaptic TrkB activation and *pre*synaptic cAMP/PKA signaling, indicating the involvement of a

retrograde messenger, whose identity remains unknown. Here, we addressed this knowledge gap using a combination of complementary approaches. Immunoelectron microscopy revealed the presence of Gs-coupled adenosine A_{2A} receptors (A_{2A}Rs) at MC axon boutons. Using selective pharmacology and a cell-specific *Adora2a* knockout strategy, we found that activation of A_{2A}Rs was necessary and sufficient to induce MC-GC LTP in acute rodent hippocampal slices. By expressing a genetically encoded adenosine sensor in MC axons, we found that LTP induction was associated with a transient, TrkB-dependent release of adenosine. Interfering with adenosine release from GCs abolished LTP. Lastly, adenosine release was also detected during acute epileptic seizures induced by intraperitoneal injection of kainic acid. Thus, adenosine/A_{2A}Rs emerges as a novel retrograde signaling mechanism that mediates presynaptic LTP in the hippocampus and that could be targeted for early intervention in epilepsy.

Title: Nociceptin-stimulated dopamine transporter trafficking and its impact on reward

Authors: *N. BOLDEN, E. KAHUNO, H. E. MELIKIAN;
Neurobio., Univ. of Massachusetts Med. Sch., Worcester, MA

Abstract: Dopamine (DA) transmission is required for reward, motivation, and habit formation. The nucleus accumbens (NAcc) receives dense DAergic innervation via the mesolimbic circuit, and DA transmission in the NAcc is required for rewarding behaviors. DA signaling is restricted by the presynaptic DA transporter (DAT) which recaptures extracellular DA following synaptic release. DAT is potently inhibited by abused psychostimulants, such as cocaine, which binds to DAT and thereby increase extracellular DA. DAT surface expression is not static. DAT constitutively traffics via the endocytic recycling pathway, and both G_q- and $G_{i/o}$-coupled receptors modulate DAT surface expression by accelerating DAT internalization and surface delivery rates, respectively. Numerous studies have identified the mechanisms required for regulated DAT trafficking. Nevertheless, it remains unknown whether, or how, regulated DAT trafficking impacts DA signaling and DA-dependent behaviors, such as psychostimulant-mediated reward. In the current studies, we found that nociceptin receptor (NOPR) activation

rapidly delivers DAT to the plasma membrane in mouse *ex vivo* NAcc slices. NOPR activation in NAcc blocks cocaine's ability to increase extracellular DA, however the mechanism(s) responsible for this effect are poorly understood. We hypothesize that nociceptin-stimulated DAT surface delivery plays a central role in the effects of nociception in NAcc. Our ongoing studies leverage chemogenetics, conditional gene silencing, and *in vivo* conditional expression of trafficking dysregulated DAT mutants, to direct test whether: 1) nociceptin-stimulated DAT trafficking in NAcc is mediated by presynaptic NOPRs in DAergic terminals, 2) nociception infusion into NAcc suppresses cocaine-mediated reward, and 3) NOPR-stimulated DAT surface delivery is required for nociceptin to dampen reward. The results are expected to shed light on the role of regulated DAT trafficking in addictive behaviors.

Title: Solid supported membrane-based electrophysiology (SSME) electrophysiology meets SGLT1 and GAT1

Authors: A. BAZZONE[1], **R. ZERLOTTI**[1,2], *E. DRAGICEVIC[1], M. BARTHMES[1], N. FERTIG[1];
[1]Nanion Technologies GmbH, Munich, Germany; [2]RIGeL, Regensburg Intl. Grad. Sch. of Life Science, Univ. of Regensburg, Regensburg, Germany

Abstract: Transporter assays are often limited by the availability of labeled substrates and lack real-time data. Here, we developed functional assays to characterize the human $Na^+/Cl^-/\gamma$-aminobutyric acid (GABA) and Na^+/glucose co-transporters - GAT1 and SGLT1 - using solid supported membrane-based electrophysiology (SSME). This approach overcomes several bottlenecks of other techniques and provides new insights into GAT1 and SGLT1 transport mechanisms. In conventional electrophysiology voltage steps are used to trigger pre steady-state (PSS) and transport currents, which are commonly recorded in whole cells at a defined holding potential. Transport and PSS electrogenicity in SGLT1 and GAT1 triggered by voltage steps is postulated to be a result of transitions within the sugar and GABA-free carriers, e.g. the alternating access of the charged sodium binding sites within the empty carrier. In contrast, SSME utilizes membrane vesicles at 0 mV and the transport cycle is triggered by applying a substrate concentration gradient as the main driving force. Using SSME, we observed substrate-

induced PSS currents, most likely representing conformational transitions within the substrate-loaded carrier, which are not observed with conventional electrophysiology. We examined the impact of different driving forces on influx, efflux, and PSS currents, focusing on sodium gradients and membrane voltage. We found that internal accumulation of sodium strongly reduces Vmax, rendering sodium release rate limiting at 0 mV. Application of membrane voltage only affected the apparent KM in SGLT1, but Vmax in GAT1. We also found that transport properties in GAT1 mediated influx and efflux modes are highly asymmetric, while SGLT1 has similar properties for influx and efflux.

Title: Ammonium ion (NH_4^+) impairs Slc38 glutamine transporter function contributing to development of hepatic encephalopathy

Authors: *F. A. CHAUDHRY[1], E. H. HAMDANI[2], M. POPEK[3], M. FRONTCZAK-BANIEWICZ[3], M. N. MOEN[1], T. P. UTHEIM[4], J. ALBRECHT[3], M. ZIELINSKA[3];

Abstract: In liver failure, ammonia escapes detoxification in the liver and accumulates in the cerebrospinal fluid (CSF) where it is considered to be the main pathogenic toxin in hepatic encephalopathy (HE), a neuropsychiatric disorder belonging to the group of diseases classified as hyperammonemic encephalopathies. However, the molecular mechanisms involved have been disputed. We have previously shown that four members of the solute carrier 38 (Slc38) family of amino acid/glutamine transporters contribute to astroglial-to-neuronal shuttling of glutamine for the synthesis of glutamate and GABA. As HE is associated with dysfunctional glutamatergic and

GABAergic neurotransmission, we investigated whether ammonia perturbs the Slc38 transporters and whether this contributes to HE patho-physiology. We now show by two-electrode voltage-clamp electrophysiology on *Xenopus laevis* oocytes expressing Slc38 transporters that ammonium ions compete at the glutamine binding sites of the system N transporters Slc38a3 and Slc38a5 and thereby inhibit bidirectional astroglial glutamine transport. Ammonium ions also permeate uncoupled through the same transporters in competition with H^+, Na^+ and K^+ and may perturb astroglial intracellular pH, membrane potential and K^+-buffering. To further test a relation between Slc38a3 and HE, we knocked-down Slc38a3 by transcranial injection of *vivo morpholino* (VM) oligomers in mice. This results in cerebral cortical edema, lower extracellular glutamine content and reduced total brain glutamate, indicative of disrupted neurotransmitter synthesis, all mimicking events contributing to HE development. Finally, in the azoxymethane (AOM) mouse model of acute liver failure (ALF) we demonstrate downregulation of Slc38a3 protein and impeded astroglial glutamine release followed by cytotoxic edema. Altogether, our data mechanistically demonstrate differential regulation of four Slc38 glutamine transporters by NH_4^+ and suggest a primary role of these transporters in the pathophysiology of HE.

Title: Allopregnanolone terminates benzodiazepine-resistant tetramethylenedisulfotetramine (TETS)-induced status epilepticus in mice after failed midazolam treatment

Authors: *D. ZOLKOWSKA, R. JUNG, M. A. ROGAWSKI;
Dept. of Neurol., Sch. of Med., Univ. of California, Davis, Sacramento, CA

Abstract: Tetramethylenedisulfotetramine (TETS), a potent GABA-A receptor antagonist, is a highly lethal neurotoxin that induces convulsive status epilepticus (SE) in humans that is often refractory to treatment. Benzodiazepines such as midazolam (MDZ) are used for initial treatment of SE, including following a chemical exposure emergency such as with TETS. Often seizure termination fails to occur, especially when therapy is delayed. Current federal guidelines for the pre-hospital treatment of chemical exposure induced SE recommend treatment with a 10 mg

dose of MDZ administered intramuscularly (IM), followed 10 min later by a second 10 mg dose MDZ if the first one is not effective. Our previous studies have shown that allopregnanolone (5α,3α-P), a neurosteroid positive modulator of synaptic and extrasynaptic GABA-A receptors, may provide an effective treatment option in benzodiazepine refractory SE, including TETS-induced SE. In the present study, we determined whether IM 5α,3α-P (12 mg/kg) injected 10 min after IM MDZ (0.23 mg/kg) was more effective than 2 injections of IM midazolam in terminating TETS-induced SE in mice. To create a model mimicking the SE produced by TETS in humans, mice implanted with EEG electrodes were pretreated with a single dose of riluzole (10 mg/kg, IP) and 10 min later received a lethal dose of TETS (0.2 mg/kg, IP). Riluzole does not inhibit TETS-induced SE but does protect against the rapidly lethal effects of TETS in mice, providing a model of persistent seizure activity. Video EEG recording was carried out for at least 4 h after exposure to TETS. Animals were monitored for survival for 72 h after treatment. MDZ was administered at 40 min after the first myoclonic twitch and 10 min later another dose of MDZ (0.23 mg/kg IM) or 5α,3α-P (12 mg/kg, IM) was administered. In mice treated with 2 doses of MDZ, persistent convulsive seizures were not terminated. The animals did not appear to be visibly sedated at any time following the dual MDZ treatment. Addition of 5α,3α-P after MDZ, led to rapid termination of behavioral and electrographic SE as assessed by EEG power. The latter treatment terminated persistent seizures within 6.7 ± 2.4 min and increased 72 h survival from 0% (2 doses of MDZ) to 100%. Animals receiving MDZ and 5α,3α-P experienced sedation with loss of righting reflex for 1.19 ± 0.12 h, but fully recovered. Our results demonstrate that replacement of the second dose of MDZ with 5α,3α-P overcomes benzodiazepine resistant TETS-induced SE and effectively terminates TETS-induced behavioral and EEG seizures. Transient sedation occurred with adjunctive 5α,3α-P but all animals fully recovered without apparent long-term adverse effects.

Title: Status epilepticus treatment by metabolic modulators

Authors: *D. SKWARZYNSKA[1], K. REKAWEK[1], J. KAPUR[2];
[1]Univ. of Virginia, Charlottesville, VA; [2]Dept Neurol., Univ. Virginai Hlth. Sci. Ctr., Charlottesvle, VA

Abstract: Rationale: We tested whether β-hydroxybutyrate (BHB) and the specific lactate dehydrogenase (LDH) inhibitor, oxamate, can terminate Status Epilepticus (SE), which is a neurological emergency requiring rapid seizure termination to protect life. The ketogenic diet is a promising remedy for patients with refractory SE. However, it takes time to attain ketosis in patients with ongoing SE. Therefore, drugs that could mimic the therapeutic effect of KD action but act much faster are desirable. **Methods:** SE was induced by continuous hippocampal stimulation as previously described (Lewczuk et. al. 2018). Briefly, we stereotaxically implanted 7-8 weeks old C57Bl/6 mice with a bipolar insulated stainless-steel electrode in the left hippocampus, bilateral supra-dural cortical electrodes, and a cerebellar reference electrode. A week after the electrode implantation, we connected the animals to a video-EEG monitoring system and set stimulation intensity to twice the after-discharge threshold (ADT). We applied 10 sec stimulus trains followed by a 5 sec off period for 60 min. We injected mice intraperitoneally with BHB (1g/kg), oxamate (1g/kg), or saline 15 minutes after the development of autonomous seizure. We evaluated the duration and severity of EEG and scoring behavior on the Racine scale. **Results:** Oxamate treatment significantly shortened SE duration in comparison to saline-injected control mice (median SE duration in saline- versus oxamate-treated mice: 263.5 and 63 minutes respectively; n = 5 each, p = 0.0233). Moreover, severe behavioral seizures (grades 4 and 5) were less frequent following oxamate injection. The oxamate-treated animals returned to normal behavior faster than control mice (n = 5 each, p = 0.0033). In addition to changes in behavioral manifestations, we detected changes in EEG with fewer high-frequency discharges and power EEG attenuation quickly following oxamate treatment. Similarly, SE duration in BHB-treated mice was significantly shorter than saline-injected mice (median SE duration in saline- versus BHB-treated mice: 240 and 100 minutes respectively p = 0.0289; n = 8 each). In addition, the median behavioral seizure scores were lower in the BHB-treated group when compared to saline-injected mice (n = 6 each, p=0.002). We observed a gradual attenuation of power EEG and high-frequency discharges along with seizure severity, which became less common in BHB-treated mice than control animals. **Conclusions:** Targeting metabolic pathways by directly affecting the metabolite concertation (BHB) or enzyme activity (LDH) represents a promising strategy to treat SE. Ongoing studies explore these drugs' effect on neuronal excitability.

Title: Therapeutic monitoring using NMR based metabolomics in drug resistant epilepsy in a Ghanaian adult population

Authors: *P. K. MANTE, J. DANQUAH, M. ASARE;
Kwame Nkrumah Univ. of Sci. and Technol., Kumasi, Ghana

Abstract: It has been hypothesized that epilepsy patients present with unique chemical signatures and metabolic pathways in the brain and may influence efficacy of antiepileptic drugs (AEDs). The aim of our study is to assess the brain metabolic differences between the drug-responsive and drug-resistant Ghanaian epileptic patients in order to establish the metabolic background for drug-responsiveness in epilepsy. 30 drug-resistant epilepsy patients (median age: 23 years; males: 56%) and 31 drug-responsive patients (median age: 25 years; males: 49%) were clinically assessed with EEG. The control group consisted of 20 patients (median age: 21 years; males: 50%) with no neurological disorders. Serum samples were analyzed with ^{1}H-NMR on 400 MHz spectrometer and spectra analyzed using univariate and multivariate with the application of correction for age variation. Drug-resistant epilepsy patients group was exhibited by increased levels of serum creatine, glycine, lactate, lipids and glycoproteins; levels of citrate and choline decreased as compared to the drug-responsive and control groups. Levels of choline, glycine and lactate were significantly correlated with seizure control and number of AEDs in use by patients. NMR-based metabolomics could provide information on efficacy of antiepileptic drug treatment in epilepsy patients.

Autónoma Metropolitana Unidad Iztapalapa, CDMX, Mexico; [5]Fisiología, Inst. Politecnico Nacional, México, Mexico

Abstract: Levetiracetam (LEV) is an anticonvulsant drug effective for seizure control in patients and different animal models of epilepsy. However, approximately 30% of patients do not respond to LEV treatment. Until now, little is known about the resistance to LEV treatment. Thus, the objective of this study was to identify gene expression profiles in the dentate gyrus of epileptic rats that responded or did not respond to LEV treatment. For this purpose, male Wistar rats were divided into the following groups: Control + LEV (nonepileptic rats treated with the drug), R (LEV-responders) and NR (LEV non-responders). Epilepsy was induced by systemic administration of lithium plus pilocarpine and was determined by monitoring behavior using video recordings. LEV treatment (300 mg/kg/d) lasted one week and was accomplished with osmotic mini-pumps. After treatment, microarrays were used, together with a bioinformatic analysis based on Genetic Ontology categories, to identify alterations in the dentate gyrus genome among R and NR rats. The results showed more altered genes in the NR group (742) compared to the R group (418). Within the gene profile of NR rats, greater overexpression of genes related to inflammation, neuronal reorganization and astroglial activation was found (C1AQ, C1QB, C1QB, PTGS2, PTAFR, SOX11, BDNF, CD44, TESC, VIM, GSN, S100A10 and S100A4), while genes related to neurotransmission were more under-expressed (GABRD, GABRR3, GRM8, SYT4, SYT10). Only the R group overexpressed NPYR2, which may mediate a protective mechanism. Thus, effective LEV treatment increased NPY2R gene expression and decreased overexpression of genes related to the reorganization of neuronal circuits and the microenvironment, as well as to neuronal, glial and astrocytic hypertrophy.

Abstract: We studied the effect of opioidergic modulation on seizure responses to electroshock stimulation in DBA/2J (D2) and C57BL/6J (B6) mice using a combination of genetic and pharmacological approaches. In genetic studies, we show that constitutive deletion of the mu opioid receptor (MOR) gene, *Oprm1*, results in a significant reduction of maximal electroconvulsive shock (ECS) seizure threshold in homozygous *Oprm1* knockout mice compared to respective wild type litter mates independent of genetic background (i.e. D2 or B6). In pharmacological studies, we report that administration of morphine for 4 days via a subcutaneously implanted pellet (25 mg) significantly reduces the expression of maximal ECS seizures in both D2 and B6 wild type mice. Conversely, pretreatment of D2 and B6 mice with naltrexone (1-10 mg/kg, i.p.) increases maximal ECS seizure susceptibility in both strains. We also report that higher doses of naltrexone (100-300 mg/kg, i.p.) elicit generalized behavioral seizures, with D2 mice displaying significantly greater susceptibility than B6. Overall, our data show that inhibition of opioidergic neurotransmission mediated by the MOR, either genetically via gene knockout or pharmacologically via antagonist pretreatment, increases ECS seizure susceptibility in mice, whereas MOR activation via full agonist pretreatment decreases ECS seizure susceptibility. Further, the greater proconvulsant effect of high dose naltrexone in D2 compared to B6 mice suggests that endogenous opioids may be involved in the robust difference in seizure susceptibility between these two classic inbred mouse strains, or that non-specific or off-target drug action is involved. We conclude that modulation of opioidergic function represents a viable means of ameliorating seizures and treating epilepsy.

Title: Activity enhancement by D cycloserine prevents post-stroke epilepsy.

Authors: *Y. ADHIKARI[1], X. JIN[2];
[1]Stark Neurosciences Res. Inst., Indianapolis, IN; [2]Stark Neurosci. Res. Inst., Indianapolis, IN

Abstract: Homeostatic plasticity is a slow adaptive process that allows neurons to adjust their synaptic strength to compensate for perturbations in network activity. Homeostatic control of cortical excitability, connectivity and plasticity is crucial for normal brain functions. Abnormalities in homeostatic plasticity results in hyperexcitability of neuronal network which is a key pathological feature of epilepsy. After brain insults loss of neurons and synapses causes activity deprivation in the surviving neurons. To compensate for the lost function, the surviving neurons use the homeostatic plasticity mechanism to scale up excitation and/or scale down inhibition to attempt to reach the physiological range of neuronal activity. This causes transition of the surviving neurons from initial hypoactivity to hyperactivity state which increases the excitability of the network resulting in epileptogenesis. After stroke, a transient hyperactivation of NMDARs occurs which is followed by a profound and long-lasting loss of function of NMDARs. This decrease in functional NMDAR could result in activity deprivation in the surviving neurons, thereby triggering homeostatic plasticity . We hypothesize that enhancing NMDAR activity by D-cycloserine, (a partial NMDAR agonist) during this critical time window will compensate for the activity deprivation caused by loss of function of NMDARs . This would prevent homeostatic plasticity in surviving neurons and prevent post-stroke epilepsy. In this study we induced photochemical stroke in 8 weeks old YFP mice and administered (30mg/ kg/day, i.p.) from day 3-15 after stroke. We report evidence that DCS administration in this time window decreases seizure susceptibility after photochemical stroke. These findings identify activity enhancement as a target for therapeutic intervention to alleviate post stroke epilepsy.

Title: Encircling supragranular laser scalpel cuts around a seizure focus attenuate seizure propagation without any behavioral effects in a mouse model of focal epilepsy

Authors: *S. LIEBERMAN[1], D. A. RIVERA[2], R. MORTON[2], A. HINGORANI[2], T. SOUTHARD[1], L. JOHNSON[3], J. REUKAUF[2], R. E. RADWANSKI[2], M. ZHAO[4], N. NISHIMURA[2], O. BRACKO[2], T. H. SCHWARTZ[5], C. B. SCHAFFER[2];

Abstract: About 5% of all epilepsy cases are due to traumatic brain injuries that lead to focal seizures. Focal epilepsy is characterized by seizures that initiate in one location and propagate out to larger areas. 45% of patients with focal epilepsy unfortunately either start as or become refractory to medical management and the only alternative is neurosurgical resection of the focus that often leaves patients with neurologic deficits. Previous work utilizing two-photon imaging of mice showed that cells in the supragranular layers of the neocortex are consistently activated first during horizontal seizure propagation. Therefore, it has been theorized that these lateral connections could be severed to stop seizure propagation while maintaining other connections to sustain neural function. Using tightly-focused femtosecond duration laser pulses, we can now make micrometer sized cuts deep below the surface of the brain without damaging the surrounding tissue. We tested the long-term efficacy of laser cuts in layers II-IV surrounding a chronic neocortical seizure focus as well as determined the effect these cuts have on neuronal structure and sensory-motor function. Chronic focal neocortical seizures were initiated through a microinjection of iron chloride. Control animals had 85% of seizures propagate while mice with laser cuts had only 5% of seizures propagate. Seizure metrics including duration, max band power, and area under the curve at the seizure focus showed that non-propagated seizures in mice with laser cuts were indistinguishable from propagated seizures in control animals, indicating that without laser cuts these seizures would have propagated. Laser cuts themselves only caused minor structural changes including a small scar with slight gliosis at one month and an acute drop in blood flow at the cut border that recovered within a week. To determine the effect of laser cuts on normal function we localized laser cuts to forelimb motor cortex and saw only minor acute deficits in a skilled reaching task that returned to normal within days. Ultimately, this laser scalpel approach was effective in blocking seizures and caused negligible structural and functional deficits indicating that it could be a viable approach for future treatment of drug-resistant focal neocortical epilepsy.

Title: The relationship between ApoE and lipid dysregulation in glia of the PS19 mouse model of tauopathy.

Authors: *A. LITVINCHUK[1], K. LIN[2], N. BIEN-LY[2], H. P. BENTON[2], S. DAVIS[2], J. SUH[2], J. D. ULRICH[1], G. DI PAOLO[2], D. M. HOLTZMAN[1];
[1]Dept. Neurol., Washington Univ. in St. Louis, Saint Louis, MO; [2]Denali Therapeut., San Francisco, CA

Abstract: Emerging evidence suggests that the accumulation of certain lipids in glia is linked to enhanced inflammatory responses and, thus, could significantly promote neurodegeneration in the context of Alzheimer`s disease (AD). Apolipoprotein E (apoE) plays an essential role in brain lipid homeostasis; furthermore, the presence of the apoE4 allele is the strongest genetic risk factor for developing late-onset AD compared to most common apoE3 and protective apoE2 alleles. Several studies detect lipid droplets in cultured human apoE4 iPSC-derived astrocytes and microglia; transcriptomic and lipidomic profiling of these cells reveals upregulation of cholesterol/matrisome and inflammatory pathways. Additionally, recent studies documented an increase in free cholesterol and cholesteryl esters in microglia of apoE KO mice following demyelination that led to enhanced inflammasome activation. Therefore, apoE may modulate cellular toxicity through regulation of lipid pathways and inflammation. However, it is not known if lipid accumulation in glia mediates toxic effects in vivo in the context of tauopathy. Here, we utilized the P301S tau transgenic mice with a targeted replacement of murine apoE with human ApoE4, ApoE3, or ApoE KO to dissect the role of apoE isoforms in glial lipid metabolism. We demonstrate that microglia from aged P301S/ApoE4 mice accumulate a significant amount of large BODIPY-positive lipid inclusions within lysosomes compared to control mice. By performing unbiased FACS coupled with lipidomics of forebrain samples and sorted microglia and astrocytes from ApoE KO, ApoE KI and P301S/ApoE KI mice, we demonstrate that microglia accumulate significant amounts of specific cholesteryl esters, sphingolipids and diacyl glycerols in an ApoE-isoform and Tau-dependent manner. These changes could contribute to impaired lysosomal function, defects in lipid clearance and subsequent neuroinflammation observed in aged tauopathy mice. We also show significant changes in levels of specific cholesteryl esters in sorted astrocytes that occur in an Apoe-dependent manner but are not further affected by tau pathology. Finally, by performing lipidomics on bulk forebrain samples, we detect altered levels of plasmalogens and BMPs in P301S/ApoE KI mice compared to control groups indicating that other cell types could also contribute to regulation of lipid homeostasis in brains of aged tauopathy mice. Together, we demonstrate that ApoE4 promotes lipid accumulation in glia in the setting of tauopathy. We hypothesize that reducing the accumulation of some of these lipid species, particularly in microglia, could be anti-inflammatory and neuroprotective.

Title: Ozone air pollution exposure impairs plaque-associated microglia and alters the peri-plaque microenvironment through a bi-directional lung-brain axis

Authors: *H. J. GREVE[1], C. GARZA LOMBO[1], A. L. DUNBAR[1], C. AHMED[1], M. THANG[1], E. J. MESSENGER[1], C. L. MUMAW[1], J. A. JOHNSON, Jr.[1], U. P. KODAVANTI[3], A. L. OBLAK[2], M. L. BLOCK[1];

Sch. of Med., Indianapolis, IN; [3]Cardiopulmonary and Immunotoxicology Branch, Publ. Hlth. and Integrated Toxicology Div., U.S. Envrn. Protection Agency, Research Triangle Park, NC

Abstract: An increasing body of epidemiological reports implicates components of outdoor air pollution, such as ozone (O_3), as a risk factor for Alzheimer's disease (AD). However, the mechanisms underlying this increased risk with O_3 are poorly understood. Due to its reactive chemistry, O_3 is unable to pass beyond the respiratory tract to directly interact with the brain parenchyma, pointing to an important role for O_3-induced peripheral changes in triggering CNS effects. The Lung-Brain Axis hypothesis holds that pulmonary damage from inhaled pollutants, such as O_3, causes circulating signals to augment CNS disease, particularly AD, but the underlying mechanisms remain largely unexplored. To begin to address these issues, 8-10-week-old male 5xFAD mice, a model of AD, and littermate control animals were exposed to O_3 (0, 0.3, 1.0 ppm) for 13 weeks (4 hours/day, 3 days/week). Thioflavin S staining in the brains of 5xFAD mice showed a dose-dependent increase in the number of plaques in the cortex and hippocampus of the 1.0 ppm O_3 exposed group, demonstrating that subchronic O_3 exposure augments amyloid neuropathology. Analysis of the plaque microenvironment showed decreased microglial-plaque association without a change in total number of microglia, suggesting that O_3 may perturb the microglia plaque response. Further, using spatial proteomics through Nanostring's GeoMX DSP platform, an O_3-induced dysregulated protein expression was observed in both the peri-plaque

microenvironment as well as in plaque distant regions of the cortex, suggesting that O_3 exposure dysregulates the CNS response to amyloid pathology at the level of the peri-plaque microenvironment. Specifically, protein expression of microglial markers (Clec7a, P2rx7, and MerTK), Aβ processing proteins (BACE1, ADAM10, IDE), phosphor-tau, and damage and immune markers (S100b, MBP, CD169) were altered in O_3-exposed brains. Analysis of the pulmonary response of 5xFAD and WT mice to O_3 showed an increase in total cells, macrophages, and neutrophils in the bronchoalveolar lavage (BAL) of 5xFAD mice, but not WT controls. Taken together, these data support that subchronic O_3 exposure, a model of urban air pollution, exacerbates AD-like neuropathology, impairs microglia-plaque association, dysregulates protein expression at the level of the peri-plaque microenvironment, and that ongoing neurodegenerative pathology may regulate pulmonary and peripheral immune response to O_3, which has crucial implications for how air pollution my affect neurodegenerative disease.

Title: Potential Neuroinflammatory Benefits of Low-dose Naltrexone and the Development of Alzheimer’s Disease in h-tau Mouse Models

Authors: *S. NEFF[1], J. O. SANCHEZ[1], A. BOOTH[1], M. U. ALI[1], A. VILLATORO[1], J. M. FLINN[2];
[2]Psychology, [1]George Mason Univ., Fairfax, VA

Abstract: Rates of Alzheimer’s Disease (AD) among American adults are predicted to increase by 22% between 2020 and 2025, and is being called a public health crisis by the CDC. The underlying pathology marking the changes in behavior and cognition seen in AD are the accumulation of amyloid plaques and tau tangles, and research has suggested a role of neuroinflammation in the development of AD. One promising treatment, low-dose Naltrexone (LDN), has the potential to modulate inflammatory pathways in the brain involved in the development of AD. Using the rTg4510 h-tau mouse model with wildtype (WT) mice as a control, we began administering LDN or Phosphate-buffered saline (PBS) by intraperitoneal injection beginning at 2 months, every other day for 6 weeks. We tested 4 groups, including WT

LDN (n = 12), h-tau LDN (n = 12), WT PBS (n = 12), h-tau PBS (n = 12). Naltrexone was diluted by 0.1 mg Naltrexone per 1 kg water, and the amount of LDN administered to each mouse was based on body weight at the time of injection at 1 ml per 1 g. The mice not receiving LDN injections received 20 ml PBS injections. Mice were tested at 3.5 months of age for spatial memory deficits using the Morris Water Maze (MWM) behavioral testing method. ANOVA showed significant results of genotype, with WT mice performing significantly better than h-tau mice ($p < .001$) for latency to platform. There were no statistically significant differences between LDN and PBS injection types ($p > .05$) for latency. Additional behavioral tests and Western Blot analyses will be performed.

Title: Astrocytic BMAL1 regulates protein aggregation in mouse models of alpha-synuclein and tau pathology

Authors: *P. W. SHEEHAN, M. KANAN, C. NADARAJAH, J. PATTERSON, B. BENITEZ, O. HARARI, L. BRASE, A. A. DAVIS, E. S. MUSIEK;
Washington Univ. In St. Louis, Saint Louis, MO

Abstract: The circadian clock regulates inflammatory responses in the peripheral immune system, though its function in neuroinflammation is poorly understood. Deletion of the master circadian clock transcription factor BMAL1 abrogates cellular circadian clock function and can be used to probe cell-type specific functions of the clock. Our lab has previously shown that *Bmal1* deletion induces oxidative stress, astrocyte activation, and increased β-amyloid plaque deposition in mice. Given these findings, we hypothesized that deletion of *Bmal1* would increase pathology in other protein aggregation models. Therefore, we tested the effects of *Bmal1* deletion in a model of alpha-synuclein (aSyn) aggregation and spreading using a preformed fibril (PFF) injection model. Unexpectedly, we found that global *Bmal1* deletion significantly decreased aSyn spreading throughout the brain. Because *Bmal1* deletion drives cell-autonomous astrocyte activation, we examined aSyn pathology in astrocyte-specific *Bmal1* knock out mice (Aldh1l1-Cre^{ERT2};Bmal$^{f/f}$) and found that deletion of *Bmal1* in astrocytes was sufficient to decrease aSyn pathology. Furthermore, we generated novel mouse lines to test the loss of *Bmal1*

on tau aggregation. We found that global *Bmal1* deletion strongly mitigates tau pathology, an effect that was once again recapitulated using astrocyte-specific *Bmal1* knock out mice. We observed that astrocytic *Bmal1* deletion rapidly induced astrocyte-specific expression of BAG3, a chaperone protein previously implicated in the degradation of aggregated tau and synuclein. To test whether BAG3 overexpression might be the mechanism driving the decreased protein aggregation observed in astrocyte *Bmal1* knockout mice, we developed an *in vitro* astrocyte PFF uptake assay and found that loss of *Bmal1* increased PFF uptake, which was reduced to baseline after simultaneous knockdown of *Bag3*. To investigate the relevance of BAG3 in human disease, we looked at a single nucleus RNA-sequencing database of patients with autosomal dominant Alzheimer's Disease (ADAD). Interestingly, we found that BAG3 was specifically upregulated in activated astrocytes in patients with ADAD. Ongoing studies are examining the effect of BAG3 knockdown on aSyn spreading in astrocyte-specific *Bmal1* KO mice. Overall, these findings suggest that early astrocyte activation via *Bmal1* deletion prevents neurodegenerative protein aggregation, possibly through the upregulation of BAG3. This novel data suggests that targeting astrocytic protein degradation machinery could be a therapeutic strategy for mitigating Alzheimer's disease, Parkinson's disease, and other neurodegenerative diseases.

Title: Elucidating the effect of the antibiotic altered microbiota on amyloid deposition as influenced by TREM2 in mouse model of amylodosis.

Authors: *M. E. BOSCH, A. NAMBIAR, H. DAVID, S. PARHIZKAR, D. HOLTZMAN; Washington Univ., St. Louis, MO

Abstract: Alzheimer disease (AD) is the most common neurodegenerative disease that causes progressive memory loss and cognitive decline in people over the age of 65. Longitudinal biomarker studies indicate AD pathology begins in a preclinical phase when Aβ accumulates over 15-20 years prior to the onset of cognitive dysfunction. The preclinical phase affords the

opportunity to identify alterations in pathways that develop before the onset of symptoms that could provide important insight into mechanisms underlying disease progression. One such pre-clinical symptom could be microbiome dysbiosis. The microbiome has many vital homeostatic functions including regulating immune functions and neurological development. Multiple studies have shown that AD patients have a significantly different microbiome composition compared to healthy, age-matched controls. Interestingly, when the microbiome is altered in mouse models that develop Aβ deposition either by antibiotics or complete ablation, there is a significant reduction of Aβ deposition, improved memory function, decreased neuronal loss, and reduced microglial neuroinflammation. These studies demonstrate that alterations in the gut microbiome are connected to AD pathology and may be linked with systemic inflammation resulting in prolonged neuroinflammation and disease progression. Recent genome-wide association studies found mutations within microglia TREM2 (e.g. R47H) increases the risk of developing late-onset AD by 2-4 fold. Our lab has published that loss of TREM2 function in models with Aβ deposition causes' increased Aβ deposition and decreased plaque-associated microglia leading to increased dystrophic neurites around plaques. The exact mechanism of how TREM2 contributes to AD progression is unknown. Therefore it was hypothesized that altering the microbiome via antibiotic treatment in amyloid-depositing mice will improve microglial Aβ recognition and reduce plaque burden in R47H amyloid depositing mice. To test this, R47H or WT mice were gavaged with antibiotics or vehicle daily from P14 to P21. At 4.5 months old, antibiotic treated mice had larger cecum weights signifying a disruption in gut flora. Initial results indicate that antibiotic treatment reduces Aβ plaque size in R47H AD mice compared to controls. Antibiotic treatment also enhanced microglia clustering around amyloid plaques and decreased microglia branch length in R47H AD mice compared to controls indicating an alteration in microglia activation state. These data suggest that altering the microbiome has the potential to impact Aβ-linked pathology via microglia.

The Bluefield Project to Cure Frontotemporal Dementia
BrightFocus Foundation

Title: Proteomics connects microglial GPNMB upregulation to neuroinflammation and neurodegeneration in a mouse model of frontotemporal dementia caused by progranulin deficiency

Authors: *T. KUKAR[1], P. MERINO[1], G. TAYLOR[1], M. WANG[1], M. HUANG[2];
[1]Dept. of Pharmacol. and Chem. Biol., Emory Univ., Atlanta, GA; [2]Second Xiangya Hospital, Xiangya Sch. of Med., Central South Univ., Changsha, China

Abstract: Mutations in the *GRN* gene, encoding progranulin (PGRN), are a common cause of Frontotemporal dementia (FTD) and lead to PGRN haploinsufficiency. PGRN is composed of 7.5 repeating domains termed granulins (GRNs 1-7) that are joined by linker regions. We have discovered that PGRN is processed into ~6 kDa granulins within the lysosome, where we hypothesize they are critical for lysosome homeostasis (Holler et al, *eNeuro*, 2017 Aug 18;4(4)). However, the molecular mechanisms caused by decreased lysosomal PGRN/granulin levels that lead to FTD, Alzheimer's disease (AD), and other neurodegenerative disorders are still unknown. To gain insight into the mechanisms of FTD pathogenesis, we performed an unbiased quantitative proteomic analysis of whole-brain tissue from wild-type ($Grn^{+/+}$) and progranulin knockout ($Grn^{-/-}$) mice at 3 and 19-months of age using Tandem-Mass-Tag (TMT) isobaric labeling mass spectrometry. In 19-month-old $Grn^{-/-}$ mice, 119 proteins were increased, and 20 proteins were decreased compared to $Grn^{+/+}$ mice. The most significantly upregulated protein in the brains of 19-month-old $Grn^{-/-}$ mice was Glycoprotein NMB (GPNMB), motivating us to investigate GPNMB in more detail. GPNMB is a type-I transmembrane glycoprotein of unknown function in the brain. We find GPNMB is predominantly expressed by microglia and strongly upregulated in $Grn^{-/-}$ mice with age. Importantly, microglia in brains of human FTD-*GRN* cases also upregulate GPNMB. Recently, GPNMB was found to be upregulated by microglia surrounding amyloid plaques in AD. Moreover, upregulation of GPNMB is a marker of degenerative disease-associated microglia (DAM). Additionally, genetic variants in *GPNMB* are associated with Parkinson's disease. Thus, GPNMB is broadly involved in neurodegeneration and may represent a novel drug target. However, it is unclear whether upregulation of GPNMB in microglia is protective or deleterious. Because overexpression of GPNMB is deleterious in several diseases, we hypothesize that microglial upregulation of GPNMB in $Grn^{-/-}$ mice activates pro-inflammatory pathways that contribute to neurodegeneration. We are currently testing this hypothesis, by crossing $Grn^{-/-}$ and $Gpnmb^{-/-}$ mice and determining how elimination of GPNMB alters lysosome dysfunction, inflammation, and neurodegeneration in a mouse model of progranulin deficiency. Data from these experiments will: a) help decipher the role of microglial expression of GPNMB in mediating inflammation and neurodegeneration caused by loss of PGRN and granulins and b) provide insight whether targeting GPNMB is a novel, viable therapeutic approach.

Title: Neuronal oxidative stress at amyloid plaques is not caused by microglia but is correlated with dysfunctional lysosome accumulation

Authors: *S. WENDT, B. A. MACVICAR;
Ctr. for Brain Health/Psychiatry, Univ. of British Columbia, Vancouver, BC, Canada

Abstract: Intense oxidative stress occurs at Alzheimer's Disease (AD) plaques contributing to synaptic dysfunction and neuronal death yet the triggers for generating reactive oxygen species (ROS) remain elusive. Microglia are thought to contribute to AD pathology and to modify ROS generation by acquiring neuroprotective or neurotoxic phenotypes. Here we report new imaging strategies using genetically encoded roGFP redox sensors to simultaneously image microglia and neuronal redox states in live cells in vivo and in paraformaldehyde fixed brain tissue with additional immunocytochemistry. By employing these tools, we found that microglia preferentially surround and engulf dystrophic neurites (DNs) with the greatest degree of cytoplasmic oxidation around amyloid plaques in 5xFAD mice. High levels of cytoplasmic oxidation in DNs correlated with elevated LAMP1 and ubiquitin thereby linking dysfunctional lysosomes to oxidative stress in DNs. Long-term in vivo 2-photon imaging revealed highly dynamic interactions between microglia and DNs. When microglia were depleted from 5xFAD mice by administering PLX3397, oxidative stress surprisingly was exacerbated which correlated with even greater elevations of LAMP1. Interestingly, we also confirmed the previously reported neuroprotective effect of microglia depletion in 5xFAD mice and found reduced levels of neuronal loss after treatment. Our data highlights two seemingly paradoxical functions of microglia in 5xFAD mice: While microglia ameliorate redox stress in DNs they also promote the loss of neurons. Our novel approaches to study microglia and neuronal redox levels simultaneously allow to further dissect the underlying redox mechanisms and identify key pathways of neurotoxic and neuroprotective microglial functions in AD.

Abstract: The in utero environment is well known to influence CNS development and behavioral phenotypes, effects that can last into adulthood. However, long-term cognitive reprogramming has never been evaluated in the context of sleep-disordered breathing (SDB) during pregnancy, despite its alarming increase in recent years and detrimental consequences. Alzheimer's Disease (AD) among other neurocognitive disorders, has been observed to be strongly correlated with sleep apnea, a manifestation of SDB. Here, we examined the 5XFAD Alzheimer's mouse model after in utero exposure to gestational intermittent hypoxia (GIH), a hallmark of SDB during pregnancy. We tested the hypothesis that GIH exposure will compound the cognitive and behavioral phenotypes previously observed in 5xFAD mice to reveal further deficits. Pregnant dams received intermittent hypoxia (2 min alternating 6.5%/21% O2) or normoxia (2 min alternating 21% O2/21% O2) for 12 hrs/day from gestational days 10-18. Offspring were then grown up to 4 mo, at which point behavioral tests such as marble burying, Y-maze, and novel object recognition were conducted every two months across the lifespan to 8 months. Preliminary behavioral data demonstrated sex-dependent declines in cognitive function of 5xFAD with exposure to GIH. After final behavior testing, brains were harvested for immunohistochemistry analysis. Imaging analysis demonstrated sexually dimorphic alterations in microglial immune response with exposure to GIH. These data support sex-specific alterations in cognitive function in AD mice based on early life exposures.

Abstract: Alzheimer's Disease (AD) is the most common neurodegenerative disease that disproportionately affects an aged population. AD exhibits a wide array of pathologies including amyloid plaques, neurofibrillary tangles, neuroinflammation, neuronal loss, brain atrophy, and cognitive decline. Many efforts to treat the disease rely on targeting plaques or tangles, but there is still much to learn about AD in its other pathologies. Epidemiological evidence points to the use of over-the-counter NSAIDs such as aspirin or ibuprofen, but clinical trials fail to show a significant benefit. A deeper investigation is required into the pathway that NSAIDs target which is the cyclooxygenase (COX) pathway. The COX pathway is controlled by prostaglandins which have multiple receptors and many functions including inflammation, nociception, sleep, reproduction, and vascular function. In the brain, prostaglandin D2 (PGD2) is the most abundant prostaglandin, the one that increases most under pathological conditions, and plays roles in sleep and inflammation. PGD2 signals through the DP1 and DP2 receptors and their activation will either raise or lower intracellular cAMP levels, respectively. We addressed the role of PGD2 signaling in AD with Fischer transgenic 344-AD (TgF344) rats that express the AD related human genes "Swedish" amyloid-precursor protein (APPswe) and Δ exon 9 presenilin-1 (PS1ΔE9). TgF344 rats exhibit age-dependent amyloid plaques, tau tangles, neuronal loss, microgliosis, and cognitive decline. Our imunohistochemical analysis of hippocampal tissue found that DP2 is detected mostly in neurons. Moreover, TgF344 rats exhibited higher DP2 levels in neurons of the CA1 region than their wild type (WT) littermates. In contrast, DP1 was expressed in microglia. TgF344 rats also exhibited higher levels of DP1 in microglia of the CA1 (stratum lacunosum moleculare) region and DG (hillar) region than their WT littermates. Our cognitive behavioral analyses using two hippocampal-dependent assays, the 8-arm radial arm maze and the active place avoidance test, established that WT rats performed significantly better than the TgF344 rats. Our findings demonstrate that the levels of DP1 and DP2 receptors are altered in TgF344 rats specifically within the CA1 and DG regions of the hippocampus. Thus, modulating the activity of these receptors could help dampen AD pathology and offer a new therapeutic strategy.

Title: Modulated integrin signaling plays a role in anticholinesterase-induced synaptopathy in hippocampal explants

Authors: J. J. TUTON, M. F. ALMEIDA, B. A. BAHR, *K. L. G. FARIZATTO;
Biotech. Res. and Training Ctr., Univ. of North Carolina - Pembroke, Pembroke, NC

Abstract: Organophosphates (OPs), a deadly class of poisons which inhibit acetylcholinesterase, lead to cholinergic crises and produce the risk of excitotoxic injuries (e.g. seizure pathology), long-term neurological problems, and death. OPs are used worldwide for agricultural pesticides and as warfare agents used by terrorist groups and state actors. Understanding the synaptoxic profile of OPs is vital for public health and long-term treatment strategies. OP-mediated synaptopathology has been described (Farizatto et al. 2017 *J Mol Neurosci* 63:115; Farizatto et al. 2019 *Sci Rep*.9:6532), with the latter study identifying an involvement by integrin-type adhesion responses. From *C. elegans* to the mammalian brain, integrins are linked to synaptogenesis, synaptic modulation, and axon regeneration (Bahr 2000 *J Neurosci Res* 59:827; Eva & Fawcett 2014 *Curr Opin Neurobiol* 27:179; Hisamoto et al. 2018 *Nat Commun* 9:3099). Here, hippocampal tissue cultures were exposed to the OP toxin paraoxon (Pxn) to decipher if the evident synaptic vulnerability is influenced by integrins, using the β1-integrin inhibitor (BIO 5192). Additionally, a set of treated hippocampal slices were subsequently followed with a toxin washout procedure. Synaptic changes were assessed by immunoblot, immunohistochemistry, and correlational analyses. Pxn exposure caused a dramatic loss of pre- and postsynaptic staining among neuropilar dendrites, occurring in correspondence with abnormal induction of adhesion responses through theβ1 integrin. Such an increase in β1 integrins was evident across the hippocampal dendritic fields. Adhesion responses are mediated by multiple types of complex adhesion molecules. Interestingly, in the Pxn exposure model, the distinctive adhesion response was mediated solely by the β1-typeintegrin family when assessed in parallel with neurexin and NCAM. To further examine the integrin's role during OP-mediated synaptopathology, we co-treated the Pxn-exposed tissue with a neuroprotective trifluoromethylketophenoxypentyl analog, and observed that the integrin-type response was offset by the neuroprotectant which also helped stabilize synaptic markers. Similar results were found with the toxin wash-out procedure. Additionally, the synaptic compromise observed in Pxn-exposed explants was not exhibited after the application of the β1-integrininhibitor, suggesting that blocking β1 integrin signaling appears to attenuate the unique synaptotoxicity mediated by Pxn. These findings postulate that integrins

can respond to excitotoxic insults and induce distinct cell signaling that influences synaptic integrity and maintenance.

Title: Cholinergic Preservation as a Mechanism of Resilience in the Oldest-Old

Authors: *S. P. MAXWELL[1], M. K. CASH[1], S. DARVESH[1,2,3];
[1]Med. Neurosci., [2]Med., Dalhousie Univ., Halifax, NS, Canada; [3]Chem. and Physics, Mount St. Vincent Univ., Halifax, NS, Canada

Abstract: Background: A subpopulation of the oldest-old, individuals 80 years of age and older, maintain cognitive abilities comparable to individuals who are decades younger. Both the rostral prefrontal cortex (rPFC) and hippocampus are implicated in cognitive function mediated, in part, by cholinergic innervation via the basal forebrain. The aim of this study is to evaluate the deposition of neuropathological proteins in the oldest-old rPFC and hippocampus and evaluate cholinergic system preservation as a potential mechanism of cognitive resilience. **Methods:** Human formalin-fixed rPFC and hippocampal tissues from male and female cognitively normal oldest-old (CNOO) individuals over the age of 80 were examined and compared to sex- and age-matched Alzheimer's disease tissues. Neuropathological load was examined with immunohistochemical staining for β-amyloid (Aβ), tau, α-synuclein, and phosphorylated Tar DNA-binding protein-43 (TDP-43). The presence of cholinergic dysfunction was evaluated using histochemical staining for butyrylcholinesterase (BChE) and acetylcholinesterase, and immunohistochemical staining for choline acetyltransferase (ChAT). Neuropathological findings

were analyzed using a modified CERAD neuropathological protocol. ChAT was analyzed qualitatively. **Results:** The rPFC and hippocampus had significant deposition of abnormal protein aggregates characteristic of neurodegeneration. While cholinesterase-positive plaques were observed in the regions examined in the CNOO cases, cholinesterase-positive plaque deposition was greater in AD cases, indicating a specificity to AD-associated pathology. ChAT activity was normal in the CNOO and reduced in the AD rPFC and hippocampus. **Conclusion:** The CNOO maintain cognitive function despite significant neuropathological burden. Maintained cholinergic connectivity to the rPFC and hippocampus may contribute to cognitive resilience in the CNOO.

Title: Human iPSC microglia for assessing new treatments in neurological diseases

Authors: *F. SIMON, K. WALKER, J. BELLEC-DYEVRE, C. CANCIO, M. PAQUET, E. ESNEAULT;
Porsolt S.A.S., Le-Genest-Saint-Isle, France

Abstract: Microglial activation, and the ensuing inflammatory response in the central nervous system, plays an important role in neurodegenerative diseases such as Alzheimer's and Parkinson's. Activated microglia, in addition to their role in phagocytosis, may induce the secretion of pro-inflammatory cytokines, including TNF-α and Il-6, as well as caspase 1 activation via the NLRP3 inflammasome, which controls the release of Il-1beta and Il-18.
The aim of the present study was to assess functional and physiological properties of microglia derived from human induced pluripotent stem cells (human iPSC) by measuring the expression of proinflammatory cytokines secreted following LPS stimulation and their ability to phagocytose bacterial particles.
Expression levels of IL-6, IL-8, IL-10 and TNF-α were clearly increased in the supernatants at 6 and 24 hours following LPS stimulation, demonstrating microglial activation. These effects were partially inhibited by Dexamethasone, a synthetic glucocorticoid, used for its anti-inflammatory properties. The addition of an adenosine triphosphate pulse following LPS was required to induce Il-1 beta secretion, confirming the activation of the inflammasome pathway
Microglia functionality was assessed via kinetic monitoring of the phagocytosis of bacterial particles, coupled with pH-Rodo fluorochrome. An increase of fluorescent signal was observed over time, and activated microglia exhibited functional phagocytosis. This effect was fully

inhibited in presence of Cytochalasin D, an inhibitor of actin polymerization.
These results suggest that human iPSC-derived microglia exhibit functional characteristics similar to human microglia, including phagocytosis and cytokine-mediated inflammatory responses. This translational model may be used to study neuroinflammation, a crucial hallmark of neurodegenerative disorders in humans, and to assess the efficacy of early-stage therapeutic targets.

Title: Mitochondria-lysosome contact regulation and function in neurodegenerative diseases

Authors: *J. CISNEROS, G. C. SHUM, Y. C. WONG;
Northwestern Univ. Feinberg Sch. of Med., Chicago, IL

Abstract: Multiple neurodegenerative diseases including Parkinson's disease and Charcot-Marie-Tooth disease have been genetically and functionally linked to defects in mitochondria and lysosomes, suggesting that proper regulation of these two organelles is critical for maintaining neuronal homeostasis. Importantly, inter-organelle contacts form between mitochondria and lysosomes, allowing for their crosstalk at dynamic mitochondria-lysosome contacts sites. Using advanced live cell confocal microscopy, we have examined how mitochondria-lysosome contact sites are dynamically regulated and their roles in regulating mitochondrial and lysosomal functions. Mitochondria-lysosome contacts mediate the bidirectional regulation of both mitochondrial and lysosomal network dynamics, and are further regulated by multiple protein complexes on both organelles. Furthermore, mitochondria-lysosome contact regulation and functions are disrupted by mutations in various neurodegenerative diseases including both Parkinson's disease and Charcot-Marie-Tooth disease. These findings further support a key role for this pathway in regulating neuronal homeostasis, and in potentially driving the etiology of multiple neurological disorders associated with mitochondrial and/or lysosomal dysfunction.

Abstract: New neurons are generated in the hippocampus past the developmental period and childhood well into adult life, a process that has been extensively investigated in rodents, but that remains controversial in humans. The hippocampus is also notable for its vulnerability in Alzheimer's disease (AD), as pathological markers are observed in this structure early during the course of the disease. Many of the operational functions affected by AD depend at least partially on proper hippocampal function, and multiple animal and histopathological studies indicate that adult hippocampal neurogenesis is affected during AD. However, the exact mechanisms of interaction between these two processes remain poorly elucidated, particularly due to the inadequate translation of rodent animal model-derived knowledge to both the dementia and neurogenesis fields. In light of the above, we propose the use of non-human primate models (*rhesus* macaques) recently developed by our group - including the injection of synaptotoxic amyloid β oligomers (AβOs) in the cerebroventricular space and the viral induction of tau expression in the entorhinal cortex - to understand the effects of AD-related proteins over the progenitor and proliferating populations of the primate hippocampus. To accomplish those goals, we will employ modern immunohistochemistry, microscopy, and segmentation and reconstruction techniques, allowing us to visualize the different components of the neurogenic niche and the effects of aging, amyloid, and tau proteins over those components in a highly controlled setting. Our preliminary data suggest a substantial and selective decrease in the number of immature neurons in the granular zone of the dentate gyrus ($Tuj1^+$) of adult macaques injected with synthetic AβOs compared to scramble peptide controls. The magnitude of this decrease was similar to that observed between aged and young animals. At the same time, exogenous tau expression has minimal effect on the number of $Tuj1^+$ neurons compared to

uninfected controls, despite the abundant presence of phosphorylated tau in the dentate gyrus and the underlying subgranular zone. Our results suggest that amyloid oligomers are capable of driving neurogenic deficits in AD even in the absence of tau aggregation, with neurogenic deficits possibly accompanying the synaptic dysfunction promoted by amyloid early in the course of the disease. Therefore, early pharmacological intervention against amyloid pathology may be a valuable strategy to preserve adult hippocampal neurogenesis in physiological and pathological situations.

Title: Fibrinogen-induced oxidative stress in neurons

Authors: *N. SULIMAI, J. BROWN, D. LOMINADZE;
Univ. of South Florida, Tampa, FL

Abstract: Traumatic brain injury (TBI) is associated with systemic inflammation accompanied with an elevated level of fibrinogen (Fg) and increased cerebrovascular permeability, which could result in the translocation of Fg from non-ruptured vessels to the extravascular space. We previously found that extravasated Fg was deposited between blood vessels and astrocyte endfeet. This effect was coincided with increased neurodegeneration and a reduction in short term memory (STM) during mild-to-moderate TBI (m-mTBI). We also showed that the association of Fg with astrocytic intercellular adhesion molecule-1 (ICAM-1) and cellular prion protein (PrP^C) caused astrocyte activation, expression of pro-inflammatory cytokines, production of reactive oxygen species (ROS), and astrocyte death. We aimed to investigate if Fg can directly interact with neurons via its neuronal receptors ICAM-1 and PrP^C and if this effect can cause oxidative stress affecting neuronal viability. Primary mouse brain cortical neurons from C57BL/6 mice were grown on Poly-D-Lysine and laminin-coated glass-bottomed 24-well or 8-well chambers at the density of 200,000 cells/well. Neurons were treated with various concentrations of Fg or with Fg in the presence of function-blockers of its receptors ICAM-1 or PrP^C for 3 or 24 hours. All groups contained the thrombin inhibitor hirudin to prevent conversion of Fg into fibrin. Associations of Fg with neuronal ICAM-1 and PrP^C were characterized with a proximity ligation assay. The expressions of pro-inflammatory marker interleukin 6 (IL-6) and

the generation of ROS, mitochondrial superoxide, and nitrite in neurons were assessed. Fg-induced neuronal death was assessed with a live/dead assay. We found that 1 mg/ml of Fg reduced neuronal viability (86±2% of live cells) compared to that in the control group (97±2% of live cells). A strong association of Fg with neuronal ICAM-1 and PrP^C, accompanied with the overexpression of IL-6 and the generation of ROS, mitochondrial superoxide, nitrite, and the resulting neuronal apoptosis and death were found. These effects were reduced by blocking the function of neuronal ICAM-1 and PrP^C, suggesting that the direct interaction of Fg with its neuronal receptors can induce overexpression of IL-6 and the generation of ROS, nitrite, and mitochondrial superoxide, ultimately leading to neuronal death. These effects can be a mechanism of neurodegeneration and the resultant STM reduction seen during m-mTBI and Alzheimer's disease.

Abstract: Despite the effectiveness of antiretroviral therapy (ART), HIV associated neurocognitive disorders (HAND) remains highly prevalent, and the aging population is at risk of developing HIV associated dementia (HAD), a severe and debilitating condition. Studies in HIV+ patients implicate acute viremia and inflammation in driving central nervous system (CNS) impairment. Non-human primates such as rhesus monkeys, are a powerful model to understand HAND pathogenesis, given the high similarities with humans in terms of the CNS structure, immune and inflammatory responses. In this pilot study, 7 female monkeys were infected with a neurotropic simian immunodeficiency virus (SIV) that induces similar pathology to that observed in HIV+ patients. An additional 4 age-matched female animals were analyzed as controls. Plasma peak viremia was observed in all animals within a few weeks, and brains were

investigated to test the hypothesis that the virus can invade and establish a viral reservoir in the CNS. Preliminary data show that, despite moderate systemic viremia (PVL range: 200-22,000 cp/ml), SIV rapidly and actively establishes a presence in the CNS, including the hippocampus and the superior temporal sulcus (STS), two major regions involved in cognitive functions. SIV replication was also observed within the cerebrospinal fluid (CSF) (23-900 cp/ml) and the virus was also detected in the choroid plexus, associated with CD4+ cells. High-resolution confocal microscopy showed blood brain barrier disruption and several sites of neuroinflammation across several brain regions. Notably, a robust neuroinflammatory response driven by reactive round-shaped microglia was observed within the hippocampus and STS. Altogether, our data shows rapid SIV establishment and dissemination within several brain regions, in a process driven by infected-activated microglia, with direct consequences for neurons and spine loss. Acute viral establishment within the CNS has significant implications for the cognitive functional deficits observed in HAND patients. An SIV-monkey model, highly translatable to humans, may help shed light on understanding the mechanisms underlying the cognitive dysfunction observed in HAND and HAD patients.

Title: Differential synaptic engagement by tau and Ab oligomeric species suggests distinct synaptic toxicity across Alzheimer’s disease and related tauopathies.

Authors: *M. MARCATTI, A. FRACASSI, M. MONTALBANO, N. PUANGMALAI, N. BHATT, C. NATARAJAN, B. KRISHNAN, R. KAYED, G. TAGLIALATELA;
Mitchell Ctr. for Neurodegenerative Dis. - Dept. of Neurol. - Univ. of Texas Medica, UTMB, Galveston, TX

Abstract: Alzheimer’s Disease (AD) is characterized by gradual cognitive decline driven by the targeting of synapses by small oligomers of both Aβ (AβO) and tau (TauO), which results in synaptic dysfunction that ultimately underscores disease progression. Consequently, there is ample consensus that targeting oligomer binding to synapses would be an effective therapeutic

concept for AD. However, recent failures of clinical trials of Aβ-directed therapeutics suggest reduced effectiveness of targeting Aβ in clinically manifest AD, redirecting attention onto TauO whose levels increase later in the disease timeline. In support of this view, here we show that recombinant TauO, human brain derived tau oligomers form Alzheimer's disease (BDTO-AD) and Progressive Supranuclear Palsy (BDTO-PSP) as well as AβO, target synapses with different dynamics. Using synaptosomes isolated from the hippocampus and frontal cortex of brain mouse slices and postmortem brain specimens from cognitively intact elderly humans, we demonstrated that higher TauO concentrations effectively oucompete AβO and become the prevailing synaptic-associated species. On the other hand, although lower levels of AβO did not alter TauO binding, higher AβO concentrations resulted in increased TauO binding to human synapses. Immunofluorescence analyses of mouse primary cortical neurons treated with AβO and/or TauO fully supported these data. Consistent with these observations, functional FASS-LTP studies in human synaptosomes revealed that the TauO- induced suppression of chemical long-term potentiation (cLTP) is not affected by the concomitant presence of AβO. Moreover, depletion of synaptosome surface proteins by PK pre-treatment abolished the effect of TauO in reducing AβO synaptic binding; on the other hand, the effect of AβO in increasing TauO synaptic binding was not affected by PK. Taken together, our results provide deeper insight into the interplay between AβO and TauO that contributes to synaptic dysfunction at the basis of the cognitive decline in AD. Furthermore, we observed different synaptic engagement and internalization profiles among the analyzed BDTOs,
suggesting different synaptic toxicity of TauO across the tauopathies spectrum. Overall, our results suggest that at the advanced stages of AD, when tau levels increase, TauO become the main synaptotoxic species and likely an effective therapeutic target. Furthermore, subtle disease-specific differences in the dynamic of BDTOs engagement of synapses may underscore different clinical presentations among the tauopathy spectrum.

Res. Inst., Pasadena, CA; [9]Dept. of Neurosci., Monash Univ., Melbourne, Australia

Abstract: Cerebral microvascular dysfunction significantly contributes to early cognitive impairment and dementia. Here we analyzed blood-brain barrier (BBB) permeability and cerebral blood flow (CBF) in relation to early cognitive decline in *APOE3*-homozygotes (ε3/ε3) and *APOE4*-carriers (ε3/ε4; ε4/ε4). A total of 143 participants (86 females [60.1%]), including 74 *APOE3*-homozygotes and 69 *APOE4*-carriers, underwent neuropsychological evaluations and magnetic resonance imaging (MRI). Dynamic contrast-enhanced and 3D pseudo-continuous arterial spin labeling (pCASL) MRI were used to estimate BBB permeability and CBF, respectively. Participants were classified in cognitively unimpaired (CU) and mild cognitive impairment according to the global Clinical Dementia Rating scale (CDR=0 and 0.5, respectively). We found that in CU and MCI individuals, there was no difference in CBF levels in grey matter (GM), hippocampus (HC), and parahippocampal gyrus (PHG) between *APOE3*-homozygotes and *APOE4*-carriers (Figure 1A-C), but higher BBB permeability values were observed in the hippocampus of *APOE4*-carriers compared with *APOE3*-homozygotes (Figure 1D). In a subgroup of 46 participants (21 CU *APOE3*-homozygotes, 18 CU *APOE4*-carriers, and 7 *APOE4*-carriers with CDR=0.5) who underwent a second MRI approximately 2 years after the first MRI, we observed a significant reduction of CBF in *APOE4*-carriers with mild cognitive impairment, but not in CU individuals (Figure 1E-F). These preliminary results suggest that BBB breakdown in *APOE4*-carriers precedes CBF alterations.

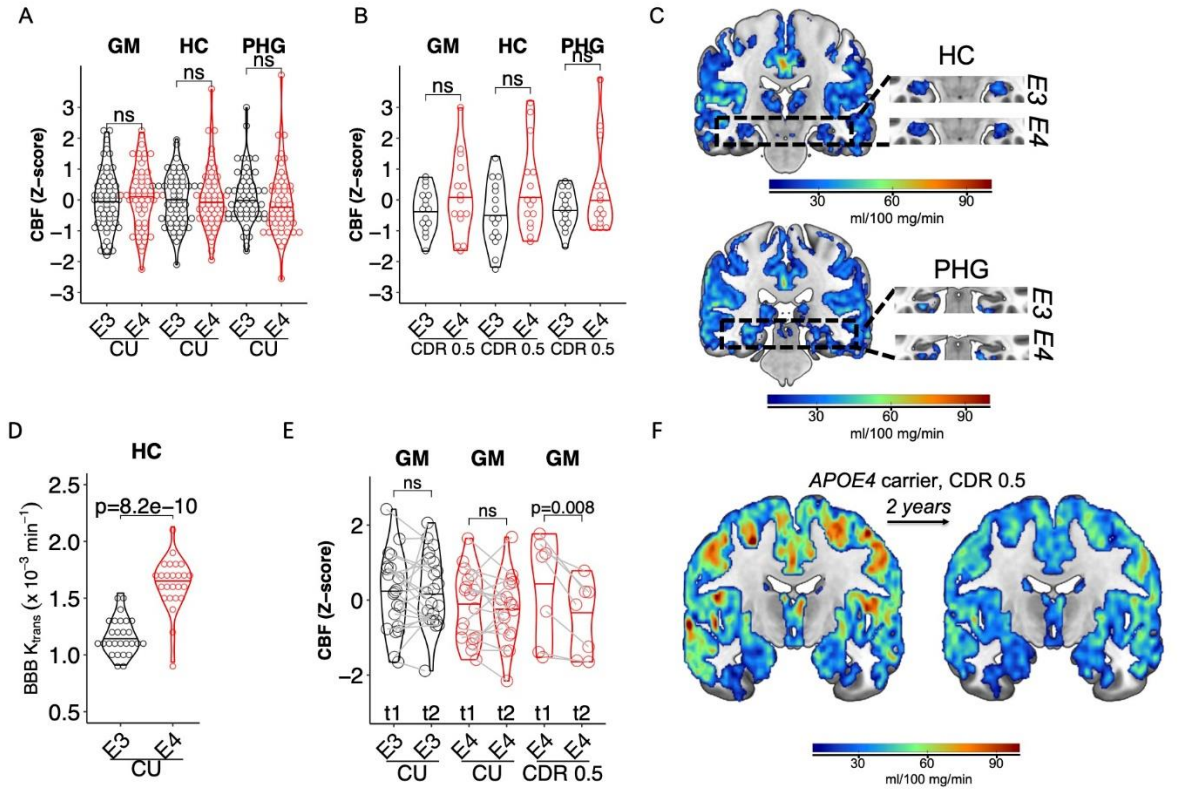

Figure 1: Standardized cerebral blood flow (CBF) levels in grey matter (GM), hippocampus (HC) and parahippocampal gyrus (PHG) in APOE4-carriers (red) compared with APOE3-homozygotes (black). No significant difference is observed in these 3 regions between APOE4-carriers and APOE3-homozygotes, both in cognitively unimpaired (CU) (**A**) and in participants with CDR=0.5 (**B**). ns, by ANCOVA controlling for age and sex. **C**) Representative CBF maps of APOE3-homozygotes and APOE4-carriers in HC (top) and PHG (bottom). **D**) BBB permeability is significantly higher in CU APOE4-carriers compared with APOE3-homozygotes. p<0.001, by ANCOVA controlling for age and sex. **E**) After 2 years follow-up, CBF in GM is significantly reduced in APOE4-carriers with mild cognitive impairment (CDR 0.5; n=7), but is not significantly altered in CU APOE3-homozygotes (n=21) and CU APOE4-carriers (n=18). Significance by paired t-test. **F**) Comparison of CBF maps in GM of an APOE4-carrier with CDR=0.5 at the first timepoint (left) and after a 2-year interval (right).

Title: Apolipoprotein E4 impairs neurovascular regulation via brain-resident macrophages

Authors: *A. ANFRAY, Y. HATTORI, J. SEO, M. SANTISTEBAN, S. AHN, G. WANG, J. ANRATHER, L. PARK, C. IADECOLA;
Weill Cornell Med., New York, NY

Abstract: The apolipoprotein E4 (ApoE4) causes cerebrovascular oxidative stress and impairs neurovascular regulation in humans and mice. However, the cellular sources mediating the deleterious neurovascular effect of ApoE4 remain unestablished. Perivascular and leptomeningeal macrophages (PVM) juxtaposed to pial and penetrating vessels mediate neurovascular dysfunction in models of Aβ accumulation and hypertension through oxidative stress. We tested the hypothesis that PVM are also involved in the deleterious neurovascular effect of ApoE4. We monitored the cerebral blood flow (CBF) in the somatosensory cortex of ApoE4 (human) targeted replacement (ApoE4-TR), ApoE3-TR, or wild-type (WT) mice under urethane-chloralose anesthesia by laser-Doppler flowmetry (both sexes; age 3-4 months; n=5/group). In ApoE4-TR mice, the increase in CBF produced by neural activity (whisker stimulation; WS) or by topical application of the endothelium-dependent vasodilator acetylcholine (ACh) was attenuated compared to ApoE3-TR (CBF increase-WS: ApoE3-TR: 24±4%; ApoE4-TR: 10±2%; -56%; Ach: ApoE3-TR: 20±2%; ApoE4-TR: 11±4%; -44%; $p<0.05$ from ApoE3-TR). In WT mice, neocortical superfusion of recombinant ApoE4 (rApoE4; 10 µg/ml) attenuated CBF response induced by WS (-62%; $p<0.05$ from rApoE3) or by neocortical superfusion of ACh (-48%; $p<0.05$ from rApoE3). The attenuation in the CBF increase produced by WS or ACh was associated with increased oxidative stress in PVM, assessed with DHE as a ROS marker with 2 photon microscopy *in vivo* (+33%) & FACS *ex vivo* (+38%; $p<0.05$ from rApoE3). Neocortical application of the Nox2 inhibitor gp91ds-tat (1 µM) prevented the rApoE4-induced attenuation of CBF responses to WS or ACh ($p>0.05$). Furthermore, PVM depletion using clodronate (-80%) prevented the attenuation in cerebrovascular responses and oxidative stress in WT mice induced by rApoE4 ($p>0.05$ from rApoE3). Next, we investigated if ApoE4 in PVM is required for the neurovascular dysfunction in ApoE-TR mice. To this end, after non-lethal irradiation, we transplanted ApoE4 BM into ApoE3 mice to repopulate their perivascular space with ApoE4 PVM. In ApoE3 mice transplanted with ApoE4 BM, the increase in CBF induced by WS or by ACh was attenuated compared to ApoE3 mice receiving ApoE4 BM (WS: -59%; ACh: -60%; $p<0.05$ from ApoE3◊ApoE4). These findings indicate that PVM are the critical cells required for the Nox2-derived ROS production underlying the neurovascular dysfunction induced by ApoE4 and raise the possibility that PVM may be therapeutic targets to counteract the deleterious neurovascular alterations observed in individuals with the ApoE4 genotype.

Title: Lrp1 as a modulator of hippocampal neurogenesis and neurodegeneration

Authors: *K. DIETERT, S. MAHESULA, P. REED, S. SPRAGUE, E. KOKOVAY, N. SAYRE;
Univ. of Texas Hlth. San Antonio, San Antonio, TX

Abstract: Neurodegenerative disease causes the death of 1/3 of senior citizens, with a prevalence projected to triple by 2050. This expected public health crisis will be exacerbated by a lack of disease-modifying treatments. As the most commonly diagnosed neurodegenerative disorder, Alzheimer's disease (AD) is characterized by a pathological loss of memory function due to hippocampal degeneration. Preservation of hippocampal neurogenesis protects from memory loss in AD, suggesting that improved understanding of molecular processes underlying neurogenesis could lead to more efficacious therapies. Neural stem cells (NSCs) migrate from the subgranular zone niche to integrate into hippocampal circuitry. The chemokine receptor CXCR4 plays a fundamental role in this migration—loss of CXCR4 activity causes hippocampal memory deficits in mouse models, and CXCR4 polymorphisms were identified as risk factors for several neurodegenerative diseases. Our lab has identified a **novel** regulator of CXCR4 - low density lipoprotein receptor related protein 1 (LRP1), which is also implicated in AD. LRP1 expression is decreased in AD patients. LRP1 is also involved in trafficking ApoE4, amyloid beta, and tau - all of which play a role in AD pathogenesis. We used a Nestin-Cre inducible mouse model to knockout LRP1 in NSCs of adult mice. We found that LRP1 knockout caused a 10-fold loss of CXCR4 expression and deficits in ischemia-stimulated migration from the subventricular zone. Male and female mice lacking NSC LRP1 also displayed spatial memory deficits at 9 months of age (6 months after knockout), suggesting dysregulated hippocampal function. Given this, **we hypothesize that LRP1 regulates CXCR4 in the subgranular zone NSCs to enhance hippocampal memory function.** Ongoing research is testing our hypothesis via hippocampal functional tests and *in vitro* trafficking/expression assays. We expect our research to elucidate a previously unknown link between three independently identified effectors of neurodegenerative disease: LRP1, CXCR4, and neurogenesis.

Title: Enhancing APOE lipidation in human iPSC-derived models with a clinically tested HDL mimetic peptide

Authors: K. FREDRIKSEN, A. VEGOE, T. O'BRIEN, *L. LI;
Univ. of Minnesota, Minneapolis, MN

Abstract: The greatest risk factor for developing late onset Alzheimer's disease (AD) is the APOE gene, which in humans has 3 alleles; APOE2 (E2) is protective against AD, APOE3 (E3) is neutral, and APOE4 (E4) increases AD risk. APOE is primarily produced and secreted by astrocytes, where it plays a key role in lipid metabolism and transport by binding lipids to form high-density lipoprotein (HDL)-like particles in the interstitial and cerebrospinal fluid. APOE interacts with amyloid-beta (Aβ), and APOE lipidation regulates Aβ aggregation and clearance. The level of lipidation is isoform dependent; E2 exhibits efficient lipidation and facilitates Aβ clearance, whereas E4 is poorly lipidated and impedes Aβ clearance. Previous studies in our laboratory have shown that a clinically tested 18-aa HDL mimetic peptide, 4F, increases APOE lipidation and secretion in primary human astrocytes as well as primary murine astrocytes and microglia. Furthermore, 4F mitigates the inhibitory effect of Aβ on APOE secretion and lipidation. Our current studies aim to corroborate these findings in human induced pluripotent stem cell (iPSC)-derived models, including astrocytes and 3D cerebral organoids. Human iPSCs from E2, E3, or E4 homozygous individuals were differentiated into cerebral organoids and treated with 4F. Preliminary results show that 4F enhances APOE secretion and lipidation in cerebral organoids derived from all three human APOE isoforms. Further studies are underway to investigate the interactions of 4F with Aβ in iPSC-derived astrocytes and the impact of 4F on AD-related pathologies in iPSC-derived cerebral organoids. The results are expected to reinforce the therapeutic potential of HDL-mimetic peptides for AD.

Abstract: Introduction: Alzheimer disease (AD) is the most prevalent neurodegenerative disorder, affecting over 50 million people worldwide. Age and genetic variation can place individuals at high risk for developing AD, yet a subset of people at higher risk resist pathology and do not develop disease. Recent studies implicate corpora amylacea (CA) activity may be involved in AD pathology. Normally, CA function in the clearance of brain waste products by amassing cellular debris and extruding it into the CSF. The bundles travel to the cervical lymph nodes where they are phagocytosed. The proper functioning of CA may play a role in AD resistance, and might be influenced by age, degree of pathology, and genetic risk. AD genetic risk can be partially estimated by characterizing apolipoprotein (APOE) alleles. E4 carriers are 3-4 times more likely to develop AD than E3/E3 homozygotes, and E4/E4 homozygotes are 12-16 times as likely.
Objective: In this study, we first determined if CA are detected in the dentate gyrus and examined their frequency in a pilot study of AD hippocampal tissue samples. We then quantified differences in CA population in the dentate gyrus by APOE status, age, and extent of tau neurofibrillary tangle (NFT) pathology (B score, Montine et al., 2012).Methods: Postmortem brain hippocampal tissue sections from a pilot study of 14 AD donors were stained with hemotoxylin and eosin (H&E). Using the Motic slide scanner, sections were digitized at 40x. Aperio ImageScope software was used to manually quantify and normalize the number of CA in the dentate gyrus. A general linear model tested association of CA count in the dentate gyrus with APOE E4 carrier status (carrier vs non-carrier), adjusting for age at death, sex, and B score as covariates. Results: CA could be visualized on digital scans of H&E-stained sections. Although not statistically significant, CA count is lower in APOE E4 carriers (n = 9, mean: 3.02

CA/mm2) compared to APOE E4 non-carriers (n = 5, mean: 4.17 CA/mm2). In APOE E4 carriers higher B score (greater NFT pathology) was negatively correlated with CA count (correlation coefficient: -0.34), which was also not statistically significant.Conclusions: A small decrease in CA count was detected in the APOE E4 carriers, in whom increasing tau pathology was also correlated with lower CA counts. The correlation is intriguing and currently being tested in a larger dataset. These results suggest CA could play a role in AD pathologic progression by influencing innate tau clearance.

Title: Establishing an iPSC-derived platform to study apolipoprotein E genotype in brain cell types and its effect on extracellular vesicle cargo and bioactivity

Authors: *A. VERDUZCO[1], L. CAMPANATI[1], W. GAOR[1], K. K. BALDWIN[2], H. T. CLINE[1];
[1]Neurosci., The Scripps Res. Inst., La Jolla, CA; [2]Genet. and Develop., Columbia Univ., New York, NY

Abstract: Intercellular communication mediates astrocyte and microglia regulation of neuronal homeostasis and synaptic dynamics. The fact that in early asymptomatic Alzheimer’s disease (AD) dysregulation of astrocyte and microglia metabolism accompanies a dysregulation of synaptic function suggests an important role for intercellular communication in the onset and progression of neurodegenerative diseases like AD (Johnson et al., 2020). We are interested in studying the effects of apolipoprotein E ε4 (APOE4), a genetic risk factor for AD, on extracellular vesicles (EVs), an avenue of communication that may be implicated in regulating synaptic function. We are developing a repertoire of human induced pluripotent stem cells (iPSCs) from healthy 80+ year-old (Wellderly) donors with either homozygous APOE3 or APOE4 genotypes and are generating induced astrocytes (iAs) and microglia (iMGLs) to study cell type specific EV cargos and bioactivity. I generated iAs from APOE3 iPSCs by forced expression of transcription factors SOX9 and NFIB (Canals et al., 2018). iAs express an array of astrocytic markers by real-time quantitative polymerase chain reaction (RT-qPCR), including

S100B, GLAST, GLT-1, GFAP, HEPACAM, and AQP4, as well as S100B and GFAP by immunocytochemistry. iMGLs were generated by differentiating both APOE3 and APOE4 iPSCs first into hematopoietic progenitor cells (HPCs) and then into microglia using astrocytic and neuronal factors that mimic the environment of the developing brain (McQuade et al., 2018). At days 28 and 34 of differentiation from HPCs, iMGLs of both genotypes express macrophage lineage markers IBA1 and PU.1, microglia marker TREM2, and homeostatic microglia marker P2RY12 by RT-qPCR. By immunocytochemistry, 96% and 98% of iMGLs express IBA1, and 96% and 97% of iMGLs express TREM2 from APOE3 and APOE4 genotypes, respectively. Functional characterization revealed that more than 95% of iMGLs of both genotypes have phagocytic activity after a 16hr incubation with pre-opsonized fluorescent latex beads. Furthermore, 100% of iMGLs of both genotypes are capable of phagocytosing fluorescently labeled β-amyloid fibrils after an 18hr incubation. This repertoire of iPSC-derived astrocytes and microglia will serve as a platform on which to investigate how APOE genotype alters cell-type specific EV cargo and bioactivity.

Title: Alzheimer’S disease risk factors are further dysregulated in patients with seizure history.

Authors: *A. J. BARBOUR, D. ISAACS, X. LI, D. J. IRWIN, F. E. JENSEN, D. M. TALOS; Univ. of Pennsylvania Perelman Sch. of Med., Philadelphia, PA

Abstract: Alzheimer’s Disease (AD) is highly comorbid with epilepsy with more than 20% of AD patients presenting clinically identifiable seizures, which we have recently linked to an exacerbation of AD neuropathology (Gourmaud et al. 2021). Significant genetic risk factors for AD include apolipoprotein E4 (APOE4), bridging integrator 1 (BIN1), and TREM2 (triggering receptor expressed on myeloid cells 2). Interestingly, APOE4 and BIN1 have been clinically linked to epilepsy independent of AD and TREM2 has been shown to be reduced in mouse models of epilepsy. Thus, we hypothesized and that APOE4, BIN1, and TREM2 are further

dysregulated in AD patients with seizure history. To test our hypothesis, we examined temporal lobe from control and AD cases with (AD+Sz) and without (AD-Sz) known seizure history for APOE4, BIN1, and TREM2 using Luminex immunoassays and Western blot analysis. Tissue samples were obtained from the Center for Neurodegenerative Disease Research (CNDR) at the University of Pennsylvania (Philadelphia, PA) with local IRB approval. Data from all AD were compared to controls and AD+Sz were compared to AD-Sz by unpaired t-tests. Luminex multiplex assay of temporal lobe tissue revealed a significant increase in APOE4 concentrations in AD patients compared to controls (n=5-20/group, $p<0.01$) with a trend towards an increase in AD+Sz compared to AD-Sz (n=10/group, $p=0.06$). Further, TREM2 concentrations were significantly reduced in AD cases compared to control (n=5-20, $p<0.05$), and in AD+Sz compared to AD-Sz (n=10, $p<0.05$). Western blot analysis of temporal lobe revealed no difference in BIN1 expression between AD and controls, but a significant decrease of BIN1 levels in AD+Sz versus AD-Sz (n=8-9, $p<0.01$). Overall, our data demonstrate that AD risk factors are further dysregulated in patients with seizure history and may underlie seizure exacerbation of AD neuropathology.

Title: Machine learning classification and quantification of Alzheimer’s disease pathology within human hippocampal subregions

Authors: L. KOROBKOVA[1], K. T. JONES[2], R. P. CABEEN[1], C. A. MILLER[2], *M. S. BIENKOWSKI[1];
[1]USC Stevens Neuroimaging and Informatics Inst., Keck Sch. of Med. of USC, Los Angeles, CA; [2]Dept. of Pathology, USC, Los Angeles, CA

Abstract: Alzheimer’s disease (AD) has recently become more appreciated as a neurodegenerative disease with multiple subtypes and pathological heterogeneity. AD pathology (amyloid plaques and tau neurofibrillary tangles (NFTs)) is differentially distributed within anatomical structures over progressive disease stages, but quantification of pathology across multiple brain subregions within whole post-mortem tissue sections is difficult and is most often

qualitatively scored by a trained neuropathologist. To rapidly quantify the distribution of AD pathology, we developed a machine learning and image registration approach to classify various pathological features from histologically-stained hippocampal/temporal lobe tissue sections obtained from the USC ADRC Neuropathology Core. For each patient, two adjacent coronal sections stained for amyloid (4G8 immunostaining) and tau (Gallyas histochemical stain) were imaged using a whole slide scanning microscope. Tissue sections were manually annotated to create subregion segmentation masks used to delineate anatomical subregion boundaries. To differentially characterize anatomical features of AD pathology, we classified and segmented different types of histology labeling: amyloid (4G8 intracellular vs. extracellular dense vs. extracellular diffuse), tau (intracellular Gallyas), and neuritic plaques (extracellular colocalization of 4G8 and Gallyas labeling). Our cross-sectional study reveals specific alterations of neuritic plaques and NFTs with respect to APOE gene variants and AD progression. As expected, the number of dense neuritic plaques and tau NFTs increased with AD progression. However, we also found anatomical subregion-specific effects of APOE genotype on tau and amyloid pathology. Additionally, we found that diffuse amyloid labeling increased with AD progression significantly greater than dense neuritic plaque formation and was mostly concentrated in entorhinal cortex, parasubiculum, and presubiculum regions. Overall, the precise anatomical localization of pathological aggregates is consistent with a model of a disease progression along specific axonal pathways.

Title: Cgrp signaling contributes to mild traumatic injury-induced post-traumatic headache and cognitive deficit

Authors: *K. CZERPANIAK[1], Y.-Q. CAO[2];
[2]Anesthesiol., [1]Washington Univ. in St. Louis, St. Louis, MO

Abstract: Post-traumatic headache (PTH) and memory loss are some of the most common symptoms following mild traumatic brain injury (mTBI). Despite the prevalence of mTBI in humans, the underlying mechanisms remain unclear and treatment options are unavailable.

Previous research suggests a role for calcitonin gene-related peptide (CGRP) signaling in PTH, which raises the possibility of treating mTBI with therapeutics targeting CGRP. Other studies reported that early and repeated anti-CGRP monoclonal antibody treatment blocks behaviors related to PTH, but whether CGRP signaling contributes to mTBI-induced cognitive impairment has not been tested. In this current study, we used both genetic and pharmacological approaches to test whether CGRP signaling plays a role in PTH-related behaviors and cognitive deficits in a mouse model of mTBI. First, mice were subjected to an mTBI procedure that resulted from a closed head weight-drop. Then, PTH was evaluated by measuring facial mechanical thresholds using von Frey filaments. Recognition and spatial memory were evaluated with the novel object recognition (NOR) test and object location test (OLT). Both wild-type male and female mice subjected to mTBI showed profound reduction of facial mechanical threshold as well as deficit in NOR and OLT assays. When compared to their wild-type controls, neither male nor female CGRP knockout mice exhibited increased sensitivity to von Frey filaments after mTBI, supporting that endogenous CGRP signaling mediates mTBI-induced PTH. Similar to these results, CD-1 mice that received anti-CGRP monoclonal antibody treatment immediately after injury and then every six days until day 18 post-mTBI did not develop PTH-related behaviors when compared to the mTBI group that received control IgG treatment. However, 3-14 days after the cessation of anti-CGRP antibody treatment, 60% of these mice showed a significant reduction in facial mechanical threshold, suggesting that long-term antibody treatment may induce compensatory neurochemical changes that affect basal nociception. Interestingly, results from the NOR test reveal that both male and female CGRP knockout mice did not display any deficit after mTBI, but did show poor performance in the OLT. Similarly, the anti-CGRP monoclonal antibody completely prevented mTBI-induced NOR deficit, but these mice still exhibited a spatial memory impairment in the OLT. In conclusion, these results suggest that CGRP signaling plays a role not only in mTBI-induced PTH, but in non-spatial recognition memory decline as well.

Title: Complement mediated cognitive decline in chronic phases post traumatic brain injury

Authors: *K. MALLAH[1], C. COUCH[2], M. ALSHAREEF[3], D. BORUCKI[4], X. YANG[1], A. ALAWIEH[5], S. TOMLINSON[1];
[1]Microbiology and Immunol., [2]Hlth. Sci. and Res., [3]Neurolog. Surgery, [4]Neurosciences, Med. Univ. of South Carolina, Charleston, SC; [5]Neurosurg., Emory Univ. Sch. of Med., Atlanta, GA

Abstract: Traumatic Brain Injury (TBI) can result in dementia and cognitive decline in chronic phases after injury. Studies have shown a significant increase in the hazard ratio of developing dementia after sustaining a brain injury, a ratio which lasts for years after initial insult. The underlying pathological mechanisms that link TBI to cognitive decline are not well understood. We have previously shown that the complement system is implicated in mediating secondary injury and cognitive deficits up to 1 month after murine TBI. In this work, we studied the role of complement in mediating ongoing cognitive decline measured at 3 and 6 months after murine controlled cortical impact. We employed a battery of behavioral tasks to assess cognitive performance after TBI, and results were correlated with histopathological analysis focusing on complement deposition and glial response (microglia and astrocytes). We also assessed the therapeutic potential of complement inhibition for reducing a chronic neuroinflammatory response and reversing cognitive decline. Cognitive decline after TBI in untreated animals was coupled with complement deposition in the perilesional area, as well as with expanded microgliosis and astrogliosis to the contralateral hemisphere of brains by 3 months after TBI. However, cognitive decline, complement deposition and gliosis, measured at 3 and 6 months after TBI, was reversed by treatment with the complement inhibitor CR2-Crry, even when treatment was initiated 2 months after insult. Lesion volume was also reduced in CR2-Crry vs. vehicle treated mice at 6 months post-TBI, although not at 3 months post-TBI. Using high resolution fluorescence microscopy, we linked cognitive decline to a reduction in synaptic density which resulted from microglial phagocytosis of complement (C3) opsonized synapses, and which was reversed with complement inhibition. For CR2-Crry treatment starting at 2 months after injury, a weekly dose of CR2-Crry was required for improvement, and a short transient treatment paradigm was not protective at 6 months after injury. Taken altogether, the data show persistent complement deposition in the brain at chronic timepoints after initial insult, and which is correlated with ongoing cognitive decline and a persistent neuroinflammatory response, all of which can be reversed by complement inhibition.

Title: The role of spreading depolarizations in the acute behavioral deficits associated with mild traumatic brain injury in mice

Authors: *N. J. PINKOWSKI, M. MARTINEZ, C. J. MEHOS, R. A. MORTON;
Neurosciences, Univ. of New Mexico, Hlth. Sci. Ctr., Albuquerque, NM

Abstract: It is estimated that 42 million people experience a mild traumatic brain injury (mTBI) worldwide every year. mTBIs are often diagnosed by the acute symptoms including nausea, dizziness, headaches, and disorientation. The underlying cellular and physiological mechanisms of the acute symptoms are currently unknown. It has long been hypothesized and recently confirmed that spreading depolarizations (SDs) occur in mTBIs. Spreading depolarizations are massive waves of complete depolarization and the loss of chemical gradients that travel slowly through grey matter resulting in the suppression of cortical activity for multiple minutes. We hypothesize that SDs are a key underlying mechanism of the acute behavioral deficits associated with an mTBI. We will utilize a closed skull impact model in mice that reproducibly initiates an SD. We assess acute behavior in an open field arena with motion tracking software and a series of behavioral tasks that are collectively scored as the neurological severity score (NSS). To investigate the role SDs have in the acute behavioral deficits, we use KCl and optogenetic approaches to initiate an SD in the absence of an impact. We found that mTBIs are associated with a significant increase ($p= 0.0042$) in the NSS relative to sham treated animals ($n=8$). Interestingly, in a subset of mTBI animals there was no SDs initiated by the impact ($n=2$). These animals did not display deficits in the NSS relative to sham treated animals. SDs alone (initiated via KCl or optogenetics) were associated with similar deficits in the NSS as the mTBI animals but were significantly different from their respective saline or sham controls. Current studies are using pharmacological approaches (memantine) to block the SD in the mTBI animals and investigating the acute behavior. Collectively, these studies suggest that SDs play a key mechanistic role in the acute behavioral deficits associated with mTBIs. Understanding the cellular and physiological mechanisms underlying the acute behavioral deficits associated with mTBIs will identify particular targets for intervention and promote brain recovery and repair.

Title: Chemically-functionalized single-walled carbon nanotubes increase the expression of glial fibrillary acidic protein in the mouse primary astrocytes exposed to severe in vitro traumatic brain injury

Authors: *K. PILIPOVIć[1], I. JURIčKI[3], T. MLADENIć[2], A. HAREJ HRKAć[1], N. GRŽETA[1], V. PARPURA[4], G. ŽUPAN[1];

Abstract: Astrocytes are central nervous system (CNS) cells with an important role in neuronal regeneration following brain injury. This study aimed to investigate the effects of single-walled carbon nanotubes (SWCNTs), chemically functionalized with poly-m-aminobenzene sulfonic acids (PABS), on the oxidative protein damage and the expression of the glial fibrillary acidic protein (GFAP) and the inducible nitric oxide synthase (iNOS) in astrocytes exposed to an *in vitro* model of severe traumatic brain injury (TBI). Primary mouse astrocytes were grown on 6-well plates with deformable membranes and subjected to stretch injury, mimicking severe TBI. PABS-SWCNTs were applied to severely injured cells at 1 h post-injury. Cells were collected at 24 h following stretch and the lysates were prepared for the analyses. The dot blot method was used to detect the levels of oxidatively damaged protein. Western blot analyses were used to determine the expressions of GFAP and iNOS. Non-treated cells were used as the control. Dot blot assay demonstrated that the stretch injury and the treatment with PABS-SWCNTs did not cause a significant change in the levels of oxidatively damaged proteins. We observed no change in the expression of the inflammatory marker iNOS. Conversely, the application of PABS-SWCNTs significantly elevated the expression level of GFAP compared to the results obtained in the samples of both control cells and the non-treated, severely stretched astrocytes. Our preliminary results suggest that the application of the investigated nanomaterial, applied as a colloidal solute, to the primary astrocytes exposed to severe *in vitro* TBI causes an increase in the GFAP levels. This is a finding with possible relevance related to the role of GFAP in the trafficking of glutamate transporters which needs to be further explored. This research was fully supported by the Croatian Science Foundation grant UIP-2017-05-9517 to KP.

Title: Role of mitochondrial fission in progressive neurodegeneration and memory deficit after traumatic brain injury

Authors: *P. S. SRIDHARAN[1], Y. KOH[2], E. MILLER[1], E. VÁZQUEZ-ROSA[4], M.-K. SHIN[4], K. Z. FRANKE[4], X. QI[3], A. A. PIEPER[4];
[1]Neurosci., [2]Pathology, [3]Physiol. and Biophysics, Case Western Reserve Univ., Cleveland, OH; [4]Psychiatry, Univ. Hosp., Cleveland, OH

Abstract: In the past decade, there has been an increasing incidence of traumatic brain injury (TBI), which is linked to a 2-4-fold increase in risk for developing dementia later in life. We are modeling this in our laboratory using an injury system that induces components of global concussion, acceleration/deceleration, and blast wave exposure. TBI in people presents as a progressive and chronic neurodegenerative injury characterized by neuropsychiatric impairment, including cognitive deficits and depression. Currently, there are no available treatments that slow the progression of neurodegeneration and associated symptoms after TBI. Mitochondrial fission-fusion dynamics have been identified as an important component of pathogenesis in Alzheimer's disease, which TBI patients are at an especially elevated risk of developing. In the present study, we investigate the potential efficacy of a pharmacologic inhibitor of mitochondrial fission, called P110, in mitigating the progression of symptoms after TBI.
Male and female C57/bl6 mice were subjected to either TBI or sham injury at 2 months of age, and subsequently treated with either P110, a specific peptide inhibitor of mitochondrial fission, or vehicle control by daily intraperitoneal injection. Following treatment, mice were tested for neurocognitive deficits using a battery of behavioral tests, including novel object recognition (NOR), open field test, elevated plus maze, and tail suspension test. Brain tissues were then processed for western blot analysis and staining.
Drp1, the primary mediator of mitochondrial fission, is the target of the P110 peptide inhibitor. Mice subjected to TBI showed an elevation in Drp1 expression 24 hours post-injury, with levels returning to normal after 2 weeks. This suggests a transient elevation in mitochondrial fission. Two weeks after TBI, mice showed a memory deficit in NOR, and P110 treatment was protective. Treatment was then ceased, and the same mice, when tested in NOR 6- and 9- months post-injury, showed sustained memory protection. When P110 treatment initiation was delayed until 8 months after injury, it did not restore normal cognition. All behavioral experiments were blinded for analysis and repeated in at least 2 separate cohorts. No sex differences were observed.
Our results indicate that early inhibition of mitochondrial fission after TBI is protective against neurodegeneration and memory loss, and that this brief treatment produces a lasting protective effect from chronic memory deficits as well. Future directions will focus on investigation of the

mechanisms by which imbalance of mitochondrial fission and fusion after TBI mediates neurodegeneration.

Title: Deficits in catecholamine signaling of the prefrontal cortex following repetitive mild traumatic brain injury

Authors: L. HORVAT[1], A. FOSCHINI[2], D. P. FOX[2], J. P. GRINIAS[1], B. D. WATERHOUSE[2], ***D. M. DEVILBISS**[2];
[1]Chemistry/Biochemistry & Res., Rowan Univ., Glassboro, NJ; [2]Cell Biol. and Neurosci., Rowan Univ. Sch. of Osteo. Med., Stratford, NJ

Abstract: Recurring mild traumatic brain injuries (TBI) are a large class of the 1.7-3.8 million reported injuries each year. Regardless of severity, TBI is a complex pathophysiological process resulting in behavioral and cognitive deficits that include impairments in arousal, attention, decision-making, and other executive functions. Repetitive mild injuries can produce cumulative and long-term cognitive deficits and increase the susceptibility for further injury after each mild TBI. Catecholamine systems, including the locus coeruleus (LC)-norepinephrine (NE) and the ventral tegmental-dopamine (DA) pathway, are critical regulators of these higher executive processes affected by TBI. Furthermore, impaired NE and DA signaling within the prefrontal cortex (PFC) circuitry is implicated in the pathogenesis of the cognitive and neuropsychiatric symptoms following *single* moderate to severe TBI. However, the effects of mild TBI and *repetitive* TBI on catecholamine system function are poorly understood. Methylphenidate (MPH) and other psychostimulants that elevate NE and DA within the PFC have been used as a putative treatment strategy to recover normal cognitive function after injury. However, limited and inconsistent findings exist on the efficacy of MPH for treating the cognitive impairments following mild TBI due to small sample sizes, poor patient stratification, and limited dose ranges. The objectives of the current study were to determine the extent of NE and DA dysfunction and response to therapeutic doses of MPH in rats following a repetitive mild closed-skull TBI. Baseline NE efflux within the PFC and responsiveness to MPH challenge were

significantly impaired after repetitive mild TBI. However, simultaneous quantification of DA within the PFC did not show comparable deficits in baseline levels or responsiveness to MPH challenge. Behavioral measures of arousal demonstrated reduced wakefulness only after repeated mild TBI. Finally, important sex differences were found, with males exhibiting substantially lower baseline NE levels and responses to MPH challenges compared to females after repeated mild TBI. These findings provide critical insight into the sensitivity of catecholamine systems to repeated mild TBI and support for the role of noradrenergic fiber injury in the cognitive deficits resulting from repeated injury.

Title: Innovative treatment for TBI-microbleed induced chronic inflammation in neural substrates for motor, cognitive and anxiety disorders

Authors: *P. BOSE[1,2,3], J. HOU[1,2], S. TSUDA[2,1], D. PLANT[1], B. RENGERT[1], R. RUPARELIYA[1], K. ZHANG[1], H. SHROCK[1], G. M. DOOLEY[1], S. LULU[1], A. CHAMBERS[1], C. BLUM[1], R. J. BERGERON[5], F. J. THOMPSON[1,4];

Abstract: Acceleration/deceleration closed head traumatic brain injury (CH-TBI) induces damage of micro-vessels which results in endothelial shear injury, blood brain barrier (BBB) dysfunction, and micro-bleeding. Microbleed-derived iron can provide enduring oxidative stress and inflammation, further breakdown of the BBB tight junctions, and cell death through multiple inflammatory pathways. The current studies tested the influence of CH-TBI (n=20) and the therapeutic impact of an iron chelator (n=19) on hallmark chronic disabilities in a rodent model. Mild/moderate CH-TBI was produced using our previously reported protocol (450 g/1.25m). An iron chelator, NaHBED (n=10) treatment was initiated at PO Day-0 and continued for 2 weeks (50 mg/kg/day, SQ). The control animals received an equal volume of saline (SQ; n=7). Tests for

motor, anxiety, and cognitive functions were conducted at multiple time points during 9 months of post-injury study. Clinically relevant MRI (SWI/QSM, T2* map, and DTI), immunohistochemistry (IHC) and histology were performed to chart the time course for iron deposition and inflammation. Our data to date revealed long-term enduring disabilities in motor/vestibulomotor, anxiety, and cognitive behaviors following CH-TBI, and significant reductions in these disabilities in the NaHBED treated animals. IHC and histology studies of TBI tissues showed patterns of a) iron deposition and disruption of BBB, b) increased expression of markers for inflammation (activation of NF-kB via TLR4 pathway, proinflammatory cytokines, proIL-1β, TNFα, etc.), c) pyroptosis of neuronal cells in specific regions essential for the studied motor, cognitive, and anxiety behaviors, and d) loss of regulatory noradrenergic and trophic supports in these regions. Tissue from the NaHBED-treated animals exhibited robust normalization of each of these markers. Collectively, our studies demonstrate that: 1) TBI-induced microbleeds contribute to the development and persistence of multiple chronic disabilities, 2) iron deposited via TBI induces BBB disruption, and accelerates neuroinflammation and neuronal cell death, and 3) this collective trauma portfolio of chronic disability and inflammation can be attenuated by an iron chelator therapy. Taken together, iron chelator treatment offers the potential for a mechanism-based therapy that addresses a significant contributor of long-term TBI disabilities, contributes to trophic support for neuronal and vascular healing, and enhances neuroplasticity for adaptive compensation.

Title: Neuroprotective Effects of Tamoxifen in Xenopus laevis Model of Focal Impact Injury

Authors: *S. SPRUIELL ELDRIDGE[1,1], A. K. SATER[2,1];
[1]Biol. and Biochem., [2]Univ. of Houston, Houston, TX

Abstract: Traumatic brain injury (TBI) is the leading cause of disability worldwide and has produced lasting effects on the lives of over 5.3 million people in the U.S. alone. While the initial injury causes mechanical damage, the secondary injury produced by the inflammation cascade around the site of a lesion can be equally harmful, producing lasting motor, sensory, behavioral, and cognitive deficits. The complex role of astrocytes in mounting and modulating the inflammatory cascade after an injury has been extensively studied, as have the

neuroprotective effects of estrogen compounds in mammalian model organisms. Although astroglial cells are essential in limiting neuronal damage, regulating inflammation, and repairing tissues following a TBI, estrogen compounds that reduce the hyperactivation of astrocytes have been shown to reduce secondary injury without sacrificing the necessary post-injury activity of astrocytes.
Objective: To evaluate the effect of tamoxifen treatment on neuronal survival and astrocyte activation near the wound site, edema accumulation levels, and behavioral output after an induced focal impact brain injury in *Xenopus laevis*.
Design: In this study, we induced a focal impact (FI) injury to the optic tectum in the midbrain of stage 55 *Xenopus laevis* tadpoles. Animals were randomly divided into sham injured (n=18, FI injured + vehicle treated (n=18), FI injured + tamoxifen treated (n=18), and sham + tamoxifen (n=18), in accordance with the performed power analysis. Behavioral assays were performed for consecutive days following treatment and/or injury. At time points of 3, 24-, 48-, 72-, and 168-hours post-injury, brains were collected, and immunofluorescence staining, edema quantification, and qRT-PCR were performed.
Results: Our results demonstrate that administering tamoxifen immediately after a focal impact injury produces sustained upregulation of critical neuroprotective genes: *timp 1, bdnf, manf, and steap4*. It also appears to modulate the injury-driven increase in brain water content and reduce the elevated expression of *aquaporin-4,* suggesting a possible role in regulating edema. Tamoxifen also attenuated behavioral deficits of injured animals in visual preference, open field, and spot avoidance assays. These results suggest that tamoxifen is neuroprotective: it improves behavioral recovery, modulates neuronal death and astrocyte activation, and decreases edema accumulation. These findings, consistent with published literature in mammalian models of spinal cord injury, suggest that tamoxifen could represent a potential therapeutic intervention in regulating inflammation following a focal impact injury.

Title: Therapeutic impact of noradrenergic upregulation following closed head traumatic brain injury (CH-TBI)

Authors: *F. J. THOMPSON[1,2], J. HOU[1,3], S. TSUDA[1,3], D. PLANT[1], S. NADEAU[1,4], P. BOSE[1,3,4];
[1]Brain Rehabil. Res. Ctr., Gainesville, FL; [2]Dept. of Neurosci., [3]Dept. of Anesthesiol., [4]Dept. of Neurol., Col. of Medicine, Univ. of Florida, Gainesville, FL

Abstract: TBI induces significant and enduring cognitive, anxiety, and motor disabilities. Our previous and current studies demonstrate significant injury of the locus coeruleus nucleus, projection fibers, and systematic loss of noradrenergic (NA) innervation to cognitive, anxiety, and motor neural substrates following acceleration/deceleration CH-TBI. Behavioral/physiological function studies have also revealed that these losses of NA innervations correlated with alterations in cognitive, anxiety, and motor functions. NA projections are critical for regulation of the excitability of spinal- and vestibulo-spinal reflexes, motor cortex gait coordination, blood brain barrier (BBB), inflammatory signaling, and BDNF production. Our preliminary studies have also revealed chronic inflammation in the essential neural substrates for cognitive, anxiety, and motor functions. Accordingly, use of agents that target and upregulate NA expression, correlated with measures of TBI-induced disabilities, could provide additional insights into the role of NA injury in TBI pathobiology. Thus, the objective of this study was to test the therapeutic impact of NA agonists on hallmark TBI disabilities in a rodent model of CH-TBI. We hypothesized that a desirable strategy for NA therapy following TBI would be intrinsic upregulation of NA expression to produce a more integrated and regulated NA function in downstream innervated substrates. We compared behavioral/physiological function measures in TBI and TBI/NA agonists treated animals to evaluate the potential therapeutic impact of NA upregulation on TBI disabilities. We used Methylphenidate, which blocks the norepinephrine (NE) transporter, prolonging the re-uptake of NE, and upregulates the effectiveness of intrinsically distributed NE. In addition, we tested therapy with phenylephrine and ephedrine (direct adrenergic agonists) to evaluate the more selective contribution of adrenergic alpha-1 vs alpha & beta receptor activation, respectively, for treatment efficacy. These studies were carried out in CH-TBI and CH-TBI/treated animals. Mild/moderate TBIs were produced by a 450-gram weight drop (1.25 meter) impact on the helmeted head. Methylphenidate (0.5 mg/kg; oral), phenylephrine (0.6 mg/kg; SQ), and ephedrine (3.8 mg/kg; SQ) treatments were initiated one week following injury. Although differential, collectively, significant decreases were observed in the TBI-induced cognitive, anxiety, and motor disabilities in the treated animals compared to saline-treated TBI animals. However, the therapeutic impact of methylphenidate was most robust and consistent across all three behavioral measures

Title: Local and global blood flow and arrival time (ASL) associations with pain intensity in patients with chronic back pain

Authors: *L. HUANG[1], A. VIGOTSKY[2], Y. CHEN[1], T. PARRISH[1], T. J. SCHNITZER[1], A. V. APKARIAN[1];
[1]Northwestern Univ., Chicago, IL; [2]Northwestern Univ., Evanston, IL

Abstract: Arterial spin labeling (ASL) is a noninvasive magnetic resonance imaging (MRI) technique that uses magnetically labels arterial blood to obtain estimates of cerebral blood flow (CBF) and bolus arrival time (BAT). Yet, to date, its application to the study of the patients with chronic back pain (CBP) has been relatively limited. A total of 86 CBPs (male = 46; age = 56 ± 13 years old; BMI = 30 ± 6; pain (numeric rating scale, NRS) = 69/100 ± 15/100; pain duration = 45 - 2661, median = 417 weeks) were included in this study and scanned on a clinical 3 Tesla Siemens Magnetom Prisma scanner. CBF and BAT images were registered to MNI space and mean values of both CBF and BAT images within gray matter (GM) were calculated, referred as $mCBF_{GM}$ and $mBAT_{GM}$. Multiple regression revealed that NRS, together with age, gender, BMI, and log(pain duration) accounted for 16.50% of variance of $mCBF_{GM}$ ($F(5, 76) = 3.08$, $p = 0.016$) and 21.98% of variance of $mBAT_{GM}$ ($F(5, 76) = 4.28$, $p = 0.002$), where NRS was significantly associated with $mCBF_{GM}$ ($p = 0.026$) and $mBAT_{GM}$ ($p = 0.015$), respectively. To identify brain regions in which NRS was associated with CBF or BAT, the participants were divided into discovery ($n = 50$) and validation ($n = 36$) groups matched on age, gender, BMI, and log(pain duration). One cluster for CBF (left temporal pole, $p < 0.001$ (discovery) and $p = 0.02$ (validation)) and 2 clusters for BAT (left temporal pole, $p < 0.001$ (discovery) and $p = 0.03$ (validation); right superior parietal lobule, $p = 0.002$ (discovery) and $p = 0.03$ (validation)) were revealed (discovery) and replicated (validation) after family-wise cluster error correction ($p < 0.01$) was applied. The finding that ASL signal was both globally and locally associated with pain intensity after adjusting for the effects of age, gender, BMI, and pain duration suggests it may provide additional information to increase our understanding of the neuropathology in CBP patients. However, the relationship between ASL signal and other, more established fMRI techniques, such as functional connectivity and BOLD variability, remain to be elucidated.

Title: Hippocampal volume, FKBP5 genetic vulnerability and childhood trauma compound risk for chronic multisite pain in the UK Biobank cohort

Authors: *L. J. AYOUB[1,2], J. J. LOBO[3], S. LINNSTAEDT[3], M. MOAYEDI[1];
[1]Fac. of Dent., Univ. of Toronto, Toronto, ON, Canada; [2]Krembil brain institute, Univ. Hlth. Network, Toronto, ON, Canada; [3]Univ. of North Carolina, Chapel Hill, NC

Abstract: Chronic musculoskeletal pain affects up to 47% of individuals around the world. Chronic multisite musculoskeletal pain (CMP) affects multiple body sites, and its severity is characterized by the number of body sites affected for more than three months. However, risk factors contributing to the development and severity of CMP remain unknown. Risk factors for chronic musculoskeletal pain include a smaller right hippocampus, a risk allele of the *FKBP5rs3800373* and early childhood trauma. However, whether the relationship of these factors compound the effect of CMP severity has not been investigated. Here, we test the relationship between these factors using a large cohort of individuals with chronic musculoskeletal pain from the UK Biobank. We tested three preregistered hypotheses: (1) *FKBP5rs3800373,* and (2) hippocampal volume, and (3) their interaction is associated with CMP. In secondary analyses, we assessed whether this interaction is moderated by early childhood trauma. We used linear regression modelling to test these hypotheses. We included 36,822 participants (52.4% women; 63.6 ± 7.5 years). First, we did not find statistically significant main effect associations between *FKBP5rs3800373* (β=-0.003, p=0.701) and CMP nor hippocampal volumes (left: β=-0.005, p=0.238; right: β=-0.007, p=0.130) and CMP. However, we did observe a statistically significant interaction between *FKBP5rs3800373* and right hippocampal volume (β=-0.020, p_{corr}=0.01), but not left hippocampal volume (β=-0.015, p_{corr}=0.12) on CMP. Specifically, individuals with two *FKBP5rs3800373* risk alleles had the strongest association between right hippocampal volume and CMP, such that smaller right hippocampus was statistically associated with increased CMP severity (β=-0.031, p=0.045). In a sub-cohort of individuals with available data on early childhood trauma (n=25,280), the interaction between childhood trauma severity (frequency of childhood trauma types) and right hippocampal volume on CMP was significant in individuals with 1 (β=-0.084, p=0.006) or 2 (β=-0.168, p=0.042) *FKBP5rs3800373* risk alleles. This suggest that in individuals with increased levels of childhood trauma and with *FKBP5rs3800373,* the smaller right hippocampus was associated with CMP severity. Overall, our findings show that the interaction between a

smaller right hippocampus and *FKBP5rs3800373* genetic risk is associated with CMP, and this association is further moderated by childhood trauma. Our results identify risk factors for CMP and indicate that further work studying causal relationships between these factors is warranted.

Title: Resting state fMRI hyperalignment reveals a generalizable fine scale structure of evoked cortical response to noxious stimuli

Authors: *B. PETRE[1], M. CEKO[2], N. P. FRIEDMAN[3], M. C. KELLER[3], M. A. LINDQUIST[4], T. D. WAGER[1];
[1]Psychological and Brain Sci., Dartmouth Col., Hanover, NH; [2]ICS, Boulder, CO; [3]Dept. of Psychology & Neurosci., Univ. of Colorado Boulder, Boulder, CO; [4]Biostatistics, Johns Hopkins Univ., Baltimore, MD

Abstract: Cortical feature representations include meso-scale information that is heterogeneous across individuals. This has limited their characterization beyond individual brain structures where simple functions like columnar stimulus mappings can be studied in individual subjects. Connectivity hyperalignment provides an indirect but scalable and generalizable alternative: matching functional connectivity profiles across subjects to build a common model of brain function that aligns fine scale idiosyncratic task evoked responses. We used resting state fMRI to hyperalign responses to noxious heat and pressure stimulation of the fingers (N=104 subjects), stimuli that are likely distinguished at the mesoscale. We found hyperalignment reduced interindividual differences in evoked responses and improved local nociceptive modality discrimination throughout the cortex.
Hyperalignment revealed widely distributed fine-grained, striated patterns of evoked responses. This coincided with significant improvements in searchlight-based between-subject correlations (BSCs) of evoked responses for 88% of the cortex and decreases in BSCs for 0.06% of cortex relative to non-hyperaligned data (permutation test, FDR $p < 0.05$). The largest improvements were in the insula and premotor areas, including putative primary nociceptive areas like SII. We performed a searchlight sweep of each hemisphere with linear support vector machines to test

out-of-subject discrimination of noxious modality. Without hyperalignment, 31.9% of the cortex discriminated modality (>55% accuracy, FDR $p<0.05$, max 71%, contralateral PFm) vs. 73.2% of the cortex with hyperalignment (max 75%, contralateral SII). No searchlight showed significant decrease in accuracy after hyperalignment. Improvements were predominantly outside of typical thermosensory areas, especially in dorsolateral prefrontal cortex and posterior parietal cortex (peak improvement: area 8Av, proportion z-test: $z=6.3$, classification improvement = 0.18, $p < 1e-5$), but significant improvements were also present in somatomotor cortices (best contralateral improvement: BA1, $z=5.6$, 0.15 accuracy improvement, $p = 0.0002$). We show connectivity hyperalignment effectively captures a common model of cortical nociceptive representation. This model reveals that different modalities of noxious stimuli have divergent effects on cortical activity that are fine scaled but widespread, distributed outside of classic thermosensory areas, and translate across individuals. This demonstrates the viability of hyperalignment for characterizing a generalizable fine structure of cortical nociceptive processing.

Title: Deep-phenotyping of real and imagined pain across eight-body sites in an n-of-1 design

Authors: *M. SUN, C. I. BANGO, K. BO, T. D. WAGER;
Psychological and Brain Sci., Dartmouth Col., HANOVER, NH

Abstract: The neural representation of pain reflects some combination of the processing of incoming sensory and contextual information that may be organized into separable components of neural activity pertaining to location, stimulation, and aversiveness. We had a single-subject (the first author, a 32 year-old Asian American male) undergo repetitive functional magnetic resonance imaging (fMRI) scans to deeply phenotype the neural activity of each pain component. To develop these components, eight body-sites (left and right cheek, left and right forearm, left and right calf, chest, and abdomen) were thermally stimulated with a Peltier thermode at painful heat and non-painful warm intensities repetitively for 12-13 seconds for 34 runs over seven sessions (days). Concomitantly, the subject was periodically asked to imagine each body site

being intensely burned by the attached thermode while no heat was applied for the same period of time. We hypothesized that there would be overlapping and distinct neural representations for each component (sensation, aversion, and location) of pain. To address the hypotheses, the contrasts generated at the second-level included (1) stimulated painful heat and non-painful warmth vs. all other conditions for the stimulation component, (2) stimulated painful heat and imagined painful heat vs. all other condition for the aversiveness component, and (3) body-site specific runs vs. all other runs for the location component. Significant activations were found for each component after family-wise error-correction at the $p < .05$ level. Heat pain specific activity was primarily centered on activity in the temporoparietal junction (TPJ), while warm stimulation activity featured a less intense and more distributed pattern. Imagination specific activity featured activation distributed across the brain with a cluster of activation centered within primary visual cortex (V1). Body-site specific activations consistently featured activity in three regions: TPJ, V1, and orbitofrontal cortex. Our results suggest that deep-phenotyping of pain components within an individual is possible and that common information areas such as body-site representations can be activated from a top-down (i.e., imagination) and bottom-up (i.e., thermal stimulation) pathway. This work increases the specificity of existing pain and cognitive signatures to differentiate activations across eight-body sites at the individual level, which has promising implications for the role of fMRI in precision medicine.

Title: Prediction of cognitive behavioral therapy outcomes using baseline posterior cingulate cortical responses to pain catastrophizing in fibromyalgia

Authors: *J. LEE[1], M. P. BERRY[2], L. ISARO[3], A. LAZARIDOU[3], M. PASCHALI[3], A. GRAHL[1], M. L. LOGGIA[1], D.-M. ELLINGSEN[1], A. D. WASAN[4], R. R. EDWARDS[3], V. NAPADOW[1];
[1]Radiology, Athinoula. A. Martinos Ctr. For Biomed. Imaging, Charlestown, MA; [2]Radiology,

Athinoula A. Martinos Ctr. for Biomed. Imaging, Charlestown, MA; [3]Anesthesiol., Perioperative and Pain Medicine, Brigham and Women's Hosp., Boston, MA; [4]Anesthesiol. and Perioperative Med., Ctr. for Innovation in Pain Care, Univ. of Pittsburgh, Pittsburgh, PA

Abstract: We found that the posterior cingulate cortex (PCC) encodes pain catastrophizing in fibromyalgia (FM) patients (Lee et al., 2018). Catastrophizing-linked PCC activity may be an important phenotypic factor that shapes long-term fibromyalgia outcomes; it is not clear, however, if PCC activation can also predict individual differences in clinical outcomes for psychological therapies targeting pain catastrophizing.

We enrolled 118 FM patients (all female, age=41.2±12.3), who were randomized into two treatment groups (cognitive behavioral therapy, CBT; and pain education, EDU). Patient-reported outcomes such as Pain Catastrophizing Scale (PCS) and Brief Pain Inventory (BPI) were collected before and after 8 weeks of therapy (PRE and POST, respectively). Neuroimaging (fMRI) data were collected prior to treatment during a cognitive task wherein patients engaged with catastrophizing (CAT) or neutral (NEU) statements, and instructed to reflect on the statements' applicability to their daily experience of FM pain. Univariate covariance analysis was performed to link baseline pain catastrophizing-specific 'CAT-NEU' brain activities to treatment effects (POST-PRE for PCS and BPI).

Of 118 FM patients, 82 patients finished PRE-therapy fMRI scans, reporting significant post-therapy improvements for PCS (change=-7.5±9.4, $P<0.00001$) and BPI (severity, change=-0.4±1.6, $P=0.029$) scores. The CBT group showed greater decrease in PCS compared to EDU groups, while the changes in both groups were significant (CBT=-8.9±9.3, $P<0.00001$; EDU=-4.6±9.1, $P=0.012$; $P_{CBTvsEDU}=0.049$). CBT group showed significant decrease in BPI (CBT=-0.6±1.5, $P=0.005$; EDU=0.0±1.7, $P=0.914$; $P_{CBTvsEDU}=0.12$) with no significant group difference. Greater pain catastrophizing-specific brain responses at baseline were correlated with less reduction in PCS scores in vPCC ($r=0.40$, $Z>3.1$; also significant for CBT group alone, $r=0.39$) and with less reduction in BPI severity in dPCC ($r=0.31$, $Z>2.3$).

We replicated previous findings linking vPCC activation with patient-reported catastrophizing and dPCC activation with fibromyalgia pain severity. We extend these findings by evaluating the predictive capacity of baseline PCC activation for FM treatment outcomes; greater baseline PCC activation during pain catastrophizing prompts was predictive of reduced benefit. This implies that baseline brain activity to pain catastrophizing may serve as an important predictive biomarker offers neural mechanisms how pain influences cognitive and emotional processes, and guide recommendations for better individualized treatment optimization.

Abstract: Chronic post-surgical pain (CPSP) is defined as pain that develops or intensifies after surgery and persists more than 3 months excluding other causes of the pain (IASP definition). While most individuals recover from post-surgical pain within 6 to 12 weeks, an estimated 20 to 50 percent will experience persistent pain for months or years after the surgery. In addition to increasing the burden on patients and the health system, the need to manage intractable pain increases the risk for opioid-related adverse outcomes. There is an urgent need to identify factors (biomarkers) that can help predict who will undergo a transition from acute to chronic pain after surgery. Such biomarkers could inform the development of preventive and/or therapeutic targets, aid in diagnosis, and help monitor disease progression and treatment. Pain presents a particular challenge because its mechanisms span the central and peripheral nervous systems, and pain is modulated by the immune and endocrine systems. While innovative biomarkers have been developed in small-scale studies, large-scale discovery and evaluation of promising biomarkers will be required. The *NIH Common Fund Acute to Chronic Pain Signatures (A2CPS) Program* addresses this need. This landmark multidisciplinary longitudinal study aims to identify CPSP-related signatures, or patterns, made up of multiple biomarkers; we anticipate these signatures will lead to a better understanding of the neurophysiological mechanisms underlying CPSP and to the discovery of novel targets for the prevention and treatment of chronic pain. A2CPS will explore the factors that contribute to resilience and susceptibility to chronic pain after either total

knee replacement or thoracic surgery in 3,600 individuals across 10 clinical sites in the U.S. It will incorporate a comprehensive set of symptom-based, psychosocial, neuroimaging, genomic, proteomic, lipidomic, and metabolomic biomarkers prognostic of the transition to chronic pain. A2CPS combines a biomarker-validation approach to test carefully selected candidate biomarkers together with a discovery-science approach aimed at identifying new mechanistic causes of pain and therapeutic targets. Here, we describe the A2CPS study design, measures and biomarkers, along with the rationale for selecting them. We also describe the organization of the consortium and how it addresses the opportunities and challenges inherent in the large team-science paradigm. Finally, we describe future opportunities for the scientific community in accessing and utilizing the study's data and analytic resources.

Title: Signal or noise? Task-independent voxels can jointly decode painful tasks

Authors: *A. D. VIGOTSKY[1,2,3], R. JABAKHANJI[3,4], M. N. BALIKI[3,5,7], A. APKARIAN[3,4,5,6];
[1]Dept. of Biomed. Engin., [2]Dept. of Statistics, Northwestern Univ., Evanston, IL; [3]Ctr. for Translational Pain Res., [4]Dept. of Physiol., [5]Dept. of Physical Med. & Rehabil., [6]Dept. of Anesthesia, Northwestern Univ., Chicago, IL; [7]Shirley Ryan AbilityLab, Chicago, IL

Abstract: Decoding mental states, such as pain, is a lofty goal in cognitive neuroscience. To decode, investigators commonly build and tune complex models using regions of interest; e.g., brain areas that correlate with a task of interest. We previously demonstrated that the voxels in these task-correlated areas are highly redundant for decoding—a random sample of 10% of a decoder's voxels performs just as well as using all of them. Here, we push this concept further by

systematically evaluating the decoding power of all voxels in the brain using the Neurosynth meta-analytic map for the term “pain”. We binned voxels by their absolute magnitude to create 10 decoders: the first (HIGH) had the greatest 10% of absolute voxel weights (each voxel is strongly correlated with “pain”) and the tenth (LOW) had the lowest 10% of absolute voxel weights (each voxel is nearly orthogonal to “pain”). Using 4 different datasets (total N=113), we evaluated the performance of the 10 decoders to discriminate pain from several different control tasks (visuomotor, touch (×2), vision, audition, and heat). Remarkably, three of the six conditions (visuomotor, touch, and vision) saw little-to-no degradation in discrimination performance (AUC) from HIGH to LOW. In the remaining tasks (touch, audition, and heat), AUCs decreased from HIGH to LOW by ~0.2, and only heat decreased to chance level. Despite the degradation in these latter conditions, this simple analysis powerfully reveals the presence of widespread information across the brain that can be leveraged for decoding. Linear combinations of voxels that should be nearly orthogonal to activation maps associated with pain contain enough information to decode acute pain from some, but not all, other stimuli.

Title: The weak, inconsistent relationship between pain variability and relief in randomized clinical trials

Authors: *S. TIWARI[1,2], A. D. VIGOTSKY[2,3], A. V. APKARIAN[2,4];
[1]Illinois Mathematics and Sci. Acad., Chicago, IL; [2]Ctr. for Translational Pain Res., [3]Departments of Biomed. Engin. and Statistics, [4]Departments of Physiology, Anesthesiology, and Physical Med. & Rehabil., Northwestern Univ., Chicago, IL

Abstract: Greater baseline variability is associated with greater pain relief in those who receive a placebo. However, it is unclear how generalizable this relationship is or if it is strong enough to be predictive. In this study, we analyzed data from two randomized clinical trials to add to the body of results from previous studies. Results differ between the two placebo groups: the placebo group in Study 1 showed a null correlation between baseline variability and response ($r(43) = 0.01$), whereas the placebo group in Study 2 showed a moderate, negative correlation

(r(33) = -0.43). Drug and no-treatment groups also showed differing correlations (Study 1: No Treatment: r(18) = -0.70; Study 2: No Treatment: r(12) = 0.23; Drug: r(35) = -0.35). When analyzed together, baseline pain variability was only able to account for 17% of variance in pain relief in Study 1 and 13% of variance in Study 2, leaving much variance unaccounted for. Even after controlling for other factors (such as baseline pain), the inability of baseline pain variability to account for substantial variance in pain response highlights that previously published results on the relationship between pain variability and treatment response are weak and inconsistent. Importantly, the relationship appears to be neither consistently specific nor sensitive to improvements in the placebo group, challenging claims in the literature. As a result, researchers and clinicians should not solely rely on using baseline pain variability as a determinant of treatment response but it may be useful to include as a covariate to improve analytical efficiency.

Title: The interaction of cingulate cortex activity, pain catastrophizing, and cognitive performance while experiencing pain

Authors: *S. MARGERISON[1], A. FURMAN[1], S. KRIMMEL[2], M. KEASER[3], T. J. MEEKER[4], D. A. SEMINOWICZ[5];
[2]Neural and Pain Sci., [1]Univ. of Maryland Baltimore, Baltimore, MD; [3]Univ. of Maryland Baltimore, BALTIMORE, MD; [4]Dept. of Neurosurg., Johns Hopkins Med. Inst., Baltimore, MD; [5]Dept of Neural & Pain Sci., Univ. of Maryland, Baltimore, Baltimore, MD

Abstract: Pain is a biopsychosocial phenomenon impacted by emotion and cognition. Pain catastrophizing is one factor contributing to the pain experience and is associated with increased pain levels and increased cognitive complaints among those with chronic pain. In addition, pain itself impacts cognitive function in those with chronic symptoms. We sought to determine how cognitive performance and pain catastrophizing relate to activity in the anterior midcingulate cortex (aMCC) and the subgenual anterior cingulate cortex (sgACC). Data from two existing fMRI datasets collected from healthy controls using a Siemens 3T Prisma MRI scanner with a 64 channel head coil were used. During the scans, participants performed the Multi-Source Interference Task (MSIT), a cognitive task developed to provide multiple sources of distraction. Our task included three levels of difficulty based on procedures by Seminowicz and Davis

(2007). This task was performed with and without pain and performance was measured by reaction time. Pain catastrophizing was assessed using the Pain Catastrophizing Scale (PCS). The effect of pain during the most difficult task on total BOLD signal of the sgACC and aMCC (n=24) and functional connectivity of the sgACC to the amygdala (n=12) and of the aMCC to the dorsolateral prefrontal cortex (dlPFC) (n=24) were calculated. We found that total BOLD signal at the aMCC was correlated with slower reaction time ($r = 0.491$, $p = .015$). There was also a non-significant negative correlation between PCS score and total aMCC activation ($r = -0.318$, $p = .130$). Total activation of sgACC during the pain condition was associated with slower response times ($r = .404$, $p= .050$). Our findings relative to the aMCC are consistent with prior studies. As the sgACC has been implicated in the regulation of stress and emotion, the association of sgACC total activation with slower response may indicate increased regulation needed to stay on task, resulting in reduced performance during the pain condition for those people. The relationship between cingulate activity, pain catastrophizing, and response time highlights the complex role the cingulate cortex plays in how pain affects cognitive function. Ongoing work will expand these findings to a larger population and further explore the role of the cingulate cortex in managing pain and task demands by using dynamic causal modeling to explore directionality of effect and expand connectivity analysis to more limbic structures, including insular cortex and hippocampus. Greater understanding of the complex relationship between pain and cognitive function is necessary for the successful treatment of those who experience chronic pain.

Title: Trigeminal Nerve Abnormalities are Related to Pain Intensity in Myogenic Temporomandibular Disorders: a Probabilistic Tractography Study

Authors: *B. KAYA[1], I. CIOFFI[1], L. A. HENDERSON[2], M. MOAYEDI[1];
[1]Fac. of Dent., Univ. of Toronto, Toronto, ON, Canada; [2]Univ. of Sydney, Sydney, Australia

Abstract: Myogenic temporomandibular disorders (mTMDs) are a painful condition affecting the muscles of mastication, causing mild to severe pain. In the past, mTMDs were traditionally thought to be idiopathic functional musculoskeletal pain disorders with no known etiology.

Recent evidence has shown that patients with TMD have abnormalities in the muscles of mastication, and the ascending trigeminal nociceptive system. However, there is mixed evidence on whether the microstructural organization of trigeminal nerve at the root-entry zone (REZ) into the pontine segment of the brainstem is abnormal in mTMD. A recent genome-wide association study has identified abnormalities in axon guidance genes in those with mTMD, indicating that perhaps the morphology or trajectory of the nerve may be abnormal. Probabilistic tractography allows for *in vivo* reconstruction of white matter tracts, and provides both qualitative and quantitative metrics of white matter trajectory and connectivity. Here, we aimed to compare the trajectory of the trigeminal nerve in patients with mTMD, compared to pain-free controls using probabilistic tractography. We investigated a previously collected cohort (Henderson Lab, University of Sydney) of chronic mTMD patients (5 M, 18 F; M = 43.86, SD = 14.03 years) and controls (5 M, 18 F; M = 47.51, SD = 14.84 years). 6 patients had pain on the right side, 1 patient had pain on the left, 12 patients had bilateral pain, and 4 patients did not report the side of pain. We delineated REZ and cisternal (CS) segments of the bilateral trigeminal nerves. Next, we performed probabilistic tractography in two directions: (1) from the CS in to the REZ (i.e., tracks going into the brainstem), and (2) from the REZ towards the CS (i.e., tracks going towards the face), to determine whether brainstem connectivity or nerve topography was abnormal in those with mTMD, respectively. We found that only the tracts towards the face of the right trigeminal nerve had significantly lower connectivity values in mTMD, compared to controls ($p<0.05$). This aligns with the most of the TMD cohort reporting right sided or bilateral pain. These abnormalities were significantly negatively correlated with self-reported pain intensity on the day of the MRI scan ($r= p<0.05$). This is the first study to perform tractography of the trigeminal nerve in chronic mTMD, and to identify trajectory abnormalities, in the absence of microstructural abnormalities. These data provide further evidence that chronic mTMD is associated with neuromuscular abnormalities.

Title: State predictions in primary olfactory cortex

Authors: T. STENSOLA, ***H. STENSOLA**, M. PATWA, E. DEWITT, Z. F. MAINEN; Champalimaud Ctr. for the Unknown, Lisbon, Portugal

Abstract: Being able to predict future states of your environment based on past experience is a powerful tool for adaptive behavior. Several theories exist that formalize the use of predictions for behavior and neural coding. In Bayesian frameworks, predictions take the form of priors, and are combined with incoming sensory information. In predictive coding frameworks, sensory signals are compared with a generative internal model to produce prediction error signals. While behavioral support for these theories is strong, the evidence of their implementation in neural circuits is controversial. To study the effects of predictability on sensory neural codes, we combined odor-based virtual reality with large-scale chronic electrophysiology in head-fixed mice. We recorded neural responses in primary olfactory cortices while paired odors were presented sequentially. While primary responses to odors have been well characterized in these cortices, modulation of those responses when predicted has received little focus. We presented odor pairs with a brief temporal separation. The first odor predicted the second odor and on a small subset of trials, the predictive odor was omitted to assess the responses to the second odor without the prior. On the single cell level, responses to the second odor were significantly modulated by the presence of the predictive first odor. Separate subsets of cells showed increases and decreases in response magnitudes. Across sessions and animals, the average response modulation was close to zero, suggesting that the predictive first odor acts as a prior that rotates the second odor representational space without changing the overall population firing rate. This shows that the prior modifies the odor representation. Surprisingly, some cells started responding to the second odor before its onset given the predictive first odor. The onset of the second odor response was also earlier on the population level. Linear decoders showed increased performance in decoding the first odor stimuli before their onset when predicted. Thus, the prior is explicitly represented before the onset of the second odor. Our data show that odor representations in primary olfactory cortices are powerfully modulated by sensory prediction, and suggest that priors are represented as rotations of the primary representation space.

Title: Cortico-bulbar feedback supports behavioral flexibility during rule-reversal

Authors: *D. E. HERNANDEZ[1], A. CIUPARU[2], P. GARCIA DA SILVA[3], M. C. VELASQUEZ[4], B. REBOUILLAT[5], M. GROSS[1], M. B. DAVIS[1], R. C. MURESAN[2], D. F.

ALBEANU[1];
[1]Neurosci., Cold Spring Harbor Lab., Cold Spring Harbor, NY; [2]Transylvanian Inst. of Neurosci., Cluj-Napoca, Romania; [3]Champalimaud Fndn., Lisbon, Portugal; [4]Nuffield Dept. of Clin. Neurosciences, Oxford Univ., Oxford, United Kingdom; [5]DÉPARTEMENT D'ÉTUDES COGNITIVES, ÉCOLE NORMALE SUPÉRIEURE, Paris, France

Abstract: To survive, animals flexibly adjust their actions to relevant changes in the world. Mice are expert at recognizing odorants in ever-changing sensory scenes. Yet, little is known about: (1) how odorant representations are modified upon sudden changes in stimulus contingency and (2) how changes in feedforward and feedback odorant representations causally relate to behavior. The piriform cortex (PC) receives input from both the olfactory bulb (OB) and association areas (e.g. orbitofrontal cortex). Furthermore, the PC sends rich top-down feedback and controls the activity of the OB outputs, in a cell-type specific manner. It is, thus, ideally positioned for integrating sensory input and experience-based sensorimotor predictions.To determine whether the cortico-bulbar feedback supports behavioral flexibility, we trained mice in a Go/No-Go rule-reversal task (>85% accuracy) and monitored the activity of feedback boutons (GCaMP5/7b vs. GFP controls) across bulb layers via multiphoton microscopy (n = 12 mice; 53 sessions). Within the same session (~270 trials), the reward contingency was switched (4 reversals) across blocks of contiguous trials (~45), rewarding either the odor or sound cue. To disambiguate reward-related signals from signatures of motor activity, in a subset of experiments, a 500 ms delay was imposed between the cue offset and the reporting period. Cortical feedback boutons showed dense responses (55% responsive boutons vs ~4% in naïve animals) aligned to specific trial events. Strikingly, individual boutons mirrored closely the block-structure of the task and changed, within seconds, their response kinetics, shape, and amplitude to the same sensory cue, following each rule-reversal. Cortical feedback matched the *perceived* current reward-rule and slightly lagged in updating, similarly to the animal's behavior. We trained and cross-validated classifiers (multi-layer perceptrons) to decode task features ranging from stimulus identity and trial contingency to behavioral outcome. The classifiers' performance for each variable rapidly increased during cue-delivery and peaked during the delay epoch. The performance remained high throughout lick-reporting, and for several seconds after reward collection. In ongoing experiments, we are assessing the effects of optogenetically suppressing the cortical-bulbar feedback on the rule-switching behavior and on OB output activity.Thus, the cortical-bulbar feedback carries information related to stimulus identity, contingency, and behavioral outcome, which is readily re-formatted across different rules of engagement in evolving environments.

Title: Neural correlates of time and place in the olfactory bulb of freely-moving mice

Authors: M. A. BROWN[1], T. FINDLEY[1], S. C. STERRETT[3], A. P. WEIBLE[2], M. KARLSSON[4], A. L. FAIRHALL[5], J. M. MURRAY[1], *M. C. SMEAR[1];

Abstract: Odors provide useful navigational and episodic information, but however numerous the odorant receptor genes in an animal's genome, there is no receptor for time or place. To optimally orient by olfactory information, brains must incorporate odor-driven activity into representations of self-movement and -location. While a feedforward model might predict that such multimodal integration would be implemented in "high-level" areas, recent studies in other sensory modalities demonstrate that motor- and location-related signals are common in primary sensory areas. Motivated by these findings, and given the strong reciprocal connection between olfactory system and hippocampus, we hypothesized that the olfactory bulb might also encode navigational information. To test this hypothesis, we captured the sniffing and movement of mice while recording spiking activity in their olfactory bulb, in the absence of experimenter-applied stimuli or tasks. We first compared breathing and spiking between head-fixed and freely-moving states. During head restraint, sniffing is arrhythmic -- intersniff intervals are broadly distributed. In striking contrast, without restraint respiration is organized into discrete rhythmic states lasting minutes. Intersniff intervals are more metronomic and inversely proportional to movement speed. In the bulb, we found that many units fired preferentially at characteristic times after inhalation, as previously reported. In addition, many units fired preferentially at characteristic sniff frequencies, particularly during free movement, often in correspondence with the rhythmic states of sniffing. In addition to these time-selective signals, we also found that many olfactory bulb neurons are place-selective during free movement. To test whether this position-selective activity carries usable information about the mouse's location, we decoded position from small ensembles of 20-50 simultaneously recorded units. We could decode the mouse's position with above-chance accuracy in all sessions. Thus, even during spontaneous behavior and ambient stimuli, information about time and place can be read out from the activity of the olfactory bulb. A mouse needs to know where and when it encountered different smells: olfactory information must be contextualized and incorporated into cognitive maps of environment and self. Our results suggest that this contextualization process begins as soon as olfactory information enters the brain.

Title: Configural responses to odor mixtures in head-fixed mice

Authors: D. KLYMYSHYN[1], *L. B. COHEN[2,3];
[1]Dept. of Cell. and Mol. Physiol., Yale Univ. Sch. of Med., New Haven, CT; [2]Dept. of Cell. and Mol. Physiol., Yale Univ., New Haven, CT; [3]Brain Sci. Institute, Korea Inst. of Sci. and Technol., Seul, Korea, Republic of

Abstract: Odor mixtures can exhibit configural (the mixture is considered to have an odor different from any of the individual component odorants) or elemental (the components in a mixture are recognizable) properties. However, it remains unclear whether the olfactory bulb, the brain structure that mediates the first stage of olfactory information processing, might contribute to the configural perception of certain odor mixtures. The aim of the present study was to compare elemental and configural perception of odor mixtures in head-fixed mice in lick/no-lick discrimination task. In this study we used a binary odor mixture (citronellal-octanal) that elicited configural responses in freely moving rats (Kay et al, (2003). We followed a procedure for motivating mice by limiting their access to water as was initially described by Guo et al, (2014). All mice undergoing water restriction were monitored daily for hydration, weight, ruffled fur, and movement. The head-fixed mice were trained in a lick/no-lick discrimination task where animals were rewarded with water for licking in response to binary citronellal-octanal mixtures of two different ratios, 1:1 and 3:1 (citronellal-octanal). Water was not available for trials with the non-rewarded odor (hexanol) and licking on those trials was punished with a longer inter-trial interval. Licking was signaled by mice breaking a light path in a Bpod r2 water port with their tongue. All mice learned to avoid licking in no-lick trials during the first session and reached a learning criterion (60% correct responses) within 100 - 220 trials. To determine whether the perception of the odor mixtures is elemental or configural we compared the response to the mixture, the individual components, and a novel odor (isopentyl acetate). The response to the individual components and the novel odor were similar to each other and were different from the response to the mixture and to hexanol, showing that the mixture perception was configural.

Title: Effect of trigeminal input on binary odor mixture perception

Authors: *H. LI[1,3], C. LEE[2], Z. LEVERONI[4,3], S. MISLITCHI[5,3], L. M. KAY[1,3];
[1]Dept. of Psychology, [2]The Col., The Univ. of Chicago, Chicago, IL; [3]Inst. for Mind and Biol., Chicago, IL; [4]St. John's Col., Annapolis, MD; [5]St. John's Col., Santa Fe, NM

Abstract: The experience of smell can be modulated by the trigeminal system and its interactions with the olfactory system, but how chemesthesis in the nose interacts with olfactory perception is not fully understood. Trigeminal nerve endings in the olfactory sensory epithelium are stimulated by most odorants and activate cell bodies in the trigeminal ganglion. Neither the behavioral effects nor the underlying mechanisms of their interactions have been systematically characterized. Almost all odorants stimulate the trigeminal nerve, some even at low concentrations. Thus, it is reasonable to postulate that the influence of trigeminal input is almost always at play in odor perception, especially for odor mixtures, and most natural odorants are blends of many different monomolecular odorants. From the standpoint of olfactory psychophysics, there is also no satisfactory theory that predicts the perceptual qualities of even a binary mixture, and some of the confounds in prior approaches may come from ignoring the role of trigeminal-olfactory interactions. To address how trigeminal activation may play a role in odor mixture perception, we trained rats to discriminate 4 different pairs of monomolecular odorants of varying relative trigeminal intensities and profiles, and asked them which of the two odorants a binary mixture smells like while varying ratios of the two odorants systematically. We predicted that comparative trigeminal intensities of component odorants would help explain overshadowing. All odor mixtures tested showed some degree of overshadowing of one component by the other, when we accounted for differences in volatility. The magnitude of difference in component trigeminal intensities did not predict the degree of overshadowing in the binary mixtures we tested. However, the data do suggest that the component of higher trigeminal intensity is overshadowed by the trigeminally weaker odorant in a binary mixture. To better inform a systematic comparison of trigeminal profiles of odorants used, we also recorded and compared electrophysiological responses in the olfactory bulb and trigeminal ganglion under anesthesia with the same odorants used for behavioral analysis.

Title: Odor identification in novel olfactory environments is selectively impaired in a mouse model of autism

Authors: G. H. OTAZU;
New York Inst. of Technology, Col. of Osteo. Med., Old Westbury, NY

Abstract: Aversion to novel stimuli in autism affects quality of life. We developed a behavioral paradigm to study the effect of novel background odors on odor discrimination in a mouse model of autism. We trained wild type mice to discriminate target odors in known background odors. When tested, WT mice could discriminate known targets in novel background odors, a task similar to the visual CAPTCHA used to distinguish humans from computers. Using glomerular intrinsic imaging data, we showed that WT mice used an algorithm that required less training data than a linear classifier or nearest neighbor classifier. The *Cntnap2*$^{-/-}$ mouse model of autism learned simple odor discriminations at the same rate as WT mice. *Cntnap2*$^{-/-}$ mice were also able to learn to identify odors in weak backgrounds as well as WT mice and CNTNAP2 knockout mice matched WT mice performance in the presence of known backgrounds. However, performance fell almost to chance levels in the presence of novel backgrounds. WT mice use a robust algorithm for detecting odors in novel environments and this computation is selectively affected in a mouse model of autism.

Title: Dimensionality of perceptual odor representations increases across the central olfactory pathways

Authors: *V. SAGAR, T. KAHNT;
Neurol., Northwestern Univ., Chicago, IL

Abstract: The central olfactory system transforms chemical information of odor molecules into a unified olfactory percept. Previous work suggests that the piriform cortex (PirC) supports odor perception, whereas the orbitofrontal cortex (OFC) is involved in higher-order olfactory cognition. However, the nature and dimensionality of odor encoding in these areas has not yet been determined. Addressing this question requires mapping neural responses to a large number of odors. Here we combined computational modeling with a high-precision functional mapping approach to examine the encoding of odors in different olfactory areas. We collected functional magnetic resonance imaging (fMRI) responses to 160 monomolecular odors from individual subjects (18 h of fMRI hours per subject, N=3). In a first step, we used representational similarity analysis to quantify the unique contribution of chemical structure and perceptual quality to neural response patterns. The difference between the represented perceptual and chemical information was significantly larger in the OFC compared to the PirC and amygdala, with perceptual quality emerging as the dominant driver of odor-evoked responses in the OFC. Moreover, we used voxel-wise encoding models to determine the specific perceptual features encoded in these areas. We found that the dimensionality of the perceptual feature space encoded in neural responses differed significantly across olfactory areas, with a simple and low-dimensional representation in PirC, and complex and high-dimensional perceptual feature spaces in the OFC. These findings challenge the notion that odor perception occurs at the level of PirC, and suggest that OFC plays a key role in supporting a rich and multi-dimensional representation of our olfactory environment.

Title: Pharmacological manipulation of the apical cochlear amplifier reveals unique mechanical encoding properties for encoding sound

Authors: *G. W. S. BURWOOD[1], A. L. NUTTALL[1], A. FRIDBERGER[2];
[1]Oregon Hearing Res. Ctr., Oregon Hlth. & Sci. Univ., Portland, OR; [2]Biomed. and Clin. Sci., Linkoping Univ., Linkoping, Sweden

Abstract: The apex of the mammalian cochlea is the location where speech and music frequency sounds are transduced into auditory nerve impulses. Recent reports have highlighted the fundamental differences between not only the mechanics of the cochlear apex and high frequency base, but also that of the basilar membrane and reticular lamina at each location. Using data obtained by our minimally invasive guinea pig preparation and our spectral domain optical coherence tomography system, we describe the relative motion of components within a single midmodiolar plane the apical cochlea, showing the organ of Corti from three locations from an area comprising the final 20% of the cochlear spiral. The displacement, phase and inter-location group delay in response to single and multi-tone stimuli are reported. Preparations were given IP furosemide, a loop diuretic agent which abolishes endocochlear potential. Endocochlear potential is known to be required for maximum force generation by electromechanical somatic motility outer hair cells. Measurements were made before and during exposure to furosemide, and post mortem. Overall cochlear sensitivity was monitored using gross neural threshold response at the round window, to a 2 kHz tone. In this way, we elucidate the outer hair cell force dependent component of transverse organ of Corti motion, and assess how it changes with distance to the helicotrema. We found that the cutoff frequencies of the three iso-intensity tuning curves measured from the reticular lamina at these cochlear locations were closer than has been predicted by tonotopic mapping of the cochlea. In fact, the most apical region did not display the lowest cutoff frequency - contrary to expectations. Additionally, we found that the average group delay difference between two locations separated by one half cochlear turn is minimized in vivo. This phase delay minimization was abolished by furosemide and following euthanasia, and was not affected in preparations that did not respond to IP furosemide. Our data also show that signal processing mechanisms within the cochlear apex may emerge partially from the gradual change in amplification capacity and nonlinearity with respect to distance from the helicotrema, altogether suggesting an emphasis on temporal sensitivity in a distributed system, over place coding.

Title: Otolith Endorgans Hair Cell Polarity-Specific Segregation of Primary Vestibular Afferent Fibers to the Brainstem and Cerebellum in Chick Embryo

Authors: W. GHERMAN[1], K. REJENT[2], A. BHAVSAR[2], P. W. FRANK[3], D. GIOVANNUCCI[2], *A. MAKLAD[4];
[2]Neurosciences, [3]Med. Educ., [1]Univ. of Toledo, Toledo, OH; [4]Neurosciences, Univ. of Toledo, Perrysburg, OH

Abstract: Perception of linear acceleration and head position relative to the line of gravity pull is the function of the utricle and a saccule in mammals. One of the most conserved features of the vestibular system of all vertebrates is the morphological polarity of the hair cells. In all vertebrate, the otolith endorgans hair cell morphological polarity is reversed across a line known as striola. The function of this polarity reversal at the striola is currently unknown. In mammals, one polarity domain outside the striola was found to project almost exclusively to the cerebellum, whereas the other polarity inside the striola projects almost exclusively to the brainstem. The current study is designed to test whether the central projection of the different polarity domains in the otolith endorgans in other classes in vertebrate: Aves. Lipophilic retrograde tracers (NeuroVue Red and NeuroVue Maroon) were implanted in the vestibular nuclei and the nodulus and uvula of the cerebellum, respectively, in post-fixed pre-hatching chick embryos. After the diffusion time was complete, the maculae of otolith endorgans were dissected out and examined with confocal microscopy. In the macula of the utricle, Neuro Vue Red placed in the vestibular nuclei retrogradely labeled a distinct domain of hair cell located inside the striola region, whereas the NeuroVue Maroon retrogradely labeled hair cells located outside the striola. Similarly, in the macula of the saccule, NeuroVue Red implanted in the vestibular nuclei labeled an area of the hair cells located inside the striola region, whereas, NeuroVue Maroon labeled an area of the hair cells outside the striola. No area of overlap or double labeled cells were seen in the different domains. Our data suggest that the central segregation of the primary otolith afferent of the different polarity domain reported previously in mammals is also conserved in other classes such as Aves.

Title: Functions of GRXCR2 in hearing and deafness

Authors: *B. ZHAO;
Indiana Univ. school of medicine, INDIANAPOLIS, IN

Abstract: Stereocilia of cochlear hair cells are specialized mechanosensing organelles that convert sound-induced vibration to electrical signals. The base of the stereocilia, which is the site of stereocilia pivoting, is organized by several proteins necessary for human hearing and essential for stereocilia morphogenesis and function. GRXCR2, localized at the base of stereocilia, has been found to be critical for the morphogenesis of stereocilia through its interaction with taperin, an actin regulatory protein also concentrated at the base of stereocilia. Rescuing the morphological defects of stereocilia in *Grxcr2*-null mouse by reducing taperin expression level only partially restores its hearing, suggesting that GRXCR2 interacts with some other proteins required for auditory perception. Recently, we identified a novel interaction between GRXCR2 and CLIC5. Disrupting their interaction *in vivo* has minimal effects on stereocilia morphogenesis but leads to moderate hearing loss at lower frequencies and severe hearing loss at higher frequencies, strongly suggesting that the interaction between GRXCR2 and CLIC5 is essential for normal hearing. Thus, our study provides a foundation for future investigations of the functions of a protein complex in the basal region of stereocilia critical for sound perception.

Title: The potassium channel subunit Kv1.8 (Kcna10) differentially shapes tuning, gain, and response latency of type I and II vestibular hair cells

Authors: *H. R. MARTIN[1], S. D. PRICE[2], A. LYSAKOWSKI[2], R. A. EATOCK[1];
[1]Neurobio., Univ. of Chicago, Chicago, IL; [2]Dept. of Anat. & Cell Biol., Univ. of Illinois at Chicago, Chicago, IL

Abstract: Vestibular hair cells (HCs) convert head motions into receptor potentials that drive downstream gaze and postural reflexes, spatial navigation, and gravity sensation. In amniotes, type I and II HCs (HCI and HCII), express large K^+ conductances with different voltage dependence and inactivation, which differentially shape receptor potential gain, tuning, and timing. We investigated the roles in HCIs and HCIIs of $K_V1.8$, an understudied channel encoded by the Kcna10 gene. $K_V1.8$-null animals lack vestibular evoked potentials normally evoked by transient head motions (Lee et al, 2013). We stimulated HCs with voltages, currents, or hair bundle deflections and recorded whole-cell currents and voltages from HCs in intact utricles from $K_V1.8$-null mice and wildtype (WT) and heterozygous littermates (postnatal days 5-279). We show that $K_V1.8$ is necessary for the dominant but very different K^+ conductances in HCI and HCII, and that these K^+ conductances differentially affect response gain, tuning, and timing.
$K_V1.8^{-/-}$ HCIs lacked the large, low-voltage-activated, non-inactivating K^+ conductance ($g_{K,L}$, V_{half} = -85 ± 2 (SE) mV) specific to mature WT HCI. The residual outward rectifier (V_{half} = -41 ± 1 mV) was partly blocked (47 ± 13 %) by the K_V7 blocker, XE991. The input resistance of $K_V1.8^{-/-}$ HCIs was 20-fold greater than that of WT HCIs. As a result, the receptor potential evoked by hair bundle deflections increased in size but slowed, producing a lower low-pass corner frequency (~20 Hz vs. ~400 Hz) and greater phase lag.
$K_V1.8^{-/-}$ HCIIs lacked the fast-inactivating, α-DTX-sensitive A-type conductance (g_A, V_{half} = -34 ± 1 mV) typical for WT HCII. The small residual conductance (V_{half} = -32 ± 1 mV) was a non-inactivating delayed rectifier. Without g_A, the membrane potential evoked by current steps was more likely to show electrical resonance, had longer latency, and recovered more slowly after depolarization. In response to sinusoidal mechanical stimulation, the $K_V1.8^{-/-}$ HCII receptor potential had a significantly lower best frequency (8 ± 2 Hz vs 17 ± 4 Hz) and greater phase lag above 5 Hz.
Thus, $K_V1.8$ is necessary for two distinct conductances ($g_{K,L}$ and g_A) in neighboring HCs. Immunocytochemistry localizing $K_V1.8$ to the basolateral membranes of HCIs and HCIIs and other evidence that it is conductive (Lang et al, 2000; Dierich et al, 2020) suggests that $K_V1.8$ is a pore-forming subunit of both $g_{K,L}$ and g_A. $K_V1.8$ also contributes to a non-inactivating outward rectifier (V_{half} = -2.2 ± 0.4 mV) in cochlear inner HCs (Dierich et al, 2020). $K_V1.8$ may partner with other K_V1 subunits in the different HC types or be subject to other forms of modification.

Title: Nonquantal transmission at the vestibular hair cell-calyx synapse

Authors: *A. GOVINDARAJU[1], I. H. QURAISHI[2], A. LYSAKOWSKI[3], R. EATOCK[4], R. RAPHAEL[1];
[1]Rice Univ., Houston, TX; [2]Dept. of Neurol., Yale Sch. of Med., New Haven, CT; [3]Dept. of Anat. & Cell Biol., Univ. of Illinois at Chicago, Chicago, IL; [4]Neurobio., Univ. of Chicago, Chicago, IL

Abstract: Vestibular hair cells transduce head movement and inform neural pathways that control gaze, balance and orientation. In mammals, birds and reptiles, vestibular afferent neurons form a uniquely shaped synaptic terminal, termed a calyx, around vestibular type I hair cells. This arrangement supports nonquantal transmission (NQT), a neurotransmitter-independent mechanism of coupling changes in hair cell potential to changes in calyx potential. The existing view is that a large low-voltage-activated potassium conductance in the hair cell (gKL) drives potassium accumulation in the synaptic cleft and depolarizes the calyx membrane. However, a full biophysical model of NQT has not been developed and the role of other aspects of the system remain unclear, including the role of ion channels present on the calyx inner face membrane (Kv7, HCN) and the possibility of changes in electrical potential within the synaptic cleft space. Here we present a computational model of NQT that integrates existing experimental observations into a coherent picture. We show that changes in electrical potential in the synaptic cleft are necessary to explain fast post-synaptic currents that were recently observed. Changes in electrical potential in the cleft advance the phase of the calyx response, facilitating faster synaptic transmission of vestibular stimuli than can be explained with potassium accumulation alone. Together, both processes may contribute to the mechanistic basis for the speed of vestibular reflexes which involve peripheral vestibular afferents. The theoretical approach we have developed may be further extended to investigate neurotransmitter-independent modes of synaptic communication in other systems such as the retina.

Title: Persistent and resurgent sodium currents enhance spiking excitability in mouse vestibular ganglion neurons.

Authors: *S. BAEZA LOYA, R. A. EATOCK;
Neurobio., Univ. of Chicago, Chicago, IL

Abstract: The vestibular inner ear transmits information to the brain via two populations of primary vestibular ganglion neurons (VGNs) which differ in the regularity of action potential (AP) timing. Studies of isolated VGNs have shown that irregular neurons are less excitable than regular neurons, producing transient and sustained spiking in response to current steps, respectively. Although voltage-gated sodium (Na_V) currents drive the rising phase of APs, their contributions to excitability and regularity differences are not fully understood. Na_V currents in VGNs are dominated by transient (inactivating) currents but can include persistent (noninactivating) and/or resurgent currents (which flow after relief from inactivation block). Here we consider the impact of different Na_V current modes on patterns of AP firing.
Whole-cell recordings were taken from mouse VGNs (postnatal days, (P)3-25) isolated and cultured overnight. In a sample of 78 VGNs, all had large transient Na_V currents blocked by 1 μM TTX; 42 had persistent current (P3-25), 6 had resurgent current (P11-20), and 4 (P11-20) had both persistent and resurgent currents. Application of $Na_V1.6$ blocker 4,9-anhydro-tetrodotoxin (4,9-ah-TTX) partially blocked all three current modes, indicating that a substantial portion of each is carried through $Na_V1.6$ channels. In current clamp, application of 4,9-ah-TTX decreased neuronal excitability: increasing current threshold for spiking in all VGNs and decreasing AP rate in sustained (regular) VGNs.
We lack ways to experimentally isolate the effects of transient, persistent, and resurgent currents on spiking because they flow through the same channel subunits. Therefore, we adapted a conductance-based VGN model with transient Na_V current (Hight and Kalluri, J Neurophysiol 116:503, 2016), adding persistent and resurgent currents (Venugopal et al., PLoS Comput Bio 15(6): e1007154, 2019) and adjusting expressions for properties measured in our VGNs. The addition of persistent and resurgent current components had a negligible effect on firing by the model transient (irregular) VGN. For the model sustained (regular) VGN, adding persistent and resurgent currents decreased first-spike latency (delay relative to stimulus onset) and increased spike rate.
These results suggest that increasing Na_V channel availability in the after-spike interval with persistent and resurgent currents may enhance excitability and hence regularity of regular VGNs. The difference in regularity may represent distinct encoding strategies, with regular afferents using a rate code and irregular afferent using a temporal code. Title: Transformation of acoustic information to sensory decisions in parietal cortex

Authors: *J. D. YAO, K. O. ZEMLIANOVA, D. H. SANES;
New York Univ., New York, NY

Abstract: The ability to integrate sensory information over time - often called temporal integration - is fundamental for guiding perceptual decisions. Perceptual decision-making has been studied at the level of stimulus representations in sensory cortex, and in higher cortical areas that are thought to produce premotor decision-related signals. Here, we ask how the neural representations of sensory information are transformed in the auditory-recipient parietal cortex, a region that is causally associated with sound-driven perceptual decisions (Yao and Sanes, 2020). To examine this, gerbils were first trained and tested on an appetitive alternative forced-choice (AFC) auditory temporal integration task. Specifically, gerbils were required to discriminate between amplitude modulated (AM) noise at 4 versus 10 Hz across a range signal durations (100-2000 ms). Task performance was poor at very short AM durations (100-300 ms), improved with longer durations, and reached an optimum at ~600-800 ms. Our previous work revealed a causal relationship between this behavioral read out of auditory evidence accumulation and the activity of auditory cortical projections to parietal cortex (Yao and Sanes, 2020). To determine how a parietal cortex encoding mechanism could support the behavioral result, we conducted wireless recordings of single-unit activity from neurons in parietal cortex while gerbils performed the auditory task and while they were disengaged from the task (i.e., passive listening to the identical acoustic stimuli). During task performance, individual neurons displayed a sharp rise in firing rate that peaked prior to the animals' decision. To evaluate the read out of population activity, we used a linear classifier procedure that applies a support vector machine algorithm to decode 4 versus 10 Hz stimulus conditions from simultaneously recorded parietal cortex neurons during each session. Decoder performance during task performance was strongly correlated with behavioral outcomes across stimulus conditions, leaving open whether the parietal representation was purely motor or included a sensory component. To address this, we evaluated decoder performance during disengaged sessions, and found a representation of the AM rate across a range of signal durations. Our findings suggest that parietal cortex neurons represent both the acoustic stimulus and sound-driven decision, demonstrating the progression of auditory processing downstream of auditory cortex.

Title: Sensitivity to unpredicted song perturbations in an avian auditory cortex

Authors: *M. T. L. HAPP, A. BAHLE, M. FEE;
MIT, Cambridge, MA

Abstract: In order to navigate their environments, intelligent agents must detect when stimuli are novel and surprising. Unpredictable stimuli are important for (1) recognition and learning of novel stimulus patterns and (2) learning from outcomes that differ from agents' expectations or goals. These two key aspects of novelty detection are illustrated by songbirds learning to sing, making songbirds excellent model organisms for the study of novelty detection.
In the song learning process, juvenile birds must (1) form a memory of a tutor song and (2) detect deviations from that learned template in the juvenile bird's own renditions. The first step requires recognition and learning of a novel stimulus pattern (the tutor song), and the second requires detection of deviation (in the bird's own rendition) from a familiar template (the internalized tutor song). What brain circuits underlie these processes? A secondary auditory area known as the caudomedial nidopallium (NCM) is believed to be important for the formation of the tutor song memory, and it is well known that neurons in this region habituate in a rapid and long-lasting manner to novel songs (Chew et al., 1995). This phenomenon, known as stimulus-specific adaptation (SSA) has been proposed to be crucial for the formation of memories for novel songs (including the tutor song). Once this memory is formed, it can serve as a template with which the young bird's developing song can be compared. However, the comparison circuit has not yet been identified.
As a clue in this search for a comparison circuit, we report the discovery of neurons in NCM that are sensitive to acoustic perturbations (e.g. white noise bursts and gaps of silence) to familiar songs, but not to identical perturbations of the same song before repeated exposure. Recordings were made using neuropixels probes to record from hundreds of single and multi-units in NCM of the zebra finch (Taeniopygia guttata). Birds were head-fixed and presented with familiar and perturbed auditory stimuli. We propose that the stimulus-specific adaptation and deviance detection may work in tandem to subserve the song learning process, first by song memory formation and then by detection of deviation from a learned template.

Title: Expectation of self-generated sounds drives predictive processing in mouse auditory cortex

Authors: *N. AUDETTE[1], W. ZHOU[2], D. M. SCHNEIDER[2];
[1]Ctr. for Neural Sci., [2]New York Univ., New York, NY

Abstract: Sensory stimuli are often predictable consequences of one's actions, and behavior exerts a correspondingly strong influence over sensory responses in the brain. Closed-loop experiments with the ability to control and perturb the sensory outcomes of specific animal behaviors have revealed that neural responses to self-generated sounds are suppressed in the auditory cortex, suggesting that prediction may play a critical role in local sensory processing. However, it is unclear whether this phenomenon derives from a precise movement-based prediction, if the cortex can support local implementation of predictions, or how it affects the neural representation of incoming stimuli. We address these questions by designing a behavioral paradigm where mice learn to expect the predictable acoustic consequences of a simple forelimb movement. Dense neuronal recordings from auditory cortex revealed suppression of neural responses that was strongest for the expected tone during a narrow time window surrounding the specific sound-associated movement. Predictive suppression was concentrated in layers 2/3 and 5, preceded by the arrival of movement information in deep layers, and driven by motor-sensory coupling rather than task engagement, behavioral relevance, or reward association. Despite large-scale suppression at the population level, the auditory cortex retained a sparse representation of expected self-generated sounds, while a substantial population of auditory cortex neurons in L2/3 and L5 encoded prediction errors. These findings illustrate that expectation, learned through motor-sensory experience, drives layer-specific predictive processing in the mouse auditory cortex.

Title: A pupillometric assessment of pre-pulse inhibition in sensory gating in mice

Authors: *S. JOSHI[1], S. SMITH[1], Z. H. MRIDHA[1], J. DEGEE[1], D. CONNOLLY[2], J. HOLDER[3], R. C. SAMACO[4], M. J. MCGINLEY[1];

Abstract: Pupil size is widely used as a non-invasive metric of brain state. Previous studies have shown links between pupil size and the activity in major neuromodulatory systems such as the locus coeruleus norepinephrine (LC-NE) and basal forebrain acetylcholine (BF-ACh) systems. However, evoked or baseline changes in pupil size and its relationship with the activation of such systems under different perceptual or behavioral conditions remains poorly understood. Here, we test the use of pupillometry in measuring sensory information gating in the auditory system. Using a novel paradigm in head-fixed mice, we measured the response of the pupil to a loud tone when presented alone and when preceded by a weaker tone – a prepulse. Since no behavioral response is required in this paradigm, pupil and neuromodulatory responses are less confounded by motor activity than in behavioral tasks.
We present our preliminary findings showing attenuation of pupil responses by the prepulse and changes in neuromodulator levels due to tone alone and tone plus prepulse. To test whether such pupil indexed sensory gating is affected by neural dysfunction, we focused on the *MECP2* and *SHANK3* genes that are involved in neural development and synapse function. Mutations in these genes are associated with autism spectrum disorders (ASD). We measured pupil responses in *MECP2* and *SHANK3* mutant mice and found reliable difference in both baseline and evoked pupil size compared with wild type littermates.
Since pupil responses are sensitive to the sound level and to the presentation of a prepulse, these findings provide a link between pupil size and attentional blink – the attenuation of sensory processing while a previous stimulus is being processed. Our findings also show that pupil measurements are sensitive to the effects of specific genetic mutations associated with ASD on sensory information gating. In ongoing experiments, we are probing the neural circuit basis of these effects.

Title: Predictive coding in songbird secondary auditory cortical neurons

Authors: *S. RUDRARAJU[1], B. H. THEILMAN[2], T. GENTNER[3];
[1]Psychology, [2]Neurosciences, [3]Psychololgy, UC San Diego, La Jolla, CA

Abstract: Predictive coding (PC), a theoretical framework in which the brain compares a generative model to incoming sensory signals, has been employed to explain perceptual and cognitive phenomena, and has inspired computational models. There is little understanding, however, of how PC might be implemented at a mechanistic level in individual neurons, particularly within the auditory system. Using natural birdsongs, we examined responses of single neurons (n = 214) in caudomedial nidopallium (NCM), an analog of higher-order auditory cortex, in anesthetized European starlings listening to conspecific songs. We first trained a simple feedforward, single layer, temporal prediction model (TPM; Singer et al., 2018) to predict short segments (10.5 ms) of future birdsongs based on past 170 ms spectrographic samples while varying the number of TPM hidden units (256, 128, 64 and 32 units) to define a "latent" predictive feature space of corresponding dimensionality. To examine the predictive coding of NCM neurons, we modeled the composite receptive field (CRF) of each neuron, using the Maximum Noise Entropy method (MNE; Kozlov et al., 2016, Fitzgerald et al., 2011), in which the stimulus representation was either the short-time Fourier transform spectrogram or the projection of the spectrogram into a TPM latent space . This yielded a version of each neuron's CRF fit to either (1) all features of conspecific song (fft-CRF) or (2) only the predictive features of song (TPM-CRF). As a control, we also computed the CRF for the spectrogram projected into the latent space of an auto-encoder (AVGN; Sainburg et al., 2020) matched in dimensionality to the TPM. The TPM-CRFs yield significantly better predictions of each neuron's empirical spiking response to novel song, accounting for 60.41% of the response variance (mean r = 0.71±0.04), compared to both the fft-CRF ($p < 3.1 \times 10^{-32}$, paired t-test) and the AVGN-CRF ($p < 1.1 \times 10^{-35}$, paired t-test). The AVGN-CRFs also outperformed the spectrogram-based fft-CRFs. Almost all of the observed CRF model improvement can be attributed to the contribution of non-linear CRF components; the linear component of all the CRF models yielded similar response predictions. Thus, the auditory responses of NCM neurons are best modeled collectively by a signal representation that captures covariant structure in the predictive spectrotemporal acoustic features of song. This provides strong support for the notion of a predictive auditory code in songbirds.

Title: Visual stimuli modulate responses to single and multiple sounds in the macaque inferior colliculus

Authors: *M. N. SCHMEHL, J. M. GROH;
Neurobio., Duke Univ., Durham, NC

Abstract: Visual cues can influence brain regions that are sensitive to auditory space (for review, see Schmehl & Groh, *Annual Review of Vision Science* 2021). However, how such visual signals in auditory structures contribute in the perceptual realm is poorly understood. One particularly interesting possibility is that visual inputs help the brain distinguish among different sounds, allowing better localization of behaviorally relevant sounds in a noisy environment (i.e., the cocktail party phenomenon). Our lab previously reported that when two sounds are present, auditory neurons may switch between encoding each individual sound across time (Caruso *et al*., *Nature Communications* 2018). We sought to study how pairing a light with one of two sounds might change these time-varying responses (e.g., Atilgan *et al*., *Neuron* 2018).
To test this, we trained one rhesus macaque (*Macaca mulatta*, female, 14 years old) to localize one or two sounds in the presence or absence of accompanying lights. While the monkey performed this task, we recorded extracellularly from single neurons in the inferior colliculus (IC), a critical auditory region that receives visual input and has visual and eye movement-related responses. We found that pairing a light with a sound can change an IC neuron's response to that sound, even if the neuron is unresponsive to light alone. Further, when two sounds are present, pairing a light with one of the sounds can change a neuron's time-varying response to the two sounds. Together, these results suggest that the IC alters its sound representation in the presence of visual cues, providing insight into how the brain combines visual and auditory information into a single perceptual object.

Title: The impact of acoustic environment on noise invariance in the zebra finch auditory cortex

Authors: *S. M. MOSELEY[1], C. D. MELIZA[2];
[1]Dept. of Psychology, Univ. of Virgina, Charlottesville, VA; [2]Dept. of Psychology, Univ. of Virginia, Charlottesville, VA

Abstract: Vocal communication requires the ability to detect a signal of interest within a background of competing sounds with similar acoustics (the "cocktail-party problem"). This ability has been attributed to neurons that selectively respond to a signal of interest while being robust to increasing levels of background noise. Noise-invariant neurons have been observed in several nonhuman species, but it is not yet known how they develop. We hypothesize that noise-invariance requires early experience in complex acoustic conditions. Zebra finches (*Taeniopygia guttata)* are an excellent model for studying communication in noise to test this hypothesis. Because zebra finches live in large colonies, not only must adults solve the cocktail-party problem, but young fledglings need to isolate their tutor's song from the colony background in order to learn and copy that song into adulthood. We predict that this early exposure to colony noise instructs the development of noise-invariant neurons in the zebra finch pallium. We expect that the effects of the absence of colony noise on noise-invariance can be seen as early as the song learning phase of zebra finch development and that these differences in noise-invariance will persist into adulthood. To test this, we reared birds in either the presence or absence of colony noise. Single-unit recordings were performed across the auditory pallium in both song-learning juveniles and adults. During recording, subjects were presented conspecific stimuli embedded in colony noise at varying signal-to-noise ratios. To quantify noise-invariance, neural responses to original stimuli and stimuli embedded in noise were compared using average firing rates and a linear decoder. Consistent with predictions, average firing rates are more noise-invariant in song-learning juveniles that were raised with colony noise.

Title: A default role of the auditory cortex in goal-directed discrimination learning

Authors: *C. DRIEU[1], Z. ZHU[1], A. WANG[1], K. FULLER[1], S. ELNOZAHY[1], S. OSTOJIC[2], K. KUCHIBHOTLA[1];
[1]Johns Hopkins Univ., Baltimore, MD; [2]Ecole Normale Superieure, Paris, France

Abstract: Learning how to optimally respond to cues in the environment is crucial for survival. Previously, we showed that goal-directed learning can be dissociated into two behavioral phases: rapid 'acquisition' in which stimulus-action contingencies are learned, and slower 'expression' that gradually reveals the learned content. At the neuronal level, the auditory cortex (AC) is well positioned to play a role in both learning processes as it receives sensory, motor, valence and contextual signals. However, whether and how the AC is involved in both learning processes is unknown. We address this using probabilistic optogenetics and two-photon calcium imaging over learning. We train mice on a pure tone, go/no-go task where mice learn to lick to a tone (S+) and withhold from licking to another (S-); contingency learning is assayed daily using probe trials when reinforcement is unavailable. We optogenetically inactivate the AC on 90% of reinforced trials during learning and measure behavioral performance on probe trials (no inactivation). We observe a robust delay in learning, suggesting a critical role for the AC in contingency acquisition. In separate mice, we test the role of AC in expression by inactivating AC on 50% trials during learning and comparing trials with and without inactivation. Mice discriminate poorly when AC is inactivated early in learning. Surprisingly, this deficit gradually wanes and by the end of learning is only minimally present. These data argue that the AC enables expression but then teaches itself out. How then are these learning phases implemented in the AC? To address this, we use longitudinal, two-photon calcium imaging of the same large population of excitatory neurons in L2/3 of AC over learning (1,050±124 neurons/mouse). We isolate learning-related dynamics by comparing mice learning the task (n=4) to those passively listening to the same tones (n=2). To uncover low-dimensional structure in our high-dimensional data, we use clustering methods and unsupervised low-rank tensor decomposition (TCA). We observe distinct neural clusters whose stimulus selectivity evolve at the rates of acquisition and expression. Interestingly, learning enhances S- representation more prominently than the S+, suggesting a feedforward role in behavioral inhibition. TCA preliminarily reveals a striking reward component in which S+-responsive neurons shift to firing during reward consumption, suggesting a direct role in reward learning. Overall, our work suggests a default but temporary role for the AC in discrimination learning that is mediated by a network that shifts from being largely stimulus-driven to one that is optimized for behavioral needs.

Title: Filtering properties of the auditory cortex of mice during attentive listening

Authors: C. BARDIN[1], S. WOLF[1], L. SWALES[1], A. LOURDIANE[1], A. MOLINERI[1], L. BOURDIEU[1], C. VENTALON[1], S. A. SHAMMA[2], Y. BOUBENEC[2], ***J.-F. LEGER**[1];
[1]CNRS - Ecole Normale Superieure, PSL, Paris, France; [2]Lab. des Systemes Perceptifs, Paris, France

Abstract: Auditory attention is a rich and complex process that allows the mind to select specific information. It provides us with the ability to focus only on a fraction of our acoustic environment, as for instance when we attend to a single speaker's voice in a multi-speaker background. It has been shown in ferrets and in mice that attention can modulate the activity in the primary auditory cortex (A1). Sound feature encoding and extraction at this first cortical stage depend not only on the physical nature of the acoustic stimuli, but also on whether listening is performed passively or during an active task. However, although active listening is thought to help select relevant sounds from the noisy background, it is still unclear how A1 modulation leads to a filtering process. Previous studies have shown conflicting observations in A1, with either an increase (Fritz et al. Nat.Neurosci 2003) or decrease (Otazu et al. Nat. Neurosci. 2009) in the selectivity of A1 neurons to sounds on which attention is focused, or a combination of both (Kuchibhotla et al. Nat. Neurosci. 2016). How these different categories of modulation may contribute to a filtering attentional process and ultimately enhance effective perception of target or noisy sounds remains elusive. We address this question by recording the superficial layers of A1 with two-photon microscopy in mice performing either an operant auditory discrimination task or passively listening to the same sounds. We developed an approach to monitor the animal's readiness for the task, using fine movements of body parts extracted with DeepLabCut. This monitoring shows that our expert mice mobilize their attentional resources based on the structure of the protocol that presents active and passive trials in distinct blocks, with only 2-3 trials required to understand any block category transition. Optical recordings reveal strong inhibition in response to the target sound during attentive episodes for the majority of cells in the supragranular layers. However, a minority of neurons remain strongly responsive to the target, increasing the contrast between them and the rest of the silenced cells in A1, and resulting in a potential global filtering effect for the brain structures reading this A1 activity. Further characterization of this minority of cells shows that a fraction is also active when the reward is expected, suggesting a role that goes beyond the strict perception of acoustic information.

Title: Movement-related activity in auditory cortex changes as mice learn to expect a self-generated sound

Authors: *W. ZHOU, N. AUDETTE, D. M. SCHNEIDER;
Ctr. for Neural Sci., New York Univ., New York, NY

Abstract: To properly process sensory stimuli generated by one's own movements, the brain may use predictive processing in which copies of movement information are used to modulate sensory responses to self-generated stimuli. In mouse auditory cortex (ACtx), baseline and sound-triggered activity are influenced by movement, including a marked suppression of sound-evoked responses during movement compared to rest. This suppression of sound responses during movement can be shaped by learning to reflect the properties of self-generated sounds. Here, we show that activity in ACtx right before an expected self-generated tone is also modulated by movements and may contain information about the upcoming sound. We developed a simple task in which mice push a lever and hear a predictable self-generated tone. We recorded the activity of neurons in auditory cortex on the first and last days of training with the sound-generating lever. We found that baseline population firing rates in ACtx ramp up several hundreds of milliseconds before the self-generated tone and continue until the sound is heard. Both regular-spiking (RS) and fast-spiking (FS) units are involved in the ramping-up; and the change is much more strongly observed in deeper layers. Comparing the last session of training to the first, we noticed that the increase of pre-tone activity becomes more significant with learning, especially among those units that are responsive to the expected self-generated tone frequency. This change in activity was particularly concentrated in RS neurons. Across animals, the change in pre-tone activity before and after learning was weakly correlated with emergence of predictive suppression during sound playback. Together, these findings suggest that pre-tone activity during movement in ACtx may facilitate the processing of self-generated sounds.

Title: Spatial and temporal precision of inhibitory and excitatory neurons in the murine dorsal lateral geniculate nucleus

Authors: A. S. GORIN[1], S. AHN[1], V. SURESH[2], U. M. CIFTCIOGLU[1], Y. SU[3], Y. MIAO[1], F. T. SOMMER[4], J. A. HIRSCH[1];
[1]Neurobio., [2]Biol. Sci., [3]USC, Los Angeles, CA; [4]Univ. California, Helen Wills Neurosci Inst., Helen Wills Neurosci. Inst., Berkeley, CA

Abstract: Local inhibitory interneurons within the dorsal lateral geniculate nucleus (dLGN) of the thalamus innervate relay cells and each other to influence every spike sent to cortex. Visual processing in dLGN has been studied mainly in cat, where almost all relay cells have receptive fields made of two concentric subregions, a center and a surround, that have the opposite preference for stimulus polarity. Further, there are push-pull responses within each subregion—e.g. bright stimuli placed in an On subregion excite and dark ones inhibit. Push is supplied by retinal ganglion cells that have the same center sign as the target cell. Because local interneurons in cat also have center-surround receptive fields, we hypothesized that they synapse with relay cells of the opposite center sign to provide pull. It is difficult to target interneurons *in vivo*, however, and study their responses in depth. Moreover, pull is only one example of inhibition in dLGN; computational studies, for instance, suggest that inhibition from local interneurons in cat dLGN improves temporal precision in relay cells. Thus, with the dual goals of learning about intrathalamic inhibition and how this compares across species, we turned to mouse and used optogenetics to target interneurons. Our previous work showed that the largest single class of murine relay cells had center-surround receptive fields with push-pull responses; most other relay cells had various types of overlapping On-Off responses. This diversity suggested that mechanisms and forms of inhibition differ across species. Using spike-triggered analyses, we identified murine interneurons with On, Off, On-Off, and center-surround receptive fields and also found that the range of receptive-field sizes was similar for interneurons and relay cells. Thus, individual interneurons can provide feature-specific inhibition to their targets. Given that relay cells and interneurons provided information over similar spatial scales, we asked if they fired with equivalent temporal precision by calculating the reliability of spike trains across repeated presentations of natural movies shown at different contrasts. Although, a subset of interneurons were as temporally precise as the most reliable relay cells, as a population,

interneurons were less precise. In addition, relay cells fired with increasing reliability as stimulus strength reached the maximum, but this trend was less robust for interneurons and saturated at lower contrasts. Thus, our results suggest inhibition generated within dLGN conveys diverse visual features, varies over a wide range of spatial scales, can be precisely timed, and is sensitive to stimulus contrast.

Title: Structure and function relationships of interneurons in the carnivore and rodent lateral geniculate nucleus of the thalamus

Authors: *S. AHN[1], R. MELTZER[1], A. KUMAR[1], A. GORIN[1], D. ALSTON[2], V. SURESH[1], M. A. FOX[3], J. A. HIRSCH[1], M. E. BICKFORD[2];
[1]USC, Los Angeles, CA; [2]Univ. of Louisville, Louisville, KY; [3]Virginia Tech. Carilion Res. Inst., Roanoke, VA

Abstract: Local interneurons in the dorsal lateral geniculate nucleus (dLGN) of the thalamus influence every spike visual cortex receives; they provide feedforward inhibition to each other and to relay cells. Here, we focused on understanding structure/function relationships in inhibitory circuits in dLGN from a comparative perspective using species with good (carnivore) versus poor (rodent) visual acuity. Our anatomical studies were motivated by whole-cell recordings from thalamic interneurons in vivo. For carnivore interneurons, membrane currents were dominated by serial, unitary inhibitory postsynaptic currents, each of which was preceded by a depolarizing notch. These recordings suggested the presence of triadic circuits in which pairs of interneurons share input from the same retinal afferent and connect with each other via dendrodendritic synapses. By contrast, recordings from rodent interneurons exhibited trains of unitary excitatory postsynaptic currents, indicating different types of connectivity between species. To explore synaptic connections in inhibitory circuits, we first used transmission electron microscopy to analyze single sections of GABA-stained tissue of ferret and mouse. Our

results revealed numerous dendrodendritic synapses between interneurons. To gain a fuller view of synaptic arrangements that include interneurons, we made 3D reconstructions using tissue prepared with serial block-face scanning electron microscopy. We found triads involving two interneurons in both species; however, there was great variation between species. First, there were substantial differences in the composition of synaptic glomeruli, the structures in which triadic circuits usually occur. In carnivore, glomeruli involved a large central retinal bouton surrounded by several interneuronal dendrites. Rodent glomeruli, conversely, comprised only few interneuronal dendrites encircled by small retinal boutons, and the interneurons that participated in triads also received input from multiple retinal terminals. In addition, in carnivore alone, we found interneuronal dendritic segments that did not receive retinal input but formed many connections with other interneuronal dendrites. Further, dendrodendritic synapses between interneurons were evenly distributed between shafts and appendages in carnivore but concentrated on appendages in rodent. These results suggest that there is a more powerful and flexible inhibition in carnivore versus rodent dLGN.

Abstract: Visual information from retina is processed by neural circuits in the dorsal lateral geniculate nucleus (LGN) of the thalamus prior to reaching cortex. Almost all relay cells in dLGN of highly visual animals have receptive fields with a stereotyped profile--a center-surround arrangement of On and Off subregions that have push-pull responses to stimuli of the opposite contrast (i.e., where a bright stimulus excites, a dark one inhibits and vice versa). This is the most common receptive field structure for relay cells in the rodent geniculate as well (~ 40%). The remaining relay cells have variations of On-Off responses that are sometimes sensitive to stimulus direction or orientation, properties that inhibition appears to sharpen. We asked how local interneurons might contribute to push-pull and other forms of inhibition in

mouse. To address this issue, we developed a preparation that allows us to identify interneurons optogenetically during multielectrode recordings. We tested competing hypotheses about whether or not interneurons provide a one-size-fits-all form of inhibition to relay cells, as is largely the case in mouse cortex, or if the inhibition they provide is feature specific. Our results lend support for the latter idea--interneurons had diverse types of receptive fields, including center-surround, On, Off, On-Off varieties.
Our ultimate aim is to learn how interneurons influence the spike trains relay cells transmit to cortex. Toward this goal, we have begun to build computational models that predict responses of each type of interneuron we sampled. This step is necessary because it is impossible to optimize stimuli (e.g., size, contrast) for every cell, given that recording times are limited and multiple units are mapped at once. Thus, we used a generalized linear model framework to fit changes in firing rate of optotagged interneurons elicited by sparse-noise stimuli (bright and dark squares flashed separately at randomized positions in the stimulus grid), using two linear components in the case of On-Off cells. These models performed well, achieving values for explained variance of 70% or above. Our next step will be to build integrate-and-fire models of murine relay cells. Then, we will transform the interneurons' spike trains to synaptic conductances and combine these with the integrate-and-fire models to explore how inputs from different types of local interneurons might generate the patterns of visually-evoked inhibition we have observed during whole-cell recordings from relay cells.

Title: The mouse vLGN circuit organization underlying its role in visual behaviors

Authors: *C. BEIER, M. THURMAN, M. THOMSEN, R. KOMAL, S. HATTAR;
Section on Light and Circadian Rhythms, Natl. Inst. of Mental Hlth., Bethesda, MD

Abstract: Light perception is parsed into retinal pathways that drive image-forming vision (pattern vision, gaze control) or directly affect light-influenced behaviors (circadian photoentrainment and the effects of light on sleep, feeding, pupil size and mood). Retinal ganglion cells (RGCs) convey visual features such as color or motion to targets in the brain.

Light-influenced behaviors are driven by a subset of RGCs, the intrinsically photosensitive RGCs (ipRGCs). Understanding visual feature integration or segregation in the brain is key to understanding how mammals respond to their environment. The mouse ventral lateral geniculate nucleus (vLGN) provides a unique opportunity to investigate this, as it is the only brain region to receive both convergent (rostral vLGN) and divergent (caudal vLGN) innervation from image-forming RGCs and ipRGCs. Here, we investigate the circuit organization and function of the mouse vLGN.We mapped efferents and afferents of vLGN *Penk*^{Cre} and *Nos1*^{Cre} cell types with Cre-dependent anterograde viruses and monosynaptic rabies G-deleted virus. Chemogenetic manipulation, using Tetanus toxin (TenT) or excitatory DREADD with CNO to silence or activate cells, revealed the role of vLGN *Penk*^{Cre} cells in modulating pupil size. We then investigated *c-Fos* induction within the vLGN following circadian phase shifting light pulses.The rostral vLGN does not show the same cellular stratification as the caudal vLGN. *Penk*^{Cre} cells send projections to the suprachiasmatic nucleus (SCN) and the olivary pretectal nucleus. *Nos1*^{Cre} send projections to the SCN. *Penk*^{Cre} cells, but not *Nos1*^{Cre} cells, in the caudal vLGN are post-synaptic to ipRGCs. *c-Fos* induction in the caudal vLGN increases in *Penk*^{Cre} cells in response to a phase advancing light pulse but shows minimal change to a phase delaying light pulse compared to dark controls. Silencing/activating vLGN *Penk*^{Cre} cells causes an increase/decrease in pupil constriction during a light step.We find that circuit organization in the vLGN changes along the rostral-caudal axis and reflects retinal innervation to the vLGN. Not only do *Penk*^{Cre} cells modulate pupil size, but our data suggests they may modulate phase advancements in response to a light pulse. *Nos1*^{Cre} cells, which stratify with image-forming RGC inputs, also send projections to the SCN and could play an unexpected role in circadian photoentrainment. Taken together, this suggests the caudal vLGN circuit organization maintains visual feature segregation to modulate pupil size but integrates visual features to modulate circadian photoentrainment.

Title: Distinct contributions of arousal and movement to visual responses in dLGN

Authors: *K. PEELMAN[1], A. DEL CASTILLO VALERIO[2], B. HAIDER[1];
[1]Biomed. Engin., Georgia Tech. and Emory Univ., Atlanta, GA; [2]Georgia Inst. of Technol., Atlanta, GA

Abstract: Neural responses to sensory inputs depend on behavioral factors such as changes in arousal, movement, and cognition. These effects have been measured throughout cortex but less so in thalamus. Studies of head-fixed mice agree that locomotion strongly affects responses in visual cortex, but effects in lateral geniculate (dLGN) remain unclear; some studies suggest no impact of locomotion, while others suggest increased baseline and evoked activity, with broadening of visual spatial selectivity. Locomotion partly exerts these effects by increasing arousal, as inferred by measuring pupil dilation. It remains unclear how arousal impacts visual responses in dLGN in the absence of locomotion, and if this affects spatial selectivity. We addressed these questions by recording continuous changes in pupil size and periorbital facial movements in awake, head-fixed, stationary mice (n = 6), while simultaneously recording dLGN neurons (n=288) with high-density NeuroNexus and Neuropixels probes. We used pupil area to distinguish high and low arousal levels, and distinguished high and low motion energy due to spontaneous movements of the face and eye. We presented visual stimuli (7° squares, 0.1s duration) spanning > 90° of one visual hemifield, and examined spatiotemporal responses in the receptive field (RF) as a function of pre-stimulus arousal and motion energy levels. We found that arousal level shaped dLGN responses more strongly than movement. Baseline firing was significantly greater with higher versus lower arousal ($p<0.05$). These effects were not simply reflective of movement: baseline firing was similar across trials with low versus high motion energy ($p = 0.10$). However, visually evoked activity was significantly reduced at high arousal ($p<0.05$), and these effects were also not entirely due to movement: evoked firing was similar for low versus high motion energy ($p = 0.80$). Finally, we examined effects on spatial selectivity by measuring changes to RF width. RF widths were preserved across arousal levels (9.7° vs 9.2° ; $p=0.20$), despite significant changes to spontaneous and evoked firing. However, RF widths were significantly greater (9.8° vs 8.9°; $p<0.05$) during trials with high versus low levels of movement, and this broader spatial selectivity was most apparent on trials with high arousal ($p<0.05$). Our preliminary results suggest that in stationary mice, arousal level modulates spontaneous and visually evoked activity of dLGN neurons with minimal effects on spatial selectivity. These effects are not simply explained by movement levels. Movement does appear to broaden spatial selectivity, but only when arousal is also elevated.

Title: Correlating extracellular spike shapes and neuronal responses in the lateral geniculate nucleus of awake macaques

Authors: *S. SUN[1], J. S. PEZARIS[2];
[1]Dept. of Neurosurg., [2]Massachusetts Gen. Hosp., Boston, MA

Abstract: Have we identified all cell types in the lateral geniculate nucleus of the thalamus (LGN)? Unlike the exhaustive determination of the retina, key populations in LGN may have been missed through sampling bias. Of retinal cells projecting to LGN, 80% carry signals associated with classic thalamic responses. We want to identify the missing 20% through rigorous analysis of LGN recordings in awake monkeys.

Extracellular spikes (or action potentials) are instrumental in studying neuronal responses. Spikes are dominated by brief negative-voltage excursions when measured with traditional extracellular metal electrodes, caused by the action of sodium and potassium channels. Spike waveforms have been used to classify the visual pathway cells into either regular-spiking or fast-spiking units, commonly associated with excitatory and inhibitory neurons, respectively. With the development of dense multi-electrode arrays (MEA) and sophisticated spike-sorting algorithms we can now sample the brain, and in particular the LGN, with detailed identification of spike waveforms and reduced sampling bias to reveal previously overlooked signals.

Using these tools, we attempt to characterise the full range of neuronal responses in the LGN of awake monkeys. We find three distinct classes of spike waveforms: negative-dominant waveforms (55%) consistent with what is commonly reported as regular- or fast-spiking or broad- and narrow- spiking; triphasic waveforms (23%) that are like negative-dominant waveforms but have an initial positive peak; and positive-dominant waveforms (22%) that are not often reported in the literature. We correlate these spike classes against the response characteristics of corresponding cells to visual mapping stimuli to identify relationships between spike shape and neuronal class (magnocellular, parvocellular, koniocellular or, importantly, other). A little more than half of the cells (58%) had their receptive field (RF) successfully mapped. Out of the remaining non-mapped LGN cells, 89% responded (with statistical significance) to the mapping stimulus versus the immediately preceding uniform screen. This observation indicates that, due to the sampling biases inherent with traditional electrodes, the population of LGN cells may be broader than what we originally thought as standard. The ongoing effort will answer the question of what spike shapes and visual responses characterise the missing 20% of LGN cell types.

Title: Spike encoding of increment sensitivity in macaque retinal ganglion cells and LGN neurons

Authors: *K. M. RAMSEY[1], L. C. SINCICH[2];
[1]Optometry and Vision Sci., UAB Neurosci. Grad. Programs, Birmingham, AL; [2]Dept. of Vision Sci., Univ. of Alabama At Birmingham, Birmingham, AL

Abstract: Retinal ganglion cells (RGCs) and neurons in the lateral geniculate nucleus (LGN) shape the visual signals conveyed from the retina to the brain. At the perceptual level, the intensity response function of individual cone photoreceptors varies between cones and depends on distance from the fovea (Harmening et al. 2014). As a result, we wondered if psychometric thresholds from single cones are limited by RGC or LGN spiking responses, which may be seen by computing comparable neurometric functions. We analyzed optic tract and LGN extracellular recordings made during receptive field center stimulation in response to increasing increment contrast steps (Sincich et al. 2007). Fourteen ON cells were analyzed: 7 parasol, 2 midget, 2 parvocellular, and 3 magnocellular. We examined 3 spike coding techniques as a function of time over each stimulus trial: spike count, summed instantaneous spike frequency (ISF), and summed probability of LGN spiking given an RGC spike train (P(spike)). These data were fit with 3 neurometric functions: Michaelis-Menten, exponential, and logistic. Estimated threshold values were defined as the half-height response in the fits. Response suppression at high contrasts was evident in 6 parasol cells; fitting for these was done only on the rising arm of the data. Three parasol cells were excluded because sampling at low contrasts was insufficient to produce useful fits. Other cells did not show suppression at high contrasts. The logistic function fit the summed P(spike) data better than the other two fitting functions; this was true for all RGC cells. For most cells, summed ISF fits resulted in the highest threshold estimates compared to the fits for spike count or summed P(spike), while fits of spike count tended to result in lower thresholds. RGC threshold values were lowest for parasol cells, averaging ~0.5 log units below midget cells. In contrast, the average difference between magnocellular and parvocellular neurons was negligible; however stimuli were not luminance matched for these cells. Parasol cells had steeper neurometric slopes than midget cells, for all fit types. Parvocellular and magnocellular neurons had similar slopes regardless of fit type. These exploratory analyses show more diversity in the neurometric function between RGC cell classes than LGN cell classes, suggesting sensitivity to contrast will be more distinct at the retinal level than the thalamic level. Future work will examine how these analyses may be used for responses to single cone targeted

stimulation, and help set contrast ranges for experiments that may identify the relationship between neurometric functions and human psychometric performance.

Title: Identifying the layers in the human LGN using quantitative and functional MRI

Authors: *I. YILDIRIM[1], K. HEKMATYAR[2], K. A. SCHNEIDER[1,2];
[1]Dept. of Psychological and Brain Sci., [2]Ctr. for Biomed. and Brain Imaging, Univ. of Delaware, Newark, DE

Abstract: Identifying the magnocellular (M) and parvocellular (P) parts of human lateral geniculate nucleus (LGN) has been challenging yet remains an important goal because of the different functional properties of these pathways in the brain. Previous research used the magnitude of responses to different types of stimuli that bias M and P regions (e.g. Denison et al., 2014). However, a problem with this functional separation has been raised due to the hilum of LGN showing higher response amplitudes (DeSimone & Schneider, 2019), confounding the responses to tailored stimuli. To resolve the discrepancy in the literature, we have employed three methods that do not depend on stimuli-tuned responses to anatomically and functionally segment the LGN layers. **Method:** Three participants were scanned with a 3T Siemens Prisma magnetic resonance imaging (MRI) scanner in multiple days. We used a quantitative method (qMRI) measuring T1 relaxation time (qT1) as well as two functional MRI (fMRI) experiments to measure the eye dominance signals in LGN. For the qMRI scans, an MP2RAGE sequence (0.7 mm isotropic, TR = 5 s, TE = 3.6 ms, TI_1/TI_2 = 0.9/2.75 s, α_1/α_2 = 3/5°) was used to calculate qT1 maps. By averaging 16 qT1 maps of each subject, we outlined the six LGNs. For the fMRI scans (multiband sequence, 1.5 mm isotropic, TR = 1.5 s, TE = 39 ms), two visual tasks were used in separate days in ten 5-minute sessions. In one task, subjects viewed a checkboard flickering at 4Hz while alternately opening one eye and closing the other for 15 s. In the second task, both eyes remained open but a grating rotating at 1 cycle/s was shown alternating between eyes using a polarizing filter synchronized to a ProPixx projector and polarized glasses. **Results:** By fitting the qT1 maps in each LGN to a 2-component Gaussian mixture model, we separated the M and P regions. These regions were in line with the anatomical expectations; the dorsolateral P voxels had shorter T1 relaxation than M voxels, suggesting more myelination in

the P layers. With the fMRI data, we aimed to identify the contralateral eye layers of the M and P as these are distant in LGN. The categorization of the eye dominance was correlated but not entirely consistent between the two tasks. The organization of the contralateral layers were more accurate with the task having one eye closed at a time; nevertheless, the contralateral M layer did not appear reliably, probably due to this layer being thin and most ventral. **Conclusion:** These results indicate that functional segregation of the LGN remains challenging. We suggest that using quantitative methods are more promising to identify M and P layers and multiple methods should be used to reliably segregate the layers functionally.

Title: Excitotoxic lesions in the ferret retina differentially impact X and Y dorsal lateral geniculate neurons

Authors: *J. YANG[1], K. R. HUXLIN[2], F. BRIGGS[1];
[1]Dept. of Neurosci., [2]Flaum Eye Inst., Univ. of Rochester, Rochester, NY

Abstract: The dorsal lateral geniculate nucleus (dLGN) of the thalamus relays the majority of inputs from the eyes to the brain. It contains physiologically distinct neuronal types that make up parallel processing streams for incoming visual information. Although much is known about the functional properties of dLGN neurons in the intact visual system, surprisingly little is known about neurophysiological changes that may occur after removal of retinal input, as may occur in retinal disease. Here, we address two significant, open questions: 1) what happens neurophysiologically when the dLGN is deprived if its retinal input; and 2) does loss of retinal input differentially impact dLGN neurons in the parallel streams? We induced excitotoxic lesions of the retina in ferrets by injecting kainic acid (KA) into one eye. We verified retinal ganglion cell (RGC) loss in the lesioned eye with electroretinography and Optical Coherence Tomography. We measured visually evoked potentials, the thickness of the retinal nerve fiber layer, and counted fluorescently-tagged RGCs. We also recorded from dLGN neurons contralateral and ipsilateral to the KA-injected eye using multi-electrode arrays and measured their responses to a variety of visual stimuli including drifting sinusoidal gratings and white noise m-sequences. Our preliminary data suggest that RGCs with large somas are preserved

compared to those with small somas in the injected ferret retinas. Correspondingly, we observed normal transient responses but altered sustained responses among dLGN neurons recorded contralateral to the lesioned eyes. Some dLGN neurons contralateral to the lesioned eye exhibited spatial receptive fields that reflected enhanced cortical input. Together, these findings show that the Y retinogeniculate pathway may be less susceptible to degeneration compared to the X pathway. The alteration in spatial receptive field structure also suggests that dLGN neurophysiology may shift to reflect intact corticogeniculate input. Together, our findings reveal that retinal lesions produce changes in both the temporal and spatial receptive fields of dLGN neurons, although these effects may vary across the parallel streams.

Title: What is a face (neuron)? A psychophysics study of synthetic preferred stimuli for face-selective neurons

Authors: A. BARDON[1], *W. XIAO[2], C. R. PONCE[3], M. S. LIVINGSTONE[4], G. KREIMAN[2]; [1]Caltech, Pasadena, CA; [2]Harvard Univ., Boston, MA; [3]Neurosci., Washington Univ. At St. Louis, Saint Louis, MO; [4]Harvard Med. Sch., Boston, MA

Abstract: In the primate, inferior temporal cortex (IT) is known to contain neurons that show generally stronger activity in response to images of faces compared to images of other objects. These so-called ‘face neurons’ have been studied extensively, but there remain questions about how well this designation captures their functional properties. Ideally, a face neuron’s responses should align with the subjective perception of a face. Yet, face neurons also respond to clocks, fruits, single eyes, and other objects that share features visually related to but dissociable from faces. To define the functional properties of face neurons more thoroughly, we used a recently described algorithm, XDream (Ponce, Xiao et al. 2019), to synthesize stimuli that strongly activated classically defined face-selective neurons in macaque monkeys; we did the same with non face-selective neurons. A key advantage of XDream is that it can create stimuli not limited to realistic pictures or object categories. We then asked human participants to assess the content of the synthetic images and natural photos (face and non-face objects including cars, fruit, etc.), with particular focus on how much images were perceived as being face-like. We found that while subjects perceived animal features in synthetic images, they generally did not perceive

synthetic images as particularly face-like. Nevertheless, synthetic images tailored to face-selective neurons were perceived as more face-like than control non-face photos and than synthetic stimuli tailored to non face-selective neurons. Moreover, among natural images, there was significant correlation between the subjects' 'faceness' ratings and face-neuron responses to images, even only among non-face images. However, this correlation was reduced when including synthetic images, which received relatively low faceness ratings yet evoked some of the highest firing rates. In summary, we discovered novel stimuli that evoked high firing from face neurons, are perceived as somewhat face-like by humans, yet are clearly not faces. This shows that face neurons are not as categorically tuned as was previously hypothesized. These results are compatible with other recent work on IT, suggesting that IT may be better described as tuned to visual features rather than semantic or perceptual categories.

Title: Towards developing a nonhuman primate model to dissect the neural mechanisms of atypical facial emotion processing in autism spectrum disorder

Authors: *K. KAR;
McGovern Inst. for Brain Res., MIT, Cambridge, MA

Abstract: Recognizing others' moods, emotions, and intent from facial expressions lies at the core of human interpersonal communication and social engagement. This relatively automatic, visuocognitive feature that neurotypically developed human adults take for granted show significant differences in children and adults with autism spectrum disorder (Adolphs et al. 2001). Rhesus macaques are one of the most appropriate animal models to investigate these vision-based, social behaviors because 1) macaques' ability to perform human-like facial emotion recognition 2) our ability to perform targeted fine-grained neural measurements and perturbations in macaques 3) the relevance and translational value of the experimental inferences given the established brain homologies between humans and macaques. Furthermore, we can map the sensory representations across the macaque visual pathways onto specific parts of current artificial neural network (ANN) models of primate vision (Yamins et al., 2014; Kar et al., 2019) to generate specific neural circuit level hypotheses. Here, first I have used macaque brain-tissue mapped artificial neural network (ANN) models of primate ventral stream as a neural circuit level hypotheses generation tool. Interestingly, the ANNs' image-level behavioral patterns

better matched the neurotypical subjects' behavior than those measured in the ASD population (stimuli and task adopted from the Wang and Adolphs, 2017 study). This behavioral mismatch was most remarkable when the ANN behavior was decoded from units corresponding to the primate inferior temporal (IT) cortex. ANN-IT responses also explained a significant fraction of the image-level behavioral predictivity associated with neural activity in the human amygdala (Wang et al. 2017), strongly suggesting that the previously reported facial emotion intensity encodes in the human amygdala could be primarily driven by projections from the IT cortex. Second, preliminary results from both neural recordings in the macaque IT cortex and corresponding behavioral measurements are consistent with these ANN predictions. Taken together, these results support the use of an ANN-guided approach towards developing an NHP model to investigate the neural markers of atypical facial emotion processing in ASD.

Title: Is that...a monkey? Macaques detect conspecific features in images synthesized by ventral stream neurons.

Authors: *K. MUELLER[1,2], M. BURKEMPER[1], C. R. PONCE[1,2];
[1]Neurosci., Washington Univ. in St. Louis, St. Louis, MO; [2]Neurobio., Harvard Med. Sch., Boston, MA

Abstract: Prototype theory suggests we categorize objects by comparing them to an abstracted average, an internal “prototype” of examples we have experienced (Rosch, 1973; Leopold et al., 2001). If true, this suggests neurons may encode abstractions of key visual attributes in the natural world. We recently showed images can be synthesized under the guidance of neurons from the macaque ventral stream using naturalistic image generators and search algorithms (Ponce, Xiao et al., 2019). When applied to neurons in inferotemporal cortex (IT), this approach often generated images with visual attributes present in pictures of monkeys, as confirmed by neural networks and human visual judgements (Bardon et al. and Kreiman, in prep.). However, it is unknown if monkeys find any similarity between these response-optimized images (termed “prototypes”) and images of conspecifics. Do monkeys find some prototypes are monkey-like and, more fundamentally, can they abstract visual features from photographs? To pursue these questions, we implanted two macaques (A and B) with chronic microelectrode arrays in areas

V1, V4, and IT and synthesized prototypes from single- and multiunit activity. The animals were then trained in a forced decision task in which a pair of images was presented - one sampled from a target category (e.g., monkeys) and another from a distractor category (e.g., wheels, flowers). Making a saccade to the target image resulted in a large reward; distractor choices triggered a time-out. Training photographs were recreated using the generator to control for visual style. When subject performance surpassed 75%, probe trials were introduced and randomly rewarded. Probe image pairs included a neuronal prototype and a random generator image. When trained with conspecifics as the target category, monkeys selected IT prototypes over random generator images more often (A: 59%, SD = 2.5%; B: 78%, SD = 15.7%) and selected V1 prototypes less often (A: 43%, SD = 8.1%; B: 49%, SD = 9.7%). This suggests higher perceived similarity between monkey images and IT prototypes. Next, to validate task design and explore their ability to abstract image features, we trained the animals on geometry-based categories. Targets included scenes with triangular objects (e.g., road signs, hats, cones) and distractors included scenes with round objects (e.g., wheels, coins, balls). In probe trials following training, monkeys were more likely to choose artificial, solid-color triangles over solid-color circles (A: 78%, SD = 0.9%; B: 78%, SD = 0.5%). Together, these results suggest monkeys can abstract visual concepts from the natural world, and neurons of the ventral stream likely encode these concepts.

Title: The macaque ventral stream shows a hierarchical structure for animal-feature encoding

Authors: *Z. ZHANG[1], T. S. HARTMANN[2,3], M. S. LIVINGSTONE[2], R. T. BORN[2], C. R. PONCE[1,2];
[1]Neurosci., Washington Univ. in St. Louis, St. Louis, MO; [2]Neurobio., Harvard Med. Sch., Boston, MA; [3]Perceptive Automata, Boston, MA

Abstract: Are there organizing principles for information encoding along the primate ventral stream? Neurons in each visual area are often tested with different types of stimuli, ranging from simple (e.g., lines in V1) to complex (faces in inferotemporal cortex, IT); however, this strategy limits functional comparisons across areas. By comparing neuronal responses to a given stimulus set across areas, we set out to identify brain-wide organizing principles and determine if these

principles are shared by learning-based models of the ventral stream (convolutional neural networks, CNNs).
We measured the responses of neurons in V1, V4, and IT to large natural scenes (N = 6 monkeys, ~448 distinct cortical sites). We mapped responses in non-overlapping regions within each scene, interpolating these responses to every pixel — a technique inspired by weight-sharing convolutional operations of CNNs and applicable to the brain (Arcaro *et al.*, 2020). The resulting "feature maps" served as a common metric across brain regions and CNN layers. To interpret these maps, we (1) used the automated pipeline of DeepLab (Chen *et al.*, 2017) to segment objects within each scene and (2) recruited human annotators to segment each scene using labels independently assigned to it by Google Cloud Vision. Using these segmentations as masks, we tested whether neurons and hidden units in CNNs responded higher inside the masks than outside of them. We quantified this response difference using an area-under-the-curve-based statistic (AUC). As a control, we shuffled the response regions for each scene.
We found these segmentation masks predicted a hierarchy of responses across the ventral stream. Masks identified regions with increased neuronal activity for IT better than they did for V4, and for V4 better than for V1 (AUC mean ± SEM; IT: 1.09 ± 0.04; V4: 0.77 ± 0.03; V1: 0.43 ± 0.02). Notably, semantic masks isolated V1 responses better than they did for shuffled controls (AUC for shuffled maps, across areas: -0.02 ± 0.02 to 0.00 ± 0.01). Generally, CNNs did not show the same hierarchical relationship as the ventral stream, although CNNs with better BrainScore rankings (Schrimpf *et al.*, 2020) showed trends towards this pattern. Finally, classic saliency algorithms (GBVS, Harel *et al.*, 2006) produced maps that correlated best with IT feature maps (Pearson correlation; IT: 0.38; V4: 0.22; V1: 0.20).
Together, these results suggest the monkey ventral stream is partially organized to encode salient background-isolated objects, particularly those containing animal features —even within V1. We conclude that CNNs trained to prioritize animal-like representations may serve as better models of the ventral stream.

Title: Climb high and gaze far: mapping tuning landscapes of the ventral stream via image optimization and manipulation

Authors: *B. WANG[1,2], C. R. PONCE[1,2];
[1]Neurosci. Dept., Washington Univ. In St. Louis, Saint Louis, MO; [2]Neurobio., Harvard Med. Sch., Boston, MA

Abstract: Vision scientists often characterize neuronal function using tuning curves, defined as neuronal response as a function of a continuous variable. These variables are chosen *a priori* and often control geometric shape transformations (e.g., curvature). Tuning curves have been difficult to define in naturalistic image spaces, partly due to these spaces' high dimensionality and a lack of consensus on parameters. To study neurons in naturalistic image spaces, we used an image manifold parametrized by a deep generative network. Using an evolutionary algorithm (CMAES), we let each neuron "choose" its own image domain of interest via neuron-guided image search. Once a highly activating image evolved, we these experiments on two monkeys, driven by neurons recorded from V1/V2, V4, and IT. Using pre-trained CNNs as models of the visual hierarchy, we also conducted the same experiments in silico.
We found driving neurons across the ventral stream exhibited smooth, bell-shaped tuning peaks on the manifold, reminiscent of classical tuning curves. These peaks were wider and taller than those measured in classic spaces like orientation and curvature. When comparing the neuronal tuning along the ventral stream (from V1 to IT), we found tuning functions became sharper (per Kent function parameter κ, mean±SEM, V1, 0.7±0.1; V4, 1.8±0.2; IT, 3.2±0.3), image search converged more slowly (V1, 12±1 generations; V4, 21±3; IT, 29±2), and generator dimensionality required to achieve high activation became larger. We found these patterns also emerged in CNNs. These findings suggest that neurons in higher visual cortices encode combinations of visual attributes that are statistically rarer and more specific than those in early visual cortex. Finally, we developed data-driven CNN models to identify highly activating features contained within each evolved image. Using tensor factorization, these models can be interpreted as a spatial combination of filters encoding simpler patterns. The models reproduced the neuronal image search process *in silico*, predicted responses to other images and generated cleaner images that also activated the neuron highly. We found IT neurons needed a larger number of filters to model accurately (V1, 3.1±0.4; V4, 4.8±0.6; IT, 6.4±0.5), consistent with their more complex selectivity.
Together, these findings suggest that neurons in the ventral stream are well-designed to encode for image transformations spanning nearly all of image space. Our analysis pipeline extends classic approaches in vision with a novel paradigm that informs us of neuronal tuning in the natural world.

Title: As simple as possible, but not simpler: measuring the complexity of neural representations and their relationship to natural scenes

Authors: O. ROSE[1,3], J. K. JOHNSON[1], B. WANG[2,3], ***C. R. PONCE**[1,3];

Abstract: Fast and accurate visual object recognition is key to survival, allowing animals to identify food, predators, and conspecifics in their environment. Early theories of efficient coding suggested the visual system compresses the world by learning to represent features where "information was concentrated" (Attneave, 1954) such as contours, and emphasized that these features would be relevant to behavior (Barlow, 1961). These early views were validated by the discovery that neurons in posterior visual cortex respond to edges and curvature. Still, it remains unclear what other information-rich features are encoded by neurons in more anterior cortical regions such as inferotemporal cortex (IT). Here, we used a generative deep neural network to synthesize images guided by neuronal responses from across the visuocortical hierarchy (neurons at the border of V1/V2, V4 and IT). We refer to these images as "prototypes," as they are hypothesized to represent abstracted features of the visual world. We found IT neurons took longer to develop their prototypes compared to neurons in V1/V2 and V4, as expected if IT encodes more specific patterns. Prototypes varied across areas: V1/V2 prototypes frequently contained achromatic edges, while V4 and IT prototypes contained higher curvatures quantitatively associated with specific visual attributes present in faces, bodies, and fruits. Per measures of complexity such as minimal description length, prototypes were more complex than classic artificial stimulus sets, but less complex than images created spontaneously by the generator or encoded by neural networks. Additionally, prototypes resembled salient visual features and semantic content of natural images, as indicated by the animals' eye movements. Overall, these results suggest prototypes are learned information-rich features akin to contours, supporting the view that the neural code for object recognition is based on compressed features of behavioral relevance.

Title: Social information shapes intrinsic visual representations in ventrolateral prefrontal cortex

Authors: *O. ROSE[1,2], C. R. PONCE[1,2];
[1]Neurosci., Washington Univ. Sch. of Med., Saint Louis, MO; [2]Neurobio., Harvard Med. Sch., Boston, MA

Abstract: Prefrontal cortex (PFC) is thought to use sensory input to determine behavioral responses, with studies reporting flexible neuronal activity that tracks task demands. This flexibility is called adaptive coding (Duncan, 2001), and suggests PFC gains functional properties needed to solve a given task. However, studies investigating PFC function during passive fixation report maps of sensory organization (Wilson et al, 1993; Romanski & Goldman-Rakic, 2002; Haile et al, 2019). This raises questions: do individual PFC neurons have inherent sensory tuning? Does task learning induce sensory tuning in non-selective neurons or change existing selectivity in tuned neurons? Or do task demands recruit neurons with suitable selectivity? Here we characterized visual response properties of ventrolateral PFC (vlPFC) neurons in male macaques (C, D) trained only on passive fixation. We implanted 32-channel chronic microelectrode arrays, allowing for stable longitudinal recordings from the same cortical sites. We characterized inherent visual properties of these sites, mapping receptive fields (RFs) and selectivity with photographs and artificial images. We found a small subset of vlPFC sites with reliable RFs in both subjects, showing eccentricity (median ± SE) of 17.40° ± 0.11 (monkey C) and 11.43° ± 0.03 (monkey D). Additionally, up to 28% of the 32 vlPFC sites (C: 2.00 ± 0.02 sites; D: 6.00 ± 0.08) showed visual selectivity for individual images; this selectivity was best evoked by images of conspecifics, and could even be measured in sites without a classical RF. Selectivity was then assessed using ethological categories (e.g. macaque fear grin and perinea, fruit, human faces). This selectivity was linked to reward, with some vlPFC neurons showing significantly reduced reward responses after subjects viewed images of perinea or open-mouth threats. Up to 53% of vlPFC sites (n = 32) were selective following image presentation until reward delivery (median ± SE, C: 6.5 ± 0.05 sites; D: 2.5 ± 0.03), and up to 34% were selective following reward delivery (C: 4.5 ± 0.03 sites; D: 2.5 ± 0.02). We then used generative networks to synthesize highly activating images (“prototypes”) under guidance from these neurons (as in Ponce, Xiao et al., 2019). Prototypes contained visual attributes highly reminiscent of conspecifics, such as fur colors/textures, face- and body-like shapes. These results suggest many vlPFC sites have intrinsic visual tuning for conspecific social information. We are investigating if/how task learning changes inherent selectivity of these vlPFC sites, with the goal of characterizing acquired sensory coding schemes used by vlPFC neurons.

Abstract: A variety of electrophysiology tools are available to the neurosurgeon for diagnosis, functional therapy, and neural prosthetics. However, no tool can currently address these three critical recording needs: (i) a surgical method that can reach any cortical region in a minimally invasive manner; (ii) record microscale, mesoscale, and macroscale resolutions simultaneously; and (iii) record from multiple brain regions. We present a novel device whose form is based on the stereo-EEG (sEEG) and the physics describing our technique which we refer to as stereo-LFP (sLFP). sLFP quasi-static EM modeling predicted improved signal-to-noise and directional sensitivity when recording as far as 4mm from a neural source. In our model, we also compare the amplification and sensitivity of microelectrodes (varying dimensions) to state-of-the-art directional leads now commercially available. To validate this model with *in vivo* data, we implanted a novel 128-channel array, sLFP array, into the rat barrel cortex and stimulated 9 whiskers. sLFP was manufactured using polyimide-based microelectrodes wrapped onto a stainless-steel stylet for an outer diameter of 610-μm (Fig.1A). A small burr hole was made above the barrel cortex where a tetrode is first implanted, and 9 whiskers are stimulated (Fig.1B). sLFP was next implanted in the same location. Our results showed agreement with the EM predictions regarding amplitude and SNR improvement relative to microwires. To test our ability to measure distant sources, we used a linear discriminant analysis model to predict which whisker was stimulated. An example confusion matrix of sLFP relative to a tetrode in a 5-class model (Fig.1C). Table 1 summarizes key differences between tetrodes and sLFP. All comparisons are statistically significant (Tukey's test).

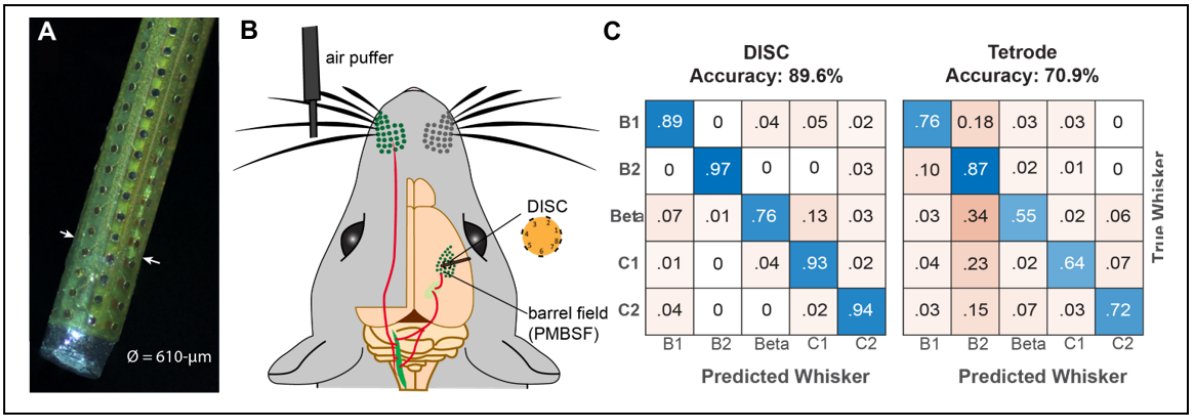

TABLE 1. 5-CLASS AND 9-CLASS WHISKER IDENTIFICATION (N=8)

Device	*Avg Waveform Amplitude, µV*	*5-Class Accuracy* [a]	*9-Class Accuracy*
MW/ Tetrode	95 ± 85 (SD)	68.7	52.0
sLFP	233 ± 214 (SD)	91.7	81.3

Title: Task-dependent increase in broadband power is an electrophysiologic marker of focal thalamic activity

Authors: *B. T. KLASSEN, G. OJEDA VALENCIA, L. M. JACKSON, T. J. KAUFMANN, K. J. MILLER;
Mayo Clin., Rochester, MN

Abstract: The architecture of the human thalamus is currently indirectly inferred from human histopathologic and non-human animal studies. Given that movement-related increases in broadband power from electrocorticography recording have been previously shown to identify

specific motor cortical subregions involved with a particular movement, we explored whether this phenomenon can also be used to localize motor subregions of thalamus. We performed serial human thalamic local field potentials recordings using an electrode moved through multiple locations during deep brain stimulation surgery in 10 subjects. During the recording at each location, subjects alternated between 5 second epochs of rest and 5 second periods of contralateral hand movement. Power spectra were generated for each epoch using Welch's overlapping periodogram method (1 second window, 50% overlap). Spectra from all movement and rest epochs were separately averaged. The difference between the power in the 65 to 95 Hz band during movement versus rest was used as a proxy for task-related change in broadband activity. Task-related differences in prominent low-frequency oscillations (patient-specific sub-ranges within 5 to 30 Hz) were analyzed per individual oscillation and in aggregate. Significance was determined using unpaired T tests at a threshold of $p=0.05$. Sites of each recording were identified on each subject's MRI brain using the final DBS electrode implant site as a common point of reference. We find that recording sites showing statistically significant increases in broadband power during movement tend to tightly cluster in areas predicted to represent motor thalamus, whereas sites showing statistically significant reduction in the power (desynchronization) of low frequency oscillations are more diffusely distributed. This finding is replicated across all subjects. These results suggest that a task-dependent increase in broadband power is an electrophysiologic marker of focal thalamic activity and may be useful to delineate specific thalamic subregions on an individual subject basis.

Movement associated thalamic activation patterns: (A) Serial recordings were obtained from multiple thalamic locations during electrode decent towards the target in a motor subregion of thalamus (Vim) during deep brain stimulator placement in human subjects being treated for tremor. (B) Power spectra were computed at each recording site during subject hand movement (red) or rest (black). The difference between spectra during movement versus rest at each site were compared for both broadband activity (using 65-95 Hz band as a proxy) and bands containing patient-specific low-frequency oscillations (in this case 5 - 16 Hz). Each recording site was registered to the subject-specific brain MRI, and the distribution of sites with statistically significant differences (unpaired T test, p=0.05 threshold) was more spatially discrete for broadband shifts (C) than for low-frequncy oscillations (D).

Title: Living in the moment: Revisiting univariate and bivariate iEEG feature distribution dynamics across the circadian cycle

Authors: *I. BALZEKAS[1], V. KREMEN, JR[2], V. SLADKY[1], D. HERMES[1], G. A. WORRELL[1];
[2]Neurol., [1]Mayo Clin., Rochester, MN

Abstract: Background: Brain state dynamics are often studied with univariate and bivariate spectral features such as power in band (PIB) and coherence. The variability and nonstationarity of these data are managed by normalization and detrending, but these techniques may obscure meaningful dynamics, especially when comparing brain data with behavioral states occurring at broader timescales such as mood. With increasing interest in ambulatory brain recordings for behavioral decoding, we revisited the question of how electrographic features are distributed. **Objective:** The goal of this poster is to illustrate the distributions of common univariate and bivariate iEEG features across the circadian cycle throughout the brain. **Methods:** We applied standard pre-processing and feature calculation methods to intracranial electroencephalographic (iEEG) recordings from a patient who underwent iEEG monitoring for seizure onset zone localization. Relative PIB and coherence were calculated in 5, 10, and 30 second epochs from four days of continuous recording from 80 electrodes with concurrent visual sleep staging. No seizures occurred during this period. Electrodes from the seizure onset zone and epochs with epileptiform spikes were excluded from analysis. Each timeseries was used to build an overall feature distribution and a timeseries of feature distributions from 5-minute rolling windows. Mean, variance, skewness, and kurtosis were calculated for the overall and rolling feature distributions. **Results:** Overall relative PIB showed skewness ranging from -2 to 2 and kurtosis ranging from 0 to 5 depending on the electrode, band, and state. Although unbalanced with more samples available from the awake state, in the rolling window for relative PIB, skewness and kurtosis showed the largest shifts during sleep with NREM stages showing average increases in skewness and kurtosis compared to awake, with one contact in the frontal lobe, for example, showing significantly increased skew in the low and high gamma bands and kurtosis in the theta, beta, low gamma, and high gamma (Wilcoxon Rank-Sum, $p < 0.001$, $n1 = 684$, $n2 = 6778$). For many bipolar electrode pairs, coherence measurements wherein both electrode pairs had concurrent spectral peaks in the relevant band were relatively rare. **Conclusions:** Our illustration of the sensitivity of neural feature distributions to behavioral state highlights opportunities to consider the statistical properties of neural timeseries in conjunction with standard feature values. Characterizing iEEG statistical properties and dynamics at varying time scales should support robust experimental designs for behavioral sampling and decoding.

Title: Intra-operative SPES; the influence of propofol on local brain networks in epilepsy patients

Authors: *S. BLOK[1,2], D. VAN BLOOIJS[1], H. G. E. MEIJER[3], G. J. M. HUISKAMP[1], P. VAN EIJSDEN[1], F. S. S. LEIJTEN[1];
[1]Brain, UMC Utrecht, Utrecht, Netherlands; [2]Sci. and Technol., [3]Fac. of Electrical Engineering, Mathematics and Computer Science, Applied Analysis, Univ. of Twente, Enschede, Netherlands

Abstract: Background: Single Pulse Electrical Stimulation (SPES) can be performed in epilepsy patients with subdural electrocorticography to reveal underlying brain networks. Neural mass models (NMMs) can simulate such an individual brain network. In the future, we want to explore the use of a NMM-based replica of the patient´s brain to evaluate various resection strategies during surgery. This approach could significantly reduce long-term intracranial monitoring or even make it redundant. We then have to know the influence of anesthesia (propofol) on these networks. Method: In a retrospective analysis (n=6), we compared SPES networks derived from two and ten stimuli. We calculated the total, positive and negative agreement. We compared the absolute number of Early Responses (ERs), the in-degree, out-degree and betweenness centrality. In an experimental study (n=6), we performed SPES twice: during long-term intracranial EEG monitoring, using ten stimuli and under propofol anesthesia at grid-explantation, using two stimuli. We calculated the above network parameters as well as the N1- and N2-peak latencies of ERs. Finally, we titrated coefficients (gain and time constants) of the NMM to simulate the change of N1 and N2 responses during propofol. Results: The network parameters calculated for the retrospective analysis showed a significant correlation ($p<0.05$) between the two stimuli and ten stimuli setting for five out of six patients, while for the experimental study we found a significant correlation in four out of six patients. All network parameters showed, on average, a lower value during propofol-SPES. We observed increased peak-latencies during propofol. This was simulated in a NMM by decreasing the gain and increasing the time constant of fast inhibition. Conclusion: Networks derived from two instead of ten stimuli per stimulation pair are similar. Effective connectivity based on SPES remains similar during propofol anesthesia.

Modulating the fast inhibition in the NMM can simulate the experimentally observed effect of propofol on ERs.

Title: BIC-BCI2000: A general-purpose hardware and software platform for chronic intracranial neuromodulation

Authors: *A. BELSTEN[1], *A. BELSTEN[1,2], G. SCHALK[3], S. WORRELL[3], F. MIVALT[3], I. KIM[3], S. MESSINA[3], T. KAUFMANN[3], N. STAFF[3], D. HERMES[3], G. A. WORRELL[3], K. MILLER[3], P. BRUNNER[1,2];
[1]Washington Univ. in St. Louis Sch. of Med., St. Louis, MO; [2]Natl. Ctr. for Adaptive Neurotechnologies, Albany, NY; [3]Mayo Clin., Rochester, MN

Abstract: Neuromodulation using intracranial electrical stimulation is effective in the therapeutic treatment of epilepsy, Parkinson's, essential tremor, and depression. However, contemporary neuromodulation devices depend on having a fundamental understanding of the beneficial effect of electrical stimulation on the underlying electrophysiological pathology, and thus provide limited benefit in developing therapies for less well-understood neurological disorders and diseases. Our study aimed to overcome this limitation by developing a general-purpose hardware and software platform for neuromodulation research and development based on the CorTec Brain Interchange (BIC) and the BCI2000 general-purpose software platform. The BIC is a fully implantable and inductively powered neuromodulation device intended for human use. It supports recording and stimulation through 32 electrodes. While the BIC supports autonomous operation (i.e., rapid stimulation based on prevalent signal conditions), it also allows

for streaming of the recorded signals to external applications to analyze signals and initiate stimulation in real time. These two operation modes facilitate the entire range of scientific and clinical investigation of neuromodulation therapies, ranging from the formulation of the scientific hypothesis, over initial validation of the therapeutic intervention, to the eventual clinical trial. Our study worked towards this goal by developing an integrated BIC-BCI2000 system. We implanted the BIC system in a beagle canine. Two AirRay 16-channel grids were subdurally placed over the left and right sensorimotor cortex via a bilateral craniotomy. Over the 77 days of implantation, we performed electrocorticographic (ECoG) recordings in the behaving and asleep canine using the BCI2000 software. Analysis of the recorded ECoG signals revealed the expected oscillatory activity in the beta band. This initial demonstration of the BIC-BCI2000 system demonstrates the viability of general-purpose hardware and software platforms for neuromodulation research and development.

Title: A Wearable and Mobile Health Platform for Automatic Responsiveness Testing in Epilepsy (ARTiE): An EMU Pilot Study

Authors: *L. WHEELER[1,2,3], V. KREMEN, JR[2,3], K. MCQUOWN[5], V. SLADKY[2], B. BRINKMANN[2,3], Z. AHMAD[6], C. YOTTER[6], C. BENJAMIN[6], J. GIACINO[7], B. C. JOBST[8], G. A. WORRELL[4], H. BLUMENFELD[9];
[1]Mayo Clin. Grad. Sch. of Biomed. Sci., Rochester, MN; [2]Neurol., [3]Physiol. and Biomed. Engin., [4]Mayo Clin., Rochester, MN; [5]Windy City Labs, Chicago, IL; [6]Neurol., Yale Univ., New Haven, CT; [7]Physical Med. and Rehabil., Spaulding Rehabil. Hosp., Boston, MA; [8]Neurol., Dartmouth-Hitchcock Med. Ctr., Lebanon, NH; [9]Dept. of Neurol., Yale Univ. Sch. of Med., New Haven, CT

Abstract: Rationale: Alteration of consciousness (AOC) during seizures is a hallmark of epilepsy, leading to increased morbidity, mortality, and reduced quality of life. Assessment of AOC level is crucial to accurate diagnosis and management of people with epilepsy (PWE). However, current AOC testing during seizures has mainly been limited to hospital settings, and is further limited by a lack of standardization, sparse testing, delay to testing, poor interrater and test-retest reliability. The absence of a standardized AOC assessment tool for testing PWE in naturalistic environments has limited investigation of AOC mechanisms and its impact on patients. To address this clinical gap, we develop an application for automated responsiveness testing in epilepsy (ARTiE) utilizing a smartphone and smartwatch. **Methods:** The ARTiE system was validated in the Epilepsy vEEG Monitoring Unit. Patient inclusion criteria were: 1) epilepsy diagnosis; 2) age 18 years or older; 3) ability to participate in behavioral tasks at baseline. The ARTiE system (Apple iPhone, Apple watch & cloud) administers the behavioral assessment sequence and records verbal and motor responses. The devices have bidirectional wireless connectivity allowing remote assessment initiation and data synchronization. Upon automated or visual seizure detection a remote server notification automatically launches testing that includes verbal questions and commands to test receptive and expressive language, orientation, motor praxis, and memory recall. The assessment adaptively increases the number of loops based on patient performance. **Results:** Thirteen adult PWE were enrolled. A total of 56 baseline, 6 clinical, and 9 subclinical automated triggered events were captured testing motor, memory, and orientation in PWE. During baseline testing, subjects achieved 98.5% for motor task, 100% for memory registration, 100% for orientation, and 87.5% memory retrieval performance. There were no significant differences between baseline and subclinical seizure testing. Clinical seizures showed reductions of 10.7% in motor, 10.5% in verbal, and 20.8% memory retrieval tasks compared to baseline. Generalized tonic-clonic seizure testing showed maximum impairment at testing initiation with 0% memory registration, 0% motor task, and 0% orientation task completion. The subject returned to 100% motor task, 100% orientation, and 0% memory retrieval by the end of testing. The subjects reported they enjoyed working with the

technology and are interested in future studies in their home environment. Future applications include integration of ARTiE with a fully implantable neurostimulation and sensing device.

Abstract: Rationale: Long-term data collection using implantable neural sense and stimulation (INSS) devices in patients with epilepsy enables investigation of ultradian, circadian and infradian rhythms in sleep, seizures, interictal epileptiform discharges (IED), and brain impedance. It has long been recognized that IED and seizures have circadian patterns. Recent studies also highlight the importance of circadian changes in brain extracellular space, and the functional role of slow-wave sleep and the associated increase in extracellular space volume that is hypothesized to provide improved metabolite and protein clearance. The direct evidence for increased extracellular space volume during sleep primarily comes from rodent studies, and a

few human imaging studies with limited temporal sampling. Here we investigate a potential surrogate of extracellular volume, the brain electrical impedance in hippocampus (HPC) and anterior nucleus of thalamus (ANT) over multiple months in four ambulatory humans with drug resistant epilepsy.
Methods: We collected several months of continuous iEEG and impedance measurements from each of 4 patients with drug resistant epilepsy implanted with an investigational INSS and living in their normal home environments. Continuous iEEG was used to precisely assess sleep states using machine learning algorithms. Impedance was measured in 15-minute intervals in bilateral ANT and HPC to analyze the relationship between sleep states and impedance cycles (Pearson's Correlation Coefficient and Mann-Whitney U test) using 31 days and nights of data.
Results: The ANT and HPC electrical impedance followed a distinct circadian rhythm with period ranging between 23.36 and 24.81 hours. We observed a phase shift in the maximum and minimum between ANT and HPC impedance with Pearson's Correlation Coefficient of 0.604 (p &lt .001), while the left and right HPC shows a high correlation 0.700 (p &lt .001) without any phase shift. Moreover, impedances of both HPC and ANT shows a distinct correlation with sleep (0.504 and 0.507 both p &lt .001) with the average absolute impedance change, across all measured leads, between wake and sleep $26.3 \pm 13.2\ \Omega$ (p &lt .001).
Conclusion: We show human brain impedance cycles with a circadian rhythm that varies across different behavioral states and brain locations. Further research of this phenomena and the relationship of impedance to sleep, seizures, epileptiform interictal discharges may prove useful for understanding the role of the extracellular space in seizure generation in temporal lobe epilepsy.

Title: Electrical stimulation responses in human ventral temporal cortex cluster by shape and stimulation site on intracranial EEG

Authors: *H. HUANG[1], N. M. GREGG[2], G. OJEDA VALENCIA[3], B. H. BRINKMANN[2], B. N. LUNDSTROM[2], G. A. WORRELL[2], K. J. MILLER[4], D. HERMES[3];

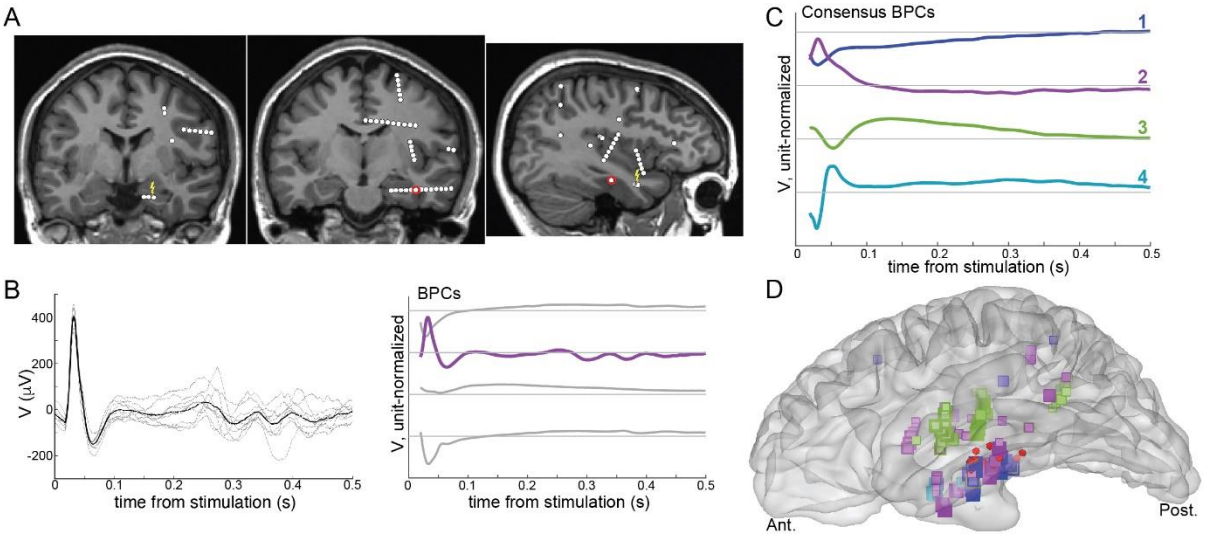
Abstract: Motivation
Human ventral temporal cortex (VTC) is highly connected to serve its function in object perception. Electrical brain stimulation can be used to study how inputs from other brain regions drive responses in the VTC. To map the variability of inputs, we recorded intracranial EEG (iEEG) in human VTC in response to single pulse stimulation of other regions and we clustered responses by shape and anatomical location of stimulation site.
Methods
We recorded iEEG data in 7 patients who had been implanted for epilepsy monitoring. We stimulated pairs of electrodes at multiple sites in the brain with a single pulse every 5 to 7s and measured corticocortical evoked potential (CCEP) responses within the collateral sulcus and lateral occipitotemporal sulcus of the VTC. Using a novel unsupervised machine learning method, we uncovered 2 to 4 distinct response shapes, which we term basis profile curves (BPCs), from the 20 to 500 ms post-stimulation interval and characterized the anatomical



distribution of stimulation sites that cluster to each BPC.

Results

IEEG recordings from both regions of the VTC showed evoked potentials of high amplitude following stimulation of several other regions. Some of the BPCs concentrated at amygdala, anterior hippocampus, and insula, while another BPC concentrated at the posterior hippocampus. Stimulation of lateral cortical sites, such as at middle temporal gyrus, evoked yet another BPC. We tested the model's between-subject reliability by calculating consensus BPCs using collateral sulcus responses from 5 subjects and then predicting the responses from a 6th subject. We found that the anatomical distribution of consensus BPCs in the 6th subject largely matched that of the first 5. There was greater between-subject variability when recording in the lateral occipitotemporal sulcus.

Conclusion

Characterizing distinct shapes in stimulation responses provides a novel description of connectivity in the VTC. We derive connectivity maps that reveal different inputs from cortical and limbic structures.

From stimulation responses in one subject to consensus BPCs across 5 subjects. (A) T1-weighted MRI slices from subject 1 illustrating one recording site in the collateral sulcus (red) and one stimulation site in the amygdala (yellow). (B) Left: individual trials (gray) and mean across trials (black) of stimulation-recording pair in (A). Right: BPCs at recording site in (A) calculated from all stimulation site responses. Responses to amygdala stimulation cluster to the BPC highlighted in purple. (C) Consensus BPCs from 5 subjects calculated by k-means clustering of all subject BPCs. (D) Anatomical distribution of stimulation sites from 5 subjects projected onto an MNI brain, colored and scaled by consensus BPC cluster and strength.

Title: A validated BIDS app for the automated detection of early evoked responses and mapping of connectivity in IEEG

Authors: *M. A. VAN DEN BOOM[1], D. VAN BLOOIJS[4], N. M. GREGG[2], G. OJEDA VALENCIA[1], B. N. LUNDSTROM[2], G. A. WORRELL[2], J. F. VAN DER AAR[5], G. J. M. HUISKAMP[4], K. J. MILLER[3], F. S. S. LEIJTEN[4], D. HERMES[1];

Abstract: Several studies have combined intracranial monitoring with single pulse electrical stimulation to map and characterize connectivity in the human brain. Through systematic stimulation of electrode pairs with a brief pulse, early responses can be identified on other electrodes, indicating connectivity between the stimulated and measured site. While standardized approaches are essential for scientific reproducibility and automated inclusion in clinical workflows, the methods that are used to identify response profiles vary between studies, with each applying their own criteria. Some studies rely purely on the visual inspection of the average response signal, whereas others apply some form of automatic detection. The extension of the BIDS standard to include intracranial EEG (iEEG) now allows us to standardize this process and we present an open-source BIDS app that performs automatic detection of early evoked responses (i.e. the deflection within the first 100ms after stimulation, also known as N1 or P1). The output of the app was validated against visually inspected and manually annotated data of 14 participants recorded at two different hospitals. The initial detection algorithm that relies on the identification of relative local extremums in the average signal, provided a detection accuracy of around 90%. Depending on the context, more strict detection (e.g. in a clinical setting) or less strict detection (e.g. in a research setting) could be applied. As such, the app provides the ability to adjust various detection parameters and produces two additional output metrics that can be used to further raise the sensitivity or specificity, or serve as an alternative detection input value. One metric provides a measure of response consistency (i.e. inter-trial reliability), whereas the

other metric gives an indication on the typicality of the response shape. The app produces data-files and visualizations of the detection results per channel and per stimulated electrode-pair. In addition, connectivity visualizations are generated that allow for easy visual inspection of connectivity. Altogether, this BIDS app provides automated methods that could serve as a standardized and easy-to-use tool for a reliable detection of early evoked responses in both clinical and research settings.

Title: Functional ultrasound neuroimaging reveals heterogenous organization of directional response fields in lateral intraparietal cortex of nonhuman primates

Authors: *W. S. GRIGGS[1], S. L. NORMAN[1], C. RABUT[2], C. DEMENÉ[5], V. N. CHRISTOPOULOS[3,6], M. TANTER[5], M. SHAPIRO[2], R. A. ANDERSEN[4];

Abstract: The posterior parietal cortex (PPC) is an important area for the transformation of spatial information into accurate motor movements. PPC sub-regions such as the lateral intraparietal area (LIP) and the parietal reach region (PRR) are especially important for saccades and reaches, respectively. However, our understanding of these areas' functional organization is incomplete, in part due to technical challenges. While electrophysiology recordings can only record from small regions of the PPC at a time, fMRI and other whole-brain techniques have insufficient spatiotemporal resolution. Now, functional ultrasound imaging (fUSI) is available as an innovative neuroimaging technique that measures cerebral hemodynamics with exceptional spatiotemporal resolution (100 μm and up to 10 ms) and a large field of view (several cm) (Macé et al., *Nature Methods*, 2011). These specifications are ideally suited to recording detailed

activity of multiple cortical regions in parallel in nonhuman primates (Norman et al., *Neuron*, 2021). In this study, we used fUSI to record changes in cerebral blood volume (CBV) in PPC of two awake behaving nonhuman primates. Each animal performed memory-guided saccades to targets throughout their visual field. We analyzed the distribution of response fields within each coronal plane of PPC. We found that many subregions within and across coronal LIP planes had different directional tuning, although predominately for the contralateral space. We also found substantially more activity in LIP compared to PRR during our saccade task, supporting the respective roles of LIP and PRR for eye and hand movements. These results address a fundamental gap in our understanding of LIP's functional organization by developing mesoscopic maps of direction specificity previously unattainable with fMRI or electrophysiology methods. These mesoscopic maps reveal a highly heterogeneous organization within LIP with many small patches of neighboring cortex encoding different preferred directions.

Title: Distinct patterns of whole body coding in motor cortex and posterior parietal cortex during neural prosthetic control

Authors: *K. KADLEC[1], T. AFLALO[1], J. A. GAMEZ[1], E. ROSARIO[2], N. POURATIAN[3], R. A. ANDERSEN[1];
[1]Div. of Biol. and Biol. Engin., Caltech, Pasadena, CA; [2]Res. Inst., Casa Colina Hosp. and Centers For Healthcare, Pomona, CA; [3]UCLA, Los Angeles, CA

Abstract: The segregation of motor plans based on the part of the body to be moved (effector) is classically thought to occur early in the plan's formation. For example, in posterior parietal cortex (PPC) of non-human primates, studies show distinct functions across sub-regions, such as

coding for eye movements in lateral intraparietal area and hand grasp movements in the anterior intraparietal area. The separation of effectors has also been observed in motor cortex (MC), where stimulation and neuroimaging studies suggest the organization of the body from head to toe is from lateral to medial cortex respectively. Recent findings from human single-neuron studies have revealed much more diversity in action representation than expected in both PPC and MC, with multiple effectors being encoded in small populations. These results are difficult to interpret together in the context of previous findings. Further, comparing different brain regions from different studies is difficult given variability both between individuals and behaviors. In the current study, we simultaneously recorded from single neurons in human PPC and MC (hand knob) of a tetraplegic patient enrolled in an ongoing brain-machine interface study. The participant attempted 2-D movements using 12 effectors (head to foot, left and right side). PPC demonstrated nearly equivalent, though still discriminable, coding for all tested body parts. In contrast, MC showed a clear preference for the contralateral distal hand, as expected from anatomy, with reduced, albeit significant, tuning to the other effectors, bilaterally. In a subsequent experiment, we found that movement representations for multiple body segments were preserved even when the causal impact of this activity could drive task errors (i.e. unwanted movements). This suggests that coding for multiple effectors is a robust feature of the recorded neural populations. Such robust encoding suggests that our findings in a tetraplegic individual may be representative of motor-intact individuals, but further work is needed to confirm this. Overall, the results show greater overlap in effector coding than anticipated in both regions, especially in PPC where the strength of representation was comparable across the entire body.

Title: Preserved motor representations enable neural prosthetic control of individual fingers

Authors: *C. GUAN[1], T. AFLALO[1], C. Y. ZHANG[1], E. ROSARIO[2], N. POURATIAN[3], R. A. ANDERSEN[1];
[1]Div. of Biol. and Biol. Engin., Caltech, Pasadena, CA; [2]Res. Inst., Casa Colina Hosp. and Centers For Healthcare, Pomona, CA; [3]UCLA, Los Angeles, CA

Abstract: Paralyzed individuals can control prosthetics using brain-machine interfaces (BMIs), even long after spinal cord injury. What neural mechanisms enable this BMI control? Do BMI users activate preserved motor circuits, or have they learned novel activity patterns specific to BMI control? We first demonstrate that a tetraplegic human participant can control an individual-finger BMI through intracortical recordings from the posterior parietal cortex. Control performance exceeded previously known results. We then show that the neural representational structure of these attempted finger movements matches the representational structure previously measured in able-bodied subjects. Furthermore, we identify multiple functional processes that dissociate in time, first encoding motor-production-like representations, which are followed approximately 170ms later by sensory-like representations. This pattern is consistent with PPC encoding a state estimate of the body. Our results suggest that pre-existing neural representations are preserved after injury. BMI users can then reengage these preserved representations during neural prosthetic control. Future neural prosthetics may be able to extend functionality by leveraging the structure of these able-bodied-like representations.

Title: Neural prosthetic context profoundly shapes single-neuron responses while preserving the functional distinctions between human motor and posterior parietal cortices.

Authors: *T. AFLALO[1], J. A. GAMEZ[1], K. KADLEC[1], S. SAKELLARIDI[1], C. GUAN[1], E. ROSARIO[2], N. POURATIAN[3], R. A. ANDERSEN[4];
[1]Div. of Biol. and Biol. Engin., Caltech, Pasadena, CA; [2]Res. Inst., Casa Colina Hosp. and

Centers For Healthcare, Pomona, CA; [3]UTSouthwestern, Dallas, TX; [4]Div. of Biol. and Biol. Engin., Calif Inst. of Technol., Pasadena, CA

Abstract: A classic perspective is that distinct functions of the brain are organized into separate regions of cortex. However, recent work complicates this view; e.g., neurons in primary visual cortex correlate with movements in the dark, and small patches of cortex respond to all parts of the body. These discrepancies in the functional organization of cortex are relevant for neural prosthetic applications. Is it necessary to target specific cortical areas to harness specific functional signals, or does the intrinsic diversity of cortical signals combined with plasticity and novel demands blur distinctions between cortical regions?
Here, we study neural population coding of motor plans in the human posterior parietal cortex (PPC) and motor cortex (MC) during neural prosthetic control of a computer cursor. These regions are associated with motor planning and execution, respectively, providing a testbed to probe functional specialization. We tested planning activity across three experimental contexts: planning 1) while the cursor was locked in place (cursor *decoupled* from brain activity), 2) while the cursor was free to move, but the task enforced a hold period (cursor *coupled* to brain activity), and, 3) during continuous *sequential* movements in which the participant planned the next movement simultaneous with the current movement execution.
We found that context profoundly shapes neural responses in both PPC and MC. When neural activity during planning is *decoupled* from cursor movement, MC shows comparable levels of planning activity to PPC. When neural activity is *coupled* to cursor movement, MC activity drops 3-fold relative to PPC. Finally, during *sequential* movements, there was no measurable planning activity in MC, while planning in PPC persisted. Thus, while MC can express planning activity, this activity is fragile, and disappears under contextual pressures. PPC is also shaped by context. In *coupled* and *decoupled* contexts, population encoding during planning and execution were functionally overlapping (e.g. population codes were highly correlated). However, in the *sequential* task, PPC planning and execution neural subspaces orthogonalized, minimizing cross-talk between movement representations. Similar to PPC, MC planning and execution activity were highly overlapping in the *decoupled* and *coupled* contexts.
Our results demonstrate clear functional distinctions between cortical regions despite the novel functional demands imposed by the neural prosthetic system. However, task context strongly shapes neural populations and may account for reported discrepancies in the functional organization of cortex.

Title: Decoding reaching direction from macaque dorsal and ventral premotor and primary motor cortex

Authors: J. G. RAMIREZ[1], S. DE SCHRIJVER[3], T. DECRAMER[2], T. THEYS[4], ***P. JANSSEN**[1];
[2]Lab. voor Neuro- en Psychofysiologie, [1]KU Leuven, Leuven, Belgium; [3]Ku Leuven, Leuven, Belgium; [4]Lab. Exp. Neurochirurgie En Neuroanatomie, Leuven, Belgium

Abstract: Primary and premotor cortex are involved in visually guided motor behavior. To compare the decoding performance of reaching movements in premotor and primary motor cortex, we implanted three 96-channel Utah arrays in ventral premotor area F5c, dorsal premotor area F2 and primary motor cortex M1 in two macaque monkeys that were trained to perform a 3D center-out task on a touchscreen. Using DeepLabCut, we tracked the position of the wrist while the monkeys performed the task, and correlated this with the neural activity. We propose a nonlinear extension of a recent algorithm for modelling neural activity (Preferential Subspace Identification or PSID) to develop a high-performance brain-machine interface. In our method, we first extracted latent neural dynamics using PSID. Then, we applied a nonlinear transformation to the extracted dynamics, after which the transformed dynamics were used to build a regression model to predict the behavioral states at each 50 ms timestep. When tested with two rhesus monkeys performing a 3D center-out task, our approach has yielded highly accurate decoding ($r^2 = 0.88$) while having a reduced latency (order of microseconds) making it convenient for online decoding. Moreover, we have obtained promising decoding results using the neural activity in a passive observation task with a simulated robot in a 3D virtual environment performing the same 3D center out task. Finally, we tested the decoding capacity of each individual area using our method in one of the monkeys. We obtained comparable peak performance in M1 ($r^2 = 0.87$) and PMd ($r^2 = 0.85$) and lower though significant decoding accuracyin the F5c sector of PMv ($r^2 = 0.52$). Thus, robust and fast decoding of reaching movements is possible from neural activity recorded in PMd, M1 and to a lesser extent PMv.

Title: Beyond error correction to improve brain-computer interfaces using error-related potentials

Authors: *A. XAVIER FIDÊNCIO[1,2], T. GLASMACHERS[4], C. KLAES[3], I. IOSSIFIDIS[1]; [1]Inst. of Computer Sci., Ruhr West Univ. of Applied Sci., Mülheim an der Ruhr, Germany; [3]Dept. of Neurosurg., [2]Knappschaftskrankenhaus Bochum, Bochum, Germany; [4]Inst. for Neural Computation, Ruhr-Universität Bochum, Bochum, Germany

Abstract: Error-related potentials (ErrPs) are known to be elicited in the human brain during the brain-computer interaction as a direct reaction to not only self-made errors, but also to mistaken actions performed by an external system. Current literature on non-invasive BCIs refers to seven different ErrPs and show that these signals can be generated under different experimental paradigms. This has motivated an increased interest over the last years in the integration of these signals into different BCI systems to improve their performance, since the ErrPs provide a convenient source of feedback to the system with no extra workload being given to the subject. Several works have successfully shown the improvement achieved while using the ErrPs signals to undo the perceived error in different systems. However, more research is still necessary regarding the use of the decoded error information going beyond just error correction. For this reason, we investigate alternative strategies to integrate the ErrPs in different BCI systems to improve their overall performance. These error signals can be reliably measured using Electroencephalography (EEG) and usually wet electrodes are applied. In this work, however, we record EEG data using a Brain Products LiveAmp amplifier and the Xpress Twist cap with 32 active dry electrodes, which decreases experiment preparation time, but imposes new challenges regarding the signal-to-noise ratio.

Our first approach is focused on gesture-based BCIs using Electromyography (EMG) data as input, in which different supervised learning strategies triggered by the ErrPs to adapt an existing EMG-decoder to a new subject are tested. Additionally, we investigate the integration of the ErrPs as reward signal in a reinforcement learning framework to learn the correct mapping between measured input signal to BCI control commands. Simulation results show the feasibility of this approach for different ErrPs decoding accuracies in an EMG-based BCI. Preliminary results on online application including two subjects is, however, so far limited by the low ErrPs decoding accuracy of around 60%.

Hence, while error signals are an important source of additional and relevant information for BCIs, their effective use is highly dependent on their accurate detection and classification. Therefore, we additionally investigate the application of different machine learning algorithms such as regularized linear discriminant analysis (rLDA), support vector machine (SVM) and more complex neural network-based models using time- and/or frequency domain features to reliably decode the ErrPs signals in a single-trial basis.

Title: Fusinet - an artificial neural network for generalized decoding of movement intention using functional ultrasound neuroimaging

Authors: *S. L. NORMAN[1], W. S. GRIGGS[1], C. RABUT[1], D. MARESCA[2], V. N. CHRISTOPOULOS[3], C. DEMENÉ[4], M. TANTER[4], M. G. SHAPIRO[1], R. A. ANDERSEN[5]; [1]Caltech, Pasadena, CA; [2]Delft Univ. of Technol., Delft, Netherlands; [3]Div. of Biol. and biological Engin., Univ. of California, Riverside, Riverside, CA; [4]Physics for Med. Paris, INSERM, CNRS, ESPCI Paris, PSL Res. Univ., Paris, France; [5]BBE, Calif Inst. of Technol., Pasadena, CA

Abstract: Brain-machine interfaces (BMIs) directly link the brain to external devices. They already enable users with chronic paralysis to control neuroprosthetics, including robotic arms and computer cursors. They promise future applications in smart home control, speech prosthetics, and closed-loop neurostimulation. However, the most advanced BMIs are still highly invasive and typically require re-training or re-calibration between subsequent sessions and different users. Recently, functional ultrasound imaging (fUSI) was introduced as a revolutionary hemodynamic technique that is minimally invasive (i.e. epidural) and portable while maintaining excellent spatiotemporal resolution (100 micron, up to 10 Hz) and a wide field of view (~2 cm). Previously, we showed that fUSI can be used to decode the neural correlates of movement planning in non-human primates (NHPs) - including timing, direction, and effector - before movement was executed and with single-trial sensitivity (Norman et al., *Neuron*, 2021). These results represented the first steps toward ultrasound-based BMIs that are less invasive, high resolution, and scalable. However, previous fUSI movement decoding models still required subject and session-specific re-training. Although fUSI imaging data are visually similar between NHPs and recording sessions, small movements and deformation of the brain parenchyma limit the performance of univariate decoding techniques that rely on pixel-wise changes in activity. Here, we present “fUSInet”, a convolutional neural network (CNN) that extends the capabilities of fUS-BMIs using a single model for generalized decoding between two NHPs and across recording sessions spanning 45 months. fUSInet recognizes the location and activity of cortical regions in NHP posterior parietal cortex (PPC) relative to reliable anatomical landmarks (e.g. intraparietal sulcus). It is therefore robust to animal- and session-specific changes in the precise

location of regions with specialized motor function, e.g. spatial planning. Thanks to this attribute, fUSInet outperforms previous fUSI models in decoding movement direction and effector within a single subject and day. In addition, performance is sustained when training on a corpus of fUSI data from one subject to classify novel data from a second subject or from subsequent scanning sessions, i.e. days. These results represent an important step toward BMIs that are less invasive and generalizable to naïve subjects and require less frequent re-training.

Title: Neural population dynamics during vocal behavior

Authors: *P. M. TOSTADO[1], E. M. ARNEODO[2], T. GENTNER[2], V. GILJA[3];
[1]Bioengineering, [2]Psychology, [3]Electrical and Computer Engin., UCSD, La Jolla, CA

Abstract: The increasing capacity of neuroscientists to record the electrophysiological activity of large numbers of individual neurons permits the possibility of understanding brain dynamics that may appear imperceptible in individual unit responses. This is of particular interest when studying complex natural behaviors, like vocalization. To better understand the neural mechanisms that enable complex motor-vocal behavior, we recorded the simultaneous activity of 145 single neurons in the robust nucleus of the arcopallium (RA), a forebrain motor region, of male zebra finches engaged in unconstrained vocal behavior. We apply latent factor-based models to gain insight into the temporal dynamics of neural populations that drive vocal production. The characteristic stereotypy of zebra finch songs allows us to record high numbers of unconstrained, yet highly similar vocalizations in free-behaving birds. We find that the spiking activity across populations of individual RA neurons is well described by a pattern of smooth trajectories in the latent neural space during stereotyped singing (Figure 1). Moreover, the dynamics of the low-dimensional state-space of RA neural trajectories track single notes

categorically and reflect more subtle variability across different renditions of the bird's song. Similar observations are reported in populations of cortical neurons of the primary motor cortex (M1) of macaques during movement generation (Gallego et al. 2018). Our results point to common principles that may underlie the encoding of complex natural motor actions in specific brain regions or circuits.

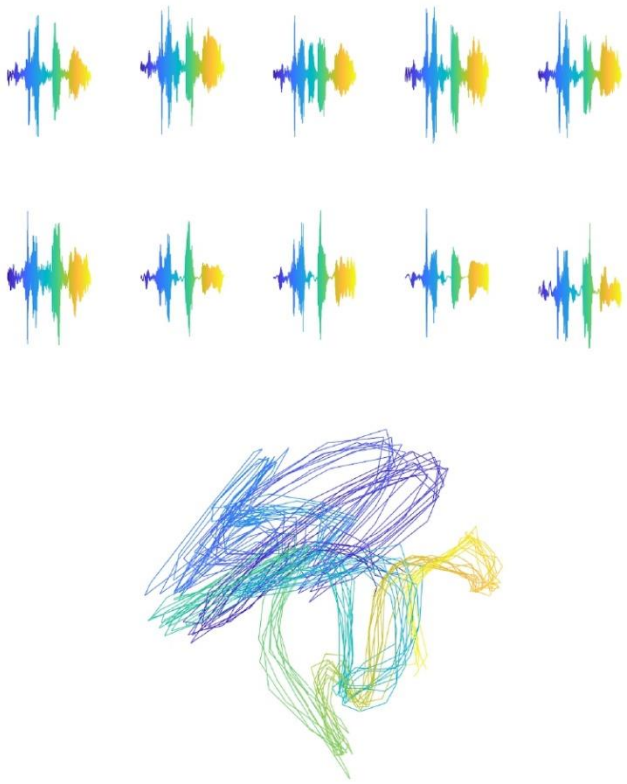

Figure 1. Ten examples of the raw audio waveforms of recorded vocal renditions of zebra finch song (top). Corresponding neural trajectories extracted from the population activity of RA 145 neurons and projected on a 3D latent neural space (bottom).

Title: Morphology, Biomechanics, and Function of Leg Campaniform Sensilla in Drosophila melanogaster

Authors: *G. DINGES[1], K. FENG[2], T. BOCKEMÜHL[1], A. BLANKE[3], A. BÜSCHGES[1]; [1]Univ. of Cologne, Cologne, Germany; [2]Queensland Brain Institute, Univ. of Queensland, St Lucia, Australia; [3]Rheinische Friedrich-Wilhelms-Universität Bonn, Bonn, Germany

Abstract: Locomotion is a crucial component of animal survival that must be adaptable to be consistently successful. This adaptability is necessary for walking insects to overcome complex and changing terrains. During walking, sensory organs monitor motor output and provide dynamic feedback, both modifying and reinforcing, onto central network components. Campaniform sensilla (CS), cuticular sensory organs found on the majority of insect limb segments, encode highly dynamic strains that occur in the cuticle. In *Drosophila melanogaster*, leg CS research remains limited, and it is unclear how different CS and whole CS fields encode specific strains or which are necessary and sufficient to alter motor programs. The genetic tractability of *D. melanogaster* provides the opportunity to study these organs and their complex network interactions without the limitation of only using mechanical manipulations. To understand the interplay of morphology and function we utilized high-resolution imaging and optogenetic manipulations to investigate CS function in *D. melanogaster*. We targeted the outer morphology of CS using electron microscopy and thereby demonstrated interindividual and interleg variability in CS number and positions. Further, we used nano-computed tomography to investigate complex morphological CS field arrangements. This underlined that CS substructures unite individual CS within a field and might alter both the magnitude and direction of strains. To then correlate CS morphology with function, we tested how CS subsets influence leg movements and coordination using transient optogenetic manipulations in intact walking flies. This demonstrated the involvement of small CS subsets in two leg CS fields for these behaviors, highlighting their importance for both kinematic and temporal coordination. Inhibiting varying CS subsets leads to alterations in interleg coordination, while activation of the same subsets was sufficient for eliciting limb movements that changed joint angles. Interestingly, the effects of both inhibition and activation show that different leg types respond differently to CS feedback. Connecting CS morphology in the context of species-specific biomechanics with behavior

requires experiments investigating each of these aspects as part of a holistic system. Our work underlines the diversity in leg CS morphologies, how this diversity can affect field biomechanics, and the function of different constellations of CS in walking and postural control.

Title: Flexible, adaptive control of escape behaviour in mice

Authors: *S. C. LENZI, L. COSSELL, B. GRAINGER, S. F. OLESEN, T. BRANCO, T. W. MARGRIE;
Sainsbury Wellcome Ctr. for Neural Circuits and Behaviour, UCL, London, United Kingdom

Abstract: Innate behaviours are a powerful model for understanding how sensory information is used by the brain to select behaviour. Predator avoidance behaviours such as freezing and escape are of particular interest since these stimulus-evoked responses represent behavioural manifestations of a dynamic decision-making process that is fundamental to survival (Evans et al., 2018). Over the lifespan of an individual, however, the threat value of particular agents in the environment undergoes constant revision (Cooper & Blumstein, 2015) and repeatedly escaping to a particular stimulus may no longer be the optimal behavioural strategy (Rossier et al., 2020). This form of cognitive control and learning highlights not only the flexibility of innate behaviour in general (Tomsic et al., 2017), but presents an elegant model for understanding how environmental experience influences behavioural choice at the level of neuronal circuits. To begin to understand what ethological factors shape this type of adaptive control we devised an experimental paradigm to probe the key determinants of escape behaviour and its learned suppression in the laboratory mouse, *Mus musculus*. First, we found that robust escape to visual looming stimuli is strongly influenced by factors such as social context, but not environmental enrichment. Second, we found that mice can rapidly learn to suppress escape to looming stimuli and that its abolishment can persist for weeks. This learned suppression of innate escape (LSIE) is not a generic adaptation to threat stimuli since flight responses to novel live prey and simulated auditory threats presented in the same arena location are maintained. Finally, we found that a critical determinant for the expression of LSIE is the temporal history of threat escape, suggesting that the underlying process is not simply desensitisation to repeated presentation of threat stimuli. Therefore, multiple ethological factors shape threat avoidance in mice. This rich

behavioural plasticity together with tractable genetics can be exploited to understand how neuronal circuit plasticity gives rise to flexible decision-making.

Title: Identification of pain hypersensitivity phenotypes across genetically diverse mouse lines.

Authors: *J. BURDGE, I. ABDUS-SABOOR;
Columbia Univ., New York, NY

Abstract: Identification of pain hypersensitivity phenotypes across genetically diverse mouse lines. Justin Burdge[1], Ishmail Abdus-Saboor[1].[1] Columbia University
The same pain can cause wildly different reactions depending on who experiences it. The key to understanding why lies in the genetics that underlie the pain pathway. Pain genes have led to the identification of multiple components of the peripheral pain way and how they lead to the sensing of painful stimuli and could in the same way be used to elucidate the pain pathway in the central nervous system (CNS). Identifying these central pain genes is essential to understanding the neural pathways that the brain uses to construct the sensation of pain and execute pain behaviors in response to noxious stimuli. Here we use the model of thermal escape jump, a behavior that originates from the brain, to examine how genetic variation leads to differences in pain behavior independent of pain sensitivity. We tested 18 genetically diverse inbred mouse lines to determine the levels of escape jump behavior they showed when place on a hot plate at either extreme hot or cold temperatures, and then tested them for thermal sensitivity to heat and cold for comparison. Our results found that C57/BL6 mice, which are commonly used in pain research, are an outlier in terms of thermal escape jump behavior when compared to non C57 strains. Comparisons with several strains showed decreases in this behavior which could not be explained by differences in thermal sensitivity. This testing found heightened jumping behavior without any significant difference in thermal sensitivity, with C57BL/10SnJ mice, a subline of C57 mice, showing more than 10 times the jumping behavior exhibited by C57/BL6 mice. Further when tested for general escape behavior using the tail suspension assay C57/10SnJ mice showed twice the escape behavior as C57BL/6J mice. Critically, these findings indicate that these differences in jumping behavior are not caused by changes in nociception, resulting from

differences in the periphery, but instead to the behavioral response itself which could only result from changes in the CNS. These results establish C57BL/10SnJ mice as targets for genetic analysis through which the specific neural circuitry underlying behavioral reactions to pain could be established.

Title: Investigating a potential magnetocaloric mechanism for magnetic field transduction by C. elegans.

Authors: *T. AWE[1], C. BAINBRIDGE[1,2], P. FREEBAIRN[1], A. G. VIDAL-GADEA[1]; [1]Sch. of Biol. Sci., Illinois State Univ., Normal, IL; [2]Univ. of Rochester Med. Ctr., New York, NY

Abstract: The magnetic field of the earth is used in navigation by many species across taxa. While the list of species able to navigate their environment with the use of the earth's magnetic field continues to grow, little is understood about the molecular and cellular underpinnings of this behavior. Two main mechanisms have been proposed for magnetic field transduction. The light-dependent mechanism is hypothesized to involve cryptochromes working in the retina of some species to generate magnetosensitive radical pairs in the presence of light. The second, more prevalent, mechanism hypothesized involves the presence of magnetic particles coupled to stretch receptors in the tissues of many magnetosensitive species: the magnetomechanic mechanism. Recently, Bell et al (2019) proposed an alternative rotating magnetocaloric transduction mechanism involving the detection of heat generated by magnetic nanoparticles as they move through the earth's magnetic field. We previously showed that the nematode *C. elegans* orients to magnetic fields in a light-independent manner. Detection of magnetic fields by *C. elegans* is mediated by a pair of polymodal sensory neurons, AFDs. These neurons are the primary thermosensory neurons in *C. elegans* and respond to minute changes in temperature. We are working to establish the mechanism for magnetic transduction in *C. elegans*, performing experiments designed to test the potential use of magnetocaloric and magnetomechanic transduction mechanisms. To this end, we exposed worms to either strong magnetic pulses, or to oscillating magnetic fields, and testes their ability to orient to magnetic fields. Our current findings favor a magnetocaloric mechanism for magnetic orientation in worms. *C. elegans* is an

excellent system for studying the molecular, cellular, and behavioral basis of magnetic field detection.

Title: Mosquito host seeking is a persistent state for temporal multimodal integration

Authors: *T. SORRELLS, A. PANDEY, A. ROSAS, L. VOSSHALL;
Rockefeller Univ., New York, NY

Abstract: Female *Aedes aegypti* mosquitoes seek out humans to bite them and obtain a meal of blood. To perform this task, they require sensory cues from multiple different modalities to bite at high rates. Although this task can take minutes, how long the behavior is sustained and whether host cues are integrated over time is unknown. We used optogenetic tools and machine learning-based classification of behavior to investigate how mosquitoes respond to multimodal host cues. We found that the host cue carbon dioxide induces a persistent internal state change that outlasts the stimulus by several orders of magnitude. This host-seeking state is characterized by increased search behaviors and altered responses to subsequent heat and taste stimuli. This state is only found in host-seeking female mosquitoes; other sensory stimuli tested did not induce persistent responses. Furthermore, we found that the gene *fruitless*, which controls persistent social behaviors in other insects, controls the persistence but not the initial carbon dioxide response in mosquitoes. This suggests that the *fruitless* functions of sexual dimorphism and persistent activity were co-opted during the evolution of mosquito feeding behavior. Our results demonstrate that mosquitoes integrate multisensory information about their human hosts over minutes through a persistent internal state.

Title: The neural circuit underlying light-avoidance behavior in Drosophila larvae

Authors: *D. SAVAS[1], A. SORKAÇ[2], Y. SAVVA[3], M. TALAY[4], G. BARNEA[2];
[2]Neurosci., [1]Brown Univ., Providence, RI; [3]Shape Therapeutics, Inc., Seattle, WA; [4]Mol. and Cell. Biol., Harvard Univ., Boston, MA

Abstract: Sensory systems collect information about the environment and employ neural circuits to process this information to elicit appropriate behavioral responses and maximize survival of the organism. To understand how these circuits function, a combined approach including anatomical and behavioral analyses is required. *Drosophila melanogaster* is a great model to study such circuits due to the vast availability of resources and tools and its ease of use. The larvae of *Drosophila melanogaster* exhibit a robust light-avoidance behavior, also known as photophobia. Previous studies identified two distinct types of neurons that are necessary for photophobic behavior: the light detecting Rh5 photoreceptor in the larval visual organ and the prothoracicotropic hormone (PTTH)-expressing neurons in the central brain. However, how information from the Rh5 photoreceptor neurons is conveyed to the PTTH neurons remains unknown. To examine this, we modified the circuit tracing tool *trans*-Tango, such that it would be suitable for tracing circuits in fly larvae. We termed this version *trans*-Tango MkII. Our anatomical analysis revealed that Rh5 and PTTH neurons are not directly connected. Rather, they are connected through two types of clock neurons: Rh5 photoreceptor neurons synapse onto the 5^{th} Lateral Neuron (5^{th} LaN), which then synapses onto one of the two pairs of dorsal neurons, DN2s. The DN2s, in turn, synapse on the PTTH neurons allowing for a linear information flow from the Rh5 photoreceptors to the PTTH neurons. We complemented these anatomical studies by functional analysis whereby we combined selective inhibition of the various types of clock neurons in behavioral assays. This analysis revealed that the 5th LaN and DN2s are necessary for the larval photophobic behavior since inhibition of these neurons yielded lower levels of photophobia compared to genetic controls. We next aimed to examine whether the activation of the 5^{th} LaN and DN2s is sufficient to elicit photophobia. To this end, we used selective optogenetic activations of either of these neurons in Rh5 photoreceptor mutant larvae that are deficient in photophobic behavior. This analysis revealed that indeed activation of the 5^{th} LaN and DN2s rescues photophobic behavior, whereas environmental and genetic controls do not. As a control, we exposed the Rh5 mutant animals to the light source used for optogenetic activation and they did not show any aversion or attraction to the stimulus. Our study revealed a linear neural circuit consisting of four layers that underlies the photophobic behavior in *Drosophila* larvae.

Abstract: Jellyfish are free-swimming, radially symmetric organisms with complex behaviors that arise from coordinated interactions between distinct, autonomously functioning body parts. This behavioral complexity evolved without a corresponding cephalization of the nervous system. The systems-level neural mechanisms through which such decentralized control is achieved remain unclear. Here, we address this question using the jellyfish, *Clytia*, and present it as a new neuroscience model. We describe a coordinated, asymmetric behavior in which food is passed from the umbrellar margin to the central mouth via directed margin folding. Using newly developed transgenic jellyfish lines to ablate or image specific neuronal subpopulations, we find, unexpectedly, that margin folding reflects the local activation of neural subnetworks that tile the umbrella. Modeling suggests that this structured ensemble activity emerges from sparse, local connectivity rules. These findings reveal how an organismal behavior can emerge from local interactions and functional modularity in the absence of a central brain.

Title: Epigenetic regulation of developmental song learning in juvenile zebra finch

Authors: *G. KUNZELMAN[1], S. E. LONDON[2];
[2]Dept of Psychology, [1]Univ. of Chicago, Chicago, IL

Abstract: Neural properties that regulate developmental learning are particularly difficult to define because both maturation and experience can influence number of cells, cell subtypes, cellular functionality, and synaptic connections, all features that influence learning and memory. The complement of protein coding and noncoding RNAs transcribed from the genome largely determines these cellular properties. Transcription is regulated by transcription factors (TF), proteins that bind "regulatory" genomic regions at transcription factor binding sites (TFBSs). Epigenetic modifications, including those on histone proteins, modulate TFBS accessibility. H3K27ac is a histone modification that reliably denotes accessible TFBSs. To empirically determine the neural properties that support learning of complex behavior, we paired chromatin immunoprecipitation for H3K27ac and high-throughput DNA sequencing (ChIP-seq), and a well-known developmental learning paradigm in zebra finches. We assayed the auditory forebrain, a region required for sensory song learning. We bioinformatically identified differentially accessible genomic regulatory regions and TFBSs in juveniles who differed based on age, sex, and prior song experience, factors that are central to the ability to learn song during development. Based on the differential peak numbers, age has the most robust effect on the H3K27ac-associated regulatory regions. In males, the biggest difference was between two ages when sensory song learning is robust. The TFBSs within these differential regions indicate that neurogenesis, gliogenesis, and neuronal differentiation are driving these developmental changes regulated by a combination of maturation and accumulated song experience. Interestingly, older, age-matched males that differed only in their prior exposure to tutor song were not as distinctly different, suggesting that the extent of changes in the H3K27ac-associated regulatory regions is largely set by maturation by this stage. We found the most robust sex differences in birds still capable of sensory song learning, and overrepresented TFBSs suggest that neuronal circuit organization is differentially regulated between males and females across maturation. This is interesting because both males and females form sensory song memories as juveniles but only males sing; these data suggest a sex difference in sensory song learning mechanisms. Together, our comprehensive evaluation of epigenetically-defined accessible regulatory regions allows for novel insight into the emergence of neural learning circuits in a brain area required for developmental learning of a complex behavior.

Title: Chemotaxis in a neuromechanical model of C. elegans

Authors: M. IVANITSKIY, V. BOOTH, *E. GOURGOU;
Univ. of Michigan, Ann Arbor, MI

Abstract: *C. elegans* nematodes exhibit a wide variety of behaviors, including chemotaxis and associative learning, with only a very limited amount of neural circuitry. Although the connectome of *C. elegans* is mapped, the weights of the connections are not, making the modelling of behavior an open problem. Here we build on our previous work and extend a neuromechanical model for *C. elegans* locomotion to display chemotaxis mediated by a single chemosensory neuron. Chemotaxis is achieved through incorporating the chemosensory neuron AWA, as well as the interneurons AIY and RIA, the latter having bidirectional connections to proprioceptive motor neurons. We use an evolutionary algorithm to optimize the model parameters to exhibit chemotaxis via locomotion towards a food source. We find that simply extending the neural model of chemotaxis in a point worm to the neuromechanical model results in a poorly performing model worm. The suggested model, with additional network complexity due to the AIY and RIA interneurons, and their bidirectional connections to SMDD and SMDV, is found to perform more realistically. We postulate that the RIA-SMDx reciprocal connections, suggested in the literature, allow the chemosensory control circuit to compensate for varying proprioceptive feedback introduced by navigation towards a food source. We are working on introducing learning in the form of synaptic plasticity, to account for known cases of food-triggered associative learning. We envision this work to provide the framework for modeling and understanding more complex, whole-body *C. elegans* behaviors.

Title: Models of juvenile zebra finch song changes using data-driven acoustic features

Authors: *S. BRUDNER[1], J. GOFFINET[1], J. M. PEARSON[2], R. D. MOONEY[3];
[2]Biostatistics and Bioinformatics, [1]Duke Univ., Durham, NC; [3]Duke Univ. Dept. of Neurobio., Durham, NC

Abstract: Song copying by juvenile zebra finches has emerged as a powerful laboratory model for aspects of imitative learning, including human speech learning. However vocal behavior data is high-dimensional and complex, qualities that introduce analysis challenges. Efforts have been made to improve the tractability of vocal behavior analysis, recently including the use by our group and others of variational autoencoders (VAEs), an unsupervised dimensionality reduction technique. Here we extend previous work on VAE-based vocal features to the analysis of vocal changes during zebra finch development. In particular, we develop two approaches: (1) in song learning "forward models," we explicitly model the dependence of syllable acoustic distributions on animal age by developing age-dependent multivariate gaussian distributions in VAE latent space; (2) in song learning "reverse models," we predict animal age from vocal features, enabling us to assess the maturity of individual song renditions. We show that our models reproduce state-of-the-art results about circadian rhythms in syllable maturation. Our models also reveal circadian changes in rendition-to-rendition syllable variability, consistent with a prior report, while also allowing us to explore previously inaccessible aspects of this variability. Finally, we use these methods to show that a variety of circadian behavioral features associated with learning to copy a tutor's model song also occur in the behavior of isolate juveniles without an appropriate tutor model.

Title: Recognition of birdsong syllables with ultra-sparse spike sequence representations

Authors: *L. E. S. TAVARES, D. Z. JIN;
Deptartment of Physics, Pennsylvania State Univ., University Park, PA

Abstract: Birdsong is important for research in vocal learning and communication in animals. For many research questions, accurate annotations of individual vocal elements are indispensable. However, manually annotating large sets of songs can be cumbersome and expensive. While tools for automatic recognition of syllables exist, they either require large amounts of pre-annotated data or have sub-optimal accuracy. Such limitations discourage adoption of current automatic tools in research.
Here, we present a method for automatic syllable recognition that requires only a few training exemplars and achieves error rates low enough for practical applications. As new annotations become available, the system's accuracy can be continuously improved. We show results for a number of songbirds commonly used in neuroscience experiments.
Our method represents vocal objects as sequences of overlapping acoustic events. Groups of feature-detecting neurons encode the onsets and offsets of these events into ultra-sparse sequences of spikes. Continuous recognition is done by a template-matching scheme, which compares the relative delays of the spikes to stored templates and integrates them over time. To ensure that all acoustic events are detected, including those eliciting weak responses, we also adopt a threshold adaptation mechanism, which modifies the neuron's receptive field and makes it less selective. In a second stage, a layer of specialized binary decision making units selects a single prediction for each syllable in the song. This prevents insertions arising from the adaptation mechanism. The final output is a list of syllable onset times, offset times and labels. We demonstrate our results for Bengalese finches, zebra finches and canaries. The phrase structure of the canary song allows us to further improve the recognition results by predicting entire phrases rather than individual syllables within them. We show that, for most birds, the error rate can be as low as 5% with less than 10s of training data, outperforming existing deep learning tools for continuous syllable recognition. In addition, the error decreases as more data becomes available for training.

Title: Segmenting vocalizations for downstream analysis with a deep neural network, TweetyNet

Authors: *D. NICHOLSON;
Emory Univ., Washington, DC

Abstract: Many analyses of experiments studying vocal learning and control require time-consuming annotation of the individual elements of animal vocalizations. For example, many

researchers studying birdsong annotate a syllable of interest manually, with a GUI. Other methods for analyzing vocal behavior do not require annotation of individual elements. Instead they require segmentation of audio into two categories: vocalizations and non-vocalizations. All of the segments labeled as "vocalization" are then passed to a downstream algorithm, for example those that compute measures of similarity. It remains unclear how reliable and robust different algorithms for segmentation are. To further understand this, here we test a deep neural network architecture we developed, TweetyNet (https://github.com/yardencsGitHub/tweetynet), as a "front end" for segmenting audio into vocalizations that are then passed to downstream algorithms for further analysis. Previously we demonstrated that TweetyNet automates detailed syllable-level annotation of very large datasets of Bengalese Finch and canary song (https://www.biorxiv.org/content/10.1101/2020.08.28.272088v2). Here we show that TweetyNet performs well as a simple binary classifier, dividing audio into vocalization and no-vocalization segments. TweetyNet reliably recovers segments of zebra finch song (http://ofer.hunter.cuny.edu/songs) and bat vocalizations (https://www.nature.com/articles/sdata2017143), achieving near-perfect accuracy (~99% frame error rate across all animals). Experiments in progress test the robustness of this approach with simulated noisy data, and test application of TweetyNet to human speech. We will also give an update on development of our toolbox that makes it easier for researchers to apply neural networks models to the study of animal vocalizations (https://vak.readthedocs.io/en/latest/).

Title: Estimating the Number of Hidden States in Birdsong Syntax

Authors: *J. LU, D. Z. JIN;
Dept. of Physics, Pennsylvania State Univ., University Park, PA

Abstract: Syllable sequences in the songs of many songbird species such as the Bengalese finch and the canary are variable and complex. Such sequences follow long-range rules (Jin & Kozhevnikov 2011 and Cohen et al. 2020), and cannot be described by the basic Markov model, where each syllable is represented by only one state. Instead, the long-range rules need to be captured with several states representing the same syllable. With such a “many-to-one” mapping from the states to the syllables, the statistical state transition models become the Partially

Observed Markov Model (POMM) (Jin & Kozhevnikov 2011 and Jin 2009). However, it is unclear how to estimate the number of states for each syllable from the observed syllable sequences. Here we propose a efficient algorithm to solve the problem. The key is to construct the moment matrix. For each syllable, we find the past subsequence of length N preceding the syllable, and the future subsequence of length N following the syllable. The number of transitions from each past subsequence to each future subsequence is counted and normalized so that the sum is equal to 1. These numbers become entries to the moment matrix for the syllable. We then use Singular Vector Decomposition (SVD) to find the optimal low rank approximation to the moment matrix. The approximation is statistically validated by finding the p-value through the bootstrap resampling of the sequences. The estimated rank is the number of the hidden states for the syllable. When the underlying process is POMM, our algorithm returns a lower bound that is necessary to describe the song syntax given the finite data. In tests with birdsong-like random POMMs, we show that the lower bound approach the true number of hidden states as the number of observed sequences increases. Our algorithm also provides indications when the syllable sequences are not describable with POMM. A simple example of such sequences is A^nB^n, where n copies of syllable A's are followed by exactly n copies of syllable B's (Gentner et al. 2006). We find that as the number of observed sequences increases, the number of states for each syllable keeps increasing with no sign of converging to finite values. This is indicative of sequences beyond the capabilities of POMM. We show how our algorithm provides insights into interesting problems such as the learning of song syntax in the Bengalese finch (James et al. 2020).

Title: Analysis of budgerigar vocalizations

Authors: *A. R. ZENDER[1], L. ACKERT-SMITH[2], M. A. LONG[2], D. Z. JIN[1];
[1]Dept. of Physics, Pennsylvania State Univ., University Park, PA; [2]Neurosci. Inst., NYU Sch. of Med., New York, NY

Abstract: Parrots are capable of an astounding degree of vocal learning and rich social interactions, making them a potentially important model system for understanding the neural

basis of vocal communication. However, the interactive vocal repertoire of the parrot remains poorly understood. Here we use advanced methods to study vocal exchanges in the budgerigar, a small Australian parrot. Pairs of birds were placed in an arena with 2-4 microphones and 4 cameras for continuous recordings lasting several months. We observed the vocalizations of the birds while they were together as well as while they were separated by various partitions designed to selectively impair visual and/or tactile access. We developed a range of computational tools to analyze their vocalizations including contact calls, alarm calls, and warble. Audio files were segmented into potential vocalizations using the wave envelope, and nine acoustic features were computed; the median values of each resulted in 9-dimensional vectors corresponding to single vocal elements. A support vector machine (SVM) was then employed to group the elements into contact calls, alarm calls, warble, and various sources of environmental noise. To optimize the performance of the SVM, we used a greedy search to show that the best accuracy occurred when using just five of the acoustic features, yielding an error of 7.3 percent on our data set compared with hand labeled designations. We used these classifications to examine the impact of the partition conditions on vocal use. In initial observations, we found that both visual and tactile occlusion led to a significant change in vocal behavior, suggesting that multimodal sensory interaction may be an integral part of parrot communication.

Title: Sequence-dependent modulation of neural activity in the songbird basal ganglia

Authors: *A. WOOD, R. CHHIBBER, S. J. SOBER;
Biol., Emory Univ., Atlanta, GA

Abstract: Skilled motor behaviors such as speaking, writing, or playing the piano require a combination of fine control of moment-to-moment movement kinematics and flexible sequencing of longer behavioral “motifs”. The basal ganglia are a group of subcortical nuclei implicated in a wide range of motor and cognitive functions, including motor kinematics and

motor sequencing. The songbird Bengalese finch (*Lonchura striata*) has a song-specialized basal ganglia nucleus (Area X) which has previously been implicated in both kinematic and sequential modulation of song. Area X contains neurons that are homologous to mammalian striatal and pallidal neurons. Using *in vivo* electrophysiology in adult male Bengalese finches, we first show that classes of Area X striatal and pallidal neurons can be separated by firing properties. We hypothesized that individual Area X pallidal neuron activity reflects both phonological and sequential information. To test this, we assess the tuning of individual neurons by analyzing activity at points in song where syllable sequencing is variable using a bootstrap analysis of premotor firing rates and linear correlations. Our preliminary data display strong tuning for sequence but an apparent lack of tuning for phonological structure, consistent with reinforcement learning models of song learning which predict that Area X integrates dopaminergic reward signals with contextual information about recent motor commands.

Title: Shared neural circuit mechanisms for auditory and non-auditory guided vocal learning in adult songbirds

Authors: *J. MCGREGOR[1], A. GRASSLER[1], P. I. JAFFE[3], A. L. JACOB[2], M. S. BRAINARD[4], S. J. SOBER[2];
[2]Biol., [1]Emory Univ., Atlanta, GA; [3]Neurosci. Grad. Program, UCSF, San Francisco, CA; [4]Dept Physiol., UCSF Ctr. For Integrative Neurosci, San Francisco, CA

Abstract: Songbirds and humans share the ability to use sensory feedback to guide the learning of their vocal output, and both species have evolved unique neural circuitry that is specialized for promoting vocal learning. Auditory feedback is particularly important for shaping vocal output, and numerous prior studies have revealed the neural mechanisms underlying auditory-guided vocal learning. Non-auditory signals can also shape vocal output. However, the neural circuit mechanisms that underlie non-auditory vocal learning are unclear. Here, we assessed whether and how non-auditory feedback guides vocal learning in adult songbirds. First, we tested whether non-auditory feedback cues (cutaneous electric shocks) are sufficient to drive adaptive changes in vocal output. Next, we assessed the role of LMAN, the output nucleus of a specialized vocal

learning neural circuit, in this novel form of vocal learning. Finally, we evaluated the necessity of dopaminergic input to Area X, the basal ganglia nucleus of this vocal learning circuit, in non-auditory vocal learning. We found that this song learning circuit and its dopaminergic inputs are necessary for non-auditory vocal learning, demonstrating that this neural pathway is not specialized exclusively for processing auditory feedback to reshape vocal behavior. The ability of the songbird vocal learning pathway to process both auditory and non-auditory information to guide changes to vocal output may reflect a general principle for the neural systems that have evolved to support vocal learning across species.

Title: Behavioral and physiological responses to social defeat stress and to BDNF-active drugs vary over the light-dark cycle

Authors: *E. SHAUGHNESSY, M. G. WELCH, A. M. ROSENHAUER, K. MALHAM, K. L. HUHMAN;
Georgia State Univ., Atlanta, GA

Abstract: Social stress is a salient risk factor for neuropsychiatric illnesses including major depressive disorder, post-traumatic stress disorder, and other anxiety disorders. Brain-derived neurotrophic factor (BDNF) has been implicated in the pathophysiology and treatment of these disorders, but there are conflicting data regarding the potential therapeutic use of BDNF-related manipulations in treating them. Our lab has shown that administration of an agonist (7,8-DHF) for the BDNF cognate receptor Tropomyosin receptor kinase B reduces the behavioral response to social defeat stress (Rosenhauer et al 2019). Conversely, Berton et al. (2006) showed that BDNF signaling is necessary for the behavioral response to social defeat stress. One difference between the studies is that the former ran behavior during the dark (active) phase of the daily light-dark cycle, whereas the latter studies were run during the light (inactive) phase. The purpose of this study was to determine whether responses to social defeat and to BDNF vary over the light-dark cycle and, if so, what brain regions are likely involved. In the first experiment, male (n=25) hamsters were defeated or experienced the no defeat protocol in the

light or the dark phase of the daily cycle, given 7,8-DHF (5mg/kg in 50% DMSO 50% saline) or vehicle, and tested for conditioned defeat 24 hours later. Administration of 7,8-DHF decreased social avoidance when defeat, treatment, and testing occurred during the dark phase. Conversely, animals that were defeated, received 7,8-DHF, and were tested in the light showed an increase in social avoidance. Next, we examined neural activation of selected brain regions in the putative neural circuit that controls responses to social defeat stress in male (n=28) and female (n=25) Syrian hamsters using the immediate early gene product C-Fos as a marker. As in Experiment 1, hamsters were defeated or not during the dark or the light phase and immediately given 7,8-DHF or vehicle. 90 minutes later, brains were collected and processed for C-Fos immunohistochemistry. There were significant main effects of sex, defeat, and 7,8-DHF in specific brain regions. In particular, there were significantly more C-Fos-positive cells in all regions in males than in females. There was a significant effect of defeat on C-Fos in the infralimbic (IL) cortex and anterior cingulate cortex (ACC), but this effect was observed only in hamsters defeated and tested during the dark phase but not during the light phase. Together, these data underscore the importance of considering lighting and circadian variables when assessing the therapeutic potential of new treatments for stress-related disorders.

Title: (3α,5α)3-hydroxypregnan-20-one (3α,5α-THP) fails to attenuate stress-induced increases in serum corticosterone in male and female rats, but has sex and region specific effects on CRF expression

Authors: *G. BOERO, R. E. TYLER, C. A. TODD, T. K. O'BUCKLEY, I. BALAN, J. BESHEER, A. L. MORROW;
Univ. of North Carolina At Chapel Hill, Chapel Hill, NC

Abstract: Neuroactive steroid (3α,5α)3-hydroxypregnan-20-one (3α,5α-THP, allopregnanolone) is the most potent positive modulator of $GABA_A$ receptors. It has previously been reported that 3α,5α-THP or 3α,5α-THDOC attenuate basal and stress-induced hypothalamic corticotropin-

releasing factor (CRF) mRNA expression as well as ACTH and corticosterone (CORT) serum levels in male rats (Patchev et al., 1994; 1996; Owens et al., 1992). We recently showed (Boero et al, 2021) that 3α,5α-THP regulation of basal levels of CRF are sex and region dependent. In this study, we investigated 3α,5α-THP regulation of stress-induced CRF across brain in male and female Sprague Dawley rats. Rats were injected with 3α,5α-THP (15mg/kg, IP) in hydroxypropyl-beta-cyclodextrin (45%) or an equivalent volume of vehicle and after 15 min subjected to a) 30 min of restraint stress (RS), sacrificed instantly or after 3hrs, or b) 10 min of swim stress (SS), return in their cage and sacrificed 10 min later. Brains and blood were harvested for western blot measurements of CRF and ELISA assay for CORT. Data were analyzed statistically by 2-WAY ANOVA followed by the Tukey's post-hoc test. In male rats, RS increased CRF levels 3hrs after the stress (Hyp +76%, $p<0.05$; CeA +74%, $p<0.05$; NAcc +176%, $p<0.05$; VTA +96%, $P<0.05$); no stress effect was detected in hippocampus. Serum CORT levels were elevated in male rats immediately after the RS (+495%, $p<0.0001$), and was still high 3hrs later (+272%, $p<0.05$). After SS, CORT levels increased as expected (+319%, $p<0.001$). 3α,5α-THP did not attenuate either stress response in male rats. In female rats, RS increased CRF levels immediately after stress, in hypothalamus (+100%, $p<0.01$) and hippocampus (+36%, $p<0.05$), and 3α,5α-THP attenuated the CRF stress response. No stress effect was detected in CeA, NAcc and VTA. Immediately after RS, serum CORT levels increased in female rats (+157%, $p<0.05$), but not 3hrs later. Moreover, SS induced a significant increase of serum CORT levels in female rats (+202%, $p<0.01$). 3α,5α-THP did not alter the CORT stress response after RS or SS. The data indicate that 3α,5α-THP only inhibits stress-induced CRF in hypothalamus and hippocampus of female rats. We previously showed (Boero et al., 2021) higher basal 3α,5α-THP levels in those brain areas of female vs male rats. Therefore higher basal levels, in addition to 3α,5α-THP administration, might attenuate the stress response in specific brain areas of female rats. Further studies will occur to clarify the role of 3α,5α-THP in the stress response.

Title: Effects of chronic cannabis vapor self-administration on the neuroendocrine stress response in rats

Authors: *N. C. GLODOSKY[1], C. CUTTLER[1], T. G. FREELS[2], A. N. MALENA[1], H. R. WRIGHT[1], D. E. GINDER[1], H. V. WEIMAR[1], R. J. MCLAUGHLIN[1];
[1]Washington State Univ., Pullman, WA; [2]Univ. of Massachusetts Med. Sch., Worcester, MA

Abstract: Stress is a significant risk factor for a multitude of mental, cardiovascular, metabolic, and immune diseases. Cannabis users report stress relief as their primary reason for use, although studies have found a positive relationship between cannabis use and the prevalence of stress-related disorders. Evidence from our lab indicates a blunted stress response in humans following chronic cannabis exposure. Specifically, we have shown that sober chronic cannabis users displayed a significantly smaller increase in cortisol following a stressor compared to non-using controls. However, these studies were unable to determine whether cannabis use directly *causes* alterations in the stress response, or whether an attenuated stress response represents a pre-existing risk factor for cannabis use. Additionally, it remains unclear what mechanisms are responsible for these neuroendocrine alterations in cannabis users.
Male and female Sprage Dawley rats (n=12/sex/group) were trained to self-administer vaporized cannabis containing 69.9% THC at one of four extract concentrations (0, 75, 150, or 300 mg/ml) daily for 30 days. Half of the rats were subjected to a 30 min acute restraint stress challenge 24 h after the final self-administration session while the other half served as no stress controls to assess stress reactivity. Given that corticotropin-releasing hormone (CRH) activity in the central nucleus of the amygdala (CeA) contributes to the emotional response to stressors, which is dampened in chronic cannabis users, we extracted brains from cannabis- and vehicle-exposed rats following acute stress (or no stress) exposure to assess CRH peptide content and CRH receptor type-1 (CRHR1) protein expression in the CeA under stress or non-stress conditions. Female rats earned significantly more vapor deliveries than male rats. Pre-vapor stress reactivity was not a predictor of self-administration rates in either sex. Importantly, cannabis self-administration reduced stress reactivity in female, but not male, rats specifically at the 150 mg/ml dose, which was also the concentration that was most readily self-administered in both sexes. Studies examining CRH and CRHR1 protein expression in the CeA are ongoing, but we predict that cannabis-exposed rats will have lower stress-induced CRH peptide content in the CeA compared to non-exposed rats.
These studies provide a foundation for understanding the consequences of chronic cannabis use and by using an animal model with strong internal and ecological validity, we are in an excellent position to identify causal effects of cannabis use and determine the neurobiological mechanisms by which they occur.

Title: Orexins through receptor subtypes (Orx_1 & Orx_2) differentially gate stress-prompted phenotype development

Authors: *J. YAEGER[1], T. R. SUMMERS[2], C. H. SUMMERS[2];
[2]Dept. of Biol., [1]Univ. of South Dakota, Vermillion, SD

Abstract: Stress-induced disorders, like anxiety, depression, and post-traumatic stress disorder (PTSD), are difficult to treat, in part, due to variability in both symptoms and treatment outcomes. These qualities, too, have made a mechanistic understanding of the pathophysiology associated with the disorders elusive and difficult to assess. As individuals react differently to stress, and therefore experience unique consequences of stress, it is sensible that an exploration of phenotype formation during periods of stress might uncover avenues toward treatment options for anxiety, depression, and/or PTSD. Using a preclinical assessment tool, the Stress Alternatives Model (SAM), a Go-No Go paradigm in which social stress promotes behavioral phenotype bifurcation (Escape/Resilient & Stay/Susceptible), we identified roles for the orexin system in regulating phenotype formation. Orexins (Orx_A & Orx_B) are hypothalamus-produced neuropeptides that regulate a range of behaviors, including arousal, feeding, motivation, and sleep. These neuromodulators have wide influence over several brain regions by targeting and activating two receptor subtypes (Orx_1 & Orx_2). In a series of experiments, we identified transcriptional relationships between orexin receptor genes in key brain areas, namely hippocampus, prefrontal cortex (PFC), and amygdala, and behavioral outcomes (like fear freezing) associated with phenotype development. In particular, in the basolateral amygdala (BLA), Orx_1 mRNA (*HCRTR1*) expression is positively correlated with freezing behavior in Escape mice, while Orx_2 (*HCRTR2*) is negatively associated with this response in Stay animals. Further, we revealed a role for the two orexin receptor subtypes in mediating stress behavioral responses in a counterbalanced fashion. Pharmacological inhibition (or genetic knockdown) of BLA Orx_1 promotes Escape/Resiliency, an effect that is mimicked with Orx_2 agonism. Alternatively, inhibition of Orx_2 and stimulation of Orx_1 prompts differential behaviors. Further, in the BLA Orx_1 antagonism has a dominant transcriptional effect on Stay animals causing increases in Orx_2, ERK_1, and BDNF expression. Contrastingly, Orx_2 inhibition promotes a reduction in Orx_2 and increases in $PLC_{\beta 1}$ and BDNF in Escape mice. Interestingly, orexin receptors in the BLA are mostly found on different cells with Orx_1 co-localizing predominantly with CamKIIα (a glutamatergic neuron marker) and Orx_2 being expressed more frequently with GAD67 (GABA neurons). Together, these results suggest Orx_1 and Orx_2 work together to balance stress responsivity.

Title: Promotion of social stress in females reveals sex-independent viability of Orx_2agonist for the treatment of affective disorders

Authors: *C. H. SUMMERS[1], J. D. W. YAEGER[1], M. JOHN[1], W. J. KORZAN[3], R. P. WATERS[4], T. R. SUMMERS[2];
[1]Biol., Univ. of South Dakota, Vermillion, SD; [2]Biol., Univ. of South Dakota, VERMILLION, SD; [3]Norwegian Univ. of Life Sci., As, Norway; [4]Dept. of Biol., Univ. of Mary Washington, Fredericksburg, VA

Abstract: The onset of affective disorders (like anxiety & depression) often coincides with stressful situations; however, individuals react differently to these encounters, making them difficult to diagnose, treat, and assess. Additionally, females are disproportionately affected by these disorders. While social stress is potent and prevalent in both humans and preclinical models used for the study of psychiatric disorders, female mice are difficult to study in the laboratory due to ineffective or exhaustive strategies for the induction of social stress. Using the Stress Alternatives Model (SAM), a behavioral paradigm in which test mice experience social stress from a larger aggressor mice promoting them to diverge into distinct stress-related phenotypes (those that exhibit enhanced fear conditioning/susceptible & those that display active avoidance/resilience), we tested a new technique for inducing social stress in females. Large male retired breeders (CD1 mice) were conditioned to act aggressively toward female mice (C57BL/6) by pairing interactions with a mild shock. The greatest reaction from CD1 aggressors appeared to be observed when the shock was elicited during anogenital sniffing. Despite CD1-induced aggression levels being similar during trials, distinct and important differences were observed between male and female SAM behavior. For example, female mice tend to show more active avoidance behavior and faster active avoidance time. Further, female mice exhibit more motivation toward active avoidance and lower, overall, fear freezing. The stage of the estrous cycle also seemed to be important as female mice in proestrus exhibited lower fear freezing and more social preference in the Social Interaction/Preference (SIP) Test. As we have recently demonstrated that the orexin system is important for mediating stress responses in males, we further assessed this in females. The orexin system is composed of two neuropeptides (Orx_A & Orx_B), produced in the lateral/dorsomedial-perifornical hypothalamus, that act as neuromodulators by targeting two orexin receptor subtypes (Orx_1 & Orx_2). While Orx_A shows equal binding preference for both receptors, Orx_B exhibits a greater affinity for Orx_2. In both

males and females, whole brain (intracerebroventricular) activation of Orx_2 receptors promotes enhanced social preference and resilience in the SIP Test. Together, these results characterize a unique method for promoting social stress in females and suggest a viable option for the treatment of stress-related disorders in both males and females by selectively activating Orx_2 receptors.

Title: Characterizing the Role of Estradiol in Neural Systems Underlying Social Stress Susceptibility in Female Rats

Authors: *S. E. MOTT[1], B. S. POPE[2], S. K. WOOD[1];
[1]Univ. of South Carolina Sch. of Med., Columbia, SC; [2]Univ. of South Carolina, Columbia, SC

Abstract: Repeated exposure to social stress is a common risk factor for the development of anxiety disorders. Women are twice as likely as men to suffer from anxiety. However, this increased susceptibility in females is confined between the onset of puberty and the end of menopause, suggesting that ovarian hormones may contribute to this disproportionate risk of stress-related disorders. We have shown that witness stress (WS), a model of social stress in which a female rat is subjected to witnessing an aggressive social defeat encounter between a male intruder and a novel male resident, produces anxiety-like behaviors selectively in intact, cycling female rats. Ovariectomized (OVX) females are largely resistant to WS, but estradiol replacement reinstates these anxiety-like behaviors. Moreover, intact females, but not OVX, exposed to WS exhibit a distinct increase in corticotropin releasing factor (CRF) expression in the central amygdala (CeA), a stress sensitive brain region. The current study seeks to understand specific 17-β estradiol (17-βE)-induced neural regulation that may contribute to the heightened susceptibility to social stress among females. Following recovery from OVX or sham surgery, female rats were treated with either 17-βE(10μg/rat, s.c.) or vehicle (0μg/rat, s.c.) and one hour later, were exposed to WS or control handling. WS/control episodes were video recorded to measure burying, freezing, and rearing behaviors, and blood samples were collected one hour after WS/control to assess corticosterone (CORT) levels. Rats were perfused and brains were collected two hours after WS/control. To quantify activity of CRF neurons, brains were sliced

coronally and immunohistochemistry was used to double label for CRF and cFos in various stress sensitive regions. Behavioral responses were shown to be regulated by 17-βE; WS-evoked burying evident in intact females was decreased by OVX and reinstated by 17-βE. However, there was no effect of WS or 17-βE on freezing or rearing behaviors. Additionally, 17-βE increased WS-induced plasma CORT levels. cFos positive CRF expression in the CeA was robustly enhanced by 17-βE during WS, but not control. Conversely, in the CA1 and CA3 subfields of the hippocampus, there was no effect of WS or 17-βE on cFos expression in CRF positive neurons. Analysis of stress sensitive brain regions including the hypothalamic paraventricular nucleus and locus coeruleus are ongoing. Taken together, these findings suggest that 17-βE is paramount in facilitating the anxiety-like responses to WS and support the role of the CeA as a region-specific regulator of these responses.

Title: High-yawning rats are more susceptible to dopaminergic D3 agonists than low-yawning males

Authors: *J. EGUIBAR[1], C. CORTES[2], A. TRUJILLO[3], A. UGARTE[4], O. ISIDRO[5]; [1]Benemerita Univ. Autonoma De Puebla, Puebla, Pue., Mexico; [2]Benemérita Univ. Autonoma de Puebla, Puebla, Mexico; [3]Facultad de Ciencias Biológicas, Benemérita Univ. Autonoma de Puebla, Puebla, Pue., Mexico; [4]Inst. de Fisiología, Benemérita Univ. Autonoma de Puebla, Puebla, Pue,, Mexico; [5]Inst. de Fisiología, Benemérita Univ. Autonoma de Puebla, Puebla, Pue., Mexico

Abstract: We selectively inbred two sublines from Sprague-Dawley strain, the high-yawning (HY) had 20 yawns/h and the low-yawning (LY) one order of magnitude lower frequency with just 2 yawns/h. We showed previously that (-)-quinpirole induced more yawns in the HY with respect to LY male rats. The aim of this study was to analyze the effects of two D_3 specific agonists 7-OH-DPAT and PD-128907 on yawning frequency.All the subjects were maintained under standard conditions. Control rats received saline (NaCl 0.9%) or different doses of two D3 agonists by s.c. injection in the dorsal neck region. The experiment last 1 h and observed in a Plexiglass cage and we measured simultaneously yawning and recording them using The Observer XT (Noldus Technologies, The Netherlands) by two trained observers.Our results

showed that both agonists induced higher frequencies of yawning in the HY with respect to LY rats. The 7-OH-DPAT induced the highest yawning frequency with de 5 μg dose and with PD-128907 the 100 μg was the most effective dose. In conclusion, the HY male rats are more sensible to the effects of the specific D3 dopaminergic agonists probably due to differences in the neural circuits involved in the regulation of yawning.

Title: Emerging activity dynamics and noradrenergic modulation of prelimbic cortical neuronal ensembles during heroin seeking

Authors: *E. M. DONCHECK, R. I. GRANT, E. V. ROMANOVA, C. W. BOWEN, E. J. SANDAGO, K. T. WINSTON, P. N. SIEGLER, K. M. VOLLMER, L. M. GREEN, M. S. BELL, J. M. OTIS;

Abstract: Determining the neurobiological basis for relapse in opioid use disorder will facilitate identification of more effective treatment targets. Drug-associated cues are a common relapse trigger, as they can provoke cravings and compulsive drug seeking. Cue-induced drug seeking requires activation of the prelimbic medial prefrontal cortex (PL), which coordinates appetitive behaviors but is dysregulated in substance use disorder. PL is comprised of highly heterogeneous cell types, and this diversity has obscured the precise identification of how PL circuit dynamics orchestrate drug seeking. To address this issue, we developed a head-fixed heroin self-administration procedure to allow longitudinal tracking of PL neuronal activity simultaneous with behavior. To measure the activity of PL projection neurons during this task, we virally labeled these neurons for calcium imaging (AAVdj-CaMKIIa-GCaMP6s) and implanted a GRIN lens dorsal to PL. Subsequent two-photon recordings simultaneous with heroin self-administration reveal reductions in calcium event frequency and amplitude in PL neurons following heroin self-administration, effects which persist through extinction. Interestingly, this hypoactivity was rescued to baseline conditions during cue-induced reinstatement in a manner

that was time-locked to drug-associated cue presentation. As local noradrenergic signaling can rapidly increase PL activity and mediates drug-cue memory retrieval, we hypothesized that inputs from the locus coeruleus (LC) may contribute to the rescue of PL activity during reinstatement. In support of this idea, we find that chemogenetic inhibition of LC-PL axon terminals blocks cue-induced reinstatement of heroin seeking. Surprisingly, this effect was persistent as mice failed to reinstate upon a subsequent cue test, whereas control mice reinstated across multiple tests. Effects of chemogenetic LC inhibition on PL neuronal activity during cue-induced reinstatement revealed differences in excitatory activity dynamics during the CNO test which, like suppression of reinstatement, persisted upon retest. Analyses are underway to track changes in activity dynamics of discrete ensembles and single cells throughout heroin self-administration, extinction, and reinstatement. These findings support the hypothesis that activity in LC-PL noradrenergic axons rescues activity in downstream PL projection neurons for cue-induced reinstatement of heroin seeking.

Title: Activity in paraventricular thalamostriatal neurons is necessary and sufficient for the suppression of reward seeking but is dysfunctional following opioid use

Authors: *K. M. VOLLMER[1], L. M. GREEN[1], R. I. GRANT[1], E. M. DONCHECK[1], K. T. WINSTON[1], E. V. ROMANOVA[1], P. N. SIEGLER[1], C. W. BOWEN[1], J. M. OTIS[1,2]; [1]Neurosci., [2]Hollings Cancer Ctr., Med. Univ. of South Carolina, Charleston, SC

Abstract: Suppression of reward-seeking behaviors under inappropriate circumstances is necessary for survival. Opioids have been shown to dysregulate this behavioral inhibition, such that individuals with opioid use disorder (OUD) will compulsively seek opioids even when that behavior is maladaptive or counterproductive. Despite this knowledge, the neural circuits that are responsible for the suppression of reward seeking have not been fully characterized. Recent work from our laboratory, and the work of others, suggests that the posterior paraventricular nucleus of

the thalamus (pPVT) may be involved. Specifically, the pPVT has strong connectivity with the nucleus accumbens (NAc), and pPVT-NAc neuronal activity is often suppressed during reward seeking and feeding but activated when reward seeking would be inappropriate, such as during conditions of stress or satiety. However, it is unclear whether pPVT-NAc activity is necessary and sufficient for the suppression reward seeking, and whether chronic opioid use modifies this circuit's role in motivated behaviors is unknown. Using a sucrose self-administration task, we find that optogenetic stimulation of pPVT-NAc neurons suppresses sucrose self-administration and cue-induced reinstatement of sucrose seeking. Next, we find that optogenetic inhibition of pPVT-NAc neurons unleashes these behaviors under inappropriate circumstances, specifically under conditions of stress or after extinction training. Surprisingly, the inhibition of sucrose-seeking behaviors through pPVT-NAc stimulation was abolished by a single systemic injection of heroin, suggesting that opioids may reorganize or dysregulate this circuit in some manner. In further support of this idea, using an i.v. heroin self-administration task we find that optogenetic stimulation of pPVT-NAc neurons does not suppress cue-, drug-, or stress-induced reinstatement of heroin seeking, unlike sucrose seeking. Finally, using *in vivo* two-photon calcium imaging, we investigated the influence of sucrose versus heroin self-administration on the activity of pPVT-NAc neurons. Overall, we find that pPVT-NAc neuronal activity is highly suppressed in mice that have self-administered heroin, but not sucrose, an effect that persists for weeks beyond their last heroin self-administration session. Overall, our data show that activity in pPVT-NAc neurons is necessary and sufficient for the suppression of natural reward (sucrose) seeking, whereas activity in this circuit is both suppressed by heroin use and incapable of preventing the heroin-seeking behaviors.

Neurosciences, Med. Univ. of South Carolina, Charleston, SC

Abstract: In substance use disorder (SUD), cravings and relapse to drug use emerges in a manner that coincides with dysregulated activity in the prefrontal cortex (PFC). Research using the drug self-administration procedure in rodents confirms that activity within a subregion of PFC, the prelimbic medial PFC (PL-PFC), is necessary for reinstatement of drug seeking provoked by distinct relapse triggers (including drug-associated cues, the drug itself, and stressors). However, the PL-PFC is a highly heterogeneous structure with diverse neuronal ensembles that differentially contribute to behavior, and how these unique neuronal ensemble dynamics might contribute to reinstatement is unclear. Furthermore, despite the convergent requirement of PL-PFC activity for reinstatement, it is unknown whether different relapse triggers provoke drug seeking through overlapping or distinct neuronal ensembles. Here, we paired a novel head-fixed drug self-administration task with simultaneous two-photon imaging of PL-PFC projection neurons to characterize the neuronal ensemble dynamics that differentially evolve during cue-, drug-, and stress-induced reinstatement. Mice received microinfusions of a genetically encoded calcium indicator (AAVdj-CaMKIIa-GCaMP6s) and GRIN lens implantation dorsal to PL to allow visualization of PL-PFC projection neurons across each of the reinstatement tests. Preliminary spectral clustering analyses reveal heterogeneous neuronal ensembles that differentially encode active lever pressing behavior during each of the reinstatement tests, with both excitatory and inhibitory responses for each test. Longitudinal tracking analyses are currently underway to compare PrL-PFC ensemble and single cell activity dynamics across cue-, drug-, and stress-driven reinstatement to determine the extent of their potential overlap and contribution to reinstatement.

Title: Characteristics and function of paraventricular thalamus synaptic inputs to nucleus accumbens cell populations in the context of sucrose and opioid seeking

Authors: *L. GREEN, K. M. VOLLMER, R. I. GRANT, E. M. DONCHECK, K. T. WINSTON, E. V. ROMANOVA, P. N. SIEGLER, C. W. BOWEN, E. J. SANDAGO, M. S. BELL, J. M. OTIS;
Neurosci., Med. Univ. of South Carolina, Charleston, SC

Abstract: Suppression of inappropriate or maladaptive reward-seeking behaviors is critical for survival, and yet compulsive opioid seeking and taking occurs despite negative consequences in opioid use disorder (OUD). Recent work from our laboratory, and the work of others, suggests that the posterior paraventricular thalamus (pPVT) plays a crucial role in suppressing inappropriate or maladaptive reward seeking. However, the downstream mechanisms whereby this occurs, and the influence of opioid use on this circuit, remains unclear. Here we use a combination of viral strategies, transgenic mouse lines, patch-clamp electrophysiology, and optogenetics to characterize the innervation of the pPVT projection neurons onto cell-type specific NAc neurons. Overall, data confirms previous work showing that pPVT innervates dopamine D1 receptor (D1+) expressing medium spiny neurons (MSNs), dopamine D2 receptor (D2+) expressing MSNs, and parvalbumin (PV+) expressing interneurons in the NAc. Interestingly, the pPVT-NAc synaptic input onto PV+ interneurons was stronger than that onto MSNs, and was selectively dependent on calcium permeable AMPA receptors (CP-AMPArs). Thus, we next determined if the inhibition of reward seeking caused by pPVT-NAc stimulation requires CP-AMPArs. Data confirms that optogenetic stimulation of pPVT-NAc neurons abolishes sucrose self-administration, whereas self-administration is rescued through intra-NAc infusion of a CP-AMPAr antagonist (IEM-1460), but not antagonists that inhibit D1 signaling (SCH23390) or D2 signaling (Raclopride). Overall, our data support the idea that pPVT-NAc neuronal activity suppresses natural reward (sucrose) seeking through the activation of CP-AMPArs on downstream PV+ interneurons. Ongoing work investigates the influence of opioid use on pPVT inputs to each of the identified downstream cell populations. Together, these data aid in the identification of precise circuits that are required for the suppression of reward seeking and how they are modified in OUD.

Title: Characterization and functional interrogation of dorsomedial prefrontal neuronal ensembles during conditioned reward seeking

Authors: *R. I. GRANT, E. M. DONCHECK, K. M. VOLLMER, K. T. WINSTON, E. V. ROMANOVA, P. N. SIEGLER, H. HOLMAN, C. W. BOWEN, J. M. OTIS;
Med. Univ. of South Carolina, Charleston, SC

Abstract: Exclusive cell populations within the dorsomedial prefrontal cortex (dmPFC) have been shown to exert control over distinct aspects of reward seeking via divergent activity patterns. However, response heterogeneity exists within these populations that cannot be fully explained by their projection target or genetic profile. To fully characterize this heterogeneity, we used two-photon calcium imaging in awake, behaving mice to measure the activity of dmPFC excitatory output neurons throughout Pavlovian sucrose conditioning. Unsupervised spectral clustering of dmPFC neuronal responses revealed five neuronal ensembles that each encode specific information related to delivery of a sucrose reward, presentation of reward-predictive cues, and behavioral responses to those cues. These ensembles uniquely molded their activity patterns across daily training sessions and stabilized after learning, such that each ensemble's activity could be used to reliably predict unique aspects of the behavior task. These results demonstrate that dmPFC neuronal ensemble dynamics evolve over the course of cue-conditioned reward learning, yet the causal function of each ensemble for reward-seeking behavior remains less clear. To this end, we have begun single-cell optogenetic experiments to functionally manipulate the activity of each dmPFC neuronal ensemble *in vivo*, in the context of both natural reward seeking and drug reward seeking.

Title: The Effects of Kratom Alkaloids on Mesolimbic Dopamine Release

Authors: P. MANUS[1], L. C. RINGER[1], S. A. TOWERS[1], N. B. PAIGE[1], C. R. MCCURDY[2], ***D. B. LESTER**[1];

[1]Psychology, Univ. of Memphis, Memphis, TN; [2]Medicinal Chem., Univ. of Florida, Gainsville, FL

Abstract: Kratom, derived from the plant *Mitragyna speciosa*, is reported to produce stimulant-like effects at low doses and opiate-like effects at high doses. Mitragynine (MG) and 7-hydroxymitragynine (7-HMG) are the major psychoactive constituents of kratom, but the neural mechanisms of these alkaloids are not clear. Given that the effects of kratom are often compared to those of drugs with a high abuse liability, the current study aimed to determine the effect of MG and 7-HMG on reward-related neurotransmission. *In vivo* fixed potential amperometry was used to quantify stimulation-evoked phasic dopamine release in the nucleus accumbens (NAc) of anesthetized male and female mice. During dopamine recordings, mice received an i.p. injection of either MG (1, 15, or 30 mg/kg i.p.), 7-HMG (0.5, 1, or 2 mg/kg i.p.), or vehicle, and dopamine recordings continued for 90 min. Using specific stimulation parameters, dopamine autoreceptor functioning was measured 30 min post injection. Sex effects were observed following MG but not 7-HMG. In males, there was a significant time x MG dose interaction with the low dose seeming to increase dopamine release relative to vehicle and the higher doses towards the end of the recording period. However, follow-up tests revealed no significant dopamine release differences between doses at specific time points. Low dose MG also increased dopamine autoreceptor functioning (+50% from vehicle) in males. Regarding 7-HMG, both sexes responded similarly with a significant time x 7-HMG dose interaction effect on dopamine release. Follow-up tests revealed significant differences between 7-HMG doses from 60-90 min post injection, with the low dose increasing dopamine release (+18% from vehicle) compared to the high dose (-22% from vehicle). 7-HMG did not alter dopamine autoreceptor functioning. Neither MG nor 7-HMG altered the clearance rate of stimulation-evoked dopamine, indicating no drug effect on dopamine transporter functioning. In conclusion, dose effects were observed following both MG and 7-HMG. The low dose of MG (1 mg/kg) affected dopamine release in males more than females, potentially through actions on dopamine autoreceptors, and in both sexes the low dose of 7-HMG (0.5 mg/kg) increased dopamine release while the high dose (2 mg/kg) had the opposite effect. Although these increases in dopamine release are considerably less than those normally observed in stimulants with a high abuse liability, these findings do suggest that MG and 7-HMG alter dopamine transmission. An increased understanding of the neural mechanisms of kratom may provide insight on its potential uses and abuse liability.

Title: Sex and chronic stress alter the distribution of glutamate receptors within rat hippocampal CA3 pyramidal cells following oxycodone conditioned place preference

Authors: *A. DOLGETTA[1], M. JOHNSON[1], K. FRUITMAN[1], L. SIEGEL[1], Y. ZHOU[2], B. S. MCEWEN[3], M. KREEK[2], T. A. MILNER[1];
[1]Feil Family Brain and Mind Res. Inst., Weill Cornell Med., New York, NY; [2]The Lab. of the Biol. of Addictive Dis., [3]Lab. of Neuroendocrinology, The Rockefeller Univ., New York, NY

Abstract: Ionotropic glutamate receptors, GluN1 and GluA1, have a key role in the neurobiology of opioid addiction and pain modulation. This project elucidates how sex and chronic immobilization stress (CIS) impact the redistribution of glutamate receptors within rat hippocampal CA3 pyramidal cells following oxycodone (Oxy) conditioned place preference (CPP). Four groups of female and male Sprague-Dawley rats subjected to CPP were used: Saline- (Sal) and Oxy-injected (3mg/kg, I.P.) naïve rats; and Sal- and Oxy-injected CIS rats. Sections from each group were labeled with antibodies to GluN1 (BD Biosciences) or GluA1 (Millipore Sigma) and their subcellular distribution within CA3 pyramidal cell dendrites was examined by electron microscopy. Scientific rigor was ensured by having the same experimenters handle rats, labeling tissues from each group in one experiment, and conducting blinded analyses. GluN1: Sal-females compared to Sal-males had elevated cytoplasmic and total dendritic GluN1. Following Oxy CPP, females had reductions in near plasmalemmal, cytoplasmic and total dendritic GluN1, whereas males had no changes. CIS Sal-females and males compared to naïve counterparts had elevated total dendritic GluN1. CIS Oxy-males (which did not acquire CPP) had increased GluN1 on and near the plasmalemma, and in the cytoplasm of dendrites and in dendritic spines. GluA1: There were no differences in GluA1 dendritic distributions in naïve Sal- and Oxy-female and male rats. CIS Sal-males compared to naïve Sal-males had increased plasmalemmal and total dendritic GluA1. Also, CIS Sal-males had more GluA1-labeled spines than CIS Sal-females. CIS Oxy-males compared to CIS Sal-males had an increase in cytoplasmic and total dendritic GluA1, whereas females had no changes. In summary, Oxy CPP reduced the plasmalemmal dendritic GluN1 pools available for ligand binding in females but not males. CIS alone resulted in internalization of GluN1 from the surface of dendrites in females and increased pools of GluA1 available for binding in males. When CIS preceded behavior, available pools of GluN1 increased in Oxy-males. In conclusion, these results show that Oxy CPP alone and stress alone decrease glutamatergic signaling in females without significantly impacting males, and the combination of Oxy CPP and stress enhance glutamatergic signaling in males without significantly affecting females. Combined with our prior studies, this data supports the idea that hippocampal mechanisms affecting opioid addictive behaviors in response to chronic stress differ between males and females.

Title: Effects of a combination treatment comprising the selective norepinephrine reuptake inhibitor, atomoxetine, and the NMDA receptor co-agonist, D-serine, on sustained attention in male rats

Authors: *Z. V. REDDING, K. SABOL;
Univ. of Mississippi, University, MS

Abstract: Many people live with impaired sustained attention, including individuals with ADHD or schizophrenia. Common treatments for impaired attention include stimulant medications; however, such drugs are associated with negative side-effects and are unsuitable for certain populations (e.g., those with schizophrenia). Stimulants improve attention via effects on dopamine and norepinephrine (NE) systems. Simultaneous targeting of other neurochemical systems could prove a safe and effective strategy. For example, glutamate acting at NMDA receptors is thought to function with NE to promote cognitive processes including perception (Mather et al., 2016). We tested a combination treatment comprising the NE reuptake inhibitor, atomoxetine (ATX), and the NMDA receptor co-agonist, D-serine. Male Sprague-Dawley rats (n=16) performed a two-choice reaction time task. A rat nosepoked in a central aperture for 0.3 - 6.0 sec. A stimulus light then illuminated above a left or right aperture. The rat exited the central aperture and quickly nosepoked beneath the illuminated light for a water reward. Each response was broken into an initiation time (IT) and a movement time (MT) to isolate attentional processes. IT is the time from stimulus presentation until the rat initiates a response. The mode of IT distributions represents attentive sensorimotor processing speed, while IT distribution skew (devmode; mean minus mode) is thought to reflect lapses in attention (Leth-Steensen et al., 2000; Sabol et al., 2003). All rats experienced three counterbalanced sets of repeated measures (saline + saline, D-serine + saline, ATX + saline, and D-serine + ATX). Drugs were administered via i.p. injection 30 minutes before testing. IT mode was unaffected by any treatments. IT devmode and trials completed were reduced and MT was slowed by ATX alone and by the combination of D-serine and ATX. Importantly, the combination treatment reduced IT devmode more than ATX alone without slowing MT or reducing the number of trials completed more than ATX alone. The lack of effects on IT mode suggests that the present treatments do not affect attentive sensorimotor processing speed. On the other hand, simultaneous blockade of NE reuptake and

enhancement of NMDA receptor activation appears to reduce attentional lapses more effectively than either strategy alone. Furthermore, this combination approach does not appear to exacerbate potential movement or motivational side effects of NE reuptake blockade (see Redding et al., 2019). These results could inform the development of safer treatments that improve quality of life in a wide range of people living with impaired attention.

Title: Orexin-1 receptor antagonism alleviates dizocilpine-induced attentional impairments in an NMDA receptor hypofunction model of schizophrenia

Authors: *E. B. MANESS[1], P. C. LITTLE[2], J. A. BURK[2];
[1]Psychiatry, Harvard Med. Sch., Boston, MA; [2]Psychological Sci., William & Mary, Williamsburg, VA

Abstract: Schizophrenia (SZ) is a complex neuropsychiatric condition that is associated with impaired attentional processing and performance. Failure to maintain attention is thought to result from a hyper-reactive basal forebrain cholinergic system that cannot support increasing attentional load, and available antipsychotics often fail to address this pervasive symptom. Acute systemic administration of psychotomimetic NMDA receptor antagonists, which reproduce the NMDA receptor hypofunction observed in SZ, elevates cortical acetylcholine release and disturbs attentional systems. Both orexin (hypocretin) receptor subtypes (orexin-1 and orexin-2) are expressed on corticopetal cholinergic neurons, suggesting that their suppression may lessen basal forebrain excitability and reduce attentional deficits stemming from a hypercholinergic state. A previous experiment in our lab showed that rats trained in a sustained attention signal detection task performed worse and responded less when given the NMDA receptor antagonist dizocilpine (MK-801: 0 and 0.1 ip), and these impairments were reversed following co-administration of the dual orexin receptor antagonist filorexant (MK-6096: 0, 0.1, and 1.0 mM ICV), suggesting orexin receptor antagonism attenuated dizocilpine-induced overstimulation of cortical regions critical for sustained vigilance. To parse the unique role of the orexin-1 receptor, rats in the present experiment (N = 17) received either saline or dizocilpine injections in tandem with the orexin-1 receptor antagonist SB-334867 (0, 3, or 6 µg ICV) prior to attention task performance across six sessions. As was previously found, dizocilpine diminished performance

in signal trials, slowed correct response latency regardless of trial type, and increased the number of omitted trials. Similarly with filorexant, SB-334867 ameliorated dizocilpine-induced deficits in signal trials, and it also quickened response times, though this was more prevalent in males. Unlike filorexant, SB-334867 did not lessen omissions following dizocilpine exposure, perhaps a reflection of the role of the orexin-1 receptor in satiety-linked motivation. Thus, we propose that the orexin-1 receptor is an important target for minimizing the attentional deficits associated with NMDA receptor antagonism.

Title: Muscarinic M1, but not M4, receptor antagonism impairs divided attention in male rats

Authors: *P. J. MCLAUGHLIN, P. R. NICKLAS, M. L. KIEFER, M. A. WHALEN, M. T. STEWART, E. M. BENNETT, J. R. BECHTOLD, B. A. MILLER;
Psychology, Edinboro Univ. of Pennsylvania, Edinboro, PA

Abstract: It has never been more important to understand divided attention, given its role in the multitasking activities that are pervasive in modern living. We first validated a novel operant divided attention task with the muscarinic antagonist, scopolamine. As expected, scopolamine impaired performance of an auditory high response rate sustained attention task, both alone and in the presence of a distracting visual nosepoke task. This is most likely due to greater task difficulty in the latter divided attention version. Our animal model therefore has features of many human divided attention tasks: a main cognitive task that must be continuously monitored, and a secondary distractor activity of a different modality and response set. We then compared antagonists of the M1 and M4 muscarinic acetylcholine receptors, because scopolamine is nonspecific, and because these two receptor subtypes are the targets of putative dementia medications. The M1-preferring antagonist telenzepine impaired divided attention at the lowest dose tested (1.0 mg/kg i.p.), but did not significantly affect performance in the absence of the distractor task. In contrast, the M4-preferring antagonist tropicamide was ineffective (at up to 10.0 mg/kg). Our results strongly implicate the M1 muscarinic receptor in divided attention, and we suggest that M1 agonists may reverse deficits in this important cognitive domain.

Title: Effects of M1/M4 receptor agonism and M2 receptor antagonism on attention in rats

Authors: G. SMITH, F. REID, ***J. BURK**;
William & Mary, Williamsburg, VA

Abstract: The cholinergic system plays an important role in regulating attentional processing. Diseases such as Alzheimer's Disease are known to degrade cholinergic neurons and result in a wide range of cognitive deficits, including attentional deficits. The present experiments assessed the roles of a M1/M4 receptor preferring agonist, xanomeline, and a M2 receptor antagonist, methoctramine, on attentional performance in rats. Sprague-Dawley adult rats (n = 12) were trained in a two-lever visual sustained attention task in which correct performance required discrimination of a short visual signal compared with trials when no visual signal was provided. After reaching stable task performance, rats were given xanomeline (6.0 mg/kg, ip), methoctramine (1.0 mg/kg, ip), or vehicle prior to task performance. The results indicate that methoctramine, but not xanomeline, has beneficial effects on attentional performance. Overall, these findings suggest that the M2 receptor is a viable target for treating cognitive deficits associated with decreased cholinergic activity. The lack of beneficial effects of xanomeline is consistent with recent evidence that xanomeline administration in vivo produces greater activation of M4 receptors compared with M1 receptors. Future studies investigating the role of M1 in attention should focus on drugs that are more selective for the M1 receptor.

Title: Optogenetic activation of norepinephrine neurons in the locus coeruleus enhances visual spatial attention performance in non-human primates

Authors: *S. GHOSH, J. H. R. MAUNSELL;
Neurobiology, Neurosci. Inst., Univ. of Chicago, Chicago, IL

Abstract: The locus coeruleus (LC) norepinephrine (NE) neuromodulatory system is implicated in arousal and attention, and regulates activity in many brain areas including visual attentional pathways. Behaviorally relevant sensory stimuli drive phasic spiking of LC-NE neurons, as do motor responses in goal directed behaviors. It is unknown whether the LC-NE neuromodulation of sensory processing plays a causal role in altering perceptual detectability and spatial attention performance. To test this, we selectively expressed excitatory opsins (ChR2) in LC-NE neurons of two rhesus monkeys. We optogenetically activated LC-NE neurons for 400 ms, starting 200 ms before a 200 ms visual stimulus presentation on a random half of the trials while the monkeys performed an attention demanding visual orientation change detection task. In alternating blocks of trials spatial attention was directed to one of two locations in opposite visual hemifields. In separate experimental sessions, we recorded from population of multiple LC-NE neurons and measured stimulus-locked sensory responses while the monkeys did the same attention task. We found that stimulus-locked optogenetic activation of LC-NE neurons enhances visual spatial attentional performance. Perceptual detection of stimulus orientation-changes in the visual hemifield contralateral to the stimulated LC was enhanced when the animal's attention was directed to that hemifield (mean ± SEM change in behavioral sensitivity (d'): monkey S, 0.64 ± 0.05, N = 10, $p < 10^{-6}$; monkey P, 0.37 ± 0.05, N = 11, $p < 10^{-4}$). In contrast, LC activation had no detectable effect on the animal's discrimination of ipsilateral orientation changes. This unilateral effect was also seen when monkeys directed equal attention to both stimulus locations. Spike responses (n = 53) recorded from LC-NE neurons in these animals showed stronger sensory stimulus-locked firing when monkeys directed their attention to the contralateral visual hemifield location compared to the ipsilateral location. Increased spiking of LC-NE neurons associated with the shift in spatial attention and the unilateral effect of optogenetic activation of LC-NE neurons on attention performance are consistent with the ipsilateral LC connectivity with the forebrain attention control areas. Together, these results demonstrate that the phasic LC activity can rapidly modulate attentional behavior with spatial specificity.

Title: A graded yet variable relationship between pupil diameter and locus coeruleus activity

Authors: *J. MCBURNEY-LIN, M. MEGEMONT, H. YANG;
Univ. of California, Riverside, Moreno Valley, CA

Abstract: A longstanding hypothesis in the field of arousal and attention involves the relationship between pupil diameter and activity in the locus coeruleus (LC), where pupil diameter is often treated as a non-invasive readout of LC activity (e.g., Aston-Jones and Cohen, 2005; Gilzenrat et al., 2010; Preuschoff et al., 2011; Konishi et al., 2017; Clewett et al., 2018; Aminihajibashi et al., 2020). However, to the best of our knowledge, we do not know whether or how pupil diameter is linked to LC activity in a graded manner, or to what extent this relationship may hold. Furthermore, we do not know the extent to which pupil diameter can be used to make accurate inference of LC activity. To address these questions, we recorded the spiking activity from optogenetically-tagged single units (n = 17) from LC simultaneously with pupil tracking in head-fixed mice (DBH-Cre;Ai32). We established a graded relationship between pupil size changes and LC spiking activity, where pupil dilation increased monotonically with the number of LC spikes. However, substantial variability exists in this relationship such that ideal observer analysis cannot accurately predict the majority (> 90%) of LC spiking from pupil size changes. Next, to test whether pupil size changes better reflect population-level LC activity, we optogenetically activated groups of LC neurons and quantified the evoked pupil responses. We found that pupil responses exhibited large session-to-session fluctuations to identical optical stimulation, in sharp contrast to the stable LC responses. Importantly, baseline pupil diameters were similar and thus cannot explain the differences in evoked pupil responses. To understand what may underlie the variable pupil responses, we examined a subset of pupil-LC recordings where mice were trained to perform a go/no-go tactile detection task (Yang et al., 2016). We found that the variations in motivational state during task performance at least partially explained the variations in the pupil-LC relationship. Together, our data show that substantial state-dependent variability exists in the overall graded relationship between pupil size and LC, which seriously impedes using pupil diameter to make accurate inference of LC activity. Our current study substantiates and extends our previous findings that LC activity and pupil size changes represent distinct task-related events (Yang et al., 2021).

Title: Effects of psilocybin and the serotonin 5-HT_{2A} antagonist M100,907 on attention measured in the rodent continuous performance task

Authors: *A. RAHBARNIA[1,3], P. J. FLETCHER[3,1,2];
[1]Psychology, [2]Psychiatry, Univ. of Toronto, Toronto, ON, Canada; [3]Biopsychology, Ctr. For Addiction and Mental Hlth., Toronto, ON, Canada

Abstract: In humans, impaired attention is a feature of several neuropsychiatric disorders including substance abuse, major depression and anxiety disorders. Attention has been shown to be modulated by the serotonin neurotransmitter system. Recently, the serotonin 5-HT_{2A} receptor agonist and hallucinogen psilocybin (PSI) has been investigated as a treatment for disorders that are characterized in part by attention deficits. However, few studies have investigated whether psilocybin has a direct effect on attention (Barrett et al., 2020, Higgins et al., 2021). Using an established test of attention in rodents, the continuous performance task (CPT), we evaluated whether PSI influences the attentional performance of mice. Additionally, as PSI's potential therapeutic effects are thought to arise from 5-HT_{2A} stimulation, we also evaluated the effects of the 5-HT_{2A} receptor antagonist M100,907 for comparative purposes. Mice were trained in a touchscreen-based system to distinguish between target and non-target visual stimuli (2s stimulus duration) for milkshake reward. Once mice reached a stable level of performance, they were tested following injections of PSI (0, 0.3, 1 and 3 mg/kg s.c.) or M100,907 (0, 0.1, 0.3, and 1 mg/kg s.c.) They were then tested following injection with PSI (0, 0.3 and 1 mg/kg) and M100907 (0, 0.1, 0.3) mg/kg on a more difficult version of the CPT with a variable stimulus duration (1, 0.75, 0.5, and 0.25s). Performance was evaluated via signal detection theory measures including hit rate, false alarm rate, target discrimination (d') and response bias (C), as well as perseverative responding. On the basic task the highest dose of PSI decreased target discrimination (lower hit rate) and perseverative responding, and induced a more conservative response bias (less likely to respond). There were no effects of PSI at other doses. M100,907 had no effect on target discrimination, but reduced perseverative responding, while inducing a more conservative response bias. On the more difficult task, overall attentional performance was reduced, PSI had no effects, and M100,907 induced similar performance changes as on the basic task. We also examined the effects of PSI and M100907 on locomotor activity. The highest PSI dose and all M100,907 doses significantly reduced locomotor activity. Taken together the results of these experiments suggest that exposure to M100,907 and high doses of PSI may acutely impact performance on the CPT. However, these results may be in part due to drug-induced locomotor deficits. Further work is required to investigate whether PSI may impact attention in more cognitively demanding tasks or following repeated PSI exposure.

Title: Disrupted choline clearance and sustained acetylcholine release in vivo by a common choline transporter coding variant associated with poor attentional control in humans

Authors: *E. DONOVAN[1], C. AVILA[2], V. V. PARIKH[3], M. FENOLLAR FERRER[4], R. D. BLAKELY[5], M. SARTER[6];
[2]Psychology, [1]Univ. of Michigan, Ann Arbor, MI; [3]Psychology & Neurosci., Temple Univ., Philadelphia, PA; [4]LABORATORY OF MOLECULAR & CELLULAR NEUROBIOLOGY, Natl. Inst. of Mental Hlth., Bethesda, MD; [5]Biomed. Sci., Florida Atlantic Univ. - Charles E Schmidt Co, Jupiter, FL; [6]Psychol, Univ. of Michigan Dept. of Psychology, Ann Arbor, MI

Abstract: Transport of choline via the neuronal high-affinity choline transporter (CHT; SLC5A7) is essential for cholinergic terminals to synthesize and release acetylcholine (ACh). In humans, we previously demonstrated an association between a common CHT coding substitution (rs1013940; Ile89Val) and reduced attentional capacity as well as attenuated frontal cortex activation. Here, we used a CRISPR/Cas9 approach to generate mice expressing the I89V substitution and assessed, using in vivo cortical choline biosensing, CHT-mediated choline transport, and ACh release. CHTmediated clearance of choline in mice expressing one or two Val89 alleles was reduced by over 7-fold relative to wild type (WT) mice, suggesting dominant-negative effects. Choline clearance in CHT Val89 mice was further reduced by neuronal inactivation. Deficits in ACh release, 5 and 10 min after repeated depolarization at a low, behaviorally relevant frequency, support an attenuated reloading capacity of cholinergic neurons in mutant mice. The density of CHTs in total synaptosomal lysates and neuronal plasma-membrane-enriched fractions was not impacted by the Val89 variant, indicating a selective impact on CHT function. Consistent with this hypothesis, structural modeling revealed that Val89 may attenuate choline transport by changing the ability of choline to induce conformational changes of CHT that support normal transport rates. Our findings suggest that diminished, sustained cholinergic signaling capacity in the frontal cortex underlies perturbed attentional performance in individuals expressing CHT Val89. Our work supports the utility of the CHT Val89 mouse model as a valuable model to study heritable risk for cognitive disorders arising from cholinergic dysfunction.

Title: Utilizing fluorescent reporters of neuromodulator activity to assess brain-state-related cortical acetylcholine and norepinephrine dynamics

Authors: *E. NEYHART, C. L. SMITH, M. A. GALDAMEZ, N. ZHOU, Z. H. MRIDHA, J. DE GEE, M. J. MCGINLEY, J. REIMER;
Neurosci., Baylor Col. of Med., Houston, TX

Abstract: The brain naturally transitions between a variety of arousal states throughout the day which affect the way information is processed. Within the state of wakefulness there are subtle, transient substates which fluctuate on the order of minutes to seconds and are accompanied by rapid changes in sensory processing. Cortical activity of neuromodulators such as acetylcholine (ACh) and norepinephrine (NE) have been associated with these transient substates and their behavioral correlates (locomotion and pupil diameter), and are thought to have a direct role in influencing changes in sensory processing. However, it is not yet understood on a fine spatiotemporal scale when and where ACh and NE are spontaneously available across the cortex during these rapidly fluctuating substates. Recently-developed G-protein-coupled-receptor-based fluorescent reporters of neuromodulator activity, such as GACh and GrabNE, offer the potential to resolve these questions. However they have yet to be characterized extensively in vivo. The current study utilized in vivo two-photon imaging to record activity of virally-expressed GACh and GrabNE in various cortical regions of male and female C57/BL6 mice. Both agonists and antagonists of ACh and NE were injected to the visual cortex to obtain in vivo dose-response curves of the sensors. GACh and GrabNE activity were also recorded simultaneously with mutated versions of the sensors, green fluorescent protein alone, and another ACh fluorescent reporter (iAChSnFR) as a control. Then, heterogeneity of spontaneous ACh and NE activity in visual, somatosensory, auditory, and motor cortex was assessed, as well as the temporal relationship of these neuromodulators to locomotion and pupil diameter. Findings regarding the responses of GACh and GrabNE to actual changes in cortical neuromodulator levels will help to interpret the results of further studies utilizing these sensors in vivo. Understanding the spatial scale at which cortical ACh and NE spontaneously fluctuate across waking states sheds light on how different modes of information processing are being produced. Furthermore, better-defining

the link between pupil diameter, locomotion, and actual activity of ACh and NE will help validate these external correlates of brain state changes as reporters of neuromodulator activity.

Title: Quantification of Fos neuroactivity using photoacoustic imaging in vivo with validation by ex vivo immunofluorescence

Authors: *J. I. MATCHYNSKI[1], R. MANWAR[2], N. SADIK[1], K. M. MAKKI[3], T. J. CILLEY[1], A. R. WOZNICKI[3], S. KALLAKURI[1], B. T. HOPE[4], K. AVANAKI[2], S. A. PERRINE[5], A. C. CONTI[5];

Abstract: Current functional neuroimaging techniques, such as functional magnetic resonance imaging, rely on indirect consequences (the hemodynamic response) to quantify neural activity. With the development of a photoacoustic (PA) imaging system and use of transgenic rodent technology, we propose a more direct method to map and quantify activated neurons using a Fos-LacZ transgene reporter system in rats. Fusion of Fos with the lacZ gene gives active (Fos+) cells the ability to cleave pro-chromogenic substrates, such as X-gal, into PA-detectable products. In this study, we quantified the neuroactivity-based PA signal in Fos-LacZ transgenic rats following cued fear conditioning or chemical and behavior control conditions following intrathecal administration of X-gal. Immunohistochemistry for Fos, NeuN, and beta-galactosidase was quantified in a subset of animals for validation. Homozygous Fos-LacZ Wistar female and male rats (N = 80 total) underwent acquisition of cued fear conditioning and intrathecal X-gal administration 60 minutes after the conclusion of fear conditioning. Twenty-four hours later, rats were anesthetized and a cranial window was created in the skull. PA imaging of Fos-dependent neuroactivity in the medial prefrontal cortex (mPFC) *in vivo* was immediately conducted and the signal strength was quantified. All PA imaging used an 18.5

MHz, 128 element L22-14v linear array ultrasound transducer to record PA signal produced by pulsed laser illumination directed with a custom optical fiber bundle. A second group of animals, identically prepared (N = 48), was perfused 90 minutes after fear conditioning or control conditions. Brain tissues were triple labeled with antibodies against NeuN, Fos, and beta-galactosidase for e*x vivo* validation using cell count analysis and colocalization. Images were quantified using Matlab and the FIJI version of ImageJ. We report and compare fear response and Fos-expression from quantified *in vivo* PA images after X-gal administration and quantify triple-labeled confirmatory *ex vivo* immunofluorescence images acquired. Our data demonstrate significant differences in fear responding, PA signal strength, and cell counts between fear conditioned animals and vehicle or behavioral controls. Correlational data of fear response and Fos-expression *in vivo* and *ex vivo* is also reported. Using this novel functional molecular photoacoustic approach, we demonstrate an *ex vivo* validated method of monitoring activated (Fos+) neurons, i.e. neuronal ensembles, *in vivo* with high spatial resolution and specificity.

Title: Repetitive traumatic brain injury induces chronic anxiety, forepaw thermal sensitivity and neuroinflammation in rats

Authors: *S. KALLAKURI[1,3], N. SADIK[1,3], A. C. CONTI[1,3], K. E. BOSSE[1,3], C. BIR[2], S. A. PERRINE[1,3];

Abstract: Repetitive blast traumatic brain injuries (rbTBI) are a common cause of chronic pain as well as anxiety and cognitive deficits in many U.S. Veterans. Persistent neuroinflammation has been postulated to be a key player; however, much of the current knowledge on long-term rbTBI changes are primarily related to behavioral changes with a limited focus on underlying inflammation. To address this knowledge gap, this study assessed neuroinflammation in conjunction with changes in pain and anxiety at chronic post-rbTBI timepoints. Anesthetized

Sprague Dawley rats were subjected to rbTBI (one blast exposure/day for 3 consecutive days using a shock tube) or sham procedures. Following rbTBI or sham procedures, surface righting duration was immediately measured, and 1 or 3 months after rbTBI or sham procedure, anxiety-like behavior was measured by elevated plus maze (EPM) and pain behavior was tested by forepaw thermal withdrawal latency to radiant heat exposure. Perfused, fixed brain sections were collected following behavioral testing and assessed for neuroinflammation using immunofluorescence for microglial and astrocytic proliferation in the prefrontal cortex. Ionized calcium-binding adapter molecule 1 and glial fibrillary acidic protein were measured in astrocytes and microglia. Acutely, rbTBI animals showed a prolonged duration to surface right compared to sham animals. At both 1- and 3-month post-blast, rbTBI rats displayed anxiety-like behavior, indicated by decreased open arm time/entries, and they had higher pain sensitivity as indicated by shorter thermal withdrawal latency compared to sham-controls. A high number of microglia and astrocytes were observed in rbTBI animals compared to sham. Overall, these data suggest the development of anxiety-like and thermal sensitivity changes long after rbTBI which may be mediated by the underlying chronic inflammatory state. Future studies will be directed at understanding the effects of rbTBI on opioid-taking behaviors and the ensuing neuropathology.

Abstract: Drug addiction is a major societal issue that negatively impacts an individual's well-being and relationships. A growing body of literature suggests the existence of differential trajectories in the different phases of addiction between females and males. There is, however, a paucity of knowledge on the impact that addictive substances, such as opioids, have on cognitive function, particularly on spatial learning and memory during drug withdrawal in females and males. In fact, preclinical studies that examine sex differences in cognition are lacking and those

examining learning and memory, particularly using a Barnes maze, are even sparser. As a precursor to studies we are currently undertaking that examine opioid-induced cognitive changes, we assessed baseline cognitive function using a Barnes maze assay in both the sexes. Female and male Sprague-Dawley rats were trained to reach a hidden goal box on a custom-made 20-hole Barnes maze apparatus. Each animal was subjected to 3 trials per day for a total of 5 days. To encourage rats to locate the hidden area, aversive visual (bright light) and auditory (80 dB white noise) cues were used. Preliminary results indicate reduced time to reach the goal box with progressive training in both the sexes over days. Also, male rats showed a prolonged duration to reach the goal box compared to female rats on the second day, otherwise, no other significant differences were observed. Vaginal lavage and cytological characterization of estrous phase have been collected and are being analyzed for insights into associated hormonal cycling interactions with behavior in females. Future studies will be directed at understanding the effect of drugs of abuse, including fentanyl and oxycodone, on cognitive function in females and males. Additionally, we intend to more directly investigate the impact of noradrenergic signaling on Barnes maze behavior following opioid administration using the noradrenergic neurotoxin N--N-ethyl-2-bromobenzylamine (DSP-4). Conceptually this will be examined during drug-withdrawal as it is often considered a stressor that leads to relapse behavior in addictions.

Title: Neuronal ensemble in the medial prefrontal cortex is involved in anxiety-like behavior in rats with a history of binge cocaine administration and drug-abstinence

Authors: *A. GHEIDI[1], A. T. TROMBLEY[1], N. SADIK[1], S. KALLAKURI[1], J. I. MATCHYNSKI[3], K. KARAVIDHA[1], S. BRUMMELTE[2], B. T. HOPE[4], S. A. PERRINE[1]; [2]Dept. of Psychology, [1]Wayne State Univ., Detroit, MI; [3]TNP, Wayne State Univ. Sch. of Med., Detroit, MI; [4]Behav Neurosci, NIH/NIDA, Baltimore, MD

Abstract: Cocaine abuse remains a public health problem with no FDA-approved medications to treat cocaine use disorder. Previous results show that rats given chronic binge-pattern cocaine administration display a disinhibited hyper-exploratory phenotype in novel environments,

indicative of anxiety-like behavior. A growing body of evidence also suggests that targeted neuronal ensemble ablation in the medial prefrontal cortex (mPFC) can affect cocaine seeking and taking behaviors. Therefore, we assessed the contribution of mPFC neuronal ensembles in the disinhibited hyper-exploratory phenotype observed in a rat model of chronic binge cocaine administration. Female and male heterozygote *Fos-LacZ* Wistar rats were administered either cocaine (15 mg/kg/injection) or saline (1 ml/kg/injection) for 14 days using a binge-pattern administration paradigm (3 times daily at 1-hour intervals) followed by 14 days of forced abstinence (in the home cage). Injections took place in locomotor activity chambers (LMA) on days 0, 1 and 14 and their respective home cages on other days. Rats were then assessed for novelty induced exploration in a black plexiglass open field box. After 90 minutes, the time point of maximum Fos expression and hence β-galactosidase expression in *Fos-LacZ* rats, Daun02 or vehicle was intracranially-injected bilaterally into the mPFC. After 3 days of rest in the home cage, all rats were tested for cocaine-induced hyper-exploratory behavior on a raised elevated plus maze consisting of closed/open arms. Our results show that a sexually dimorphic LMA response to cocaine occurred over the 14 days of cocaine administration, with females showing greater behavioral sensitization. Additionally, rats treated with cocaine displayed higher anxiety-like behavior by spending less time in the center of open field following 14 days of cocaine withdrawal. In the elevated plus maze, cocaine-treated rats who received vehicle injections continued to show anxiety-like behavior, but Daun02 chemoablation of mPFC neuronal ensemble attenuated cocaine-induced anxiety-like behavior by increasing time/entries in open arms. The finding that ensemble ablation of one context carries over to a new context is an interesting finding and suggests a shared neuronal ensemble in anxiety provoking stimuli of the mPFC. Furthermore, neuronal ensembles that underlie anxiety-like behavior during cocaine withdrawal can contribute to dysfunction of the mPFC that plays a role in drug-relapse.

Univ. of California Davis, Davis, CA

Abstract: Humans have a remarkable capacity to use an internal model of the environment to make inferences about unseen outcomes. Such an adaptive behavior may depend on the ability to update our models by learning the causal relationships between the received outcome and the underlying latent cause from choice. For example, upon eating a delicious nectarine, a model-based agent would assign credit to the summer season as the latent cause of ripe stone fruits, leading to the inference that peaches are also in season. How the human brain assigns credit for important outcomes to such latent causes is unknown. We scanned hungry healthy participants (N=25) while they tracked two probabilistic systems of stimulus-reward associations for two desserts, with each system comprising two stimuli of different visual categories but sharing the same probabilities for leading to each reward. We hypothesize that 1. At feedback time, the causal choice reactivates in different subregions within the occipital-temporal cortex depending on the visual category it belongs to (face, body part, scene, tool), as well as an inferred stimulus sharing the same latent cause 2. The underlying latent cause is reinstated in the lateral orbitofrontal cortex (OFC). Behavioral results from a Bayesian learning model and logistic regressions analyses show that participants efficiently learned to track reward probabilities both from their choice and the inferred stimulus in the same system (direct and indirect choices, 1-back: $t(24) > 3.5$ $p<0.001$). An univariate analysis of the Kullback-Leibler divergence as a measure of belief confirmation of stimulus-outcome probabilities at feedback shows significant effects in the OFC, ventromedial prefrontal cortex and hippocampus ($t(24)>4.3$, $p<0.0001$, uncorrected). To test for hypothesis 2, we used multivariate pattern analysis with a cross-validation approach to test for a reinstatement of the causal choice identity at feedback time across runs. Left lateral OFC and hippocampus show a significant decoding accuracy relative to label-shuffled permutations, consistent with a role of OFC in choice reactivation during credit assignment ($t(24)>3.7$, $p<0.001$, uncorrected). Ongoing analyses will test the brain regions responsible for credit assignment to the inferred stimulus at feedback time and a common representation for the latent cause. These findings support a model whereby choices and inferred causes are reinstated at feedback time, coincident with prediction errors, to drive plasticity between co-active neural ensembles for the outcome and cause in the service of learning.

Title: Capturing mediodorsal thalamus and orbitofrontal cortex interactions in primate cognition

Authors: B. A. L. PERRY[1], J. MENDEZ[1], *A. MITCHELL[2];
[1]Exptl. Psychology, [2]Univ. of Oxford, Oxford, United Kingdom

Abstract: Anatomical evidence in mammals shows that the mediodorsal thalamus (MD) is a key component within wider prefrontal thalamocortical networks. Accordingly, damage to, or disruption of MD function impairs specific types of complex learning and decision making in primates. Yet, the underlying mechanisms behind the influence of MD on the frontal cortex during these higher order cognitive processes remain unknown. In the current study, two male rhesus macaques were trained to perform a touchscreen-based visuo-spatial discrimination learning task prior to having recording chambers implanted above the MD and orbitofrontal cortex (OFC). All experimental procedures were approved and conducted under a United Kingdom Home Office Project Licence issued to Dr Mitchell. After recovery, we established the precise coordinates to target the MD and the OFC using magnetic resonance imaging (MRI). Once the animals had re-established their pre-procedure learning rates, we recorded task related neural activity from the MD and OFC using multi-contact probes that were lowered before each testing session. MD and OFC units were modulated during specific phases of a trial, responding differently to the trial onset, when the visuo-spatial images first appeared on the touchscreen; when the monkey made a response to the touchscreen; and before or after the delivery of the smoothie reward for correct trials. We also observed some MD and OFC units progressively modulated their responses throughout the session, coinciding with improved cognitive performance. Finally, during correct trials, some MD units were phase-locked to OFC local field potentials, suggesting prefrontal thalamocortical interactions support learning. Our evidence highlights different, but complementary and interactive neural activity between the MD and OFC during learning of a visuo-spatial discrimination task.

Title: Orbitofrontal cortex mediates meta-learning of reinforcement learning

Authors: *R. HATTORI[1,2,3,4], S. CHEN[1,2,3,4], H. YOU[1,2,3,4], M. HATTORI[1,2,3,4], J.-H. CHOI[1], B. LIM[1], T. KOMIYAMA[1,2,3,4];

Abstract: The meta-reinforcement learning (meta-RL) framework, which uses RL over fast and slow timescales, has been successful in training deep RL networks that generalize to new environments. This framework uses slow plasticity-based RL to build a recurrent network that performs fast trial-by-trial RL in an activity-based, plasticity-free manner. It has been hypothesized that the recurrent neural network in the prefrontal cortex may mediate meta-RL in animals, but the evidence is scarce. Here we show that the orbitofrontal cortex (OFC) of the prefrontal area is critically involved in both fast and slow aspects of meta-RL in mice. We trained mice and artificial meta-RL networks on a probabilistic reversal learning task across sessions during which they showed meta-learning and improved their trial-by-trial RL policy. By optogenetic suppression of synaptic plasticity, we showed that synaptic plasticity in OFC was necessary for this across-session meta-learning of RL but not for the within-session trial-by-trial RL in experts. After the meta-learning, OFC population activity robustly encoded history-based value signals, and transient optogenetic OFC inactivation impaired the ability of mice to exploit the value on each trial. Longitudinal tracking of OFC neural activity during training by in vivo 2-photon calcium imaging through GRIN lens revealed that the across-session meta-learning slowly stabilizes population value coding in accordance with the ongoing behavioral policy. All these experimental results from OFC were consistent with simulations from artificial meta-RL networks. Our results indicate that two distinct RL algorithms with distinct neural mechanisms and timescales coexist in OFC to support adaptive decision making.

Title: Social learning in a novel operant conditioning paradigm in rats

Authors: *R. TROHA[1], M. GOWDA[1], J. LEVIN[1], A. BUZZANCA[1], Q. HU[1], E. J. MARKUS[2]; [1]Univ. of Connecticut, Storrs, CT; [2]Univ. of Connecticut, Storrs Manfld, CT

Abstract: Social learning is an important survival mechanism. For example, learning to find food in an environment requires less time and energy and encompasses less exposure to danger when following a conspecific familiar with the environment. In humans, social imitation plays an important role in development (Bandura 1961). Although this form of learning has been well-documented in humans, most research in animals has focused on social transmission of fear**.** Previous research in our lab focused on development of a behavioral task in which an observer animal learned to find food on a T-maze by watching a demonstrator animal. Although observers eventually learned the task, much training was needed and effects were minimal. The goal of the current study was to develop an improved behavioral paradigm in which socially driven appetitive conditioning can be studied. Animals were trained in an apparatus consisting of two conjoined operant chambers, with one chamber containing an observer rat and the other containing a demonstrator rat. The observer was trained to respond at a nose poke in their own chamber on the same side which the demonstrator responded. Therefore, the observer learned to watch the demonstrator response and mimic the behavior in its own chamber. An additional non-social control task was used in which animals were trained to observe a plastic ball being illuminated. An important feature of this task is the ability to expose animals to many trials in one training session. This resulted in faster and more robust learning compared to previous work in our lab. Once learning was achieved, behavior was then analyzed using DeepLabCut. This deep learning approach allowed precise tracking of both the observer and demonstrator, even under constantly changing lighting conditions. Overall, observer animals performed better when observing a trained demonstrator compared to the ball stimulus. Results also showed that observers oriented themselves towards the demonstrator during the demonstrator response period. This orientation was gradual, in that observers oriented more towards the demonstrator as the demonstrator approached the nose poke receptacle. Results also showed that observers oriented more towards a demonstrator rat compared to an inanimate cue object. The initial orientation of the observer animal at the start of the trial also significantly affected response accuracy. This novel task may be used in future experiments to probe the neural circuits underlying this form of learning. These future results could have implications for treatment of disorders where social deficits are seen.

Title: Social factors influence solo and dyad male rat pairs during novel open field exploration

Authors: *Q. HU, S. LEE, S. AHMED, L. HORBAL, T. A. PIETRUSZEWSKI, E. J. MARKUS;
Univ. of Connecticut, Storrs, CT

Abstract: Exploration of a new environment is an essential component of animal behavior, providing potentially crucial information regarding sources of food, shelter, and mates. Eilam and colleagues (Weiss et al., 2015) found that male rats explore familiar arenas differently in the presence of another male rat. In the current study, we examined interactions of paired male rats during exploration of a novel environment. Nine-month old male F344 rats (Harlan, IN), with free access to food and water were used for this experiment. Animals were paired for 7 days prior to and throughout testing. The open field exploration was assessed using a Plexiglas enclosure (70.5cm L X 70.5cm W) with a white plastic floor of the same area. During experimental trials, either one or two rats were placed in the southeast corner of the open field and allowed to explore for fifteen minutes. Videos of the trials were then analyzed using DeepLabCut (Mathis et al., 2018) to obtain position information of the subjects. The software allowed for tracking of multiple body parts of multiple animals. Rats were placed in the novel environment either individually or in pairs. This was repeated the following day. On the first (novel) day, solo rats traveled a greater distance, explored a larger area, and spent less time in the outer zone than paired rats. Stranger rat pairs spent more time in the outer zone and interacting with their nose to nose in close proximity than familiar pairs. These effects were not found on the following day.

Title: A direct lateral entorhinal cortex to hippocampal CA2 circuit conveys social information required for social memory

Authors: *J. LOPEZ-ROJAS[1], C. A. DE SOLIS[1], F. LEROY[2], E. R. KANDEL[3], S. A. SIEGELBAUM[4];

Abstract: The hippocampus is essential for forming and storing declarative memories, including social memory, the ability of an animal to recognize and remember a conspecific. To serve this mnemonic function, the hippocampus relies on a variety of external inputs. Despite recent advances in our understanding of the brain circuits supporting social memory, little is known about the role of the entorhinal cortex (EC), which provides the primary source of multimodal sensory input from neocortex to hippocampus. Here we report that the classical trisynaptic pathway, in which information from EC is powerfully but indirectly routed to hippocampal CA1 and CA2 pyramidal neurons (PNs) through dentate gyrus (DG) and CA3 (EC-DG-CA3-CA1/CA2), is dispensable for social memory. Rather, social memory depends on the direct relay of social information from EC to dorsal CA2 PNs, which receive uniquely strong direct inputs from EC compared to their CA1 and CA3 neighbors. Moreover, the information routed to CA2 is specifically provided by inputs from the lateral EC (LEC), rather than from medial EC. Thus, our findings highlight the behavioral relevance of the strong direct LEC pathway to CA2 in mediating the integration of complex sensory cues required for social memory.

Title: The geometry of social and spatial representations in the hippocampal region dorsal CA2

Authors: *L. BOYLE[1], L. POSANI[1], S. IRFAN[2], S. A. SIEGELBAUM[1], S. FUSI[1];
[1]Columbia Univ., New York, NY; [2]Barnard Col., New York, NY

Abstract: The ability to recognize other individuals is a crucial component of social behavior. The hippocampus plays an important role in this process, as silencing the hippocampal subregion dorsal CA2 impedes the storage, consolidation, and recall of social recognition memory. However, it is not clear what kind of information and which modalities are represented in the CA2 region during social interaction. Specifically, there is an open question whether and how social novelty and conspecific identity are represented in CA2, and how these social variables interact with non-social spatial features in the neural code. To investigate these questions, we used the Amigo2-Cre mouse line and performed miniscope calcium recordings of dorsal CA2 pyramidal neuron activity in awake, behaving mice exposed to different combinations and placements of novel and familiar individuals. We then characterized CA2 neural population representations using a decoding approach to explore the relationship between social and non-social variables during social interaction. We found that the identity of novel as well as familiar conspecifics is consistently encoded in neural activity in dorsal CA2 during social interaction. These representations are abstract with respect to spatial features, as they are maintained across different positions of interacting individuals. By comparing novel and familiar individuals, we found that social novelty is robustly encoded in neural activity, and that this "social novelty signal" is abstract with respect to spatial as well as social identity variables, as the difference in novelty could be consistently decoded across different positioning and different identities of the interacting individuals. Our results suggest that CA2 robustly encodes both social novelty and identity across different contexts and that the geometry of these neural representations is abstract.

Title: Social odor coding in CA2 and its disruption in a mouse model of the 22q11.2 Deletion Syndrome

Authors: *S. BIGLER[1], S. HASSAN[2], S. A. SIEGELBAUM[3];
[1]Columbia Univ., NEW YORK, NY; [2]Neurosci., Columbia Univ., New York, NY; [3]Dept of Neurosci., Columbia Univ. Coll P & S, New York, NY

Abstract: Schizophrenia Disease (SZD) is one of many neurological disorders in which social memory is impaired; SZD patients have more difficulty recognizing previously-presented faces than their neurotypical counterparts have. At the cellular level, SZD patients show a decrease in the density of inhibitory parvalbumin (PV) interneurons in the CA2 region of the hippocampus.

Interestingly, these two phenotypes—social memory deficits and lower CA2 PV density—are reflected in a mouse model of the human 22q11.2 Deletion Syndrome (22q11.2DS), a disorder strongly linked to SZD. This mouse model (referred to as *Df(16)A*$^{+/-}$) also exhibits reduced feedforward inhibition and changes in intrinsic firing properties of CA2 pyramidal neurons, due in part to upregulation of TREK-1 K^+ current, suggesting a link between altered CA2 activity and social memory deficits in 22q11.2DS. Furthermore, silencing CA2 in wild-type mice disrupts social memory formation while restoring function to pathologically hyperpolarized CA2 neurons of *Df(16)A*$^{+/-}$ mice by administration of the TREK-1 antagonist spadin rescues their social memory deficit. We have confirmed that the population-level activity of CA2 pyramidal neurons contains sufficient information to distinguish social odors (urines) from distinct, novel conspecifics. We measured CA2's ability to encode unique social odor stimuli in a head-fixed Go/No-Go Odor Discrimination Task with 2-photon calcium imaging. Water-restricted mice were trained to lick a water port in response to one social odor (GO odor) to receive a water reward and to withhold licking to another social odor (NOGO odor) with no punishment. Here we report a profound behavioral deficit in social odor discrimination in this task comparing *Df(16)A*$^{+/-}$ mice to their neurotypical littermates as these mice fail to withhold licking to the unconditioned social odor stimulus. We are now using 2-photon imaging to assess the ability of CA2 population activity to encode and distinguish unique social odor stimuli in *Df(16)A*$^{+/-}$ versus wild-type mice, and to determine how CA2 firing and odor discrimination in the *Df(16)A*$^{+/-}$ mice is impacted by TREK-1 blockade with spadin. In this manner, we will gain further insights into the importance of CA2 in social coding and the impacts of its disruption in the 22q11.2DS mouse model.

Title: Dorsal and ventral hippocampus cell firing patterns in response to novel stimuli

Authors: *S. LEE, R. TROHA, Q. HU, I. STEVENSON, E. J. MARKUS;
Univ. of Connecticut, Storrs, CT

Abstract: In both humans and rats, the hippocampus is important for memory and navigation. Individual hippocampal neurons are spatially tuned, and fire in specific physical locations. Together, these "place cells" provide a representation or map of an environment. However, if the environment or behavioral context is altered, a place cell can change its firing pattern or "remap". The hippocampus is a long structure with multiple sub-regions of diverse connections. Much is known regarding place cell activity in the dorsal region of the hippocampus, since these are close to the surface of the brain and relatively accessible. Less is known about ventral hippocampal place cell activity located much deeper in the brain. We have constructed a 64-channel hyperdrive, with 16 independently moveable tetrodes targeting both dorsal and ventral regions. Firing characteristics were determined while we recorded single units simultaneously from dorsal and ventral hippocampus as rats performed a familiar/well learned task (traversing a linear track). After the hippocampal representation of the familiar task was determined, one of the two arms was rotated to a novel position. We measured how the spatial tuning of these neurons were modified when rats experienced this novel spatial environment. Similarly, we compared the hippocampal representation of the familiar task with novel social (conspecific) and olfactory (female bedding and coyote urine) experiences. We will determine dorsal and ventral hippocampal representations of a familiar maze configuration, the development of a new representation, and the degree to which the developed representation is stable. Specifically, overall firing rates and place field characteristics will be examined. Taken together, these data provide insight into the relationship between different regions of the hippocampus during the processing of a novel experience.

Title: Region-specific CaMKII-dependent synaptic plasticity is necessary for unique aspects of social recognition learning

Authors: *M. PHILLIPS, P. PARRA-BUENO, R. YASUDA;
Max Planck Florida Inst. for Neurosci., Jupiter, FL

Abstract: Determination of the appropriate social behavior is an essential and dynamic neural calculation in communal animals and, reflecting the complexity of the task, is dependent on proper function of numerous brain regions connected by long-range circuitry. The regions involved in social recognition memory include dorsal CA2 (dCA2), ventral CA1 (vCA1), and the prelimbic region of the medial prefrontal cortex (PL), which form a continuous, unidirectional circuit. Previous work using optogenetic and chemogenetic approaches has found that perturbation of any of these regions or their connections is sufficient to disrupt social memory. However, the mechanism of these approaches is to alter neuronal resting potential, and, due to the highly connected nature of the social memory circuit, altering the firing patterns in upstream regions alters the function of all downstream regions. Additionally, this approach does not allow us to determine which aspects of social memories each region is responsible for encoding via synaptic plasticity. These technical limitations have made it difficult to parse the unique roll of each region in social recognition memory. To address this, we utilize a photo-activatable AIP2 to inhibit CaMKII (paAIP2) in order to impair synaptic plasticity without affecting neuronal firing pattern. We plan to systematically express this genetically encoded modifier in each region (dCA2, vCA1, and PL) and wirelessly activate paAIP2 during a freely interacting social learning paradigm. By using computer vision to track and annotate a plethora of naturalistic behaviors, we will determine the necessity of region-specific synaptic plasticity to shape social behavioral choices and define each region's unique roles in these choices. Our preliminary data has found that perturbation of CaMKII in vCA1 during social learning impairs social discrimination in most interaction types, yet results in a strong in a preference for familiar conspecifics in nose-nose sniffing. While future experiments aim to compare these results to CaMKII perturbation in dCA2 and PL, these data are the first evidence for the necessity of CaMKII-dependent plasticity in vCA1 for social discrimination learning.

Title: Serotonin modulation of a medial septal circuit tunes social memory stability

Authors: *X. WU[1], W. MORISHITA[1], K. T. BEIER[3], B. D. HEIFETS[2], R. C. MALENKA[1]; [1]Psychiatry & Behavioral Sci., Stanford Univ., Palo Alto, CA; [2]Anaesthesiology, Perioperative and Pain Med., Stanford Univ., Stanford, CA; [3]Physiol. and Biophysics, Univ. of California, Irvine, Irvine, CA

Abstract: The ability to remember familiar conspecifics, termed social memory, is critical for an animal's behaviour in its social environment. In recent years, extensive evidence supports the importance of the distinct hippocampal subregions, dorsal CA2 (dCA2) and ventral CA1 (vCA1), as well as some of their projection targets in the regulation of social memory. However, little is known about the relevant extrahippocampal input regions. Here, we present evidence that the medial septum (MS), which was not previously associated with social behaviour, sends inputs to the hippocampus that are required for social memory. Furthermore, we find that 5-HT modulation of the MS specifically and bi-directionally influences social memory formation. Using *TRAP2;Ai14* mice to take an unbiased approach for identifying dCA2 and vCA1 input regions that are not involved in object memory but are activated during social encounters, we identified elevated activity in the MS during social interactions compared to object interaction. Retrograde and anterograde tracing experiments revealed strong projections from the MS to the dCA2 and vCA1. Chemogenetic inhibition of the MS→dCA2 projection, but not the MS→vCA1 projection impaired social memory. Furthermore, optogenetic inhibition of MS→dCA2 inputs impaired the acquisition but not the expression of social memory. Strikingly, we found that chemogenetic excitation of the MS can prolong social memory. The MS contains multiple cell types but pharmacological experiments revealed a critical role only for MS glutamatergic cells in social memory formation. *Ex vivo* slice experiments demonstrated that novel social interactions increased MS→dCA2 excitatory synaptic strength. Reversing this increase with an i*n vivo* LTD induction protocol in the MS→dCA2 inputs prior or after social interaction ablated social memory. Results from a final set of experiments support a critical role for 5-HT modulation of the MS in social memory: (1) Infusion of a specific 5-HT1b receptor (R) antagonist into the MS disrupted social memory. (2) Activity of MS glutamatergic cells increased during a novel social interaction in a 5-HT1bR-dependent manner. (3) Bidirectional modulation of median raphe 5-HT inputs in the MS bidirectionally influenced social memory. (4) Infusion of a 5-HT1bR agonist into the MS prolonged social memory in wild-type mice and rescued social memory deficits in an autism-associated mouse model. Together these findings reveal a 5-HT modulated MS→dCA2 circuit that is required for the regulation of social memory.

Aging is associated with alterations in multiple aspects of prefrontal cortex (PFC)-mediated executive functions, including working memory, behavioral flexibility, and decision making. Such cognitive alterations can be modeled in rats, but almost all such work to date has been conducted exclusively in males. Taking advantage of the recent availability of aged females, we began initial evaluations of young adult (6 mo.) and aged (22 mo.) Fischer 344 x Brown Norway F1 hybrid rats of both sexes in intertemporal choice (delay discounting), working memory, probabilistic reversal learning, and progressive ratio tasks, on all of which aged males have been shown previously to differ from young adult males. In the intertemporal choice task, in which rats made choices between a small food reward delivered immediately vs. a large food reward delivered after a variable delay period (0-60 s), aged males chose the large, delayed reward more than young adult males (consistent with previous finding), whereas young and aged females did not differ. In the delayed response working memory task, in which rats had to remember the location of a lever over a 0-24 s delay period, young adults of both sexes performed more accurately than their aged counterparts. In contrast, in the probabilistic reversal learning task, in which rats had to learn to discriminate between two levers that were reinforced at different probabilities and then switched multiple times per test session, there were no age differences in the number of reversals achieved in males, whereas aged females achieved fewer reversals than young adult females. Finally, in the progressive ratio task, in which the number of lever presses required to earn a food reward increased with each successive reward earned, aged rats of both sexes made fewer lever presses than their young adult counterparts. Data from this initial experiment largely replicate previous findings of age differences in executive functions in male rats, but suggest that aging may have qualitatively or quantitatively different effects on executive functions in females. These differences further highlight the importance of using both sexes in studies employing animal models of cognitive aging.

Abstract: Legalization of recreational and medical cannabis has led to greater numbers of cannabis consumers, with individuals over the age of 65 being one of the fastest growing demographics of new users. While cannabis may offer some benefits to older adults (e.g., helping with pain, sleep, and appetite), little is known about the implications of cannabis use on cognition in this age group. Understanding the impact of cannabis on cognition in older adults is particularly critical as age-associated deficits in cognitive functions supported by both prefrontal cortex (PFC) and hippocampus are well-documented, and these same cognitive functions are impaired by acute administration of cannabis or cannabinoids (e.g., delta-9-tetrahydrocannabinol, THC) in young adults. These data suggest that cannabis use might exacerbate or even accelerate age-associated cognitive decline. The overarching goal of the current study was to use a rat model to determine how acute exposure to cannabis smoke influences cognition in young and aged subjects. In this study, the effects of acute cannabis smoke exposure were evaluated in male and female young adult (6 months) and aged (24 months) Fischer 344 x Brown Norway F1 hybrid rats using both a PFC-dependent delayed response working memory task and a hippocampal-dependent trial-unique non-match to location (TUNL) task performed in touchscreen operant chambers. A semi-randomized, within-subjects experimental design was used, such that performance of each subject was assessed under multiple dosing conditions. Specifically, cognitive performance was assessed in separate sessions immediately following exposure to smoke generated from burning 0, 3, or 5 cigarettes, with a 48-hour wash-out period between sessions. In the working memory task, cannabis smoke had opposite effects in young and aged male rats, tending to impair performance in young but enhance performance in aged. Preliminary data in females show that cannabis smoke tended to impair hippocampal-dependent TUNL performance in young rats but enhance performance in aged rats. Assessment of blood THC following cannabis smoke exposure revealed trends toward higher and more variable THC levels in aged compared to young rats. One conclusion from this study is that acute cannabis smoke exerts differential effects in aged compared to young subjects. The data also suggest that cannabis may influence cognition differently as a function of sex. Future work on the mechanisms of cannabis-mediated cognitive enhancement could clarify these

age- and sex-specific effects and better elucidate the potential utility of cannabis use in older adults as a cognitive enhancer.

Title: Maternal separation causes behavioral and neuroendocrine alteration in middle- aged female rats that are partially reversed by ovariectomy

Authors: *M. ROQUE[1,2], N. LAJUD[2], R. RUIZ[3];
[1]Univ. Nacional Autonoma De Mexico, Morelia, Mexico; [2]Neurodevelopment, Ctr. de investigacion Biomedica de Michoacan, Morelia, Mexico; [3]Ctr. de investigación biomédica de Michoacán, Morelia, Mexico

Abstract: Early life stress (ELS) in the form of maternal separation causes age- dependent behavioral and neuroendocrine alterations in male rats, however the interaction between age-dependent hormonal decline and ELS has never been studied in female rats. The aim of this work was to analyze the effects of ELS on behavior and neuroendocrine parameter in a model or post-menopause middle- aged rats. Entire litters of Sprague Dawley rats were randomly distributed into Control (undisturbed) and Maternal Separation (3 hours a day from postnatal day 1 to 14, MS180) groups. At 10 months of age, animals were ovariectomized (OVX), or remained under standard conditions (STD), and further allowed to recover for 2 months prior to the tests. When evaluating ELS and OVX as independent factors, we observed that MS180 affected cognitive performance in the Morris water maze (MWM), increased immobility time and latency to immobility in the forced swimming test (FST). MS180 increased the area under the curve in the glucose tolerance test. On the other hand, OVX affected cognitive performance in MWM and decreased struggling time in the FST. However, when analyzing the interaction of stress and OVX we observed that MS180 + OVX rats' behavior in the MWM and the FST was not significantly different from CONT + STD; however, MS180 + OVX significantly increased the area under the curve in the glucose tolerance test. In conclusion, our results indicate that ELS shows an age-dependent effect on female rats that could be partially modulated by gonadal hormones.

Abstract: Objective & Rationale Our objective is to elucidate the influences of stress on brain aging. Brain aging appears to be a primary risk factor for the development of prominent neurodegenerative pathologies; stress exposure has been shown to accelerate brain aging. Glucocorticoid (GC) signaling is thought to play a key role in stress' negative impact on brain function. The GC-dependent downstream effector molecule, Sgk1, is increased with both stress and aging; however, little work has been done to examine the cell-type Sgk1 splice variant expression after GC exposure in hippocampus. The hippocampus is a particularly appropriate model structure for brain aging studies based on its well-established role in cognition and memory, its manifestation of aging changes, its expression of hormone receptors, and its vulnerability to neurodegenerative disease. Here, we used the *ex vivo* hippocampal slice preparation to examine GC signaling properties in young and aged male and female rats. **Methods & Results** Hippocampal slices were maintained in oxygenated artificial cerebrospinal fluid at 32°C in an interface chamber, and incubated in either 0.1% DMSO or 3.5 µM corticosterone for 2 hours. RNA was then isolated, and concentration and integrity was assessed. cDNA was synthesized and then diluted (1:10). Real-time PCR was then performed with forward and reverse primers for Sgk1 and Sgk1.1. An increase in Sgk1 mRNA was expected with GC exposure. However, the observed increase showed only a trend towards significance. Sgk1.1 is not regulated by GCs, as it lacks a GC response element in its promotor; however, its mRNA showed a significant increase in expression. **Conclusions** This well-established slice preparation typically used for electrophysiology also is appropriate for investigating age-related GC driven Sgk1 signaling. In this preparation, GC exposure is sufficient to drive Sgk1 mRNA expression. These findings are preliminary and need to be confirmed through replication and validation of probe design. Further, adjustments to dose, duration, number of samples, as well as pre-vetting with electrophysiological techniques may be appropriate. This model may also be appropriate to:

Establish GC concentration-effect relationships, identify responding cell-types using IHC or *in situ* hybridization, and investigate pharmacologic interventions (e.g., progesterone, RU-486, and A-205). Goals in the long term: Establish hippocampal gray and white matter Sgk1 transcriptional profiles, quantify Sgk1 variant cell-type specific localization after treatment, and test Sgk1 and progesterone-based interventions in hippocampal function with stress and aging.

Title: Sleep duration and architecture in a rat model of normal cognitive aging

Authors: *C. MYRUM[1], Z. UTTKE[1], M. STELZNER[1], P. R. RAPP[2];
[1]Natl. Inst. on Aging, Baltimore, MD; [2]Neurocognitive Aging Section, NIH, Natl. Inst. on Aging, Baltimore, MD

Abstract: Here we examined whether cognitive outcome is related to sleep/wake physiology, as evaluated by electroencephalography (EEG) and electromyogram (EMG) analyses. The experiments capitalized on a well-established rat model of normal cognitive aging, where outbred Long-Evans rats were tested on a hippocampus-dependent version of the Morris water maze. As reported in previous studies, we observed greater inter-individual variability among aged animals, resembling the increased variability observed in aged humans. Rapid eye movement (REM) sleep, non-REM (NREM), and wake states were then manually scored based on EEG/EMG signatures for each state. The most notable preliminary findings, in groups of 4 to 6 rats, are as following: (1) Compared to young animals, aged rats spent less time in REM sleep ($p=0.01$); (2) Aged rats with intact spatial memory spent less time in REM sleep ($p=0.01$) than young rats, while REM deficits were less severe in aged rats with memory impairment ($p=0.057$); (3) Aged rats with intact spatial memory displayed more fragmented sleep than young rats ($p=0.048$); and (4) Delta power was significantly lower in aged rats compared to young animals ($p=0.04$). Given that aging in humans is generally accompanied by a decrease in the overall amount of sleep, an increase in sleep fragmentation, and a decrease in delta power during NREM sleep, the similarities with Long-Evans rats observed here may be useful for identifying the causes and/or consequences of age-related changes in sleep. These preliminary data also

suggest that aged rats with good spatial memory may be more resilient to age-related changes in sleep. Since evidence from humans indicate that sleep earlier in life may influence cognitive functioning later in life, longitudinal studies in this model and others may also therefore be warranted.

Title: Cognitive performance in aged rats associates with alter status of excitatory inputs onto interneurons in the dentate gyrus.

Authors: *C. MORENO NARANJO[1], D. SEVERIN[1], M. KOH[1], J. ZHOU[3], M. BRIDI[1], P. WORLEY[3], M. GALLAGHER[1], A. KIRKWOOD[2];

Abstract: Aging often impairs mental abilities, including learning and memory. Recent studies have identified hyperactivity within the medial temporal lobe, in particular lateral entorhinal cortex (LEC) and the CA3/DG hippocampal subfields, as a dysfunctional condition common to cognitive impairment in aged rats and elderly humans diagnosed with mild cognitive impairment. In a previous study, we evaluated the status of synaptic inhibition and excitation in the LEC->DG pathway in a behaviorally characterized Long-Evans rat model of aging that discriminates aged impaired (AI) and aged unimpaired (AU) individuals and found that the recruitment of inhibition by LEC activation was selectively reduced in AI subjects. We are using whole-cell recording in slices to examine candidate mechanisms. First, we tested the effects of overexpressing Neuronal Pentraxin-2 (NPTX2) in LEC cells. NPTX2 is an extracellular protein released by excitatory neurons in an activity-dependent manner that is crucial for stabilizing AMPA receptors at synapses onto parvalbumin-positive inhibitory interneurons (PV-INs). Overexpression of NPTXs restored the balance of excitation and inhibition in the LEC->DG pathway of AI rats suggesting a reduced recruitment of PV-INs in AI. Next, using an AAV.mDlx.GFP transfection approach to visualize interneurons in the aged rats we found evidence that the number of excitatory LEC inputs converging onto dentate PV-INs is reduced in

AI rats. We are currently testing the hypothesis that a reduction in NPTX2 is the primary contributing factor to the altered balance of excitation/inhibition in the LEC->DG of AI rats.

Title: Synaptic culprits underlying cognitive decline in the aged brain

Authors: *T. LIU[1], V. MATHESH[1], J. FALCO[1], M. MOTA[1], K. M. HARRIS[2], L. M. KIRK[2]; [2]Ctr. for Learning and Memory, [1]Univ. of Texas at Austin, Austin, TX

Abstract: Age-related cognitive decline is developing into one of the biggest challenges in modern society. As the population ages, our health system is becoming stressed. During normative aging, cognitive changes are not associated with neuron loss; instead, changes in synapse structure have become the focus of inquiry. Aged Long Evans rats (25-27 months) were categorized as aged learning impaired (AI) or aged learning unimpaired (AU) compared to young adult controls (YA; 3-6 months) using the Morris water maze (MWM). Serial section electron microscopy of dendrites and their synapses from hippocampal area CA1 revealed that AI rats had increased excitatory synapse size and fewer inhibitory synapses onto CA1 dendrites. Thus, there was a dramatic increase in the excitatory/ inhibitory ratio along dendrites from AI rats compared to YA controls, providing synaptic evidence for age-related hyperexcitability underlying cognitive decline. Dendrites from AU rats are being analyzed to determine whether these changes are ubiquitous with aging or if they are specific to age-related learning impairments. Presynaptic components are also being analyzed. These data provide new clues about the synaptic culprits that undermine brain reserve and resilience in aged animals with cognitive decline.

Title: Changes in hypoxia-inducible factor expression in aged hippocampus

Authors: *B. SNYDER, H.-K. WU, B. TILLMAN, T. F. FLOYD;
Anesthesiol. & Pain Mgmt., Southwestern Med. Ctr., Dallas, TX

Abstract: The hippocampus (HIPP) is susceptible to hypoxic insults and conditions which confer hypoxia increase during aging, potentially underlying HIPP vulnerability to acute bouts of hypoxia (i.e., stroke or surgery). Alpha isoforms of hypoxia-inducible factors (HIFa) initiate protective hypoxic responses and are dysregulated in aged cortex, but their action within the HIPP has not been fully delineated. We hypothesize that HIFa protein expression is impaired in aged hippocampus and coupled with deficient transcription of downstream genes during acute hypoxia.

Mice, aged 3, 9, 18, & 24 months (mo), were exposed to normoxia (21% oxygen [O_2]) or hypoxia (8%) for 3 hours. Coronal sections containing the hippocampus were immediately collected and flash frozen, sliced on a cryostat into 10 um slices, and mounted on slides. Protein expression of HIFa was assayed by immunohistochemistry (IHC). *In situ* hybridization (ISH) was used to probe mRNA of 10 genes in the HIF pathway: HIF1a (*hif1a*), HIF2a (*epas1*), erythropoietin (*epo*), vascular endothelial growth factor (*vegf*), glucose transporter (*glut1*), lactose dehydrogenase-A (*ldha*), phosphoglycerate kinase1 (*pgk1*), & pyruvate dehydrogenase kinase 1 (*pdk1*). Fluorescence intensity of IHC was captured on a Leica DMI8. ISH slides were scanned on a Zeiss Axioscan. Intensity or the number of ISH spots per HIPP was processed in FIJI. Results were normalized by HIPP area and ANOVAs with Bonferonni post-hoc comparisons performed in JMP 14.

Basal expression of HIF1a protein was elevated within the HIPP of aged mice and stabilization decreased with age under 8% O_2. A similar pattern was observed in *hif1a* mRNA. Only the 24 mo group exhibited a basal elevation of HIF2a protein. Basal expression of *epo, vegf, mct1, and mct4* mRNA was elevated in aged HIPP. Basal expression of *glut1, ldha, pgk1,* & *pdk1* mRNA was lower in aged HIPP. The 3 mo transcriptional changes observed during 8% O_2 showed trends for reversal in aged HIPP.

The age-related elevation of HIFa and changes in gene expression suggests mild hypoxia exists during aging. Genes involved in metabolism maintain energy substrates for neuronal signaling during hypoxia. The changes observed here indicate there may be deficits in metabolic genes necessary to maintain cognitive processes during aging-related hypoxia. Future studies will focus upon potential points of failure in the regulation of HIFa in the HIPP during aging, as well as the contribution of metabolic and trophic HIF-genes to synaptic plasticity in the HIPP.

Title: Vortioxetine, a multimodal antidepressant, reverses cognitive impairments associated with androgen deprivation therapy using the gonadotropin-releasing hormone antagonist, degarelix in a middle-aged rodent model

Authors: *A. VAIANA[1,2,3], J. GELFOND[4], T. JOHNSON-PAIS[3,5], R. LEACH[3,6], C. RAMAMURTHY[3,7], I. THOMPSON[5,8], D. MORILAK[1,2,3,9];

San Antonio, San Antonio, TX; [8]Dept. of Urology, Christus Santa Rosa Hosp., San Antonio, TX; [9]South Texas Veterans Hlth. Care Syst., San Antonio, TX

Abstract: Androgen deprivation therapy (ADT) is a mainstay treatment for late-stage prostate cancer. However, ADT induces cognitive impairment in over half of patients and increases the likelihood of dementia and Alzheimer's disease. These impairments significantly reduce quality of life for cancer survivors. Unfortunately, there are few treatment options available to patients to prevent or reverse these deficits. Previously we demonstrated in a rodent model of ADT that young adult male rats exhibit deficits in attentional set-shifting and spatial learning after surgical castration. These cognitive processes, mediated by the medial prefrontal cortex (mPFC) and hippocampus, are also disrupted in ADT patients. Vortioxetine is a multi-modal antidepressant which improves cognition in depressed patients, and we hypothesized that it may improve cognition after ADT. We found that chronic dietary vortioxetine (28 mg/kg/day, 21 days) was able to reverse the deficits in set-shifting and spatial learning in castrated animals. To increase the translational relevance of our model of ADT, the current study investigates cognitive impairments induced by chemical castration with the gonadotropin releasing hormone antagonist, degarelix. Further, the average age of onset in prostate cancer patients is approximately 65, so we used middle-aged 12-month-old rats, an age at which mild age-related cognitive impairments emerge. Young and middle-aged rats were injected with 3 mg/kg degarelix in 5% mannitol. Controls received a vehicle injection of 5% mannitol. Animals were then fed vortioxetine or control chow through completion of the novel object location (NOL) test

and the attentional set-shifting test (AST). There were no baseline differences between young and middle-aged control rats in either test (p=0.85). ADT trended toward impaired visuospatial memory and set-shifting at both ages (NOL: young p=0.07/aged p=0.15; AST: young p=0.08/aged p=0.16). Vortioxetine trends towards a reversal of impairment on NOL and on AST (NOL: young p=0.08/aged p=0.19; AST: young p=0.15/aged p=0.16). More animals will be added to these groups to achieve sufficient power for analysis. Experiments are underway to investigate changes in functional connectivity of the mPFC and dHipp in the aged population by measuring changes in evoked local field potentials. Our early results indicate that vortioxetine may reverse ADT-induced cognitive decline in middle-aged animals with chemical castration, indicating that it could be useful in mitigating cognitive changes in older men treated for prostate cancer.

Abstract: Background: The purpose of our study is to understand the role of RALBP1 in oxidative and mitochondrial dysfunction in relation to aging. The Ralbp1 gene encodes the 76 kDa protein Rlip (aka RLIP76), is transcriptionally regulated by EP300, a CREB-binding protein that is important for the synaptic plasticity, memory, long-term potentiation and stress-protection in neurons. Rlip is a stress-responsive/protective transporter of glutathione conjugates (GS-E) and xenobiotic toxins. **Methods:** A total of 10 male 10-month-old mice (5 WT and 5 $Rlip^{+/-}$) were tested for neurocognitive function using open field maze, Morris Water Maze, Y-maze, and rotarod instruments. Brain tissues obtained from cohorts of wild-type and $Rlip^{+/-}$ mice were analyzed for oxidative stress markers, expression of genes that regulate mitochondrial fission/fusion, and synaptic function. **Results:** We evaluated whether Rlip deficiency in mice

may develop AD like loss of cognitive function and mitochondrial dysfunction. Behavioral, basic motor and sensory function tests in $Rlip^{+/-}$ mice revealed cognitive neuropsychiatric impairements. Our studies also revealed a significant increase in the levels of oxidative stress markers and alterations in expression of genes and protein involved in mitochondrial biogenesis in brain tissues of these mice. **Conclusions:** Present studies have shown that partial suppression of Rlip protein associated increase in oxidative stress and the associated mitochondrial dysfunction might be implicated in the development of AD processes. Our findings also indicate a potential role of an unknown Rlip-NRF2 interaction that is impaired in AD. Therefore, the restoration of Rlip activity and endogenous cytoprotective mechanisms may be a safe and effective strategy to protect against AD.

Title: Candidate enhancers in the psychiatric-associated third intron of CACNA1C show activity in P28 mouse brain

Authors: T. WARREN[1], L. SU-FEHER[2], E. CASTILLO[3], J. L. HAIGH[4], K. CICHEWICZ[1], J. T. LAMBERT[5], *A. NORD[3];
[1]UC Davis, Davis, CA; [2]Ctr. for Neurosci., [4]Dept. of Neurobiology, Physiol. and Behavior, [3]Univ. of California, Davis, Davis, CA; [5]Univ. of California Davis, Davis, CA

Abstract: *Cis*-regulatory elements such as enhancers play critical roles in the spatiotemporal regulation of gene expression in the developing brain. Genome-wide association studies (GWAS) have consistently linked a large block in the third intron of the gene *CACNA1C* with risk for psychiatric disorders, including schizophrenia and bipolar disorder. We adapted an enhancer reporter assay known as STARR-seq for delivery into the mouse brain using recombinant adeno-associated virus (rAAV) as an expression vector to test candidate enhancers for activity in postnatal mouse brain. Using this method, we identified three strong enhancers in the risk region of *CACNA1C* in postnatal day (P) 7 mouse brain. Follow-up testing of our top identified enhancers in *CACNA1C* shows they continue to drive strong expression of a reporter gene in mouse brain through P28. This approach enables *in vivo* testing of disease-associated cis-

regulatory elements across multiple stages of development. Such functional examination of enhancers will be critical toward dissecting the regulatory activity of enhancers in the brain and how enhancer sequence variation contributes to brain development and neurological disorders.

Title: Sex-differences in selectively bred high- and low-responder rats: spatial gene expression in the dorsal hippocampus

Authors: *M. WASELUS, E. HEBDA-BAUER, M. DAI, F. MENG, H. AKIL, S. J. WATSON, Jr.;
Mol. Neurosci. Inst., Univ. of Michigan, Ann Arbor, MI

Abstract: Historically, our laboratory has used radioactive in situ hybridization to localize and quantify differences in gene expression in various brain regions. Our selectively-bred lines of high- and low-responder rats (bHR and bLR, respectively) are advantageous in that we can use this model to study two “extreme” behavioral phenotypes (e.g., differences in locomotor activity in a novel environment, propensity to self-administer drugs of abuse, and anxiety-like behaviors). In situ hybridization has been used to measure gene expression in the brains of these rats which can then be mapped back on to behavioral differences. Unfortunately, traditionally used radioactive in situ hybridization studies are labor-intensive and costly, with only a finite amount of material available from a single subject thus limiting the number of genes examined. Recently, spatial transcriptomics, most recently the Visium Spatial Gene Expression solution developed by 10X Genomics (Pleasanton, CA), allows RNA-seq on a small region of interest within tissue sections, reducing the hands-on processing time and increasing the number of genes examined in a single study while retaining spatial resolution. Brains from the 68^{th} generation of our selective breeding colony were used to examine both bHR/bLR- and sex differences in gene expression in the dorsal hippocampus of adult rats. One section per “condition” (bred line x sex) was collected from a bHR and bLR family per slide, allowing each slide to function as its own

independent study. Adjacent sections were collected on a second slide to serve as a technical replicate. A second bHR and bLR family was used to examine bHR/bLR and sex differences, serving as a biological replicate. Our initial results indicate that all Visium samples were of high quality for use in downstream analyses. We first wanted to demonstrate that known markers of sex differences were different male and female rat brain, regardless of breeding background. To that end, we found two examples of Y-linked genes (i.e., Eif2s3y and Kdm5d) are expressed in the brains of male, but not female, rats. Furthermore, specific genes of interest are differentially expressed in the brains of adult bHR and bLR rats, consistent with other ongoing internal studies. Our conclusions thus far indicate that in our hands, Visium has the potential to be a powerful tool for elucidating differences in gene expression between not only male and female rats, but also selectively bred bHR and bLR rats. Further studies will allow us to combine single cell data generated by our group with spatial datasets to determine the precise localization of gene expression differences within larger brain structures.

Title: Molecular atlassing with MERSCOPE: A new spatial transcriptomics technique accurately reveals the organization of the mouse brain transcriptome

Authors: *G. EMANUEL, J. HE, J. HE;
Vizgen, Cambridge, MA

Abstract: Biological systems are comprised of numerous cell types, intricately organized to form functional tissues and organs. Building molecular atlases to fully understand the structure and function of each cell within the brain is now a key aspect of neuroscience research. Atlas initiatives using single-cell RNA sequencing can characterize cell types based on their RNA expression profiles. However, the tissue organization is lost when cells are dissociated for single-cell sequencing, making it difficult to study how the cellular heterogeneity is contributing to the function of the tissue. Furthermore, accurately characterizing each cell within the brain is challenging due to the low expression of many functionally important genes such as nonsensory G-Protein coupled receptors (GPCRs). GPCRs mediate signaling and may play vital roles in brain aging and neurodegenerative disorders but are difficult to analyze. Thus, the ability to completely spatially profile GPCR expression across the brain with cellular context can enable a deeper understanding of brain tissue. A spatial transcriptomics technique with high detection

efficiency and single molecule resolution is required to build a complete molecular atlas. Vizgen's in situ genomics platform MERSCOPE™ enables the direct profiling of the spatial organization of intact tissue with subcellular resolution. MERSCOPE is built on multiplexed error robust in situ hybridization (MERFISH) technology that uses combinatorial labeling, sequential imaging, and error-robust barcoding to provide the highest detection efficiency and resolution available for spatial genomics. In a single experiment, hundreds of thousands of cells can be spatially profiled with high accuracy and reproducibility. To demonstrate the power of MERSCOPE, we mapped 483 genes across three different positions of the mouse brain with three biological replicate tissue slices per position. We constructed a panel that includes canonical cell type markers and GPCRs to spatially profile gene expression across the brain. Among the approximately half-billion total transcripts detected, we successfully located notably low expressing nonsensory GPCRs such as Oxtr, Tshr, and Insr. We also demonstrated a strong correlation (r=0.88) between the number of transcripts detected to bulk RNA sequencing. From MERSCOPE's cell segmentation, we clustered cells by gene expression, identified different cell types, and mapped their spatial organization. The MERFISH mouse brain receptor map establishes MERSCOPE as a leading technique for molecular atlassing, empowering scientists to find greater insights into healthy versus diseased tissue.

Title: Spatial distribution of transcriptomic neuronal types across the whole cortex determined by in situ sequencing

Authors: *X. CHEN[1], S. FISCHER[2], J. GILLIS[2], A. M. ZADOR[2];
[1]Allen Inst. for Brain Sci., Seattle, WA; [2]Cold Spring Harbor Lab., Cold Spring Harbor, NY

Abstract: The mammalian cortex is composed of myriad long-range projection neurons that enable communication within the cortex and between the cortex and other brain structures. Previous studies using single-cell RNAseq have revealed tremendous diversity in the gene expression of cortical projection neurons, but how these transcriptomic types of neurons are distributed across the whole cortex is largely unknown. Here we determined the transcriptomic identities of 1.2 million neurons across a mouse hemi-brain and mapped their spatial distribution using a high-throughput in situ sequencing pipeline. Consistent with previous studies, known transcriptomic subclasses of neurons are differentially distributed within the isocortex, across cortex-like structures, and across non-cortical brain structures. Beyond the subclass-level divisions, we found gradients of gene expression that map onto spatial gradients within the isocortex. Our approach is high throughput and can be conveniently scaled up to interrogate brain-wide cell type distribution across development and aging, across genotypes, across species, and across individual animals. Furthermore, our data provide a foundation for future interrogation of cell type long-range connectivity at a whole-brain scale.

Title: Single nucleotide resolution profiling techniques based on eCLIP reveal functional neuronal miRNA target sites and their regulatory features

Authors: *S. A. MANAKOV, D. C. COX, K. SHEN, A. A. SHISHKIN, K. B. CHAPMAN; Eclipse Bioinnovations, San Diego, CA

Abstract: Techniques that can identify functional miRNA sites and their regulatory features are important for characterizing pathology of neuronal health, plasticity, and development of therapeutics. Methods to experimentally read out miRNA targets in the form of miRNA:target chimeric reads exist, but their application was limited due to complexity of library preparation and low rate of chimeras. N6-methyladenosine (m6A) modification in first position at miRNA target sites (t1-A) reduces efficacy of miRNA binding raising possibility that m6A can derepress miRNA sites, but modifications in the genomic environment of miRNA target sites were not yet

characterized with high resolution since single nucleotide profiling of m6A is challenging. We developed miR-eCLIP, an AGO2 eCLIP assay with chimeric ligation, and combined it with two different enrichment strategies to enrich for chimeric reads specific to a gene of interest or an miRNA of interest. We demonstrate the utility of gene specific enrichment by enriching chimeric reads for the Amyloid Beta Precursor Protein (APP) gene in HEK293xT cells. This methodology revealed five miRNA target sites in the 3'UTR of the APP transcript, three of which were co-targeted by 3 to 5 seed family member miRNAs. Co-targeting of the same seed site on the mRNA transcript by multiple miRNA family members is consistent with previous reports that knock-outs of individual miRNAs often has only mild effects on gene expression.To demonstrate the utility of miRNA-specific probe-based enrichment, miR-eCLIP with enrichment for miR-124 chimeric reads was conducted in miR-124 transfected cells. This technique identified hundreds of functional targets and RNAseq conducted in parallel confirmed that these targets have reduced expression levels. Moreover, targets were identified quantitatively, with greater number of chimeric reads associated with greater repression. Finally, we also developed m6A-eCLIP where m6A antibodies are UV crosslinked to RNA, and m6A is read out with a single nucleotide resolution by identifying reverse transcriptase termination at crosslinks. We also applied m6A-eCLIP to HEK293xT RNA and generated a map of over 200,000 m6A sites. Analysis of the m6A map showed that this modification was depleted in a 10 nt window around the functional miR-124 sites, suggesting that m6A modifications in close proximity to miRNA target sites may interfere with miRNA binding. In conclusion, we show that eCLIP techniques are suitable to study targets of neuronal miRNAs and genes on examples of miR-124 and APP gene. We believe these methodologies will be a useful tools for researchers studying neuronal miRNAs, their regulation and function.

Abstract: Spatial profiling of gene expression is an essential complement to single cell transcriptomics methods, providing an unbiased method for building spatial maps that inform on cell type locations, proportions and interactions. These maps will ultimately be critical in deciphering brain circuitry and function from development through neurodegenerative disease. We have built a spatial transcriptomics data production pipeline to perform multiplex, error-robust fluorescence in situ hybridization (MERFISH) and related techniques at scale in multiple species, which will make profiling of multiple brain areas feasible. Here we describe our pipeline structure, and the resulting cell type mapping results obtained from human middle temporal gyrus as well as mouse primary visual cortex.

Title: Enhancer AAVs for targeting layer 6 IT Car3 type neurons and Claustrum

Authors: *E. L. MORIN, A. E. SEDENO-CORTES, C. TRADER, J. GIBSON, J. L. BENDRICK, M. TAORMINA, R. GALA, S. YAO, J. WATERS, H. ZENG, B. TASIC, T. L. DAIGLE;
Allen Inst. For Brain Sci., Seattle, WA

Abstract: Enhancer-based AAVs for targeting at the cell class-, subclass-, or type-specific levels can be combined with the evolved, blood-brain barrier-crossing PHP.eb capsid for whole-brain labeling with relative ease in mouse (Graybuck and Daigle, et al., Neuron 2021 and Mich et al., Cell Reports 2021). Here, we describe the generation and characterization of a collection of enhancer-based AAVs targeting a distinct, transcriptomically-defined type of intratelencephalic (IT) neuron: Layer 6 (L6) IT Car3. The cell bodies of these deep layer projection neurons reside in many cortical areas as well as in claustrum, an enigmatic region reciprocally connected to all cortical regions and thought to coordinate or conduct this connectivity. We identified putative enhancers for this cell type via the integrative analysis of single cell (sc) RNA-seq with scATAC-seq data from mouse primary visual cortex and cloned these into viral vectors expressing recombinases or fluorescent reporters. Individual viruses were delivered into the retroorbital sinus of Ai193 transgenic mouse, a TIGRE3.0 Cre- and Flp-dependent cell-filling

fluorophore reporter, or into C57Bl/6J mice. Viral labeling patterns were examined by serial two-photon tomography (TissueCyte) four weeks post-infection. Image datasets were registered to the Allen Mouse Common Coordinate Framework v3.0, and the fluorescent signal was segmented to construct regional labeling densities and confirm viral labeling in L6 and claustrum. Additionally, computational methods for two-color quantification of these cells are being developed, by means of a custom Unet segmentation algorithm, which will enable detailed examination of viral labeling patterns at single-cell resolution across the entire brain. Additional molecular validation (scRNA-seq profiling and multiplex FISH) of virally-labeled cells located in the primary visual cortex and claustrum will be performed to confirm cell type identity and the completeness of labeling. This work establishes a level of systematic characterization of enhancer-based viral genetic tools that did not previously exist and is critical for scaling the development of viral tools to access diverse brain-wide neuronal cell types.

Title: Transcriptomic analysis of neuronal sub-populations using RNAscope™ guided Digital Spatial Profiling

Authors: *A. VANSCHOIACK[1], E. A. BROWN[1], A. DIKSHIT[2], S. BASAK[2], L. PAN[1], K. FUHRMAN[1], Y. LIANG[1], J. BEECHEM[1];

Abstract: Defining the molecular architecture of gene expression within the brain is critical for understanding normal brain function and for developing and testing new hypotheses toward understanding and treating neurological disorders and disease. Substantial advances have been made within the last decade to enable detailed molecular characterization of neuronal populations within the mouse and human brain but have been limited by low-plex (IHC/IF/ISH) and/or low throughput (LCM, IMC) or lacking spatial resolution (single cell RNAseq). Here, we demonstrate a combinatorial approach of using RNAscope ISH-IF to guide spatial whole-transcriptomic profiling of excitatory and inhibitory neuronal populations within mouse coronal FFPE sections. Spatial transcriptomic profiling of 5um FFPE sections from four C57BL/6 mice was performed using NanoString's Mouse Whole Transcriptome Assay and the Co-detection

workflow from ACD, a Bio-Techne brand, for simultaneous RNA and protein detection, with NeuN protein visualized in combination with *Vglut1*, *Vglut2*, and *Vgat* mRNA to identify excitatory and inhibitory neuron populations. The dual ISH-IF images were captured with the GeoMx Digital Spatial Profiler (DSP) and used to identify regions in the cortex, hippocampus, and striatum within a single coronal section. Using the unique ability of GeoMx to segment and independently profile cell populations using fluorescence guided morphology, we profiled and analyzed excitatory and inhibitory neurons separately in each identified ROI, quantitating expression of the whole transcriptome in neuronal subpopulations throughout the brain with average detection in each population ranging from 5000-8000+ genes. High concordance was observed between gene expression detected by GeoMx and representative genes quantified by RNAScope, and data were also benchmarked against the Allen Brain Atlas resources as independent validation of both cell-type specific (Cell Types scRNA-seq data) and spatial (Mouse Atlas ISH database) gene expression. In conclusion, we have established a workflow enabling whole transcriptome data from spatially mapped neuron populations within healthy mice and demonstrate high precision and accuracy of the approach. We demonstrate gene expression differences in excitatory and inhibitory neurons based on spatial localization, highlighting the critical importance of spatial context in transcriptomic analysis. These data and workflow can be used as standards to inform future profiling studies in mouse models of neurological disorders and disease.

Title: Concomitant transcriptomic and proteomic profiling using TurboID proximity labeling

Authors: *C. C. RAMELOW[1], S. SUNNA[1], S. RAYAPROLU[1], M. SAMPSON[2], N. T. SEYFRIED[3], S. SLOAN[2], S. RANGARAJU[1];
[1]Neurol., [2]Human Genet., [3]Biochem., Emory Univ., Atlanta, GA

Abstract: Biological and therapeutically relevant insights into cellular disease mechanisms of neurons and glia can be obtained by complimentary molecular profiling of the transcriptome and proteome of these cells. While mutually exclusive transcriptomic and proteomic pipelines are available, the information surveyed is often from different cells leading to poor correlation between the transcriptome and proteome. Thus, our overall goal was to develop a method for concomitant cell type-specific analyses of RNA and protein. To accomplish this, we utilized a proximity-labeling strategy that uses the biotin ligase, TurboID, to efficiently label the proteome, in a mouse microglial BV2 cell line. For proof-of-concept *in vitro* experiments, we created a BV2-TurboID cell line that stably expresses TurboID fused to a nuclear export sequence. Biotin treatment of BV2-TurboID cells resulted in robust biotinylation of the cellular proteome as confirmed by Western blot and by label-free quantitation mass spectrometry (LFQ-MS) of biotinylated proteins enriched with streptavidin beads. LFQ-MS revealed that TurboID biotinylates several RNA-binding proteins (RBPs) including ribosomal units, suggesting that transcripts associated with RBPs may also be pulled down simultaneously with proteins. To test this hypothesis, we homogenized BV2-Turbo and control BV2 cells, enriched biotinylated proteins with streptavidin beads while maintaining RNA-protein interactions, and then eluted RNA. Quality control studies showed negligible mRNA from streptavidin pulldowns from control BV2 cells, while BV2-Turbo pulldowns had larger mRNA yields with high quality. NanoString neuroinflammatory profiling (800 genes) of whole cell RNA from control BV2 and BV2-Turbo cells and streptavidin pulldowns from both cell types were performed. We observed a 23-fold higher mRNA yield in the BV2-Turbo pulldowns compared to control BV2 cells for 550 genes included in the analyses. Transcript abundances from whole cell RNA and BV2-Turbo pulldowns were highly comparable (R^2=0.97 and no differentially expressed genes) with equivalent abundance of microglial genes (e.g., *Spp1* and *Apoe*) suggesting a faithful transcriptome capture. Since we have optimized the pipeline for this method, our novel TurboID proximity labeling approach can simultaneously capture cell type-specific transcriptomes and proteomes. We are now validating this method in other cell types using RNA-seq and MS approaches. Once validated, this concurrent RNA and protein profiling approach can be applied to *in vivo* and *ex vivo* model systems to investigate the distinct roles brain cell types play in development, aging, and disease.

Title: Transcriptional and Anatomical Diversity of Medium Spiny Neurons in the Primate Striatum

Authors: *J. HE[1], M. KLEYMAN[5], J. CHEN[1], A. ALIKAYA[1], K. M. ROTHENHOEFER[1], B. E. OZTURK[2], M. WIRTHLIN[5], A. C. BOSTAN[3], K. FISH[4], L. BYRNE[2], A. R. PFENNING[5], W. R. STAUFFER[1];
[1]Neurobio. Dept., [2]Ophthalmology Dept., [4]Psychiatry Dept., [3]Univ. of Pittsburgh, Pittsburgh, PA; [5]Computat. Biol. Dept., Carnegie Mellon Univ., Pittsburgh, PA

Abstract: The striatum is the interface between dopamine reward signals and cortico-basal ganglia circuits. It is critical for learning, cognition, movement, reward, and emotional responses. The striatum can be anatomically and functionally divided into the caudate and putamen, including striosome and matrix compartments, and the ventral striatum, including nucleus accumbens (NAc), olfactory tubercle, and interface islands. Medium spiny neurons (MSNs) constitute the vast majority of striatal neurons and are traditionally classified as direct- or indirect-pathway neurons, though further diversity has been shown in rodents. Here, we profiled MSN-diversity in non-human primates (NHPs) striatum. Using a combination of scRNA-seq and FISH we defined molecularly distinct MSN subtypes including (1) dorsal striatum MSN subtypes associated with striosome and matrix compartments, (2) ventral striatum subtypes associated with the nucleus accumbens shell and olfactory tubercle, and (3) an MSN-like cell type restricted to m-opioid receptor rich islands in the ventral striatum. We show that there are conserved patterns of continuous variation throughout the striatum, but that each transition between MSN subtypes is characterized by discontinuities in gene expression. Archetypal analysis revealed further axes of variation by revealing a significant caudate signal characterized by the expression of *OPRM1*, and a unique, *TAC3*-positive NAc shell D1-MSN archetype. Together, these results constitute a 'roadmap' for investigating cell type-specific information processing in the striatum.

Title: Foxr1 is necessary for survival and proper brain development

Authors: *H. WAXMAN, A. MOTA, G. LAGANI, U. BEFFERT, A. HO;
Boston Univ., Boston, MA

Abstract: In the developing brain, complex and precisely timed sequences of cellular signaling are mediated by transcription factors (TFs) which drive expression of critical proteins. As such, understanding the identities of these TFs and their transcriptional networks will be paramount to understanding the etiology of neurodevelopmental disorders. The NIH Undiagnosed Disease Network identified a rare human missense mutation in *FOXR1* linked to an individual presenting with postnatal microcephaly, progressive brain atrophy, and global developmental delays. FOXR1 belongs to a large family of TFs known as *forkhead*, named for the abnormal head shape in *Drosophila* mutants. While the FOX family is relatively understudied, a subset have been demonstrated to play essential roles during brain development including FOXG1, FOXC2, FOXL2, FOXP1, and FOXP2. To date, the function of FOXR1 is unknown. Human FOXR1 shares 66% amino acid sequence identity with its mouse homologue. Using primers specific for mouse *foxr1*, we demonstrated by qPCR that *foxr1* mRNA was detected in several tissues including heart, liver, lung, and elevated expression in the brain at embryonic day 17. To better understand the role of FOXR1 in mammalian brain development, we analyzed newly developed mice that lack the *foxr1* gene, generated with the CRISPR/Cas9 gene editing system. Single guide RNAs were designed to target intron one and the majority of exon 4, thus destroying the exon 4 splice acceptor. This leads to a deletion of exons 2, 3 and majority of exon 4, resulting in a 976 bp deletion. We found that mice lacking *foxr1* displayed a severe survival deficit, while surviving newborn *foxr1* knockout mice had reduced body weight. Further examination of newborn *foxr1* knockout brains revealed a decrease in cortical thickness and enlarged ventricles compared to littermate wild-type mice, suggesting that loss of *foxr1* leads to atypical brain development. Combined, these results suggest *foxr1* is necessary for normal brain development. Future studies will further elucidate the specific temporal, cellular, and anatomical expression profile of *foxr1* expression and define foxr1 transcriptomic regulation associated with brain development.

Title: Differences in post-stroke immune response outcomes in adult rats prenatally exposed to alcohol

Authors: *M. R. PINSON, S. BAKE, A. M. ADAMS, S. PANDEY, F. SOHRABJI, R. C. MIRANDA;
Neurosci. and Exptl. Therapeut., Texas A&M Univ. Col. of Med., Bryan, TX

Abstract: Prenatal alcohol exposure (PAE) can result in increased risk for cardiovascular disease and peripheral and central immune system dysfunction which may contribute to negative outcomes post-stroke. To test this hypothesis, timed-pregnant Sprague-Dawley rats were exposed to binge-like episodic ethanol vapor or ambient air during the latter half of gestation. Pups were allowed to age to 12 mo at which point they underwent surgeries for middle cerebral artery occlusion (MCAO), a model for cerebrovascular stroke. At 2 days post-MCAO, animals were euthanized and plasma, liver, spleen, mesenteric adipose, and brain hemispheres were collected. Liver and spleen were weighed and normalized to body weight and PAE animals were determined to have decreased normalized liver weight, an effect that was predominantly driven by males as revealed by post-hoc analyses. Additionally, leukocytes were isolated from blood, spleen, and cortex/hippocampus, ipsilateral and contralateral to the lesion at 2 days post-MCAO. Specifically, we saw an increase in circulating neutrophils in PAE animals, predominantly in males. Additionally, we observed a lower CD4+:CD8+ ratio in circulation and lower levels of IL-17 in circulating Th17 cells in PAE animals. Correlational analyses revealed sex-specific relationships between immune cell populations and stroke outcomes of infarct size and neurological score. Together, these data suggest potential mechanisms by which PAE animals may suffer worse outcomes from secondary insults that occur in adulthood. Understanding the impact of PAE on immune response post-stroke will result in better, FASD-informed health management of adults.

Title: Thalamic and basal forebrain nuclei are vulnerable to permanent cell loss after neonatal ethanol exposure

Authors: *J. F. SMILEY[1], P. VADDI[2], C. BLEIWAS[1], S. CANALS-BAKER[1], E. C. DIAS[1], D. A. WILSON[1], M. SAITO[1];
[1]Nathan Kline Inst. for Psychiatric Res., Orangeburg, NY; [2]Nathan Kline Inst., Orangeburg, NY

Abstract: It is well known that neonatal ethanol exposure causes a spike of neuronal apoptosis in the brain, but for most brain structures the extent of permanent neuron loss that persists into adulthood is unknown. We and others previously demonstrated that cholinergic cells in the basal forebrain are especially vulnerable to this treatment, with as much as 40% reduction of cell number. In the present study we evaluated total neuron number in the basal forebrain (medial septal nucleus and vertical diagonal band), and compared the severity of neuron loss to that of several forebrain and brainstem neuron populations. C57Bl mice were injected with ethanol at postnatal day 7 (P7), and total Nissl-stained neuron numbers were evaluated by stereological methods at early adulthood (P70). Cell number estimates showed that ethanol caused especially severe reductions (20-40%) of total neuron number in both the basal forebrain region and the sub-nuclei of the anterior thalamic complex. In contrast, the cingulate cortex had a smaller reduction (10-20%) that was modestly more pronounced than that of total neocortex. Similarly, neuron numbers were not significantly reduced in cholinergic, dopamine and serotonin cells of the brainstem. The findings indicate that the basal forebrain and anterior thalamus are especially vulnerable to neonatal ethanol. Ongoing studies are investigating the mechanisms of ethanol vulnerability in these neuron populations. Supported by NIAAA R01-AA023181.

Title: Cdkl5 deficiency augments inhibitory input into the dentate gyrus that can be reversed by deep brain stimulation

Authors: *Q. WANG[1,2], S. HAO[1,2], B. TANG[1,2], Z. WU[1,2], J. TANG[1,2];
[1]Jan & Dan Duncan Neurolog. Res. Inst., Houston, TX; [2]Dept. of Pediatrics, Baylor Col. of Med., Houston, TX

Abstract: CDKL5 deficiency disorder (CDD) is a neurodevelopmental disease caused by mutation of the X-linked gene cyclin-dependent kinase-like 5 (*CDKL5*). CDD is characterized by severe intellectual disability, gross motor impairment, early-onset epilepsy, and autistic features. Mouse models of CDD recapitulate the cognitive deficits and other characteristics of this condition. Although loss of CDKL5 affects a number of molecular pathways, very little has been discovered about the physiological effects of these changes on the neural circuitry. We therefore assessed the hippocampus-dependent behavior, synaptic plasticity, and local circuit activity in a unique CDKL5 knockout mouse model with exon 6 deletion (B6.129(FVB)-*Cdkl5*$^{tm1.1Joez}$/J). We found that CDKL5 haploinsufficiency in both male *Cdkl5*$^{-/y}$ and female *Cdkl5*$^{+/-}$ mice impair hippocampus-dependent learning and memory in multiple tasks including fear conditioning, passive avoidance, and Morris water maze. *In vivo*, loss of CDKL5 reduces long-term potentiation of the perforant path to the dentate gyrus and augments feedforward inhibition in this pathway. *Ex vivo*, *Cdkl5*$^{-/y}$ mice have decreased excitatory, but increased inhibitory synaptic transmission in dentate granule cells, confirming that excitatory/inhibitory input into the dentate gyrus is skewed toward inhibition after CDKL5 ablation. Furthermore, injecting the GABAergic antagonist gabazine into the dentate improved contextual fear memory in *Cdkl5*$^{-/y}$ mice. Finally, chronic forniceal deep brain stimulation rescued hippocampal memory deficits, restored synaptic plasticity, and relieved feedforward inhibition in *Cdkl5*$^{+/-}$ mice. Together, our findings suggest that CDKL5 is important for maintaining proper dentate excitatory/inhibitory balance for hippocampal memory and forniceal DBS as the possible translational intervention for treating CDD.

Title: Prenatal alcohol exposure enhances Toll like receptor (TLR4)-4 and NLRP3 inflammasome actions and paradoxically prolongs nerve injury-induced pathological pain following morphine treatment

Authors: *S. NOOR[1], M. S. SUN[1], *A. A. PASMAY[1], A. K. F. OROPEZA[1], C. D. RUFFANER-HANSON[1], M. V. V. NYSUS[2], D. C. JIMENEZ[1], D. D. SAVAGE[1], C. F. VALENZUELA[1], E. D. MILLIGAN[1];

Abstract: Our prior work demonstrates that adult prenatal alcohol exposed (PAE) male rats with minimal nerve injury develop allodynia (pathological light touch sensitivity) in concert with aberrant peripheral and spinal glial and immune activation. Nerve-injured PAE rats display heightened proinflammatory cytokine production (IL-1β and TNF-α) typically produced following activation of the innate immune receptor, TLR4, and intracellular protein complex, Nod-like receptor family pyrin domain containing 3 (NLRP3) inflammasomes. This suggests that PAE-related adaptations prime peripheral macrophages and central nervous system (CNS) glia to over-respond to subtle challenges through exaggerated TLR4 and NLRP3 inflammasome reactivity. Interestingly, morphine, a standard opioid pain therapeutic, binds the μ-opioid receptor and glial TLR4 leading to NLRP3 inflammasome activation. Therefore, we hypothesized that PAE primes immune cell reactivity through augmented TLR4 activation and downstream NLRP3-mediated proinflammatory cytokine release, that is exacerbated by exposure to morphine treatment. We predicted morphine paradoxically prolongs allodynia following adult-onset peripheral nerve injury in PAE offspring through aberrant NLRP3 activation. Results confirm that PAE is a risk factor for developing allodynia in adult female mice with minor injury. Following minor nerve injury, morphine treatment (10 mg/kg, 5 subsequent days) significantly prolongs allodynia in PAE mice, while Sac control mice spontaneously resolve sooner. Moreover, selectively blocking NLRP3 inflammasome activity via MCC950 (i.v. 10 mg/kg) treatment reversed the morphine-prolongation of allodynia observed in PAE mice. *In vitro* studies were designed to examine the TLR4-NLRP3-dependent enhanced reactivity of PAE immune cells to typical immune stimuli with/without morphine treatment. Data show morphine further enhances NLRP3 inflammasome activity, as measured by flow cytometric detection of intracellular levels of active Caspase-1 and IL-1β release (by ELISA) from PAE leukocytes. *In vitro* culture data further confirmed MCC950 actions on inhibiting IL-1β release specifically, but not TNFα. Together, these data provide evidence that PAE exaggerates morphine-induced

immune activation via the TLR4-NLRP3 pathway and may be predictive of adverse responses to opioids intended for pain therapeutics in individuals with FASD.

Title: A ROLE FOR CALCIUM SIGNALING IN THE ETHANOL-INDUCED ABERRANT TANGENTIAL MIGRATION OF PRIMORDIAL CORTICAL GABAERGIC INTERNEURONS

Authors: *S. M. LEE, P. W. L. YEH, H. H. YEH;
Geisel Sch. of Med. At Dartmouth, Hanover, NH

Abstract: Alcohol consumption during pregnancy places the unborn child at risk for fetal alcohol spectrum disorders (FASD). While the diagnosis and management of FASD takes place postnatally, the underlying pathoetiology remains incompletely understood but is arguably embryonic. In mice, prenatal exposure to ethanol escalates tangential migration of cortex-bound primordial GABAergic interneurons, and this has been postulated to affect cortical circuit function and contribute to long-term excitatory/inhibitory imbalance. Previously, we found that ethanol potentiates $GABA_A$ receptor-mediated depolarization in tangentially migrating GABAergic interneurons. Here we investigated the downstream signaling mechanisms of ethanol-enhanced GABA depolarization underlying aberrant tangential migration.
First, we asked whether ethanol exposure potentiates calcium influx via L-type calcium channels (LTCC) in migrating GABAergic interneurons. Immunohistochemical staining confirmed that tangentially migrating Nkx2.1Cre/Ai14 GABAergic interneurons express Cav1.2 at embryonic day (E) 16.5, the canonical neuronal isoform of the LTCC. Exposure to liquid diet containing 5% ethanol from E13.5-16.5 did not change the expression levels of LTCC in the embryonic brain. In addition, whole-cell patch clamp electrophysiology revealed the presence of high-voltage activated nifedipine-sensitive LTCC in E16.5 Nkx2.1Cre/Ai14 embryos. This calcium influx

mediated by LTCC was potentiated following acute exposure to 18mM ethanol (80mg/dl or 0.08%), equivalent to 5% binge ethanol exposure paradigm *in vivo*.
Second, we assessed if LTCC is involved in ethanol-induced aberrant tangential migration of GABAergic interneurons. To this end, we treated organotypic slice cultures with control, nifedipine, ethanol, and nifedipine + ethanol-containing medium. Co-treatment of ethanol and nifedipine prevented the effect of ethanol on migration. We found that maternal treatment from E13.6 to E16.5 with liquid diet containing 5% ethanol along with nifedipine (0.15mg/kg body weight) also normalized tangential migration *in vivo*.
The present study provides a mechanistic link implicating calcium as an important intermediary in the ethanol-induced aberrant migration of immature GABAergic cortical interneurons reported in our mouse model of FASD.

Title: Activation of the anterior cingulate cortex ameliorates anxiety in a preclinical model of fetal alcohol spectrum disorders

Authors: *H. M. HWANG, K. HASHIMOTO-TORII;
Children's Natl. Med. Ctr., Washington, DC

Abstract: Prenatal alcohol exposure (PAE) results in a broad range of neurobehavioral issues in patients with fetal alcohol spectrum disorders (FASD). One prominent lifelong comorbidity in these patients is anxiety. Both preclinical and clinical studies suggest that disrupted hypothalamic-pituitary-adrenal (HPA) axis is a reason for increased risk of anxiety disorders in FASD. However, changes in brain circuitry or molecular pathways, other than the HPA axis, have not yet been elucidated fully in FASD. The anterior cingulate cortex (ACC) is one of the brain regions associated with anxiety. Studies show malfunctioning of the ACC is associated with hyperactivity of the amygdala - the hub for fear processing - in patients with anxiety disorders, and stimulation of the ACC decreases neuronal activity in the amygdala. In this study, we evaluated whether ACC and amygdala connectivity plays a role in anxiety-like phenotype

due to PAE. Pregnant CD1 mice were exposed to alcohol (4g/kg body weight) at gestational day 16 and 17, during the peak of corticogenesis, and offsprings were assessed for behavioral changes at postnatal day 30. Behavioral analysis revealed a typical anxiety-like phenotype in PAE group: significant reductions in self-grooming time and open arm time in the elevated plus maze (EPM) compared to control group. We also found that stress hormone (corticosterone or CORT) concentration is significantly high in PAE group in both resting state and after EPM test, and their level significantly correlated with open arm time. C-Fos, immediate early gene marker, immunohistochemistry identified significantly decreased activity in the ACC but increased activity in the basolateral amygdala (BLA) in PAE group after EPM test. Furthermore, double-immunofluorescence of c-Fos with inhibitory (PV) or excitatory (VGLUT2) markers showed a significant loss of excitatory neuronal activations in the ACC. To confirm if the reduction in ACC activity in PAE group is responsible for anxiety-phenotype, we chemogenetically stimulated excitatory neurons employing the Designer Receptors Exclusively Activated by Designer Drugs (DREADD) method. Clozapine N-oxide (CNO) administration to AAV5-CaMKIIa-hM3D(Gq)-mCherry virus injected PAE mice showed a significant improvement in open arm time in the EPM test accompanied by a significant increase of c-Fos level in the ACC but a decrease in the BLA. In summary, our data suggest that a decreased activity of excitatory neurons in the ACC that regulate BLA activity due to PAE underlies anxiety-like behavior and demonstrate that stimulating the ACC can be a potential regimen to alleviate anxiety symptoms in FASD patients.

Title: Forebrain-specific knockout of Cited2 leads to transcriptome disruptions in intermediate progenitor cells and results in disrupted neocortical developmental behavioral alterations

Authors: *N. WAGNER, J. L. MACDONALD;
Dept. of Biology, Program in Neurosci., Syracuse Univ., Syracuse, NY

Abstract: The mammalian neocortex develops from a single layer of neuroepithelial cells to form a six-layer heterogeneous mosaic of differentiated neurons and glial cells through a complex choreography of temporally and spatially restricted transcription factors and epigenetic

regulators. One recently identified epigenetic regulator that is essential for the precise development of the neocortex is CITED2 (CBP/p300 Interacting Transactivator with ED-rich termini). *Cited2* is highly expressed by intermediate progenitor cells (IPCs) in the subventricular zone during the generation of the superficial layers of the neocortex at embryonic day 15.5 (E15.5). Previous work showed that mice with a forebrain-specific conditional knockout of *Cited2* (cKO) exhibit reduced proliferation of IPCs embryonically through previously unresolved mechanisms. This leads to reduced thickness of the superficial layers, reduced corpus callosum volume, and disruptions in balanced neocortical arealization. We have found that these morphological abnormalities are sufficient to generate behavioral alterations that are associated with neurodevelopmental disorders, including decreased ultrasonic vocalizations as neonates, and an increase in rearing behavior and lack of habituation following repeated acoustic startle as adults. Excitingly, our data suggest that *in utero* folic acid supplementation is sufficient to ameliorate neocortical morphological abnormalities in the *Cited2* cKO, though the effect of folic acid supplementation on cKO behavior remains unknown. Ongoing work is aimed at uncovering the molecular mechanisms by which CITED2 functions in IPCs to regulate neocortical development and behavior. We compare the transcriptomes of purified IPCs from the developing cortex of E15.5 *Cited2* wild-type and cKO littermates to identify genes that are regulated by CITED2 in the developing neocortex. Taken together, these results identify the *Cited2* cKO as a novel system to test how *in utero* environmental exposures lead to altered neocortical development and life-long alterations in behavior.

Title: New in vivo AAV strategy to treat SLC6A8 deficiency

Authors: *G. FERNANDES-PIRES[1], L. DURAN-TRIO[2], M. LANZILLO[2], L. TENENBAUM[3], O. BRAISSANT[1];
[1]Clin. Chem., Univ. Hosp. of Lausanne, Lausanne, Switzerland; [2]Clin. Chem., Univ. Hosp. of Lausanne, LAUSANNE, Switzerland; [3]Lab. of neurotherapies and neuromodulation, Univ. Hosp. of Lausanne, Lausanne, Switzerland

Abstract: BACKGROUND: Creatine (Cr) is synthetized by the enzymes AGAT and GAMT, and specifically taken up by the transporter SLC6A8. Deficit in its endogenous synthesis or transport leads to Cerebral Creatine Deficiency Syndromes (CCDS). AGAT, GAMT and SLC6A8 deficiencies are inborn error of metabolism (IEM) characterized by brain Cr deficiency causing neurodevelopmental delays and intellectual disability. While AGAT and GAMT deficiencies are improved with Cr treatment, SLC6A8 deficiency cannot. We develop adeno-associated virus (AAV) gene therapy in our SLC6A8$^{Y389C/y}$ knock-in rat model as proof of concept for SLC6A8 deficiency treatment. We present here AAV9 CNS transduction of both WT and *Slc6a8*$^{Y389C/y}$ rat males with mCherry fluorescent protein and functional Slc6a8 transporter.
METHODS: WT and KI males were injected at postnatal day 11 intracisternally with 10µl of ss-AAV9-2YF-mCherry or ssAAV9-2YF-CMV-SLC6A8-Flag suspensions (10^{12} vg/ml). Animals were sacrificed at 5 and 16 weeks post-injection to assess AAV9 transduction efficacy and cellular tropism. Starting from 5 weeks post-injection, a subgroup of ssAAV9-2YF-CMV-SLC6A8-Flag-injected KI males were exposed to daily Cr treatment (2g/kg*day).
RESULTS: We observed a widespread mCherry transduction in most CNS regions (cortex, hippocampus, medulla oblongata, cerebellum, spinal cord). As compared to non-injected KI males, ssAAV9-2YF-CMV-SLC6A8-Flag-injected KI males showed partial restablishment of body weight gain and body-mass index (BMI).
DISCUSSION: Our strategy appears as promising to treat SLC6A8 deficiency, with encouraging brain Cr increase as well as body weight and BMI corrections. While still effort-demanding in terms of improvement, this approach may become available in near future to treat the so far untreatable SLC6A8 deficiency.

Abstract: Neurofibromatosis type 1 (NF-1) is an autosomal dominant genetic disorder predisposing patients to a range of complications, including benign tumor formations in the nervous system, altered cellular function, short stature, bone abnormalities, and increased rates of cognitive and developmental disorders. NF-1 is caused by mutations in the *NF1* gene, which encodes neurofibromin (Nf1), a large protein that functions as a negative regulator of Ras signaling and mediates pleiotropic organismal and cellular functions. Emerging evidence suggest that Nf1 regulates metabolism: NF-1 patients show a reduced body mass index, alterations in metabolites, lower incidences of diabetes, and increased resting energy expenditure. These changes in metabolism may contribute to complications and symptoms associated with NF-1. The extent and mechanisms by which Nf1 affects metabolism and energy expenditure are not well understood. Using the *Drosophila melanogaster NF1* ortholog, we show that Nf1 regulates metabolic homeostasis via neuronal mechanisms. *Drosophila* Nf1 is ~60% identical to the human protein and similarly mediates Ras signaling. Our data show that the loss of Nf1 increases metabolic rate via a Ras-GAP-related domain, increases metabolic rate, feeding rate, starvation susceptibility, and alters lipid stores and turnover kinetics. These metabolic alterations are independent of locomotion and grooming activity and map to a restricted subset of neurons in the ventral nervous system. Acute activation of this neural circuit mimics the loss of Nf1 function by increasing metabolic rate when stimulated. These data indicate that Nf1 may regulate changes in neuronal metabolic control, suggest that cellular and systemic metabolic alterations may be a pathophysiological mechanism of NF-1, and provide a platform for investigating the cellular role of neurofibromin in metabolic homeostasis.

Title: Conditional spinophilin knockout mice as a novel model for detailing striatal MSN-specific mechanism underlying rodent repetitive behavior

Authors: *C. W. MORRIS, D. S. WATKINS, A. J. BAUCUM, II;
Indiana Univ. Sch. of Med., Indianapolis, IN

Abstract: Dysfunction of metabotropic glutamate receptor 5 (mGluR5) activity in striatal medium spiny neurons (MSNs) is associated with numerous psychiatric disorders in humans and repetitive grooming in rodents, an evolutionarily conserved motor repertoire composed of a complex pattern of motor actions. Therefore, understanding striatal-specific signaling mechanisms by which mGluR5 causes repetitive grooming can increase our knowledge of how motor programs become pathological. Spinophilin, the most abundant protein-phosphatase 1 (PP1) targeting protein in the striatal post-synaptic density (PSD), prevents activity-dependent endocytosis of mGluR5 in heterologous cells and primary cortical neuron cultures. However, the extent to which spinophilin functions in striatal MSNs to mediate mGluR5-driven grooming dysfunction is unclear. To address this, we introduce a conditional spinophilin knockout (KO) mouse model to detail MSN-specific mechanisms by which spinophilin regulates mGluR5 function using behavioral and biochemical analyses. Behaviorally, we detail spinophilin's MSN-specific roles in mediating acute and chronic forms of mGluR5-driven repetitive grooming. Biochemically, we determine that spinophilin's protein interaction with mGluR5 in rodent striatum positively correlates with basal and pathological grooming behavior. Lastly, we introduce the use of adeno-associated viruses (AAVs) to deplete or replete spinophilin expression in adult striatal MSNs to draw a causal relationship between spinophilin and mGluR5 function. Overall, our results suggest spinophilin is critical for mGluR5-dependent striatal plasticity underlying grooming pathology in rodents. Moreover, we conclude that spinophilin, and/or MSN-specific spinophilin interacting proteins, may serve as future therapeutic targets to fractionate pathologically grouped actions in psychiatric disorders, such as obsessive-compulsive spectrum disorders (OCSDs) and autism spectrum disorder (ASD).

Title: Selective $mGlu_1$ potentiation enhances cortical inhibition to rescue schizophrenia-like cognitive and social deficits induced by phencyclidine (PCP)

Authors: *D. J. LUESSEN[1,3], I. GALLINGER[2,3], J. T. MAKSYMETZ[4], P. CONN[1,3];
[1]Pharmacol., [2]Vanderbilt Univ., Nashville, TN; [3]Warren Ctr. for Neurosci. Drug Discovery, Nashville, TN; [4]Genentech, San Francisco, CA

Abstract: Accumulating evidence suggests that selective activators of the $mGlu_1$ subtype of metabotropic glutamate (mGlu) receptor may provide a promising novel therapeutic approach for the treatment of schizophrenia. Genetic studies in humans reveal an association of the human gene encoding $mGlu_1$ (*GRM1*) and, specifically, loss of function single nucleotide polymorphisms in *GRM1* with schizophrenia, raising the possibility that $mGlu_1$ signaling is critical to the function of brain circuits underlying symptoms associated with this disorder. Multiple clinical and preclinical studies support the hypothesis that loss of GABAergic inhibitory transmission in the prefrontal cortex (PFC) and other forebrain regions may play a critical role in the pathophysiological changes underlying behavioral deficits in schizophrenia patients, including cognitive and social impairment. This is especially interesting in light of our recent studies demonstrating that activation of $mGlu_1$ increases inhibitory transmission in the PFC by selective excitation of somatostatin-expressing GABA interneurons. Here, we leverage recently developed positive allosteric modulators (PAMs) selective for $mGlu_1$ to examine whether $mGlu_1$ activation might reverse electrophysiological effects and behavioral deficits induced by subchronic treatment with phencyclidine (scPCP), an NMDA receptor antagonist commonly used to model cortical pathophysiology relevant to behavioral and cognitive deficits observed in schizophrenia patients. Using ex vivo whole-cell patch-clamp electrophysiology, we found that scPCP decreased the frequency of spontaneous inhibitory postsynaptic currents onto layer V pyramidal cells of the PFC. This cortical disinhibition was reversed by $mGlu_1$ activation, suggesting that $mGlu_1$ activation is a pertinent mechanism to restore inhibitory signaling in the PFC. Importantly, the $mGlu_1$ PAM VU6004909 effectively reversed scPCP-induced deficits in prepulse inhibition of acoustic startle, novel object recognition and social interaction in a three-chamber assay. In combination with our previous reports that $mGlu_1$ PAMs possess antipsychotic-like efficacy and reverse deficits in inhibitory transmission in the PFC, the current study provides strong evidence that $mGlu_1$ PAMs could serve as a novel approach that could reduce positive symptoms while also treating cognitive and social deficits in schizophrenia patients, providing an exciting improvement over current antipsychotics.

Title: Antipsychotic-like effects of a CB_2 PAM in mice

Authors: *D. J. FOSTER, T. ISHMAM, J. KALBFLEISCH, C. LINDSLEY, P. J. CONN; Warren Ctr. For Neurosci. Drug Discovery, Nashville, TN

Abstract: Currently approved drugs for treating schizophrenia all target D_2 dopamine receptors. While these drugs show efficacy in the clinic, this efficacy often does not translate across different symptom domains, and a subset of patients are treatment-resistant. Novel therapeutic strategies that diverge from targeting the D_2 receptor are desperately needed to provide a more diverse arsenal of therapeutic options. We and others have previously demonstrated that positive allosteric modulators (PAMs) targeting the M_4 muscarinic receptor can induce robust antipsychotic-like effects in numerous rodent models. We previously reported a surprising role for CB_2 cannabinoid receptors in that these receptors are required for M_4 PAM-mediated effects on regulating dopamine signaling and mediating antipsychotic-like efficacy. These results raised the possibility that targeting the CB_2 receptor directly could be a novel strategy for achieving antipsychotic-like efficacy. Here we report that administration of a CB_2 PAM can reverse amphetamine-induced deficits in sensorimotor gating and that these effects are blocked by the CB_2 antagonist AM630. We go on to show that administration of CB_2 PAM reduces the hyperlocomotion induced by either amphetamine or the NMDA receptor antagonist MK-801. These results indicate that directly targeting the CB_2 receptor is sufficient to mediate antipsychotic-like efficacy and provide additional evidence that the CB_2 receptor could be an exciting novel target for treating schizophrenia.

Title: Alterations of hippocampal free intracellular zinc and total serum zinc levels in GPR39 knockout mice subjected to pentylenetetrazole kindling model of epilepsy and treatment with TC-G 1008

Authors: *U. DOBOSZEWSKA[1,2], J. SAWICKI[3], A. RAFALO-ULINSKA[4], K. SOCALA[2], M. PIEROG[2], D. NIEOCZYM[2], B. SZEWCZYK[4], M. MACKOWIAK[4], I. SOWA[3], P. WLAZ[2]; [1]Jagiellonian Univ. Med. Col., Krakow, Poland; [2]Animal Physiol. and Pharmacol., Maria Curie Sklodowska Univ., Lublin, Poland; [3]Analytical Chem., Med. Univ. of Lublin, Lublin, Poland; [4]Maj Inst. of Pharmacol., Polish Acad. of Sci., Krakow, Poland

Abstract: Introduction: The G-protein coupled receptor 39 (GPR39) is activated by zinc ions and was suggested as a novel drug target for treating epileptic seizures. TC-G 1008 is a highly specific agonist of GPR39. We found that TC-G 1008 facilitated the development of pentylenetetrazole (PTZ) kindling. Using GPR39 knockout (KO) mouse line we verified that GPR39 is a target for TC-G 1008 in regard to PTZ-induced epileptogenesis. Our results argue against the hypothesis that activation of GPR39 alleviates seizures. Free zinc is responsible for signaling, both extracellularly (for example at GPR39) and intracellularly. Free intracellular zinc ($[Zn^{2+}]_I$) may be associated with epileptogenesis. We therefore examined this pool of zinc in GPR39 KO in the PTZ model of epilepsy. **Methods:** GRP39 KO mouse model was generated by the Mouse Genome Engineering Facility (crisprmice.eu). The model was generated in mixed genetic background (C57BL6/Tar x CBA/Tar), a deletion of 44 bp causing p.Lys38fs*57X frameshift mutation was introduced. Male GPR39 KO and WT mice were subjected to PTZ-kindling (approval number 72/2019 of the Local Ethical Committee in Lublin). GPR39 KO and WT mice received vehicle or TC-G 1008 (10 mg/kg, i.p.) 30 min before each dose of PTZ (25 mg/kg, i.p.). 24 h after the last dose of PTZ, tissue was harvested. Total serum zinc concentration was measured using Inductively Coupled Plasma Optical Emission Spectrometry. $[Zn^{2+}]_I$ was measured in hippocampal sections using membrane-permeable fluorescent probe Zinpyr-1. The sections were double stained with DAPI. Additional sections were treated with membrane-permeable zinc chelator, TPEN, before staining with Zinpyr-1 and DAPI. The sections were imaged using Leica DM6000 B microscope. Data were analyzed using Image J and Graph Pad Prism v. 5.03, by the Two-way ANOVA and a Bonferroni multiple comparison test. **Results:** Serum zinc concentration was decreased in GPR39 KO mice subjected to PTZ-kindling, compared to WT mice subjected to PTZ kindling. Chronic administration of TC-G 1008 did not affect serum zinc concentration in either GPR39 KO or WT mice subjected to this procedure. $[Zn^{2+}]_I$ did not difer between GPR39 KO and WT in this model. Moreover, chronic treatment with TC-G 1008 increased $[Zn^{2+}]_I$ in the CA3, CA1 and DG regions of the hippocampus of WT mice, but not in GPR39 KO mice. **Conclusion:** Increased $[Zn^{2+}]_I$ in WT mice chronically treated with TC-G 1008 may be associated with increased maximal seizure score in these mice (our previous data), thus suggesting that $[Zn^{2+}]_I$ may participate in aggravation of epileptogenesis following activation of GPR39. Serum zinc is not a marker for TC-G 1008 administration.

Title: Metabotropic receptor 2 deletion effects on behavioral flexibility in mice

Authors: *M. LITTLEPAGE-SAUNDERS[1], M. J. HOCHSTEIN[1], K. AMELGA[1], G. E. HOMANICS[2], K. A. JOHNSON[3];
[1]Uniformed Services Univ. of the Hlth. Sci., Bethesda, MD; [2]Anesthesiol., Univ. Pittsburgh, Pittsburgh, PA; [3]Dept. of Pharmacol., Uniformed Services Univ., Bethesda, MD

Abstract: Substance use disorders (SUD) are chronic brain disorders that affect more than 19 million adults in the United States (SAMHSA, 2018). In order to develop more effective treatments for SUD, it is key to understand the brain mechanisms and behavioral adaptations that contribute to drug misuse including high levels of drug consumption. Preclinical studies have linked loss of metabotropic glutamate receptor 2 (mGlu2) function with increased vulnerability to heavy consumption of drugs including alcohol, heroin, and cocaine. However, the mechanisms by which loss of mGlu2 function enhance drug consumption are not fully understood. Because mGlu2 is a major regulator of glutamatergic transmission in the basal ganglia, and basal ganglia glutamatergic transmission plays important roles in addiction-related behavioral processes such as learning, action control, and behavioral flexibility, it is possible that impaired mGlu2 function leads to changes in these behaviors that might facilitate heavy or inflexible drug use. To test this, we evaluated adult male and female mice with a conditional deletion of mGlu2 from glutamatergic telencephalic neurons including cortical neurons (mGlu2 flox;Emx1-IRES-Cre mice) in operant behavior tasks that assess goal-directed vs. habitual action control. We trained mice to lever press for palatable food pellets on a random ratio reinforcement schedule, then performed devaluation and contingency degradation experiments to assess the effects of mGlu2 deletion on goal-directed and habitual action control. Compared with control mice, male mice lacking mGlu2 showed impaired contingency degradation. However, male mice lacking mGlu2 demonstrated normal devaluation after reinforcer prefeeding. This finding suggests that in male mice, mGlu2 deletion specifically impairs the ability to update behavior in response to a change in action-outcome contingency. Ongoing experiments will evaluate potential sex differences in mGlu2 regulation of habitual behaviors. Future studies will assess how circuit-specific impairments in mGlu2 function, particularly in corticostriatal circuits, contribute to inflexible behaviors including habits.

Title: Constitutive and acute effects of PACAP gene knockout on behavior, physiology, and the transcriptome

Authors: *D. BAKALAR[1], S. C. SWEAT[1], G. L. DROSSEL[1], S. Z. JIANG[1], B. S. SAMAL[1], N. STROTH[1], W. XU[1], L. ZHANG[2], H. ZHANG[1], L. E. EIDEN[1];
[1]Natl. Inst. of Mental Hlth., Bethesda, MD; [2]Physiology/Medicine, Natl. Autonomous Univ. of Mexico, Mexico City, Mexico

Abstract: The role of neuropeptides in brain function has been investigated both via the use of pharmacological agonists and antagonists to provoke or inhibit outputs and using mice deficient in the peptide or its receptor(s) (knockout mice). Functional deficiencies in adult neuropeptide-deficient mice could be due to genetic or non-genetic immediate effects at the time of experimentation, or to effects occurring during development. These differences in turn could reflect developmental or neuromodulatory roles for a given neuropeptide. To dissociate the acute versus constitutive transcriptomic, physiological, and behavioral effects of PACAP deficiency, we examined the *Adcyap1* KO mouse and the corresponding *Adcyap1r1* KO mouse. Using microarray, we demonstrate that in the constitutively (from conception) *Adcyap1* (PACAP) knockout mouse there is a cohort of genes (constitutively PACAP-Regulated Genes, or cPRGs) whose basal expression is altered in PACAP-deficient mice as compared to wildtype controls in multiple brain regions, and additional genes (acutely PACAP-Regulated Genes, or aPRGs) whose basal expression is the same in wild-type and knockout mice, but whose alteration in response to a physiological challenge is impaired in the absence of PACAP expression. The identified genes are confirmed with qRT-PCR. We identify a behavioral phenotype (repetitive jumping) which is dramatic in constitutive *Adcyap1* KO mice, but is not phenocopied by either the PACAP receptor PAC1 KO or by post-natal knockout of *Adcyap1*. This indicates a developmental rather than an acute role of PACAP that may be reflected in the expression of cPRGs, such as *Pttg1* and *Xaf1*, as no changes in these cPRGs are detected by qRT-PCR in post-natal *Adcyap1* knockout tissue or by microarray in PAC1 KO tissue. On the other hand, blunted responses to restraint stress (hypophagia and corticosterone elevation) seen in PACAP-deficient mice are phenocopied in PAC1 deficient mice, suggesting a 'real-time' (neuromodulatory) role for PACAP-PAC1 signaling. Distinguishing constitutive and acute effects of neuropeptide deficiency reveals the changing functions of neuropeptides through the lifespan.

Title: Patient-specific structural connections are predictive of seizure propagation pathways

Authors: *D. N. ANDERSON[1], E. H. SMITH[1], J. E. LEWIS[1], C. M. CHARLEBOIS[2], B. J. PHILIP[1], B. L. JOHNSON[3], A. Y. PETERS[3], B. J. NEWMAN[3], A. M. ARAIN[3], T. S. DAVIS[4], K. S. WILCOX[5], J. D. ROLSTON[1];

Abstract: *Rationale.* Patients experiencing drug-resistant seizures may undergo intracranial monitoring to localize their seizure onset zone; however, high patient-to-patient variation in the seizure onset zone may complicate diagnosis and may explain the mixed success in therapies across epilepsy patients. Evaluation of patient-specific networks may help identify important pathways in each patient's seizure propagation network. The purpose of this study was to correlate seizure propagation to patient-specific structural imaging with the long-term goal of improving targeting of the seizure network through surgical intervention. *Methods.* We analyzed a cohort of patients (n=7) undergoing invasive stereo-electroencephalography (SEEG) at the University of Utah. We acquired pre-operative MRI, diffusion-weighted imaging (DWI), and post-operative CT. We localized and registered the SEEG electrodes in the post-operative CT to the structural MRI and DWI. Using the clinically defined seizure onset zone (SOZ) as the seed location, we calculated probabilistic tractography and quantified the likelihood of axonal connections and average path length from the SOZ to each SEEG contact, as defined by a 1 cm radius around each contact's centroid. Using wavelet spectrogram analysis, we determined the seizure onset time based on when the power in the dominant frequency band surpassed the median power for each channel. We correlated the probability of axonal connections and the average connection length to the time of seizure onset for each SEEG contact using Pearson's correlation. *Results.* A total of 588 SEEG contacts were implanted across 7 patients, who experienced 44 clinical seizures across 10 clinically defined SOZs. We found that connection probability and path length were statistically significant predictors of seizure onset times per channel (*t*-test, $p < 0.05$) for 18/44 seizures and 23/44 seizures, respectively. Importantly, patients with significant structure and function correlations for the majority of their seizures had better clinical outcomes (Engel score I or II) compared to patients with poor structure and function correlations (Kruskal-Wallis, Tukey-Kramer post-hoc, $p < 0.05$). *Conclusions.* These results demonstrate that increased connections and shorter path lengths from the SOZ may predict seizure propagation pathways. Based on outcome scores, a better structure and function correlation may correlate to more precise SOZ localization. Isolating seizure propagation pathways through structural connectivity has the potential to improve targeting of surgical interventions, and thus improve clinical outcomes.

Title: Differences in topography of slow wave activity between focal seizures with versus without impaired consciousness and sleep: a high-density EEG study

Authors: K. SHOGER[1], ***A. SELTE**[1], B. SEVAK[1], R. VERHAGEN[2], E. JUAN[3], G. FINDLAY[1], T. BUGNON[1], A. MENSEN[1], R. MAGANTI[1], G. TONONI[1], A. STRUCK[1], M. BOLY[1];
[1]Univ. of Wisconsin-Madison, Madison, WI; [2]Vrije Univ., Amsterdam, Netherlands; [3]Univ. of Amsterdam, Amsterdam, Netherlands

Abstract: Rationale: Previous intracranial EEG (iEEG) studies suggested that impaired consciousness during focal seizures is linked to increases in slow-wave activity (SWA). Here we used high-density EEG (HDEEG) to investigate topographical differences between focal seizures with preserved vs impaired consciousness (FA vs FIA), wake and non-rapid eye movement (NREM) sleep.
Methods: Ictal HDEEG recordings were performed on focal epilepsy patients at the University of Wisconsin-Madison Epilepsy Monitoring Unit during two seizure types: FIA (n = 19 from 7 patients, mean age 43 ± SD 11, 4 females; focus location in bilateral temporal: n =2; R temporal: n = 4; and R occipital: n = 1) and FA (n = 7 from 3 patients, mean age 38 ± SD 9, 1 female; focus locations in R temporal: n = 2; and R occipital: n = 1). HDEEG data were filtered between 1-25 Hz, with visual rejection of noisy epochs and channels. Seizure data was concatenated with sleep (N2 and N3 stages, matching 18/19 FIA and 5/7 FA) and wake data before Independent Component Analysis. Topographies of EEG power in the SWA (delta, 1-4 Hz), theta (4-8 Hz) and sigma (12-15 Hz) bands and delta/beta (15-25 Hz) ratio were compared between FA, FIA, wake, and N2-N3 sleep (both for absolute and spatially Z-scored values). Random effects analysis used Statistical Parametric Mapping software (threshold set at $p<0.05$ with correction for multiple comparisons at voxel or cluster levels).
Results: Compared to both FA and wake, FIA seizures were characterized by more widespread increases in SWA, theta and spindle power. However, there was a significant topographical difference: FIA seizures displayed more anterior frontal SWA while FA showed significantly more central SWA (Z-scored analysis). Interestingly, spindle power was increased both in frontotemporal and central channels during both FA and FIA compared to wake; but significantly less SWA and spindle power were present during focal seizures than during N2 and N3 sleep.
Conclusion: Altogether, these results suggest sleep-like activities even during seizures with preserved awareness (FA), with a pattern resembling light NREM sleep. FIA seizures showed more widespread sleep-like activities compared to both FA and wake, with a topography

resembling deeper NREM sleep. Interestingly, the involvement of medial prefrontal cortex in SWA and spindle activities were decreased overall during focal seizures compared to sleep, suggesting differences in the involvement of subcortical arousal systems.

Title: Low frequency novel interictal EEG biomarker for localizing seizures and predicting outcomes

Authors: *B. N. LUNDSTROM, B. BRINKMANN, G. A. WORRELL;
Mayo Clin., Rochester, MN

Abstract: Objective and Rationale: Localizing hyperexcitable brain tissue to treat focal seizures remains challenging. We want to identify the seizure onset zone (SOZ) from interictal EEG biomarkers. We hypothesize that a combination of interictal EEG biomarkers, including a novel low frequency marker, can predict mesial temporal involvement and can assist in prognosis related to surgical resections. **Methods and Results:** Interictal direct current wide bandwidth invasive EEG recordings from 83 patients implanted with 5,111 electrodes were retrospectively studied. Logistic regression was used to classify electrodes and patient outcomes. A feed-forward neural network was implemented to understand putative mechanisms. Interictal infraslow frequency EEG activity was decreased for SOZ electrodes while faster frequencies such as delta (2-4 Hz) and beta-gamma (20-50 Hz) activity were increased. These spectral changes comprised a novel interictal EEG biomarker that was significantly increased for mesial temporal SOZ electrodes compared to non-SOZ electrodes. Interictal EEG biomarkers correctly classified mesial temporal SOZ electrodes with a specificity of 87% and positive predictive value of 80%. These interictal EEG biomarkers also correctly classified patient outcomes after surgical resection with a specificity of 91% and positive predictive value of 87%. **Conclusions:** Interictal infraslow EEG activity is decreased near the SOZ while higher frequency power is increased, which may suggest distinct underlying physiologic mechanisms. Narrowband interictal EEG power bands provide information about the SOZ and can help predict mesial temporal involvement in seizure onset. Narrowband interictal EEG power bands may be less useful for

predictions related to non-mesial temporal electrodes. Together with interictal epileptiform discharges and high frequency oscillations, these interictal biomarkers may provide prognostic information prior to surgical resection. Computational modeling suggests changes in neural adaptation may be related to the observed low frequency power changes.

Title: Signatures of loss of consciousness during focal impaired awareness (FIA) and focal aware (FA) seizures.

Authors: *U. GORSKA[1], C. KOZMA[1], C. PAPANTONATOS[2], M. GROBBELAAR[1], E. JUAN[3,1], A. STRUCK[2], H. BLUMENFELD[4], G. TONONI[1], M. BOLY[1,2];
[1]Dept. of Psychiatry, [2]Dept. of Neurol., Univ. of Wisconsin-Madison, Madison, WI; [3]Univ. of Amsterdam, The Netherlands, Netherlands; [4]Yale Sch. of Med., New Haven, CT

Abstract: Loss of consciousness (LOC) occurring during epileptic seizures can cause life-threatening repercussions. While it was shown that cortical sleep-like activities accompany LOC during focal impaired awareness seizures (FIAS), this activity was not yet explicitly studied in focal aware seizures (FAS).
Here we quantified clinical signs of LOC based on videoEEG review and scoring of both behavioral responsiveness and/or amnesia of seizures, and intracranial EEG (iEEG) activity during 102 FIAS and 36 FAS from 35 human patients both in the seizure onset zone (SOZ) and areas remote from SOZ. We first compared iEEG slow-wave activity (SWA, i.e. delta power, 1 -

4 Hz) and beta/delta ratio (a validated marker of cortical arousal), and further high gamma power (80 - 150 Hz) and high gamma phase-locked to lower frequencies (phase-locked high-gamma [PLHG]; a marker of ictal recruitment), and their evolution from the first to the second half of seizures.
While delta power was increased in most brain regions during FIAS, it only increased in the SOZ during the second half of the seizure for FAS. Interestingly, we however observed widespread decreases in beta-delta ratio in all areas outside of the SOZ (frontal, temporal, and parieto-occipital regions) not only in FIAS, but also in FAS ($p<0.01$ for all reported comparisons). During FIAS, PLHG increased in SOZ and temporal lobe for FIAS, while it showed a whole-brain decrease during FAS. Similarly, high gamma power increases against baseline ($p<0.01$) were found in all brain areas during FIAS - while it decreased across the whole brain during FAS. Both PLHG and high gamma features were found to be higher in FIAS compared to FAS. Taken together, these results suggest that sleep-like activities may be present not only during FIAS but also, to a smaller degree, during FAS. Such sleep-like activities may account for milder symptoms such as distractedness or attenuated perception of the environment, that many patients describe during FAS seizures. Future studies will investigate differences in cortical topography associated with LOC and directly compare ictal sleep-like activities to nocturnal sleep iEEG in the same patients.

Title: Seizure detection in human intracortical electroencephalography using joint entropy estimations

Authors: *L. YAMADA[1], T. OSKOTSKY[2,3], P. NUYUJUKIAN[2,3,1,4,5];
[1]Electrical Engin., [2]Bioengineering, [3]Neurosurg., [4]Wu Tsai Neurosciences Inst., [5]Bio-X Inst., Stanford Univ., Stanford, CA

Abstract: Of the 1% of the world population with epilepsy, one-third have refractory epilepsy and often turn to surgical options. The clinical standard of epilepsy treatment relies on manual

review of electroencephalography (EEG) by an epileptologist and could benefit from reliable quantitative EEG (qEEG) approaches to speed up evaluation, minimize inter-reviewer variance, and deliver better care. Here we present the inverse compression ratio (ICR), a method to estimate an unbiased upper bound of joint entropy as a potential qEEG method for seizure detection. Using our data repository of 10 kHz intracortical neuroelectrophysiology across 30 participants (17 adults and 13 children, 249 total seizures), single-electrode ICR achieved an area under Receiver Operating Characteristic (ROC) curve of 0.99. Further, multielectrode ICR performed similarly to, or better than, existing qEEG methods, eliminating the need to process each electrode independently. To the best of our knowledge, this represents the first demonstration of ICR as a multidimensional estimator in biological or clinical applications. By computing an ensemble effect without imposing linearity or data structural assumptions, ICR offers an unbiased, model-free solution to the classically combinatorially intractable problem of high-dimensional joint entropy; its application may extend beyond epilepsy to other domains of biomedical signal processing.

Title: Hippocampal dentation based differentiation of healthy controls and epileptic subjects using high resolution MR images

Authors: *A. KILPATTU RAMANIHARAN, G. SELLADURAI, L. VER HOEF;
Neurol., The Univ. of Alabama at Birmingham, Birmingham, AL

Abstract: Hippocampal dentation (HD) is a complex morphological feature seen on the inferior aspect of human hippocampi that is highly heterogeneous across healthy controls (HC) and is positively correlated with memory performance. Previously we quantified HD intemporal lobe epilepsy (TLE) patients using a subjective method on T1w images and found that HD was significantly less in epileptic than contralateral hippocampi. However, the segmentation of hippocampi using standard T1w images under-estimates the depth of prominent dentes on the 3D surface rendering and subjective HD quantification is prone to inconsistency across raters. In this work, we use a novel objective HD quantification method to measure the degree of HD in HC and TLE groups using T2w High Resolution Multiple Image Co-Registration and Averaging (HR-MICRA) images. T1w and HR-MICRA images were acquired from 26 HC and 23 TLE

patients. The images were resampled to ~0.25mm isotropic. Segmentation of hippocampi was performed using Automatic Segmentation of Hippocampal Subfields software. Surface meshes were generated from the segmentations. The objective method quantifies HD by transforming a strip of a 3D surface mesh into a dimensionally reduced and lowpass filtered 2D plot followed by area-under-the-curve (AUC) calculation. Student's t-Test was used to compare the AUC values obtained using T1w and HR-MICRA images. Asymmetry in HD was calculated by subtracting the AUC values of right hippocampi from the left. One-way ANOVA was performed with Tukey post-hoc test to differentiate the asymmetry in HD between HC, left-TLE and right-TLE groups. HR-MICRA images had higher AUC values compared to T1w images ($p = 0.03$). Among HC, the AUC values were significantly greater in the left compared to their right hippocampi ($p = 0.001$). A one-way ANOVA yielded significant difference in HD among the groups, ($F(2, 46) = [3.33]$, $p = 0.04$). A post hoc Tukey test showed that HD asymmetry differed significantly between left and right TLE groups ($p < 0.05$) but not HCs with a shift in HD away from the epileptic side. Using a novel objective measurement of HD, we conclude the following: HR-MICRA images capture complex surface undulations of HD more effectively than T1w images, indicated by lower T1w AUC values; Normal individuals show a greater degree of HD (i.e.higher AUC values) in the left hippocampus than on the right, likely due to greater degree of functional specialization in the left hemisphere; There is a significant difference in the asymmetry of HD between left and right TLE, indicating a loss of HD on the epileptic side.

Title: Fully-automated MRI-based machine learning classification of patients with and without epileptic seizures following traumatic brain injury

Authors: *I. YILDIZ[1], R. GARNER[1], P. VESPA[2], D. DUNCAN[1];
[1]Keck Sch. of Medicine, USC Stevens Neuroimaging and Informatics Inst., USC, Los Angeles, CA; [2]David Geffen Sch. of Med., Univ. of California Los Angeles, Los Angeles, CA

Abstract: Traumatic brain injury (TBI) is a prevalent cause of severe disorders, including post-traumatic epilepsy (PTE). PTE is diagnosed if seizures occur at least one week post-TBI, though

they can emerge even in years after a TBI (Diaz-Arrastia et al., 2009). The unpredictable progress of PTE motivates early identification of epileptic biomarkers. The Epilepsy Bioinformatics Study for Antiepileptogenic Therapy (EpiBioS4Rx) is a multi-site project aiming to detect epileptogenesis and initiate antiepileptogenic therapy after a TBI (Duncan et al., 2018b). Magnetic resonance imaging (MRI), with particular focus on structural MRI (sMRI), has been commonly employed due to its non-invasive nature (Lutkenhoff et al., 2020). Recent methods using sMRI apply machine learning (ML) to distinguish patients who develop at least one late seizure following a TBI from those who do not experience any (La Rocca et al., 2020). Nevertheless, existing works require several preprocessing steps to extract correlation-based features predicting seizure, further cleaned from noise and non-brain voxels. To the best of our knowledge, we propose the first ML method that directly ingests sMRI without manual feature extraction and cleaning, excluding registration and skull stripping. Our work is inspired by the success of neural networks in image classification, including MRI (Bien et al., 2018). Our neural network architecture involves three branches, each automatically learning features on one of the axial, sagittal, and coronal planes. Features learned from all branches are concatenated and used to classify each MRI scan as seizure-positive or not. Our sMRI dataset contains 79 good quality scans, of which 17 are seizure-positive. We partition the dataset into training, validation, and test sets of 60%, 20%, and 20% portions, respectively, in a stratified manner. We augment seizure-positive training scans to combat class imbalance. The architecture is trained and validated to minimize classification error. We evaluate the architecture along with 95% confidence interval (Wilson, 1927) on the holdout test set. Our method attains 0.87 +/- 0.16 accuracy, 0.93 +/- 0.12 specificity, 0.66 +/- 0.23 sensitivity, and 0.64 +/- 0.23 Area Under the receiver-operating-statistics curve (AUC). In this work, we take the first successful steps of fully-automated MRI-based classification of patients with and without seizures, aiming to ease the time and effort involved in epileptogenesis biomarker identification after a TBI. Early and accurate detection of epileptogenesis via our method could facilitate successful clinical trials of medication development and antiepileptogenic therapy.

Abstract: Responsive neurostimulation (RNS) is a closed-loop, FDA-approved treatment for patients with refractory epilepsy. Most patients receiving RNS therapy experience a decrease in seizure frequency over several years. However, clinical outcomes are variable across patients. It is currently unknown how to tailor stimulation to provide seizure freedom. Our objective was to quantify the brain regions stimulated and the changes in stimulation parameters following RNS implantation. We collected retrospective pre-operative MRI and diffusion-weighted imaging, post-operative CT, stimulation settings, and clinical outcomes for 31 patients receiving mesial temporal RNS at the University of Utah. We registered pre- and post-operative imaging to identify contact locations and estimated patient-specific volumes of tissue activated (VTA) based on the latest stimulation setting. To compare stimulation across the cohort, we warped the VTA to a common atlas and a single hemisphere. Active contacts were distributed across the amygdala and hippocampus (Fig 1A). Patients usually began treatment with low current densities that increased over time (Fig 1B) based on programming guidelines from NeuroPace. The stimulation amplitude changed an average of 2.33 times per year and the average time to change stimulation montage was 2.48 years. The region of greatest VTA overlap across patients was the anterior hippocampus (Fig 1C). For most patients, clinicians increased the current density over time, modulating larger regions of the temporal lobe. However, the patients who became seizure free responded sooner and with consistently lower current density. These initial results suggest that seizure responsiveness in the first year after implantation correlates with long-term symptom relief. Further, ineffective seizure suppression in the first year may be associated with a protracted series of parameter adjustments yielding an eventual decrease in seizures over years. In ongoing work, we plan to identify predictors of seizure freedom and programming strategies that decrease response time.

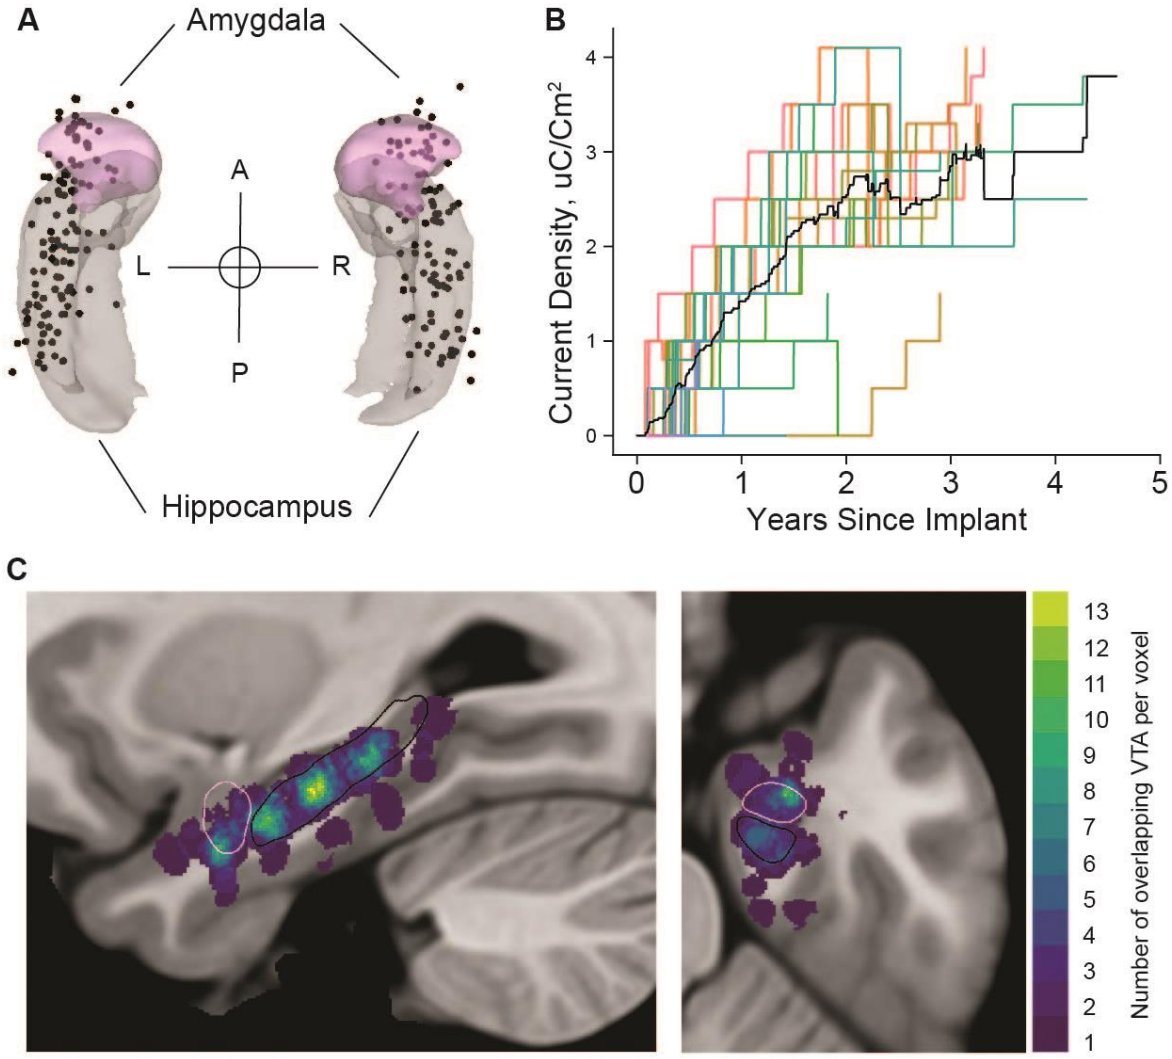

Figure 1. *A. Active Contact Locations Across Patients.* Superior view of the center of each stimulation contact implanted near the mesial temporal lobe across 31 patients (n=220 contacts). *B. Stimulation trends over time.* Each colored trace is the current density of stimulation for a single patient over time. The black trace shows the mean current density over all 25 patients currently treated with stimulation. *C. Neural Activation Patterns.* The left shows a sagittal slice of the overlapping volumes of tissue activated (VTA) within the mesial temporal lobe and the right an axial slice for each subject's most recent stimulation settings (n=23 patients). The VTA of both hemispheres have been mapped to a single hemisphere (n=42 VTA). The majority of leads implanted have 10 mm spacing (40/42). This lead spacing spread activation across the long axis of the hippocampus with maximal overlap throughout the middle of the hippocampus and within the amygdala.

Title: Overexpression of the small heat shock protein 27 reduces aggregation of transactive response DNA binding protein 43

Authors: *M. I. ABEER, M. A. GITCHO;
Delaware State Univ., Dover, DE

Abstract: Transactive response DNA binding protein 43 (TDP-43) is the major pathological protein in both amyotrophic lateral sclerosis (ALS) and frontotemporal dementia (FTD). ALS is a progressive neurodegenerative disease causing muscle weakness and a loss of voluntary muscle movements due to degeneration of motor neurons in the brain and spinal cord leading to death. FTD is the second most frequent cause of dementia accounting for ~10% of all dementia cases. Recently, pathological TDP-43 was discovered as a secondary pathology in up to 50% of Alzheimer's disease (AD) cases. TDP-43 was previously shown to bind to heat shock protein family B (small) member 1 (HSPB1 or HSP27) but no functional evaluation of this interaction has been explored. HSP27 consists of an alpha-crystallin domain that is involved in oligomerization and acts as a molecular chaperone for refolding proteins. In response to stress, HSPs work to help fold native proteins in order to reduce aggregation. Inducing expression of HSP27 has been shown to be protective of acute rejection after cardiac transplant, diabetic sensory neurodegeneration protects in a model of spinocerebellar ataxia type 17, and has been shown to reduce aggregation of amyloid. In the present study, we examine the effect of HSP27 overexpression on TDP-43 aggregation and mitochondrial morphology. A new transgenic mouse model was developed to selectively drive human HSP27 and pathological TDP-43 with a defective nuclear localization signal (ΔNLS) in the hippocampus and neocortex using the Ca^{2+}/calmodulin protein kinase (Camk2a) tetracycline-inducible system. We evaluated the following genotypes: wild-type, Camk2a/NLS, Camk2a/HSP27, and Camk2a/HSP27/TDP43ΔNLS at 4 months of age for immunohistochemistry, biochemistry (solubility fractionation), and Western blot. Preliminary *in vitro* results show that cells overexpressing HSP27 reduce aggregation and protein levels of TDP43. Mice overexpressing HSP27 in a TDP43ΔNLS background show a reduction of aggregated TDP43. We also examined protein changes in full-length TDP43, N-terminal and C-terminal fragments of TDP-43, HSP27, and apoE4. Further experiments will be carried out to investigate the expression of ubiquitin, glial fibrillary acidic protein (GFAP), synapsin-1, and ubiquitin-binding protein p62 to characterize this new model of neuronal protection. Immunohistochemical and bioenergetic experiments will be carried out to evaluate the overall brain and mitochondrial morphology upon

HSP27 overexpression. Our initial preliminary data suggests that modifying HSP27 expression may provide a point of therapeutic intervention for TDP-43 proteinopathies.

Title: Normal levels of KIF5 but reduced KLC1 levels in both Alzheimer disease and Down syndrome

Authors: *X.-Q. CHEN[1], U. DAS[2], W. C. MOBLEY[2];
[1]Depart. of Neurosciences, Univ. of California San Diego Dept. of Neurosciences, LA JOLLA, CA; [2]Dept. of Neurosciences, Univ. of California San Diego Dept. of Neurosciences, LA Jolla, CA

Abstract: Impaired axonal transport may contribute to the pathogenesis of neurodegenerative diseases, including Alzheimer's disease (AD) and Down syndrome (DS). Axonal transport is a complex process in which specific motor proteins move cargoes to and from neuronal cell bodies and their processes. Inconsistent reports point to the changes in AD in the levels of the classical anterograde motor protein kinesin family member 5 (KIF5) and the primary neuronal KIF regulator kinesin light chain 1 (KLC1), raising the possibility that anterograde transport is compromised in AD. We measured the levels of all the three KIF5 family members and KLC1 in the AD and AD-DS frontal cortex and AD temporal cortex and cerebellum in samples taken with a short postmortem interval and in the brains of young and aged adult mice in the Dp (16)1Yey/+ (Dp16) mouse model of DS and J20 mouse model of AD. There were no changes in comparison with controls in all the three KIF5 family members in either the AD or AD-DS samples when normalized to either β-actin or glyceraldehyde-3-phosphate dehydrogenase (GAPDH). Interestingly, however, samples from control brains as well as from AD and AD-DS demonstrated strong positive correlations between the levels of KIF5 family members. In contrast to the findings for KIF5, the levels of KLC1 were downregulated robustly in the frontal cortex of both AD and AD-DS brains; interestingly, this change was not seen in the AD temporal cortex or cerebellum. Studies comparing Dp16 to its euploid control recapitulated human studies in demonstrating no change in KIF5 levels. J20 mice also showed normal KIF5 levels. However,

unlike the AD and AD-DS frontal cortex, KLC1 levels were not reduced in the brains of Dp16 or J20 mice. Together, there are significant reductions in the levels of KLC1 but not KIF5 family members in AD and AD-DS, implying compromised KLC1-mediated axonal transport in these conditions.

Title: Progression of Depression-Associated Behaviors in a Mouse Model of Alzheimer's Disease Following Traumatic Brain Injury

Authors: *J. IANNUCCI, S. BEEVERS, K. PULIDO, V. ARISMENDI, L. VENKATASAMY, M. A. HOOK, F. SOHRABJI, L. A. SHAPIRO;

Abstract: Background: Traumatic brain injury (TBI) is a substantial risk factor for developing Alzheimer’s disease (AD) and related dementia. Depression occurs in 50-66% of TBI patients, and has also been shown to be a major predictor of dementia, AD, and AD-related dementia. Here, we investigated the progression of a depression-associated phenotype in both WT and AD animals following TBI. We hypothesized that exposure to TBI would worsen performance in our depression behavior battery, and that this would progress over time. **Methods:** Male WT and 5xFAD animals were subjected to a depression battery consisting of the sucrose preference test (SPT), social interaction test, and burrowing test. Animals were tested once prior to TBI to establish a baseline. WT and 5xFAD animals then underwent surgery where they received either sham or fluid percussion injury (FPI). All animals were then tested with the same depression battery one week after injury, and then once a month for the next 4 months post-injury to evaluate progression of a depression-associated phenotype. **Results:** We found that 5xFAD mice exhibited significant differences in depression-associated behaviors compared to WT prior to injury, including significantly reduced burrowing in the burrowing test and altered social interaction. Following TBI, we observed a change in performance on depression-associated behaviors in both WT and 5xFAD animals, with particular differences observed in increased social avoidance and decreased burrowing. The effects of TBI were more pronounced in 5xFAD mice compared to WT. **Conclusions:** Our results demonstrate the connection between TBI and increased depression-associated behaviors. These findings additionally highlight the potential

link between TBI and AD by suggesting a common pathological feature, and indicating that TBI may exacerbate pre-existing pathology in AD.

Illinois, Chicago, Chicago, IL

Abstract: The generation of newly born neurons in the hippocampus of rodents during adulthood has been widely accepted. This phenomenon, known as adult hippocampal neurogenesis, has been well characterized in various rodent models and has been shown to play an important role in learning and memory. However, the existence and extent of neurogenesis in the adult human hippocampus has been a topic of debate in recent years. Here, we provide evidence for the persistence of neurogenesis in the hippocampus of healthy Aging humans up to the tenth decade of their life. Moreover, we observed the presence of new neurons in the brains of patients with mild cognitive impairments (MCI) and Alzheimer’s disease (AD). We further show a significant reduction of the number of neuroblasts and new neurons in these patients, which may suggest that neurogenesis is compromised in an early stage of cognitive deterioration. In addition, the number of newly generating neurons correlates with the expression of key presynaptic proteins, previously shown to be associated with cognitive reserve. Interestingly, we observed that higher numbers of neuroblasts significantly correlated with better cognitive z-

scores, suggesting that individuals with greater numbers of neuroblasts are less likely to experience cognitive decline. Lastly, we show that the neural progenitor cells, neuroblasts, and immature neurons were distributed throughout the ventral-dorsal axis of the human hippocampus. Taken together these data suggest that hippocampal neurogenesis persists in the brain throughout life, but is compromised in AD and that enhancing neurogenesis may support cognitive function in AD.

Title: Medial prefrontal cortex pyramidal neurons exhibit hyperexcitability and synaptic dysregulation at early stage of Alzheimer's Disease modeled in 3xTg-AD mice

Authors: *N. CHOUDHURY, L. CHEN, V. T. NGUYEN, L. AL-HARTHI, **X.-T. HU**; Microbial Pathogens and Immunity, Rush Univ. Med. Ctr., Chicago, IL

Abstract: The brain regions that show an early increase of beta-amyloid (Aβ) in Alzheimer's disease (AD) overlap with the default mode network (DMN), which comprises, but is not limited to, the medial prefrontal cortex (mPFC), a key regulator of neurocognition. DMN is active during mental processes that don't require attention, but it is deactivated when undertaking neurocognitive tasks. However, such DMN deactivation is impaired in AD, often preceding the formation of the Aβ plaque and the onset of clinical symptoms. Previous studies suggest that neuronal hyperexcitability is responsible for increased DMN vulnerability to early Aβ deposition. However, possible underlying neuronal dysfunction in critical DMN brain areas, like mPFC, is unknown and has not been studied. Here we used young 3xTg-AD mice (3-5 months of age) to mimic the early stages of AD prior to the formation of cortical Aβ plaques. Patch-clamp electrophysiology was applied to assess functional activity of mPFC pyramidal neurons in brain slices from 3xTg-AD mice and it was compared with wild-type (WT) mice. Firing was evoked by moderate depolarizing currents that mimicked physiological excitatory inputs. Spontaneous

excitatory and inhibitory postsynaptic currents (sEPSCs and sIPSCs, respectively) were assessed at gap-free holding potential of -70 mV and 0 mV, respectively. Ca^{2+} spikes (indicating Ca^{2+} influx through voltage-gated Ca^{2+} channels, VGCCs) were evoked by membrane depolarization with blockade of voltage-gated Na^{+}/K^{+} channels, ionotropic glutamate and $GABA_A$ receptors. We found that firing of mPFC neurons was significantly increased, which was associated with altered membrane properties (i.e., depolarized resting membrane potential, decreased rheobase, increased input resistance, and reduced firing threshold), and significantly increased frequency of sEPSCs in young 3xTg-AD mice. Selective blockade of NMDA or AMPA receptors (R) eliminated the increased sEPSCs. There was no significant change in sIPSCs mediated by $GABA_A$Rs or Ca^{2+} spikes mediated by VGCCs in 3xTg-AD mice. Together, these novel findings demonstrate that the excitability of mPFC pyramidal neurons is aberrantly increased at the early stages of AD preceding Aβ plaque formation accompanied by enhanced glutamate neurotransmission mediated by NMDARs/AMPARs. Whether $GABA_A$R or VGCC activity will be altered at older age needs further investigation. Based upon these findings we propose that this initial mPFC neuronal hyperactivity could trigger consequential dysregulation in the brain that ultimately results in Aβ plaque formation. Further study is required to confirm or disconfirm it.

Title: Ubiquitin Immunoreactivity Identifies TDP-43 Inclusions and Marks Cortical Neurons Destined to Degenerate in a Mouse Model of Frontotemporal Lobar Degeneration

Authors: *A. CHIODINI[1], I. A. AYALA[1], **C. GEULA**[1,2], M.-M. MESULAM[1,3], K. SADLEIR[3], R. VASSAR[3];
[1]Mesulam Ctr. for Cognitive Neurol. and Alzheimer's Dis., [2]Dept. of Cell & Developmental Biol., [3]Ken and Ruth Davee Dept. of Neurol., Feinberg Sch. of Med. at Northwestern Univ., Chicago, IL

Abstract: Accumulation of TDP-43 inclusions is one of the pathological hallmarks of frontotemporal lobar degeneration (FTLD). Mouse models have shown that overexpression of wild-type or mutant human TDP-43 (hTDP-43) can result in the formation of inclusions and neuronal loss. In the human brain, TDP-43 inclusions are strongly ubiquitinated. The purpose of this study was to investigate ubiquitination within cortical neurons in a conditional transgenic mouse model expressing wild-type hTDP-43 under the control of tetracycline operator sequences (tTA). tTA and hTDP-43 transgenic mice were bred on 129SVE and FVB backgrounds respectively. Double transgenic pups were weaned at 21 days of age, at which time expression of TDP-43 was initiated. Brains were examined after 14 days, 8 weeks and 24 weeks of TDP-43 expression. Consistent with our previous findings, small round intraneuronal inclusions containing phosphorylated TDP-43 were observed in many cortical areas after 14 days of TDP-43 expression. After 8 weeks, the number of these inclusions was significantly reduced, and by 24 weeks, no inclusions were observed. This course of events matches the progression of cortical atrophy and decreased density of neurons we observed in these animals at 8 and 24 weeks of expression. After 14 days of expression, ubiquitin immunoreactivity visualized small round cytoplasmic inclusions identical to those observed with phosphorylated TDP-43 staining. In addition, intense ubiquitin immunoreactivity was observed in a subset of cortical neurons. At 8 weeks of TDP-43 expression, ubiquitin stained inclusions and neurons displayed a substantial decrease, and by 24 weeks none could be identified. Thus, as is the case in FTLD, TDP-43 inclusions is transgenic mice are highly ubiquitinated. Furthermore, prominent cytoplasmic ubiquitin immunoreactivity is present in neurons that contain inclusions. Ubiquitin immunoreactivity appears to mark neurons that are destined to degenerate, resulting in disappearance of inclusions within them and cortical atrophy.

Title: Mislocalized expression of the nuclear pore complex proteins NUP153, -93, and -214 in Alzheimer's disease brains

Authors: *M. GORAS, D. BROKAW, E. DELVAUX, P. COLEMAN;
Arizona State Univ., Tempe, AZ

Abstract: Alzheimer's disease (AD) is a progressive, neurocognitive disorder characterized by memory dysfunction. The presence of neuropathological aberrations, namely amyloid plaques, and neurofibrillary tangles, although key characteristics of this disease, have shown to be poor prognostic indicators. As such, clinical trials targeting AD neuropathology have largely been unfruitful, necessitating new research into novel mechanisms of the underlying pathways mediating cognitive decline. Nuclear pore complexes (NPCs) are the main conduits for molecular exchange across the nuclear envelope in eukaryotic cells. The NPC contains approximately 30 distinct nucleoporins (NUPs) which form a selective channel that supports the factor mediated shuttling of cargo through the NPC. Mutations in nucleoporin genes have been linked to various human diseases including neurodegenerative diseases. Tau is the major component of neurofibrillary tangles in (AD), and a recent study has suggested a role in NPC deterioration and thus nuclear cytoplasmic defects. This study however was not an extensive one and only investigated four nucleoproteins from one layer of the NPC structure. In this study, we have targeted all three major components of the NPC structure, by analyzing gene expression of representative NUPs from homogenate brain tissue and neuronal data in AD brains. Three significantly differentially expressed NUPs representing different parts of the NPC structure were selected for validation by immunohistochemistry and Western blotting in postmortem human hippocampal sections. Bioinformatic analysis revealed widespread differential NUP gene expression across multiple brain regions in AD. Our findings revealed mislocalization of cytoplasmic-facing nucleoporin NUP214 in the cytoplasm in AD and nuclear localization of inner ring and nuclear basket nucleoporins NUP93 and NUP153 in hippocampal CA1 neurons. These results and this research, represents one of the first attempts to categorize differential changes throughout the entire structure of the NPC in AD brains. Future studies will explore the hierarchical relationship between neuropathological hallmarks of AD and NPC aberrations to better understand the etiology of impaired nucleocytoplasmic transport in neurodegeneration.

Title: Mir-193a-5p as a regulator of intersectin1-short in Alzheimer's disease

Authors: *S. J. SMITH, J. A. SAUGSTAD;
Anesthesiol. & Perioperative Med., Oregon Hlth. & Sci. Univ., Portland, OR

Abstract: Alzheimer's disease (AD) is the most common form of dementia and is characterized by the accumulation of amyloid-beta (Aβ) plaques and neurofibrillary tangles in the brain. Currently, the pathogenesis underlying AD has not been established, and there are no reliable tools to detect early changes in the AD brain. Our previous studies revealed a set of microRNAs (miRNAs) that are decreased in cerebrospinal fluid (CSF) of AD patients and that serve as biomarkers to distinguish AD from neurologically normal age-matched controls. MiRNAs regulate post-transcriptional gene expression through complementary binding to target mRNAs, which largely results in repressed mRNA translation. However, which mRNAs are targeted and regulated by the AD CSF miRNAs, and how these may affect proteins involved in AD pathophysiology, is not yet known. We developed a bioinformatics pipeline to predict mRNA targets of the AD miRNA biomarkers, and identified Intersectin1-short (*ITSN1-s*) mRNA as one prominent target of the AD CSF miRNA, miR-193a-5p. ITSN1-s protein is associated with multiple pathways relevant to AD, however no studies to date have assessed the role of miRNAs or miR-193a-5p in the regulation of ITSN1-s in AD. Immunoblot analysis of post-mortem human hippocampal tissues show a significant increase in ITSN1-s protein in both male and female AD patients (n = 34) as compared to age-matched controls (n = 23). As ITSN1-s is expressed in multiple brain cell types, we also evaluated how cell type-specific expression of ITSN1-s may change in AD brains, and how altered miR-193a-5p levels may affect these changes. We examined which cell types express miR-193a-5p and ITSN1-s mRNA through miRNAscope and RNAscope paired with immunohistochemistry stains for cell type markers in AD (n = 10) and control (n = 10) post-mortem hippocampal sections. These analyses show that ITSN1-s is increased in specific brain cell types and miR-193a-5p is also changed. Additionally, we have confirmed that miR-193a-5p directly binds and regulates ITSN1-s mRNA translation through luciferase assays using HT-1080 cells (n=8), along with paired RT-qPCR and immunoblots of ITSN1-s mRNA and protein after addition of miR-193a-5p mimic to HEK293t cells (n = 8).

Title: Glutamatergic neurotransmission in the inferior colliculus affects lateralization in hemi-parkinsonian rats

Authors: *R. K. W. SCHWARTING[1,2], **L. MELO-THOMAS**[1,3];
[1]Philipps-University Marburg, Marburg, Germany; [2]Ctr. for Mind, Brain and Behavior (CMBB), Marburg, Germany; [3]Behavioral Neurosciences Inst. (INeC), Ribeirão Preto, Brazil

Abstract: Rats with 6-OHDA unilateral lesion of the medial forebrain bundle (MFB) have been used as a model for Parkinson's disease (PD). After lesion, rats exhibit lateralized deficits in spontaneous behavior, such as ipsiversive (towards the lesioned side) rotations. After systemic challenge with the dopamine D2 receptor agonist apomorphine, they exhibit contraversive (towards the non-lesioned side) rotation. The aim of the present study was to investigate whether such lateralization is attenuated by glutamatergic mechanisms in the inferior colliculus (IC), an auditory structure in the brainstem with output connections to motor pathways and movement coordination systems. For that, adult male Wistar rats received unilateral microinjection of 6-OHDA (lesion group) or saline (sham lesion group) into the MFB and microinjection cannulas were implanted bilaterally in the IC. The week later, rotation was assessed before (pre APO condition) and after apomorphine administration (post APO condition). In the pre APO condition, the spontaneous ipsiversive asymmetry disappeared after microinjection of the glutamatergic antagonist, MK-801, into the IC irrespective of the IC microinjection side (ipsi-, contra- or bilaterally to the lesion). Such an absence of asymmetry was also observed when the glutamatergic agonist NMDA was microinjected into the IC contralateral to lesion. NMDA microinjected into the ipsilateral IC produced a clear contraversive asymmetry, i.e. reverted the lateralization. In the sham lesion group, there was no effect of glutamatergic IC treatment. The contraversive asymmetry observed during the post APO condition was potentiated by MK-801 microinjected into the IC contralateral to lesion side, whereas it was unaffected when this microinjection was performed bilaterally or into the ipsilateral IC. Also, NMDA microinjected into the IC ipsi- or contralateral to lesion side did not affect contraversive asymmetry induced by APO in lesioned rats. These results support our hypothesis that the hypersensitivity of the lesioned striatum can be influenced by a glutamatergic intracollicular substrate. Further, the present data suggest that the side of the IC microinjection with respect to the lesion is particularly important. Understanding of how glutamatergic neural substrates in the IC influences motor control, classically attributed to the basal ganglia circuitry, can be useful in the development of new therapeutics to treat PD and other motor disorders.

Abstract: Parkinson's Disease (PD) is most commonly characterized by severe dopamine (DA) depletion within the substantia nigra (SN) leading to a myriad of motor and non-motor symptoms (NMS) namely, cognitive and affective dysfunction. Currently, the gold-standard treatment for late-stage PD utilizes levodopa (L-DOPA) to replenish DA loss thereby restoring motor function, however, its chronic use induces side effects like L-DOPA-induced dyskinesia (LID) and may even exacerbate some NMS. Indeed, anxiety and Parkinson's disease associated psychosis (PDAP), deleteriously impact the quality of life for PD patients, particularly in later stages of the disease. Unfortunately, they and their mechanisms remain vastly understudied. To examine L-DOPA-induced motor and non-motor side effects, this study employed a bilateral 6-hydroxydopamine (6-OHDA) lesion or sham lesion in male and female Long Evans rats (N=48). Thereafter, subjects were administered daily vehicle as control or L-DOPA (6mg/kg, s.c.) to establish LID while examining treatment-related effects on prepulse inhibition (PPI), a measure of sensorimotor gating, open field, to examine anxiety, abnormal involuntary movements (AIMs) for LID and forepaw adjusting steps (FAS) to examine lesion-induced deficits in movement. Bilaterally lesioned animals treated with L-DOPA showed the development of mild to moderate dyskinesia, with considerable variability while also exhibiting modest but significant L-DOPA-related improvement on the FAS test. Results suggest L-DOPA may also affect sensorimotor gating which was predicted in part by AIMs severity. Finally, lesioned, L-DOPA-treated rats exhibited an increase in anxiety-like behaviors. Altogether, this project established a bilateral 6-OHDA lesion rat model that displayed motor and nonmotor deficits and treatment-related side effects. By extension, this bilateral lesion approach may yield important information on symptom progression and the mechanisms that underlie them.

Title: Evaluation of the goma guar polymer to regulate intestinal motility in Hemiparkinsonism rat model

Authors: *G. REYNOSO GÁLVEZ, E. GARCÍA VALDÉS, S. GALAVIZ HERNÁNDEZ, V. GALLEGOS HERNÁNDEZ, E. A. RODRÍGUEZ PÉREZ, P. VERGARA ARAGÓN; UNAM, MEXICO CITY, Mexico

Abstract: Parkinson's disease (PD) is usually characterized by cardinal motor impairments. However, a range of nonmotor symptoms precede the motor-phase and are major determinants for the quality of life. To date, no disease modifying treatment is available for PD patients. The gold standard therapy of levodopa is based on restoring dopaminergic neurotransmission, thereby alleviating motor symptoms, whereas non-motor symptoms remain undertreated. Constipation is a problem that affects approximately 50-70% of people with PD due to alterations in the autonomic nervous system, which regulates involuntary movements of the digestive tract. In this regard, it has been reported that the administration of soluble and insoluble fiber improves the symptoms of idiopathic chronic constipation. Guar gum (GG) is a polymer of relatively recent use, derived from the seeds of the Cyamopsis tetragonoloba plant from the Leguminosae family. GG has proven to be effective in softening and improving faecal production and increasing the capacity of faeces load and sensation of faecal excretion. Amaranth grain has unique protein content. Due its composition, amaranth protein resembles the one found in milk products and it is very close to the ideal protein characteristics proposed by the Food and Agriculture Organization for human consumption. The purpose of this paper is to propose a product which chemical properties will contribute to increase the peristalsis.

Title: Is the Pink1 knockout rat a translatable animal model to evaluate prodromal cognitive and motor symptoms of Parkinson's Disease?

Authors: *I. SOTO[1], V. A. NEJTEK[2], E. KASANGA[1], M. F. SALVATORE[3];

Abstract: Parkinson's disease (PD) is a neurodegenerative disease characterized by a substantial loss of motor function and cognitive decline, which is a key non-motor symptom (NMS). Early and accurate disease detection is crucial to prevent or slow disease progression. Thus, establishing the signs of a subtle prodromal NMS symptom such as cognitive decline may indicate PD diagnosis and eventual motor decline. In a proof-of-concept study, we used the Pink1 knock-out (KO) rat in comparison to wild-type (WT) rats to longitudinally examine progressive motor decline against NMS using the novel object recognition (NOR) test. We hypothesized that Pink1 KO rats would demonstrate progressive degeneration in both locomotor and cognitive functioning,, with evidence of impaired NOR earlier than motor signs, as evaluated by locomotor activity in the open-field test (OFT). From 3-months (baseline) to 6-months old, Pink1 KO rats traveled 34% less distance and moved 28% slower during the OFT and this decline reached significance at seven months old. One month later KO rats continued to decline, with 54% less distance travelled and lower speed (69%)vs baseline. In the NOR task Pink1 KO rats showed an initial decline in discrimination score from baseline to 4-months old. This difference was not present at 5-months old, as KO rats consistently spent more time with the novel *and* familiar object compared to WT. We found no effect of habituation to the test in the first component with presentation of two identical objects, suggesting that WT recognized the familiarity of the novel object over time, whereas the KO did not. These results suggest KO rats may exhibit perseveration and memory impairment, indicating impaired executive function. In summary, Pink1 KO rats show a steady decline in speed and distance traveled starting at 6 months old, preceded by a potential deficit in learning as early as 4-months old. Our initial results suggest that the Pink1 KO rat may model the NMS of cognitive impairment and the eventual motor impairment seen in PD progression.

Title: Quantitative Analysis of Cerebellar Cortex Activity, Neurodegeneration, and Gait in Aged PINK1 Knockout Rats

Authors: *V. DEANGELO[1], J. D. HILLIARD[2], C.-H. CHIANG[3], J. VIVENTI[3,4,5,6], G. C. MCCONNELL[1];

Abstract: Parkinson's disease (PD) is a progressive neurodegenerative disorder characterized by gait dysfunction in the advanced stages of the disease. PD hallmarks include a decrease in stride length, run speed, and swing time; an increase in stride time, stance time, and base of support; dopaminergic degeneration in the basal ganglia; and cholinergic degeneration in the pedunculopontine nucleus (PPN). Gait disturbances in PD may be associated with cerebellar dysfunction. Loss of dopamine in the substantia nigra pars compacta (SNc) of the basal ganglia may result in abnormal brain activity in the cerebellum. A progressive animal model of PD is needed to understand and identify treatments for gait dysfunction. This study quantified progressive gait dysfunction in PTEN-induced putative kinase 1 knockout (P1KO) rats. Neurodegeneration and cerebellar cortical activity were investigated as potential underlying mechanisms. Male P1KO (n=4) and age-matched wild-type (WT) Long-Evans hooded (n=4) rats were implanted with a 61-channel microelectrocorticography array (μECoG) over the cerebellar cortex (anteroposterior: -10.6mm to -14.0mm and mediolateral ± 2.6mm). Electrodes were arranged in an 8 x 8 grid with 230 μm diameter spaced 420 μm apart. Open Ephys was used to record cerebellar activity at vermis lobules V and VI (a and b) at 8 months. Gait analysis using a runway system was performed at 5 and 8 months of age and included stride length, run speed, swing time, stride time, stance time, and base of support. Immunohistochemical analysis of tyrosine hydroxylase (TH) and choline acetyltransferase (ChAT) was performed at the 8 month timepoint. P1KO rats showed significant gait deficits at 5 months, but not 8 months. At 8 months a 15% loss of TH in the striatum, a 27% loss of TH-positive cells in the substantia nigra pars compacta, and no significant loss of ChAT-positive cells in the PPN was found. Spectral power in lobule VIb delta band (1.5-3Hz) significantly decreased, and increased in the theta/alpha (4-10Hz), beta (10-30Hz), and gamma (30-80Hz) bands in P1KO rats vs. WT rats. No differences were found between genotypes in power in lobules V and VIa for any frequency bands.These results suggest that dopaminergic cell loss but not cholinergic cell loss contributes to gait deficits in the P1KO model. Gait abnormalities improved at the 8 month timepoint compared to the 5 month timepoint suggesting compensatory mechanisms in the P1KO model. Pathological oscillatory activity in cerebellar vermis lobule VIb may contribute to gait dysfunction. Further

analysis is required to determine the suitability of the P1KO rat as a progressive model of gait abnormalities in PD.

Title: Apathy-like Deficits in a Rat Model of Early Parkinson's Disease

Authors: K. M. KING[1], G. K. MCCORMACK[3], J. G. NOEL-TORRES[4], A. F. S. SHACK[5], A. L. PERSONS[2], T. NAPIER[2], *A. E. KIRBY[1];

Abstract: Parkinson's disease (PD) is a progressive neurodegenerative disease characterized by motor and non-motor dysfunction. Apathy, or a loss of motivated behavior, is common (30% prevalence in de novo PD) and disabling. No specific treatments exist for apathy in PD, likely reflecting poor understanding of its pathophysiology. Goal directed behavior comprises cognitive, affective, and motor components, each of which can be affected in PD. To address this knowledge gap, we implemented in a rat model of PD tasks aimed at: detecting loss of motivation, i.e., discriminating between different components of goal related behavior, and characterizing potential confounders, e.g., motor impairment, hyposmia and anxiety. Male Sprague Dawley rats (N=8) underwent testing before and after bilateral 6-OHDA infusions into dorsolateral striatum (7.5 ug/2uL). PD-like postural stability and akinesia was measured using a forelimb stepping task. Motivation was assessed with an operant food task, i.e., a low-effort (fixed ratio 1) task in which one nose poke resulted in a palatable food reward, and the burrowing task, an ethologically relevant motivation-dependent behavior quantified by measuring the weight of displaced bedding. Olfaction and motor aspects of consumption were measured by determining the times to first contact and complete consumption of palatable food, compared between visually apparent and hidden items. An open field task measured time spent in center vs perimeter zones to indicate anxiety. After lesioning, forelimb stepping decreased ($p<.01$) and distance to first step increased ($p<.01$), validating the PD-like nature of the lesion. There was no change in the open field task, therefore the lesion was not anxiogenic. The burrowing task was unaltered for most rats, indicating that the lesion did not induce generalized

apathy. In the operant food task, the number of active nose pokes decreased during the last three minutes of the session ($p<.05$) after lesioning, but the pellets consumed per minute was stable. There was no change in latency to first poke or number of pellets consumed in the initial response period. This reduction did not reflect hyposmia, as there was no change in the speed of identifying a food pellet with olfactory cues alone. Thus, in a model of early PD, this evidence suggests a motivational deficit that selectively affects effort-based decision making during motivated behavior, and does not appear to involve olfactory dysfunction, nor anxiety, nor an impairment in the ability to perform the tasks. Future investigations will use this model to investigate the neural underpinnings of apathy-like deficits in effort-based decision making.

Title: Acute Effects of Pubertal Microbial Dysbiosis and LPS-Induced Neuroinflammation on Biomarkers Related to Parkinson's Disease

Authors: *P. ESPOSITO, K. SMITH, M. GANDELMAN, J. LIANG, N. ISMAIL;
Univ. of Ottawa, Ottawa, ON, Canada

Abstract: Parkinson's disease (PD) is the second most common neurodegenerative disorder worldwide following only Alzheimer's disease. Although many theories have attempted to explain the causes of PD, little information exist regarding its etiology. Stressors experienced during puberty can have a profound impact on brain development and functioning. A single exposure to the bacterial endotoxin lipopolysaccharide (LPS) during puberty, in mice, alters the gut microbiota and causes enduring deficits in learning, spatial memory, and sexual receptivity in adulthood. Microbial dysbiosis can influence immune responsivity and make individuals more susceptible to disorders such as, multiple sclerosis, Alzheimer's, and PD later in life (Kennedy et al., 2016). However, the acute effects of pubertal microbial dysbiosis on brain functioning related to PD remains unknown. Thus, the objective of the current exploratory research project is to examine the acute effects of pubertal microbial dysbiosis and LPS treatment on brain functioning related to PD. A total of 56 (28 male and 28 female) CD1 mice were used in this experiment. At five weeks of age, male and female CD1 mice received either broad-spectrum antibiotics or water through gavage, twice a day, for seven days. One week following antibiotic

treatment (6 weeks old), mice received an intraperitoneal injection of either LPS or saline. Sickness behaviors were monitored 2, 4, 6, and 8 hours following the LPS injection. Eight hours following the injection, mice were euthanized and brains were collected. The caudate putamen (CP) and substania nigra (SN) were extracted using micropunches and processed with a real-time quantitative PCR (RT-qPCR) to examine SNCA (synuclein alpha), IL-10, and IL17A mRNA expression. It is expected that antibiotic and LPS treatment will increase SNCA and IL-17A mRNA expression while decreasing IL-10 mRNA expression. The results from this experiment will provide insight on early indicators of PD while also furthering our knowledge of the relationship between the gut-brain axis and the development of the disorder.

Title: Oral insecticide exposure impairs intestinal function and disrupts nigrostriatal dopamine circuitry in adult mice

Authors: *A. C. WHITE[1], S. BANDLAMUDI[1], B. PFLUGER[2], J. R. CHANG[1], S. D. KELLY[3], W. CAUDLE[3], T. R. SAMPSON[1];

Abstract: Pesticide exposure increases the risk of developing Parkinson's disease (PD). PD is a progressive motor neurodegenerative disease attributable to the death of the dopamine (DA) neurons within the nigrostriatal dopamine pathway, resulting in gradual loss of motor function. Sometimes decades before motor symptom onset, individuals with PD experience a range of gastrointestinal (GI) disturbances. Gut dysbiosis also occurs in PD, and growing evidence suggests a contributory role for the gut microbiome in mediating neurological disease states. The emerging associations between PD, pesticide exposure, and GI abnormalities have led to the idea that some cases of PD may be triggered from within the gut after oral pesticide exposure. Pyrethroids, one of the most used insecticides in the world, target the nervous system and disrupt DA signaling pathways, and ingestion is one of the most common routes of pyrethroid exposure. We therefore predicted that low-dose oral exposure to the pyrethroid deltamethrin induces GI

dysfunction and disrupts nigrostriatal DA circuitry in mice. Young and aged wildtype mice of both sexes were orally gavaged weekly with deltamethrin (3 mg/kg) or a corn oil vehicle control using subchronic and chronic exposure paradigms. GI function was assessed by measuring fecal output and total intestinal transit time, and the composition of the gut microbiome was determined by 16S rRNA sequencing. PD-relevant gene and protein expression were quantified in gut and brain tissues via qPCR and western blot. Our results indicate that oral deltamethrin exposure significantly reduces fecal output, indicative of constipation, and alters gut microbial composition. In the brain, oral deltamethrin exposure significantly changed levels of proteins important for DA synthesis and reuptake compared to controls. In support of our hypothesis, these data suggest that low-dose oral pyrethroid exposure induces PD-relevant symptoms in the gut and brain of adult mice. Future studies will investigate specific roles for the gut microbiome and potential routes of transmission along the gut-brain axis in facilitating pyrethroid-induced neurotoxicity.

Title: Lycium barbarum prevents the development of classical motor impairments in the 6-OHDA animal model of Parkinson's disease

Authors: *M. H. SOERENSEN[1], R. P.-H. WANG[1], J. Y.-S. HO[2], R. C. CHANG[1,3];
[1]Lab. of Neurodegenerative Diseases, Sch. of Biomed. Sciences, LKS Fac. of Med., The Univ. of Hong Kong, Hong Kong, China; [2]Sch. of Nursing, The Hong Kong Polytechnic Univ., Hong Kong, China; [3]State Key Lab. of Brain and Cognitive Sci., The Univ. of Hong Kong, Hong Kong, China

Abstract: Parkinson’s disease (PD) is the second most common neurodegenerative disease worldwide. The disease is mainly characterized by defects in the nigrostriatal pathway, which gives rise to the well-known motor impairments patients experience. As the disease progresses the symptoms worsen, and at late stage PD patients start to experience memory deficits as well. 6-hydroxydopamine (6-OHDA) unilaterally injected into the medial forebrain bundle (MFB) of Sprague-Dawley (SD) rats has been widely used to investigate the development of PD, and this model clearly shows both motor impairments and cognitive deficits. The Chinese medicine

Lycium barbarum (wolfberry) has been shown to modulate microglial functions. Thus, we aimed to investigate whether wolfberry would prevent the development of PD-like symptoms in the classical 6-OHDA animal model. To address this, SD rats were fed either PBS or wolfberry daily prior to stereotaxic injecting sham or 6-OHDA into MFB. Rotarod was used to evaluate gross motor function of the SD rats, where 6-OHDA alone showed a clear reduction in their ability to stay on the rotarod. Interestingly, when SD rats were fed wolfberry prior to their injection of 6-OHDA, no detrimental effects of 6-OHDA on gross motor functions was observed. A similar result was observed when using cylinder test to evaluate fine motor coordination of SD rats. Apomorphine-induced rotation test was used to reflect the induced lesion, and here 6-OHDA injected SD rats showed a complete lesion. Surprisingly, wolfberry did not decrease the net rotations induced by 6-OHDA. Given the promising neuroprotective effects wolfberry had on 6-OHDA-induced motor impairments, we went on to examine spatial learning using Morris Water Maze (MWM). SD rats lesioned with 6-OHDA alone impaired spatial hippocampal functions, whereas feeding wolfberry prior to surgery protected against this. Spontaneous y-maze was used evaluate the spatial working memory. In contrast to the results obtained from MWM, SD rats with a unilateral 6-OHDA lesion showed an increase in spontaneous alternation, thus indicating improved working memory. Together these data clearly reveal a neuroprotective effect of wolfberry on 6-OHDA-induced motor impairment. Future study will focus on investigating how intake of wolfberry elicit the neuroprotective effect in the classical 6-OHDA animal model.

Title: Comparing the effects of anti-Parkinsonian medication and deep brain stimulation on eye and hand movements during visually-guided reaching

Authors: *M. J. MUNOZ[1], R. ARORA[1], Q. DRANE[1], Y. M. RIVERA[1], G. PAL[2,3], L. VERHAGEN METMAN[2], S. SANI[2], J. ROSENOW[1], L. C. GOELZ[1,4], D. M. CORCOS[1], F. J. DAVID[1];
[1]Northwestern Univ., Chicago, IL; [2]Rush Univ. Med. Ctr., Chicago, IL; [3]Rutgers Univ., New Brunswick, NJ; [4]Univ. of Illinois at Chicago, Chicago, IL

Abstract: Anti-Parkinsonian medication and subthalamic nucleus deep brain stimulation (STN DBS), two common treatments of Parkinson's disease (PD), effectively improve upper and lower limb movements. However, there is evidence that these treatments may have differential effects on eye and limb movements. This is interesting because eye and limb movements are both controlled through the basal ganglia loops, but PD and the treatment of PD may affect these effectors differently. Using a task that requires both eye and limb movements, we are able to determine if anti-Parkinsonian medication and STN DBS similarly or differentially affect upper limb and eye movements. Continuing to understand the effects of medication and STN DBS on different aspects of movement may provide insight into how these treatments are differentially affecting neural circuits. We predicted that both medication and STN DBS would improve reaching performance but that medication and STN DBS will have opposing effects on saccade performance. We had participants perform a visually-guided reaching task OFF and ON anti-Parkinsonian medication (n = 36). We also had participants complete the same task OFF and ON bilateral STN DBS while OFF medication (n = 16). Participants were instructed to fixate on a central point until a peripheral target appeared, which was the cue to then look and reach to the target. Saccade and reaching peak velocity and latency were determined using a custom MATLAB script and statistical analyses were performed in SAS using mixed models. We found that anti-Parkinsonian medication significantly decreased saccade peak velocity, while increasing reaching peak velocity. Medication increased saccade latency while having no effect on reaching latency. Additionally, bilateral STN DBS significantly increased saccade and reaching peak velocity, and decreased saccade latency while having no effect on reaching latency. These findings suggest that medication and STN DBS have differential effects on eye movements. Medication reduces saccade velocity and increases latency, while STN DBS increases saccade velocity and reduces latency. Conversely, medication and STN DBS have similar effects on visually-guided reaching, in which medication and STN DBS improve peak velocity while having no effect on latency.

Title: Stimulation maps to guide programming of deep brain stimulation

Authors: *T. NGUYEN[1,2], A. SEGURA AMIL[1,2], S. BARLATEY[1], D. ZHANG[1], M. MONTALBETTI[1], A. NOWACKI[1], C. POLLO[1];

Abstract: Deep brain stimulation is an established treatment for movement disorders such as advanced Parkinson's disease and essential tremor. The new generation of segmented leads provide clinicians with unprecedented possibilities to steer the electrical stimulation towards regions with high probability of therapeutic effect and away from regions with high probability of side effects. This holds considerable promise to improve patient outcome. However, these new leads have rendered stimulation programming more difficult and both clinicians and patients would benefit from programming tools.
Stimulation maps can provide a visual guide and highlight effective regions of stimulation. In future these maps can be used with *computer-assisted programming* to recommend stimulation settings. We have computed two stimulation maps: one map for the subthalamic nucleus to help treat Parkinson's disease, another map for the ventral intermediate nucleus of the thalamus and the posterior subthalamic area to help treat essential tremor.
For the Parkinson's disease map, we have retrospectively analyzed clinical mapping data from 83 implanted patients from two centers. First, the patients' leads were reconstructed with the open-source toolbox Lead-DBS in Matlab. Second, the volumes of tissue activated were estimated also within Lead-DBS. These volumes were weighted by their clinical score and aggregated in template space for the stimulation map. Third, voxel-wise statistical testing identified a region with significantly better than average therapeutic effect. This 'sweet spot' was inside the dorsolateral portion of the subthalamic nucleus. Forth, the overlap ratio of a stimulation volume with the sweet spot was predictive of outcome and could be used in future

for computer-assisted programming pending further studies.
Similarly for the essential tremor map, we have retrospectively analyzed chronic stimulation data from 70 patients from four centers. The sweet spot of this map hinted at the dentato-rubro-thalamic tract as the underlying structure of therapeutic effect. But a more refined analysis will be needed for prediction and computer-assisted programming.

Abstract: Transcranial direct current stimulation (tDCS) applied to the primary motor cortex (M1) improves acute motor skill acquisition in upper limb tasks in Parkinson’s disease (PD). However, the magnitude to which tDCS may be able to improve long-term motor learning in PD has not been established. The purpose was to determine the influence of long-term application of tDCS on motor learning in PD. The study utilized a randomized, double-blind, SHAM-controlled, between-subjects experimental design. Eleven men and women with PD were allocated to either a tDCS group (n = 6) or a SHAM stimulation group (n = 5). Each participant performed 9 practice sessions over a 2-week period that involved extensive practice of a complex isometric precision grip task (PGT). In addition, participants performed the PGT in 4 testing sessions that occurred at baseline and at 1, 14, and 28 days after practice ended (EOP+1, EOP+14, and EOP+28). The practice sessions were performed simultaneously with either anodal tDCS or SHAM stimulation applied over the hand area of the M1 contralateral to the primarily affected hand. tDCS was delivered at a current strength of 1 mA for a duration of 25 minutes using a M1-supraorbital electrode montage. For SHAM stimulation, the current was ramped up

and down over a 60 second period according to established blinding procedures. The PGT task involved accurately matching a target sine wave template on a computer monitor by controlling the sum of the index finger and thumb forces. All practice and test sessions were performed while participants were on medications. The primary outcome measure was the force error in the PGT, which was quantified as the average error in force relative to a target force template in each experimental session. Force error was analyzed with a 2 *Group* (tDCS, SHAM) x 4 *Test* (Baseline, EOP+1, EOP+14, EOT+28) ANOVA. The *Group* x *Test* interaction ($P = 0.771$) and *Group* main effect ($P = 0.449$) were not significant. There was a significant main effect ($P < 0.001$) for *Test* and post hoc analysis indicated that force error was lower for EOT+1, EOT+14, and EOT+28 compared to Baseline (all Ps < 0.002). However, the reduction in force error from Baseline to the 3 testing sessions was 8%, 15%, and 19% greater in the tDCS group, respectively. Although not significant due to the current low sample size and inter-individual variability, the findings indicate that long-term application of tDCS may improve motor learning to slightly greater extent than practice alone in PD.

Title: Patient-specific hyperdirect pathway activation in DBs for Parkinson's disease

Authors: *A. SEGURA AMIL, T. NGUYEN, A. NOWACKI, C. POLLO;
Inselspital Bern, Bern, Switzerland

Abstract: Deep Brain Stimulation (DBS) is an effective treatment in advanced Parkinson’s disease patients to control motor symptoms such as bradykinesia, rigidity, or tremor. DBS leads are implanted in the basal ganglia, which is connected to the cortex through, e.g., the direct, indirect and hyperdirect pathways. Recent studies suggest that DBS stimulation of the hyperdirect pathway plays an important role in the effects of the treatment.
The aim of the study was to determine an activation threshold of the hyperdirect pathway that results in the control of motor symptoms while avoiding the appearance of side effects due to activation of the corticospinal tract.

The study included 20 Parkinson's disease subjects (9 female) undergoing bilateral DBS of the subthalamic nucleus. Diffusion weighted MRI was used to perform whole-brain tractography in MRtrix3. Data pre-procesing included denoising, Gibbs unringing and distortion and eddy-current correction. The filtering algorithm SIFT2 was applied to the whole-brain tractogram to assign weights to the generated streamlines. Lead reconstruction was performed in the Lead-DBS toolbox (v2.2). Patients were clinically assessed six months after surgery, and the stimulation settings that resulted in clinical effect and appearance of side effects were used to estimate volumes of tissue activated. The hyperdirect pathway and corticospinal tract were extracted from the whole-brain tractogram using cortical and subcortical regions of interest and regions of avoidance. Finally, activation thresholds for the hyperdirect pathway and corticospinal tract were obtained using a logistic regression model.
We could establish an activation threshold of 60% of the hyperdirect pathway weights to obtain a full clinical effect, and an activation threshold of 3% of the corticospinal tract weights for the appearance of side effects.
An accurate activation threshold of the hyperdirect pathway will allow in the future a more informed and precise targeting of the hyperdirect pathway in DBS treatments for Parkinson's disease to control motor symptoms and avoid the appearance of side effects.

Title: Naturalistic sleep in Parkinson's disease assessed by actigraphy and direct recordings of the subthalamic nucleus

Authors: *A. J. BAUMGARTNER[1], L. HIRT[2], D. S. KERN[1], J. A. THOMPSON[2];
[1]Univ. of Colorado Sch. of Med. - Dept. of Neurol., Aurora, CO; [2]Univ. of Colorado Sch. of Med. - Dept. of Neurosurg., Aurora, CO

Abstract: Sleep disturbances are highly prevalent in patients with Parkinson's Disease (PD), and are closely linked with cognition, mood disorders, and patient-reported quality of life. Although deep brain stimulation (DBS) is primarily used to treat PD motor symptoms, several studies have shown added benefit for non-motor symptoms including sleep disturbance. Prior studies have used DBS electrodes to record subthalamic nucleus (STN) oscillatory activity in the form of local field potentials (LFPs) during sleep cycles. In PD patients, unique spectral patterns of STN

activity between the awake, rapid eye movement (REM) sleep, and non-REM (NREM) sleep states have been reported and provide a novel insight into sleep architecture and basal ganglia physiology. Interpretation of these findings has been technologically limited, as recordings can only be obtained during a single night inpatient hospitalization with the patient physically attached from the cranium to external equipment. In this study, we utilized a recently FDA-approved implanted pulse generator (IPG), which allows for recording LFPs simultaneously with the delivery of therapeutic stimulation, to assess sleep in the patient's home environment. Sleep was assessed by daily self-report and wrist-based actigraphy. In n = 5 subjects, recorded for 14 days/nights, we observed that LFP power in the beta frequency range (13 - 30 Hz) increases by a factor of two in the overnight hours compared to daytime, which is correlated with patient sleep times. These results provide proof of concept that an electrophysiologic biomarker recorded from the STN, using standard-of-care DBS equipment, can reliably assess sleep in the home setting. The experimental design allows for a substantial increase in the amount of data that can be collected from an individual patient and facilitates studying between-night differences in sleep architecture, which was previously not possible. Improved understanding of sleep architecture may lead to novel approaches to improve sleep disturbances in this population.

Title: Analyses of local field potentials recorded from deep brain stimulation electrodes in thalamus

Authors: *K. KUMARAVELU[1], S. L. SCHMIDT[1], Y. ZHAO[1], B. D. SWAN[1], C. S. OZA[1], J. J. PETERS[1], D. A. TURNER[2], W. M. GRILL[1];
[1]Biomed. Eng, Duke Univ., Durham, NC; [2]Neurosurgery, Duke Univ. Med. Ctr., Durham, NC

Abstract: Deep brain stimulation (DBS) of the ventral intermediate nucleus (VIM) of the thalamus (TH) is a surgical intervention that is effective in managing the symptoms of tremor in essential tremor (ET) and tremor dominant Parkinson's disease (PD). Despite the widespread use of VIM-DBS, its mechanism of action remains unclear. Further, most current DBS systems are open-loop, i.e., stimulate continuously. One of the key challenges to developing closed-loop DBS is identifying neural biomarkers that correlate with tremor. We recorded local field potentials (LFPs) from the TH using a bipolar pair of the four contact DBS lead (Model 3387 and 3389, Medtronic) in ET and PD patients who underwent surgery for either lead implantation or pulse generator replacement (n=33). Contact location was determined by identifying known anatomical landmarks (anterior commissure (AC)-posterior commissure (PC) coordinates) in pre-and post-operative MRI and CT images. We simultaneously recorded tremor using a triaxial accelerometer (Accel) placed on the hand dorsum. The spectral power of the Accel data was used as a measure of tremor. Tremor was analyzed with respect to the spectral power of LFP data and the magnitude square coherence between Accel and LFP time-series data. Finally, we used a computational model of VIM, ventral caudalis (Vc) and ventral oralis anterior/posterior (Voa, Vop) regions of the TH to determine the biophysical basis of the recorded LFP signals. The thalamic model was populated with a proportion of thalamocortical relay cells firing in burst, random, regular modes, and the distribution of burst cells across the TH was based on microelectrode recordings from humans. DBS contact locations were spread across the TH, with most lying within the Vop and VIM regions (mean distance anterior to PC: 6.4 mm, mean distance above AC-PC line: 3.8 mm). There was no correlation between tremor and LFP spectral power in the tremor band (rho = 0.0505, P = 0.36). However, there was a strong correlation between tremor and peak coherence between LFP and Accel data across all axes (rho > 0.6, P < 0.01). The relationship between peak Accel frequency and peak coherence frequency was linear with a slope of ~1 for most patients. However, few patients had peak coherence frequency double that of Accel frequency (n=9/33). Finally, the spectral power of the simulated LFP in the tremor band varied considerably with electrode locations across TH regions. This might explain the differences in LFP spectral power and lack of correlation with tremor seen in the experimental data. Understanding the biophysical basis of LFPs recorded from DBS electrode enables better identification of robust biomarkers for tremor.

Title: Cortical and Subcortical Gait Related Neuronal Modulation During Free Walking in Parkinson's Disease Patients

Authors: *K. H. LOUIE, M. S. YAROSHINSKY, P. A. STARR, D. D. WANG;
Neurolog. Surgery, UCSF, San Francisco, CA

Abstract: Cortical and Subcortical Gait Related Neuronal Modulation During Free Walking Parkinson's Disease Patients[1]Kenneth H. Louie PhD, [1]Maria S. Yaroshinsky BS, [1]Philip A. Starr, MD, PhD, [1]Doris D. Wang MD, PhD
[1]Department of Neurological Surgery, University of California - San Francisco, San Francisco, CA, 94143
Gait impairment in Parkinson's disease (PD) is a particularly debilitating symptom and refractory to conventional treatment. The initial success of adaptive stimulation paradigms in treating akinesia in PD has garnered much interest for its use to improve gait in PD. However, in order to apply adaptive stimulation algorithms for gait, gait-related biomarkers are needed. While few studies have reported gait-dependent changes in cortical or basal ganglia local field potentials (LFPs), simultaneous cortical and subcortical LFPs dynamics in relation to the gait cycle have not been studied. Here, we record sensorimotor cortical and basal ganglia LFPs from PD patients during natural, overground walking using a totally implanted bidirectional neurostimulator, Summit RC+S (Medtronic).Four PD individuals consented to participate in this study. Three individuals underwent implantation of bilateral subdural cortical paddles overlying the primary motor (M1) and sensory (S1) cortices, with deep brain stimulation (DBS) leads targeting either the bilateral subthalamic nuclei (STN) or globus pallidus interna (GPi). One individual was implanted unilaterally on the left side, with the same cortical paddle location and a DBS lead in the GPi. Brain electrodes are connected to the bilateral RC+S devices. LFPs were recorded in the on-medication, off-DBS state. Gait kinematics were measured using inertial external sensors systems, Delsys Trigno and Xsens Awinda, while the patients performed overground walking. LFP time frequency and wavelet analysis was performed across all electrodes and synchronized to each participants gait cycle. We found cyclical, gait-event and gait-cycle modulated LFP power changes in the theta (4-7 Hz), alpha (8-12 Hz), and beta (13-30 Hz) band frequencies. Increases in beta was mainly associated with heel-strike and toe-off gait events in subcortical and M1, while theta and alpha increases were mainly associated with heel-strikes only in S1. Theta, alpha, and beta band gait-related modulations was found in all recorded areas, but not in all participants. These results show that there is high modulation of motor cortical and STN/GPi low frequency power during the natural gait cycle in PD patients. These

dynamic network changes have the potential to be used as control signals for adaptive DBS synchronized to the gait cycle.

Title: Daily Low-dose Niacin Supplementation Modulates Symptoms, Inflammation, andα-synuclein in Parkinson's Disease Subjects

Authors: *M. SEAMON[1,2], S. PUROHIT[1,2], B. GIRI[3], R. CHONG[1,2], J. C. MORGAN[4,2], C. WAKADE[2,1];
[1]Augusta Univ., Augusta, GA; [2]Res. and Develop., CNVAMC, Augusta, GA; [3]Univ. of Maryland, Baltimore, MD; [4]Dept Neurobiol, Med. Coll GA, Augusta, GA

Abstract: Background: Parkinson's disease (PD) patients have lower levels of niacin compared to their age-matched, healthy counterparts. We conducted a clinical trial to restore levels of niacin in PD patients by supplementing 250 mg q.d. in addition to the subjects' typical medications. Forty-seven patients were recruited in the double-blind, placebo-controlled trial for six months (6MO), followed by 6MO of open-label niacin. All participants gave written informed consent prior to any study procedures. The randomization code was not broken until all subjects had completed the two phases of the trial. **Outcomes:** Motor symptoms and plasma levels of serotonin, inflammatory mediators, and α-synuclein were evaluated at each visit. **Methods:** Motor symptom improvement was measured using the motor portion (part III) of the Unified Parkinsons Disease Rating Scale (UPDRS). Serotonin levels were measured by HPLC. Inflammatory mediators and α-synuclein were evaluated by immunoassays. **Results:** During open-label niacin treatment (6MO-12MO), UPDRS III scores significantly decreased by 4.63 points in the niacin group (12MO of niacin), but there was no significant change in the placebo group (6MO of niacin).Serotonin levels significantly decreased by an average of 25.34 mg/dL after 6MO of placebo (p=0.011), while the niacin group had no change.In the first 6MO of the trial, the placebo group showed a significant reduction in the plasma levels of MIP-1β (p=0.012). A decrease in IP-10 (p=0.0009) was observed at 12MO compared to baseline in the

placebo group. The niacin group had significantly increased MIP-1α (p=0.02) levels at 6MO compared to baseline. Plasma levels of total α-synuclein were not different between groups with a 40% average change over six months. The mean level of α-synuclein oligomers decreased in both groups but only reached significance with the first six months of niacin treatment (p=0.048). The average level of p(ser129) α-synuclein was significantly decreased in the niacin group over 12MO (p=0.010) but increased in the placebo group (p=0.012). **Conclusion:** Together, these results suggest a disease-modifying effect of niacin in PD patients, unlike Sinemet and other common PD medications, which only aim to reduce bothersome motor and non-motor symptoms. Future clinical trials will determine whether niacin is truly a disease-modifying vitamin and should be an adjunct therapy alongside typical PD medications.

Title: Strain-level meta-analysis of Parkinson’s disease-associated gut microbiome

Authors: *K. WEST, E. RUTHERFORD, N. NARAYAN, S. IWAI, J. CHOI, S. VISWANATHAM, P. LAL, T. Z. DESANTIS;
Second Genome, Brisbane, CA

Abstract: Parkinson’s disease (PD) is a progressive neurological disorder that can be initiated by pathogenic protein-protein interactions (PPI) in the gastrointestinal (GI) tract in murine models. Namely, α-synuclein, a soluble presynaptic neuronal protein, forms aberrant aggregations in PD patients. Introduction of α-synuclein aggregates into the mouse GI tract induces α-synuclein aggregates in the brain via vagal propagation. In an α-synuclein overexpression model, aggregation was found to be dependent on GI microbial activity and, furthermore, a bacterial chaperonin protein has been shown to prevent aggregation of α-synuclein in vitro. Thus, we sought to identify from the literature the gastrointestinal bacterial strains depleted in PD as the first step in high-throughput discovery of the diverse bacterial proteins with potential therapeutic PPI with α-synuclein to reduce aggregation. Unfortunately, past reports of microbiome associations with PD have two limitations: 1) results are not concordant across cohorts and 2) the data is not resolved to specific strains. We overcame these challenges and identified precise bacterial strains associated with PD in multiple cohorts. By harmonizing publicly available microbiome sequencing data and annotating it against the StrainSelect database, we were able to conduct the first strain-level, and largest meta-analysis of PD to date. Raw 16S rRNA gene

amplicon or metagenomic sequencing data were collected from 8 studies across 5 countries and included a total of 992 PD patients and 663 control subjects. Control cohorts consisted of subjects without neurodegenerative disease. Raw data was processed using standardized pipelines to measure strain abundances. Effect sizes between case and control patients for each strain were calculated and random effects models were used to estimate the concordance of effect sizes across studies. In total, 168 and 441 bacterial strains were significantly (FDR<0.2) depleted or enriched in PD patients compared to controls, respectively. Specific known previously-isolated microbial strains from the StrainSelect database were identified with statistical support (FDR<0.2) as either elevated in PD, such as strains of Lachnospira eligens and Bacteroides_B vulgatus, or diminished in PD patients such as strains of Prevotella and Bacteroides_A plebeius. Our unique approach and findings enable therapeutic development since specific strains, and their expressed proteins and metabolites, can now be screened for interactions with target proteins of the central nervous system.

Title: A Parkinson’s Disease-Chip model system to study early onset sporadic Parkinson’s disease.

Authors: *M. OTERO[1], A. LAPERLE[1], S. SANCES[2], W. SPIVIA[3], S. BELL[1], D. LALL[1], B. ONDATJE[1], J. VAN EYK[3], C. N. SVENDSEN[1];
[1]Cedars-Sinai Regenerative Med. Inst., Los Angeles, CA; [2]Insitro, South San Francisco, CA; [3]Cedars Sinai Med. Ctr., Los Angeles, CA

Abstract: The molecular and cellular changes in midbrain cells that underlie Parkinson’s disease (PD) are complex and likely involve the interplay and eventual failure of multiple cellular systems. While traditional culture models show promise for identifying such underlying mechanisms, these monoculture models likely lack the cellular complexity and developmental maturity to capture complex changes underlying PD. Previous work from our group with microphysiological organ-chips demonstrated improved neuronal maturity when co-cultured with multiple cell types including brain microvasculature endothelial cells and astrocytes and significant changes in synuclein levels in iPSC derived dopamine neurons from patients with

early onset PD. The current objective is to develop robust and reproducible human vascularized models of midbrain tissue as a PD-chip, determine cellular and molecular disease signatures, and test the efficacy and blood-brain barrier transport of candidate therapeutics. iPSC derived dopamine neurons can survive in the top channel of the chips for up to 28 days along with isogenic brain derived endothelial cells on the bottom of the chip creating a functional blood brain barrier. Comprehensive cellular and molecular studies are ongoing, including genomic, transcriptomic, proteomic, metabolomic, and electrophysiological assays. Single nuclei RNA-sequencing demonstrates multiple cell types within these PD-chips. With this model in place we are now testing various approaches to modulating synuclein levels including the use of oligonucleotides that can be administered either to the brain side or the blood side of the 2-chamber PD chip in order to simulate the ability of the compound to cross the blood-brain barrier and assess any reversal of disease signature.

Title: Altered HSPA5 proteostasis may be a key disease phenotype in young onset sporadic Parkinson’s Disease

Authors: *A. LAPERLE[1], M. G. OTERO[1], N. YUCER[1], A. STOTLAND[2], J. VAN EYK[3], C. N. SVENDSEN[1];
[1]Cedars-Sinai Board of Governors Regenerative Med. Inst., Los Angeles, CA; [3]Medicien, [2]Cedars Sinai Med. Ctr., Los Angeles, CA

Abstract: Parkinson’s Disease (PD) is classically characterized by the progressive loss of dopamine (DA) neurons in the substantia nigra as well as the presence of cytoplasmic inclusions known as Lewy bodies and Lewy neurites within specific brain regions. Inclusions contain large amounts of the protein α-synuclein, which is also associated with a rare form of genetic PD caused by triplication of the *SNCA* gene. iPSC-based models derived from patients with monogenic mutations in PD-related genes show accumulation of α-synuclein in DA neurons; however, monogenic mutations account for only a minority of PD cases. Our publication showed that induced pluripotent stem cells (iPSCs) from sporadic young onset PD (YOPD) patients have a distinct disease signature that included an accumulation of α-synuclein, as well as other disease-related phenotypes including reduced lysosomal proteins and function. We found that a class of phorbol ester compounds can correct this disease signature. We are now investigating

the molecular alterations that cause this disease signature and the efficacy of phorbol ester drugs to alter these phenotypes. In order to study complex protein dynamics in these DA neuron cultures, we employed a novel pulse-chase azidohomoalanine (AHA) labeling technique. The AHA label is incorporated into newly synthesized proteins during the pulse and degradation of newly synthesized proteins is monitored through a subsequent chase. Analysis of DA using this AHA paradigm demonstrates significantly altered synthesis and degradation of labeled proteins in YOPD iPSCs compared to control iPSCs. Critically, YOPD neurons exhibited reduced synthesis of the key endoplasmic reticulum (ER) chaperone and ER-associated degradation (ERAD) master regulator BIP/HSPA5 as well as reduced turnover of this important protein. High resolution imaging of these YOPD neurons indicated α-synuclein pathology in perinuclear/ER regions. Interestingly, the phorbol esters identified in our previous work that stimulate proteasomal dependent α-synuclein degradation also led to not only dephosphorylation of BIP/HSPA5 but also increased protein levels. The impaired synthesis of BIP/HSPA5 and perinuclear α-synuclein accumulation in YOPD and the responsiveness of this key regulator to a class of compounds that alter the distinct disease signature identified in these neurons suggest that ERAD is a critical pathway in the molecular pathogenesis of YOPD.

Title: Combining human iPSC and Organ-Chip technologies for modeling the gut-brain axis in patients with Parkinson’s disease

Authors: *M. WORKMAN, J. MOSKOWITZ, D. NABOULSI, A. BREDA, D. P. B. MCGOVERN, S. DEVKOTA, C. N. SVENDSEN;
Cedars-Sinai Med. Ctr., Los Angeles, CA

Abstract: Interaction between the gut microbiome and central nervous system (CNS) has been implicated in a range of neurodegenerative conditions including Parkinson’s disease (PD). However, the connection between the microbiome, gut, and brain has been particularly difficult to study in humans and animal models. Using induced pluripotent stem cell (iPSC) technology, patient-specific cells can be differentiated into cell types relevant to PD. Poly(dimethylsiloxane)-based microphysiological systems, also known as Organ-Chips, have microengineered 3D

chambers that enable the co-culture of different iPSC-derived cell types to model conditions of human disease *in vitro.* Here we present our progress in developing an Intestine-Chip and Brain-Chip from iPSCs that recapitulate several *in vivo* molecular functions and can be fluidically linked to simulate the gut-brain axis. The top channel of the Intestine-chip contains barrier forming intestinal epithelial cells, which when combined with continuous media flow enables co-culture with complex intestinal microbiota. The Brain-Chip contains a top channel seeded with disease-relevant dopaminergic neurons and microglia, and a bottom channel lined by brain microvascular endothelial-like cells. The porous membrane between the two channels allows for the establishment of a blood-brain barrier. We are now using this multi-organ-chip platform to interrogate the contribution of various gut microbes and microbial metabolites in promoting CNS disease pathology. By generating these from patients with heritable forms of PD, we are beginning to explore how systemic organ-organ interactions and microbial crosstalk are involved in promoting neurodegenerative disease.

Abstract: Parkinson’s disease (PD), a multifactorial and complex disorder, affects 1 to 2% of the population over 65 years of age and its incidence is rising. PD is mainly characterized by the selective degeneration of dopaminergic neurons in the nigro-striatal pathway. The low levels of

dopaminergic fibers observed in the striatum of patients at PD onset support the hypothesis that axons die back prior to neuronal perikaryal degeneration. Dysregulation of pathways associated with mitochondrial function is one of the mechanisms that might explain this phenomenon. Interestingly, the protein Miro1 (encoded by RhoT1), an element of the motor/adaptor complex, has a key role in mitochondrial trafficking, morphology and calcium-buffering capacity. Miro1 also interacts with several PD related genes including Parkin, Pink1, LRRK2 and α-synuclein. In fact, an altered function of Miro1 was found in fibroblast of PD patients. Finally, in 2019, mutations in the RhoT1 gene were for the first time reported as causative of PD.Here, we investigate the role of Miro1 in an eventual accumulation of dysfunctional mitochondria in the axons of dopaminergic neurons, which might result in retrograde neurodegeneration. To assess this, we used induced pluripotent stem cells obtained from a PD patient with a RhoT1 mutation (p. R272Q) to generate midbrain organoids (MO). The MO we developed resemble the human midbrain in terms of structural organization and cellular composition. MO are enriched in dopaminergic neurons (~60% at day 30) and recapitulate key pathological features of PD. Miro1 mutant MO were assessed at different time points: 20, 30, 60 and 90 days in culture. qPCR analysis showed no alteration in RhoT1 mRNA levels compared with healthy controls. High content imaging analysis and western blotting showed a significant reduction in the levels of tyrosine hydroxylase (TH, dopaminergic neuron marker) in mutants MO from day 30 onwards as well as a lower TH complexity than healthy MO. Mitochondrial impairments were observed in Miro1 mutant MO using the Agilent Seahorse cell mito stress test at day 35. Interestingly, at the same time point, levels of mitochondrial specific reactive oxygen species, measured by MitoSOX-based flow cytometry, are increased in Miro1 mutant MO. Altogether, our work current findings not only further corroborate the utility of our MO model for PD studies, but it also supports the involvement of Miro1 in mitochondrial impairments. Therefore, we provide data that elucidate the role of Miro1 in PD, which might point for a PD dopaminergic degeneration caused by Miro1-dependent mitochondrial dysfunction.

Title: Role of Brain Derived Neurotrophic Factor in Regulating Mitochondrial Function and Dendrite Homeostasis

Authors: *M. SWAIN[1], R. DAGDA[2], M. DAGDA[2], R. K. DAGDA[2];
[1]Univ. of Nevada, Reno Integrative Neurosci. Grad. Program, Reno, NV; [2]Pharmacol., Univ. of Nevada, Reno, NV

Abstract: **Background:** Mutations in PTEN-induced Kinase 1 (PINK1), a large serine/threonine kinase targeted to mitochondria, leads to juvenile onset forms of Parkinson's Disease (PD). We have recently published that PINK1-deficient primary cortical neurons exhibit a significant loss of dendritic arbors characterized by fragmented mitochondria, increased oxidative stress, and reduction in dendritic mitochondria. In addition, PINK1-deficient neurons show a reduction in the synthesis and extracellular release of mature form of BDNF, a neurotrophin that promotes dendrite outgrowth by binding to the tropomyosin receptor kinase B (TrkB). In addition, previous studies have shown that a cleaved form of BDNF can modulate oxidative phosphorylation in mitochondria suggesting that BDNF can confer neuroprotection in part by maintaining mitochondrial health. **Problem:** the molecular mechanisms by which the mature form of BDNF modulates mitochondrial function remains to be elucidated. We hypothesize that BDNF modulates mitochondrial function, morphology, and content in dendrites to maintain dendritic arbors in healthy neurons and reverse dendrite/mitochondrial pathology in PINK1-deficient neurons. **Methods/Results:** preliminary data obtained from time-lapse confocal microscopy, immunofluorescence-based assays, and Seahorse Bioscience XF24e Analyzer, shows that exogenous administration of human recombinant BDNF (35 ng, 2-24 hrs) can reverse mitochondrial fragmentation by stimulating PKA-mediated phosphorylation of Drp1, restores anterograde mitochondrial trafficking in dendrites, enhances oxidative phosphorylation and transmembrane potential, and restores mitochondrial trafficking in PINK1-deficient primary cortical neurons similar to wild-type. In an *in vitro* chemical model of PD, we observed that exogenous administration of BDNF reversed the loss of dendrites and blocked cell death induced by an acute exposure to the complex I inhibitor rotenone. Mechanistically, time lapse confocal imaging data suggest that BDNF regulates mitochondrial function in part by fostering the trafficking of TrkB-BDNF signaling endosomes to the mitochondrion. In aggregate, our compiled fluorescence and biochemical data suggest that BDNF regulates mitochondrial health, morphology, and function to maintain dendrite health in healthy neurons and confer neuroprotection against ROS-mediated cell death in two *in vitro* genetic and chemical models of PD.

Abstract: Loss of mitochondrial complex I (MCI) in substantia nigra (SN) dopaminergic neurons is a hallmark of Parkinson's disease (PD). Yet, whether this change contributes to PD pathogenesis is unclear. To address this question, intersectional genetics was used to delete the catalytic subunit of MCI in mouse dopaminergic neurons. Surprisingly, MCI disruption induced a Warburg-like shift in metabolism that enabled neuronal survival, but which triggered a progressive loss of the dopaminergic phenotype that was first evident in nigrostriatal axons. This axonal deficit was accompanied by motor learning and fine motor deficits, but not by frank levodopa-responsive Parkinsonism - which only emerged with later loss of SN dopamine (DA) release. Thus, MCI dysfunction alone is sufficient to cause a progressive, human-like Parkinsonism in which loss of nigral DA release makes a critical contribution to motor dysfunction - contrary to the current PD paradigm.

Abstract: Gut microbiome-brain interactions have been implicated in a wide range of neurological conditions, including Parkinson's disease (PD). Motor dysfunction in PD is primarily associated with the selective dysfunction and loss of nigrostriatal dopaminergic neurons, potentially due to their relatively high energetic demand in comparison to other neurons. In this context, defects of mitochondria function may underlie vulnerability to neurodegeneration through effects on cellular respiration and accumulation of oxygen reactive species. Our group has recently demonstrated that the gut microbiome mediates motor deficits, induces neuroinflammation, and exacerbates α-synuclein (α-syn) pathology in mice. Various metabolites produced by gut bacteria have the potential to modulate host metabolism, but a link between the microbiome and brain mitochondrial function remains to be determined. Using α-syn overexpressing (ASO), we investigated the influence of the microbiome on mitochondrial function and motor performance. Herein, we reveal that the gut microbiome induces accumulation of α-syn in mitochondria from the mouse brain, and alters mitochondrial complex I and II respiration. Furthermore, alterations in striatal gene and protein expression suggest a role for the microbiome in regulating mitochondrial protein metabolism and affecting oxidative stress. Analysis of the brain metabolome revealed the microbiome's imprint on region-specific changes in metabolite levels that may be linked to susceptibility to neuronal dysfunction. Motor testing of mice with or without microbiomes uncovered associations with striatal oxidative stress and enhanced progression of symptoms. Collectively, our data demonstrates that the gut microbiome influences mitochondrial functions in the brain of α-syn overexpressing mice, uncovering novel insights into environmental contributions to the pathophysiology of PD.

Title: Dj-1 regulates the neurite outgrowth in the dopaminergic neurons

Authors: *R. CHEN[1], C. MARTINEZ-ACEVES[1], E. GOUCHER[1], J. TANG[1], M. GRAHAM[1], W. CARTER[1], W. MANDEMAKERS[2], V. BONIFATI[2], E. JONAS[1];

Abstract: Familial Parkinson's disease (PD) protein DJ-1 is required for stimulation dependent new protein synthesis in dopaminergic neuron (DN) processes. DJ-1 knockout DN culture and DJ-1 patient fibroblasts provide useful assays for early pathological alterations in PD patients' brains. We studied mitochondrial functional properties (morphology/ bioenergetics) in fibroblasts obtained from different DJ1 PD patients and aged-match healthy individual. We further investigated observed abnormalities in DNs isolated from the DJ-1 KO mouse midbrain.Mutations in DJ-1 and DJ-1 KO increase mitochondrial uncoupling and hamper extension and branching of dopaminergic neuronal processes, in part secondary to loss of the F1 complex of the ATP synthase, exposing the free c-subunit leak channel and causing ATP synthase inefficiency and low ATP levels. We found age dependent loss of ATP synthase β subunit was accelerated in the DJ-1 KO mice and isolated neurons, correlated with the loss of growth of the dopaminergic processes in isolated neurons and in vivo in the aged striatum, where we also observed loss of vesicle docking. In DJ-1 PD patients' fibroblasts, we further observed overall protein synthesis rates are low and synthesis rates of ATP synthase β subunit protein are dramatically decreased in patient cells and in DJ-1 KO brain tissue (baseline and after neuronal stimulation). We found that changes in ATP synthase stoichiometry are also associated with mitochondrial morphological changes including increased electron density in the mutant fibroblasts, a low number of cristae, a reduction in mitochondrial length and an increased number of total mitochondria per measured area.New protein synthesis is crucial for cells to respond to extra- and intracellular cues and to repair or remodel use-dependent damage at neuron growth cones and branch points. Protein synthesis rates were rescued in patient cells by ATP synthase β subunit overexpression, presumably by normalization of mitochondrial inner membrane coupling. DJ-1 is bound to ATP synthase β subunit and to its mRNA. We therefore suspected that the mechanism of decreased growth and branching of DJ-1 deficient DNs is related to a lack of DJ-1 trafficking of mRNAs to distal neurites. Our preliminary data show that indeed mRNA levels for ATP synthase β subunit, although not significantly different in the somata, are strikingly low in DJ-1 KO neuronal processes. These observations suggest a connection between ATP synthase complex stoichiometry, mitochondrial plasticity, protein synthesis rates, dopamine release sites and PD. These findings comprise a promising new strategy to develop therapies for PD patients.

Title: Differential gene expression in whole blood as predictive biomarkers in a rat model of early-stage Parkinson disease

Authors: *S. A. LECHNER[1], J. M. WELSCH[1], S. C. GAMMIE[2], C. A. KELM-NELSON[1]; [1]Dept. of Surgery | Div. of Otolaryngology, Univ. of Wisconsin-Madison, Madison, WI; [2]Dept. of Integrative Biol., Univ. of Wisconsin, Madison, WI

Abstract: The molecular pathology of Parkinson disease (PD) in the early stages is poorly understood; as such, there are no specific predictive or diagnostic tests. To address early-stage biological questions, this work uses a validated animal model of early-onset and progressive PD, a genetic rat with a loss of function in the *Pink1* gene. Male *Pink1*-/- rats demonstrate progressive hindlimb and forelimb motor deficits by mid-to-late adulthood (8 months of age) as well as brainstem and muscle pathology including various markers of inflammation. The greater purpose of this work is to identify dysregulated pathways within the blood of young *Pink1*-/- rats (2-4 months of age) that appear prior to the onset of limb motor signs in this PD model. Specifically, we hypothesized that loss of *Pink1* would alter expression (pathways) in the blood, resulting in characteristic gene signatures that overlap between young (2-4mo) and old (14-16mo) animals and that these may constitute early predictors of limb motor deficits. To accomplish this, limb motor testing (open field test) was performed, immediately followed by the collection of whole blood RNA and serum protein samples from male rats: *Pink1*-/- rats (young, *n*=16; old, *n*=16) and wildtype (WT) controls (young, *n*=16; old, *n*=16). To determine age-related genetic differential expression, the Illumina® Total RNA-Seq TruSeq platform was used to profile differential expression of genes. Statistically significant genes (WT vs. *Pink1*-/- at each timepoint) were identified and ENRICHR gene enrichment was used to identify the top up-regulated biological pathways. Within the young rats, there were few up-regulated genes (*n*=19) but included interleukins and RAS protein activators. Older rats had an extensive list of up-regulated genes (*n*=553) and significant pathways including cytokine-cytokine receptor interaction, TNF signaling pathway, MAPK signaling pathway as well as necroptosis. Next, serum samples were probed for inflammation-related protein markers, CRP and TNF-α, and compared to open field limb motor behavior. The data showed that *Pink1*-/- rats have increased circulating levels of CRP and TNF-α compared to WT controls, that also increased with age.

These findings parallel to what is observed in human subjects with PD diagnoses. Within *Pink1*-/- rats, protein levels were significantly negatively correlated to total movement in the open field test; lesser motor patterns were associated with increased TNF-α levels. In general, these data identified several blood biomarkers and pathways that may predict PD limb movement in a rat model and are key candidates for comparative work to human datasets as well as for drug-repurposing.

Abstract: Abstract: Our recent epigenomic analysis using cell and animal models as well as human substantia nigra tissues revealed that epigenetic dysregulation plays a role in the etiopathogenesis of PD. However, a comprehensive understanding of how epigenetic histone marks modulate neurodegeneration remains elusive. Herein, through RNA-Seq and ChIP-Seq analyses on mitochondria-impaired cell models of PD, we confirmed that environmental chemicals that inhibit mitochondrial function induce histone H3K27ac deposition and alter neuronal enhancer activities and transcriptomic profile in dopaminergic neuronal cell models. Further mechanistic studies revealed a significant imbalance in HAT/HDAC, particularly increased expression of p300, and thereby contributing to hyperacetylation of H3K27. Mitochondrial inhibiting pesticide also inhibited proteasome activity, indicating the altered

bioenergy deficits can impair proteasome machinery in dopaminergic neuronal cells. Interestingly, proteasome inhibitor treatment shares a similar H3K27ac dysregulation of mitochondrial inhibition. Notably, the p300/H3K27ac inhibitor GNE-049 reversed mitochondrial impairment induced H3K27ac epigenetic dysregulation. Collectively, our results provide a comprehensive perspective on H3K27ac dysregulation following mitochondrial dysfunction and proteasome impairment and suggest that epigenetic-based personalized pharmacogenetic strategies can be developed for PD treatment. **Support:** R01ES027245, R01ES026892, R01NS100090 and R01NS088206, Eugene and Linda Lloyd Endowment and Armbrust Endowment.

Abstract: Riboflavin Transporter Deficiency (RTD) is a rare neurodegenerative disease affecting motor neurons (MNs), caused by loss-of-function mutations in *SLC52A3* and *SLC52A2* genes, encoding riboflavin transporters hRFT2 and hRFT3, respectively. Clinical presentation includes respiratory failure, progressive ponto-bulbar paralysis, bilateral sensorineural deafness, and muscle weakness[1]. As riboflavin (RF) is the precursor of the coenzymes flavin mononucleotide (FMN) and flavin adenine dinucleotide (FAD), it's abnormally low levels result in defective functionality of flavoproteins, many of which are involved in cellular bioenergetics, DNA repair, protein folding and cell survival processes[2].Previous work by our group demonstrated altered energy metabolism pathways depending on mitochondria and peroxisomes, accompanied by cytoskeletal derangement[3-5]. These studies took advantage of induced Pluripotent Stem Cells (iPSCs) technology, to produce *in vitro* models recapitulating RTD pathogenesis. In the present work, we studied MNs differentiated from patient-specific iPSCs to perform combined ultrastructural and confocal analyses, aimed at characterizing the cellular pathomechanisms associated to RTD. Our data obtained by TUNEL assay and immunofluorescence using specific apoptotic markers demonstrate increased RTD cell death

during neurogenesis. Consistently, Focused Ion Beam/Electron Microscopy (FIB/SEM) and conventional SEM showed profound alterations in patients' cells including: (i) abnormally short neurites with few branches, suggesting inability to properly differentiate into MNs; (ii) great abundancy of extracellular vesicles budding from the membrane, possibly indicating abnormal cell-cell communication and/or apoptotic blebs; (iii) conspicuous swellings along neurites, interpreted as sign of neurodegeneration; (iv) abnormal mitochondria characterized by few, deranged *cristae*, confirming persistence of mitochondrial damage after differentiation.Overall, our work contributes to the knowledge on the multiple cellular alterations associated to RTD neuronal phenotype, supporting a central role played by mitochondrial apoptosis in its pathogenesis, thus indicating potential targets for future therapies.[1]Green, P et al. Am. J. Hum. Genet. 2010; 86: 485.[2]Balasubramaniam, S et al. J. Inherit. Metab. Dis 2019; 42(4): 608.[3]Colasuonno, F et al. Oxid. Med. Cell. Longev 2020; 6821247 [4]Colasuonno, F et al. Title: Study of neuronal activity in co-culture of iPSC-derived astrocytes and motoneurons obtained by patients affected by riboflavin transporter deficiency.

Authors: *V. MAGLIOCCA[1,2], C. MARIOLI[1,2], E. BERTINI[2], M. TARTAGLIA[2], C. COMPAGNUCCI[2], T. PERSICHINI[1];
[1]Univ. of Roma Tre, Rome, Italy; [2]IRCCS Children's Res. Hosp. Bambino Gesù, Rome, Italy

Abstract: Riboflavin Transporter Deficiency (RTD) is a rare autosomal recessive disease that arises in childhood and is caused by mutations in the genes *SLC52A3* or *SLC52A2*, encoding for the human Riboflavin Transporters hRFT2 and hRFT3, respectively. The specific role of these transporters is to absorb the vitamin riboflavin (RF) [1]. RF is the precursor of flavin adenine dinucleotide (FAD) and flavin mononucleotide (FMN), two biological cofactors which are involved in different metabolic oxidation-reduction reactions, especially in mitochondrial processes. For these reasons, RTD patients exhibit oxidative stress that impairs neuronal differentiation. Fortunately, RF administration in combination with other antioxidant treatments ameliorates the symptoms of the pathology in different patients [2]. To better understand the mechanisms involved in RTD pathogenesis, we used patient-derived induced pluripotent stem

cells (iPSCs). We have reprogrammed patients' fibroblasts into iPSCs and induced them to differentiate into motoneurons (MNs) and astrocytes (ASTROs). It is known that RTD MNs are shorter than healthy ones, have less branches and have impaired neuronal activity [3]. Since it has been highlighted the role of the antioxidant response of astrocytes in the protection against neurotoxicity, as well as in the improvement of morphology and neuronal activity, we aimed our study to understand if RTD MNs phenotype could ameliorate when RTD MNs are grown in co-culture with ASTROs. In this study, we obtained control (Ctrl) and patient ASTROs, which are positive for GFAP and EAAT2 and used them to perform RTD ASTROs-RTD MNs and Ctrl ASTROs-RTD MNs co-cultures, with and without direct contact. Neuronal function was evaluated in co-cultures by determining intracellular calcium (Ca^{+2}) levels following Ionomycin stimulation. The data obtained show that when in co-cultures, RTD MNs present intracellular Ca^{+2} levels similar to those of Ctrl MNs. We performed the co-culture experiments also by purifying ASTROs exosomes and adding them to the MNs cultures, to understand if the direct contact is required to ameliorate the RTD MNs phenotype or factors released by ASTROs can also influence the RTD phenotype. Our results support the hypothesis that ASTROs can improve neuronal activity and plasticity in RTD MNs compared to RTD MNs alone both by direct contact and by secreting important factors supporting neuronal health. We conclude that the ASTROs have a relevant role in the pathophysiology of RTD and we need more studies for a better understanding. 1. Callaghan B. J Inherit Metab Dis. 2019 Jul. 2.Marioli C. Title: Investigating the collapse of proteostasis in p97-related ALS using IPSC-derived motor neurons

Authors: *J. KLICKSTEIN, R. KHANNA, R. GANJI, M. RAMAN;
Tufts Univ. Sch. of Med., Boston, MA

Abstract: Introduction: Amyotrophic lateral sclerosis (ALS) is a fatal neurodegenerative disease characterized by upper and lower motor neuron degeneration. In the majority of ALS cases, degeneration is preceded by hallmark molecular events including TAR DNA-binding protein 43

(TDP-43) mislocalization and endoplasmic reticulum (ER) stress.
In the last decade, p97/VCP/CDC48 (p97) has been discovered to cause ALS as well as other protein aggregation diseases. p97 is an ATPase that binds and extracts ubiquitinated substrates from membranes or multi-protein complexes. Through this action, p97 participates in a myriad of cellular processes including ER-associated degradation, autophagy, and mitophagy, among others. p97 is targeted to its functions by protein adaptor interaction with the N-terminal domain. Studies have shown that p97 mutations alter adaptor interaction suggesting that mistargeting of p97 may lead to disease; however, these studies have not been performed in motor neurons. As a hub for cellular processes, it remains unknown which functions of mutant p97 are impaired. Uncovering the specific pathways altered in p97-related ALS will provide insight into salient processes that engender ALS pathogenesis.
Methods: To study the role of p97 in ALS, we have developed a novel isogenic model p97-related ALS using CRISPR gene editing to introduce the most common mutations: R155H and R159H. All studies have been performed with two clones to control for potential off-target effects.
Results: Using a novel differentiation paradigm, we can produce spontaneously active, mature motor neurons within 3 weeks. This protocol produces TUJ1 and ChAT positive cells by day 20 that exhibit spontaneous action potentials. p97 mutations do not alter the efficiency of differentiation; however, these mutations reduce the proportion of spontaneously active neurons. Additionally, mutant neurons display induction of ATF4, increased LC3b, and TDP-43 mislocalization. Using immunoprecipitation, we found altered adaptor association to p97 which is dependent on cell type (IPSC vs motor neuron) with some adaptors increasing association and others decreasing. We have performed quantitative proteomics on motor neurons and IPSCs (9-plex with 3 replicates per genotype each cell type). Network analysis revealed significantly altered cellular processes and functions that were unique to each cell type.
Conclusions: Our novel isogenic model of mutant p97 ALS recapitulates the phenotypes seen in ALS patients. Altered adaptor association and cellular processes due to p97 mutations are cell-type specific highlighting the importance of using a physiological model.

Title: An allelic series of SCYL1 mutations identifies molecular interactions essential for function

Authors: *A. CASSIDY[1], E. KULIYEV[2], D. B. THOMAS[1], S. GINGRAS[3], H. CHEN[1], S. PELLETIER[1];
[1]Med. and Mol. Genet., Indiana University-Purdue Univ. Indianapolis, Indianapolis, IN; [2]St. Jude Children's Res. Hosp., Memphis, TN; [3]Dept. of Immunol., Univ. of Pittsburgh, Pittsburgh, PA

Abstract: SCYL1 is a multidomain protein thought to regulate several essential cellular functions including membrane protein trafficking, nucleocytoplasmic shuttling of tRNAs and transcription via interactions with several molecular complexes. In both humans and mice, inactivating *SCYL1* mutations cause a multisystem disorder characterized by recurrent episodes of liver failure, growth retardation and progressive motor dysfunction resulting from the loss of spinal motor neurons. However, the molecular mechanisms underlying SCYL1 deficiency syndrome has remained elusive. Here we report the characterization of an allelic series of genetically engineered mice harboring *Scyl1* separation-of-function mutations disrupting individual or several molecular interactions. Our results demonstrate an essential role for the proper localization of SCYL1 to the ER-Golgi Intermediate Compartment and its homo-oligomerization for function in vivo and suggest that defective mRNA trafficking and/or metabolism represents a major disease mechanism in SCYL1 deficiency syndrome. Mice expressing mutant forms of SCYL1 that disrupt SCYL1-tNRA interaction, oligomerization, or subcellular localization exhibited growth retardation and developed motor dysfunction. On the other hand, although defective protein trafficking and faulty transcription were viewed as major disease mechanisms in SCYL1 deficiency syndrome, our findings do not support this notion. Mice harboring mutations in *Scyl1* that prevented interaction between SCYL1 and the membrane coat protein complexes COPI, COPII or several other factors involved in protein trafficking, and mice expressing a form of SCYL1 lacking transcriptional activity showed no overt abnormalities. Together, our findings identify key molecular interactions essential for SCYL1 function in vivo and provide the foundation for further studies exploring the potential role of SCYL1 in regulating tRNA trafficking and/or metabolism.

Abstract: The plurality of cases of Hereditary Spastic Paraplegia (HSP), a disease in which dieback degeneration of the corticospinal tracts leads to gait deficiencies, results from mutations of *SPAST,* the gene that encodes spastin, a microtubule-severing protein. The hSPAST-C448Y mouse, which expresses both wild-type mouse and mutant human spastins, displays these disease hallmarks. However, the corticospinal tracts do not show abnormal axonal swellings that are typical in postmortem tissues of patients. Here, the hSPAST-C448Y mouse was crossbred with a Spast-knockout mouse that displays axonal swellings but no gait deficiency or corticospinal dieback. The crossbred animals displayed axonal swellings, and also earlier onset and more extreme gait deficiencies and corticospinal dieback than the hSPAST-C448Y mouse. The spinal cords of the crossbred mice showed changes in microtubule modifications and HDAC6 activity similar to the hSPAST-C448Y mice, not the knockout mouse. Collectively these results indicate that gain-of-function of toxicity is the etiology of *SPAST*-based HSP (also called HSP-*SPG4)*, but that haploinsufficiency contributes to the disease by making the corticospinal tracts more vulnerable to the toxicity of the mutant protein. An advanced type of Diffusion Magnetic Resonance Imaging identified the dieback degeneration in isolated spinal cords, portending a biomarker for assessing the status of patients.

Title: Chronic recording of spontaneous and evoked muscle activity from the VML wound model of Canine Biceps Femoris during recovery from injury

Authors: *M. JAVIDI[1], S. A. JOHNSON[2,3], R. CRUM[3], S. F. BADYLAK[2,3,4], D. J. WEBER[1]; [1]Dept. of Mechanical Engin., Carnegie Mellon Univ., Pittsburgh, PA; [2]McGowan Inst. for Regenerative Med., [3]Sch. of Med., [4]Dept. of Bioengineering, Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Abstract Volumetric muscle loss (VML) is common for soldiers wounded in overseas conflicts. Recovery of muscle function from injury requires regeneration of muscle and nerve tissues and reinnervation of the new muscle tissue. Chronic nerve stimulation at sub levels of motor threshold has been suggested as an effective approach to accelerate muscle and nerve regeneration after injury. In the current study, a volumetric muscle model (VML) (approximately 70% of muscle was removed) was generated in Biceps Femoris of a Canine and chronic nerve stimulation started on post-op day 1 to accelerate muscle regeneration and innervation. An implanted pulse generator was programmed to deliver nerve stimulation twice daily for 10 days post-op by stimulating of the sciatic nerve at intensity of 80% motor threshold (~400 μA catholdal pulses at 200 μs pulse-width). Stimulation pulses were delivered at 10 Hz and applied for 1(h) per day in two 30 (min) sessions, 12 hours apart. To evaluate muscle function over time during recovery from injury, EMG was recorded at 4 different locations in and around the wound bed. One electrode was placed in an uninjured portion of the muscle and three other electrodes were in proximal, distal, and lateral edges of the wound bed. Compound muscle action potentials (CMAPs) were evoked by electrical stimulation at the sciatic nerve. Recruitment curves for each of the 4 EMG electrodes were measured on post-op days 3, 7, 10, and 14. EMG also was collected during normal walking of the animal, which was done twice per day for 5 (min) and at multiple timepoints throughout 24-hour a day. Results of recruitment curves indicated gradual improvement in muscle activation in the bed and edges of wound, with the strongest activation occurring at post-op day 14, which was the last day tested. The data collected during the walking experiments shows increases in both activity level and EMG power over the 14-day recovery period. Similar improvements in EMG and activity level were observed in the daily samples taken at random intervals throughout the day. Specifically, on post-op days 2, 5 and 8 animal indicated significant signs of recovery when the average of normalized mean RMS of four leads increased by 66, 96 and 119 percent for walking tests and 118, 112 and 227 percent for random EMG measurement tests in compared to first post-op day. These preliminary results demonstrate long term nerve stimulation and recording using fully implanted devices that permit chronic control and sensing of neuromuscular activity. This animal model and implant system will be used to develop a closed-loop bioelectronic interface for monitoring and enhancing wound healing after volumetric muscle loss.

Title: Cortical and spinal cord ALS-and FTD-like neurodegenerative effects following a traumatic brain injury in a non-genetic animal model

Authors: *G. BJORKLUND[1], J. WONG[1], R. BOWSER[2], S. STABENFELDT[1];
[1]Arizona State Univ., Chandler, AZ; [2]Barrow Neurolog. Inst., Phoenix, AZ

Abstract: Traumatic brain injuries (TBIs) are a significant health problem worldwide with over 27 million cases reported annually. Primary injuries from a TBI cause immediate tissue and cellular damage followed by secondary injury sequalae that can provide opportunities for therapeutic intervention to improve outcomes in the minutes and years following an injury. These secondary injury processes, described as delayed and continual tissue damage caused by consecutive pathological processes, may contribute to chronic conditions that result in permanent functional and cognitive disabilities and a highly increased risk for the development of neurodegenerative disorders (NDDs). TBIs and repetitive brain injuries are increasingly associated with NDDs such as Alzheimer's disease (AD), frontotemporal dementia (FTD), and amyotrophic lateral sclerosis (ALS). In addition to TBIs, a variety of additional factors such as intense physical activity, chemical exposure, heavy metals exposure, and smoking are some examples of recognized causes for an increased risk of developing NDDs. In this study, we examined the neurodegenerative effects of a TBI on neurons in the forebrain and cervical spinal cord distal to the site of initial injury. Adult male C57BL/6J mice with no genetic predisposition to neurodegenerative disease were subjected to a unilateral controlled cortical impact on the primary motor cortex. Post-injury analysis includes short-term timepoints at 7, 14, and 28 days post injury (DPI) and long-term timepoints at 120 and 180 DPI. Tissue samples from the forebrain and cervical spinal cord were analyzed for pathologic biomarkers of FTD and ALS via immunohistochemistry. Specifically, neurons were examined for TAR DNA Binding Protein 43 (TDP-43) translocation from the nucleus and cytosolic accumulation with the presence of ubiquitination and hyperphosphorylation. These cellular pathologies of TDP-43 are strongly associated with AD, ALS, and FTD. Current results at the short-term timepoint indicate a significant mislocalization of nuclear TDP-43 from NEUN positive neurons in the forebrain and cervical spinal cord accompanied by an accumulation of cytosolic and ubiquitinated TDP-43. Analysis at the long-term time points indicate no difference between control mice and TBI mice in TDP-43 nuclear mislocalization. However, preliminary results suggest a decrease in total NEUN positive cells of the spinal cord in the TBI mice. As TDP-43 nuclear mislocation and

cytosolic aggregation is a hallmark of ALS and present in the majority of FTD cases, these results support a possible link between TBI and the development of FTD- and ALS-like neurodegenerative diseases.

Title: Loss of WWOX and mutations in the gene cause mitochondrial dysfunction in amyotrophic lateral sclerosis

Authors: *G. SADRI-VAKILI[1], T. PETROZZIELLO[2], S. KIM[2], S. FARHAN[2], J. ROY[2], K. VAKILI[3], J. BERRY[2], J. WALKER[2], R. MOURO-PINTO[2];

Abstract: To date, there are no effective treatments for amyotrophic lateral sclerosis (ALS), a neurodegenerative disease affecting motor neurons that leads to death within 2-5 years from diagnosis. This is due to our limited knowledge of the disease-causing mechanisms in ALS, highlighting the importance of understanding and identifying the molecular events underlying motor neuron degeneration. One candidate that may be involved in ALS pathogenesis is the WW domain-containing oxidoreductase (WWOX), a protein that is involved in neurodegenerative processes. Specifically, WWOX is decreased in post-mortem brains from Alzheimer's disease patients and mutations in the *WWOX* gene cause seizures, epilepsy and cerebellar ataxia. WWOX is involved in regulating the activity of the mitochondrial electron transport chain (mtETC) and in reducing oxidative stress through its short-chain dehydrogenase/reductase (SDR) domain. Interestingly, mitochondrial dysfunction and oxidative stress are key and early pathogenetic event in ALS. Therefore, we hypothesized that alterations in WWOX may contribute to mitochondrial dysfunction in ALS thus worsening disease progression. Our findings reveal a significant decrease in WWOX levels in ALS post-mortem motor cortex (mCTX) that correlates with faster disease progression, suggesting that loss of WWOX may play a pathogenic role in ALS. Furthermore, we have demonstrated that knocking down WWOX using siRNA decreases reactive oxygen species (ROS) in human neuroblastoma SH-SY5Y cells further supporting a link between loss of WWOX and increases in oxidative stress in ALS. We also identified several deleterious variants in *WWOX* gene in ALS cases by analyzing Project

MinE and ALSKP data sets. One of these ALS specific mutations, a stop codon mutation located at amino acid 261 in the mitochondrial binding region of WWOX SDR domain, decreases ATP levels, increases ROS levels and causes cell death in SH-SY5Y cells. These results were consistent with our findings revealing a decrease in two mtETC proteins, the mitochondrial membrane ATP synthase of complex V (ATP5A) and the cytochrome c oxidase of complex IV (COX II) in ALS mCTX. Together, our results suggest that loss of WWOX as well as mutations in the gene may cause and exacerbate mitochondrial dysfunction in ALS.

Title: Comprehensive analysis of molecular pathways involved in health of corticospinal motor neurons deficient of Alsin function

Authors: I. AGUILAR-WICKINGS[1], M. GAUTAM[1], Y. A. GOO[2], *P. OZDINLER[1]; [2]Proteomics Core, [1]Northwestern Univ., Chicago, IL

Abstract: Corticospinal motor neurons (CSMN) reside in cerebral cortex and they play an important role in initiation and modulation of voluntary movement by collecting and integrating signals from different regions of the cerebral cortex and relay that information to their spinal cord targets. Degeneration of CSMN manifests in the development of hereditary spastic paraplegia (HSP), primary lateral sclerosis (PLS) and amyotrophic lateral sclerosis (ALS). Several gene mutations are implicated with the onset of ALS, leading to motor neuron vulnerability, progressive degeneration, and dysfunction of motor neuron circuitry. Alsin is a member of a small GTPase gene family that are involved in neurite outgrowth, endosomal trafficking, and cytoskeleton maintenance. Mutations in the Alsin gene have been shown to manifest into juvenile ALS onset. The present study investigates molecular pathways implicated in the health of CSMN that are devoid of Alsin function. We previously generated and characterized UCHL1-eGFP mice in which CSMN are genetically labelled with stable eGFP expression allowing their visualization andprecise investigation. The UCHL1-eGFP mice were crossbred with AlsinKO mice to generate AlsinKO-UeGFP mice, allowing purification of AlsinKO CSMN via FACS-mediated approaches. We performed transcriptomics (RNA-Seq) and

proteomics analysis on pure populations of CSMN isolated from AlsinKO-UeGFP and AlsinWT-UeGFP mice. Our ongoing study reveals key molecular and cellular pathways that are differentially regulated due to the absence of Alsin function. The genes and proteins involved in fatty acid metabolism, immune response, and mitochondrial function were found to be differentially regulated. Our study reveals the molecular and cellular mechanisms that are involved in neuronal dysfunction in the absence of Alsin.

Title: The amyloid-β (25-35) induces changes in the expression of galectin-9 and TIM3 implicated in the modulation of the neuroinflammation in rats

Authors: *E. RAMÍREZ HERNÁNDEZ[1], O. A. GUERRERO MARÍN[2], L. VALENCIA GIL[2], L. HERNÁNDEZ ZIMBRÓN[2], M. NAVA CATORCE[2], E. ZENTENO[2];
[1]UNAM, Puebla, Mexico; [2]Univ. Nacional Autonoma de Mexico, Ciudad de México, CDMX, Mexico

Abstract: Background: Neuroinflammation has been proposed as a common factor and one of the main inducers of neuronal degeneration in Alzheimer's disease (AD) [1,4]. Galectins are a group of β-galactoside-binding lectins, that play an important role in the immune response, adhesion, proliferation, differentiation, migration, and cell growth. Up to 15 members of the galectin's family have been identified; the expression of galectin-9 and receptor TIM3 is considered a key factor in modulation of the inflammatory response [2]. The administration of $A\beta_{25-35}$ peptide into the *lateral ventricles* of rats can cause memory impairment by the activation of the inflammatory response [3]. Despite all these studies, the specific molecular mechanisms involved in this inflammatory process remains unclear. Galectin-9 (Gal-9) and TIM3 are associated with the modulation of astrocyte and microglia activation under various inflammatory conditions. The aim of this study was to evaluate if the administration amyloid-β (25-35) into *lateral ventricles* of rats increase the expression of galectin-9 and TIM3 implicated in the modulation of the neuroinflammation. **Methods:** The vehicle or $A\beta_{25-35}$ peptide (0.1 µg/µL) was

bilaterally administered in the *lateral ventricles* of the rat, and control group. On day 30, the hippocampus and dentate gyrus were assessed for immunohistochemical and western blot assays for immunodetection of astrocytes (GFAP), microglia (Iba1), Gal-9 and TIM3. **Results:** Our results show that the administration of the $A\beta_{25-35}$ peptide increases the reactivity glial cells in the hippocampus of $A\beta_{25-35}$ treated rats in comparison to the control group. This result is associated with an increase in the expression of Gal-9 and TIM3 that was detected predominantly in the cells of microglia respect to the control group. **Conclusion:** Gal-9 and TIM3 is mainly produced by activated microglia that can attenuate injuries in the peak phase of the inflammatory response, in neurodegenerative process induced by $A\beta_{25-35}$ peptide. Therefore, we suggest that Gal-9 and TIM3 are involved in the inflammatory process induced by the administration of the $A\beta_{25-35}$.1 Heneka MT et al., 2014. Nat. Rev. Title: Trem2 splicing generates different species of soluble trem2 that inhibit ltp through $gaba_a$ receptors

Authors: *M. MOUTINHO, I. CORONEL, G. V. DI PRISCO, A. P.-Y. TSAI, S. S. PUNTAMBEKAR, K. NHO, B. K. ATWOOD, G. E. LANDRETH;
Indiana Univ. Sch. of Med., Indianapolis, IN

Abstract: TREM2 is a transmembrane receptor expressed by myeloid cells which acts to regulate their immune response. Genetic studies have demonstrated that TREM2 variants confer dramatically elevated risk for Alzheimer's disease (AD). In the AD brain, TREM2 expression is induced in a subset of plaque-associated microglia and regulates their response to amyloid and tau pathology. The *TREM2* gene yields three transcripts, $TREM2^{230}$ encoding the full-length transmembrane receptor, and the alternatively spliced isoforms $TREM2^{222}$ and $TREM2^{219}$ with distinct C-termini. Soluble TREM2 (sTREM2) levels in CSF fluctuate in function of the AD clinical stage and may serve as an novel biomarker for disease progression. sTREM2 is

generated by proteolytic cleavage of TREM2^{230} receptor, releasing its ectodomain (sTREM2) to the extracellular milieu. *TREM2*^{222} and *TREM2*^{219} represent a significant fraction of *TREM2* transcripts in the human brain, and since they lack a transmembrane domain, they are postulated to be secreted and function as an additional source of sTREM2. However, *TREM2*^{222} and *TREM2*^{219} translation into protein and secretion from cells has not been assessed. Although few studies have explored the biological function of sTREM2 at supra-physiological levels, the source of sTREM2 species and their endogenous role are still unclear. Our analysis of the AMP-AD dataset revealed that *TREM2*^{230}, *TREM2*^{222} and *TREM2*^{219} transcripts are increased in the brains of AD patients. We observed similar increases by qPCR in the brain of the AD mouse model 5xFAD expressing human *TREM2*. Analysis of HEK cells transfected with plasmids encoding *TREM2* isoforms revealed that *TREM2*^{222} and *TREM2*^{219} are secreted into the extracellular milieu, in contrast to the shedding of TREM2^{230}. This is the first experimental evidence that splice isoforms of human TREM2 are translated and directly secreted from cells. These observations suggest that increased expression of *TREM2*^{222} and *TREM2*^{219} in AD may lead to higher production of sTREM2. Interestingly, sTREM2 has been shown to bind to neurons, which suggests they may exert direct effects on neuronal function. We purified sTREM2 derived from TREM2^{230}, TREM2^{222} and TREM2^{219}, and incubated murine brain slices followed by LTP analysis. All three forms of sTREM2 abolished LTP induction, and this effect was inhibited by the $GABA_A$ receptor antagonist picrotoxin. These data support the existence of a heterogeneous pool of sTREM2 species in the brain, which act to inhibit LTP through $GABA_A$ receptors. Given that sTREM2 levels are linked to AD pathogenesis and progression, our findings that sTREM2 species interfere with LTP might help to decipher their role in disease.

Title: Altered neuronal ratios and microglial activation in aging Down syndrome brains revealed by snRNA-seq

Authors: *C. PALMER[1], C. LIU[1], W. ROMANOW[2], M.-H. LEE[3], J. CHUN[2];
[1]Univ. of California San Diego, La Jolla, CA; [2]Sanford Burnham Prebys, La Jolla, CA; [3]Sanford Burnham Prebys Med. Discovery Inst., San Diego, CA

Abstract: Down Syndrome (DS) – trisomy of human chromosome 21 (HSA21) – is characterized by lifelong cognitive impairments and development of the neuropathological hallmarks of Alzheimer's disease (AD). The cellular and molecular modifications responsible for these effects are not understood. Here we conducted single-nucleus RNA-sequencing (snRNA-seq) on a total of 29 DS and non-DS control human prefrontal cortex samples. In DS, inhibitory neurons were overrepresented vs. excitatory neurons across all ages profiled. Microglia displayed profiles of aging and activation preceding and during AD neuropathology. Notably, increased expression of C1q complement genes associated with dendritic pruning was observed in young DS brains, as well as a general lack of homeostatic microglia at all ages in DS. A set of HSA21 transcription factors were implicated in driving this constitutive microglial activation. These results highlight global cellular and transcriptomic differences as novel features of the aging DS brain.

Abstract: In glioma, tumor-associated myeloid cells (TAMCs), including microglia, monocytes, macrophages, dendritic cells and granulocytes, are massively recruited and can comprise up to 50% of the total tumor mass. These diverse myeloid populations foster glioma progression by promoting angiogenesis, secreting soluble mediators to malignant cells, and suppressing local

immunity. Restraining TAMC recruitment by the glioma has beneficial effects on survival. Here, we identified that the voltage-gated proton channel, Hv1, regulates myeloid cell infiltration during glioma progression. Hv1 is a unique ion channel with high selectivity for protons. Hv1 is selectively expressed in microglia in the mouse central nervous system, and some peripheral immune populations, including monocytes, macrophages, neutrophils, and B cells. Using a GL261 mouse glioma model, we found that mice lacking Hv1 (*Hv1*$^{-/-}$) exhibit reduced tumor burden and prolonged survival compared to the wild-type mice. The prolonged survival in *Hv1*$^{-/-}$ mice is associated with slower glioma proliferation. RNA sequencing results suggest that Hv1 depletion modulate immune responses to glioma, including monocyte chemotaxis. We further performed flow cytometry to identify that *Hv1*$^{-/-}$ glioma mice have reduced monocyte and macrophage infiltration, and increased number of PD-1^{+}CD4^{+} T cells. As a result, we combined anti-PD-1 treatment with Hv1 knockout, and found that approximately 30% of *Hv1*$^{-/-}$ mice can be cured. Together, our results demonstrated that Hv1 controls tumor myeloid infiltration and shed light on the possibility of new treatment for glioma by blocking Hv1.

Br., Galveston, TX; [6]Dept. of Biol., The Univ. of Texas At San Antonio, San Antonio, TX

Abstract: Cerebral malaria (CM) is the most deadly pathology of *Plasmodium falciparum* infection, which primarily impacts children in sub-Saharan Africa. Survivors experience neurological sequelae including behavioral & cognitive defects. In *Plasmodium* infection in mice

deficient in IL-10, we showed that hyperinflammation drives deposition of fibrin(ogen) deposits that block the cerebral vasculature, as in human CM, and that glia are reactive. Anti-coagulants prevented mortality in mice and reduced gliosis. Using intravital multiphoton microscopy, we show a dynamic interplay of microglia directly with the congested vasculature. While parasite infection is limited to blood cells, this exchange suggests a mechanism of translation of inflammatory signals between the vasculature and parenchyma in experimental CM. To evaluate microglia interactions, with the congested vasculature, intravital microscopy was performed through a thin skull preparation on $IL10^{-/-}$ $CX3CR1^{GFP/-}$ $CCR2^{RFP/-}$ mice, highlighting resident microglia, and recruited CCR2+ leukocytes and their interactions with fluorescently labeled fibrinogen in eCM. These studies reveal that early in infection (3 days post infection (dpi)), coagula are transient with evidence of temporary flow disruption and emboli, while at 7 dpi thrombi show permanence and fully occlude flow. Microhemorrhages occur at 7dpi, occur proximally to thrombi and result in significant extravasation of luminal fibrinogen, which deposits in puncta in the parenchyma. We previously observed that reactive astrocytes localize to sites of clotting, and now observe a significant increase in vessel associated microglia (VAM) in infection compared to control (40% vs. 20%, $p<0.05$) at 7 dpi. VAM are primarily amoeboid, a reactive feature, compared to those away from vessels further into the parenchyma which have ramified, surveying morphology. Both flow cytometry and microscopy show that activated microglia contain fibrin(ogen) (IVM % average: 91% vs. 3% colocalization) with microscopy showing dynamic uptake by microglia processes. Microglial activation is further demonstrated by upregulation of antigen presentation molecules, MHCII and CD86. Finally, in vivo imaging reveals a qualitative increase in vasoconstriction & vasodilation. The overall picture that emerges is a dynamic progression of coagulation that ultimately leads to both microhemorrhage and the attraction of activated microglia to the vasculature, with evidence for dynamic uptake of fibrinogen by microglia, suggesting potential stimuli of activation, and supporting the interplay between hypercoagulation and neuroinflammation in eCM.

Title: Activating microglial Gi signaling by chemogenetics increases anxiety-like behaviors.

Authors: *S. ZHAO[1], J. ZHENG[1,2], L. WANG[1,2], Y. YING[1], A. DHEER[1], L.-J. WU[1,3,4];

Abstract: G protein-coupled receptors (GPCRs) regulate a wide array of physiological responses by modulating second messengers in all types of cells. Microglial GPCRs have been implied in regulating neuronal activity, neurogenesis, neuroplasticity, pain, and synaptic pruning etc. We previously identified that knockout of a microglial Gi-coupled GPCR, P2Y12, increased anxiety-like behaviors in mice. However, the consequence of activating microglial Gi protein-coupled GPCR in anxiety is still unknown. To this end, we took advantage of $CX3CR1^{creER/+}$:$R26^{LSL\text{-}hM4Di/+}$ mice to exclusively activate microglial Gi signaling by administrating CNO. Two-photon imaging showed microglia decreased ATP induced chemotaxis but did not alter morphology and surveillance in response to CNO injection. Furthermore, both male and female mice increased anxiety-like behaviors 30 min after activating microglial Gi signaling. C-fos mapping in 3 anxiety related brain regions indicates the basolateral amygdala (BLA) nuclei-specific contribution. These results suggest that activating microglial Gi-coupled GPCR increases neuronal excitability and anxiety-like behaviors in mice.

Title: Maternal hypercaloric diet triggers astrogliosis and microglia reactivity in male mouse offspring

Authors: *C. BERDASCO[1], M. ELGAZZAZ[1], E. D. LAZARTIGUES[2];
[1]Louisiana State Univ., New Orleans, LA; [2]LSU Hlth. Sci. Center-NO, New Orleans, LA

Abstract: It is well known that, in adults, obesity is associated with a state of inflammation throughout the body, including in the brain. Also, it is known that parental illnesses can impact the offspring. The objective of this work was to determine whether maternal consumption of a hypercaloric diet (HCD) during pregnancy and lactation could affect the inflammatory status of

the brain in the progeny. For this work, C57BL/6 mice females (4 months) were placed on either HCD or regular diet (RD) for 1 month prior to mating. Each litter was restricted to 6 individuals and the pups were separated after 21 days and fed RD or HCD for 9 weeks, thus creating 4 diet conditions: RD/RD, RD/HCD, HCD/RD and HCD/HCD. Male progeny brains (n=4/group) were used for immunohistochemistry against GFAP (glial fibrillary acidic protein) to identify reactive astrocytes (number and expression level) and Iba1 (ionized calcium-binding adapter molecule 1) to identify reactive microglia (expression level, activation score and morphology). HCD consumption in the perinatal phase or in adulthood, was associated with an increase in the number of $GFAP^+$ cells (HCD/RD: 12.4 ±0.5, RD/HCD: 10.1 ±0.5 and HCD/HCD: 11.9 ±0.6 compared to RD/RD: 7.6 ±0.3 cells/area, one-way ANOVA, $p<0.05$) and the overall GFAP expression level (HCD/RD: 3.25 ±0.19, RD/HCD: 2.31 ±0.11 and HCD/HCD: 2.81 ±0.08 compared to RD/RD: 1.79 ±0.06 A.U. in Integral Optical Density/Astrocyte, one-way ANOVA, $p<0.05$). Similarly, all HCD groups showed an increase in the expression level of Iba1 (HCD/RD: 7.31 ±0.5, RD/HCD: 6.45 ±0.4 and HCD/HCD: 8.29 ±0.6 compared to RD/RD: 0.37 ±0.3 A.U. in IOD/Microglia, one-way ANOVA, $p<0.05$). Also, all groups fed with HCD showed an increase in the microglia activation score (HCD/RD: 3.27 ±0.3, RD/HCD: 3.72 ±0.3 and HCD/HCD: 4.61 ±0.3 compared to RD/RD: 1.65 ±0.2 A.U. in microglia activation score, one-way ANOVA, $p<0.05$) in comparison to RD/RD group. Finally, all the mice fed with HCD showed a decrease in ramified microglia (HCD/RD: 20.2 ±3.5, RD/HCD: 15.5 ±3.4 and HCD/HCD: 15.8 ±3.6 compared to RD/RD: 53.9 ±5.5 in microglia morphology (%), two-way ANOVA, $p<0.05$). Specifically, HCD/RD group showed an increase in the hyper-ramified microglia (Hyper-ramified: 48.6 ±5.4 compared to Ramified: 20.2 ±3.5, Bushy: 12.8 ±3.4, and Ameboid: 18.3 ±3.7 in microglia morphology (%), two-way ANOVA, $p<0.05$). These data show that HCD-exposure during the perinatal period predisposes the offspring to neuroinflammation which as evidenced by the activation of microglia and astrocytes.

Title: Hematopoietic stem cell transplantation busulfan chemotherapy causes complete microglia senescence driving macrophage brain engraftment

Authors: *K. SAILOR[1], G. AGORANOS[1], S. LÓPEZ-MANZANEDA[2], S. TADA[2], B. GILLET-LEGRAND[2], C. GUERINOT[1], J.-B. MASSON[1], C. L. VESTERGAARD[1], M. BONNER[3], K. GAGNIDZE[3], G. VERES[4], P.-M. LLEDO[1], N. CARTIER[2];

Abstract: Hematopoietic stem cell transplantation (HSCT) is a treatment for various malignant and non-malignant blood diseases with over 50,000 procedures annually worldwide. Yet, despite its prevalence, it is still unclear how HSCT affects the brain. Here we performed HSCT in mice using the myeloablative chemotherapy compound busulfan. Histological and *in vivo* imaging showing gradual donor macrophage engraftment of the brain between 6 and 24 weeks post-HSCT. Imaging the same macrophages over multiple months showed they became resident and had similar surveillant processes, as compared to the microglia they replaced. Half the host microglia were depleted by 2 weeks post-HSCT, with their density plateauing, while the cells doubled their process coverage area. Adult neurogenesis in both the sub-ventricular zone and hippocampus was completely ablated within 1 week, with no recovery up to 24 weeks post-HSCT. At 2 weeks post-HSCT, lamin B1 expression was lost with concurrent high expression of SA-beta-galactosidase, indicating cellular senescence. Further, microglia expressed the senescence/anti-apoptotic marker p21, were incapable of incorporating DNA as shown with 5-ethynyl-2'-deoxyuridine labeling, and expressed pospho-gamma-H2A.X, indicating DNA repair mechanisms. We administered the colony stimulating factor-1 antagonist PLX3397 to deplete host microglia, followed by withdrawal of PLX3397, while *In vivo* 2-photon imaging allow single-cell tracking of their recovery. In control mice, 4 weeks of PLX3397 caused 85% microglia depletion and drug withdrawal caused a 90% recovery within 4 days due to microglia proliferation. In HSCT mice, no host microglia recovered after PLX3397 depletion and withdrawal, yet donor macrophages showed robust proliferation in the brain at 5 days and beyond withdrawal, populating and tiling 95% of the cortex. In all HSCT brains, no host microglia cell division events were observed across multiple days of recovery, confirming their senescent state with busulfan treatment. Our results suggest busulfan DNA crosslinking causes microglia cell cycle arrest, with the induction of senescence along an anti-apoptotic p21 pathway. After HSCT, the gradual loss of microglia, due to their inability to proliferate, causes a minimal microglia density threshold, thereby allowing the permissive engraftment of macrophages in the brain. These results show for the first time the strong effect of busulfan induced microglia senescence and provide a therapeutic strategy for future cell transplantation-based brain gene therapies.

Abstract: High-fat diet (HFD) consumption has been related to metabolic alterations, such as obesity and cardiovascular problems, and has pronounced effects on brain plasticity and memory impairment. HFD exposure has a proinflammatory effect associated with microglial cell modifications in the hippocampus, a region involved in the working memory process. However, to our knowledge, few studies using male mice have evaluated the effect of HFD consumption after exposure to lipopolysaccharide (LPS) in the perinatal period on spatial working memory and the morphological changes in microglial cells. In the present study, male mice were injected with LPS (100 μg.kg-1 body weight) on postnatal day 3 and fed an HFD for 16 weeks after weaning. Ours results indicated that HFD consumption increased body weight gain, glucose

blood concentration and microglia process (number and length) from the hilus of the dentate gyrus, as well as spatial working memory impairment in comparison to control group. Interestingly, postnatal exposure to LPS in the early developmental stage combined with HFD consumption prevented glucose blood concentration increase, mRNA expression from pro-inflammatory cytokines (TNF-α and IL-1β) and microglial process with IL-10 mRNA expression increase in hippocampus, without changes in body weight gain and spatial working memory with respect HFD group. These findings indicate HFD consumption after postnatal LPS exposure induces immune tolerance, without prevention in spatial working memory impairment on male mice. We thank A. Aguilar, A. Castilla, N. Hernandez, D. Gasca, J. Gonzalez, and Michael Conrad Jeziorski for technical assitence.

Title: Protective role of bradykinin in neuropsychiatric lupus

Authors: *M. MIZRACHI[1,2], B. DIAMOND[1,2];
[1]The Feinstein Inst. for Med. Res., Manhasset, NY; [2]Donald and Barbara Zucker Sch. of Med. at Hofstra/Northwell, Hempstead, NY

Abstract: Systemic Lupus Erythematosus (SLE) is an autoimmune disease characterized by the presence of anti-nuclear antibodies as well as a broad array of clinical manifestations affecting nearly every organ system. Neuropsychiatric syndromes affect over one half of SLE patients, presenting most commonly as headache, mood disorders and/or cognitive dysfunction. The pathophysiology of neuropsychiatric lupus has not been fully elucidated; however, it is likely triggered by cytokines such as HMGB1 and IFNa, as well as antibodies such as anti-NMDA receptor and anti-ribosomal P antibodies, passing through the blood-brain barrier and interacting with cells of the brain. We have developed a mouse model to study the effects of anti-dsDNA antibodies that cross-react with the NMDA receptor, termed DNRAbs, which are present in approximately 30% of SLE patients and whose presence in the CSF is associated with non-focal CNS manifestations of neuropsychiatric lupus.Using this model, we have previously demonstrated microglial activation, C1q-dependent dendritic pruning, enlarged place fields and behavioral deficits, which can be reversed by treatment with blood brain barrier – permeable

ACE inhibitors such as captopril. These findings suggest a therapeutic target for the treatment of neuropsychiatric lupus. However, due to the diverse role of ACE in a biologic system, it is yet to be determined how, specifically, ACE inhibitors work in this model. Whereas ACE is primarily known for its role in the renin-angiotensin system, it also plays an important role in the degradation of bradykinin.Our preliminary data suggest that bradykinin mediates the protective effects of ACE inhibitors. Furthermore, we believe this effect involves reversal of a pro-inflammatory microglial phenotype characterized in part by increased secretion of HMGB1. HMGB1 levels are elevated in serum of patients with SLE, and serum levels correlate with disease activity. In our neuropsychiatric lupus model, it has been shown that HMGB1 induces dendritic pruning by bridging NMDA receptors to C1q. In our preliminary studies with primary microglia cultures, we have shown that bradykinin treatment suppresses HMGB1 secretion. As a small peptide with numerous cleavage sites, bradykinin is rapidly degraded in serum. Therefore, to test our hypothesis in vivo, we have acquired 12 bradykinin analogues which have higher stability in plasma than bradykinin itself. Based on our preliminary data, we believe these analogues may reverse the neuropsychiatric phenotype of DNRAb+ mice. Our aim is to use these analogues to investigate bradykinin as a viable treatment target for neuropsychiatric lupus.

Title: Brain-spinal neuromodulation to improve stepping in individuals with motor complete spinal cord injury

Authors: *C. ANGELI[1,4,2], Y. P. GERASIMENKO[5,3,2];
[1]Bioengineering, [2]Kentucky Spinal Cord Injury Res. Ctr., [3]Physiol., Univ. of Louisville, Louisville, KY; [4]Frazier Rehab Inst., Louisville, KY; [5]Pavlov Inst. of Physiol, St Petersburg, Russian Federation

Abstract: Individuals diagnosed with motor complete spinal cord injury (SCI) have the capacity to recover walking in limited cases (Angeli2018, Gill2018). We have shown that spinal cord epidural stimulation (scES) combined with task specific training improved standing and stepping ability in individuals with SCI. The aim of this study is to understand mechanisms of combined

cervical spinal cord Transcutaneous Stimulation (scTS) with lumbosacral spinal cord Epidural Stimulation (scES) during non-weight bearing and weight-bearing stepping in individuals with motor complete SCI. Four individuals with complete SCI were implanted with an epidural electrode array and neurostimulator. Two individuals had received locomotor training with scES prior to the assessments and two individuals had never received locomotor training with scES. For the latter, step-scES mapping was performed prior to any assessment with the combination of cervical scTS+ lumbar scES. We collected electromyography of 6 lower extremity muscles bilaterally and performed kinematic analysis lower extremity joints during stepping in a gravity neutral device (GND) and on a treadmill with body weight support (BWST). While in the GND, individuals were asked to perform step like movements while in the presence of scES, scTS and scES+scTS. The same combinations were also assessed during stepping on BWST and manual assistance as needed. Peak to peak (PtoP) motor evoked potential generated during 2Hz scES was differently modulated during scES+scTS at C3, C5 and both sites combined. In most cases scTS at C3+C5 produced the greatest reduction in the PtoP amplitude when compared to scES alone and scES+scTS at either C3 or C5. When evaluating the integrated EMG of the tibialis anterior during stepping in the GND, a clear modulation is present when comparing scES with scES+scTS. The combination of scES+scTS at C3 and C5 sites reduces the relative difference between left and right activation promoting a more symmetrical pattern. Modulation was also present during stepping with BWST, resulting in improved coordination between flexors and extensors during the gait cycle when scES+scTS at C3 and C5 sites was applied compared to scES alone or scES+scTS at a single site. These results provide evidence the scES modulates network excitability of the injured spinal cord to allow for the integration of afferent and supraspinal descending input to generate stepping patterns. In addition, scTS applied to the cervical spine at or above the level of injury facilitate brain-spinal connectome as well as in addition to scES further modulates spinal excitability improving coordination during intentional stepping.

Title: Cardiovascular function is modulated by lumbosacral spinal networks independent from other functions

Authors: *B. DITTERLINE[1], **G. F. FORREST**[2], S. MESBAH[1], S. KIRSHBLUM[3], J. M. WECHT[4], C. A. ANGELI[5], S. WANG[1], S. J. HARKEMA[1];

Abstract: Individuals with chronic cervical spinal cord injury (SCI) experience blood pressure instability that manifests as persistent hypotension, orthostatic hypotension, and autonomic dysreflexia. This dramatically decreases quality of life and increases cardiovascular morbidity and mortality, but clinically available treatments involve temporary symptom management rather than recovery and restoration of function.
We hypothesized that targeting integrated networks may reinstate cardiovascular regulatory mechanisms, utilizing lumbosacral spinal networks when supraspinal sympathetic input was chronically compromised. In this study, we anatomically, neurophysiologically, and pharmacologically identify specific spinal and peripheral circuitry responsible for cardiovascular stability using neuromodulation in 12 individuals with chronic cervical SCI implanted with a Medtronic 5-6-5 electrode array and neurostimulator. Blood pressure instability was evident in all individuals with SCI when monitored over six hours during sitting and during a 70-degree, head-up tilt test. However, only spinal cord epidural stimulation (scES) parameters targeted for cardiovascular function (CV-scES) significantly stabilized systolic blood pressure over six hours and during head-up tilt; non-cardiovascular (Non-CV-scES) configurations did not. When using high-resolution MRI to reconstruct the lumbosacral spinal cord and functional mapping, it was determined that CV-scES configurations that stabilized blood pressure were located over spinal segments L3, L4, and L5. Administration of Tamulosin, a selective $alpha_{1A}$ receptor antagonist, interferes with the ability of CV-scES to stabilize systolic blood pressure during sitting and during head-up tilt, indicating the role of sympathetic receptors on vascular smooth muscle. These results demonstrate neuromodulation specific to the lumbar spinal cord stabilizes blood pressure in chronic human SCI. Integrated systematic neuromodulation at the lumbosacral spinal has now demonstrated the ability to improve both motor and autonomic function - devastating consequences after severe SCI - while utilizing the same epidural implantation method, providing a potential multi-modality clinical treatment.

Title: Impact of lumbosacral epidural stimulation on bowel function in persons with spinal cord injury

Authors: *S. C. ASLAN[1,2], B. UGILIWENEZA[1,2], D. WANG[1,2], E. WYLES[1,2], K. JOHNSON[1,2], T. ABELL[3,2], C. H. HUBSCHER[4,2], S. J. HARKEMA[1,2,5], **A. N. HERRITY**[1,2]; [1]Dept. of Neurolog. Surgery, [2]Kentucky Spinal Cord Injury Res. Ctr., [3]Dept. of Gastroenterology, [4]Dept. of Anatom. Sci. and Neurobio., [5]Frazier Rehabil. Inst., Univ. of Louisville, Louisville, KY

Abstract: Complications with bowel storage and evacuation are highly prevalent after spinal cord injury (SCI) and include dysmotility, chronic constipation and difficulty with evacuation, unexpected episodes of fecal incontinence, as well as autonomic dysreflexia, an abrupt rise in blood pressure associated with rectal distention and the passage of stool. Current management of neurogenic bowel dysfunction (NBD) includes optimizing stool consistency with adequate fiber and fluid intake and promoting regularly scheduled bowel emptying, primarily via mechanical rectal stimulation. However, large amounts of time are devoted to bowel programs and many individuals are also dependent on a caregiver for assistance. Epidural stimulation of the lumbosacral spinal cord (scES) has shown effectiveness in activating latent neural circuits with an ability to recover significant gains in autonomic function. The objective of the current study was to determine if scES was neuromodulatory for bowel function. Ten participants (7 males, 3 females) with motor complete chronic cervical SCI (C3-C8) completed anorectal manometry, wireless motility assessments, and questionnaires for bowel function before and after 80- (post-training 1) and 160-sessions (post-training 2) of training with scES (Cardiovascular-scES or Voluntary-scES, with and without Stand-scES). Anorectal manometry results revealed comparable resting and squeeze pressure values at baseline. By post-training 2, squeeze pressure significantly increased relative to baseline ($p < 0.05$). Rectal sensations improved at each post-training time point, occurring at a lower distention volume. Delays in upper gastrointestinal motility improved (reduced) at both post-training time points and a 50% reduction in the percentage of participants having severe NBD was evident by post-training 2. Taken together, these results indicate that scES can be used to improve anorectal dysfunction following chronic SCI, including an awareness of bowel sensations and the ability to generate sufficient squeeze pressure necessary for preventing fecal incontinence. Improved motility can reduce the occurrence of abdominal discomfort and the time needed for evacuation procedures. Even though scES was not directly configured for bowel, nor was stimulation ‘‘on’’ during assessments, sufficient excitation of neural networks, comprised of overlapping motor and autonomic networks, during training may have led to improved adaptations in internal/external anal sphincter dynamics important for storage and evacuation reflexes. Post-SCI motility changes may also involve alterations in the intact vagal neurocircuitry.

Abstract: Introduction: Spinal cord injury (SCI) results in cardiovascular dysfunctions, including orthostatic hypotension (OH), defined as a substantial drop in arterial blood pressure (BP) when assuming an upright position. OH may cause cerebral hypo-perfusion possibly linked to a chronic decline of cognitive function, and to a loss of normal ability of cerebral vessels to buffer BP oscillations potentially damaging this critical vasculature and increasing risk of stroke. OH and cerebral hypo-perfusion are difficult to manage, adversely impacting health, functional rehabilitation and quality of life. We previously showed that lumbosacral spinal cord epidural stimulation (scES), optimized for cardiovascular function (CV-scES) mitigated OH in individuals with chronic SCI. This study evaluated the acute effects of CV-scES on cerebral blood flow velocity and cerebrovascular buffering of BP oscillations in participants with chronic SCI. **Methods:** Ten individuals with chronic cervical SCI and severe cardiovascular dysfunction had a 16-electrode array implanted over the lumbosacral spinal segments. Personalized neuromodulation was comprised of specific cohorts (anode and cathode electrodes, amplitude, frequency, and pulse width selection) interleaved for a CV-scES specific configuration of parameters designed to maintain systolic BP between 110-120 mmHg and to avoid inducing lower extremity muscle activity. Orthostatic tolerance was tested with a 70° head-up tilt maneuver lasting up to 30 minutes, with and without CV-scES. Subjective pre-syncopal symptom severity was recorded using a 0-10 scale. Beat-to-beat blood flow velocity at the

middle cerebral artery (mCBFv) and mean arterial pressure (MAP) at the finger were monitored simultaneously. Sympathetically mediated cerebrovascular buffering of BP oscillations was estimated using wavelet derived phase synchronization index between mCBFv and MAP. **Results:** Compared to tilt without stimulation, CV-scES increased the tolerated tilt time (10 ± 3 vs. 30 ± 0 minutes, respectively, p=0.0003), reduced symptom severity (5.5 ± 0.9 vs. 0.2 ± 0.1, p=0.0002), reduced the fall in MAP (-28 ± 4 vs. -2 ± 4 mmHg, p=0.001), reduced the fall in mCBFv (-16 ± 2 vs. -8 ± 1 cm/s, p=0.001 and improved cerebrovascular buffering of BP oscillations indicated by reduced phase synchronization index within the ultra-low frequency range during tilt (0.64 ± 0.22 vs. 0.42 ± 0.14, p=0.05). **Conclusions:** Maintenance of BP with acute CV-scES during orthostatic stress in individuals with chronic cervical SCI is associated with improved cerebral hemodynamics and buffering of BP oscillations resulting in prolonged orthostatic tolerance.

Title: Improved cognition and cerebral hemodynamics after lumbosacral spinal cord epidural stimulation intervention in individuals with chronic spinal cord injury

Authors: B. DITTERLINE[1,2], M. COTTER[4,5], M. LUTTRELL GREENWELL[1], E. CASH[3,6], J. FISHER[1], S. WANG[1], E. REJC[1,2], S. J. HARKEMA[1,2], *J. WECHT[4,5];

Ctr., Bronx, NY; [5]Dept. of Rehabil. and Human Performance, Mount Sinai, New York, NY; [6]Brown Cancer Ctr., U of L Healthcare, Louisville, KY

Abstract: Due to impaired sympathetic control of cardiovascular regulation, individuals with chronic cervical and upper thoracic spinal cord injury (SCI) exhibit decreased resting blood pressure when compared with non-injured individuals. Hypotension has been associated with cognitive impairment in the non-injured population. Poorer cognitive performance on cognitive tasks has been reported in hypotensive individuals with SCI compared to normotensive individuals with SCI, which was related to inadequate blood pressure and cerebral blood flow

velocity responses during testing. Impaired cognitive performance after SCI impacts multiple domains, including attention and concentration, memory, abstract reasoning, verbal learning, and information processing, which delays rehabilitation and social integration and ultimately decreases quality of life and independence. However, there are no clinically available therapies to restore the underlying sympathetic deficit, and efforts to pharmacologically support blood pressure to mitigate cognitive deficits are not consistently successful. Physical exercise can prevent age-related loss of brain tissue in non-injured individuals and leads to gray and white matter growth in a variety of neural structures associated with cognition including the hippocampus and frontal, temporal, and parietal cortices. We investigated the cognitive and cerebrovascular effects of an epidural stimulation intervention to support blood pressure combined with physical exercise. Five individuals with chronic cervical SCI, implanted with a Medtronic 5-6-5 paddle array over the lumbosacral spinal cord, participated in this study. Spinal cord epidural stimulation (scES) was used 1) to target cardiovascular regulation (CV-scES) and maintain systolic blood pressure between 110-120 mmHg while sitting and 2) to facilitate standing overground (Stand-scES). Individuals participated in at least 80 daily sessions of CV-scES (6 hours) followed by Stand-scES (2 hours). Cognitive function in the domains of learning, memory, attention, and executive function domains were examined pre- and post-Intervention with simultaneous recording of cerebral blood flow velocity without active scES. Post-intervention, we found improved cognitive flexibility, verbal fluency, memory and attention which were associated with increased cerebral blood flow velocity in the middle and posterior cerebral arteries. These data suggest that targeted CV-scES combined with Stand-scES may lead to beneficial adaptations in neurovascular coupling, which has the potential to improve quality of life and independence of individuals with chronic SCI.

Abstract: Epidural stimulation for lower urinary tract function in rats with spinal cord contusion injuries Natasha Wilkins, Robert F. Hoey, Daniel Medina-Aguiñaga, Fahmi Khalifa, Beatrice Ugiliweneza, Jason Fell, Ahmed Naglah, Ayman S. El-Baz, April N. Herrity, Susan J. Harkema, Charles H. Hubscher Abstract:Spinal cord injury (SCI) can have long and life-changing effects on lower urinary tract (LUT) function. Epidural stimulation of the lumbosacral spinal cord (scES) has demonstrated clinical effectiveness for improving both bladder compliance and reflex control of voiding. Our previous pre-clinical scES mapping studies at T13-L2, L3-4, and L5-S1 in spinally intact and T9-transected male and female rats further demonstrate efficacy of scES for modulating bladder storage and emptying. In the current study, maximally effective scES for maintaining continence or for reflex voiding was applied at the same three spinal levels with two modifications: 1) female rats with incomplete T9 level injuries of different severities were examined (clinically relevant spinal contusion model); and 2) a novel miniature 15-electrode array was used to enhance specificity at each spinal cord location. The results obtained during bladder fill and void cycles conducted under urethane anesthesia indicate frequency and intensity dependent effects on void volume, inter-void interval, detrusor contraction, and external urethral sphincter (EUS) activation. Responsiveness of the LUT to scES differed based upon severity of injury, whereby contusion injuries displayed some responses similar to complete transected animals and some that were similar to spinally intact animals. Some scES cohorts, for example, improved bladder compliance, producing a low-pressure fill of the bladder for a prolonged storage period with L1 level stimulation whereas others resulted improved voiding efficiency, resulting in timed activation of the detrusor triggering a void response (L6 level stimulation). The current study's novel electrode design with improved selectivity permitted enhanced LUT function at much lower stimulus intensities without any concomitant lower hindlimb movements. The potential for selective activation of the LUT circuitry at multiple levels with differing injury severities adds to an accumulating body of evidence regarding the use of scES as a singular SCI device intervention that can programmed to target multiple systems simultaneously.

Title: Selection of lumbosacral spinal cord epidural stimulation parameters for motor and autonomic functions in persons with chronic spinal cord injury

Authors: *S. HARKEMA[1,4,2], E. REJC[1,2], A. N. HERRITY[1,2], C. HUBSCHER[5,1], G. F. FORREST[6,7], S. MESBAH[1], M. BOAKYE[1,2], C. A. ANGELI[1,4,3];

Louisville Sch. Med., Louisville, KY; [6]Kessler Fndn., West Orange, NJ; [7]Rutgers New Jersey Med. Sch., Rutgers, New Jersey, NJ

Abstract: Lumbosacral spinal cord epidural stimulation (scES) has shown effectiveness for the recovery of walking, standing, voluntary movement, cardiovascular regulation and for the restoration of voluntary and reflex control of the lower urinary tract in individuals with motor complete spinal cord injury (SCI). The lack of clear guidelines on stimulation parameters is perceived as a significant barrier toward the use of scES for functional improvement by 83% of the US physicians who participated in a dedicated survey (Solinsky et al., 2019). To date, the major challenges related to the selection of scES parameters for promoting motor and autonomic functional recovery in severe SCI individuals are that i) these parameters are task- and individual-specific; and ii) the combination of stimulation parameters potentially available is vast, as exemplified by the over 43 million different electrode configurations potentially available using a 16-electrode array. The objective of this study is to demonstrate multi-functional mapping based on personalized neuromodulation with cohorts (anode and cathode selection, pulse width, frequency, and amplitude) resulting in specific scES configurations targeting differentially motor, cardiovascular and urinary functions. Our approach combines 3D reconstruction using high resolution MRI with spatial-temporal and functional mapping for targeted motor or autonomic responses in research participants implanted with a Medtronic 5-6-5 neurostimulator and electrode array placed over lumbosacral spinal segments. Electromyographic (EMG) activity and movement, continuous measurements of blood pressure and heart rate using a non-invasive blood pressure monitoring system and/or cystometrograms were recorded depending on the functional mapping session. Data collected from thirty-two research participants with chronic SCI identified mapping configurations that were selectively effective for motor, cardiovascular and/or bladder function. Initial functional mapping studies

resulted in voluntary movements in 32/32 participants, cardiovascular regulation in 22/22 participants, and urodynamic improvements in capacity and voiding in 6/6 participants. Importantly, these results reveal the complex dynamics and interplay between motor and autonomic systems that is being integrated and regulated within the lumbosacral spinal cord below the level of SCI in humans.

Title: Robotic postural stand training with epidural stimulation improved reactive standing postural control in individuals with motor complete SCI

Authors: *C. BOWERSOCK[1], T. PISOLKAR[1], I. OMOFUMA[2], T. LUNA[2], M. KHAN[2], V. SANTAMARIA[2], C. ANGELI[1], J. STEIN[2], S. AGRAWAL[2], S. HARKEMA[1], E. REJC[1]; [1]Univ. of Louisville, Louisville, KY; [2]Columbia Univ., New York, NY

Abstract: With spinal cord epidural stimulation (scES) and activity-based training, individuals with motor complete spinal cord injury (SCI) can recover the ability to stand with independent lower limb extension by grasping onto handlebars for balance assistance. However, standing while using the upper limbs for balance assistance alters postural control strategies and limits peripheral sensory information received by the lumbosacral spinal circuitry. Enhanced rehabilitation strategies are needed to train a more functional standing environment.
The aim of this study was to determine the effect of robotic postural stand training on reactive standing postural control without the use of the upper limbs for balance assistance in motor complete SCI individuals implanted with scES. Three individuals with chronic sensory and motor complete SCI (C4 (n=2), C3 (n=1)) were recruited. Participants previously received stand training with scES using regular assistive devices for balance assistance, achieving independent knee extension.
The robotic upright stand trainer (RobUST) used in this study contains an aluminum frame with 8 motors, which control the forces applied at the trunk and pelvis by cables attached to harnesses. During the experimental sessions, the RobUST elicited lateral trunk perturbations at a participant-specific magnitude aimed at achieving ~50% successful control before training. A

constant force applied by the RobUST assisted the pelvis. For each perturbation, participants attempted to maintain standing posture without use of the handlebars. Attempts were successful if the participant maintained or regained standing posture after the perturbation without using the handlebars and without additional assistance provided by a trainer. Successful perturbation control, vertical ground reaction force (Vgrf), and lower limb EMG response were quantified for each attempt. Participants performed ~80 postural stand training sessions with the RobUST and scES, which included perturbation, stable stand, and self-initiated trunk and arm movement. Assessments were conducted pre, mid, and post training.
Successful control of lateral trunk perturbations improved from 50% pre training to 85% after training. This was associated with a 450% increase in ipsilateral lower limb EMG activity and 19% increase in ipsilateral Vgrf in response to the lateral perturbations after training. This study shows that individuals with motor complete SCI and scES can improve reactive standing postural control without the use of the upper limbs, and this improvement is associated to lower limb EMG and kinetic adaptations promoted by robotic postural stand training.

Title: Neuroanatomical mapping of the spinal cord lumbosacral enlargement in individuals with chronic spinal cord injury

Authors: *S. MESBAH[1], A. N. HERRITY[2], I. CHOPRA[1], B. UGILIWENEZA[2], C. A. ANGELI[3], Y. GERASIMENKO[4], M. BOAKYE[2], S. J. HARKEMA[1];

Abstract: Spinal cord injury (SCI) caused by acute physical trauma often results in spinal cord lesions at the site of injury, while the rest of the spinal cord remains fairly intact. Damage to the

spinal cord is complex and can affect the body with varying degrees of sensorimotor and autonomic dysfunction. The use of spinal stimulation, with electrodes placed epidurally, induces a subthreshold electric field sufficient to increase the excitability of relevant neuronal circuits in the intact portion of the lumbosacral enlargement that is capable of driving not only voluntary activity, but also restoring multi-system autonomic improvements in individuals with chronic SCI. However, there is a lack of information regarding whether various neuroanatomical factors in the intact portion of the spinal cord may play an important role in functional recovery with the application of spinal cord epidural stimulation (scES). Our recent study showed that maximizing the spinal cord lumbosacral coverage by the scES paddle electrode may lead to better functional outcomes.The goal of this study is to use MRI-based spinal cord 3D modeling and quantitative analysis to gain a deeper understanding of the neuroanatomical substrates of the spinal cord and the functional properties of the excitable tissue. Twelve individuals with clinically diagnosed chronic, motor complete SCI that were implanted with scES were included (age: 34±10.9, gender: 10 male, 2 female, time since injury: 8.2±9.9, AIS: 6 A, 6 B). High resolution MRI scans of spinal cord were recorded prior to the implant surgery. The results show that the size of the spinal cord and nerve roots, the conus tip and the relationship between the spinal cord levels and vertebral levels, particularly at lumbosacral, is variable across individuals. Volumetric coverage of the lumbosacral spinal cord ranges from 33.4% to 90.4% across participants. The location and position of the excitable tissue (spinal cord and the nerve roots) with respect to the electrode contacts varies across individuals and impacts the patterns of neurophysiological responses. Distinct regions of the spinal cord at the lumbosacral enlargement control certain muscle recruitment patterns in response to scES. Finally, using MRI-based spinal cord modeling as a guide for prediction of optimum scES paddle placement prior to the implant surgery has substantially reduced the duration of the electrophysiological mapping and number of scES placements tested in the surgery. These findings highlight the crucial role that neuroanatomical characteristics of the spinal cord specific to each individual plays in reaching maximum functional benefits with scES.

Title: The effects of core-specific and non-specific training with epidural stimulation on trunk kinematics of individuals with chronic motor complete spinal cord injury.

Authors: *K. JOSHI[1], N. SMITH[2], E. REJC[3], S. J. HARKEMA[4,6], C. ANGELI[5,6];
[1]Kentucky Spinal Cord Injury Ctr., [2]Bioengineering, [3]Kentucky Spinal Cord Injury Res. Center; Dept. of Neurolog. Surgery, [4]Kentucky Spinal Cord Injury Center; Dept of Neurolog. Surgery, [5]Bioengineering; Kentucky Spinal Cord Injury Ctr., Univ. of Louisville, Louisville, KY; [6]Frazier Rehabil. Inst., Louisville, KY

Abstract: Past evidence suggests that spinal cord epidural stimulation (scES) in individuals with spinal cord injury (SCI) as well as core-based training lead to improvement in trunk stability in activities such as tall-sit, reaching, or leaning (Gill et al., 2020). Effects of non-specific training, however, have not been explored much. The aim of this study is to compare the effects of core-based and non-core based training with scES on trunk kinematics.17 individuals with chronic motor complete SCI (Age: 35.3 ± 12.7 yrs; time post-injury: 8.8 ± 8.4 yrs) were implanted with a scES unit and were randomized into four intervention groups (Voluntary – Vol, Cardiovascular – CV, Vol with stand, and CV with stand). Vol intervention comprised tasks to improve core stability. CV intervention comprised stabilizing BP without causing any muscle activity. Each group performed two 80-session sets. Standing was added to Vol and CV groups in the second intervention set. Data was collected at 3 time-points (Post Implant, Post Int1, and Post Int2) and each individual was asked to perform core activities without and with Vol-scES. Full-body kinematics was acquired and later processed for tall sitting, forward/back lean (FB), and lateral lean (LR). Center of mass of pelvis and torso was then used to calculate anterior-posterior (AP) and lateral torso displacement along with torso velocity in all four directions. Individuals were classified as non-responders if the reduction in all velocities was < ± 10% with scES. Responders were further divided into positive, negative, and neither (multidirectional) based on how their displacements and velocities changed. For sitting, decreased displacements and velocities were the main goal. For FB & LR movements, the goal was to have the relative change in displacement be better than the change in velocity in the direction of movement, and have decreased velocities and displacements in the other direction.Responder distribution for stim conditions for all three activities showed that both Vol group and CV group responded to the two interventions. In Sitting and LR, Vol group had more positive responders at Int1 and Int2, whereas CV group had more negative and non-responders. In FB, Vol group did not have as many positive responders, however the responder distribution Post Int1 and Int2 were similar. In contrast, CV group had more positive responders at Int2. These results indicated that Vol intervention along with scES leads to improved trunk stability and control in core-specific tasks. Improvements seen in FB control in the CV group may have been influenced by stand training part of the combination training during Int2.

Title: Robotic stand training and spinal cord epidural stimulation improved standing postural control in individuals with motor complete spinal cord injury

Authors: *E. REJC[1], T. PISOLKAR[1], C. BOWERSOCK[1], I. OMOFUMA[2], T. LUNA[2], M. KHAN[2], V. SANTAMARIA[2], C. ANGELI[1], J. STEIN[2], S. AGRAWAL[2], S. HARKEMA[1]; [1]Univ. of Louisville, Louisville, KY; [2]Columbia Univ., New York, NY

Abstract: Postural control is a foundational ability to generate effective motor outputs and is drastically impaired after spinal cord injury (SCI). In the last decade, proof of principle studies showed that spinal cord epidural stimulation (scES) and activity-based training can promote the recovery of standing and walking after motor complete SCI. However, participants' postural control was always self-assisted by their upper limbs placed on assistive devices (i.e. walker), or via body weight support systems. The aim of this study was to assess the effects of robotic postural stand training with scES in 3 individuals with chronic sensory and motor complete SCI (level of the lesion: cervical (C) 4 (n=2) or C3 (n=1)). These individuals had previously received extensive stand training with scES using regular assistive devices for self-balance assistance, achieving independent knees extension. The robotic upright stand trainer (RobUST) is a motion capture-based system that consists of an aluminum frame with 8 motors, which control the forces applied at the trunk and pelvis by cables attached to a harness. RobUST can: (*i*) provide a force field (FF) environment to assist the trunk as needed. Participants can move freely within the FF boundary, while a restoring force is applied when the trunk moves beyond the FF boundary. (*ii*) elicit postural perturbations. This allowed participants to train without the use of upper limbs for balance control (free hand). Participants performed ~80 sessions of RobUST postural training with scES (5 days/week; 1 hour per session). Postural training included periods of stable standing, self-initiated trunk and arm movements, and trunk perturbations with free hands. Standing postural control was assessed prior to the beginning of training (Pre), and after ~40 (Mid) and ~80 (Post) training sessions. At Pre, only 1 individual was able to maintain consistently stable standing with free hands and No FF (i.e. outside of RobUST), and none of the participants could perform self-initiated trunk movements in the same standing condition. RobUST FF immediately enabled the practice of stable standing and trunk movements with free hands in all participants. After training, all individuals could maintain stable standing, generate controlled trunk movements and arm reaching movements while standing with free hands and No FF, receiving only external assistance for pelvis control. RobUST postural training with scES promoted remarkable standing postural control improvements, and showed potential to enhance the overall level of functional recovery after severe cervical SCI.

Abstract: Past evidence suggests that spinal cord epidural stimulation (scES) in individuals with spinal cord injury (SCI) as well as core-based training programs lead to improvement in trunk stability in activities such as tall-sit, reaching, or leaning (Gill et al., 2020). The aim of this study is to compare the acute effects of scES prior to training and also explore the effects of non-core based training. 17 individuals with chronic motor complete SCI (Age: 35.3 ± 12.7 yrs; time post-injury: 8.8 ± 8.4 yrs) were implanted with a scES unit and were randomized into four intervention groups (Voluntary – Vol, Cardiovascular – CV, Vol with stand, and CV with stand). Vol intervention comprised tasks to improve core stability. CV intervention comprised stabilizing BP without causing any muscle activity. Data was collected at 2 time-points (Post Implant and Post Int1) and each individual was asked to perform core activities without and with Vol-scES. Full-body kinematics was acquired and later processed for tall sitting, forward/back lean (FB), and lateral lean (LR). Center of mass of pelvis and torso was then used to calculate anterior-posterior (AP) and lateral torso displacement along with torso velocity in all four directions. Individuals were classified as non-responders if the reduction in all velocities was < ± 10% with scES. Responders were further divided into positive, negative, and neither (multidirectional) based on how their displacements and velocities changed. For sitting, decreased displacements and velocities were the main goal. For FB & LR movements, the goal was to have the relative change in displacement be better than the change in velocity in the direction of movement, and have decreased velocities and displacements in the other direction.Responder distribution at post implant for Vol and CV groups were similar for all three

activities. The distribution of Post Int1 for CV and Post Implant for CV was same in FB, but different in sitting and LR. The contrasting results in LR may be attributed as a secondary effect of stand training in CV+Stand group. It can be inferred that without any training, scES has an immediate effect on trunk stability and control. Not all individuals had a positive improvement with scES, however there were not many non-responders. It was also evident that except for LR, the CV group responded in a similar way to Vol-scES at post implant and Post Int1 conditions.

Topic: D.03. Somatosensation – Pain

Title: Contextual control of conditioned pain tolerance and endogenous analgesic systems

Authors: S. TRASK[1], J. S. MOGIL[2], F. J. HELMSTETTER[3], C. L. STUCKY[4], ***K. E. SADLER**[4];
[1]Dept. of Psychological Sci., Purdue Univ., West Lafayette, IN; [2]McGill Univ., Montreal, QC, Canada; [3]Deptartment of Psychology, Univ. of Wisconsin Milwaukee, Milwaukee, WI; [4]Cell Biology, Neurobiology, and Anat., Med. Col. of Wisconsin, Milwaukee, WI

Abstract: The mechanisms underlying the transition from acute to chronic pain development are unclear, but likely involve the persistence or strengthening of pain memories. Environmental context was recently described as a critical regulator of pain memory; both rodents and humans exhibit increased pain sensitivity in environments recently associated with a single painful experience. It is unknown however, how repeated exposure to a painful stimulus (unconditioned stimulus; UCS) in a unique context (with distinct olfactory and visual cues) modifies pain expression in that environment. To answer this question, we paired one context with administration of a mild visceral pain stimulus (intraperitoneal injection of 0.9% acetic acid) and a similar, but distinct, context with a vehicle injection over the course of three days. On the fourth day, animals received either a vehicle injection in both the acid-trained and vehicle-trained chamber or a 0.9% acetic acid injection in both the acid-trained and vehicle-trained chamber. Similar to previous reports, male mice exhibited conditional hypersensitivity when given a vehicle injection in the acid-trained environment on day 4, but female mice did not. However, when given an acetic acid injection on day 4, both male and female mice exhibited context-dependent pain tolerance in the acid-trained environment. Neither male nor female mice exhibited UCS-induced mechanical hypersensitivity in the acid-trained context, and female mice exhibited less acid-induced abdominal writhing in the acid-trained context than the vehicle-

trained context, despite receiving identical acetic acid injections prior to being placed into each context. This observed pain tolerance was not explained by altered stress responses as circulating corticosterone levels were similar in the acid- and vehicle-trained environments on day 4. Systemic administration of naloxone immediately before UCS administration on day 4 completely blocked the context-dependent conditioned analgesia. These experiments suggest that endogenous opioid systems are engaged as a context-dependent conditioned compensatory response for painful stimuli. Successful determination of the brain circuits involved in the recruitment of this response may allow for the manipulation of pain memories which may be maladaptive in chronic pain states.

Title: Endogenous analgesic synergy between mu opioid receptor and CB_1 receptor constitutive activity prevents chronic postoperative pain with greater efficacy in female mice

Authors: *C. NORRIS[1], A. MARTEL MATOS[2], D. D. DOS SANTOS[1], D. E. SELLEY[3], L. J. SIM-SELLEY[4], B. K. TAYLOR[1];
[1]Dept. of Anesthesiol. and Perioperative Med., [2]Univ. of Pittsburgh, Pittsburgh, PA; [3]Dept. Pharmacol. & Toxicology, Virginia Commonwealth Univ., Richmond, VA; [4]Dept. of Pharmacol. and Toxicology, Virginia Commonweatlh Univ., Richmond, VA

Abstract: The endocannabinoid system is a promising target for the treatment of chronic pain. We previously reported that μ-opioid receptor constitutive activity (MOR_{CA}) in the dorsal horn of the spinal cord (DH) maintains injury-induced latent pain sensitization (LS) in a state of remission. We hypothesized that pain remission is maintained by cannabinoid CB_1 receptor constitutive activity (CB_{1CA}) as well. C57BL/6 mice were subjected to either plantar skin/muscle incision or sham surgery. Mechanical sensitivity was tested with the application of von Frey filaments. After the resolution of mechanical hypersensitivity (21 days post-surgery), CB_1 inverse agonist AM281 (10μg) or vehicle was injected intrathecally. AM281 but not vehicle reinstated mechanical hypersensitivity in the incision but not sham groups. Dose response studies (10ng-30μg) revealed that AM281 was 100X more potent in female (ED50 4.3ng) versus male (ED50 4.3μg) mice. Next, we calculated equipotent dose ratios of AM281:CTOP (a MOR-selective inverse agonist) to be 4300:1 for males, and 4:1 for females and tested multiple doses of their combinations (10pg-10μg, i.t.). We found a 1000-fold leftward shift to the dose response

suggesting dramatic synergy. Notably, the AM281:CTOP combination was 100X more potent in female vs male mice. Next, we collected spinal cords at POD24-25, and conducted agonist-stimulated [^{35}S]GTPγ;;;S binding in isolated membranes. Injury did not change CB1 agonist (CP55,940)- or MOR agonist (DAMGO)-stimulated E_{max}, or EC_{50} values, indicating no change in G-protein activation. CP55,940+DAMGO (1:3) combination produced no stimulation greater than the predicted additive effects suggesting that synergy was occurring downstream of G-protein activation. We next studied glutamate (10s 300µM)-evoked Ca^{2+} mobilization in DH transverse slices, 21 days after incision or sham surgery. Pre-application of AM281 (5min 100µM) increased the duration of the glutamate-evoked Ca^{2+} response in female but not male mice. Previous literature suggested that the endocannabinoid system interacts with ryanodine-sensitive internal Ca^{2+} stores, so we combined AM281 with the ryanodine receptor blocker JTV519 (1µM), which blocked the effect if AM281. In summary, we report that: surgery establishes $CB1_{CA}$ that maintains LS in remission with 100X greater potency in females; in the setting of LS, AM281 exerts a sexually dimorphic effect on ryanodine-sensitive internal Ca^{2+}stores; and endogenous analgesic synergy between MOR_{CA} and $CB1_{CA}$ prevents chronic postoperative pain with 100X greater potency in females.

Title: S1pr1 agonism in the central amygdala reduces neuropathic pain

Authors: *S. R. LAMERAND[1,2], A. H. COOPER[1], P. L. SHEETS[3], B. K. TAYLOR[1];
[1]Dept. of Anesthesiol., [2]Ctr. for Neurosciences, Univ. of Pittsburgh, Pittsburgh, PA; [3]Dept. of Pharmacol. and Toxicology, Indiana Univ. Sch. of Med., Indianapolis, IN

Abstract: Sphingosine-1-phosphate receptors (S1PRs) are an emerging target for the treatment of persistent pain. An emerging literature reports that the S1PR1 agonist / functional antagonist fingolimod, an FDA-approved disease modifying agent for multiple sclerosis (MS), reduces pain-like behaviors in models of inflammatory and neuropathic pain. For example, we reported that systemic administration of fingolimod reduced mechanical allodynia in the experimental autoimmune encephalomyelitis (EAE) model of MS. This reduction in mechanical allodynia was mimicked by the S1PR1 agonist SEW2871 and blocked by the S1PR1 antagonist, W146,

indicating an S1PR1-dependent mechanism. However, the anatomical sites of action remains unclear. The central amygdala (CeA) is an important supraspinal center for the processing of nociceptive input and is an emerging target for chronic pain. Using fluorescence *in situ* hybridization, we found robust S1PR1 expression in the central nucleus of the amygdala (CeA), and so tested the hypothesis that microinfusion of S1PR1 agonists into the CeA would reduce neuropathic pain. Adult male C57BL/6 mice underwent spared nerve (SNI) at the left sciatic nerve, followed by guide cannula implantation into the right CeA. Mechanical allodynia was tested with the application of von Frey hairs (up/down method) to the plantar surface of the left hindpaw. SNI dramatically reduced mechanical threshold, peaking at 14 days post-surgery. At this timepoint, saline or S1PR1 agonist was administered into the CeA. We found that intra-CeA fingolimod (0.01ng; 300nL) or CYM5442 (0.6ng; 300nL) but not saline attenuated mechanical allodynia, with a peak effect at 10 minutes and lasting 30-45 minutes (n=5-7; 2-way RM ANOVA with Bonferroni post-test, $P< 0.05$). Additionally, we found that intra-CeA SEW2871 (0.1ug & 1.0ug; 0.2ul) but not saline attenuated mechanical but not cold allodynia with a peak effect at 15 minutes and lasting 30-45 minutes (n=8-9; 2-way RM ANOVA with Bonferroni post-test, $P<0.05$). We conclude that the CeA engages S1PR1 signaling to reduce mechanical allodynia in the SNI model of neuropathic pain. These results point to S1PR1s in the CeA as a target for future pharmacotherapy of neuropathic pain.

Title: Tonic inhibition of mechanical and cold nociception and itch by neuropeptide Y Y2 receptors in primary afferent neurons

Authors: P. BASU[1], A. MADDULA[1], H. HERZOG[2], T. S. NELSON[1], ***B. K. TAYLOR**[1]; [1]Anesthesiol., Univ. of Pittsburgh Sch. of Med., Pittsburgh, PA; [2]Garvan Inst. of Med. Res., Darlinghurst, Australia

Abstract: Exogenous or endogenous neuropeptide Y (NPY) acts at its cognate Y1 receptor in the dorsal horn of the spinal cord to tonically inhibit behavioral and molecular signs of

inflammatory and neuropathic pain. The actions of NPY at the Y2 receptor (Y2R), the other Gi-coupled receptor that is highly expressed in the somatosensory nervous system, are not as clear. Y2R is expressed in primary afferent but not spinal cord neurons, with the greatest distribution on thinly myelinated afferent neurons (both Aδ- and C-nociceptors). The function of these Y2R-expressing dorsal root ganglion (DRG) neurons has been proposed to be pronociceptive, but this has not been rigorously tested. To begin to address this gap, we first asked whether intrathecal adminstration of the Y2R selective agonist, PYY_{3-36} (0.1, 1, 3 µg/5 µL) would reduce behavioral signs of persistent pain after plantar incision or spared nerve injury (SNI) in C57BL/6 male and female mice. Surprisingly, PYY_{3-36} had minimal effect on either mechanical or thermal hypersensitivity when tested 2 days after incision or 14 days after SNI (n = 6-8 per sex per surgery; P>0.05). One possible reason for this unexpected null result is that endogenous tonic NPY activation is high and the Y2Rs are at saturation; therefore, exogenous Y2 agonists have no available Y2Rs to bind to. To test if tonic basal Y2 activation was high, we administered the Y2R antagonist, BIIE0246 (0.01- 3.0 µg, 5 µL, i.t.) in naïve C57BL/6 male and female mice. BIIE0246 did not cause heat hypersensitivity or impairment of motor coordination but produced robust pain- and itch-like behaviors including mechanical and cold hypersensitivity, and biting (directed at the abdomen, back, and tail), rearing, face wiping, and scratching. To confirm these effects were mediated by Y2 receptors at the central terminals of primary afferent neurons, we bred a $Y2R^{DRG-/-}$ conditional knockout (cKO) by crossing $Pirt^{cre}$ mice (provided by X. Dong) with $Npy2r^{fl/fl}$ mice (provided by H. Herzog). As expected, the resulting $Y2R^{DRG-/-}$ cKO mice expressed Y2 mRNA in brain (hippocampus) but not DRG. BIIE0246-induced nociceptive and itch behaviors were observed in genetic controls, but not in $Y2R^{DRG-/-}$ mice. We suggest that endogenous NPY acts at Y2R on the central terminals of primary afferent neurons to tonically inhibit nociceptive and itch transmission under normal physiological conditions.

Title: Sex differences in protein kinase A signaling of the latent postoperative pain sensitization that is masked by kappa opioid receptors in spinal cord

Authors: *P. BASU[1], L. CUSTODIO-PATSEY[2], P. PRASOON[1], B. N. SMITH[2], B. K. TAYLOR[3];
[1]Univ. of Pittsburgh, Pittsburgh, PA; [2]Univ. of Kentucky Med. Ctr., Lexington, KY; [3]Univ. of Pittsburgh Sch. of Med., Pittsburgh, PA

Abstract: Surgery leads to chronic postoperative pain (CPP) in 10-50% of patients (Kehlet et al., 2006). Although opioids can effectively treat acute postoperative pain, prolonged opioid therapy is controversial, and no other therapy provides sufficient analgesic efficacy for CPP. We used a very long-lasting model of CPP that involves latent sensitization (LS) of nociceptive neurons in the dorsal horn of the spinal cord and reported that LS is mediated by an N-methyl-D-aspartate receptor (NMDAR) > adenylyl cyclase-1 (AC1) > protein kinase A (PKA) and Exchange factor directly activated by cAMP (Epac) signaling pathway (Corder et al., Science 2013; Fu et al. 2019, 2020); however, these studies were performed in male mice only. To address this gap, we cut the plantar skin and underlying plantaris muscle in male and female mice, waited for behavioral signs of hyperalgesia to resolve, intrathecally injected the selective kappa opioid receptor-selective antagonist LY2456302 to unmask LS, and then evaluated behavioral and molecular signs of pain reinstatement. Interventions included AC1 knockout (KO) mice and pharmacological inhibitors or activators of NMDA (MK-801, 1 µg/5 µL, i.t.), AC1 (NB001, 1.5µg i.t.), PKA (H89, 10 nmol; 6-bnz, 10 nmol) and Epac1/2 (ESI-09, 10µg i.t.; 8-CPT, 3 nmol). LY2456302 but not saline vehicle reinstated mechanical hyperalgesia at the hindpaw even when administered 13 months after surgical incision, indicating that chronic pain vulnerability persists for over a year. When tested three weeks after incision in either male or female mice, we found that reinstatement of mechanical hyperalgesia was blocked with MK801, AC1 gene deletion, or NB001; the latter also attenuated LY2456302-evoked expression of the phosphorylated extracellular signal-regulated kinase (pERK), a marker of neuronal activation in the dorsal horn. Similarly, ESI-09 blocked hyperalgesia, while 8-CPT reinstated hyperalgesia in both sexes. Importantly, H89 prevented LY2456302-evoked reinstatement of mechanical hyperalgesia in male but not female mice, and 6-bnz reinstated postoperative hyperalgesia in male but not female mice. In neither sex did incision change the gene expression of KOR, GluN1, PKA, or Epac1 in the ipsilateral dorsal horn. We conclude that PKA-dependent mechanisms drive LS in a sex-dependent manner. Our results point to the development of AC1, PKA, and Epac inhibitors for the treatment of CPP, particularly PKA-selective inhibitors for men.

Title: In vivo effects of low intensity focused ultrasound in animal models of chronic pain

Authors: *A. HELLMAN[1], P. NEUBAUER[2], G. GHOSHAL[2], C. BURDETTE[2], J. G. PILITSIS[3];
[1]Univ. of Pittsburgh, Pittsburgh, PA; [2]Acoustic MedSystems, Savoy, IL; [3]Neurosurg., Albany Med. Col., Albany, NY

Abstract: ABSTRACT: **Background**: Chronic pain affects 11% of the American population. Traditionally, neuromodulatory treatment for chronic pain is invasive and involves electrical stimulation. **Objective:** Here, we propose an alternative for lower extremity pain using low intensity external focused ultrasound (liFUS) administered to the L5 dorsal root ganglion (DRG).**Methods**: Male and female rats, as well as castrated male domestic swine were utilized to establish the efficacy of liFUS on altering sensory nociceptive thresholds (Von Frey filaments (VFF), hot plate test (HPT) and pain behavior (social/motor/affective scores) in a common peroneal nerve injury (CPNI) model of neuropathic pain. Documentation of sex differences in CPNI rats and of efficacy in a second neuropathic model- vincristine induced neuropathy (VIN)- in male rats further characterized liFUS effectiveness. Safety was assessed with locomotor testing and histological assessment. We gained initial insight into mechanism of action with electrophysiological studies and assessment of cytokine levels in the DRG and dorsal horn (DH) following liFUS. **Results**: LiFUS resulted in reduction of mechanical nociceptive thresholds (VFF) for 3 days in CPNI male rats ($p<0.001$). A similar reduction and time course was seen in VIN male rats ($p<0.001$). The duration of response was significantly longer in CPNI female rats whose VFF thresholds remained elevated for 7 days ($p<0.05$). HPT in both sexes of CPNI and VIN rats were increased for 24hr post treatment ($p<0.05$). Following liFUS, locomotion was intact in all rat groups and hematoxylin and eosin and fluoro-jade staining showed no evidence of damage from liFUS. After adaptation of the device to target
deeper structures and creation of a dose response curve, we were able to confirm our data in swine. VFF thresholds were increased for 5 days ($p<0.01$). Notably pain behavior, i.e. guarding, was reduced for up to 30 days following liFUS. Locomotion and histology again confirmed safety. LiFUS reduced common peroneal nerve latency for 35-55 minutes as compared to baseline in all groups ($p<0.05$). Cytokine measurements in male CPNI rats resulted in a decrease in pro-inflammatory cytokines in DRG 72h post-liFUS (TNFa, IL6, CNTF and IL1b, $p<0.001$). **Conclusion**: Taken together, we establish efficacy of liFUS to the L5 DRG in multiple species, models, and sexes. No functional or pathological damage occurred with the treatment. We hypothesize that liFUS results in alterations of the membrane of DRG cells resulting in immediate changes in CPN conduction and longer-term changes in cytokine levels which temporally correlate with allodynic changes.

Title: Contribution of small diameter non-peptidergic primary afferent neurons to central neuropathic pain in a new, more clinically relevant mouse model of multiple sclerosis

Authors: *K. L. NGUYEN[1], S. R. LAMERAND[2], R. P. DESHPANDE[3], B. K. TAYLOR[1]; [1]Dept. of Anesthesiol. and Perioperative Med., [2]Ctr. for Neurosciences, [3]Dept. of Neurosci., Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Over 50% of multiple sclerosis (MS) patients suffer from neuropathic pain (MSNP). Current treatments give inadequate relief due to incomplete understanding of underlying mechanisms. Recent electrophysiological recordings of primary afferent neurons (PAN) in the dorsal root ganglion (DRG) following experimental autoimmune encephalomyelitis (EAE), a mouse model of MS, revealed increased afterhyperpolarization in small-diameter fibers. These data form the premise of our goal to understand the contribution of small-diameter (peptidergic or non-peptidergic) PANs to MSNP. Arguably the most common method to induce EAE is administration of myelin oligodendrocyte glycoprotein (MOG) to generate an autoimmune response targeting the myelin sheath. A MOG fragment is typically given with two adjuvants: complete Freund's adjuvant (CFA) to boost immunogenicity and pertussis toxin (PTX) to breakdown the blood-brain barrier and facilitate CNS immune cell infiltration. However, PTX can disrupt G-protein coupled receptors, cause pain, and alter autoimmune response gene expression. In 10-week-old C57BL/6 mice, we conducted the first rigorous comparison of a classic PTX EAE model with the novel non-PTX (nPTX) EAE model. We found that both PTX and nPTX EAE mouse models showed the same degree of: 1) motor deficits; 2) plantar hindpaw mechanical and cold hypersensitivity (except cold hypersensitivity resolved more quickly after PTX EAE than nPTX EAE); and 3) lumbar spinal cord demyelination. Unlike most rodent models of MS including PTX EAE, the nPTX EAE group exhibited somatosensory cortex demyelination, a core feature of MS in human patients and cold hypersensitivity. We suggest

nPTX EAE to be the most clinically relevant rodent model available to study not only MSNP, but MS in general. To evaluate the contribution of peptidergic and non-peptidergic neurons to MSNP, we induced nPTX EAE. After 12 days we administered capsaicin (10µg/mouse, i.t.) or IB4-saporin (1.5µg/mouse, i.t.) to primarily ablate peptidergic or nonpeptidergic C-fibers, respectively. Ablation efficacy was successfully confirmed with dramatic loss in DRG of TRPV1/CGRP immunoreactivity (peptidergic C-fibers) following capsaicin, and IB4 immunoreactivity (nonpeptidergic C-fibers) following IB4-saporin. IB4-saporin, but not capsaicin, partially reduced mechanical hypersensitivity and reversed cold hypersensitivity within 9 days. These data suggest nonpeptidergic but not peptidergic C-fibers contribute to MSNP. Our next studies will use genetic knockout, chemogenetic, and optogenetic strategies using $Mrgprd^{CreER}$ mice to modulate the activity of nonpeptidergic C-fibers.

Title: The gut microbiota of environmentally enriched mice regulates visual cortical plasticity

Authors: *S. CORNUTI[1], L. LUPORI[1], R. MAZZIOTTI[2], E. BORGHI[3], E. OTTAVIANO[3], G. SAGONA[4], T. PIZZORUSSO[1], P. TOGNINI[5];

Abstract: Exposing animals to an enriched environment (EE) has dramatic effects on function and plasticity of many different brain areas, including sensory systems. For example, ocular dominance (OD) plasticity, a change in the eye preference of cortical cell responses induced by monocular deprivation (MD), usually present only during a critical period of postnatal development, can be observed in adult mice raised in EE. Classically, the beneficial effects of EE on brain physiology have been explained through mechanisms that arise from the central nervous system (CNS) itself: increased hippocampal neurogenesis, changes in the excitatory/inhibitory circuit balance, structural plasticity of dendritic spines, and others. In our work, the focus has

been shifted to signals coming from the periphery of the body, providing a novel and unexpected link between the gut microbiota and EE-driven plasticity. Indeed, the intestinal microbiota has emerged as a regulator of system-wide physiology, such as immune system development, maintenance of metabolic homeostasis, and moreover, recent evidence shows that the influence of gut microbes goes beyond the periphery towards the CNS. However, little is known about how intestinal bacteria impinge on neuronal function and plasticity. In particular, the existence of a link between experience-dependent plasticity and the gut microbiota has yet to be explored. In our study, we found that EE shaped the intestinal bacteria composition. A longitudinal analysis (P20, P25, P90) of the fecal microbiota composition through 16S rRNA sequencing revealed striking differences between EE and standard (ST) raised animals, especially during adulthood. The depletion of the gut microbiota using an antibiotic cocktail (ABX) was able to prevent OD plasticity and to influence microglia morphology. Using longitudinal 2-photon imaging, we observed also a change in spine dynamics and density in EE+ABX mice compared to EE condition. Furthermore, a mass spectrometry analysis of fecal short-chain fatty acids (SCFAs) - metabolic byproducts of the gut microbiota known to influence brain function - revealed a significant increase in acetate, butyrate and propionate in EE mice. SCFA treatment alone promoted adult OD plasticity and influenced microglia morphology in ST mice suggesting that SCFA could act as a gut-brain signal to promote EE-driven plasticity. Strikingly, transferring the microbiota of EE donor mice to ST mice through fecal microbiota transplant was able to activate adult OD plasticity in the ST recipients. Overall, our work shows that experience-dependent changes in gut microbial composition are able to regulate brain plasticity.

Title: Effects of early blindness on cortical and thalamic connections of multi-modal cortex in the short-tailed opossum (Monodelphis domestica)

Authors: *C. PINEDA[1], L. A. KRUBITZER[2];
[1]Univ. of California Davis, Sacramento, CA; [2]UC Davis, Davis, CA

Abstract: Early changes in sensory input produce dramatic effects on the development of the neocortex. In congenitally blind humans, correlative evidence demonstrates cross-modal

plasticity occurs in the occipital cortex, which is active under several conditions, including during reading braille, auditory-spatial processing, and language processing. Direct evidence from animal models paints a more detailed picture of the changes occurring in the occipital cortex. Studies from our laboratory examining the early loss of vision take advantage of the highly altricial lifestyle of the short-tailed opossum (*Monodelphis domestica*). By bilaterally enucleating opossums at post-natal day 4 (P4), before the formation of retinogeniculate and thalamocortical pathways, we have demonstrated changes in the function and connectivity of the occipital cortex and other spared primary sensory areas, such as the primary somatosensory cortex. These findings recapitulate the cross-modal plasticity in the occipital cortex of early blind humans and illustrate that the loss of input from one primary sensory system has broad effects on the spared sensory systems at both cortical and subcortical levels. No one has examined the consequences of the early loss of vision on higher-order associative areas of the cortex; an area important for multi-sensory integration. We compared the connectivity of higher-order areas of the cortex of sighted and early blind opossums bilaterally enucleated at P4 using neuroanatomical tracing and histological techniques. First, we generated a standard set of coordinates relative to the opossum bregma to target our tracer injections. Then we examined the patterns of organization of cortico-cortical and thalamocortical connections of higher-order cortical area in the sighted short-tailed opossum. Characterizing the normal organization of higher-order cortical areas allowed us to compare the pattern of cortico-cortical and thalamocortical of blind and sighted short-tailed opossums. These data contribute to the growing body of knowledge about the possible cortical modifications in congenitally blind individuals.

Title: Neural mechanisms of short term monocular deprivation in primary visual cortex

Authors: R. A. MILLER, III, *D. Y. TS'O;
SUNY - Upstate Med. Univ., Syracuse, NY

Abstract: Maintaining the appropriate interocular balance, the weighting of left and right eye neural signals to the central visual pathways, is an important prerequisite for achieving the advantages of binocular vision. An altered interocular balance has been demonstrated experimentally in humans and animals following a short-term (1-3 hours) monocular deprivation (STMD). The surprising outcome is a non-Hebbian relative increase in the deprived eye (DE) gain post-deprivation, which in previous psychophysical studies may last up to 90 minutes. The

neural mechanisms underlying this STMD effect are largely unknown. We set out to reveal possible neural mechanisms underlying STMD in the responses of primate V1 neurons. Before, during and after a 1-2 hour STMD of one of the two eyes in adult macaque monkeys, single-unit V1 responses were recorded using a 32-channel linear multi-electrode array. Following the STMD, in a sample cell population (N=155), the single-unit responses revealed an average relative gain of the deprived eye (DE) responses over the non-deprived eye (NDE) responses of 29% as compared with their respective pre-STMD levels. The DE responses remained elevated for about 25 minutes, after which they returned to their pre-STMD levels. In contrast, the post-STMD NDE responses were depressed as compared with their pre-STMD levels, even beyond 25 minutes, thus suggesting possible differences in the time courses of the DE vs NDE STMD effects. Although the supragranular cell population exhibited more robust STMD effects, cells impacted by STMD were found in all V1 cortical layers and constituted 46% of the sample. Preliminary results indicated that extending the duration of the STMD period to 7.5 hours significantly enhanced the STMD effect. Overall, these results from single-unit recordings in primate V1 under the STMD protocol match several key features of the strength of STMD effect reported in the psychophysical literature, and indicate an important contribution to the STMD effect within the V1 circuitry.

Title: Non-invasive Low-Intensity Focused Ultrasound (LIFU) stimulation to promote visual cortex plasticity

Authors: *L. MESIK[1,2,4], M. CONGEDO[5], B. D. GRIER[1,2], D. SEVERIN[2,1], G. EWALL[1,2], S. PARKINS[3], T. HARRIGAN[5], K. SCHULTZ[5], G. M. HWANG[5,4], H.-K. LEE[1,2,4,3];

Applied Physics Lab., Laurel, MD

Abstract: Transcranial ultrasound stimulation has emerged as a promising non-invasive brain stimulation method, which has in principle several advantages compared to other more established non-invasive techniques, such as transcranial magnetic stimulation (TMS) and transcranial direct current stimulation (tDCS). TMS and tDCS have rather poor spatial resolution (in the range of ≥ 1 cm) and are limited to cortical activation. Deep brain stimulation is currently done via invasive electrode implantations. In contrast, transcranial ultrasound stimulation has a more refined spatial resolution (in the mm range) and has the potential to activate deep brain structures. Several studies have reported that transcranial ultrasound stimulation can induce muscle activity, sensory responses, or behavioral changes. In addition, it has been demonstrated that ultrasound activates neurons by eliciting action potentials. However, the biological consequences of ultrasound stimulation are less understood.
Here we demonstrate that low-intensity focused ultrasound (LIFU) stimulation targeted to a deep brain structure, the visual thalamus (dLGN), leads to long-term synaptic plasticity of the thalamocortical inputs to the primary visual cortex (V1) of adult mice. To demonstrate this, we expressed channelrhodopsin2 (ChR2) bilaterally in dLGN and stimulated the dLGN of one hemisphere via transcranial LIFU stimulation (0.54 MHz transducer, 50 c/p, 0.5 kHz PRF) for 1 hour under anesthesia. Mice were bilaterally enucleated prior to the LIFU stimulation to prevent visually-driven activity. Synaptic transmission from ChR2 expressing dLGN axons to V1 layer 4 (L4) neurons were measured *ex vivo* in acute V1 slices several weeks after the initial activation. We found significant depression of thalamocortical synaptic transmission in the stimulated hemisphere compared to the non-stimulated control hemisphere. Our results suggest that non-invasive LIFU stimulation can produce long-term plasticity of thalamocortical synapses in the adult V1. We are currently testing different parameters of LIFU stimulation to determine whether we can drive bidirectional long-term plasticity.

Title: Pairing a visual stimulus with micro-stimulation of the ventral tegmental area increases neural responses on the short term in higher-order visual cortex

Authors: *J. HERPERS[1], W. VANDUFFEL[2], R. VOGELS[1];
[1]KU Leuven, Leuven, Belgium; [2]Radiology, Harvard Med. Sch., Charlestown, MA

Abstract: Electrical microstimulation of the dopaminergic ventral tegmental area (VTA-EM) paired with a task-irrelevant visual stimulus feature increases its representation in the posterior inferior temporal cortex (PIT) at fMRI (Arsenault & Vanduffel, Nature Communications, 2019) and spiking level (Herpers et al., VSS, 2021). These studies suggest that VTA-EM-stimulus pairing is sufficient to induce cortical plasticity in visual cortex. However, the latter studies have only employed longer periods (multiple days) of VTA-EM-stimulus pairing. Here, we investigated whether VTA-EM-stimulus pairing also induces short term plasticity using VTA-EM and electrophysiological recordings in PIT. 2 monkeys performed passive fixation tasks while alternating between multi-unit activity (MUA) recordings or VTA-EM-stimulus pairing epochs. 4 fractal color images were used in each daily session. The PIT recordings alternated with multiple 20-minute VTA-EM epochs (~60 VTA-EM events), where one fractal image was paired with VTA-EM (STIM) while another fractal was presented as control (CON). Two other fractals (dummies) were presented only during the recordings. In both monkeys, we observed a general response reduction to all 4 fractals over the 6-7 recording epochs within a day (with alternating VTA-EM epochs), likely reflecting repetition suppression. After the first VTA-EM epoch, the CON fractal that was presented during the VTA-EM epoch, but not paired with VTA-EM, showed the largest decrease in response. When comparing the relative change in response (STIM-CON) between the recording epochs before the first VTA-EM pairing and the first post-VTA-EM recording epoch, we found a significant increase in relative firing rate to the paired fractal. This effect persisted thoughout the day but did not increase after subsequent VTA-EM epochs. The relative increase in spike rate for STIM-CON might reflect reduced repetition suppression induced by increased responses to the STIM fractal after VTA-EM-pairing. In one monkey only, the relative Fano factor and noise correlations were lower for the STIM-CON pair post-VTA-EM compared to the dummy pair.In conclusion, pairing a fractal image with VTA-EM during passive fixation can influence short term neural response properties in area PIT.

Title: Bidirectional regulation of pyramidal neuron excitability is required for reactivation of ocular dominance plasticity following dark exposure and light reintroduction

Authors: *A. BORRELL, E. M. QUINLAN;
Univ. of Maryland, College Park, MD

Abstract: Amblyopia is a common deficit in visual acuity induced by monocular visual impairment during a “critical period” (CP) of early development when plasticity in visual cortical (V1) circuits is high. Following the CP, both the induction and reversal of amblyopia is difficult, due in large part to the reduction in synaptic plasticity with age. We have shown previously that visual deprivation via dark exposure (DE) followed by light reintroduction (LRx) robustly reactivates juvenile-like plasticity in mouse V1. DE is thought to increase the firing rates of pyramidal neurons in V1 by increasing the expression of GluN2b containing NMDARs (He et al., 2006) and lowering the threshold for Hebbian plasticity at cortico-cortical synapses (Bridi et al., 2018). In addition, DE lowers the threshold for activation of MMP-9-dependent perisynaptic proteolysis at thalamo-cortical synapses, and rapid engagement by LRx is predicted to decrease excitatory drive to the cortex (Murase et al., 2019). Here we test the hypothesis that a decrease in V1 pyramidal neuron excitability induced by LRx is necessary for the reactivation of plasticity following DE in adults. We used targeted, viral-mediated expression of inhibitory chemogenetic Gi-DREADD receptors to maintain hyper-excitability of pyramidal neurons through disinhibition during DE/LRx in adult (P100+) PV-cre mice. Chronically implanted electrode arrays allowed simultaneous recording of single unit (SU) spiking output and visual-evoked local field potentials (VEPs) in V1 of awake head-fixed mice. We found that chemogenetic disinhibition of V1 significantly increased VEP amplitude (19% ±12) and regular spiking (presumptive pyramidal cell) SU spike rates (41% ± 20) across all layers (mean ± SEM) in Gi-DREADD infected, but not uninfected PV-cre control mice. Brief (3 day) monocular deprivation (MD) following LRx induced a significant negative shifts in the ocular preference of cortical responses, indicative of the reactivation of ocular dominance plasticity, in PV-cre control mice (ks test, $p = 3.68e\text{-}4$), but not Gi-DREADD infected mice. In contrast, chemogenetic disinhibition of V1 did not prevent the MD-induced reduction in acuity in response to brief MD (-28% ± 16) consistent with different anatomical loci for these two forms of experience-dependent plasticity (Stephany et al., 2014). This suggests that bidirectional regulation of pyramidal neuron excitability is required for the reactivation of ocular dominance plasticity in adults by DE/LRx.

Title: Chronic monocular deprivation reveals MMP9-independent and -dependent aspects of murine visual system maturation and plasticity

Authors: *S. MURASE[1], S. E. ROBERTSON[2], C. L. LANTZ[1], J. LIU[1], D. E. WINKOWSKI[1], P. O. KANOLD[1], E. M. QUINLAN[1];
[1]Biol., [2]Bioengineering and Biomed. Engin., Univ. of Maryland, College Park, MD

Abstract: The maturation of the mouse visual system includes experience-independent emergence of stimulus selectivity followed by experience-dependent refinement of receptive fields and acuity. Here we combine deletion of the matrix metalloproteinase MMP9 with chronic monocular deprivation (cMD) to ask which aspects of visual system maturation require the activity of this proteinase. Calcium imaging of supragranular neurons of the binocular region of primary visual cortex (V1b) of adult (>P90) wild type (WT) mice of both sexes, following delivery of AAV1.GCaMP6s to V1b (AP: 1.0 mm, MD: -3.0 mm, DV: 0.3 mm, right hemisphere for binocular C57BL/6J and MMP9$^{-/-}$ mice or hemisphere contralateral to cMD eye) demonstrated that cMD initiated at eye opening (P14) resulted in a significant reduction in the contralateral bias (CBI, (C-I)/(C+I), 0.73±0.05 for normal-reared (NR), 0.40±0.03 for cMD, *p=6.8 x 10-4, Student's T-test, n = 5 subjects), and a decrease in the strength of deprived eye visual responses to all stimulus contrasts and spatial frequencies. Despite chronic MD, V1 neurons retained selectivity for orientation ((1-CV), 0.25±0.03 for NR, 0.29±0.04 for cMD, *p<0.05, Student's T-test, n = 59, 51 neurons), direction ((1-dirCV), 0.21±0.03 for NR, 0.38±0.04 for cMD, *p<0.05, Student's T-test, n = 59, 51 neurons) and spatial frequency (mean peak SF, 0.17±0.01 cpd for NR, 0.16±0.02 cpd for cMD, p=0.47, Student's T-test, n = 5 subjects), but direction selectivity was lower in neurons tuned to high spatial frequency (>0.05 cpd) visual stimuli ((1-dirCV), 0.27±0.02 for NR, 0.20±0.02 for cMD, *p<0.05, Student's T-test, n = 94, 95 neurons). Constitutive deletion of MMP9 did not appear to impact the development of stimulus selectivity, as adult MMP9$^{-/-}$ mice had normal spatial frequency (mean peak SF, 0.16±0.04 cpd for NR, 0.11±0.003 cpd for cMD, p=0.47, Student's T-test, n = 5 subjects), orientation and direction selectivity ((1-CV), 0.25±0.02 for NR, 0.24±0.02 for cMD, p=0.44; (1-dirCV), 0.20±0.01 for NR, 0.19±0.01for cMD, p=0.50, Student's T-test, n = 104, 160 neurons). However, MMP9$^{-/-}$ mice were insensitive to plasticity engaged by cMD (CBI, 0.66±0.06 for NR, 0.70±0.02 for cMD, p=0.56, Student's T-test, n = 6 subjects), but retained other forms of experience-dependent synaptic plasticity such as stimulus-selective response potentiation (SRP, familiar: 120.4±4.7% of initial, *p=0.03, novel: 108.7±5.8% of initial, p=0.16, Student's T-test,

n = 5 subjects). Our findings demonstrate that MMP9 is obligatory for reorganization of V1b induced by cMD, but dispensable for other forms of experience-independent and -dependent synaptic plasticity.

Title: Effects of Acute Hypoxia Exposure on Early Visual and Auditory Processing as Measured with EEG

Authors: *K. J. BLACKER[1], D. G. MCHAIL[2];
[1]Envrn. Physiol., [2]Biomed. Sci., Naval Med. Res. Unit - Dayton, Wright-Patterson AFB, OH

Abstract: Hypoxia continues to be a significant aeromedical risk factor. Recent work has demonstrated that acute hypoxia disrupts automatic visual and auditory processing that can be detected at a neural level using EEG. Specifically, passively evoked ERPs were found to track the impairment of sensory processing during a hypoxic exposure. Further exploration of ERPs that occur earlier in the sensory processing stream may provide a more robust indicator of impairment and be developed as an early detection system for hypoxic threats to aircrew. Here, two early sensory ERPs were examined in response to hypoxia: visual and auditory ERPs. Participants underwent three separate experimental sessions: 1) a normoxia baseline where participants were presented with visual and auditory stimuli, separately, 2) a hypoxia session with visual stimuli presented, and 3) a hypoxia session with auditory stimuli presented. Normobaric hypoxia exposures (9.7% O_2) were delivered via a reduced oxygen breathing environment. For the visual paradigm, participants were shown a reversing black and white checkerboard stimulus and the P100 component was measured as the response to the pattern reversal every 1 second. The P100 is thought to reflect the integrity of visual information processing and arises from neural activity in primary visual cortex. For the auditory paradigm, participants were presented with pairs of auditory tones and a series of waveforms that index different stages of sensory gating were measured including the P50, N100, and P200. Typically, there is a reduction in the amplitude of these components in response to the second tone in the pair, which is known as sensory gating and reflects efficient filtering of redundant information. Under hypoxic conditions, compared to normoxia, there was a significant reduction in the

amplitude of the visual P100 component. This difference represented a 25% reduction in amplitude. For the auditory paradigm, there was no difference in sensory gating for the P50 or N100 between hypoxia and normoxia; however, the P200 component showed a trend toward lower gating scores under hypoxic conditions. Our results here are consistent with previous work showing that passively elicited ERPs in response to both visual and auditory stimuli are disrupted during hypoxia. Notably, we found a robust effect in the visual domain suggesting that the P100 may be a viable candidate as a neural biomarker of visual impairment during hypoxia. In the auditory domain, only the P200 component showed changes with hypoxia, which is consistent with previous work showing that auditory processing is affected at later stages of processing compared to the visual system.

Title: The behavioral relevance of aging-related changes to motor cortical receptor dynamics

Authors: *T. S. NOVAK[1], J. R. NOCERA[1,2], L. C. KRISHNAMURTHY[1,3], K. M. MCGREGOR[1,2];
[1]Ctr. for Visual and Neurocognitive Rehabil., Atlanta Veterans Admin. Med. Ctr., Decatur, GA; [2]Neurol., Emory Univ., Atlanta, GA; [3]Physics & Astronomy, Georgia State Univ., Atlanta, GA

Abstract: The inhibitory receptor dynamics of cortico-motor circuitry demonstrate remarkable change as a function of normal aging. However, to date, there is a lack of consensus on the functional significance of these dynamics in the context of adaptive motor skill acquisition. In the current study, we used paired-pulse transcranial magnetic stimulation (TMS) to examine intra-cortical inhibitory function in a sample of 17 healthy older adults (mean=65 ±4 years). Short intracortical inhibition (SICI) and long intracortical inhibition (LICI) TMS measures were evaluated at rest and during submaximal voluntary contraction to examine individual aging differences in state-dependent intracortical inhibition. Subjects were then split into subgroups where they performed a single session of motor sequence learning under a unique set of sensorimotor demands (low demand: 8 button sequence at 1000ms intervals (n=9); high demand: 12 button sequence at 500ms intervals (n=8)). SICI values varied significantly between subjects in both resting and event-related TMS conditions, with the sample distribution primarily exhibiting cortical facilitation. LICI values were less variable, however, the group distribution

indicated a presence of subject-dependent inhibition or facilitation with long-interval paired pulse-stimulation. Interestingly, SICI and LICI values were inversely correlated with performance adaptations (accuracy and reaction time) in the early stage of motor practice for both groups, meaning subjects with higher values of event-related facilitation performed sequential learning faster and more accurately. Moreover, correlations were consistently stronger in the high demand practice condition. The conclusions are three-fold: Relations between cortico-motor receptor function and behavioral outcomes may be best established in the context of an event-related cortical state; sufficient task constraints should be considered to address individual differences in the aging motor system; and increases in state-dependent excitability levels might act as a compensatory mechanism for older adults to quickly acquire novel motor skills. Provided motor skill acquisition is a complex, non-linear process, aging-related cortical mechanisms underlying unique timescales of sensorimotor adaptation requires further investigation.

Title: The effects of a cognitive walking program on improving motor function of the brain in older adults

Authors: *J. WANG[1], S.-J. KANG[2];
[1]Univ. of Wisconsin - Milwaukee, Milwaukee, WI; [2]Sangmyung Univ., Seoul, Korea, Republic of

Abstract: Aging is typically associated with a decline in both cognitive and motor functions of the brain. However, slowing or reversing that process may be possible through physical activity. We recently demonstrated that a walking-based indoor exercise program, called a ‘cognitive walking program’ (CWP), has beneficial effects for improving cognitive function in both physically active and sedentary older adults (Kang et al. 2021). However, it is unknown whether the same exercise program is also beneficial for improving motor function of the brain. In the current study, we investigated the effects of CWP on motor function of the brain by examining changes in the pattern of interlimb transfer following visuomotor adaptation in physically active and sedentary older adults. Healthy older adults were divided into two groups based on their

physical activity level: active and sedentary. All subjects in both groups participated in the CWP for 6 months (60 min/session, 3 sessions/week). To assess motor function of the brain, we employed a visuomotor adaptation task and examined the pattern of interlimb transfer, in terms of initial direction errors, following visuomotor adaptation. It was hypothesized that if the CWP had beneficial effects, the pattern of transfer would change from a symmetrical (i.e., transfer from the left to the right arm, and vice versa) to an asymmetrical pattern (i.e., transfer only from the left to the right arm) with the progress of the CWP, as suggested in our previous studies (Wang et al. 2011, 2016). Results showed that transfer of visuomotor adaptation occurred symmetrically in both subject groups before the subjects began the CWP, and that the symmetrical pattern was maintained even after 6 months. There was no significant difference between the two groups. These results suggest that the CWP may have beneficial effects for improving cognitive function of the brain in older adults, but not for improving motor function of the brain in older adults, at least when the motor function is reflected as the changes in the pattern of interlimb transfer following visuomotor adaptation.

Title: Facilitative effects of use-dependent learning on interlimb transfer of visuomotor adaptation in a person with congenital mirror movements

Authors: *Y. JO, M. JAVIDIALSAADI, J. WANG;
Dept Kinesiology, Univ. of Wisconsin, Milwaukee, WI

Abstract: It has been shown that use-dependent learning can facilitate interlimb transfer of motor learning in neurologically intact individuals. However, it is unknown whether it can also facilitate interlimb transfer in individuals with neurological impairment. Here, we examined the effect of use-dependent learning on interlimb transfer of visuomotor adaptation in a person with congenital mirror movements, DB, who showed no interlimb transfer previously (Bao et al. 2020; Javidialsaadi and Wang 2021). In the current study, DB first performed reaching movements with the right arm repeatedly while adapting to a visuomotor 30-degree counterclockwise rotation condition with the left arm, and then adapted to the same rotation condition with the right arm, which resulted in substantial transfer. The results show that the percentage of interlimb transfer was over 90%, which is similar to that observed in healthy young adults in our previous study results. These findings suggest that visuomotor adaptation involves two learning mechanisms: model-based learning, which is effector independent; and

use-dependent (or model-free) learning, which is effector specific. These findings also suggest that whereas both types of mechanisms can contribute to interlimb transfer of motor learning, the relative contribution of use-dependent learning can be at least as large as that of model-based learning (if not greater). Collectively, these findings indicate potential benefits of use-dependent learning for neurorehabilitation in individuals with brain lesions (e.g., cerebellar damage).

Title: Parkinson's disease does not impair implicit sensorimotor adaptation

Authors: *J. TSAY, T. NAJAFI, L. SCHUCK, T. WANG, R. IVRY;
Psychology, UC Berkeley, Berkeley, CA

Abstract: Whether implicit motor adaptation is impacted by Parkinson’s Disease (PD) remains a topic of debate, an issue that is of particular relevance given increasing evidence of interactions between reward- and error-based learning processes. Several early studies reported impaired implicit adaptation in PD, whereas recent work failed to observe deficits in this group. There is a range of methodological differences making it difficult to reconcile these disparate results. Moreover, most studies have used conventional sensorimotor adaptation tasks that fail to isolate implicit adaptation from the influence of explicit learning processes. We revisited this problem using a clamped feedback method that isolates implicit adaptation. In Experiment 1, participants reached to one visual target, while on each trial the angular position of the feedback cursor was shifted from the target (not the hand) by either 3°, 10°, 30°, or 45°, with the direction (CW or CCW) randomized. Implicit adaptation was indexed by the change in hand angle from trial n to trial n + 1. By sampling a wide range of visual errors, we could assess whether PD and their age-matched controls differ in their error sensitivity. For both groups, the adapted response scaled with the error size between 3° and 30°, and then saturated. Importantly, the function was similar for the PD and controls. In Experiment 2, participants reached to one of two locations on each trial. For each location, the direction (CW vs CCW, varied between subjects) and the size (3° or 30°, varied by location within-subjects) was fixed for 150 trials. In this manner, the effects of implicit adaptation to each invariant perturbation will accumulate over trials; as such, any subtle group differences should be magnified. The rate of adaptation was faster in response to the larger

clamp and reached a higher asymptotic value (collapsed over groups: 3° = 13.7°; 30° = 26.4°). Again, the PD and controls did not differ in terms of rate or asymptote. These null results motivated us to perform a meta-analysis of implicit adaptation and PD. We restricted the analysis to studies that reported an aftereffect, a measure that best reflects the degree of implicit adaptation without contamination from other learning processes. The effect size ranged from -2.28 to 1.09 (negative = attenuated adaptation relative to controls, positive = enhanced), with significant heterogeneity between studies (I^2 = 62%, $p < 0.01$). The mean effect size of -0.36 (95% CI = [0.03, -0.75]) was not significant, with 10 of the 15 studies including 0, the null hypothesis. Taken together, the results from the current experiments and the meta-analysis indicate that PD does not impact implicit adaptation.

Title: Post-learning alcohol ingestion as a pharmacological agent to investigate the mechanisms of motor memory consolidation

Authors: *O. DEMERS[1], R. HAMEL[2], J.-F. LEPAGE[3], P.-M. BERNIER[4];
[1]Univ. de Sherbrooke, Hâvre aux Maisons, QC, Canada; [2]Physiologie, Univ. de Sherbrooke, Sherbrooke, QC, Canada; [3]Pediatrics, Sherbrooke Univ., Sherbrooke, QC, Canada; [4]Dept. de Kinanthropologie, Univ. De Sherbrooke, Sherbrooke, QC, Canada

Abstract: Memory consolidation refers to the entirety of neuroplastic phenomena that occur following learning allowing for newly formed memories to transform into long-term memories. However, the mechanisms of this process for human motor memories remain unknown. Interestingly, human studies on declarative memories indicate that pharmacological interventions seeking to increase GABAergic activity immediately post-learning dose-dependently enhance memory consolidation. This study sought to evaluate if such intervention can also enhance motor memory consolidation by testing the following hypothesis: post-learning alcohol consumption - a pharmacological agent known to increase GABAergic activity, amongst other actions - will dose-dependently enhance motor memory consolidation as compared to a placebo condition. To that purpose, a fully within-subject and counterbalanced design was carried out where participants (n = 24; 12 males) had to adapt to a gradually introduced visual deviation and then

ingest a beverage that either contained no (Placebo), a Moderate or High alcohol dose. The alcohol doses were sex- and body weight-adjusted to reach a peak blood alcohol concentration of 0.000%, ~0.050%, and ~0.100% for the Placebo, Moderate, and High conditions, respectively. To assess consolidation, retention was assessed 24h later through reach aftereffects. Preliminary results (n = 22) revealed that, contrary to the hypothesis, alcohol did not influence consolidation. Specifically, long-term retention in both the Moderate and High conditions - on average - did not meaningfully differ from the Placebo condition (all Cohen's $d_z < 0.150$).

Title: Age-related Changes in Electrophysiological Correlates of Visuomotor Adaptation

Authors: *A. T. WATRAL[1], I. FLINT[1], L. RAJESHKUMAR[2], M. SAGUE[1], K. TREWARTHA[1];
[1]Cognitive and Learning Sci., Michigan Technological Univ., Houghton, MI; [2]Yale Univ. Sch. of Med., New Haven, CT

Abstract: Motor learning is known to progress on multiple timescales with initial rapid improvements inperformance, followed by more gradual improvements through repeated practice. Thesetimescales have been attributed to two processes that learn and forget at different rates: A fastprocess allows performance improvements to occur rapidly by adapting strongly to errors, and aslow process that responds to errors more gradually and provides slower gains in performanceover time. This latter process may contribute to solidification of a motor memory. This impliesthat different neurocognitive mechanisms are responsible for initial motor learning driven by thefast process and more gradual learning driven by the slow process. While the neuralmechanisms associated with motor learning are not fully understood, previous researchsuggests that a neurophysiological signature of context updating and learning - the P300 event-related potential (ERP) component - diminishes across learning in younger adults. Aging isassociated with diminished visuomotor adaptation, particularly in the earliest phase of learning.To examine the neurophysiological correlates of age-related changes in visuomotor adaptation,we compared the modulation of the P300 across learning between healthy younger and olderadults. Continuous electroencephalogram (EEG) recordings were acquired while participantsperformed a visuomotor rotation (VMR) task. Younger adults adapted to the rotation better thanolder adults, particularly in the earliest phase of adaptation, consistent with previous research.ERP analyses revealed that a posterior P300 (P3b) component was elicited by the

targetsduring the VMR task and the magnitude of this component was reduced across adaptation inthe younger participants. This modulation was less pronounced in the older participants. TheP3b was also larger in the first quarter of the adaptation trials in younger compared to olderadults suggesting that the ability to update working memory with task context informationfacilitated better early learning in younger compared to older adults. These observations provideinsight into the neural basis of age-related changes in sensorimotor adaptation. Modulation ofthe magnitude of the P3b across learning may reflect a shift from fast process-mediatedlearning to slow-process mediated learning and suggests that the neurocognitive mechanismssupporting performance change as adaptation unfolds.

Title: Changes GABA concentration in the sensorimotor cortex in older adults during motor skill acquisition

Authors: *G. CHAMPION[1], J. R. NOCERA[2], L. C. KRISHNAMURTHY[2], T. S. NOVAK[2], K. MAMMINO[1], K. MCGREGOR[1];
[1]Georgia State Univ., Atlanta, GA; [2]DVA, Decatur, GA

Abstract: Aging is associated with changes in cortical excitability which may affect motor learning *via* selective modulation of gamma aminobutyric acid (GABA). Previous studies using magnetic resonance spectroscopy (MRS) to measure GABA in younger adults found that GABA in the sensorimotor cortex (M1S1) tended to decrease during the execution of a repeated motor sequence. We are not aware of any studies investigating changes in dynamic GABA in older adults, who evidence slower and more variable performance during motor skill acquisition. The dynamic change in GABA density in M1S1 in older adults is currently unknown and represents a critical gap in our understanding of behavioral performance to neurometabolite changes during motor learning. As such, the purpose of the current study is to quantify changes in cortical GABA during motor learning in the aging brain. We hypothesize that older adults with greater dynamic range in M1S1 GABA levels will display more efficient motor learning. We report on a total of 14 healthy older adults aged 62 to 80 years (M = 69.71, SD = 5.68, nine females). Using MRS at 3T, we measured changes in GABA concentration in M1S1 during an eight or 12 finger-

movement motor entrainment (2 or 3 runs) and recall (2 runs) task. Seven subjects entrained on an eight-movement sequence and eight subjects entrained on a 12-movement sequence (one subject completed both sequences in separate sessions). Learning was assessed as a combination of correct finger movements and timing (500 ms per movement) across all runs. Participants were considered "learners" if they performed at 40% accuracy or greater during recall. We used Gannett for GABA quantification relative to water. For the eight-movement sequence, four out of seven subjects were learners and for the 12-movement sequence, three out of eight participants were learners. An independent samples *t*-test was performed to examine change GABA levels from Rest1 to Recall1 between learners (n = 7) and non-learners (n = 8). Learners (M = -.71, SD = .92) had a greater change in GABA compared to non-learners (M = -.07, SD = .25) with a trending significance, p = .081. There was a significant correlation between change in GABA levels from Rest1 to Recall1 and performance accuracy of Recall1, r_s = -.47, p = .04. Older adults who were able to accurately perform the task had a more dynamic range GABA levels that correlated with performance. This modulation of GABA associated with better performance could be related to changes in neuroplasticity. Although these results are in the preliminary stages, they point to a greater understanding of aging related changes in motor performance and future rehabilitation.

Title: Conflict induced relationship between multi-unit spike trains and behavior

Authors: *J. MCDONNELL, J. S. NEIMAT, A. ALHOURANI, S. WYLIE, N. VAN WOUWE;
Neurolog. Surgery, Univ. of Louisville, Louisville, KY

Abstract: *Introduction*: Deep brain stimulation (DBS) is an effective treatment option for neurodegenerative movement disorders. In Parkinson's disease, stimulating subthalamic nuclei (STN) reduces abnormal oscillations in cortico-striatal circuits caused, presumably, by a lack of dopamine. STN activity exerts an excitatory effect on inhibitory output structures of the basal ganglia, which results in suppression of action. Previous evidence suggests functional specialization in dorsal and ventral subregions of the STN based on dissociable inputs from pre-

frontal/motor and limbic regions, respectively. More recently, DBS targeting the dorsal STN, but not the ventral STN, improved the proficiency of suppressing impulsive actions triggered in a response conflict task. In the current study, we extended this work by testing the hypothesis that neuronal spike activity in dorsal STN would increase on conflict trials that required the suppression of an incorrect action impulse. *Method*: We examined bilateral STN neuronal spike activity in 6 PD patients during performance of a Simon response conflict task. The task and recording were performed intraoperatively, prior to surgical implantation of DBS electrodes. The Simon conflict task was first performed when electrodes were situated just below the dorsal border of the STN, and a second round of trials was performed when the electrode was positioned 2-3 mm ventrally. The Simon task requires a left or right directional response to a feature (color) of a spatially lateralized stimulus. When the action signaled by the location and color of the stimulus are non-corresponding thereby inducing conflict, the inappropriate action impulse must be suppressed. *Results*: Behaviorally, we replicated the typical findings of the Simon conflict task with longer reaction times and less accurate performance on non-corresponding trials compared to corresponding trials. The preliminary neurophysiological analyses suggest there was a tendency for increased multi-unit activity in the right ventral STN with non-corresponding trials. This effect was less prevalent in dorsal and left hemisphere STN. As more data is collected, additional investigation regarding the relationship between the behavioral metric derivatives and correlating spike rates of STN subregions will be deconstructed and related to trial type, laterality, and subregion. *Conclusion*: Based on the preliminary findings, we conclude that both hemisphere and STN subregion play a role in conflict processing. In furthering our understanding of this neuroanatomical relationship, a more precision based approach can be adapted across various applications and populations.

Title: The effect of limb dominance on the cortical response after mechanical perturbation to the hand

Authors: *K. HOOKS[1], K. KIANI[1], Q. FU[2];
[1]Mechanical and Aerospace Engin., [2]Univ. of Central Florida, Orlando, FL

Abstract: The ability to move through a complex world and react to changing conditions is critical for human movement. Previous electromyography (EMG) research has shown that the

response to a mechanical perturbation on the upper extremities can be divided into three components; a short-latency reflex, long-latency response, and voluntary response (20-50ms, 50-100ms , 150+ms post-perturbation, respectively). However, the cortical dynamics underlying the corrective actions after such perturbation remains largely unknown. The focus of this research is to examine the neural contributions of the ipsilateral and contralateral hemispheres following a mechanical perturbation on either right or left hand when the hand is moving to a target. We quantified the neural activity using electroencephalography (EEG) to determine the effect of limb dominance. Right-handed subjects (n=9, 4 male, 5 female, age 25.5 yrs +/- 5.02 yrs) performed unimanual up or down targeted movements (n=200 trials) with either hand using a haptic robotic device, during which a perturbation may or may not be applied. Kinematic analysis revealed no difference between hands in the spatiotemporal characteristics of the post-perturbation movement. Furthermore, we found no difference between the cortical event-related potential (ERP) of two hands during 0 to 150 ms period post perturbation[QF1] , i.e., ERP distribution in left hand conditions mirrored the distribution in right hand conditions. Lastly, event-related spectral perturbation (ERSP) analysis of the low beta frequency band (13-20 Hz) showed stronger synchronization in contralateral motor and pre-motor areas than the ipsilateral ones during 78-122 ms post-perturbation, and this synchronization was overall significantly stronger when the dominant right hand was perturbed than the non-dominant left hand (two-way repeated measures ANOVA).

Title: Startling acoustic simulation causes a greater reduction in reaction time for shoulder abduction compared to hand opening

Authors: *K. WRIGHT[1], Y. ZHAO[2,1], J. P. DEWALD[1], J. YAO[1];
[1]Physical Therapy and Human Movement Sci., Northwestern Univ., Chicago, IL; [2]Dept. of Bioengineering, Chongqing Univ., Chongqing, China

Abstract: Startling acoustic stimulus (SAS) has been proven to elicit a quick release of a prepared movement, likely via the reticulospinal tract (RST). Previous research by Carlsen et al. 2009 found that finger abduction, which is thought to be mediated by corticospinal connections, does not exhibit a startle response (SR). Their results support that the SR is primarily mediated

by the RST. Following this, Honeycutt et al. 2019 found that the SR was triggered during coordinated grasp but not individuated finger movements. Based on this, they suggested that the RST is involved in whole hand coordination, but not individual finger movements.
In this study, we investigated the effect a SAS has on RT for hand opening (OPEN) compared to shoulder abduction (LIFT). Based on the findings discussed, we hypothesized that a SAS would cause a reduction in RT for both OPEN and LIFT, with a more pronounced effect for LIFT.
To test our hypothesis, we recruited four able-bodied participants with right-hand dominance, and no known hearing deficits to perform OPEN and LIFT movement tasks. OPEN and LIFT were assigned to separate trial blocks, each consisting of 25-35 trials. All trials began with an 80 dB 'ready' sound to indicate the start of the trial. Participants were instructed to self-initiate the specified movement 5-6 s after hearing the 'ready' sound. For 90% of all trials, a 2nd sound cue was delivered 1.5-2 s after the 'ready' sound to indicate participants perform the specified movement as quickly as possible. This 2nd sound was either an 80 dB 'go' sound (67% chance) or a 115 dB 'startle' sound (33% chance). EMGs were recorded from intermedia deltoid (IDL), extensor carpi radialis (ECR), and left and right sternocleidomastoid (SCM). We calculated RT as the time between the 2nd sound cue and the onset of IDL activity (for LIFT) or ERC activity (for OPEN).
Our results showed that the SAS significantly reduced the RT for both OPEN and LIFT when compared to the 'go' condition RT. However, the difference between 'startle' and 'go' RT was significantly greater for LIFT (134.2±40.5 ms) compared to OPEN (93.4±37.3 ms). As a sign for a positive startle response, SCM activity was found in 94% of SAS trials during LIFT, but only in 56% during OPEN. Additionally, we found that the SCM activity for 'startle' trials was significantly greater for LIFT compared to OPEN. These findings are consistent with the previous literature and lend additional support to the argument that the SR is mediated by RST pathways, which tend to innervate proximal muscles more heavily as compared to distal muscles.

Title: Impairments of reaching corrections after rTMS over the human medial parietal cortex

Authors: *R. BREVEGLIERI, S. BORGOMANERI, A. BOSCO, M. FILIPPINI, A. TESSARI, A. AVENANTI, C. GALLETTI, P. FATTORI;
Univ. di Bologna, Bologna, Italy

Abstract: Human area V6A (hV6A) is located in the posteromedial part of the posterior parietal cortex and is involved in movement planning and state estimation of the arm during reaching actions. Patient studies have demonstrated that the posterior parietal cortex is also implicated in online reaching corrections. However, it is still unknown whether hV6A plays a causal role in this process. To investigate the causal role of hV6A in action reprogramming, we interfered with hV6A functions using repetitive transcranial magnetic stimulation (rTMS, 10Hz, 3 pulses) in a group of right-handed healthy participants. The position of hV6A in each participant according to the Talairach coordinates used in a previous TMS study (Ciavarro et al J Cogn Neurosci. 2013 Sep;25(9):1453-62) was assessed by frameless stereotaxic neuronavigation (Softaxic system, EMS Medical, Bologna). Participants performed visually-guided reaching movements towards targets located at different depths and directions with the arm contralateral (right) to the stimulation site (left hV6A). rTMS was delivered 50 ms after the movement onset. In a small amount of trials, the reaching target disappeared and re-appeared in a different location, so the participants had to perform in-flight adjustments of the arm trajectory. Following stimulation over hV6A, we found larger deviations of the perturbed trajectory, specifically when the perturbation required further extension of the arm. These deviations followed a specific time-course, being present in the middle of the movement and never in the final part of it. This work provides the first evidence of a functional role of hV6A in action reprogramming during reaching.

Title: Explicit motor sequence learning in Parkinson's Disease

Authors: *K. PRESBREY, K. LOUIE, M. YAROSHINSKY, D. WANG;
UCSF, San Francisco, CA

Abstract: The neural dynamics of explicit motor sequence learning in Parkinson's Disease (PD) are poorly understood, and there are currently no good treatments for impairments in motor learning in PD patients. In either a high or low dopamine state, PD patients practiced known sequences for multiple days in a typing task that required discrete sequence production upon presentation of visual cues. Clinical motor assessments were used to verify treatment state and score acute motor impairment each day of the experiment. Chronic wireless brain implants located in the cortex and basal ganglia recorded local field potential, and a custom behavioral apparatus determined finger kinematics. In this confirmatory study, patients exhibited learning, and neural activity demonstrated learning- and treatment-specific changes.

Title: Voluntary motor commands are preferentially released during restricted sensorimotor beta rhythm phases

Authors: *S. J. HUSSAIN[1], M. K. VOLLMER[2], I. ITURRATE[3], R. QUENTIN[4];
[1]Kinesiology and Hlth. Educ., Univ. of Texas at Austin, Austin, TX; [2]Natl. Inst. of Neurolog. Disorders and Stroke, Bethesda, MD; [3]Amazon EU, Barcelona, Spain; [4]Lyon Neurosci. Res. Ctr., Lyon, France

Abstract: BACKGROUND: Sensory perception and memory are enhanced during restricted phases of ongoing brain rhythms, but whether voluntary movement is constrained by brain rhythm phase is not known. Voluntary movement requires motor commands to be released from the contralateral motor cortex (M1) and transmitted to spinal motoneurons and effector muscles. However, M1 activity oscillates between excitatory and inhibitory phases that correlate with single-neuron spiking rates and descending output from M1 to the spinal cord. Here, we tested the hypothesis that voluntary motor commands are preferentially released from M1 during circumscribed phases of ongoing sensorimotor rhythms. If true, contralateral but not ipsilateral sensorimotor rhythm phase during motor command release should be biased towards a specific phase. METHODS: 21 healthy adults performed a self-paced finger movement task during electroencephalography (EEG) and electromyography (EMG) recordings. During this task, subjects viewed a series of pictures on a computer screen and pressed a button with their left index finger whenever they wished to view the next picture in the series. Single-pulse TMS was used to determine each subject's corticomuscular conduction latency between M1 and the left first dorsal interosseous muscle. Then, the time of motor command release preceding each finger

movement was estimated by subtracting each subject's corticomuscular conduction latency from movement-specific EMG onset times. Finally, we calculated the contralateral and ipsilateral sensorimotor mu and beta phase angle at this time point for each finger movement. Phase angles were averaged within each subject and separately pooled across all subjects for each frequency and hemisphere. RESULTS: 31.01 ± 13.7% and 64.94 ± 19.33% of finger movements contained mu and beta periodic activity that exceeded the aperiodic component of the power spectrum. Further, contralateral beta phase angles during motor command release clustered near the peak of the beta cycle, exhibiting a significant unimodal deviation from uniformity at 122.48° (Rayleigh's test, p=0.001). In contrast, contralateral mu phase angles, ipsilateral mu phase angles, and ipsilateral beta phase angles were uniformly distributed across all possible phases during motor command release (Rayleigh's test, p>0.25 for all). CONCLUSION: Consistent with our hypothesis, results demonstrate that voluntary motor commands were preferentially released from M1 just after the peak phase of contralateral sensorimotor beta cycles. We conclude that contralateral beta phase sculpts a fundamental aspect of voluntary human movement.

Title: A future for ecologically valid human neuroimaging: demonstration of real-time, ambulatory, low-dose PET imaging

Authors: *N. K. SIVA[1], C. BAUER[7], C. GLOVER[2], A. STOLIN[3], J. W. LEWIS[4], S. CHANDI[5], H. MELNICK[5], G. MORANO[3], B. PARKER[3], M. MANDICH[6], J. QI[8], S. MAJEWSKI[8], J. A. BREFCZYNSKI-LEWIS[2];
[1]Sch. of Med., [3]Radiology, [4]Dept Neurobio. & Anat., [5]Rockefeller Neurosci. Inst., [6]Div. of Physical Therapy, [2]West Virginia Univ., Morgantown, WV; [7]Neurosci., Univ. of Kentucky, Lexington, KY; [8]Univ. of California Davis, Davis, CA

Abstract: Background:Motion enabling human brain-dedicated PET could offer quantitative imaging with high spatial resolution of both surface and deep brain structures. Here we test the motion tolerance of a limited field-of-view prototype PET imager, AMbulabory PET (AMPET), with the goal of facilitating ecologically valid study designs and ability to scan subjects with difficulty remaining still, such as those with movement disorders, cognitive impairments, or the very young/old.
Methods:AMPET consisted of 12 silicon photomultiplier-based detectors arranged in a ring and suspended by an external support system, such that the friction-fit imager moved with the patient head. Immediately after a 1-2 millicurie bolus of F^{18}-FDG, eleven subjects (including one with a leg prosthetic, 2 removed due to data collection error) performed a 6-minute task that alternated between 30 second periods of walking-in-place and standing still. We compared motion artifact in brain vs. non-brain region of interests, and measured activity in task-appropriate (leg motor cortex, basal ganglia, thalamus) vs. non-task brain regions.
Results:A mixed effects model demonstrated no statistically significant difference in the ratio of total brain activity to activity spillover to surrounding regions for the walking and standing still periods. During image processing, we did not visually detect any blurred edges or ghosting effects that are usually indicative of motion artifacts. For task analysis, a priori leg motor cortex showed greater activity than non-motor/ non-visual-motor cortical regions ($p<0.01$). Our results were further supported by exclusively contralateral leg ROI activation in a leg amputee participant, and increased activity in basal ganglia and thalamus in a subset of 4 participants with the imager repositioned lower on the head.
Conclusion:Based on both visual and statistical measures, we found no significant motion artifacts, and task-related data were uncompromised. Furthermore, we were able to image deep brain structures, which is not possible with other motion-enabling neuroimaging modalities (EEG, fNIRS) and scanned in an ordinary laboratory without shielding, unlike MEG or MRI. The low dose enables longitudinal scanning and access to vulnerable populations. Combining motion-enabling PET with bolus-infusion delivery of radioligand could enable fMRI-like studies with minute level temporal resolution and spatial resolution within millimeters. Previously confined to highly adapted laboratory environments, real-time neuroimaging of motor functions, addiction behaviors, and social interactions could be studied in more natural settings.

Title: Brain imaging in motion: Bolus-infusion task-based FDG-PET imaging of human brain during treadmill walking

Authors: *C. GLOVER[1], N. SIVA[1], A. STOLIN[2], G. MORANO[2], A. HAHN[4], L. RISCHKA[5], R. LANZENBERGER[5], S. MELROY[3], H. MELNICK[3], K. RADCLIFF[1], S. CHANDI[1], T. WUEST[3], S. MAJEWSKI[6], J. A. BREFCZYNSKI-LEWIS[3];
[1]Rockefeller Neurosci. Inst., [2]Radiology, [3]West Virginia Univ., Morgantown, WV; [4]Dept. of Psychiatry and Psychotherapy, [5]Med. Univ. of Vienna, Vienna, Austria; [6]Univ. of California Davis, Davis, CA

Abstract: Background: While Positron Emission Tomography (PET) provides a successful method of quantifying neuronal activation in the brain, few devices allow the flexibility to image freely moving subjects. Also, most PET paradigms utilize radioligands such as the widely available metabolic marker 18F-FDG, as a bolus injection, which requires separate day visits for task vs. baseline. The present study examines a novel support system for a wearable limited field-of-view prototype PET imager, Ambulatory PET (AMPET), in combination with radioligand delivery protocols to allow for task-based imaging similar to block-design fMRI.
Methods: AMPET consists of a ring of 12 silicon photomultiplier-based detectors friction-fit to follow the patient's head movements. The Biodex Unweighing System was adapted to not only support the weight of the patient in the event of a fall, but to fully support the PET imager with a counterweight. The support system allowed the participant to walk naturally on a treadmill while wearing the imager. An EMG (muscle activity) and VICON (infrared motion detection) study (n=20) was performed with a facsimile weighted imager to test for harmful muscle activity in the neck or back and motion interference during walking movements. For 18F-FDG imager study, a bolus-infusion 18F-FDG protocol was used for a 20-minute task alternating between 5 minute intervals of walking and seated (rest). A bolus of 1.1 mCi 18F-FDG was delivered followed by a constant infusion of 0.9 mCi for the entire duration of the imaging session (n=5, 5 additional participants had a rate recording error). Analysis used an a priori leg motor cortex ROI based on a previous PET walking study (Huang et al. 2018), comparing brain activation patterns during walking and rest.
Results: The EMG study of the facsimile imager supported by the Biodex system revealed no significant increase of muscle activity for walking task. VICON data showed speed and acceleration movements were impaired (speed $t=9.2$, $p<.0001$, acceleration $t=8.2$, $p<0001$). In the AMPET imaging study, our limited field of view imager was able to capture the expected trend of higher activity in leg motor ROI in the walking period (normalized mean±sd = 0.0041±0.0008) as compared to rest (0.0039±0.0009)
Conclusion: The task-based 18F-FDG motion-enabling AMPET may allow multiple tasks and baseline scans in a single session of behaviors that require moderate motion, but not fast accelerations. Additionally, our prototype imager will allow for an advancement in neuroimaging

by permitting real-world and virtual immersive studies with free range of motion to be conducted. A higher dose of ligand is likely needed for superior image quality.

Title: Machine learning of EEG data during task visualization can distinguish between well-learned and unfamiliar motor skills

Authors: *J. SHATTUCK[1], M. R. JOHNSON[2];
[1]PantherTec, Evergreen, CO; [2]Dept. of Psychology, Univ. of Nebraska-Lincoln, Lincoln, NE

Abstract: Neural activity that occurs during imagined performance of a motor task (motor imagery) has been well established to be neurophysiologically similar to the actual performance of the motor task, albeit greatly attenuated. Machine learning classification of different visualized tasks can differentiate sleeping from drumming, listening to music or walking, etc. However, determining the skill level of the subjects visualizing the task has not been explored with this method. EEG data collected during visualization of a Known (previously acquired) skill were compared to data collected during visualization of an Unknown (non-acquired) motor skill, and analyzed with a relatively simple convolutional neural network. Our hypothesis was that a binary (Known or Unknown) skill level of the imagined task could thus be classified from the EEG data.Twenty human subjects were instructed to visualize performing a motor-based task from a first-person perspective for 2 minutes with eyes open in a quiet room. Each subject wore a 14 channel, 128 Hz portable EEG headset. Prior to the session, each subject chose two repetitive motor sequence skills (juggling, drumming or similar repetitive motion): one in which they were proficient, and the other in which they were familiar, but not at all proficient. The order of the known or unknown skill visualization was randomized across subjects.A 14x3 matrix representing the theta/alpha/beta power at each of the 14 electrodes was analyzed to detect whether the subject was visualizing a Known or Unknown skill. Data from all participants was fed into a neural network consisting of one convolutional layer and one fully connected layer,

using the DeLINEATE deep learning analysis toolbox. 70% of the data was used for training, 15% for validation, and 15% for testing, and the analysis was repeated 20 times with different random training/validation/testing splits.Average test accuracy was 73.5% (relative to a chance level of 50%). This finding suggests the potential for an artificial neural network to detect neural patterns of differences that may represent encoded motor memories via EEG during visualization of a motor sequence task.Next steps include analyzing subsets/regions of electrodes to determine with greater precision the neural substrates of such motor memories, and potentially refining our methods to achieve greater accuracy. Additional studies on subjects with varying degrees of proficiency on the same skill could offer further insights to the acquisition and storage of motor skill.

Title: A spinal microcircuit for muscle activation sequences

Authors: *C. BELLARDITA, M. MARCANTONI, O. KIEHN;
Copenhagen Univ., Copenhagen N, Denmark

Abstract: Movements as swimming and walking require a complex sequence of muscle contractions along the body. The spinal cord is the final executor of the neural code translating descending motor commands and sensory feedback into detailed and coherent patterns of muscle activity. Here, we examine how a spinal circuitry for multi-joint movements - where the V2a neurons represent the core element - converts a general motor command into detailed muscle activity for functional movements. Combining mouse intersectional genetics with *in vivo* optogenetic and electrophysiology in adult anesthetized mice, we show that short optical activation of V2a spinal neurons along the spinal cord activate discrete muscles in an ordered fashion, giving rise to a topographic map similar to the muscolotopic map formed by the motor pools. Connectivity profiles of segmentally defined V2a neurons and simultaneous electrophysiological recordings of opto-identified V2a neurons with multiple muscles revealed that V2a neurons make distinct spinal microcircuits that enable simultaneous recruitment of multiple muscles. V2a neurons form a feedforward descending excitatory system in the spinal cord that together with sensory afferents, motor neurons and muscles form functional units.

Prolonged optical activation of V2a neurons in a single unit recruit multiple muscles leading to a functional movement. In contrast, targeted i*n vivo* silencing of segmentally defined V2a neurons heavily perturbed coordinated muscle activity along the animal body in complex motor tasks as swimming. These data identify the neuronal substrate and the functional principles of a spinal circuit involved in constructing muscle activation sequences and provide the logic on how spinal circuitries sculpt muscle action over time and space for meaningful motor behaviors.

Title: Excitatory spinal v3 interneuron subpopulations diversify across hierarchical temporal and spatial developmental pathways

Authors: *D. DESKA-GAUTHIER[1], H. ZHANG[2], J. BOROWSKA[1], C. JONES[1], C. MACKAY[3], Y. ZHANG[3];
[2]MEDICAL NEUROSCIENCE, [3]Med. Neurosci., [1]Dalhousie Univ., Halifax, NS, Canada

Abstract: Neural circuits in the spinal cord are comprised of vastly heterogeneous interneurons required for appropriate execution of movement. Discrete spinal interneuron classes emerge during early embryogenesis, although by postnatal stages extensive subpopulation diversity exists within each class. While combinatorial transcription factor profiles reveal distinct molecular IN clusters, how this molecular logic is acquired and to what extent it translates into functional distinctions between spinal IN subpopulations remains largely unknown. In the current work, through a focus on the cardinal V3 interneuron class, we reveal hierarchical early embryonic temporal-spatial mechanisms underlying molecular subpopulation diversification in the mouse spinal cord. First, neurogenesis timing separates V3 interneurons into either early-born or late-born temporal subclasses upon cell-cycle exit. Second, post-mitotic spatial mechanisms further diversify V3 INs within each temporal subclass into molecularly, anatomically, morphologically, and electrophysiologically distinct subpopulations. Thus, our work reveals early embryonic temporal and spatial mechanisms as key developmental logic for the diversification of spinal interneurons into functionally distinct subpopulations.

Title: Voltage imaging in vivo shows that V3 neurons modulate swim strength

Authors: *U. L. BÖHM[1], Y. KIMURA[3], T. KAWASHIMA[4], M. B. AHRENS[5], S.-I. HIGASHIJIMA[6], F. ENGERT[2], A. E. COHEN[1];

Abstract: Motor systems must constantly adapt their output to maintain a desired trajectory. While the basic mechanisms underlying the generation of rhythmic locomotion in the spinal cord are well described, little is known about how the network modulates its output strength. A major challenge has been the difficulty of recording from spinal neurons during behavior. Here, we use voltage imaging to map the membrane potential of glutamatergic neurons throughout the spinal cord of the larval zebrafish during fictive swimming in a virtual environment. We mapped the spiking, subthreshold dynamics, relative timing and sub-cellular electrical propagation across large populations of simultaneously recorded cells. We identified a sub-population of tonic-spiking ventral V3 neurons whose spike rate correlated with swimming strength. Optogenetic activation of V3 neurons led to stronger swimming. Genetic ablation of V3 neurons led to reduced locomotor adaptation. Our study leverages the power of voltage imaging to identify V3 neurons as a critical driver of motor adaptation in zebrafish.

Title: Mapping the structure of ipsilateral inhibition in axial motor circuits

Authors: *M. SENGUPTA, M. W. BAGNALL;
Washington University, Sch. of Med., Saint Louis, MO

Abstract: The spinal cord is responsible for generating motor output. Traditionally, the field has emphasized the role of commissural inhibition that alternates with excitation in motor neurons, setting up a phase difference vital for locomotion. Ipsilateral inhibition, however, remains much less explored. Two major ipsilateral inhibitory populations in the spinal cord are the V1 (En1+) and V2b (GATA3+) classes. So far, these have been implicated in flexor-extensor alternation in limb circuits where they display a complementary, reciprocally inhibitory function. How these neurons govern axial (body) circuits, especially in the rostro-caudal (R-C) axis is still not known. To investigate whether these neurons are important in R-C coordination, we used larval zebrafish to generate a broad map of connectivity, from V1 and V2b neurons to both motor and sensory targets, using *in vivo* optogenetics and electrophysiology. V1 neurons send ascending axons towards the brainstem while V2bs send descending axons caudally. Both V1 and V2b neurons exhibit long axons running approximately 5-7 segments, but surprisingly, their postsynaptic connectivity was highly asymmetric and unique along the rostro-caudal axis. Despite projecting long axons (7+ segments), V1 neurons contacted fast and slow motor neurons only locally (< 3 segments). Premotor targets like excitatory V2a population, V2bs, and commissural neurons also received only short range V1 inhibition. In contrast, V2b neurons robustly inhibited motor and premotor targets including V1 neurons distally up to 7 segments. On the sensory front, V1 and V2b neurons also exhibited selective connectivity. Unlike its motor contacts, V1 neurons strongly inhibited Commissural Primary Ascending neurons at short and long distances indicating an important sensory gating function for V1s. V2b neurons, on the other hand, did not directly inhibit either of the two sensory targets tested implying a primarily motor related role. To test the functional implications of this organization, we built a reduced model of the unilateral spinal cord and showed that the local pattern of V1 inhibition is crucial for motor burst termination and smooth propagation of the locomotor wave. Current work is aimed at understanding the effects of V2b inhibition and how these two sources are integrated for R-C coordination. Collectively, these data show that ipsilateral inhibition is asymmetric in the R-C axis of the spinal cord in two distinct ways: V1 and V2b neurons inhibit different target populations; and they exhibit unique patterns of connectivity in the R-C axis, suggesting multiple, distinct functions of ipsilateral inhibition in motor control.

Title: Loss of Foxp2-V1 interneurons results in hyper flexion and limb discoordination during locomotion.

Authors: *O. C. MISTRETTA[1], A. E. WORTHY[1], N. M. GREENFIELD[2], J. B. BIKOFF[3], A. W. ENGLISH[1], F. J. ALVAREZ[1];
[1]Cell. Biol., Emory Univ. Sch. of Med., Atlanta, GA; [2]Emory Univ., Atlanta, GA; [3]Dept. of Developmental Neurobio., St. Jude Children's Res. Hosp., Memphis, TN

Abstract: In tetrapod animals, coordinated movement requires the orchestration of motor neuron firing that directs muscle contraction across multiple joints and limbs, thereby achieving changes in desired trajectory upon volitional commands or environmental perturbations. Such patterned motor output depends on the activity of spinal premotor interneurons. For example, flexor-extensor alternation within an individual limb relies on ipsilaterally projecting inhibitory interneurons that reciprocally inhibit flexor and extensor spinal kernels and flexor and extensor motor neurons. The largest group of spinal inhibitory interneurons with ipsilateral projecting axons are V1 interneurons, a molecularly heterogenous population that can be subdivided into at least four major clades on the basis of differential transcription factor expression. The largest of these clades is defined by expression of the Forkhead box protein P2 (Foxp2) transcription factor. Prior work has suggested that this subset exhibits characteristics reminiscent of reciprocal Ia inhibitory interneurons (IaINs) responsible for flexor/extensor coordination. To characterize the role of Foxp2-V1 interneurons during motor behaviors, we took advantage of an intersectional genetic strategy in which *En1-Cre; Foxp2-Flpo* mice were crossed with *RC-PFtox* mice, resulting in silencing of FoxP2-V1 interneurons due to expression of tetanus neurotoxin. These mice show a strong ataxic phenotype at age P5-P6, and adult mice cannot follow normal walking treadmill speeds. These motor deficits likely result from silencing Foxp1/En1 neurons in multiple systems distributed throughout the neuroaxis, including cerebellar, midbrain locomotor, dopaminergic nigral, and spinal systems. Kinematic analyses of treadmill walking in mutant animals revealed over-flexion throughout the step cycle, mainly at the hip and knee joints, consistent with prior descriptions of hyperflexion upon V1 ablation. To isolate deficits specific to spinal circuits, P7-P8 mutant mice were analyzed after L-DOPA induced air stepping. These pups demonstrate a lack of intra and interlimb coordination and, strikingly, coactivation of EMG activity of ankle flexor and extensor muscles, contrasting with normal reciprocal muscle activation, and coordination between different joints across all four limbs in wild-type mice. Our

results suggest that Foxp2-V1 interneurons are involved in flexor-extensor activation and interlimb coordination, both functions suggested in the past to be contributed by IaINs.

Title: Analyzing the performance of central pattern generators for a rat synthetic nervous system

Authors: *K. DENG[1], A. J. HUNT[2], H. J. CHIEL[1], R. D. QUINN[1];
[1]Case Western Reserve Univ., CLEVELAND, OH; [2]Portland State Univ., Portland, OR

Abstract: This work investigates how neural parameters and external inputs affect the performance of a central pattern generator (CPG) used to model mammalian locomotion. In our previous work, when designing a synthetic nervous system, choices of neural parameters were determined using genetic algorithms combined with hand-tuning. However, the impact that different intrinsic parameters have on changing the behavior of the neural controller is not fully understood. In particular, little is known about how weak mutual excitation between oscillators alters output. This hypothesized connection is based on the observation from several groups that synchronous rhythmic excitation of flexor and extensor motor neurons occur when V1 and V2b inhibition is absent. When designing a model of the CPG, the oscillation frequency is the most essential part, and a desired frequency can be attained by various combinations of neural parameters. Including the weak mutual excitation into the system limits the operation range of the CPG (i.e., it shrinks the phase orbit size in the phase plane). Another aspect to consider when designing a model of the CPG is its reaction to external stimuli or perturbations. Our results show that for CPGs oscillating at the same frequency, the external drive makes the system less sensitive to external inputs, whereas the weak connection does not change the phase response curve of the system. This study provides insights for studies of the locomotion CPG, and will benefit the design of bio-robotic controllers.

Abstract: The invertebrate ventral nerve cord (VNC), homologous to the vertebrate spinal cord, integrates sensory signals from the body with commands from the brain in order to control movements. Mapping the morphology and connectivity of each of the VNC's neurons is a crucial step toward understanding and reverse-engineering animals' motor control algorithms. We recently reported a synapse-resolution electron microscopy (EM) dataset of the VNC of an adult female fruit fly, a species that can flexibly and precisely coordinate its six legs and two wings to accomplish a wide variety of behaviors. Here, we automatically segmented cells and predicted synaptic partners across the entire EM dataset to accelerate reconstruction of the ~15,000 neurons in the adult fruit fly's VNC. Manual proofreading of the reconstructed neurons is often necessary, but this takes between a few minutes to an hour per neuron. At this speed, proofreading particular neurons-of-interest and their upstream and downstream partners can be accomplished in days to weeks. To facilitate the community's access to this dataset, we oversee a collaborative effort where members of seventeen (and counting) different labs are proofreading distinct circuits. Importantly, this open collaboration provided opportunities for remote work for students and researchers affected by lab shutdowns brought on by the pandemic. All proofreading occurs within one unified dataset, so each lab's efforts contribute to the broader goal of obtaining a fully proofread VNC connectome. Furthermore, we are building computational tools to allow users to easily annotate and query the connectome data, facilitating exploration and analysis even by users with limited programming experience. This collaborative approach to connectome proofreading is bringing VNC researchers together behind a common goal, while allowing each researcher to quickly map the structure and connectivity of the neurons they care most about.

Title: Electrical stimulation of the dorsal motor nucleus of the vagus activates the efferent arm of the inflammatory reflex shifting the cytokine balance in murine endotoxemia towards suppression of inflammation

Authors: *A. FALVEY[1], S. PALANDIRA[1], Q. ZENG[1], R. STOJCHEVSKI[1,2,3], D. AVTANSKI[1], K. J. TRACEY[1,3,4], V. A. PAVLOV[1,3,4];
[1]The Feinstein Inst. for Med. Res., Manhasset, NY; [2]Friedman Diabetes Inst. at Lenox Hill Hosp., New York, NY; [3]Donald and Barbara Zucker Sch. of Med. at Hofstra/Northwell, Hempstead, NY; [4]Elmezzi Grad. Sch. of Mol. Med., Manhasset, NY

Abstract: The inflammatory reflex is a vagus nerve-mediated and brainstem-integrated physiological mechanism that regulates immunity and inflammation. The efferent vagus nerve originates in brainstem nuclei, including the dorsal motor nucleus of the vagus (DMN). We have shown that optogenetic stimulation of cholinergic DMN neurons suppresses serum TNF levels during endotoxemia *(PNAS, 2020, 117(47):29803*). While the clinical translation of optogenetics for brain stimulation remains challenging, electrical stimulation is widely used in bioelectronic therapeutic approaches targeting the brain. However, the efficacy of altering cytokine levels using electrical DMN stimulation remained unexplored. To provide insight, we studied the effect of electrical DMN stimulation on serum pro- and anti-inflammatory cytokines in murine endotoxemia. Electrical DMN stimulation was performed in male 10-12 week old C57BL/6 mice, using a stereotaxic-guided approach. Mice were anesthetized using isoflurane and the head was positioned on a stereotaxic frame for a surgical intervention to insert a concentric bipolar

electrode into the left DMN according to Paxinos and Franklin mouse brain atlas coordinates. Electrical stimulation (50 μA, 30 Hz, 260 μs) or sham-stimulation was performed for five mins, followed by lipopolysaccharide (LPS, 0.5 mg/kg) i.p. administration. Mice were euthanized 90 mins after LPS and blood (via cardiac puncture) was collected and processed for pro- and anti-inflammatory cytokine analysis. The brain was collected for histological analysis following cardiac perfusion. Electrical DMN stimulation significantly decreased serum levels of the pro-inflammatory cytokine TNF compared with sham stimulation (1,581 ± 465 pg/ml vs 1,139 ± 357 pg/ml, n = 15 per group, P=0.0069). Electrical DMN stimulation also enhanced serum levels of the anti-inflammatory cytokine IL-10 (9,433 ± 1,491 pg/ml vs 14,784 ± 1,758 pg/ml, P=0.0284). Brainstem histological analysis, including immunostaining for choline acetyltransferase (ChAT) and confocal imaging verified the accurate positioning of the stimulating electrode in the left DMN ChAT-positive neurons - a major source of efferent vagus nerve cholinergic axons. These results indicate for the first time that the efferent arm of the inflammatory reflex can be activated by DMN electrical stimulation shifting the cytokine balance towards suppression of inflammation. These findings may enable future clinical bioelectronic approaches targeting DMN for therapeutic benefit in conditions characterised by excessive inflammation. This study was funded in part by NIH/NIGMS.

Title: Disrupted neural encoding of immune signals in vagus nerve after sepsis

Authors: *J. J. STROHL, P. T. HUERTA;
Feinstein Inst. for Med. Res., Manhasset, NY

Abstract: Studying the long-term effects of sepsis has become an increasingly important issue. As more patients survive sepsis, it has become obvious that the nervous system is a major target for the post-sepsis syndrome. Recent work has suggested that a change in vagus nerve (VN) activity may play a role in the immunological changes that take place after sepsis. In healthy mice, recordings from the VN have shown that it can encode immune-related signals, such as cytokines. The goal of this study is to determine whether the VN is altered by sepsis such that the

cytokine-specific neurograms are not correctly encoded. Sepsis was modeled with the cecal-ligation-and-puncture method in male C57BL/6 mice. After a recovery period of 4 weeks, VN recordings were performed in 16 Sham and 21 sepsis-surviving (*Sep*) mice, under isoflurane anesthesia, using cuff electrodes (CorTec, Freiburg, Germany). Recordings consisted of a baseline (BL) period (0-20 min) followed by intra-peritoneal injections of TNF (20-40 min) and IL-1β (40-60 min). In other experiments, IL-1β was given before TNF. We measured the compound action potentials (CAPs) carried by the VN axons. For each recording, we inputted the CAP frequencies at each sec into Bayesian decoding algorithms to estimate the probability that each time-point belonged to one of 3 classes: BL, TNF or IL-1β. We then compared the probabilities from the algorithm to the actual class. During BL, sepsis survivors have elevated baseline CAP frequency when compared to controls (Fig. 1A, Sham = 2.7±0.6 CAPs/s, *Sep* = 14.8±2.1 CAPs/s, $p = 5x10^{-7}$, t test). Crucially, the cytokines trigger a robust increase of CAP frequency in Sham mice (Fig. 1A, 5.8±0.8 CAPs/s, $p = 3x10^{-5}$ vs. Sham at BL, t test), whereas sepsis survivors do not change their activity after cytokine injection (Fig. 1A, *Sep* = 14.1±1.6 CAPs/s, p = 0.6 vs. *Sep* at BL, t test). The probability of predicting the correct class is higher for controls at BL (Fig. 1B; Sham = 80±5%, *Sep* = 59±5%, p = 0.006, t test) and TNF (Fig. 1B, Sham = 78±5%, *Sep* = 62±5%, p = 0.046, t test), but not significantly different after IL-1β (Fig. 1B, Sham = 81±4%, *Sep* = 73±4%, p = 0.18, t test). We show that sepsis leads to long-term changes in the function of the VN which can be directly measured using electrophysiological techniques. Sepsis survivors display a higher level of activity in the VN, reflecting a deviation from the homeostatic state. When cytokines are injected into sepsis survivors, the VN does not respond with the expected increase in activity that occurs in control mice. Our data indicate that sepsis disrupts the neural code in the VN, which likely contributes to the dysregulated brain-immune axis that is part of the post-sepsis syndrome.

Title: Transient Receptor Potential Ankyrin 1 (TRPA1) mediates afferent signals in the inflammatory reflex

Authors: *H. A. SILVERMAN[1], T. S. HUERTA[1,2], E. H. CHANG[1,2], A. CHEN[1], K. J. TRACEY[1,2,3], S. S. CHAVAN[1];
[1]Inst. for Bioelectronic Med., Feinstein Inst. for Med. Res., Manhasset, NY; [2]Donald and

Barbara Zucker Sch. of Med. at Hofstra/Northwell, Hempstead, NY; [3]Elmezzi Grad. Sch. of Mol. Med., Manhasset, NY

Abstract: The inflammatory reflex is a physiological mechanism in which afferent vagus nerve signaling activated by inflammatory mediators, is functionally associated with efferent vagus nerve-mediated output to regulate proinflammatory cytokine production and inflammation. Efferent signals in the vagus nerve terminate onto acetylcholine-producing T cell subset. Acetylcholine regulates cytokines production by interacting with alpha-7 nicotinic receptor (α7nAChR) expressed on monocytes and macrophages. Despite this extensive understanding of the efferent pathway, the afferent mechanism of the inflammatory reflex is less defined. Here we show that transient receptor potential ankyrin 1 (TRPA1) in sensory vagus neurons is sufficient to activate the inflammatory reflex and regulate cytokine production. Vagus TRPA1 was selectively activated using optopharmacology. Optovin, a selective TRPA1-ligand was placed directly on the vagus nerve prior to stimulation with 405nm light. Selective activation of the vagus nerve TRPA1 using optopharmacology stimulates the inflammatory reflex to inhibit cytokine responses to bacterial lipopolysaccharide in wild type mice (sham: 920.9 ± 87.9 pg/ml, n=9 vs. stimulated: 456.8 ± 69.4 pg/ml, n=10; Welch's T-test $p<0.001$), but no significant differences are observed in TRPA1 knock out mice (sham: 861.0±91.9 pg/ml, n=9 vs. stimulated: 795.3±92.8pg/ml, n=8; Welch's T-test p=0.622). The TRPA1-mediated cytokine reduction in wild type mice is ablated by rostral, but not by caudal vagotomy, indicating that the signals are afferent in nature (rostral n=12 vs. caudal n=9: 998.7.9±57.5 pg/ml, 794.8±49.7 pg/ml; Welch's T-test $p<0.05$). In contrast to its TNF suppressive effect in wild type mice, activation of TRPA1-signals failed to inhibit TNF levels in α7nAChR knockout mice during endotoxemia (sham: 2132±390.6pg/ml, n=10 vs. stimulated: 1562±250.5pg/ml, n=12; Welch's T-test p=.237). Taken together these results indicate that targeted stimulation of TRPA1 on afferent vagus nerve fibers is sufficient to activate the sensory arc of the inflammatory reflex and identify a potential therapeutic target for inflammation.

Abstract: Neural reflex circuits regulate inflammation and are key to maintaining homeostasis. The inflammatory reflex regulates systemic inflammation through vagus nerve signaling. While the motor efferent arm of this reflex has been described, the role of sensory neurons encoding immune mediators, and transmitting these signals to the brainstem remains unclear. Using vagus nerve recordings, our group has shown that the sensory arm of the vagus nerve transmits information linked to specific cytokines, however these recordings do not show activity at the single neuron level. Here, we use *in vivo* calcium imaging to monitor the neural activity of individual vagal sensory neurons in response to specific inflammatory mediators. We used mice that express a calcium sensor in glutamatergic neurons. Under isoflurane anesthesia, the nodose ganglion was imaged *in situ* using a 1-photon miniature microscope (Miniscope) while the inflammatory mediators tumor necrosis factor (TNF), interleukin 1β (IL-1β), or lipopolysaccharide (LPS) were applied directly to the vagus nerve. The recorded data was analyzed with a Python-based calcium imaging analysis (CaImAn) pipeline, which output calcium traces (change in fluorescence: ΔF) of individual neurons. Our results reveal that specific neurons respond to specific immune mediators. An average of 69±16.3 neurons were recorded per 1 hour imaging session. When exposed to both cytokines TNF and IL-1β, certain neurons were found to only respond to one cytokine (TNF: 23.6±10.4%; IL-1β: 19.75±15.7%), while a subset of neurons responded to both cytokines (TNF & IL-1β: 13±10.3%). IL-1β-responsive neurons had a significantly higher peak response than TNF-responsive cells (IL-1β *vs*. TNF, $p < 0.01$). This result may indicate that sensory neurons in the nodose ganglion respond differentially to specific cytokines, possibly through specific cytokine receptor binding. We also found that specific neurons were responsive to LPS. LPS-responsive neurons were found to have significantly higher peak response than the cytokine responsive neurons (LPS *vs.* TNF, $p < 0.05$), which suggests differential encoding process between cytokine receptors and potential toll-like receptor-dependent activation. These findings are the first to reveal individual vagal sensory neurons encoding information about distinct inflammatory stimuli. Further investigation may reveal fundamental principles by which the vagus nerve transmits information about inflammation to the brain. Better understanding of the neural sensing of inflammation may elucidate novel cellular targets for the treatment of inflammatory disorders.

Title: Optogenetic cholinergic stimulation of the celiac-superior mesenteric ganglia complex attenuates inflammation

Authors: *S. PALANDIRA[1,2], A. FALVEY[1], Q. ZENG[1], D. B. AVTANSKI[1,3,4], R. STOJCHEVSKI[4], L. PORETSKY[4,3], K. J. TRACEY[1,3], V. A. PAVLOV[1,3];

Abstract: The vagus nerve-based inflammatory reflex is an important physiological regulator of immunity and inflammation. In the efferent arm of the inflammatory reflex, vagus nerve cholinergic axonal endings interact with splenic nerve catecholaminergic neurons in the celiac-superior mesenteric ganglion (CSMG) complex (*Proc Natl Acad Sci USA, 2020, 117(47):29803). S*tudies using electrical and optogenetic neural stimulation have shown that vagus nerve cholinergic signaling controls pro-inflammatory cytokine levels. However, the role of the CSMG complex in the regulation of inflammation remained enigmatic. To provide insight, we examined the effect of selective optogenetic stimulation of cholinergic axonal endings in the CSMG complex on cytokine levels in murine endotoxemia. Transgenic female 10–14week-old mice expressing channelrhodopsin-2 on cholinergic, choline acetyltransferase (ChAT)-positive neurons - ChAT-ChR2 mice, were used in the experiments. Under isoflurane anaesthesia, the CSMG complex was located ventral and to the left of the abdominal aorta, along the splenic artery, superomedial to the left kidney. Blue laser light stimulation at 473 nm was delivered in square pulses for 10 mins at 20 Hz, 25% duty cycle via an optic fiber that was placed in contact with the CSMG complex. 30 mins following optogenetic stimulation or sham stimulation lipopolysaccharide (0.25 mg/kg) was injected i.p. and 90 mins later, mice were euthanized and blood, and spleen were collected and processed for analysis. Optogenetic stimulation of the CSMG complex in ChAT-ChR2 mice (n=14) significantly supressed serum pro-inflammatory cytokines and chemokines compared with sham stimulation (n=13), including TNF (401.7 ± 102.9 pg/ml vs 766.1 ± 207.2 pg/ml; $P<0.0001$) and MIP-1α (6,523 ± 3,041 pg/ml vs 10,672 ± 3,915 pg/ml, $P=0.0066$). Optogenetic stimulation also significantly increased the serum levels of the anti-inflammatory cytokine IL-10 levels compared with sham (30,779 ± 10,035 pg/ml vs 22,979 ± 9,669 pg/ml, $P=0.0427$). There was also a significant reduction in splenic TNF levels in the stimulated vs the sham group ($P=0.0023$). In conclusion, these results provide the first experimental evidence that selective simulation of cholinergic neuronal endings in the CSMG complex alters cytokine levels. These findings and further studies examining the specific contribution of vagal and sympathetic preganglionic cholinergic signaling will be instrumental for advancing our understanding of the role of the CSMG complex in the regulation of immune

responses, and of interest for developing new anti-inflammatory approaches. This study was funded in part by NIH/NIGMS.

Title: 5ht1ar deficient female mice exhibit altered neutrophil maturation dynamics and immune response during pregnancy

Authors: *A. NABILA[1], R. J. CHEN[1], J. G. TOTH[2], M. TOTH[2];
[1]Neurosci., [2]Pharmacol., Weill Cornell Grad. Sch. of Med. Sci., New York, NY

Abstract: Serotonin-1A receptor (5HT1A-R) is a pre- and post-synaptically expressed receptor that has been implicated in anxiety and depression. Activation of 5HT1A-R modulates the action of anxiolytic, antidepressant, and antipsychotic medications in the central nervous system (CNS). Consistent with these clinical data, our lab has previously reported that 5HT1A-R heterozygous (H) and null (KO) mice on the outbred Swiss Webster (SW) background display an anxiety-like phenotype on the elevated plus maze. Surprisingly, despite the lack or minimal expression of 5HT1A-R outside the CNS, we observed immunological abnormalities in the genetically 5HT1A-R deficient mice. Specifically, H (and KO) females but not males exhibited adulthood cytopenia in three hemopoietic lineages (lymphocytes, platelets, and reticulocytes). Both the anxiety and the cytopenia phenotypes were transmitted to the F1 WT offspring suggesting that once initiated by a genetic receptor deficit, the phenotypes can propagate through the maternal lineage to the next generation via non-genetic transmission. So, cytopenia in H mothers may arise due to CNS 5HT1AR-mediated regulation of the peripheral immune system; however, in the F1 offspring, maternal immunological abnormalities can lead to immune activation that alters fetal development via the placenta.To better understand the immunological consequences of the 5HT1A-R deficit and its intergenerational transmission, we used single cell RNA-sequencing (scRNA-seq) to profile peripheral leukocytes from H and SW WT mothers at gestational day 10.5. We find that neutrophils in H mothers display an upregulation in immune response genes including S100a8 and Ifitm6. Furthermore, we observed a greater proportion of immature neutrophils in H mothers which may indicate an increased release of maturing neutrophils from the bone marrow to the periphery. Our results suggest that not only are neutrophil maturation and

release altered but there is an increased gestational immune response in H mothers that may lead to an inflammatory state that regulates gestational maternal-fetal communication. Overall, we report, for the first time, of immunological consequences of a deficit in 5HT1A-R in mice.

Title: Adrenal gland regulates acute inflammation and glycemia in an acute endotoxin challenge.

Authors: *E. SANTACRUZ-MARTÍNEZ, E. SOTO-TINOCO, R. BUIJS;
Inst. de Investigaciones Biomédicas, Univ. Nacional Autónoma De México, Ciudad de Mexico, Mexico

Abstract: After an inflammatory event there are many changes in physiology. Among those is a modification of the immune system in a negative feedback manner as well as sympathetic driven parameters such as glycemia and heart rate, all of which are regulated by the nervous system. Currently, it is accepted that the immune system communicates its state of activation through cytokines. Nevertheless, the nervous system shows signs of activation before these proteins can be secreted indicating the presence of other pathways of activation. Prostaglandins are known to be immune lipidic mediators that are secreted prior to cytokines. To test whether prostaglandin could participate un this early response, its synthesis was inhibited pharmacologically in endotoxin challenged rats. Neuronal activation of the sensory elements of the nervous system was assessed by nuclear c-Fos expression in the dorsal horn of the spinal cord as well as the nucleus of the solitary tract fifty minutes after the LPS challenge. It was found that inhibiting prostaglandin synthesis prevented neuronal activation, this caused an increase in the circulatory levels of the early cytokine, tumor necrosis factor as well as changed glycemic and heart rate response. Pharmacological evidence points to regulation of these parameters via beta adrenergic receptors, nevertheless, this does not assess the role of different catecholamines capable of stimulating these receptors. The involvement of epinephrine in this antiinflammatory and glycemic reflex is approached by surgical removal of adrenal medullas, which is the main source of epinephrine. In conclusion the early activation of the sensory elements of the nervous system

is due to sensing of prostaglandin in the periphery while epinephrine is involved in regulation of early physiological reflex-like changes caused by endotoxin administration.

Title: T-cell activation in patients with multiple sclerosis on B-cell depleting therapies is as effective as that of general population in response to SARS-CoV-2 vaccination

Authors: *V. KIRSCHNER, G. FEUER, M. MALIN, J. LEI, J. LIU, M. ROCHE, J. LIN, R. ALFONSO, S. SADIQ;
Tisch MS Res. Ctr., New York, NY

Abstract: Many patients with multiple sclerosis (MS) undergo immunosuppressive B-cell depleting therapies which can severely limit their humoral immunity against SARS-CoV-2 (CoV2) infection or response to vaccination. While robust antibody production is seen in immunocompetent individuals, recent studies show that B-cell depleting therapies inhibit efficient production of antibodies against CoV2 proteins due to reduction in circulating B-cells. It is unknown how these disease modifying therapies affect T-cell responses after CoV2 vaccination, and whether there is a correlation between CoV2 antibody levels and T-cell immunity.
Our ongoing single-center study aims to determine CoV2 spike protein-T-cell reactivity in fully vaccinated, B-cell depleted MS patients treated with rituximab or ocrelizumab, two well-characterized anti-CD20 monoclonal antibody drugs. We collected peripheral blood mononuclear cells (PBMCs) and serum samples from treated MS patients and healthy control individuals at 15-93 days after completing vaccination. CoV2 IgG response was determined using anti-spike protein-based serology and levels of proinflammatory cytokine (IL-2 and INF-Ɣ) release after protein-specific T-cell stimulation were measured *ex vivo* using an ELISpot assay.
We observe that from 23 vaccinated MS anti-CD20 treated patients studied, 19 (82.6%) showed defective humoral immunity. Interestingly, most CoV2 spike IgG negative patients (17 out of 19, 89.5%) presented a positive T cell response with strong IL-2 and INF-Ɣ expression. These results suggest the generation of a partial adaptive immune response to CoV2 vaccination in B-cell depleted individuals, driven by a functionally competent T-cell arm. Investigation into the role of T-cell response in these individuals is crucial to identifying their levels of protection against COVID-19.

Title: In vivo two-photon imaging of meningeal B cells

Authors: *H. J. BARR[1], A. J. WALKER[2], T. M. FISHER[3], L. DISSING-OLESEN[3], B. A. STEVENS[4];
[1]Harvard Med. Sch. Grad. Program In Neurosci., Boston, MA; [2]Harvard Med. Sch., Boston, MA; [3]F.M Kirby Neurobio. Ctr., [4]Howard Hughes Med. Inst., Boston Children's Hosp., Boston, MA

Abstract: The central nervous system (CNS) is ensheathed by meninges, protective membranes that harbor a rich diversity of immune cells. Among the adaptive immune cells that localize to the meninges, B cell populations have recently been observed within the dura proximal to calvarial bone marrow. Notably, a distinct wave of B cells colonizes the meninges during the early postnatal period, yet real-time characterization of the dynamics of these meningeal cells has remained elusive. We developed an *in vivo* approach to studying the dynamic interplay between B cells residing in the calvarial bone marrow and the meninges via two-photon imaging through the intact skull. Using custom headplates and fixation devices in juvenile mice aged P12-P17 expressing GFP under the control of Mb1 (*Mb1-Cre;mT/mG*), a B cell antigen receptor gene, we gained optical access to the bone marrow and dural sinuses. Transcranial imaging along the sagittal sinus confirmed both the presence of B cells in the dura and of specialized channels connecting the bone marrow and meninges for bidirectional B cell transport. B cells were relatively stable within both niches, with little movement and rare exchange of cells between compartments. However, administration of niche-disruptive drugs decreased the stability of B cells within their respective niches and increased trans-compartmental movement. Together, these results show that two-photon microscopy through the intact skull of transgenic mouse pups is a robust model in which to study the real-time dynamics of meningeal lymphocytes and the niche they reside in.

Skin grafting is an effective tool for treating various conditions such as third-degree burn, but the longevity of the transplant needs to be improved. Upon allogeneic graft, the host mounts an immune response against the transplant which results in its rejection. An effect managed clinically using immunosuppressive treatment. Our work in neuro-immunology has shown that skin nociceptor neurons control immune exhaustion against innate and adaptive immune cells. Here, we sought to test whether these neurons are activated in the context of skin grafting and, if so, do they promote immune-mediated rejection. To induce rejection, 8-week-old male C57BL6 (autograft) or BALB/c (allograft) mice underwent a 10mm skin biopsy which was immediately grafted to C57BL6 mice whose sensory neurons are either intact ($TRPV1^{wt}DTA^{fl/wt}$, $Na_V1.8^{wt}DTA^{fl/wt}$) or genetically ablated ($TRPV1^{cre}DTA^{fl/wt}$, $Na_V1.8^{cre}DTA^{fl/wt}$). To measure immune influx to the skin, the mice were also implanted with polyvinyl alcohol (PVA) sponges which were removed and immunophenotyped on day 1 and 3. In littermate control mice, we found that skin rejection occurs on day 19 in mice who received an autograft but on day 15 for the one that received an allograft. Interestingly, we discovered that sensory neuron ablated mice were protected from rejection, eliminating the allograft transplant on day 18. Next, we postulate

that the delay in rejection may be due to a reduced immune cells activation in nociceptor ablated mice or an increase in immune cells exhaustion. When compared with autograft, our data shows that allograft littermate control animals have higher immune infiltration, characterized by innate immunocytes on day one and adaptive immune cells on day 3. Interestingly, nociceptor depleted mice showed reduced number and activation (defined as PD1+) of skin infiltrating CD8+ and NK cells than allograft littermate control mice. Multiplex cytokine array also showed reduced skin IL-4 and MCP-1 levels in allograft sensory neuron ablated mice. Overall, sensory neuron ablation reduces immune influx and transplant rejection. These data support the existence of a maladaptive neuro-immune network mediating skin graft rejection and paved the way for sensory neuron targeted treatment to promote graft longevity.

Title: Broad histone serotonylation domains associate with neurodevelopmental gene expression programs

Authors: *J. C. CHAN[1], A. RAMAKRISHNAN[1], M. BEDFORD[2], L. SHEN[1], H. LI[3], I. S. MAZE[1];
[1]Icahn Sch. of Med. at Mount Sinai, New York, NY; [2]The Univ. of Texas MD Anderson Cancer Ctr., Smithville, TX; [3]Beijing, Tsinghua University, China

Abstract: Brain development is a complex organizational process that can be altered by genetic variants, environmental perturbations, aberrant monoaminergic signaling, and more. In particular, dysregulation of the serotonin (5-HT) system has been implicated in the pathophysiology of neurodevelopmental disorders including autism spectrum disorders (ASD), yet the molecular mechanisms underlying 5-HT contribution to neurodevelopment remains unclear. Recently, our lab identified a novel epigenetic role for 5-HT, whereby this biogenic monoamine can be transamidated to glutamine 5 of histone H3 (H3Q5). Deposition of 5-HT at this site stabilizes neighboring H3K4me3, resulting in the combinatorial H3K4me3Q5ser modification that recruits specific regulatory machinery to increase permissive transcription.

Interestingly, an additional role of H3K4me3 ‘broad’ domains has been described. Broad H3K4me3 peaks that span over 4 kb correspond to enhanced transcriptional activation and associate with cell-specific processes, such as synaptic signaling in neurons. In postmortem brains from ASD patients, aberrant spreading of H3K4me3 domains has been observed, though how this dysregulation occurs is unclear. Our current studies examine histone serotonylation involvement in the organization of H3K4me3 spreading to impact neurodevelopment. To determine whether H3Q5 serotonylation associates with broad H3K4me3 peaks, we performed chromatin immunoprecipitation coupled to sequencing of H3K4me3Q5ser in mouse embryonic forebrain tissues. Indeed, characterization of H3K4me3Q5ser peaks indicate this dual modification exhibits broad patterning, occupying 4-to-35 kb across the genome. Moreover, broad H3K4me3Q5ser domains associate with loci that enrich for neurodevelopment-associated pathways. Spreading of H3K4me3 peaks is regulated, in part, by the enzyme Lysine methyltransferase 2e (Kmt2e). To determine whether H3Q5 serotonylation influences Kmt2e recruitment, we used a high-throughput methyl domain reader array that evaluates binding between recombinant chromatin reader domains and modified histone tail peptides. Along with isothermal calorimetry, we show that the Kmt2e PHD finger binds H3K4me3Q5ser peptides more extensively than H3K4me3 alone, suggesting H3Q5 serotonylation may enhance Kmt2e recruitment to regulate H3K4me3 spreading. Ongoing work focuses on the contribution of Kmt2e to organization of H3K4me3Q5ser broad domains and subsequent impact on neuronal gene expression programs. These studies offer a novel role for histone serotonylation that, if disrupted, may contribute to the etiology of neurodevelopmental disorders.

Abstract: Monoamines are traditionally regarded as chemical signals that act extracellularly on surface bound receptors in brain. However, recent work from our lab demonstrates that non-vesicular monoamines have receptor-independent functions that are mediated via transamidation reactions onto glutamine residues of protein substrates. We selectively isolated dopaminylated proteins in brain utilizing a novel endogenous chemical tagging method to specifically immunoprecipitate dopaminylated proteins. Immunoprecipitations coupled to mass spectrometry identified novel dopaminylated proteins in synaptic fractions isolated from nucleus accumbens (NAc), including multiple isoforms of CaMKII, with their dopaminylation states regulated by drugs of abuse (e.g., heroin self-administration/SA). We further characterized CaMKII dopaminylation utilizing *in vitro* enzymatic assays coupled to mass spectroscopy, where we identified glutamine 285 (Q285) as the selective site of dopaminylation on γCaMKII. γCaMKII is a synapse-to-nucleus signaling molecule involved in the shuttling of calmodulin (CaM) to the nucleus to promote phosphorylation CREB, among other downstream signaling events. Utilizing primary striatal-cortical co-cultures, we identified a blockade of CaM shuttling upon dopamine treatment, despite γCaMKII's entry to the nucleus. We additionally observed that this phenomenon is dopamine receptor independent and provide evidence of a direct role for Q285dop on CaM binding. Ultimately, we hypothesize that the presence of this modification on γCaMKII may change our conceptualizations of post-synaptic dopaminergic signaling in brain, where dopamine may not only act at the cell surface, but also infiltrates post-synaptic cells and directly modifies the proteins therein to mediate important cellular signaling events.

Laval, Ville de Québec, QC, Canada; [4]Chem. Biol. Program, Mem. Sloan-Kettering Cancer Ctr., New York, NY

Abstract: Background: The field of neuroepigenetics has recently implicated chromatin phenomena in the etiology of major depressive disorder (MDD). While it has been demonstrated that dysregulation of histone posttranslational modifications may be involved in the deleterious transcriptional processes that promote physiological maladaptations in MDD, the field still has only a limited understanding of the underlying mechanisms contributing to this disorder. Data from our laboratory suggest potential alternative mechanisms of action for monoamines, where the presence of serotonin in the dorsal raphe nucleus (DRN) may directly mediate transcriptional responses related to various forms of serotonergic plasticity, and the subsequent mediation of mood.Methods: Mice were subjected to chronic social defeat stress (CSDS) and behavioral response was analyzed via social interaction (SI), classified as either stress-susceptible or resilient. Each cohort was 1) sacrificed 24h post-CSDS, 2) subjected to 30 days of fluoxetine vs. water treatment, or 3) underwent viral surgery to block serotonylation. Human tissue were obtained from a brain bank.Results: We detected a decrease in serotonylation and an enrichment in ubiquitin pathways in MDD patients and male/female mice 48h post-CSDS. Serotonylation levels were significantly increased 30 days post-CSDS, an effect that is reversed with fluoexetine treatment. Blocking serotonylation resulted in significantly greater SI than control groups.Conclusion: Globally blocking serotonylation in DRN promotes a resilient response to CSDS, and there is an accumulation of serotonylation that promotes a long-term vulnerability to stress, possibly through ubiquitination.

Abstract: The overall risk for developing major depressive disorder (MDD) is determined by a complex interaction between heritable genetic variants that confer increased vulnerability to MDD in the presence of stress exposure and other adverse experience. Mechanistic understanding of this gene-environment interface requires characterization of epigenomic processes within the unique regulatory context of disease-relevant cell types, but to date this approach has not been applied to MDD. Here, we use cell population-specific chromatin accessibility profiling to map the active repertoire of gene regulatory elements in a brain region relevant to MDD, the orbitofrontal cortex (OFC). Although relatively understudied in human MDD, the orbitofrontal cortex (OFC) integrates internal homeostatic states, emotion, and motivating stimuli in order to flexibly guide behavior. Functional imaging studies consistently find significant OFC dysfunction in MDD patients, however, the molecular and cellular substrates underlying these neuroplastic changes in the OFC are not well understood. Here, we utilized FANS coupled - Assay for Transposase-Accessible Chromatin-Sequencing (ATAC-seq) to capture the chromatin regulatory signature of both neuronal and glial cells in the OFC of MDD vs. control patients. We mapped genetic risk for MDD to active chromatin regions in non-neuronal OFC cell-types, and identified MDD-specific open chromatin regions (OCRs), present exclusively in non-neuronal OFC cells. Characterization of these MDD-specific OCRs revealed a key role for the chromatin remodeling protein ZBTB7A, which is known to facilitate transcription of NF-kB inflammation pathway genes, and is enriched in astrocyte cell-types, though its role in neuropsychiatric disease has not been explored. In a series of functional validation studies, we utilized a preclinical rodent model of stress vulnerability to show that overexpressing (OE) ZBTB7A specifically in rodent OFC astrocytes is sufficient to induce behavioral deficits, widespread inflammatory gene expression, and aberrant neuronal hyperactivity in response to a mild stressor. Importantly, our data demonstrate that ZBTB7A OE in OFC astrocytes reverses the same changes in gene expression and neuronal activity that support adaptive behavioral responses to mild stress, suggesting a key role for astrocyte plasticity in vulnerability to stress exposure. Together, these data demonstrate that epigenetic regulation of inflammatory signaling in astrocytes impairs neuroadaptive responses to stress, with direct implications for the role of astrocyte plasticity in OFC dysfunction and MDD pathology.

Title: Seasonal expression of 5-alpha reductase in corticolimbic brain regions of a diurnal rodent

Authors: *A. COSTELLO[1], K. LINNING-DUFFY[1], C. VANDENBROOK[1], J. S. LONSTEIN[2], M. BORTOLATO[3], L. YAN[1];
[1]Psychology, [2]Neurosci Program, Michigan State Univ., East Lansing, MI; [3]Pharmacol. and Toxicology, Univ. of Utah, Salt Lake City, UT

Abstract: 5-Alpha-Reductase (5AR) is a key enzyme catalyzing the biosynthesis of numerous neurosteroids that regulate affect and cognition. In humans, administration of 5AR inhibitors is associated with increased risk for depression. In laboratory mice and rats, higher levels of 5AR in limbic structures are associated with reduced anxiety- and depressive-like behaviors, while downregulating 5AR leads to increased anxiety- and depression-like behaviors. In songbirds, brain 5AR expression has been reported to undergo seasonal changes. However, it is unclear whether the same fluctuations occur in mammals, and the extent to which the changes in 5AR are involved in Seasonal Affective Disorder (SAD), a major depressive disorder caused by seasonal fluctuation in the level of ambient light. To begin exploring these questions, the present study utilized a diurnal rodent, the Nile grass rat (*Arvicanthis niloticus*). Unlike the most commonly used laboratory rodents (i.e., mice or rats) that are nocturnal and sleep most during the day, Nile grass rats sleep most at night, like humans. Our group's previous studies using grass rats have found that reducing daytime light exposure, which is etiologically relevant to SAD in humans, leads to increased depression- and anxiety-like behaviors, impaired spatial memory, and disrupted male copulatory behaviors. To investigate the seasonal regulation of 5AR, male and female grass rats housed in 12:12 hr light/dark (LD) cycle were randomly assigned to two conditions involving different light intensity during the day, a summer-like bright light (1000 lux) and winter-like dim light (50 lux) for 4 weeks. Gene expression of two 5AR isoforms Srd5a1 and Srd5a2 within the prefrontal cortex (PFC), anterior cingulate cortex (ACC), dorsal hippocampal subregion CA1, and the basolateral amygdala (BLA) were quantified using real-time qRCR. The results revealed that winter- or summer-like daylight intensity

condition had no significant effect on the expression of Srd5a1 in the brain regions examined. However, there were numerous sex differences found. Within BLA, males had higher expression of srd5a1 than females and there was a sex by light interaction for Srd5a2. Within the PFC, males had higher expression of Srd5a2 than females. The sex- and region-specific responses of 5AR genes to light condition indicate complex and dynamic changes in the biosynthesis of neurosteroids over season in the diurnal brain and suggest the involvement of 5AR in the behavioral detriments caused by daytime light deficiency.

Title: Postpartum scarcity-adversity drives aberrant maternal behavior and induces a hypodopaminergic start in the rat dam and adult female offspring

Authors: *M. RINCÓN-CORTÉS, A. GRACE;
Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Postpartum adversity is one of the strongest predictors for the emergence of postpartum depression (PPD) in humans and a translational risk factor widely employed in relevant rodent models. Parental care is disturbed under conditions of adversity and/or chronic stress, including low resource environments, and in PPD. Nonetheless, the neural changes associated with these adversity-induced maladaptive behavioral states remain poorly understood. Here we show that postpartum scarcity-adversity can be modeled in rats by providing the rat dam with limited bedding and nesting (LBN) materials, which stresses the dam and mimics the effects of a stressful and low resource environment in potentiating maltreatment/neglect in humans. Indeed, LBN exposure from postpartum days (PD) 2-9 increased adverse caregiving behaviors directed at pups, impaired pup retrieval and increased FST immobility (t-tests: n=7-9 per group, $p < 0.05$). Given that mesolimbic dopamine (DA) function is an important mechanism for motivated maternal behavior and implicated in the pathophysiology of PPD, we assessed the impact of postpartum scarcity-adversity on *in vivo* electrophysiological properties of ventral tegmental area (VTA) DA neurons at two timepoints (n=5-7 per group). We found reduced numbers of active VTA DA neurons in LBN dams at PD 9-10 ($p < 0.01$) but not PD-21 ($p=0.54$),

suggesting a transient impact on VTA population activity in LBN dams. Finally, we assessed the transgenerational impact of early life scarcity-adversity exposure on VTA DA function by conducting VTA recordings in adult female offspring and found a long-lasting attenuation in VTA DA activity (n=6-8 per group, $p < 0.01$). These findings highlight a link between adversity-induced deficits in DA function and disrupted maternal behavior, suggesting the VTA/mesolimbic DA system as a potential mechanism by which postpartum scarcity-adversity drives disrupted maternal behavior, and early postnatal programming of adult VTA function in the offspring.

Title: Cortico-cortical relay of acoustic information to mouse Orbitofrontal cortex: relevance for neuropsychiatric disorders.

Authors: *A. TRIPATHI, S. SULIS SATO, P. MEDINI;
Integrative Medial Biol. Dept., Umeå Univ., Umea, Sweden

Abstract: Cortico-cortical relay of acoustic information to mouse orbifrontal cortex: relevance for neuropsychiatric disorders.
Anushree Tripathi, Sebastian Sulis Sato and Paolo Medini
The Orbitofrontal cortex (OFC) is salient for emotional regulation due to its reciprocal interactions with central brain areas such as the amygdala. These affective responses, disturbed in several psychiatric disorders are often driven by acoustic inputs. Indeed, auditory hallucinations are common hallmark of psychosis in both mood and thought disorders. Here we investigated the underlying cortico-cortical connectivity relaying acoustic information to mouse OFC. We also explored the sensitivity of this pathway to neuromodulators such as dopamine and neurosteroids as well as to sensory gating, impaired in dysexecutive syndromes. Retrograde tracers in the OFC revealed input cells in all auditory cortices, and clear acoustic responses were measured in OFC by local field potentials. Auditory responses were abolished by pharmacological and chemogenetic inactivation of the above identified pathway. The OFC auditory responses were reduced by local application of both dopaminergic agonist, Apomorphine and neurosteroid Allopregnanolone. Noticeably, apomorphine action lasted more in OFC compared to auditory areas and was modality-specific, whereas neurosteroids´ action

was sex-specific. Finally, the OFC acoustic responses reverberated to auditory cortex via feedback connections and displayed sensory gating, a phenomenon of local origin, not detectable in input auditory cortices.Taken together, our data demonstrates the cortico-cortical connectivity behind acoustic responses in the OFC, their dramatic sensitivity to dopamine and neurosteroid modulation, and to sensory gating by local OFC microcircuit action. Further illustration of the role of the OFC input-output circuits in auditory hallucinations can be studied in mice with targeted and clinically relevant mutations, in terms of behavioral responses to emotionally salient sounds.

Title: Sex-specific effects of photoperiod on dopamine signaling in the nucleus accumbens

Authors: *A. N. JAMESON[1], J. K. SIEMANN[2], J. R. MELCHIOR[3], E. S. CALIPARI[5], D. G. WINDER[2], C. A. GRUETER[7], B. A. GRUETER[6], D. G. MCMAHON[4];

Abstract: Circadian photoperiod, or day length, has a powerful influence on the function of neural circuits responsible for behavior. Photoperiodism is the response of an organism to seasonal changes in day length. Seasonal Affective Disorder (SAD) is an example of photoperiodism in which depressive symptoms are more prevalent and severe during winter months. Previously, our lab developed a novel mouse model that demonstrates photoperiodic input shapes long-term function of dorsal raphe (DR) serotonin neurons as well as affective behavior. However, little is known about an extended circuit beyond the DR that is sensitive to photoperiod and ultimately programs behavior. The DR projects to reward circuit regions that we hypothesize are also impacted by photoperiod. Within the reward circuit, the nucleus accumbens (NAc) is a ventral striatal region that integrates excitatory and neuromodulatory inputs to coordinate behavior. The NAc is highly implicated in reward processing and affective behaviors-thus, we predict that photoperiod-driven changes to the NAc result in changes to behavior. Here

we show that photoperiod programs dopamine (DA) dynamics in the NAc and DA-dependent behavior. Male and female mice were exposed to short (8hrs light, 16hrs dark), long (16hrs light, 8hrs dark), or equinox (12hrs light, 12hrs dark) photoperiod conditions. Using *ex-vivo* fast-scan cyclic voltammetry, we found that female mice in the long, summer-like photoperiod condition showed elevated DA release and reuptake rate in the NAc. Interestingly, male mice did not show differences in DA measures by photoperiod. We also assessed cocaine-induced hyperlocomotion in male and female short, long, and equinox mice. Short photoperiod female mice show a blunted locomotor response to cocaine, while male mice showed no differences by photoperiod. Our results indicate that photoperiod has a sex-specific effect on DA dynamics in the NAc that ultimately affects behavior. These results further our understanding of sex differences in mood disorders, especially in SAD. More importantly, we demonstrate that sex and environmental factors play a large role in DA dynamics and DA-dependent behavior, and both lighting conditions and the inclusion of females should be taken into consideration in future research.

Title: The suprachiasmatic nucleus regulates anxiety-like behavior in mice

Authors: *K. A. PETERSEN[1], C. A. VADNIE[2], L. EBERHARDT[1], M. HILDEBRAND[1], A. J. CERWENSKY[1], H. ZHANG[1], J. N. BURNS[1], D. BECKER-KRAIL[1], L. DEPOY[1], R. LOGAN[3], C. A. MCCLUNG[1];

Abstract: Individuals suffering from mood and anxiety disorders often show significant disturbances in sleep and circadian rhythms. Animal studies indicate that circadian rhythm disruption can cause increased depressive and anxiety-like behavior, but the underlying mechanisms are unclear. One potential mechanism to explain how circadian rhythms are contributing to mood disorders is through dysregulation of the suprachiasmatic nucleus (SCN) of

the hypothalamus, known as the “master pacemaker”. To investigate the role of the SCN in regulating depressive and anxiety-like behavior in mice, we directly manipulated the neural activity of the SCN using three optogenetic stimulation paradigms. First, acute stimulation of the SCN in the active phase (circadian time 14-16, CT14-16) during behavioral testing resulted in increased anxiety-like behavior. Chronic stimulation of the SCN late in the active phase (CT21) to advance rhythms shortened the period and dampened the amplitude of homecage activity rhythms. Lastly, repeated stimulation of the SCN at unpredictable times during the active phase dampened, fragmented, and reduced the stability of homecage activity rhythms. In both chronic SCN optogenetic stimulation paradigms, dampened homecage activity rhythms (decreased amplitude) were associated with increased measures of anxiety-like behavior. Unexpectedly the change in period of homecage activity rhythms was not directly associated with any mood-related behavior. Furthermore, we did not observe consistent correlations between homecage activity amplitude and depressive-like behavior in stimulated mice. Taken together, these results indicate that SCN-mediated dampening of rhythms is directly correlated with increased anxiety-like, but not depressive-like behavior in mice. This work is an important step in understanding how specific SCN neural activity disruptions affect mood and anxiety-related behavior.

Title: Disruption of the homeostasis and progression of oligodendroglial lineage, associating immune oligodendrocytes with prefrontal cortex hypomyelination in a depression mouse model

Authors: *A. G. KOKKOSIS, M. M. MADEIRA, S. E. TSIRKA;
Pharmacol. Sci., Stony Brook Univ., Stony Brook, NY

Abstract: Background Major Depressive Disorder (MDD; depression) is a chronic debilitating illness affecting yearly 350 million people worldwide. Emerging evidence shows that oligodendrogenesis and myelination are highly sensitive to stressful experiences and psychosocial input, with significant oligodendrocyte progenitor cell (OPC) reductions and white

matter deficits being reported in MDD patients. In a mouse model of depression, we demonstrate that chronic psychosocial stress can induce significant compromises of oligodendroglial-lineage (OLN) homeostasis, associating immune oligodendrocytes (ImOL) with OPC maturation arrest and myelin deficits. **Methods** The Repeated Social Defeat Stress (RSDS) paradigm (10 days) was utilized to study the early (6 days) and post RSDS stages (10+5 days and 10+15 days) in 8-12-week-old male C57BL/6J, *CX3CR1*-GFP$^+$, *CSPG4*-EGFP$^+$ mice. Behavioral tasks were performed to categorize the socially defeated mice as susceptible (S; depressive-like) and resilient (R; non-depressive) to stress. Naïve non-stressed (C) mice were included in the study. The study focused on the MDD-affected areas: prefrontal cortex (mPFC), ventral and lateral orbital cortex (VO-LO) and forceps minor (fmi). **Results** A time-dependent characterization of OLN cells revealed significant long-lasting losses of OPC populations (PDGFRα$^+$, CSPG4$^+$), and severe myelin deficits (MBP$^+$, CNP$^+$, MOG$^+$, MOBP$^+$) in the mPFC of the S mice. In addition, chronic stress led to a transient proliferation surge (BRDU$^+$, Ki67$^+$) of OPCs in early RSDS and a subsequent differentiation to immature (Pre-OLs; O4$^+$) and mature OLs (GST-π$^+$) post-RSDS. In addition, chronic psychosocial stress led to excessive oxidative stress (2-OH-Ethydine), activation of integrated stress responses (p-eIF2α/ATF4/CHOP axis), and impaired morphology in OPCs (Sholl and branched-structure analyses), leading to OPC apoptosis and OL reductions post-RSDS. Using a sn-RNAseq dataset from the PFC of MDD patients (Nagy et al., 2020), we were able to identify a novel OL population, the Im-OL, expressing immune-related components: MHCII, C3, P2RY12, in the S groups post-RSDS. Of importance, significant microglial recruitment (CX3CR1) and phagocytosis of MHCII-tagged myelin (CX3CR1$^+$CNP$^+$ MHCII$^+$) in S mice suggest that ImOL populations might act as recruiters of innate immunity and concomitant myelin deficits during depression. **Conclusions** Our data exhibit that chronic stress can significantly compromise the OLN homeostasis and lead to OPC/OL reductions, suggesting that the ImOLs might contribute as an instigator of myelin deficits in a depression mouse model.

Topic: G.09. Drugs of Abuse and Addiction

Title: The effects of sex and ovarian hormones on morphine-induced anxiety and withdrawal behaviors

Authors: *T. DENNIS;
Neurosci., St. Mary's Col. of Maryland, St. Marys City, MD

Abstract: Addiction is a chronic and relapsing brain disease that levies a high cost on both the individual and on society. Although women have been traditionally understudied in addiction, there is a consensus that female and male populations exhibit unique profiles of drug use and addiction for multiple drugs of abuse (including opioids). For example, women (and female rats) exhibit a “telescoping effect” in which they transition from first use to addiction more quickly than men (and male rats). Differences in opiate withdrawal are also present, with male rats displaying more severe symptoms of somatic withdrawal earlier on, and female rats displaying a more protracted withdrawal syndrome. Ovarian hormones, such as estradiol and progesterone, have also been implicated in addiction. For example, high circulating levels of estradiol are associated with increased drug-seeking behavior. High circulating progesterone, on the other hand, is associated with decreases in drug-seeking behavior. Much less, however, is known about how ovarian hormones might influence somatic withdrawal and anxiety-related behaviors in response to opiate withdrawal. To understand this relationship, we performed a study in which female and male rats received experimenter-administered escalating doses of morphine (or saline) twice daily for ten days, followed by somatic withdrawal observation (12, 24, 36, 48, 60, 72, 84, 96, and 108 hrs into withdrawal), elevated plus maze testing (12 and 108 hrs into withdrawal), and light-dark box testing (12 and 108 hrs into withdrawal). Prior to the initiation of the study, all female rats received ovariectomies and all male rats received sham surgeries. Following surgery, a four day cycle of subcutaneous hormone supplementation was provided to mimic cycling in the female rats (First Day - 0.1ml 5µg estradiol; Second Day - 0.1ml 5µg estradiol; Third Day - 0.1ml 250µg progesterone; Fourth Day - peanut oil). Male rats also received daily injections of peanut oil, but never received estradiol or progesterone. To understand the extent to which ovarian hormones contribute to anxiety during earlier and later withdrawal, multiple groups of female rats received staggered hormone supplementation so that estradiol or progesterone levels were highest during anxiety testing. Very preliminary evidence suggests that regardless of hormone treatment, morphine-treated female rats display more anxiety-related behavior compared to their matched saline-treated groups both 12 and 108 hours into withdrawal (a phenomenon not yet observed in male rats). The running of additional planned cohorts as well as the analysis of somatic withdrawal observation is currently underway.

Title: Intranasal administration of GDNF plasmid DNA nanoparticles reduces reinstatement of intravenous drug self-administration in a rat model of opioid use disorder (OUD)

Authors: *B. L. WASZCZAK[1], F. M. VASSOLER[2], K. E. BUDGE[3], S. B. ISGATE[3], H. MOJAHED YAZDI[4], U. K. VANI[4], E. N. POTHOS[4], O. SESENOGLU-LAIRD[5], L. PADEGIMAS[5], R. C. MOEN[5], M. J. COOPER[5], E. M. BYRNES[3];
[1]Pharmaceut. Sci., Northeastern Univ., Boston, MA; [2]Dept. of Biomed. Sci., [3]Comparative Pathobiology, Tufts Univ. Cummings Sch. of Vet. Med., North Grafton, MA; [4]Integrat Physiol & Pathobiol, Prog. in Pharmacol & Exp Therapeut. & Neurosci., Tufts Univ. Sch. of Med., Boston, MA; [5]Copernicus Therapeutics, Inc., Cleveland, OH

Abstract: Relapse is a persistent threat to long term recovery for individuals with OUD. During recovery, craving is a key factor in the decision to reinitiate drug use. Intravenous self-administration reinstatement models provide a measure of relapse-related drug seeking behavior with high construct validity and provide a measure of "wanting" or "craving". Glial cell-line derived neurotrophic factor (GDNF) has been proposed as a therapy to reduce relapse in substance use disorders. Here, we assessed the effects of intranasal delivery of GDNF plasmid DNA nanoparticles (NPs) on relapse vulnerability by examining context-induced (spontaneous) reinstatement in long access (6h/day) oxycodone (OXY) self-administering rats following 30 days of forced abstinence. Adult male Sprague Dawley rats were implanted with jugular catheters and trained to selectively press an active lever for OXY (0.1 mg/kg/infusion; 6 h/day; 12 training days) using a fixed ratio 1 (FR1) schedule for 9 days followed by FR5 for 3 days to increase responding. On Day 13 all animals were tested for their level of motivated responding for OXY using a progressive ratio (PR) schedule. The PR schedule increases response requirements (number of lever presses) after each drug infusion, which tests animals' motivation to obtain the drug by increasing the effort required to obtain a single dose. On Day 14 animals were anesthetized with ketamine/dexmedetomidine and intranasally administered either saline vehicle or pGDNF DNA NPs (90 μg DNA) with groups counterbalanced based on both their total drug intake (comparable OXY exposure) and their responding during PR (comparable willingness to work for OXY). All animals then underwent forced abstinence for 30 days. Context-induced reinstatement was tested by returning all rats to the self-administration chamber and measuring active lever pressing over 90 min. Only saline was available in the syringe. Active lever pressing served as a measure of drug seeking. Results indicated that intranasal pGDNF NPs significantly decreased reinstatement in rats that exhibited similar amounts of OXY intake and progressive ratio (PR) responding prior to drug infusion ($p=0.028$; OXY+veh n=12, OXY+ pGDNF NPs n=12). Even relatively high responders treated with pGDNF NPs demonstrated reduced reinstatement behavior, suggesting efficacy over a range of intake levels and in animals demonstrating robust PR responding. These data support our hypothesis that intranasal GDNF DNA NPs may correct a prolonged reward deficit instigated by the chronic use of opioids, and they strongly endorse the clinical translational potential of intranasal pGDNF DNA NPs as a treatment to reduce opioid relapse.

Title: Early social isolation stress increases addiction vulnerability to heroin and alters c-Fos expression in mesocorticolimbic system

Authors: *Z. WANG, A. SINGH, Y. XIE;
Univ. of Kansas, Lawrence, KS

Abstract: ***Rationale***: Adverse psychosocial factors during early childhood or adolescence compromise neural structure and brain function, inducing susceptibility for many psychiatric disorders such as substance use disorder. Nevertheless, the mechanisms underlying early life stress-induced addiction vulnerability is still unclear, especially for opioids. ***Objectives***: To address this, we used a mouse heroin self-administration model to examine how chronic early social isolation (ESI) stress (5 weeks, beginning at weaning) affects the behavioral and neural responses to heroin during adulthood. ***Results:*** We found that ESI stress did not alter the acquisition for sucrose or heroin self-administration, nor change the motivation for sucrose on a progressive ratio schedule. However, ESI stress induced an upward shift of heroin dose response curve in female mice, and increased motivation and seeking for heroin in both sexes. Furthermore, we examined the neuronal activity (measured by c-Fos expression) within the key brain regions of the mesocorticolimbic system, including prelimbic cortex (PrL), infralimbic cortex (IL), nucleus accumbens (NAc) core and shell, caudate putamen, and ventral tegmental area (VTA). We found that ESI stress dampened c-Fos expression in PrL, IL and VTA after 14-day forced abstinence, while augmented the neuronal responses to heroin-predictive context and cue in IL and NAc core. Moreover, ESI stress disrupted the association between c-Fos expression and attempted infusions during heroin-seeking test in PrL. ***Conclusions***: These data indicate that ESI stress leads to increased seeking and motivation for heroin, and this may be associated with distinct changes in neuronal activities in different subregions of the mesocorticolimbic system

Title: Modulation of reward sensitivity by morphine administration and physiological state

Authors: *R. M. DONKA, B. G. RODRIGUEZ, T. M. HSU, M. F. ROITMAN, J. D. ROITMAN;
Psychology, Univ. of Illinois, Chicago, Chicago, IL

Abstract: Physiological need states such as hunger and thirst drive organisms to perform goal-directed motivated behavior. Reward-circuitry in motivated behavior may be engaged by the positively reinforcing properties of needed food and fluid or by the negatively reinforcing properties of alleviation of the need state and its associated negative affect. In drug addiction, the induction of negative affect and subsequent alleviation through drug taking supports relapse through similar negative reinforcement. Here we examine changes in sensitivity of intracranial self-stimulation of the medial forebrain bundle under differing physiological need states as an index of reward sensitivity. We hypothesized that acute states of physiological need would increase reward sensitivity, while chronic states of physiological need would decrease reward sensitivity. Additionally, we hypothesized morphine withdrawal would decrease reward sensitivity. Stimulating electrodes were implanted in the medial forebrain bundle at the level of the lateral hypothalamus and animals were trained to lever press for stimulation (n = 17). Using a rate-frequency protocol we determined the threshold stimulation frequency (theta) that was reinforcing for each individual subject. We then measured how changes in physiological state altered theta and overall task engagement using a within-subjects design. We found that acute water deprivation, acute food deprivation, and chemogenetic activation of glutamatergic neurons in the subfornical organ (SFO) in water-sated animals decreased theta, indicating an increase in reward sensitivity compared to states of satiety. Additionally, total lever pressing increased in states of acute physiological need indicating a higher level of task engagement. We observed a small increase in theta values under chronic water restriction, indicating a decrease in reward sensitivity. Morphine administration and withdrawal both increased thetas, indicating a decrease in reward sensitivity. Lever pressing was significantly reduced during morphine administration and returned to baseline during withdrawal. Collectively, these results suggest that acute states of physiological need generally increase reward sensitivity while chronic need states generally reduce reward sensitivity despite specificity in food and fluid intake in response to need.

Title: Intermittent Access to Oxycodone Engenders Robust Drug-Seeking and Dopaminergic Changes in the Nucleus Accumbens

Authors: *K. R. SAMSON, R. A. ESPAÑA;
Neurobio. and Anat., Drexel Univ. Col. of Med., Philadelphia, PA

Abstract: One of the major barriers in successful treatment of opioid use disorder is the persistence of drug craving during periods of abstinence, which contribute to high relapse rates. Dopamine neurotransmission in the mesolimbic pathway has been implicated in opioid reward and reinforcement, but the precise mechanisms by which dopamine may drive drug craving has not been elucidated. To examine the extent to which opioid craving during abstinence is associated with alterations in dopamine neurotransmission, female and male rats self-administered oxycodone under an intermittent access schedule of reinforcement. Following self-administration, rats underwent a forced abstinence period. Cue-induced seeking tests were conducted on the first day of abstinence and at the end of the 14-day abstinence period to assess oxycodone craving. Eighteen hours following the final seeking test, we performed *ex vivo* fast scan cyclic voltammetry recordings in the nucleus accumbens core. Preliminary results suggest that intermittent access to oxycodone engendered distinct behavioral phenotypes, yielding a group of “low-seeking” rats and a group of “high-seeking” rats. Interestingly, both groups displayed dysfunctional dopamine transmission, compared to oxycodone-naïve rats. Ongoing experiments will attempt to determine how intermittent access to oxycodone influences dopamine transmission early in the abstinence period. These observations suggest that exposure to oxycodone engenders distinct behavioral phenotypes, with potentially similar underlying dopamine dynamics.

Title: Relation among potential measures of morphine vulnerability in rats

Authors: *W. WHITE[1], I. M. WHITE[2];
[2]Psychology, [1]Morehead State Univ., Morehead, KY

Abstract: When rats are given 5.0 mg/kg morphine, they show considerable individual differences in the magnitude of their change in activity 12 to 24 hours later: Most animals show a substantial reduction in activity (acute withdrawal sensitive), while others show virtually no change (acute withdrawal insensitive), compared to saline control. The intensity of acute withdrawal following drug administration could be an important determinant of abuse liability, and so identifying predictors of the magnitude of acute withdrawal may be important. The present study continued to assess the predictive relation between potential measures of drug vulnerability and acute withdrawal intensity. Adult male Wistar rats were run on several behavioral procedures thought to yield measures predictive of drug vulnerability, and potentially of acute withdrawal intensity. These measures included percent of time spent in a closed as opposed to an open arm of an elevated maze (a measure of caution); distance moved in a novel open field (a measure of exploration); and degree of conditioning to a CS in a sign/goal tracking task (a measure of sign responsiveness). In addition, to assess aspects of prior morphine receipt that might predict intensity of acute withdrawal, subjects received different doses of morphine (1.25, 2.5, or 5.0 mg/kg), acutely or repeatedly, and the locomotor response to these doses was assessed during the first several hours following treatment (short-term period) and from hours 12 to 24 post treatment (acute withdrawal period). We describe only a couple of the more suggestive relations obtained. Though none of the behavioral measures was significantly correlated with withdrawal intensity, high exploration predicted low short-term locomotor activity to higher morphine doses. In addition, a lower short-term response to higher doses of morphine predicted a more intense acute withdrawal. Overall, results suggested that a behavioral measure of morphine's short-term inhibitory effect, such as a measure of arouse-ability, might predict morphine acute withdrawal and morphine vulnerability.

Title: Environmental enrichment facilitates early abstinence from heroin in male and female rats

Authors: E. D. BARRERA[1], P. TIMKEN[1], E. LEE[1], H. GOLDSTEIN[1], D. PARASRAM[1], A. VASHISHT[2], *R. RANALDI[1,2];
[1]Queens Col. - City Univ. of New York, Flushing, NY; [2]The Grad. Ctr. of CUNY, New York, NY

Abstract: Opioid dependence is a chronic public health issue. Although pharmacological and behavioral treatments are effective in promoting short-term abstinence they are still largely ineffective in preventing relapse. Environmental enrichment (EE), when implemented non-concurrent with drug exposure, has been shown to diminish drug-seeking in rodent models of cue-induced reinstatement. We have previously demonstrated that EE can significantly reduce cue-induced heroin seeking in male and female rats after periods of craving incubation. Here we tested whether these beneficial effects of EE extend to true (self-initiated) abstinence in males and females. We trained male (N=13) and female (N=16) rats to self-administer intravenous heroin (0.05 mg/kg/infusion) during 3-h sessions, under an FR1 schedule of reinforcement where contingent lever presses were followed by the presentation of a light cue and heroin infusion. After 18 self-administration sessions the rats were randomly assigned to housing; half were placed into EE and the other half into non-EE housing where they stayed for the remainder of the experiments. Thereafter, rats began the abstinence phase. Here 2/3 of the metal rod flooring adjacent to the levers was electrified and the other 1/3 consisted of a no-shock zone. Rats could self-administer heroin in 35-min daily sessions under an FR2 schedule of reinforcement. The current intensity was increased daily by 0.04 mA if the drug-paired lever was pressed in the previous session. This continued daily until abstinence criteria - 3 consecutive sessions without drug-paired lever presses - were met. This was followed by a 35-min cue-induced relapse test during which a non-contingent light-cue was presented every 5 min and current strength was set at 25% of the established abstinence current. Rats in the EE condition reached abstinence criteria in significantly fewer sessions than those in the non-EE condition. Also, abstinence criteria were met significantly earlier in females than males. Finally, cue-induced relapse was significantly higher in females compared to males regardless of housing condition. Our findings provide evidence for the therapeutic efficacy of enrichment in facilitating drug-abstinence and elucidate sex differences in cue-induced relapse that may aid in the development of treatments focusing on relapse prevention.

Title: Interleukin-1 receptor-associated kinase 4 (IRAK4) in the nucleus accumbens regulates opioid-seeking behavior

Authors: *R. WU, J. LIU, J. VU, D. M. DIETZ, J.-X. LI;
Univ. at Buffalo, Buffalo, NY

Abstract: Opioid addiction remains a severe health problem. While substantial insights underlying opioid addiction have been yield from neuron-centric studies, the contribution of non-neuronal mechanisms to opioid-related behavioral adaptations has begun to be recognized. Toll-like receptor 4 (TLR4), a pattern recognition receptor, has been widely suggested in opioid-related behaviors. Interleukin-1 receptor-associated kinase 4 (IRAK4) is a kinase essential for TLR4 responses, However, the potential role of IRAK4 in opioid-related responses has not been examined. Here, we explored the role of IRAK4 in cue-induced opioid-seeking behavior in male rats. We found that morphine self-administration increased the phosphorylation level of IRAK4 in the nucleus accumbens (NAc) in rats; the IRAK4 signaling remained activated after morphine extinction and cue-induced reinstatement test. Both systemic and local inhibition of IRAK4 in the NAc core attenuated cue-induced morphine-seeking behavior without affecting the locomotor activity and cue-induced sucrose-seeking. In addition, inhibition of IRAK4 also reduced the cue-induced reinstatement of fentanyl-seeking. Our findings suggest an important role of IRAK4 in opioids relapse-like behaviors and provide novel evidence in the association between innate immunity and drug addiction.

Title: Cell-type specific ventral pallidum regulation of heroin seeking and refraining behavior

Authors: *B. N. KUHN[1], E. DERESCHEWITZ[2], A. M. KALASKY[2], P. W. KALIVAS[3]; [1]Neurosci., [2]Med. Univ. of South Carolina, Charleston, SC; [3]Neurosci. Res., Med. Univ. S Carolina, Charleston, SC

Abstract: Substance use disorder is a chronic neuropsychiatric disorder characterized by compulsive drug seeking and relapse, in spite of attempts to remain abstinent and refrain from drug use. While significant scientific effort had been put into understanding the neurobiological basis of addiction-related behaviors, less has been done to disentangle the neural circuitry underlying the motivation for drug seeking versus refraining (i.e. withholding drug seeking). Recent work has shown that the dorsolateral ventral pallidum (dlVP) mediates both drug-seeking and refraining behavior, but does so in a cell-type specific manner following cocaine self-administration training. In the current study, transgenic mouse lines expressing Cre recombinase selectively in either glutamate, GABA or enkephalin cells were used. A cre-dependent stimulatory DREADD (Designer Receptors Exclusively Activated by Designer Drugs) was injected into the dlVP of male and female mice, following which mice underwent heroin self-administration training for 10 days. Next, a 1-week forced abstinence period was imposed, after which extinction training (12 sessions) commenced. A test for cue-induced reinstatement followed extinction training. Cell-specific chemogenetic stimulation of dlVP cells occurred during late extinction training and during a test for cue-induced reinstatement using a within-subject design. Contrary to previous finding using cocaine self-administration, stimulation of dlVP glutamate cells had no effect on heroin seeking during extinction training; however, akin to work using cocaine, stimulation did attenuate cue-induced reinstatement of heroin-seeking behavior. Conversely, stimulation of dlVP GABA and enkephalin cells enhanced cue-induced reinstatement of drug-seeking behavior, but did not affect behavior during extinction training as was shown with work using cocaine. These results demonstrate that dlVP cell specific regulation of drug seeking and refraining is conserved across drug classes, albeit with subtle differences. Ongoing work using the same mouse lines are employing an intersectional chemogenetic approach to further dissect cell-type specific circuitry mediating heroin-refraining and seeking behavior. Specifically, the effects of selective stimulation of the glutamatergic projection from the dlVP to the lateral hypothalamus, and the GABAergic projection from the dlVP to the subthalamic nucleus are underway. Taken together, these data will advance our understanding of the cell-type specific dlVP pathways that may contribute to attenuating drug relapse.

Title: Characterization of the rat nucleus accumbens transcriptome after acute injection or chronic self-administration of morphine using single nuclei RNAseq

Authors: *B. C. REINER[1], Y. ZHANG[2], E. DAVILA PEREA[1], J. BEN NATHAN[1], K. RAGNINI[1], T. N. FERRARO[3], W. BERRETTINI[1], H. D. SCHMIDT[1], R. CRIST[1]; [1]Psychiatry, [2]Biobehavioral Hlth. Sci., Univ. of Pennsylvania Perelman Sch. of Med., Philadelphia, PA; [3]Biomed. Sci., Cooper Med. Sch. of Rowan Univ., Camden, NJ

Abstract: Opioid use causes broad transcriptomic changes across many regions of the brain. In animal models, acute injection and self-administration result in distinct gene expression profiles suggesting differences between the proximal effects of opioids and neural adaptations to chronic exposure. However, studies identifying how these phenotypes affect the transcriptome of neuronal cell types is limited. The goal of the current study is to compare the transcriptomic changes following acute injection and chronic self-administration of morphine using single nucleus RNA sequencing (snRNAseq). Male Brown Norway rats (n=5/group) were treated with a single intraperitoneal injection of morphine or saline. A second cohort of rats (n=6/group) were given surgically-implanted jugular catheters and assigned to either 10 days of morphine self-administration in a FR1 operant conditioning model or yoked saline control. Brains from all animals were snap frozen and nucleus accumbens samples were punched. SnRNAseq libraries were generated using the 10x Genomics Chromium Controller and sequenced on a NovaSeq 6000. The R package Seurat was used for quality control and to cluster nuclei based on transcriptomic data. Identities of clusters were determined using expression of known cell-specific marker genes. The R package MAST was used to analyze differential expression between cases and control in each cluster separately for the acute and chronic groups. Ingenuity Pathway Analysis and FUMA were used for analysis of canonical pathways and upstream regulators. 27 transcriptomically distinct clusters of nuclei were identified. In these clusters, acute morphine injection resulted in 1,106 differentially expressed genes (DEGs), compared to 2,453 DEGs in the chronic self-administration model. The majority of DEGs for both treatment paradigms were observed in oligodendrocytes, astrocytes, and D1 and D2 medium spiny neurons. However, the specific DEGs identified in these cell types were largely unique to either acute or chronic morphine treatment. Cell type-specific differential expression was observed for numerous genes previously linked to opioid phenotypes (e.g. Oprm1, Hspa4, Pde10a). Pathway analysis revealed cell type-specific activity changes. These data indicate that both acute and chronic morphine exposure result in notable cell type-specific transcriptomic changes in the nucleus accumbens, and identification of DEGs and activated pathways with prior connections to opioids provides validity for our findings and suggests that future work must focus on the roles specific cell types play in opioid use disorder.

Title: Coordinating Memory with Stimulation: Strength And Congruency Of Stimulation Patterns In Comparison To Native Neural Codes

Authors: *B. ROEDER[1], X. SHE[2], M. RILEY[1], B. MOORE[2], D. SONG[2], T. BERGER[2], S. DEADWYLER[1], R. HAMPSON[1];
[1]Wake Forest Sch. of Med., Winston Salem, NC; [2]USC, Los Angeles, CA

Abstract: Human memory is subject to decline and loss due to disease and injury. Social and economic costs of Alzheimer's Disease, Traumatic Brain Injury, Stroke and other conditions are billions of dollars per year. Development of a neural prosthetic for human memory requires understanding how hippocampal stimulation interacts with natural or "native" neural codes present during stimulation. Previously, this laboratory used a combined Delayed-Match-to-Sample+Delayed Recognition (DMS-DR) task to study how effectively different stimulation patterns modulate memory performance. The results of this task also allow exploration of how stimulation and native neural codes interact.
The standard DMS-DR task presents Sample, Match and Nonmatch images from five categories (animal, building, plant, tool, vehicle). However, if the original (Sample) image is ambiguous (i.e. a grey square instead of a category image), there is minimal category-specific native neural activity, and Match phase choices are randomized. In those cases, stimulating with category patterns during the Sample phase increases the rate that categories associated with the selected stimulation pattern in the DMS match phase (Deadwyler et al, 698.05, SFN2019, Chicago, Il), suggesting that stimulation "writes" the stimulated category information into the hippocampus. Furthermore, random stimulation produces either no change or a slight decrease in memory performance (Hampson et al. J. Neural Eng, 2018, 15:036014).
To further assess the interaction or interference between stimulated and native neural codes, we examined DMS+DR tasks where the categories of the Sample image matched the stimulation pattern. When stimulation patterns were modeled from a subject's neural recordings, we

observed over 13% of category and patient combinations had increased memory performance, just over 79% had no change, and 7% had decreased performance. When patterns were derived from models constructed across one or more other subjects, 8% of category and patient combinations had increased memory performance, 84% had no change, and 8% had decreased performance.
This interaction suggests that two components dictate how a stimulation pattern will interact with a native code, the strength of the pattern and how congruent the pattern is to native codes. We propose that "strength" results from the relationship of neurons active natively to stimulation activated neurons. "Congruence" indicates how well stimulated patterns emulate native patterns. Further exploration of pattern congruency and strength are important to the ability to create, select, and adjust patterns for desired neural prosthetic stimulation outcomes.

Title: Coordinating Memory with Stimulation: Off-Target Application of Content Codes

Authors: *R. HAMPSON[1], B. ROEDER[1], M. RILEY[1], X. SHE[2], B. MOORE[2], D. SONG[2], T. W. BERGER[2], S. DEADWYLER[1];
[1]Wake Forest Sch. of Med., Winston Salem, NC; [2]Biomed. Engin., USC, Los Angeles, CA

Abstract: In the adjacent poster, we studied the strength and congruence of hippocampal stimulation as it affects Human memory. Development of a neural prosthetic for human memory also requires an understanding of the effects of stimulation that is deliberately noncongruent with natural or "native" neural codes already present at the time of stimulation.
Stimulation during a combined Delayed-Match-to-Sample+Delayed Recognition (DMS+DR) task that utilized images in five categories (animal, building, plant, tool, and vehicle) resulted in both increases and decreases in memory when the category pattern used to stimulate did not match the category of the sample image (Hampson et al, 698.04, SFN 2019, Chicago, Il). For

these studies we modeled stimulation patterns from neural recordings taken while subjects performed a DMS task with Sample pictures categorized as containing animal, building, plant, tool or vehicle images. While it was intended that the modeled "codes" were specific to only the desired category, many images contained "shared content," such as plant in pictures of both animals and buildings. Thus, there may be overlap between modeled codes for different categories.
On tasks where the stimulated Sample code was deliberately "noncongruent" (i.e. did not Match the category of the stimulation pattern) and the patterns were specifically derived form that individual subject's own neural recordings, we observed that over 10% of category and patient combinations had increased memory performance, approximately 76% of combinations had no change in performance, and 13% had decreased memory performance. When the stimulation codes were derived from neural recordings from one or more other (donor) subjects; over 10% of category and patient combinations had increased memory performance, 84% of combinations had no change in performance, and 5% had decreased memory performance.
Decreases in DMS+DR performance suggests noncongruent codes that are sufficiently strong to interfere with native codes. In contrast, increases in performance may result from "weak" codes, however, that is unlikely due to prior results of no change (or decrease) in performance due to random stimulation pattern. More likely, there is overlap in between codes for the separate categories, which can result in improved performance, particularly where the stimulated code is able to "write-in" at least partial category information as with ambiguous Sample trials.

Title: Coordinating Memory with Stimulation: Decoding Spatio-Temporal Patterns of Spikes with Small Sample Size Using a Double-Layer Multi-Resolution Classifier

Authors: *X. SHE[1], B. M. ROEDER[4], G. NUNE[1], B. LEE[2], S. SHAW[6], A. NGUYEN[6], C. HECK[1], C. LIU[1], S. A. DEADWYLER[5], R. E. HAMPSON[5], T. W. BERGER[3], D. SONG[3]; [1]USC, Los Angeles, CA; [2]USC, San Marino, CA; [3]Biomed. Engin., USC, Los Angeles, CA;

[4]Neurosci., [5]Wake Forest Sch. of Med., Winston Salem, NC; [6]Rancho Los Amigos Rehabil. Ctr., Los Angeles, CA

Abstract: We build a double-layer multiple temporal-resolution (multi-resolution) classifier for decoding single-trial behavioral/cognitive information from spatio-temporal patterns of spikes. The structure of this classifier is designed specifically for solving the highly underdetermined estimation problem caused by high-dimensional spike patterns, the small sample size, and taking into account the unknown optimal temporal resolution for decoding spikes. The double-layer multi-resolution classifier consists of two layers. In the first layer, to solve the underdetermined problem resulting from the small sample size and the very high dimensional input and output signals, B-spline basis functions are applied to reduce dimensionality; *L*1-regularized logistic regression (LASSO) classifiers are used to achieve sparse model estimation. Multiple classifiers with different B-spline resolutions are employed to include a wide range of temporal resolutions of neural signals. Each classifier serves as a base-learner to classify spatio-temporal patterns with a given temporal resolution. A bagging-based sampling strategy is used to further reduce the estimation variances of these classifiers. In the second layer, another LASSO classifier takes outputs of first-layer classifiers as inputs to make the final output prediction. This ensemble classifier serves as a meta-learner that combines multiple temporal resolutions to classify the spatio-temporal patterns of spikes. Results in both synthetic and experimental data show that this classifier can accurately decode high-dimensional spike patterns using a small number of instances. The double-layer classifier consistently outperforms the single-layer classifier by utilizing multi-resolution spatio-temporal features of spike patterns in classification. The decoding classifier also provides signature functions that represent spatio-temporal characteristics of spike patterns most relevant to classifications.

Title: Coordinating Memory with Stimulation: Hippocampal Stimulation in the Injured Brain

Authors: *M. RILEY[1], B. M. ROEDER[1], X. SHE[2], B. MOORE[2], D. SONG[2], T. W. BERGER[2], S. A. DEADWYLER[1], R. E. HAMPSON[1];
[1]Physiology/Pharmacology, Wake Forest Sch. of Med., Winston Salem, NC; [2]Biomed. Engin., USC, Los Angeles, CA

Abstract: Beneficial effects from experimental treatments are not distributed equally among all participants of the study nor are approved treatments fully beneficial for all patients. Some patients see a larger improvement of outcomes or a larger decrease in negative symptoms while others may see barely any effects. Our lab has shown that encoding of stimuli in memory could be enhanced or impaired using hippocampal stimulation based upon different categories in human models (Hampson et al. J. Neural Eng, 2018, 15:036014).
Recently we tested different models used to influence short-term memory in human hippocampal ensemble activity during performance of a task for specific categories of visual stimuli that would either match the category or would match to a different category (See Roeder et al, and Hampson et al, this session). In human patients undergoing Phase II invasive monitoring for intractable epilepsy, recordings from an initial DMS (training) session were employed to determine neuron firing patterns for five categories of images; animal, building, plant, tool, and vehicle.
We used the Multiple-in-Multiple-Out (MIMO), the Memory Decoding Model (MDM), and a combination of both models to test five different image content categories and stimulated using patterns positively and negatively correlated with each category. Calculation of specific stimulation patterns prior to the stimulation session allowed to identify CA1 and CA3 neurons as stimulation targets.
Of our subject population, a subset had previously undergone either a repeated and/or mild-to-moderate brain injury (RMBI) or a traumatic brain injury (TBI). The subject's medical history was unknown to the experimenters while conducting the experiment. When examined compared to control subjects, these subjects showed a much larger increase when using positive stimulation patterns and a much larger decrease when using negative stimulation patterns. Each model as well as the combined stimulation from both models showed these same behavioral changes on our DMS task, indicating that this type of hippocampal stimulation was effective at improving memory performance.
These results provide evidence that models for memory stimulation are more beneficial for previously-injured patients in aiding when performing cognitive tests than control patients who had not suffered a brain injury previously. Additionally, they emphasize the justification for continuing to develop this technology to aid people who have suffered brain injuries.

Title: Temporal context modulates encoding and retrieval of overlapping events

Authors: *D. E. SMITH, I. L. MOORE, N. M. LONG;
Univ. of Virginia, Charlottesville, VA

Abstract: Interference between overlapping events occurs due to a tradeoff between encoding the present event and retrieving the past, overlapping event. Temporal information - 'when' something occurred - is a defining feature of episodic memory and can cue retrieval of a past event. However, the influence of temporal overlap, or proximity in time, between events on interference is unclear. To test the effect of temporal overlap on interference, we conducted a human scalp electroencephalography (EEG) study in which subjects were explicitly directed to either encode the present event or retrieve a past, overlapping event. Critically, we manipulated temporal overlap between events by varying the distance between pairs of objects, whereby the closer two objects are in time, the greater their temporal overlap. We find that greater temporal overlap between two objects leads to selective interference and impaired memory for past objects when the top-down goal is to encode the present object. We used pattern classification analyses to measure the extent to which participants engaged a 'retrieval state' -- a brain state distinct from encoding in which attention is directed internally. We find that greater temporal overlap leads to automatic retrieval of a past event, independent of top-down goals to either encode or retrieve. The retrieval state that we observe likely reflects a general retrieval mode, rather than retrieval success or effort. Together, these findings provide insight into the role of temporal overlap on interference and memory formation.

Title: Episodic encoding in the infant brain revealed through subsequent memory

Authors: *T. S. YATES[1], C. T. ELLIS[1], N. B. TURK-BROWNE[1,2];
[1]Psychology, [2]Wu Tsai Inst., Yale Univ., New Haven, CT

Abstract: Episodic memories from infancy and early childhood are rare later in life, raising questions about whether they were encoded in the first place. Such infantile amnesia in adults and behavioral tasks in children suggest that episodic memory abilities, and the hippocampal circuits they require, may not mature until as late as middle childhood. However, recent neurophysiological studies of young rodents and neuroimaging studies of human infants and toddlers suggest that the infant hippocampus is functional and contributes to some forms of early learning. Whether and how the hippocampus supports episodic encoding in infants under two years has never been tested. We collected fMRI data from awake infants while they performed a variant of the subsequent memory design commonly used in adult cognitive neuroscience. Encoding trials presented an image of a face, object, or scene on an attention-getting psychedelic background. Test trials were inserted continuously into the trial sequence at study-test lags of 30-90 seconds. These trials displayed two images, the old item and a new item from the same category, in a visual paired comparison task. Looking time to the old and new items was coded offline to quantify an item-specific novelty/familiarity preference, as a marker of recognition memory strength. We then back-sorted the encoding trials based on this later test preference, to identify brain regions whose activity during encoding predicted subsequent novelty/familiarity. To date, a partial sample of 10 infants has been collected. We first contrasted task activation for trials containing faces, objects, and scenes, and found robust and selective neural responses in infant visual cortex that aligned with category-selective regions from an adult meta-analysis. We then used a parametric model to relate encoding activity to the proportion of looking to the old item at test. Preliminary results indicate involvement of brain regions in infants that have been linked to episodic memory in adults, including in the medial temporal lobe. This ongoing research contributes to an emerging body of evidence that infants may have more robust memory abilities and more developed memory systems than typically credited.

Title: Multivariate decoding of memory brain states across the lifespan

Authors: *I. L. MOORE, N. M. LONG;
Univ. of Virginia, Charlottesville, VA

Abstract: Healthy older adults typically show impaired episodic memory, memory for when and where an event occurred, but intact semantic memory, knowledge for general information and facts. We hypothesize that these effects can be explained by an increased tendency to enter into and remain in a 'retrieval state,' a brain state in which attention is focused internally in an attempt to retrieve prior knowledge. A retrieval state is neurally distinct from and trades off with an 'encoding state,' a brain state in which attention is focused externally. To test our hypothesis, we conducted a scalp electroencephalographic (EEG) experiment in which younger and older adult participants explicitly engaged in encoding and retrieval states. Specifically, participants viewed a list of common objects (e.g. bench, apple; List 1 objects), then viewed a list of non-identical, but categorically related objects (e.g. a new bench, a new apple; List 2 objects). On each List 2 trial, participants were instructed to either encode the current List 2 object (e.g. the new bench) or retrieve the categorically related List 1 object (e.g. the old bench). We measured memory for all objects in a two-alternative forced choice recognition task. Both younger and older adults showed better memory for List 2 objects paired with the 'encode' compared to the 'retrieve' instruction. Numerically, older adults showed worse List 2 memory compared to younger adults, supporting the interpretation that older adults are more likely to engage in retrieval during List 2. We used multivariate pattern classification to assess the extent to which participants engaged in encoding and retrieval states. We find above chance classification for both younger and older adults, meaning that distinct electrophysiological signatures support encoding vs. retrieval. We assessed classifier evidence -- a continuous measure of how confident the classifier is that the current trial is an 'encode' or 'retrieve' trial -- across the List 2 stimulus interval (2000 ms). We find that dissociations between encode and retrieve trials occur earlier in the stimulus interval for older compared to younger adults. Together these findings suggest that engagement of encoding and retrieval states, specifically in terms of temporal dynamics, differs across the lifespan and may relate to episodic memory deficits observed in healthy aging.

Title: Automated segmentation outperforms manual segmentation of the infant hippocampus

Authors: *J. T. FEL, C. T. ELLIS, N. B. TURK-BROWNE;
Psychology, Yale Univ., New Haven, CT

Abstract: The hippocampus, critical for learning and memory, undergoes substantial changes in the first years of life. Investigating the developmental trajectory of hippocampal structure and function requires an accurate method for segmenting this region from anatomical MRI scans. Although manual segmentation is often regarded as the "gold standard" approach, at least in adults, it is time-consuming, requires considerable expertise, and relies on variable landmarks across labs. These drawbacks have fueled the pursuit of automated segmentation methods. However, little is known about the reliability of these automated protocols in tracing the hippocampus of human infants, particularly given the greater noise and lower quality of anatomical scans in infants. Here we evaluate the efficacy of different approaches for automated hippocampal segmentation in infants. As part of an awake, task-based protocol, we collected short T1-weighted anatomical scans from 42 sessions with infants aged 4 to 23 months. For each session, two trained tracers manually segmented the hippocampus as a benchmark measurement of inter-rater reliability. Four different automated methods for hippocampal segmentation were considered: adult anatomical average template, infant anatomical average template (derived from infant data linearly and nonlinearly aligned into standard space), FreeSurfer software, and Automated Segmentation of Hippocampal Subfields (ASHS) software. Although the adult anatomical template failed to approximate manual segmentation data accurately, the infant anatomical template adequately predicted the infant data of both tracers. FreeSurfer generated moderately accurate segmentations that approached the average inter-rater reliability of manual segmentations; however, this came at the cost of over-estimating hippocampal volumes. ASHS generated the most reliable and least biased hippocampal segmentations, even exceeding manual inter-rater reliability. ASHS was successful despite being trained on T1-weighted anatomical scans that were low-quality and noisy by conventional standards. Hence, automated methods can provide accurate, generalizable segmentations in infants that make it possible to accelerate and improve the study of the developing hippocampus.

Title: Can You Scan Lefties? The Effect of Handedness on fMRI Activation in a Recognition Memory Paradigm

Authors: L. GOULDING, **I. HAMM**, *B. KIRWAN;
Brigham Young Univ., Provo, UT

Abstract: About 11% of the world population is left-handed, a significant minority of the potential research participant pool for functional MRI (fMRI) studies. However, convention in fMRI research dictates that these participants should be excluded from analysis due to evidence that left-handed participants may have a different pattern of lateralization of specific functions than right-handed participants. This could alter results in fMRI studies, as different areas of the brain may be activated by the same task in these individuals. This hypothesis has been tested for some cognitive processes, but has yet to be thoroughly tested in memory research despite the frequent exclusion of left-handed individuals from research projects. The current study investigates the lateralization differences between N=26 left- and N=27 right-handed participants while they performed an encoding and recognition memory task for words and faces. Additionally, we measured participants' laterality index by administering a semantic fluency task. At encoding, we found one cluster of activation in the right posterior cingulate cortex, where there was a handedness by subsequent memory effect interaction collapsing across words and faces. There was no interaction between words and faces and handedness at encoding. At retrieval, we found no interaction between handedness and trial outcome. Conversely, there were several clusters that demonstrated a significant interaction between stimulus type (words, faces) and handedness including the left inferior frontal gyrus, left angular gyrus, right angular gyrus, and left superior medial gyrus. In order to measure if including left-handed individuals in fMRI studies would alter results significantly, we calculated memory effects in a priori ROIs for the right-handed participants only, and then examined the effect of substituting in progressively more left-handed participants for right-handed participants. We found that subsequent memory effects at encoding were not reduced by adding in left-handed participants. However, at retrieval, significant memory effects diminished in the bilateral precuneus for faces and in the left hippocampus for words when substituting in six and five left-handed participants, respectively. These findings suggest that while the blanket exclusion of left-handed individuals in memory research is not warranted, exclusion for research in specific ROIs may be justified.

Title: Common genetic variation modulates lithium-induced neural progenitor proliferation

Authors: *B. D. LE[1], J. M. WOLTER[2], N. MATOBA[2], J. M. VALONE[1], A. L. ELWELL[2], N. AYGÜN[1], D. LIANG[1], M. J. LAFFERTY[1], K. P. COURTNEY[2], J. PIVEN[3], M. J. ZYLKA[4], J. L. STEIN[2];

Ctr., Univ. of North Carolina At Chapel Hill, Chapel Hill, NC

Abstract: Neural progenitor cell proliferation during human fetal development shapes the structure of the cerebral cortex. Dynamic regulation of gene expression orchestrates this process and is tuned both by inherited genetic effects and exposure to developmentally relevant stimuli. Lithium, a common neuropsychiatric treatment also found ubiquitously at trace amounts, is one such stimulus that impacts neural progenitor proliferation through the Wnt signaling pathway. We measured the effects of therapeutically relevant levels of lithium on proliferation in 80 genetically diverse primary human neural progenitor cell-lines. Proliferation was measured with a flow cytometry based assay that fluorescently labeled newly synthesized DNA in actively dividing cells via EdU incorporation. Low (0.75 mM) and moderate (1.5 mM) lithium exposures additively increased the proportion of proliferating cells, but a stronger non-therapeutic dose (3 mM) decreased proliferation. We performed a genome-wide association study (GWAS) to identify common genetic variants modulating the proliferative response to lithium. Comparison of GWAS signals show that genetic contributions to proliferation differ between baseline and stimulated cellular states and are stimulus and dose specific. One locus, associated with change in the number of proliferating neural progenitors in response to 1.5mM lithium, colocalized with GWAS signals for schizophrenia and bipolar disorder risk on chr3p21.1. Here we identified a single gene, *GNL3*, that exhibited lithium-responsive gene expression over a 2-24h time course following treatment. The allele associated with increased lithium-induced proliferation is also associated with increased *GNL3* expression from gene expression quantitative loci in GTEx brain tissue data. To investigate the role of *GNL3* in lithium induced proliferation, we targeted the *GNL3* promoter with dCas9-KRAB constructs and found that suppressing *GNL3* expression blunted increases in proliferation induced by lithium, showing that *GNL3* expression levels modulate proliferation responses to lithium. Our results demonstrate how a proliferation response GWAS can identify loci where genetic variation alters stimulus-specific regulation of gene expression within a key cell-type and developmental time period. Colocalization of this lithium-responsive proliferation locus and GWAS loci for complex traits like Bipolar disorder suggests a shared genetic basis for fetal neural progenitor proliferation responses and neuropsychiatric disorder risk and invites exploration into the role of *GNL3* modulating responses to lithium treatment in adult neural progenitor cells.

Title: Sex differences in gliogenic markers in neural stem cells and their extracellular vesicles are decreased by ethanol exposure

Authors: *A. H. MAHNKE[1,2], A. MILLER[1], V. YANG[1], D. D. CHUNG[1], R. C. MIRANDA[1,2]; [1]Dept. of Neurosci. and Exptl. Therapeut., [2]Women's Hlth. in Neurosci. Program, Texas A&M Univ. Hlth. Sci. Ctr., Bryan, TX

Abstract: Prenatal alcohol exposure (PAE) can result in growth and neurodevelopmental deficits, termed ‘fetal alcohol spectrum disorders’, that are estimated to affect 1-5% of children in the US. PAE can teratogenically reprogram neural stem cells to favor premature maturation and decrease self-renewal. The transcription factor nuclear factor I A (Nfia) has been shown to act as a gliogenic switch, inducing the formation of astrocytes from stem cells, and may mediate PAE-induced premature maturation of neural stem cells. Here, we investigated the effect of ethanol exposure on the expression of Nfia in neural stem cells. These cells were derived from murine GD 12.5 dorsal neuroepithelium and propagated in vitro as non-adherent neurospheres. Fetal tissues were genotyped at the time of collection to allow for the creation and propagation of sex-segregated neurosphere cultures. Neurospheres were exposed to ethanol in their mitogenic media for 5 days and subsequently collected for bulk RNA sequencing and LC-MS/MS-based proteomics. Extracellular vesicles (EVs) were also collected from cell culture media at day 5 for proteomics analysis. Using RNAseq we found that exposure to low dose (60 mg/dL) ethanol significantly decreased glial marker *Gfap* mRNA expression, contrary to our hypothesis that ethanol exposure would increase markers of differentiation. There was a sex difference in *Gfap* expression with male neurospheres trending towards higher expression of *Gfap* mRNA compared to female neurospheres. While there were no differences in *Nfia* mRNA expression, proteomics analysis showed that males neurospheres had significantly higher levels of Nfia protein and glial marker Glast/Slc1a3 across all ethanol treatment groups. Nfia protein was also present in neurosphere-derived EVs and, surprisingly, female neurosphere-derived EVs had 2.3-fold the Nfia protein level of male neurosphere-derived EVs. This sex difference in EV Nfia

enrichment decreased with increasing levels of ethanol exposure such that following exposure to a chronic use-like ethanol dose (320 mg/dL), female derived-EVs had 1.5-fold the Nfia protein as male derived-EVs. Together, these data indicate baseline sex differences in neurosphere expression of gliogenic markers and exposure to high levels of ethanol decreases this difference. Intriguingly, ethanol's effects on neural stem cell maturation may occur both through direct changes to the cellular proteome and indirectly through EV transcription factor cargo. Further work is needed to identify the mechanisms of sex-specific trafficking of Nfia to EVs.

Abstract: Prenatal alcohol exposure (PAE) can alter the growth and maturation of neural stem cells (NSCs), leading to diminished brain growth. NSCs reside in a complex microenvironment rich in sub-200 nanometer-sized extracellular vesicles (EVs), which may traffic protein, lipid, and RNA cargo between cells, as a mode of intercellular communication. Using fetal mouse derived cortical neuroepithelium, cultured ex-vivo as non-adherent neurosphere cultures, we previously found that ethanol exposure resulted in significant elevation of n miR-140-3p, in EVs, which directed NSCs towards an astroglial lineage. For this study, we further investigated the impact of ethanol on the proteome and transcriptome of NSC-EVs by employing quantitative proteomics and transcriptomics to profile the protein and RNA expression across treatment groups of 18 EV and its 18 parent NSCs.

Analyses of EVs identified ~86% of proteins needed for eukaryotic translation initiation, implying that EVs carry with them the ability to translate EV-chaperoned mRNAs in recipient cells. Statistical and pathway overrepresentation analyses showed that moderate ethanol, ~26 mM, resulted in a significant increase in proteins of the Nonsense-Mediated Decay (NMD) pathway in EVs, whereas a higher dose, ~70 mM, resulted in EV overexpression of mitochondrial proteins that constitute a Danger-Associated Molecular Pattern (mito-DAMP) pathway. NMD is a surveillance pathway that reduces errors in gene expression by eliminating premature stop codon-containing mRNA transcripts. Consequently, NMD pathway proteins sequestered in EVs are hypothesized to transfer neuroprotection to cells where the capacity to correct errors in protein translation may be depleted. Eukaryotic cells under high stress, expel mitochondrial proteins to activate 'pattern recognition' receptors and pro-inflammatory responses in target cells. Consequently, mito-DAMPs in EVs from heavy-ethanol-exposed NSCs are predicted to spread inflammation through the NSC microenvironment.
Preliminary analysis shows that that the RNA transcript reads in EV samples is biased towards a higher percentage of introns and other intergenic transcripts and a lower percentage of exons compared to parental NSCs. Combined with our proteomic data showing that EVs contain a high number of RNA-binding proteins, these data suggest that un-spliced RNA transcripts are transcribed and directly chaperoned for packaging into EVs rather than being processed into mature mRNAs. Collectively, these studies identify EVs as a novel source for communicating stress responses, in an ethanol dose-related manner, to cells within the fetal NSC niche.

Title: Buprenorphine attenuates the growth suppressive effect of methadone in human brain organoid

Authors: *H. YAO[1], W. WU[1], J. WANG[1], G. HADDAD[1,2];
[1]UCSD, La Jolla, CA; [2]The Rady Children's Hosp., San Diego, CA

Abstract: Methadone and Buprenorphine are opioids primarily used for medication-assisted treatment (MAT) for opioid use disorder. Although both drugs can lead to neonatal abstinence

syndrome (NAS) in newborns when used maternally, buprenorphine shows a significantly reduced NAS duration. Our previous work has shown that methadone can inhibit brain organoid growth, decrease synaptic transmission and suppress neural network activities. In this work, we hypothesize that buprenorphine does not affect brain organoid growth as much as methadone. Brain organoids were treated with various dosages of buprenorphine or methadone starting from the formation of embryoid body until the end of the neural induction, proliferation, differentiation and maturation stages (about a month). In the control group, the organoids grew by 30.4±4% in size from day 3 to day 24 in culture but 1 μM methadone blunted this increase to 8.1±3%. At 5 or 10 μM, methadone eliminated any increase and indeed organoids shrunk in size by -38.1±9.3% or -67.7±12.3%, respectively ($n=5$, $p<0.05$ for each group). While in the buprenorphine-treated group (at dosages of 1, 10 or 30 μM), the increase of organoid size did not differ from control. In another group of experiments, we treated organoids with 5 μM methadone plus buprenorphine at dosages of 1, 10 or 30 μM, respectively. Our data show that, while methadone alone suppressed the increase of organoid size by a third of its control rate, the addition of buprenorphine at 1, 10 or 30 μM, restored the increase of organoid size to about 8 to 25% in that duration, from day 3 to day 24 ($n=5$, $p<0.05$ for each group). We conclude that a) buprenorphine does not alter the growth rate of brain organoids as methadone does; and b) buprenorphine can eliminate the suppressive effect of methadone in organoids. These observations may explain the attenuated NAS duration in newborns treated with buprenorphine.

Title: Polysubstance exposure to ethanol and cannabinoids induces synergistic effects on mouse embryonic neural stem cell growth

Authors: *S. ROUZER, A. ADAMS, S. MAVURI, R. MIRANDA;
Texas A&M Univ. Syst. Hlth. Scien Neurosci. and Exptl. Therapeut., Bryan, TX

Abstract: Prenatal drug exposure is the leading cause of neurodevelopmental disorders worldwide, often occurring prior to pregnancy detection (~1st/early 2nd trimesters). Importantly, this gestational period corresponds with pronounced fetal neural stem cell (NSC) activity. NSCs are multi-potent cells with the ability to self-renew and proliferate, and in utero give rise to most

neurons and glia of the adult brain. Through culturing of these cells in the lab, we can investigate NSC proliferation, differentiation and survival, which is critical for treating developmental and neurodegenerative disorders. Prior research has demonstrated that the introduction of ethanol to cultured cells results in teratogenic reprogramming of NSCs. However, the impact of additional drug co-exposures is yet unexplored, despite the prevalence of simultaneous drug consumption in women of child-bearing age. Therefore, we investigated the effects of drug exposure on NSC growth in vitro using neurosphere cultures from the dorsal neuroepithelium of GD 12.5 C57/Bl6 mice. Neurospheres were exposed to a concentration range of nicotine, ethanol and/or synthetic cannabinoid CP-55940 for 5 days, at which point cells were passaged to drug-free media for future analyses. Using ImageJ/FIJI, we analyzed neurosphere area as an indication of NSC growth. Preliminary analyses revealed an acute increase in neurosphere area following co-exposure to low concentrations of ethanol and CP-55940, mimicking singular, high concentration exposure of either drug. Importantly, following serial passaging of NSCs to assess self-renewal, this synergistic low ethanol-and-cannabinoid effect was reversed, with combined exposure now contributing to reduced neurosphere area, along with a notable decrease in cell survival, compared to drug-naïve controls. Furthermore, nicotine exposure did not alter neurosphere area when combined with ethanol; rather, nicotine independently decreased neurosphere area, but only following multiple cell passages. Together, these data suggest that combined ethanol-and-cannabinoid exposure may uniquely induce premature NSC growth and subsequently stunt the growth/proliferation of future cell progeny. To identify the underlying mechanisms impaired by this embryonic polysubstance exposure, further research will incorporate immunostaining and RNAsequencing of neural growth factors within exposed NSCs.

Title: Modeling Fetal Alcohol Spectrum Disorder in Human Cerebral Organoids

Authors: *M. FISCHER[1], C. ROBBINS[1], J. P. WEICK[2];
[2]Neurosciences, [1]Univ. of New Mexico, Albuquerque, NM

Abstract: Fetal alcohol spectrum disorders (FASD) due to gestational alcohol exposure represents one of the most common causes of nonheritable lifelong disability worldwide. The specific mechanisms of alcohol's teratogenicity remain incompletely understood but the convergence of its effects on the developing brain have long been understood to contribute to lifelong deleterious cognitive and behavioral outcomes. In this study we utilized a human stem cell-based model of cortical development to determine the effects of first trimester-equivalent chronic binge alcohol exposure on the differentiation of neuronal cell populations and their progenitors. Significant alterations were discovered to the expression of a number of regionally defined transcription factors, including significant upregulation of the postero-dorsal transcription factor EMX2 and a concurrent downregulation of the antero-ventral marker SIX3 in a self-patterning human cortical organoid (hCO) system. Further single-cell sequencing revealed readily identifiable populations of stem cells, neural progenitors and post-mitotic neurons with a primarily dorsal pallial transcriptional signature in each the presence and absence of alcohol *in vitro*. Reduced complexity of fate determination processes in alcohol-exposed hCOs was determined via MONOCLE3 pseudotime-based lineage tracing analyses. Transcripts associated with the maintenance of pluripotency (ID2/4), the specification of regional cortical identity (EMX1/2, SIX3), and WNT-signaling pathways (RSPO1/2/3) were identified as primary targets of alcohol in developing and mature neuronal cells by each gene expression and protein analyses of organoid cultures. Together these data provide further support for altered cell specification and regional patterning of the developing forebrain as a primary mechanism underlying FASD.

Title: Genomic glucocorticoid action in the developing brain

Authors: *K. BERRY[1], U. CHANDRAN[1], F. MU[2], I. ROGATSKY[3], D. DEFRANCO[4,3]; [1]Univ. of Pittsburgh Ctr. For Neurosci., Pittsburgh, PA; [2]Univ. of Pittsburgh Ctr. For Res. Computing, Pittsburgh, PA; [3]Weill Cornell Grad. Sch., New York, NY; [4]Univ. of Pittsburgh Pharmacol., Pittsburgh, PA

Abstract: Prenatal exposure to synthetic glucocorticoids (sGCs) alters brain development and predisposes the developing fetus towards potential adverse neurodevelopmental outcomes. We

have used primary mouse embryonic (E14.5) neural stem and progenitor cells (NSPCs) from the telencephalon to uncover potential mechanistic bases for neurodevelopmental changes elicited by sGCs. Our previous studies demonstrated that sGCs triggered sexually dimorphic alterations in the transcriptome of embryonic mouse NSPCs. Cell-type-specific gene expression profiles tightly regulate cell fate decisions and are controlled by a flexible landscape of chromatin domains upon which transcription factors and enhancer elements act. We therefore multiplexed data from three genome-wide assays (RNA-seq, ATAC-seq (assay for transposase accessible chromatin followed by genome wide sequencing), and dual cross-linking ChIP-seq (chromatin immunoprecipitation followed by genome wide sequencing)) to identify novel relationships between gene regulation, chromatin structure, and genomic glucocorticoid receptor (GR) action in female NSPCs. These data reveal that GR binds preferentially to predetermined regions of accessible chromatin to influence gene expression that impact cell fate decisions. In addition, we identify SOX2 as a potential cell-type-enriched transcription factor that guides hormone-regulated GR action in NSPCs.

Title: Pten regulates dendritic arborization by decreasing microtubule polymerization rate

Authors: S. A. GETZ[1], K. TARIQ[2], J. R. HOWE, VI[2], P. D. SKELTON[2], J. HONG[2], ***B. LUIKART**[1];
[1]Dartmouth Col. Geisel Sch. of Med., Hanover, NH; [2]Geisel Sch. of Med. at Dartmouth, Hanover, NH

Abstract: Phosphatase and tensin homolog (PTEN) is a major negative regulator of the PI3K/Akt/mechanistic target of rapamycin (mTOR) pathway. Loss of function mutations in *PTEN* have been found in a subset of patients with macrocephaly and autism spectrum disorder. PTEN loss in neurons leads to somal hypertrophy, dendritic overgrowth and increased spine density, resulting in inappropriate connectivity of neuronal circuits. These neuronal overgrowth phenotypes are present upon *Pten* knockout (KO) and reconstitution with autism-associated point mutations. The mechanism underlying dendritic overgrowth in *Pten* deficient neurons is unclear. In this study, we examined how *Pten* loss impacts microtubule dynamics using retroviral

infection and transfection strategies to manipulate PTEN expression and tag plus-end microtubules. We found *Pten* KO neurons sprout more new processes compared to WT via multiphoton microscopy. We also found a significantly increased microtubule polymerization rate in *Pten* KO dendrites in primary cultured neurons via confocal microscopy. Further, reducing microtubule polymerization rate to the WT level was sufficient to reduce dendritic overgrowth in *Pten* KO neurons *in vitro* and *in vivo*. Taken together, our data suggests that one factor underlying dendritic overgrowth is increased microtubule polymerization. This opens the possibility for an intersectional approach targeting microtubule polymerization and mTOR with low doses of inhibitors to achieve therapeutic gains with minimal side-effects in pathologies associated with loss of neuronal PTEN function.

Title: High-resolution and automated identification of engrailed 2 transcript along spatial and cell type-specific dimensions in the ganglionic eminence of the developing mammalian brain

Authors: *J. S. MARTINEZ-FUENTES[1], M. COGSWELL[2], A. C. CASTELLÓ[4], V. BORRELL[5], S. J. RUSSEK[3];

Abstract: A variety of genetic and environmental factors contribute to autism spectrum disorder (ASD), but exactly how this occurs remains unclear. One hypothesis is that factors may converge to perturb the proper development and function of the gamma-aminobutyric acid (GABA) system of the brain. The midbrain-hindbrain patterning homeotic transcription factor engrailed 2 (En2) has been associated with ASD in humans, and a mouse model harboring a null mutation of En2 recapitulates behavioral and neuroanatomical abnormalities reminiscent of ASD as well as epilepsy. Interestingly, En2-null mice show reduced GABAergic marker expression in the hippocampus and cortex, and cultured neural stem cells of GABAergic lineage from mutant mice display deficits in neurogenic activity. How En2 dysfunction leads to neuropathological

phenotypes, including the cell and behavioral phenotypes related to forebrain function, remains unknown. Our recent *in vivo* work draws attention to the potential role of En2 in radial glial self-renewal and subsequent differentiation, with a potential impact on the birth of GABAergic interneurons and spiny projection neurons. To aid investigation into the role of En2 in the development of forebrain GABAergic neurons, we are building a detailed transcriptomic spatial map of En2 at the mouse embryonic ganglionic eminence (GE, age E13), the major birthplace of inhibitory neurons. Here, we use sensitive multiplexed fluorescence *in situ* hybridization with widefield and confocal fluorescence microscopy to reveal spatial distributions of *En2* transcripts across transcriptionally defined subtypes of progenitor cells in regions of the GE (i.e., medial, lateral, caudal GE). To this end, we apply MATLAB automated image analysis to quantify *En2* signal in thousands of individual cells along spatial and cell type dimensions. Cell types tracked are radial glia, subapical and basal progenitors, defined by a transcriptional code of overlapping expression of GABAergic lineage factors, Gsx2 and Ascl1. Data show that *En2* is regionally widespread (~60% cells show at least one *En2* transcript), but sparse in its density (1-3 transcripts per cell) across all layers of the GE. Interestingly, in the LGE, ongoing results suggest enrichment of high-expressing *En2*+ cells in the ventral subregion, potentially indicating vulnerability of cells from this area to loss of En2 function. Taken together, widespread but sparse presence of *En2* suggests this factor may play a role in cells arising from the GE, raising questions as to how En2 dysfunction along GABAergic maturation trajectories may contribute to etiology of ASD and other developmental disorders of brain function.

Title: Distribution of integrin β3 in the mouse brain

Authors: C. A. BRETT, C. J. HANDWERK, K. M. BLAND, H. N. COOK, B. D. SWINEHART, H. V. RODRIGUEZ, A. R. KALINOWSKI, *G. VIDAL;
James Madison Univ., Harrisonburg, VA

Abstract: A strong positive association has been found between mutations in integrin β3 (Itgb3) and autism spectrum disorder, but little is known about the role of integrin β3 on the structure and function of neurons and glia in vivo. Many forms of autism spectrum disorder are thought to

arise from dysfunctional dendritic arborization and dendritic spine development, and both global and brain-specific knockout of Itgb3 in mice leads to autistic-like behaviors. We have also shown that Itgb3 is required for normal dendritic arborization in layer II/III pyramidal neurons throughout the mouse neocortex and in a cell-specific manner. Prior studies suggest that integrin β3 is required in neurons of the cortex, hippocampus, and midbrain for normal brain function, and that its expression is developmentally regulated. However, the distribution of integrin β3 throughout the brain is not well characterized. We hypothesized that integrin β3 would be distributed throughout layer II/III of the cerebral cortex, the stratum pyramidale of the hippocampus, and the dorsal raphé nucleus of the midbrain. Fluorescent immunohistochemistry was used to localize integrin β3 throughout the mouse brain, and double fluorescent immunohistochemistry was used to co-label integrin β3 with various cell types. Results suggest that integrin β3 is found in multiple cell types and regions beyond the midbrain, cortex, and hippocampus. Thus, integrin β3 may serve multiple roles in the developing and adult brain.

Title: Impaired excitatory and inhibitory synaptic plasticity in the NL3-R451C mouse model of autism spectrum disorder

Authors: *M. BRUNO, S. H. STANCHEVA, L. MANNINO, M. RUBEN, A. I. POLENGHI, F. COLACI, E. M. PETRINI, A. BARBERIS;
Inst. Italiano di Tecnologia, Genova, Italy

Abstract: Autistic spectrum disorder (ASD) has been associated to genetic alterations of proteins involved in synaptic function such as the point mutation R451C in neuroligin 3 (NLGN3), a postsynaptic adhesion molecule which binds its presynaptic partner neurexin at both excitatory and inhibitory synapses. In the present study, by exploiting the transgenic NL3R451C knock-in (KI) mice as an ASD animal model, we aimed at investigating the role of this mutation in the coordination of both excitatory and inhibitory synaptic plasticity. We found that, with respect to WT condition, the $NL3^{R451C}$ protein was less expressed at the neuronal surface and showed increased lateral diffusion at GABAergic synapses. In WT animals, we observed that, in

response to a chemical protocol for the induction of synaptic plasticity (NMDA treatment), excitatory synaptic currents were depressed (LTD) whereas the inhibitory ones were potentiated (iLTP). Interestingly, such opposed synaptic plasticity was abolished in KI neurons. These effects were paralleled by changes in synaptic receptors and scaffold proteins at both excitatory and inhibitory synapses in WT and KI neurons. Indeed, after the NMDA stimulation, WT mice showed increased immunoreactivity for GABAAR and the scaffold protein gephyrin at synapses. In contrast, no significant changes were observed in KI mice. Along the same line, NMDA treatment induced the decrease of the GluA1 and GluA2 subunits of AMPA receptors in WT mice, whereas the same protocol left AMPARs unchanged in KI mice. In addition, the quantification of NLGN3 clusters fluorescence intensity revealed that, after the NMDA treatment, surface NLGN3 decreased in WT neurons while it was unaffected in KI neurons. Moreover, we demonstrate that in KI, changes in the expression of the NR2B subunit of NMDA receptor were associated with altered intracellular spatio-temporal calcium dynamics. Collectively, our results reveal that the perturbed synaptic molecular composition of both glutamatergic and GABAergic synapses and the disrupted calcium signaling induced by the NL3 R451C mutation disrupts the coordination of excitatory and inhibitory synaptic plasticity thus potentially contributing to the pathophysiology of ASD.

Title: A reduction in the autism associated gene lysine demethylase 6B (KDM6B) blocks neuronal differentiation and alters microglia activity.

Authors: *J. BUTH[1], J. EMTAGE[2], F. TURCIOS[2], A. DURRANI[2], T. ISHIDA[2], B. NOVITCH[3];
[1]Univ. of California, Los Angeles Interdepartmental Ph.D. Program In Neurosci., Los Angeles, CA; [2]Neurobio., [3]Dept. of Neurobio. & Broad Ctr. for Regenerative Med. and Stem Cell Res., UCLA, Los Angeles, CA

Abstract: Autism spectrum disorder (ASD) is a lifelong developmental disability that affects how an individual experiences and interacts with the world. Individuals experience challenges with social interaction, communication, and repetitive behaviors. Current treatments include behavioral therapy, medications, and assistive technology focused on improving the patient's quality of life, but the underlying cause remains unclear. Current studies point to deficits in synapse formation/pruning, altered excitatory/inhibitory neuron balance, increased microglial activation, and astrocytosis. Many ASD risk genes, including lysine demethylase 6B (KDM6B), regulate gene expression through chemical modification of histone and chromatin proteins. Emerging evidence suggests that KDM6B is involved in balancing microglial activation states as well as regulating neural differentiation. Microglia are known to regulate immune responses, brain homeostasis, neuronal differentiation, and synapse maintenance. KDM6B knockdown in mice is associated with a reduction in cortical neurons, but it is unclear if this is due to deficits in neuron formation, overactive microglia, or both. As many clinical trials for neurological disorders based on mouse data fail, there is a need to validate hypotheses and therapeutics with human models. In this study, we aimed to distinguish the effect of KDM6B loss in hPSC-derived NPCs and microglia (**Fig. 1**). To model a reduction in KDM6B activity, we used a highly specific inhibitor of KDM6B demethylase activity (GSK-J4) and an inert isomer (GSKJ5) as an additional control. We infected a 2D monolayer of NPCs with a lenti-Syn1-RFP virus to visualize the production of neurons. Addition of GSK-J4 resulted in fewer RFP+ neurons (**Fig 2**) indicating a reduction in neurogenesis. For microglia we assayed gene expression, proliferation, phagocytosis, and migration. Addition of GSK-J4 altered the expression of activation markers, proliferation, phagocytosis, and increased migration toward ADP (**Fig. 3-6**). These results suggest pathological changes seen in ASD due to KDM6B loss may arise from changes in NPCs as well as microglia. Understanding these cell specific effects helps narrow the possible therapeutic targets and predict possible outcomes. Future studies will focus on how KDM6B loss affects cell-cell interactions using 3D brain organoids integrated with microglia. These experiments could provide a better understanding of how ASD arises and could expand treatments to further improve quality of life.

Title: Implications for Autism Spectrum Disorders: mitochondrial dysfunction and neuronal differentiation in SH-SY5Y cells

Authors: E. BUCHANAN, E. FRICKEL, C. MAHONY, S. BAM, *C. O'RYAN;
Mol. and Cell Biol., Univ. of Cape Town, Cape Town, South Africa

Abstract: Autism Spectrum Disorder (ASD) is a heterogeneous neurodevelopmental disorder with numerous genes and biological pathways implicated in its aetiology. We previously identified differentially methylated genes enriched for canonical mitochondrial pathways in a South African ASD cohort. Mitochondrial dysfunction in this cohort was supported by metabolomic analysis. We therefore hypothesise that aberrant expression of key mitochondrial genes, such as PCCB, contributes to ASD pathogenesis via altered neurogenesis resulting from mitochondrial dysfunction. PCCB deficiency leads to an accumulation of propionate, which is used in a rat model to study ASD. We aimed to recapitulate PCCB-related mitochondrial dysfunction using sodium propionate (NaP) treatment (n=3) compared to controls (n=3) in SH-SY5Y neuronal-like cells and characterise the downstream effects on neuronal differentiation. NaP treatment significantly dysregulated mitochondrial biogenesis (1.5mM NaP/24hr), reduced mtDNA copy number (qPCR of ND1 relative to RPPH1) and upregulated PGC-1α expression (3mM NaP/24hr). In addition, NaP also resulted in mitochondrial membrane depolarisation as measured using mitotracker fluorescent staining. Changes in mitochondrial morphology (fusion and fission) were observed using cryogenic transmission electron microscopy and fluorescence microscopy, where mitochondrial hyperfusion was seen at lower NaP concentrations and mitochondrial fragmentation at higher NaP concentrations. These morphological changes were supported by altered expression of mitochondrial fusion (STOML2, MFN2) and fission (DPR1) genes. Significance was determined using a one way ANOVA ($P<0.05$). Finally, NaP-induced mitochondrial dysfunction resulted in temporal and morphological changes during neurodifferentiation, characterised by immunocytochemistry and fluorescence microscopy. Our data show that NaP treatment alters mitochondrial function and dynamics and dysregulates differentiation in SH-SY5Y cells. These findings offer insight into the potential molecular mechanisms underlying mitochondrial dysfunction and suggest a mechanism of how this may contribute to ASD aetiopathogenesis via altered neurogenesis.

Title: Increasing UBE3A in substance P (Tac1) neurons of VMHvl hypothalamic nucleus increases aggression-associated neuronal activity

Authors: *Y. NONG, M. ANDERSON;
Neurol. and Pathology, Beth Israel Deaconess Med. Center,Harvard Med. Sch., Boston, MA

Abstract: Heightened aggression is a common comorbidity of autism spectrum disorder (ASD) including excessive tantrums, irritability, and self-injurious aggressive behaviors that often requires medical treatment. Yet the molecular and neuronal circuit mechanisms underlying the ASD-associated aggression and treatment response remains undefined. We previously reported that transgenic mice with full-length *Ube3a* (*Ube3a2x* mice, modeling ASD due to maternal *15q11-13* triplication), compared with wild type littermates, display increased total attack time and attack numbers in the resident intruder task. We further found that targeted increases of *Ube3a* in the *Tac1*- or *Pgr*-expressing neurons of ventromedial hypothalamus, ventrolateral subdivision (VMHvl) increases aggression. Yet, the activity of VMHvl *Tac1* neurons during aggression has not been examined. In the current study, we used head-mounted nVista miniature microscopy (Inscopix) to image intracellular calcium dynamics (a neural activity correlate) in VMHvl *Tac1* neurons when mouse conducting aggression behavior. Activity of multiple VMHvl *Tac1* neurons with or without increased *Ube3a* were monitored in freely behaving animals to correlate *Tac1* neuron activity with aggression behavior. *AAV-hSyn-DIO-Gcamp7* or *AAV-hSyn-DIO-Gcamp7 + AAV-hSyn-DIO-Ube3a* virus were injected into VMHvl of *Tac1-Cre* male mice, and follow by implanting ProView Lens Probes, baseplate installation later. We performed a resident-intruder aggression test paradigm as follow: 5 min control followed by introducing female intruder for 5 mins, and then after removing the female, introducing a male intruder to measure the aggression behavior. Calcium images of the VMHvl *Tac1* neurons were acquired using Inscopix Data Acquisition Software during the above 20 min test paradigm. VMHvl *Tac1* neurons showed low basal activity when resident mice were alone in their home-cages. Introducing a female intruder enhanced activity in a limited subset of cells. However, introducing a male intruder dramatically increased activity of all VMHvl *Tac1* neurons identified. By summing the amplitude of calcium spike values during the 5 minute epochs during baseline, female exposure, and male exposure, we found that VMHvl *Tac1* neuron activity is increased upon male intruder addition with additional bursts of activity correlated to attack behaviors. Increasing UBE3A in these VMHvl *Tac1* neurons further elevated this neuronal activity. The results indicate VMHvl *Tac1* neuron activity strongly correlates to aggression behavior and this activity is further magnified by increased UBE3A.

Title: The psychiatric risk gene Transcription Factor 4 (TCF4) regulates the density and connectivity of a specific subclass of inhibitory interneurons.

Authors: *H.-Y. CHEN[1], B. PHAN[2], S. SRIPATHY[1], G. R. HAMERSKY[1], J. BOHLEN[1], G. SHIM[1], T. O'DONNELL[1], A. R. PFENNING[3], B. J. MAHER[4];
[1]Lieber Inst. for Brain Develop., BALTIMORE, MD; [2]Univ. of Pittsburg, Pittsburg, PA; [3]Computat. Biol. Dept., Carnegie Mellon Univ., Pittsburgh, PA; [4]Lieber Inst. For Brain Develop., Baltimore, MD

Abstract: Transcription Factor 4 (TCF4) is a type I basic helix-loop-helix transcription factor and autosomal mutations in TCF4 causes Pitt-Hopkins Syndrome (PTHS), a neurodevelopmental disorder with autistic features. The pathophysiology resulting from TCF4 haploinsufficiency or expression of a dominant negative TCF4 protein remains incomplete. During embryonic development, GABAergic interneurons originate from the proliferative zones of the ventral forebrain and in situ hybridization suggests Tcf4 transcript is enriched in this brain region. In addition, single cell RNAseq data indicates Tcf4 is highly expressed across many subclasses of GABAergic interneurons. Moreover, TCF4 is a known dimerization partner of ASCL1 (or MASH1), a critical regulator of interneuron development. Therefore, we hypothesized that TCF4 may play a critical role in regulating interneuron development and function. To test this idea, we quantified GABAergic interneuron density in a PTHS mouse model that harbors a truncated Tcf4 gene (Tcf4+/tr) and compared it to WT littermates. Immunohistochemistry (IHC) for the major cortical GABAergic markers showed a significant decrease in the PV+ population across several brain areas including medial prefrontal cortex, primary motor cortex, striatum, and basal lateral amygdala. Likewise, qPCR and cell-type specific expression analysis (CSEA) of bulk RNAseq data also predicted a significant decrease in the proportion of PV+ cells. Interestingly, this deficit was specific to PV+ cells, as IHC and CSEA analysis of SST+ interneurons was not different. Furthermore, we quantified interneuron density by crossing a tdTomato reporter line with a variety of GABAergic subclass-specific cre lines and observed that Tcf4 mutation resulted in a reduction in PV+ interneurons across all brain regions measured, while VIP+ cells showed a significant reduction only in the motor cortex and SST+ interneuron density was unchanged. Lastly, we characterized the impact Tcf4 mutation had on the physiology of PV+ interneurons by

performing targeted whole-cell electrophysiology. We observed no differences in the intrinsic membrane properties, however the frequency of spontaneous inhibitory synaptic currents was significantly reduced. Together, these results suggest that the density and connectivity of inhibitory neurons in the PTHS mouse is perturbed, and these changes may in part underlie the cognitive deficits and autistic features present within this patient population.

Title: Kv3.4 channels bind the cell adhesion molecule PCDH9 to regulate axonal pathfinding

Authors: *Y. ZHANG[1], M. CHATTERJEE[1], N. DELUCA[1], J. WU[1], M. MARABITA[2], A. BIOSA[2], N. PILATI[2], M. J. GUNTHORPE[2], C. H. LARGE[2], L. K. KACZMAREK[1]; [1]Yale Univ. Sch. Med., New Haven, CT; [2]Autifony Therapeut. Limited, Stevenage, United Kingdom

Abstract: The voltage-dependent potassium channel Kv3.4 is present in the growth cones of developing neurons, and its presence is required for accurate axonal pathfinding and elongation in embryonic neurons. The specific role of the channel in these processes is, however, unknown. We carried out a yeast two-hybrid screen of a rat brain library using the cytoplasmic C-terminal domain of Kv3.4 as bait and found that protocadherin 9 (PCDH9) was the most represented interacting protein. PCDH9 is a calcium-dependent cell-cell adhesion molecule that, like Kv3.4, is found in the growth cones of developing fibers. We confirmed this interaction by co-immunoprecipitation in both Kv3.4 expressing cell line and mouse brain tissue. To examine whether there is a functional interaction between the two proteins, we used Crispr Cas9 to knock down PCDH9 from Kv3.4 expressing cells. We found that loss of PCDH9 resulted in near total suppression of both Kv3.4 currents and Kv3.4 protein expression. Kv3.4 currents and protein levels were recovered on overexpression of human PCDH9 into the PCDH9-knockout cells. We used cultures of cerebellar granule cells, which express high levels of Kv3.4, to assess the effects of knockdown or overexpression of this channel subunit. Loss of Kv3.4 reduced axonal branching, synapse formation, and retarded the normal developmental pattern of neurite extension. Conversely, overexpression of Kv3.4 in the neurons accelerated the maturation of

neuronal morphology. Our results strongly suggest that normal function of the Kv3.4 channel requires its binding to PCDH9 and that this channel/adhesion molecule complex regulates axonal pathfinding.

Abstract: Role of voltage gated potassium channel Kv3.4 in neuronal development and neurite outgrowth
M. CHATTERJEE[1], Y. ZHANG[1], J. WU[1], M. MARABITA[2], A. BIOSA[2], N. PILATI[2], M. J. GUNTHORPE[2], C.H. LARGE[2], L. K. KACZMAREK[1];[1]Yale Univ. Sch. Med., New Haven, CT, 06510, USA and [2]Autifony Therapeutics Limited, Stevenage Bioscience Catalyst, Stevenage SG1 2FX, UK
Voltage gated Kv3.4 channels are abundantly expressed in cerebellum, hypothalamus and cerebellar cortex amongst other brain regions. These channels are involved in guidance and pathfinding of neurons during early embryonic development in mice. In this study, we explored modulation of Kv3.4 expression and its impact on the neurite extension, complexity and maturation with particular emphasis on cerebellar granule neurons in culture. In addition, we explored the effects of pharmacological modulators and blockers of Kv3.4 channel on the degree of neurite extension and the complexity of dendritic arbors. We observed that knocking down Kv3.4 expression using CRIPSR-Cas9 significantly retarded the development of cerebellar granule neurons whereas overexpressing the channels by using a plasmid expressing Kv3.4 accelerated their rate of development compared to control cells. Tetraethylammonium (TEA), a

potassium channel blocker also retarded the development of the cerebellar granule neurons, and had effects similar to those of knockdown of Kv3.4 expression. Overall, the results suggest that Kv3.4 channels play an important role in the morphological development and maturation of CG neurons.

Title: Investigating KChAP, a voltage-dependent K^+(Kv) channel interacting protein, as a putative E3 small ubiquitin-like modifier (SUMO) ligase for the Kv4 ternary complex

Authors: *L.-A. R. JANSEN[1], M. A. WELCH[1], D. J. BARO[1,2];
[1]Biol., [2]Neurosci. Inst., Georgia State Univ., Atlanta, GA

Abstract: Early studies on Kv channel interacting proteins described a novel protein, Kv Channel Associated Protein (KChAP) that interacted with Kv1 and Kv2 alpha-subunits and Kvbeta-subunits in yeast two hybrid assays, and co-immunoprecipitated (co-IP) with Kv2.1 and Kv4.3 in native heart tissue. In heterologous expression systems, KChAP co-expression enhanced the currents mediated by Kv1.3, Kv2.1, and Kv4.3, significantly decreased the currents mediated by Kv1.2 and Kv1.4, but had no effect on Kv1.5. KChAP was discovered to be identical to Protein Inhibitor of Activated STAT 3 (PIAS3). At the time, PIAS3 was thought to act solely as a transcription factor regulator, but surprisingly, transcription was not necessary for KChAP effects on the Kv4 current, IA. That is where the story ended around 2002. Subsequently, unrelated studies determined that PIAS3 was an E3 ligase for SUMO peptides, which are covalently attached to lysine residues on target proteins to modulate target protein interactions. Thus far, no link has been made between KChAP and ion channel SUMOylation. We are investigating if KChAP acts as a SUMO ligase for the Kv4 family of ion channels. Kv4 exists in a ternary complex with K^+ channel interacting proteins (KChIP1-4) and the dipeptidyl peptidase like-proteins (DPP6,10). Preliminary data show that co-expression of KChAP with KChIP2a, DPP10 and either Kv4.1, Kv4.2 or Kv4.3 increased IA relative to the expression of

ternary complex components alone. SUMOylation of Kv4.2 at K579 produced a significant 36% increase in the maximal conductance (Gmax) of IA mediated by the Kv4.2 ternary complex by reducing channel internalization (see Welch et al poster). To determine if KChAP increased the Kv4.2 ternary complex IA by SUMOylating Kv4.2 K579, we co-expressed KChIP2a and DPP10 with a SUMOylation deficient Kv4.2, Kv4.2(K579R), with and without KChAP. KChAP produced a significant increase in IA mediated by the Kv4.2(K579R) ternary complex relative to controls lacking KChAP ($p = 0.0281$, t-test); however, it should be noted that KChAP produced a significant 88% increase in IA mediated by the wild type Kv4.2 ternary complex ($p=0.004$, t-test), but only a 33% increase in IA mediated by the mutant Kv4.2(K579R) ternary complex; thus, removing a known SUMO site on Kv4.2 significantly diminished the effect of KChAP. Together, the data suggest that KChAP may be SUMOylating multiple sites on the ternary complex. Additional SUMO sites are predicted for Kv4.2, and KChIP2a and DPP10 contain high probability SUMO sites. We are performing IP experiments followed by western blots to determine if members of the ternary complex are SUMOylated by KChAP.

Title: A p38-Pin1-Kv4.2 cascade regulates hippocampal excitability and memory processing

Authors: *C. MALLOY[1], J. HU[2], J. J. GUTZMANN[3], A. PRATT[2], M. AHERN[2], D. A. HOFFMAN[4];
[1]Natl. Inst. of Hlth. Office of Intramural, Bethesda, MD; [2]Eunice Kennedy Shriver Natl. Inst. of Child Hlth. and Human Develop., Bethesda, MD; [3]NICHD, [4]NIH, Bethesda, MD

Abstract: The A-type potassium current (I_A) is a vital regulator of neuronal excitability. In rodent hippocampal CA1 pyramidal cells, this current is carried primarily by voltage-gated Kv4.2 K+ channels. Along with other voltage-gated ion channels localized in the somatodendritic compartment of pyramidal cells, Kv4.2 contributes to the firing mode of the cell. Kv4.2 functions in complex with the auxiliary subunits K+ channel interacting proteins (KChIPs) and DPLP(s) to regulate dendritic excitability and synaptic plasticity in the mouse hippocampus. Proper assembly and dynamic regulation of this complex is integral in facilitating it's role in neuronal signal processing and impairments in this process can manifest in disease. To illuminate potential molecular modifiers of the complex, we used a proteomic screen. We

identified a molecular cascade involving p38 kinase-mediated Pin1 isomerization of a C-terminal motif in Kv4.2 as a crucial regulator of Kv4.2-DPP6 binding dynamics. To probe the role of this p38-Pin1 cascade in regulating Kv4.2 function, Crispr-cas9 technology was utilized to generate a mouse model (Kv4.2TA) with abolished p38 and Pin1-Kv4.2 binding. We confirmed disruption of endogenous Kv4.2-Pin1 binding by co-immunoprecipitation from whole brain lysates. We investigated the physiological consequence of this reduced binding on neuronal and network excitability using hippocampal whole-cell patch clamp electrophysiology and behavioral seizure tests in adult mice. Kv4.2TA mice displayed reduced action potential (AP) firing frequency in response to stepped somatic current injections. This reduction in neuronal excitability was replicated by pharmacological blockade of Pin1 and p38 activity in wild type (WT) mice. To confirm a direct influence by p38-Pin1 on Kv4.2-mediated I_A, we performed voltage-clamp recordings from outside-out somatic patches pulled from CA1 pyramidal cells. Isolation of I_A revealed a significant increase in current density in patches pulled from Kv4.2TA cells relative to WT. This increase in somatic I_A and reduced neuronal excitability was accompanied by a reduction in kainic-acid induced seizure intensity. Lastly, Kv4.2TA mice displayed enhanced reversal learning in multiple tests, indicating an improvement in cognitive flexibility. Measurements of synaptic plasticity in the hippocampus of Kv4.2TA and WT mice are on-going in order to ascribe a cellular mechanism to this phenotype. We, therefore, have illuminated a novel molecular cascade that is an important regulator of hippocampal excitability and memory processing.

Title: Mechanisms of maladaptive compensation in KCNQ2-related epilepsy in patient-specific iPSC-derived neurons

Authors: *D. SIMKIN[1], M. GHARIB[1], A. L. GEORGE, JR[2], E. KISKINIS[1];
[1]Neurol., Northwestern University, Feinberg Sch. of Med., Chicago, IL; [2]Pharmacol., Northwestern Univ. Feinberg Sch. of Med., Chicago, IL

Abstract: Heterozygous loss-of-function mutations in *KCNQ2*, which encodes a voltage-gated K^+ channel subunit responsible for neuronal M-current, have been associated with neonatal developmental and epileptic encephalopathy (KCNQ2-DEE). This complex disorder manifests as severe early-onset seizures and impaired neurodevelopment due to an imbalance in neuronal

circuit activity in the brain. While the effects of *KCNQ2* mutations have been studied extensively in heterologous expression systems, their effects on the inherent properties of human neurons are poorly understood. Specifically, what remains unclear is how defects in M-current affect the electrophysiological properties of human neurons during a critical neurodevelopmental maturation period. In our recent published study (PMID 33544076), we demonstrated that iPSC-derived neurons from a patient with KCNQ2-DEE exhibit enhanced tonic burst-suppression-like firing on multi-electrode arrays (MEAs). In contrast to isogenic mutation-corrected controls, KCNQ2-DEE neuron bursting becomes progressively phasic as neurons mature. This maladaptive maturation time course is associated with upregulation of Ca^{2+}-activated K^+ channels leading to faster action potential (AP) repolarization and larger post-burst after-hyperpolarizations (AHP) over several weeks in culture. While this maladaptive homeostatic response could be replicated in control neurons by chronically inhibiting M-channels pharmacologically, it is not clear whether induction of this homeostatic response is specifically due to altered M-channel function or altered neuronal activity that results from M-channel inhibition.
Here we build upon these recent findings and use KCNQ2-DEE patient-specific and isogenic mutation-corrected control iPSC-derived excitatory neurons from multiple patients as well as unrelated healthy controls to investigate the mechanisms involved in eliciting this maladaptive homeostatic response. We find that chronic treatment of control neurons with M-channel blocker XE991 leads to an aberrant bursting phenotype while blocking other voltage-gated K^+ channels with nonspecific blocker 4AP does not. We hypothesize that upregulation of Ca^{2+}-activated K^+ channels associated with this bursting phenotype is likely a specific response to M-channel dysfunction. Because KCNQ2-DEE presents in the first days of life, targeting the underlying cause (i.e. KCNQ2) may be challenging, and identifying novel downstream targets may enable alternative therapeutic strategies.

Title: Differences between the kcnb1-integrin machinery in normal and disease states

Authors: *A. BORTOLAMI[1], W. YU[1], E. FORZISI[1], R. KADAKIA[1], F. SESTI[2];
[2]Neurosci. and Cell Biol., [1]Rutgers Univ. Dept. of Cell Biol. and Neurosci., Piscataway, NJ

Abstract: Potassium channels regulate neuronal excitability in the central nervous system. This regulationallows information processing, which eventually results in a motor response. Furthermore,neuronal excitability regulation is not the only process mediated by potassium channels; theyare also capable of eliciting biochemical events. Over the past decade, our laboratory has beenstudying a voltage-gated potassium ion channel, KCNB1, which not only explicates the canonicion-conduction function but is also implicated in cell migration through intracellular signaling. Ina previous study, we characterized the association of the KCNB1 channel with integrins,essential intramembrane proteins involved in the outside-in cell signaling. Furthermore,integrins are not the only proteins associated with this channel. Through biochemical analysis,we started to characterize the intracellular machinery associated with both KCNB1 andintegrins, which are responsible for the channel-associated biochemical signaling cascades.Evidences highlights paxillin, talin-1, and vinculin as main candidates for this role. Ourpreliminary work showed that mutations in KCNB1 found in children with epilepsy can lead tocytoskeleton remodeling impairments. Accordingly, we found that those mutants impair talin-1and paxillin activities. Thus, non-ionic functions of Kcnb1 channels proceed through integrinsand their associated machinery and these are impaired in disease conditions.

Title: Pathogenic R455H mutation of Slack (KCNT1) channels causes misregulation of β-actin translation initiation

Authors: *T. MALONE[1], Y. ZHANG[3], J. WU[3], R. CHEN[2], P. LICZNERSKI[4], E. A. JONAS[3], **L. K. KACZMAREK**[3];

Abstract: The Slack channel is a large conductance sodium-activated potassium channel expressed in the cerebral cortex and many other neuronal nuclei. Over 50 gain-of-function Slack mutations are associated with early-onset epilepsy and severe intellectual disability in humans.

One unexplained aspect of Slack pathogenesis is the source of intellectual disability in these patients. Misregulation of mRNA translation is a possible explanation for this phenotype, because Fragile X Mental Retardation Protein (FMRP), an important regulator of mRNA translation, binds the Slack protein directly and also binds Slack mRNA. The binding of FMRP to Slack stimulates its channel activity, raising the possibility that activation of Slack channels could also regulate the function of FMRP. To test this hypothesis, we used a fluorescent reporter construct with its coding region flanked by the 5' and 3' UTR of β-actin, a known FMRP binding target, and detected levels of reporter using immunoblotting and measurements of fluorescence. Both total protein and translation levels of the reporter construct were markedly increased in cells expressing the R474H Slack mutant but not the wild type control, an effect mediated by the β-actin UTRs. FRAP experiments used to visualize real-time protein synthesis found that pharmacological activation of WT Slack channels triggers increased synthesis of the reporter protein. This mechanism of activity-dependent translation is inhibited by both FMRP and its binding partner CYFIP1. We verified that this mechanism is common to both rodent and human Slack channels and that it operates in mouse cortical neurons. Current experiments are testing the mechanism by which channel activity is linked to translation and its implications for neuronal function. These findings potentially represent the first example of the direct modulation of protein synthesis by activation of an ion channel and suggest that abnormal regulation of translation may explain the intellectual disability of patients with Slack mutations.

Title: Autism spectrum disorder-associated voltage-gated potassium channel mutant Kv7.3/R230C disrupts mouse dopamine neuron activity.

Authors: *C. TSCHUMI, B. JUAREZ, M. A. QUINLAN, J. H. HAYANO, L. S. ZWEIFEL; Univ. of Washington, Seattle, WA

Abstract: Neurodevelopmental disorders (NDDs), such as autism spectrum disorder (ASD), have complex etiologies and a diversity of phenotypic outcomes. A growing body of evidence implicates deficits in mesostriatal circuitry as contributing to several aspects of behavioral

dysregulation associated with these disorders. Underlying these circuit-level dysfunctions, alterations in the brain-wide function of specific ion channels is emerging as a key factor in the etiology of NDDs.
The Kv7 family of voltage-gated potassium channels encoded by KCNQ genes are increasingly linked to NDDs including ASD. These channels are broadly expressed, including within ventral tegmental area (VTA) dopamine neurons where they regulate neuronal excitability. Voltage-gated ion channels, including Kv7s, are gated by the movement of positively charged arginine (R) residues in the S4 transmembrane domain. Mutations in all three arginine (R) residues that constitute the gating charges of the voltage sensor in the Kv7.3 subunit (KCNQ3) have been identified in NDDs including ASD. The KCNQ3(R230C) mutation exhibits an increase in potassium conductance consistent with a gain of function mutation. However, it remains unclear how gating charge mutations in KCNQ3 alter neuronal excitability.
Here we assessed the impact of KCNQ3(R230C) on VTA dopamine neuron excitability using a viral-based strategy for conditional inactivation of endogenous Kv7.3 by CRISPR/SaCas9 coupled with conditional re-expression of human wildtype (hKv7.3/WT) or mutant (hKv7.3/R2C) Kv7.3 in mice. CRISPR/Cas-9 inactivation of the mouse Kcnq3 gene alone did not alter the proportion of spontaneously active cells, but substantially increased the frequency of spontaneous and evoked action potential firing. Expression of hKv7.3/WT rescued these effects. In striking contrast, hKv7.3/R2C expression almost completely prevented spontaneous activity, decreased firing in response to depolarizing current injection, increased the spike frequency accommodation during trains of action potential firing, and broadened the action potential waveform. The opposing effects of Kv7.3 inactivation with CRISPR/Cas9 and re-introduction of hKv7.3/R2C on excitability are consistent with a gain of function in the hKv7.3/R2C channel and not a loss of function. These data demonstrate that the R230C mutation in hKV7.3 alters the action potential waveform and excitability of neurons in vivo that likely disrupts the function of multiple neural networks, including the mesostriatal dopamine system, that contribute to behavioral dysregulation in ASD.

Title: Mechanisms of KCNT1 channel gain-of-function in epilepsy and intellectual disability

Authors: *J. WU, Y. ZHANG, I. QURAISHI, M. CHATTERJEE, L. K. KACZMAREK; Yale Univ. Sch. Med., New Haven, CT

Abstract: Gain-of-function (GOF) mutations in the *KCNT1* gene, encoding the sodium-activated potassium channel KCNT1 (Slack, $K_{Na}1.1$), are associated with several distinct childhood epilepsies, all of which are associated with very severe developmental intellectual disability (ID). The underlying mechanisms of KCNT1 channel GOF in epilepsy and ID are, however, largely unknown. We have generated a mutant strain of mice with human *KCNT1* variant *KCNT1*-R474H (R455H in mouse numbering) and investigated the effect of *KCNT1*-R455H GOF variant on neural network excitability leading to seizure generation. We classified primary cortical neurons as glutamatergic and GABAergic and carried out electrophysiological recordings on the two types of neurons from wild type and R455H mutation mice. Voltage-clamp studies revealed that *KCNT1* variant R455H increased peak K_{Na} current magnitude in both excitatory glutamatergic and inhibitory GABAergic neurons. Current-clamp studies revealed that this mutation significantly increases the rate of action potential (AP) repolarization in glutamatergic neurons, leading to an increase in AP firing frequency. In contrast, the R455H mutation increases rheobase and decreases input resistance in GABAergic neurons, leading to a reduction in AP firing frequency. These finding suggest that excitatory or inhibitory neurons differ in either the KCNT1 splice variants they express, or in the spatial proximity of KNCT1 channels to sites of sodium influx. Overall, these results suggest that the *KCNT1*-R455H GOF variant leads to neural network hyperexcitability and produce early onset seizures by altering the intrinsic excitability of neurons. Seizures arise from increased excitation in excitatory neurons and reduced excitability in inhibitory interneurons. Our study may lead to novel methods and targets of treating epilepsy and neurodevelopmental disorders in patients with *KCNT1* GOF mutations.

Abstract: A key aspect of nearly all single-cell sequencing experiments is dissociation of intact tissues into single-cell suspensions. While many protocols have been optimized for optimal cell yield, they have often overlooked the effects that dissociation can have on *ex vivo* gene expression. Generation of new and reanalysis of published mouse single-cell RNA-sequencing (scRNA-seq) datasets demonstrates that use of enzymatic dissociation on mouse brain tissue induces an aberrant *ex vivo* gene expression signature, most prominently in microglia, that can significantly confound downstream analyses.

To minimize this issue in fresh tissue, we developed and validated a flexible protocol that maintains cell type diversity and yield, while preserving *in vivo* transcriptional profiles. Reanalysis of previously published mouse and human scRNA-seq of multiple tissue types reveals that many aspects of this signature are conserved across tissues/organs and species. We were further able to identify a similar signature in post-mortem human brain in newly-generated and published single-nucleus RNA-sequencing datasets, and show that this signature is induced in freshly-isolated human brain tissue and peripheral immune cells by exposure to elevated temperatures *ex vivo*.

Our results of fresh tissue dissociation provide key insight into the potential confounds of enzymatic digestion and provide a solution to allow for enzymatic digestion for scRNA-seq while avoiding *ex vivo* transcriptional artifacts in both mouse and human tissue. The results of our analysis of post-mortem and fresh human brain samples indicates that the presence of a similar signature in astrocytes and microglia may be the result of a combination of acute pre-mortem and post-mortem variables, which combined may confound the identification and interpretation of true biological signals. Together our results provide a methodological solution for preventing artifactual gene expression changes during fresh tissue digestion and a reference for future deeper analysis of the potential confounding states present in post-mortem human samples.

[2]The Miami Project to Cure Paralysis, [1]Univ. of Miami, Miami, FL

Abstract: Microglia are a critical component in the inflammatory milieu after a CNS injury - they perform diverse functions such as produce cytokines, clear cellular debris, and initiate repair. While recent studies have used single-cell RNAseq approaches to study these heterogeneous roles, most have been under homeostasis or in neurodegenerative disease. Whether microglia execute unique or conserved responses to both traumatic and degenerative disease is not well known. To address this, we performed an integrated single-cell RNAseq analysis of published datasets in neurodegeneration and traumatic injury. We observed both unique and conversed transcriptional programs across diseases and attempted to elucidate determinants of microglia fate using trajectory analysis. This comparative analysis may provide insight into the mechanisms by which microglia respond to injuries and reveal potential therapeutic targets.

Title: Distinct microglial recognition pathways mediate apoptotic cell clearance versus remodeling transcriptome and CSF1R independence

Authors: *S. ANDERSON[1], J. M. ROBERTS[1], N. GHENA[1], A. BOSCO[2], E. IRVIN[1], J. SCHWAKOPF[1], I. COOPERSTEIN[1], M. L. VETTER[3];

Abstract: Microglia are essential for developmental remodeling of the nervous system and recent single-cell RNA sequencing (scRNAseq) has uncovered substantial transcriptional diversity of microglia during brain development. We previously found that a majority of microglia (≈60%) in the postnatal mouse retina have a gene signature similar to disease-associated microglia (DAM) and microglia in developing white matter tracts (PAM/ATM), and that they do not depend upon Colony-stimulating factor 1 receptor (CSF1R) signaling for survival. Here we sought to address how developmental cues and specific signaling pathways promote these distinct microglia properties. We performed scRNAseq on postnatal (P6/P7) retinal microglia from both males and females (n=13,667 cells), and found a spectrum of homeostatic to more DAM/PAM/ATM-like states. Preventing neuronal apoptosis via loss of BAX (n=13 animals), shifted the microglia population to a more homeostatic state. Conversely, CSF1R resistant microglia (PLX3397 dosed for 3 days; n≥11 animals) were enriched for phagocytosis and lipid metabolism genes and more DAM/PAM/ATM-like microglia. Thus, recognition or clearance of apoptotic neurons drives microglia to express DAM/PAM/ATM genes and reduces dependence on CSF1R signaling. To define the signaling pathways regulating these microglia properties, we analyzed a panel of apoptotic recognition receptor knockouts. We found that complement receptor CD11b/CR3, and Mertk of the TAM family, are each required for the clearance of apoptotic retinal ganglion cells (n≥4; p=0.006 and p<0.001). The TAM receptor Axl was less important for clearance (n=8, ns), but was required for microglial independence from CSF1R (n=17; p<0.001). We further showed that loss of both Mertk and Axl shifts microglia to a more homeostatic state.
To assess whether DAM/PAM/ATM-like microglia have specialized clearance function, we showed using CD11c-DTR/GFP transgenic mice that the majority of CD11c-microglia interact with apoptotic cells (n=5; ~73%), and depleting these cells (DT) reduces clearance (n≥7; p<0.05). However, we found that depleting non-CD11c-microglia (PLX3397) similarly reduces clearance (n=10; n<0.001), suggesting CD11c-microglia may not be specialized to do so.Thus, microglial heterogeneity within the developing retina is driven by recognition and phagocytosis of apoptotic neurons. Further, Mertk and CR3 are important for apoptotic neuron clearance, Axl

is required for CSF1R independence, and CD11c-microglia arise in response to exposure to apoptotic neurons, but do not have an enhanced clearance function.

Title: Cns-associated macrophages do not repopulate from microglia

Authors: *L. WANG[1,2], J. ZHENG[1,2], T. CHEN[3], S. ZHAO[3], L.-J. WU[2,3,4];
[1]Mayo Clin. Grad. Sch., Mayo Clin., Rochester, MN; [2]Dept. of Neurosci., Mayo Clin., Jacksonville, FL; [3]Dept. of Neurol., [4]Dept. of Immunol., Mayo Clin., Rochester, MN

Abstract: Microglia and CNS-associated macrophages (CAMs) are long-live immune cells in the CNS, which can be ablated by the drug PLX3397 and fully repopulate after PLX3397 retraction. Given that both microglia and CAMs originate from the yolk sac progenitors, and that microglia are solely repopulated from the residual microglia during recovery from ablation, we wanted to investigate whether the CAMs could be replenished by microglia during repopulation. We used Tmem119-CreER:Rosa26$^{TdT/+}$ transgenic mice to genetically trace and distinguish microglia from CAMs, where microglia were Iba1^{+}TdTomato^{+} while CAMs were Iba1^{+}TdTomato^{-}. We first checked the label efficiency and specificity of this Cre-flox system, and the results showed that approximately 90% of microglia (Cd206^{-}Iba1^{+}) were labeled with TdTomato (cortex microglia 94%±5.57, hippocampus microglia 88.67%±5.77) while none of the CAMs (Cd206^{+}Iba1^{+}) are TdTomato positive. Mice were fed with the PLX3397 chow for 14 days, which successfully ablated approximately 98% of Iba1^{+} cells in the brain, and 99% of the Cd206^{+}Iba1^{+} CAMs in both the meninges and the perivascular space. PLX3397 chow was retracted from day 15, and the normal chow was supplied to let microglia and CAMs repopulate. We collected brain tissue at day 3, day 7 and day 14 of the repopulation period and examined the microglia and CAM populations by immunofluorescent staining. The results showed that no CAMs (Cd206^{+}Iba1^{+}) repopulated in the meninges, perivascular space or choroid plexus were TdTomato positive at all these timepoints. Previous studies showed that microglia with the mutation of the transmembrane protein *negative regulator of reactive oxygen species* (NRROS) expressed more CAM marker protein including Cd206, indicating the interchangeability between

microglia and CAMs under certain circumstances. Thus, it's reasonable to hypothesize that the microglia could replenish the CAMs during repopulation. However, our study demonstrated that the CNS-associated macrophages do not repopulate from microglia, further revealing the subtle differences between the microglia and CAMs. This may suggest the different roles of microglia and CAMs in various pathological conditions including encephalitis and cerebrovascular diseases.

Title: Neuro-immune organoid model reveals a role of microglia in cell stress response and emergence of neural activity

Authors: *G. POPOVA, S. S. SOLIMAN, C. N. KIM, M. G. KEEFE, K. M. HENNICK, D. SHIN, T. J. NOWAKOWSKI;

Abstract: Many fundamental questions about microglia function during brain development in humans remain unanswered as we lack experimental strategies to interrogate their function and responses *ex vivo*. Xenotransplantation of microglia into brain organoids that develop largely without myeloid lineage cells allows a systematic comparison of neurodevelopmental processes in the presence or absence of microglia. By developing a 'neuro-immune' cerebral organoid model, we systematically characterized 3D brain organoids transplanted with primary human microglia and showed that microglia integrate into the organoids and affect brain development. By performing scRNAseq analysis between transplanted and control organoids, we detected subtle but statistically significant differences at transcriptional level in a cell type-dependent manner. Unexpectedly, we found widespread expression of genes involved in type I interferon response in organoid radial glia, which becomes attenuated in the presence of microglia. In contrast, neurons appear transcriptionally invariant to microglia transplantation, but instead undergo synaptic remodeling and an accelerated maturation of network properties. Functional network activity recordings in brain organoids identified a role for human microglia in modulating synaptic density and accelerating the emergence of synchronized oscillatory network activity, similarly to what has been reported in maturing cortical organoids. In agreement with

the role of microglia in synaptic pruning, we detected synaptic material inside of the microglia cells and overall reduction of synaptic clefts in microglia-transplanted organoids. Together, our work reveals transcriptional and functional responses of the developing human neural tissue to the presence of microglia and establishes a novel model for studying neuro-immune interactions and developmental diseases in a context of human tissue.

Title: Regulation of Microglial Anti-Viral Response by Long Non-Coding RNAs

Authors: O. BURLEIGH[1], N. W. MATHY[2], K. DRESCHER[2], X.-M. CHEN[3], *A. SHIBATA[1]; [1]Biol., [2]Sch. of Med., Creighton Univ., Omaha, NE; [3]Rush Univ., Chicago, IL

Abstract: Multiple Sclerosis (MS) is the most common demyelinating disease of the central nervous system. The exact mechanisms and cause of this disease are still largely unknown; however, one leading hypothesis is that the disease is triggered by a viral infection. Theiler's murine encephalomyelitis virus (TMEV) is a single-stranded RNA cardiovirus and is commonly used to model chronic progressive MS. Long non-coding RNAs (lncRNAs) are a type of RNA that are not transcribed into protein and are at least 200 nucleotides long. LncRNAs modulate diverse cellular processes and play a key role in inflammation. The molecular mechanisms of lncRNAs in inflammatory neurodegenerative disorders such as MS are currently unknown. We hypothesized that after TMEV infection in microglia, certain lncRNAs are differentially expressed and alter the viral load in infected microglia. To test our hypothesis in vitro, we infected a murine microglial cell line (BV2) and primary murine microglia with the Daniels (DA) strain of TMEV at 5 MOI for 4 hours. Following infection, cells were rinsed with PBS, and fresh media was added. Viral infection proceeded for 24 hours before RNA was isolated for RT-qPCR analysis. To investigate TMEV infection in vivo, 4–6-week-old FBV/nJ mice were intracerebrally injected with TMEV, or Hank's balanced salt solution (HBSS) in control mice. Animals were sacrificed after 36 days during the chronic demyelination stage and cortical tissue was collected. Functional studies using knockdown or overexpression of lncRNAs were performed in BV2 cells and primary murine microglial cells using a liposomal transfection

technique. GAPDH was used as an endogenous control in RT-qPCR analysis and relative expression was calculated using the comparative Ct (ΔΔCt) method. TMEV infection of BV2s, primary microglia, and FVB/nJ mice significantly upregulated expression of lncRNA-Nostrill compared to controls. UV-inactivated TMEV failed to induce lncRNA-Nostrill in in vitro experiments. Knockdown of lncRNA-Nostrill significantly increased TMEV viral load in BV2 cells while overexpression of lncRNA-Nostrill significantly reduced TMEV viral load. A 24-hour TMEV infection in primary microglia significantly upregulated pro-inflammatory cytokines IL-1ß and TNF-α by 3.2-fold and 5.2-fold, respectively. Interestingly, there was also an upregulation of the anti-inflammatory cytokine IL-10 by 10.3-fold. Further work will investigate the underlying molecular mechanisms of lncRNA-Nostrill, its contribution to anti-viral responses in the central nervous system, and its potential role in the amelioration of demyelination in a virus-induced mouse model of MS.

Title: Purinergic signaling in microglia and potential role of neurosteroids in current modulation

Authors: *M. BARRACO[1], E. KUDOVA[2], M. A. SORTINO[1], M. CHISARI[1];
[1]Dept. of Biomed. and Biotechnological Sciences, Section of Pharmacol., Univ. of Catania, Catania, Italy; [2]Inst. of Organic Chem. and Biochem., Czech Acad. of Sci., Prague, Czech Republic

Abstract: Neuroinflammation is a hallmark of neurodegenerative diseases. It involves elevation of ATP levels and several types of glial cells, including microglia. Microglial cells express several purinergic ionotropic receptors, P2XRs, and among them P2X4 and P2X7 receptor subtypes seem to be involved in anti- or pro-inflammatory processes, respectively. Moreover, cholesterol metabolites, including oxysterols and neurosteroids, may modulate neuroinflammatory responses. In this study we tested the hypothesis that cholesterol metabolites modulate purinergic current in the BV2 microglia cell line, using patch-clamp techniques. We first isolated current elicited by P2X4 and P2X7 receptor subtypes using different ATP concentrations (5 μM and 300 μM, respectively). Then, selective antagonists for each receptor subtype were used to verify P2X4 and P2X7 current. For P2X4 receptors, 5-BDBD (10 μM)

reduced current by 70%, whereas A438079 (10 μM) nearly full inhibited P2X7 current. Afterwards, cells were exposed to cholesterol metabolites (testosterone butyrate/T-BT 20 μM, 17β-estradiol 1 μM, Δ4-dafachronic acid/DAF 10 μM and allopregnanolone/alloP 10 μM) to evaluate changes in current. To estimate P2X4 receptor modulation, cells were exposed to ATP to elicit basal current and then exposed to cholesterol metabolites for 30 s. Basal P2X4 peak amplitude (normalized to 1) was enhanced by T-BT (1.7 ± 0.15, $n = 8$, $p < 0.001$), DAF (2.46 ± 0.14, $n = 7$, $p < 0.0001$) and alloP (1.26 ± 0.07, $n = 12$, $p < 0.01$), but not by 17β-estradiol (1.09 ± 0.05, $n = 14$, $p > 0.05$). P2X7 current in BV2 cells show a strong increase with repeated ATP application. For this reason, we set a control condition where the second ATP exposure was normalized to the first one, and in a different set of experiments, we applied cholesterol metabolites for 30 s prior the second ATP application. We then normalized the increase in current to the first ATP application and we compared both normalized ATP second stimulations to evaluate any current modulation by cholesterol metabolites. P2X7 peak amplitude was not affected by any cholesterol metabolites used in this study. However, T-BT application strongly increased P2X7 receptor rise time (ATP 3324 ms ± 220.1 vs T-BT 707 ms ± 76.1, $n = 10$, $p < 0.0001$). Taken together, these data suggest that cholesterol metabolites modulate P2X4 current more ubiquitously than P2X7. P2X4 current increase elicited by several compounds and the faster rise time for P2X7 receptor by T-BT might influence intracellular pathways in microglia, suggesting new approaches to treat neuroinflammation.

Title: Microglial interaction with neurovasculature in the maintenance of blood-brain barrier in acute seizures

Authors: *K. HARUWAKA, Y. LI, L.-J. WU;
Mayo Clin., Rochester, MN

Abstract: The maintenance of the blood-brain barrier (BBB) is required for homeostasis of the brain environment. Previous studies suggest that microglia, the resident immune cells in the central nervous system, contribute to BBB protection by the direct interaction with vascular endothelial cells during systemic inflammation (Haruwaka et al., 2019). However, the role of

microglia and their interaction with neurovasculature in BBB integrity in neurological disorders is largely unknown.Recent studies demonstrated that BBB is compromised in seizures and epilepsy. As well as BBB breakdown may induce epileptic seizures (Vilet et al., 2007; Dadas and Janigro, 2019), seizure-induced BBB leakage may lead to further progression of epilepsy (Rüber et al., 2018; Mendes et al., 2019). The recovery of BBB dysfunction after seizures may improve prognosis. In addition, microglial depletion aggravates the severity of kainic acid (KA) and pilocarpine-induced acute and chronic seizures (Mirrione et al., 2010; Wu et al., 2020). Those results suggest a beneficial role of microglia in suppressing seizures. We hypothesize that microglia-vasculature interaction may have a key role BBB permeability in the pathogenesis of seizure. To this end, we investigate the role of microglia and their interaction with neurovasculature during KA-induced mouse model of seizures.We first study the time-course changes in BBB leakage in KA-induced severe seizures. After both KA intracerebroventricular (ICV) and intraperitoneal (IP) injection of KA, we found that 70 kDa dextran transiently leaked peaking 6 hours after the induction of the seizure. In addition, the percentage of vessel-associated microglia dramatically increased after 1 day and 3 days. To further delineate the role of microglia in seizure-induced BBB leakage, we used microglial ablation approaches. We found that KA-induced BBB leakage was dramatically increased in mice genetically and pharmacologically depleted of microglia. These results suggest that the protective function of microglia in BBB permeability in acute seizures.Defining microglia-vasculature interaction in BBB integrity represents an important step toward understanding the microglial function in epilepsy and may provide potential therapeutic targets for neuroprotection in compromised BBB in neurological disorders.

Abstract: Alzheimer's disease (AD) is a devastating condition that affects around 5.8 million of Americans, and these numbers are projected to reach nearly 14 million individuals around 2050. Although AD was first described more than 100 years ago, until nowadays that are not effective treatments to counteract or efficiently slow down the progression of the disease. This is likely, due at least in part, to the fact that AD animal models have been focused in the use of transgenic rodent models, failing to translate the findings to humans with the disease. We describe here a non-human primate model of AD presenting extensive tau pathology, mainly affecting the hippocampus and connected areas. Adult rhesus monkeys injected with adeno-associated viruses expressing mutant tau (P301L/S320F) in the left entorhinal cortex (ERC) show after 3 months, extensive prion-like tau propagation with full fibrillary tangles in the hippocampus, as well as pre-tangles and phospho-tau in projection areas such as the contralateral ERC and in the retrosplenial and visual cortices. Importantly, neuroinflammation is extensive in the affected areas, with a major role of microglia in pathological tau oligomer propagation. Finally, the mutant h4R injected coaptates monkey 3R tau generating more tau aggregation and spreading. These results highlight the first stages of tau pathology and propagation and support the importance of a non-human model of AD, with natural full expression of tau protein, that is highly translational to humans.

Title: Transsynaptic spread combined with glia-driven neuroinflammatory response orchestrate the neuro-invasive potential of SARS-CoV-2 in an aged monkey model of COVID-19

Authors: *A. BONILLAS[1], D. BECKMAN[1], G. B. DINIZ[1], S. OTT[1], K. K. A. VAN ROMPAY[1], S. S. IYER[2], B. A. SCHMIDT[2], J. MORRISON[1,3];

Abstract: The COVID-19 pandemic continues to affect millions of people globally, with unpredictable levels of morbidity and mortality. Recent reports state that more than 80% of patients with COVID-19 develop neurological symptoms that can vary from loss of smell,

hemorrhagic stroke, to psychiatric symptoms. Even for those who initially recover, the majority still present cognitive issues, among other neurological problems, many months after the initial infection. Considering that COVID-19 has a severe impact on the aging population, the long-term social and economic burden of the current pandemic can reach alarming levels. To understand how SARS-Cov-2 virus can affect the brain, we developed a rhesus monkey model of COVID-19 pathogenesis. In this pilot study, 4 young healthy (6-9 Y.O) and 4 aged diabetic (21-22 Y.O) rhesus monkeys were infected intranasally and intratracheally with SARS-CoV-2 at a high dose (2.5x106 plaque-forming units [PFU]) and euthanized 7 days later, capturing the peak T cell plasma response to investigate the neuro-invasive potential of the virus. Additional age-matched non-infected animals were analyzed as controls. Our initial unbiased stereological analysis shows the direct presence of several SARS-CoV-2 markers such as spike protein, nucleocapsid and double-stranded RNA (dsRNA) across several cortical regions, with significantly more viral presence and spreading in the aged diabetic animals. Olfactory regions such as the piriform, orbitofrontal, and entorhinal cortices present severe blood-brain barrier (BBB) disruption, with several myeloperoxidase (MPO) activated neutrophils, SARS-CoV-2+ infiltrating the surrounding areas only 7 days after infection. Astrocytic population doubled in the piriform of aged diabetic monkeys in comparison to the young infected ones, suggesting an accelerated mechanism of inflammatory response driven by the active presence of the virus in that likely entered through the olfactory pathway. Strikingly, activated HLA-Dr+ microglia directly attack large pyramidal neurons. SARS-CoV-2+ in the primary olfactory cortex result in robust engulfment of spine proteins such as PSD95 and synaptophysin, ultimately leading to neuronal death. Our preliminary data helps shed light on the neuro-invasive and spreading potential of SARS-CoV-2 across several brain regions in a monkey model of the disease. Identifying the underlying molecular mechanisms of the viral propagation in the primate brain will offer a unique possibility to apply the rhesus monkey model as a platform to test therapies to counteract SARS-CoV-2 spreading, and ultimately, reducing the burden of COVID-19 long-term complications.

Title: Microglia polarize in response to transactive response DNA-binding protein-43 (TDP-43) and display partial recovery after removal of the stimulus

Authors: *A. WILCOX, D. DONLEY;
Harding Univ., Searcy, AR

Abstract: Transactive response DNA binding protein-43 (TDP-43) is an intranuclear protein but mislocalization is associated with several neurodegenerative diseases including amyotrophic lateral sclerosis (ALS) and frontotemporal lobe dementia (FTD). TDP-43 is released into the extracellular space where it is sensed by microglia, the CNS-resident immune cells. Our data and the literature suggest that microglia respond to TDP-43 dysregulation by increasing CNS inflammation. The goal of this study was to determine the impact of extracellular TDP-43 on microglial function and the extent to which microglia recover after stimulation. To study the inflammatory response, cultured immortalized microglia were stimulated with TDP-43 in a 2x2 factorial design with other inflammatory stimuli. Data were analyzed by ANOVA. Using iNOS and Arginase colorimetric assays, we found that TDP-43 caused microglia to lose the ability to appropriately respond to inflammation. Stimulation with TDP-43 increased iNOS activity in response to interferon-gamma and dampened Arginase activity in response to IL-4/IL-13. These results are evidence that TDP-43 polarizes microglia to a pro-inflammatory state, thus altering the response to cytokines and other inflammatory stimuli. A natural function of microglia is engulfment of neuronal synapses. We found that extracellular TDP-43 increased microglial phagocytosis of neurons in culture. Previous research showed improvements in cognitive function when TDP-43 was removed by antibody treatment, which suggests that microglia may be able to recover after removal of the stimulus. To study recovery, cultured microglia were stimulated with TDP-43 or a vehicle; then the media was changed to remove the stimuli and allow a recovery period. Markers of activation were measured using flow cytometry and metabolic assays. After recovery, microglia had a decreased phagocytic capability as compared to TDP-43 stimulation without recovery. Microglia also demonstrated a metabolic shift toward glycolysis in response to TDP-43, consistent with a proinflammatory phenotype but returned to baseline levels of metabolic activity after recovery. These data demonstrate that dysregulated TDP-43 shifts the balance of signaling pathways toward an inflammatory phenotype, but microglia begin to recover after removal of the inflammatory stimuli. More work is needed to understand the mechanisms that control recovery and the phenotypic shifts that occur in response to extracellular stimuli. Future work will also focus on the extent to which these finding contribute to disease progression in neurological diseases such as ALS and FTD.

Title: How does sleep impact neuroinflammation in Alzheimer's disease?

Authors: *S. PARHIZKAR[1], G. MORTIMER[1], N. RENSING[1], M. GRATUZE[1], J. ROMERO[1], G. STROUT[2], D. TIMM[1], C. WANG[1], C. LEE[1], J. REMOLINA SERRANO[1], X. BAO[1], M. MANIS[1], M. FINN[1], J. Abstract: Sleep loss is associated with cognitive decline in older adults, and is likely a risk factor for Alzheimer's disease (AD), the most common cause of dementia. However, the underlying mechanisms are unclear. Recently our lab highlighted that sleep loss promotes deposition of the key pathological hallmarks of AD, Aβ and tau aggregates, in mouse models of AD. Considering the crucial role of immunomodulating genes such as the triggering receptor expressed on myeloid cells type 2 (TREM2) in clearing pathogenic Aβ aggregates, our aim was to investigate whether the sleep/wake cycle influences neuroinflammation, another key player in AD pathogenesis. Using amyloid-depositing 5xFAD mice expressing humanized TREM2 ($T2^{cv}$), we show that sleep deprivation (SD) for six hours per day over six weeks, starting at the age of plaque onset, significantly increased disease-associated microglia markers such as IBA1, Clec7a and CD68, as well as GFAP+ astroglia compared to age- and genotype-matched normally sleeping (NS) controls. Consequently, P2RY12, a marker of homeostatic microglia, decreased upon SD compared to NS 5xFAD/$T2^{cv}$ controls. This suggests that microglia and astroglia, the key immune-regulating cells in the brain, directly respond to sleep loss. We also observed elevated pro-inflammatory cytokine levels of TNFα and ILβ upon SD in brain homogenates from SD compared to NS 5xFAD/$T2^{cv}$ mice. Moreover, SD further increased fibrillar Aβ load compared to age-matched NS 5xFAD/$T2^{cv}$ mice, which may explain the elevated microglial and astroglial reactivity. However, we show similar effects in SD wild-type mice compared to NS mice, suggesting that sleep loss promotes a proinflammatory environment in the brain in the presence or absence of Aβ pathology. Additionally, we found a TREM2-dependent change in sleep/wake behavior where 5xFAD/$T2^{cv}$ mice spent more time awake in the dark phase

compared to age-matched 5xFAD mice expressing the AD-associated R47H TREM2 variant ($T2^{R47H}$) or lacking endogenous TREM2 ($T2^{KO}$). In line with these findings, the increased microglial and astroglial reactivity observed in SD 5xFAD/$T2^{cv}$ mice did not significantly change in SD 5xFAD/$T2^{R47H}$ or 5xFAD/T2KO controls, indicating a TREM2-dependent effect on neuroinflammation driven by changes in sleep. In conclusion, our findings suggest that sleep loss acts as an early pathological stressor that promotes a neuroinflammatory cascade, which may further exacerbate AD pathology, eventually leading to neurodegeneration and dementia.

Title: Macrophage interactions with axonal spheroids inhibit neurodegeneration

Authors: *S. HUNTER-CHANG[1,2], Y. YONG[2], T. VEGIRAJU[2], S. KUCENAS[2], C. DEPPMANN[1,2];
[1]Univ. of Virginia Neurosci. Program, Charlottesville, VA; [2]Biol., Univ. of Virginia Biol., Charlottesville, VA

Abstract: Axon degeneration is a key process in most pathological neurodegeneration and in all developmental neurodegeneration. As they degenerate, axons pass through an initial “latent” phase in which normal functions continue and gross morphology is unchanged, then through a “catastrophic degeneration” phase in which the axon rapidly disintegrates. This transition from salvageable quiescence to irreversible destruction might be explained by the bubble-like “axonal spheroids” that form on degenerating axons. Our previous work found that spheroid rupture releases axonal contents into extracellular space, and that these contents hasten degeneration of intact axons exposed to them. Additionally, we have observed that spheroids are marked with a

phosphatidylserine (PS) “eat me” signal known to induce engulfment by macrophages. However, whether macrophages selectively target spheroids for engulfment and how this engulfment affects the switch from quiescence to catastrophic degeneration remains unknown. To address this, sympathetic neurons were cultured in microfluidics devices with or without endogenous GFP-labeled macrophages, then the neurons were injured by enucleation. Neurodegeneration 0-4 hours post-injury was quantified as percent neuronal signal loss using confocal microscopy. Compared to uninjured conditions, neurons injured with macrophages present showed no significant increase in degeneration, while those injured without macrophages present did (n=3 uninjured, n=5 injured). Ongoing work seeks to validate these findings *in vivo* in zebrafish, *Danio rerio*, and to specify if and how macrophages preferentially contact spheroids. This work demonstrates that interactions between macrophages and axonal spheroids inhibit neurodegeneration, elucidating a new role for macrophage infiltration and debris clearance in response to neuronal injury and highlighting new targets for neurodegeneration therapies.

Title: Trem2-induced activation of microglia contributes to synaptic resilience in non-demented individuals with Alzheimer’s neuropathology

Authors: *A. FRACASSI[1], M. MARCATTI[1], R. WOLTJER[2], S. MORENO[3], G. TAGLIALATELA[1];
[1]Neurol., Univ. of Texas Med. Br., Galveston, TX; [2]Oregon Hlth. & Sci. Univ., Portland, OR; [3]Univ. Roma Tre, Rome, Italy

Abstract: The existence of individuals who remain cognitively intact despite the presence of histopathological signs of Alzheimer’s disease (AD), here referred to as “Non demented with AD neuropathology” (NDAN), suggests that some unknown mechanisms are triggered to resist cognitive impairment[1]. Synaptic dysfunction has been identified as one of the major AD causes and it is established that microglia, attracted to plaques, phagocyte damaged synapses[2]. In this context, exposed phosphatidylserine (ePS) represents a neuronal “eat-me” signal involved in

microglial-mediated phagocytosis of damaged synapses[3]. A possible candidate mediator of this process is represented by TREM2, a microglial surface receptor activated by ligands including PS. Based on TREM2 role in the scavenging function of microglia, we hypothesize that an efficient microglial phagocytosis of damaged synapses underlies synaptic resilience in NDAN, thus protecting from memory deficits. Using immunofluorescence microscopy, a comparative study of human *post-mortem* frontal cortices of aged-matched individuals, AD and NDAN individuals has been performed. The distribution of activated microglia (IBA1 and IBA1/CD68 positive cells) and the expression of phagocytic microglia-related proteins (TREM2 and DAP12) were evaluated in relation to Aβ plaques. To test the efficacy of microglia in removing debris and damaged synapses, preservation of synapses around plaques was assessed using MAP2 and tubulin βIII as dendritic and axonal markers respectively. As a further confirmation of microglial efficiency, we looked for engulfed damaged synapses inside microglial lysosomes analyzing the colocalization between PSD95 and CD68. Immunofluorescence analyses indicate higher microglial activation and TREM2 expression in NDAN individuals, as well as preserved axonal and dendritic structure around plaques *vs*. AD. High levels of PSD95 around NDAN plaques and the colocalization of PSD95 and CD68 may suggest a prompt removal of damaged synapses by hyperactive phagocytic microglia. Furthermore, taking advantage of flow cytometry techniques, a study of the ePS using Annexin V assay has been performed. Annexin V assay on synaptosomes isolated from aged-matched, AD and NDAN individuals indicates changes in the ePS in NDAN individuals, confirming the engulfment of damaged synapses. Our results suggest a higher efficiency of TREM2-induced phagocytic microglia in removing damaged synapses, underlying synaptic resilience in NDAN individuals. 1. Title: Oleoylethanolamide attenuates neuroinflammation and microgliosis induced by the cerebellar neurodegeneration of the PCD mutant mouse

Authors: *E. PÉREZ-MARTÍN[1,2], L. PÉREZ-REVUELTA[1,2], P. TÉLLEZ DE MENESES[1,2], D. DÍAZ LÓPEZ[1,2], E. WERUAGA[1,2];

[2]IBSAL, Inst. of Biomed. Res. of Salamanca, Salamanca, Spain

Abstract: The endocannabinoid oleoylethanolamide (OEA) has been proven to exert anti-inflammatory and neuroprotective effects in different animal models with brain injury of varied etiology. Indeed, a previous study of our laboratory demonstrated that the exogenous administration of OEA -prior to the onset of the neurodegenerative process- resulted in neuronal protection of Purkinje cells and improvement of the behavioral defects observed in *Purkinje Cell Degeneration* (PCD) mutant mice. In this study, we tested whether OEA treatment (10 mg/kg, i.p. at postnatal day 12) modulates neuroinflammation and attenuates microglial activation in the mouse model of severe cerebellar degeneration PCD. First, changes in mRNA levels of different proinflammatory, neurotrophic and neuroprotective factors in the cerebellum were measured by quantitative PCR in the short- (3- and 24-hours post-treatment), medium- (P20) and long-term (P30; *n*=6 animals per group). Secondly, modulation of microglial activation and its phenotype was analyzed in parasagittal sections of cerebellar vermis by immunohistochemistry at P30 when the neurodegenerative process has ended (*n*=7 animals per group). Our results showed that OEA treatment significantly reduced mRNA levels of the proinflammatory factors IFNγ, IL1β and TNFα, and increased the neurotrophic/neuroprotective factors BDNF, GAP43 and MAP2 in cerebellum 3 and 24 hours after administration. Additionally, treated animals showed an increase in the mRNA levels of all the analyzed factors in the medium term comparing with untreated animals. By contrast, a decrease in mRNA levels of IL1β and IL6 was observed in those treated animals in the long term. Finally, results from immunohistological analysis of cerebellar microglial cells showed that OEA treatment reduced the microglial density in the cerebellum of PCD mice, which was exacerbated as a consequence of neurodegeneration. These findings demonstrate the neuroimmunomodulatory properties of OEA in the PCD mouse and shed light on the possible mechanisms of action of OEA as a therapeutic agent which could be a co-occurrence among down-regulation of neuroinflammation, modulation of microglial activation and neuronal protection.

Title: The pathogenic role of c-Kit+ mast cells in the spinal motor neuron-vascular niche in ALS

Authors: M. KOVACS[1], C. ALAMON[1], C. MACIEL[1], V. VARELA[1], S. IBARBURU[1], L. TARRAGO[1], P. H. KING[2,3], Y. SI[2,3], Y. KWON[2], O. HERMINE[4], L. BARBEITO[1], E. TRIAS[1]; [1]Inst. INSERM UMR 1163, Hôpital Necker, Paris, France

Abstract: Degeneration of motor neurons, glial cell reactivity, and vascular alterations in the CNS are important neuropathological features of amyotrophic lateral sclerosis (ALS). Immune cells trafficking from the blood also infiltrate the affected CNS parenchyma and contribute to neuroinflammation. Mast cells (MCs) are hematopoietic-derived immune cells whose precursors differentiate upon migration into tissues. Upon activation, MCs undergo degranulation with the ability to increase vascular permeability, orchestrate neuroinflammation and modulate the neuroimmune response. However, the prevalence, pathological significance, and pharmacology of MCs in the CNS of ALS patients remain largely unknown. In autopsy ALS spinal cords, we identified for the first time that MCs express c-Kit together with chymase, tryptase, and Cox-2 and display granular or degranulating morphology, as compared with scarce MCs in control cords. In ALS, MCs were mainly found in the niche between spinal motor neuron somas and nearby microvascular elements, and they displayed remarkable pathological abnormalities. Similarly, MCs accumulated in the motor neuron-vascular niche of ALS murine models, in the vicinity of astrocytes and motor neurons expressing the c-Kit ligand Stem Cell Factor (SCF), suggesting an SCF/c-Kit-dependent mechanism of MC differentiation from precursors. Mechanistically, we provide evidence that fully differentiated MCs in cell cultures can be generated from the murine ALS spinal cord tissue, further supporting the presence of c-Kit+ MC precursors. Moreover, intravenous administration of bone marrow-derived c-Kit+ MC precursors infiltrated the spinal cord in ALS mice but not in controls, consistent with aberrant trafficking through a defective microvasculature. Pharmacological inhibition of c-Kit with masitinib in ALS mice reduced the MC number and the influx of MC precursors from the periphery. Our results suggest a previously unknown pathogenic mechanism triggered by MCs in the ALS motor neuron-vascular niche that might be targeted pharmacologically.

Title: Emergence of senescent cells in a toxin-induced mouse model of focal demyelination

Authors: *P. S. GROSS[1], Z. MANAVI[2], J. K. HUANG[1,2];
[1]Interdisciplinary Program In Neurosci., [2]Biol., Georgetown Univ., Washington, DC

Abstract: Multiple Sclerosis (MS) is a demyelinating and degenerative disease that is the number one neurological disability among young adults. Myelin degeneration results in denuded axons that consequently conduct signals less efficiently and eventually degenerate. In early stages of the disease, oligodendrocytes, the myelinating cells of the central nervous system, and their progenitors (OPCs), can regenerate myelin, resulting in effective remyelination. However, at later stages of the disease and with increasing age, remyelination becomes inefficient, leading to degeneration of axons and worsening of symptoms. One of the key characteristics of aging is the accumulation of senescent cells, which are apoptosis-resistant cells locked in permanent cell cycle arrest that secrete an inflammatory milieu termed the senescence associated secretory phenotype (SASP). Here, we hypothesize that the age-associated accumulation of senescent cells limits the ability of OPCs to remyelinate. Using a murine reporter line with a fluorochrome indicator expressed under the control of the $p16^{INK4a}$ locus (p16-tdt), a common marker of senescence, we found increased markers of senescent cells present after toxin-induced demyelination and throughout the process of remyelination. As early as 5 days post lesion (dpl), we found p16-tdt positive cells, with continued expression throughout and post- remyelination. Additionally, aged mice showed increased markers of senescence in the lesion compared to their young counterparts, suggesting the accumulation of senescent cells might contribute to their reduced remyelination. These results suggest that therapeutic targeting of cellular senescence, i.e. by senolytics or senomorphics, might promote remyelination at later stages of MS.

Abstract: We aim towards the design of an innovative automated multifunctional device for diagnostics of neurodegenerative diseases. The main goal is to develop cellular models and procedures with immunoglobulin G (IgG) from patient sera for diagnostic protocols related to neurodegenerative diseases (particularly amyotrophic lateral sclerosis - ALS). We will report on the preliminary signal analysis protocols for Ca^{2+} imaging data obtained with fluorescent probes in rodent astrocytes or in neurons in culture. Time- lapse recordings were made with a CCD camera. The analysis was performed by developing machine learning protocols on astrocytes or applying cross-correlation analysis on neurons (van Drongelen W. Signal Processing for Neuroscientists: Introduction to the Analysis of Physiological Systems. Amsterdam: Elsevier, 2007). Raw data from primary rat cortical astrocytes were processed with Unsupervised Machine Learning algorithms in order to train a classifier to reliably predict a class for any given test trace. Clustering with Decision Trees along with Block Bootstrapping for time series to model the traces, as well as k-Nearest Neighbours classification gave us satisfactory preliminary results. After ALS IgG application the cross-correlograms of the Ca^{2+} signaling in hippocampal pyramidal neurons in culture revealed a synchronization that was apparent in highly correlated activity (corr. coeff. >0.9) across cell pairs at physiological delays. Control IgGs (commercial or from a healthy subject) have not shown similar highly synchronous behavior. Thus, in addition to an innovative technical solution for the use of cell models in a lab-on-chip device we have started developing robust signal analysis protocols on cells *in vitro* as induced by immune humoral factors that may serve for better stratification of patients for personalized medicine.

Title: Spatial phenotypic characterization of microglia via CODEX Multiplexed Imaging reveals sub-population-level relationships with pathogenic features in Alzheimer's Disease brains

Authors: J. SINGH[1], **A. BOGACHUK**[2], N. NIKULINA[1], A. CHIOT[2], R. WOLTJER[3], A. CROTTI[4], O. BRAUBACH[1], *B. AJAMI[2];

Abstract: Recent high-throughput transcriptomics and proteomics analysis have shown a remarkable heterogeneity of microglia phenotypes across various disease conditions. Differently from neurons, microglia appearance can be characterized as a continuum between ramified and amoeboid morphologies. The transcriptional and proteomic profiles associated to each degree of morphology are potentially multiple and dependent on the healthy/pathological conditions in consideration with sex, anatomical area of the brain, and disease stage. While single-cell RNA sequencing (scRNA-seq) has been instrumental in revealing microglia sub-populations, it is lacking in spatial information and phenotypic characterization. The scarcity of fresh human brain tissue imposes a bottleneck for RNA-seq studies, while paraffin-embedded tissues are widely available in most brain banks. Using Codex superplex imaging technology, we characterize microglia sub-population localization in relationship to the distance from neurodegenerative disease pathogenic features such as senile plaques and neurofibrillary tangles (NFT) in post-mortem AD brain samples and matching controls. Codex spatial phenotyping enabled us to characterize microglia that surround amyloid plaques and NFT-filled neurons in different brain regions of AD, dementia affected individuals with no signs of amyloid plaque deposits, and Tau mutant driven FTD affected individuals, and compare them with healthy age and sex matched individuals. This study allowed us to characterize the changes of microglia phenotype in the immediate neighborhood of pathogenic features. Such observation will be instrumental to understanding the role of several Late Onset Alzheimer’s Diseases associated genes and potentially identify novel drug targets.

Title: Synaptic dysfunction as a neural mechanism for HIV-1 associated apathy

Authors: *K. A. MCLAURIN, M. N. CRANSTON, H. LI, C. F. MACTUTUS, S. B. HARROD, R. M. BOOZE;
Dept. of Psychology, Univ. of South Carolina, Columbia, SC

Abstract: Individuals living with human immunodeficiency virus type 1 (HIV-1) exhibit an increased prevalence of neuropsychiatric comorbities (e.g., apathy) relative to their seronegative counterparts. Operationally, apathy is defined as a prominent decrease in self-generated voluntary or purposeful goal-directed behaviors; a construct which can be objectively measured in preclinical biological systems. HIV-1 associated apathy was examined by quantifying goal-directed behaviors, indexed using voluntary wheel running, in ovariectomized female HIV-1 transgenic (Tg; *n*=21) and F344/N control (*n*=26) animals. Analyses of voluntary wheel running were conducted at the microstructural level (i.e., parceling running behavior into fine-grained blocks to delineate the number and length of activity bouts) to elucidate genotype-dependent alterations in goal-directed behaviors. HIV-1 Tg animals exhibited prominent alterations in goal-directed behaviors, evidenced by a profound decrease in the number of running bouts relative to control animals; alterations which persisted during both the diurnal and nocturnal cycle. With regards to running bout length, HIV-1 Tg animals displayed an increased running bout length, relative to controls, during the diurnal cycle. During the nocturnal cycle, however, an altered development of running bout length was observed in HIV-1 Tg animals. Following the completion of voluntary wheel running, medium spiny neurons (MSNs) of the nucleus accumbens (NAc), an integral component of the fronto-striatal circuit, were examined as a potential neural mechanism underlying HIV-1 associated apathy. HIV-1 Tg animals displayed prominent alterations in MSNs of the NAc, evidenced by a population shift towards increased dendritic branching complexity and a more immature dendritic spine phenotype. Additionally, examination of the location of dendritic spines on MSNs in the NAc revealed decreased synaptic connectivity in HIV-1 Tg animals. Collectively, HIV-1 Tg animals displayed apathetic behaviors for a natural reward; behaviors which may be due, at least in part, to synaptic dysfunction in MSNs. Funded by: DA013137, HD043680, MH106392, NS100624.

Title: Abnormal intraneuronal β-amyloid accumulation in the hippocampus and prefrontal cortex and neurocognitive deficits in aging HIV-1 Tg rat and human HIV+ brain

Authors: *H. LI[1], K. MCLAURIN[1], C. MACTUTUS[1], B. LIKENS[1], S. L. CHANG[2], W. HUANG[2], R. BOOZE[1];
[1]Univ. of South Carolina, Columbia, SC; [2]Inst. of NeuroImmune Pharmacol., Seton Hall Univ., South Orange, NJ

Abstract: HIV-associated neurocognitive disorders (HAND) occur with increasing prevalence in aging HIV-1+ patients. To investigate the aging process in patients with HIV-1, we conducted two complementary studies 1) to elucidate abnormal protein aggregates (β-amyloid) in the aging HIV-1 transgenic (Tg) rat hippocampus and prefrontal cortex (PFC), and 2) to validate our findings on HIV+ human brain tissue from the HIV-associated neurocognitive disorder (HAND) patients. First, a longitudinal experimental design was utilized to evaluate the progression of temporal processing, assessed using gap prepulse inhibition (gap-PPI), in HIV-1 Tg and F344/N control rats from postnatal day (PD) 240 to PD 540. HIV-1 Tg rats exhibited prominent alterations in the progression of temporal processing relative to control rats; a deficit that was more pronounced in female HIV-1 Tg rats relative to males. Second, immunohistochemistry staining (IHC) and Western blot analysis were used to detect the expression of β-amyloid and amyloid precursor protein (APP) in the hippocampus and PFC of aging (14 month old) HIV-1 Tg and F344/N control rats. The data indicated that an abnormal intraneuronal β-amyloid accumulation was present in both the hippocampus and PFC in HIV-1 Tg rats when compared to F344/N control rats. Furthermore, significantly higher expression of APP was detected in the CA3 region of the hippocampus in F344/N control rats, relative to the HIV-1 Tg rats. We also used the DiOlistic labelling of dendritic spines to identify the intracellular consequences of β-amyloid accumulation. Finally, 9 autopsy HIV-infected cases (including hippocampus and PFC) from aging HIV-associated neurocognitive disorder (HAND) patients were used to assess the β-amyloid expression. The results showed intraneuronal β-amyloid expression both in the hippocampus and PFC, with no clear amyloid plaque pathology in these brain regions. Additionally, abundant Iba1+ cells co-localized with HIV-1 mRNA fluorescence signals,

providing strong evidence that microglia are the cell types harboring HIV-1 virus in the aging HAND brain. Overall, the abnormal intraneuronal β-amyloid accumulation in HIV+ will be critical for understanding the age-related neurocognitive deficits and assessing therapeutic interventions.

Title: Assessment of autophagy markers in HIV-seropositive participants with respect to antiretroviral therapy and neurocognitive status

Authors: *M. MCGRAW[1], E. ANDRAKA[1], S. OPSTEEN[1], L. PRICHARD[2], B. TIWO[4], E. T. OVERTON[2], G. R. CUTTER[3], S. HEATH[2], J. SHACKA[1];

Abstract: Due to the success of antiretroviral therapy (ART), people with HIV (PWH) now exhibit near-normal life expectancies. However, a large percentage of PWH still suffer from several comorbidities including HIV-associated neurocognitive disorders (HAND). Previous studies have determined that the autophagy-lysosomal pathway (ALP) is dysregulated in peripheral blood mononuclear cells (PBMC) from PWH. Function of the ALP can be determined by assessment of autophagic flux, by quantifying the accumulation of autophagosomes in the presence or absence of lysosome inhibition. However, prior studies have not evaluated autophagic flux in specific populations of PBMCs, nor have they evaluated the impact of HAND or ART. This study tests our hypotheses that autophagic flux is compromised in PWH and is further compromised as a function of HAND. PBMCs were obtained from the following cohorts of participants in the ACTG-5303 study: without cognitive decline (N=12) before and after 48 weeks of ART (N=12), and with mild-moderate cognitive decline before and after ART (N=12). PBMCs were also obtained from HIV- participants (N=7). CD8+ T-cells were purified from PBMCs and then incubated for 24h in the presence or absence of chloroquine (CQ; 30 μM), a weak base that inhibits lysosome function, and in turn causes autophagosomes to accumulate.

Western blot analysis of cell lysates was performed to assess levels of LC3-II, a selective marker of autophagosomes, and p62, an ALP substrate. Levels of p62 and LC3-II in CD8+ T cell lysates were significantly lower in all HIV+ participant groups compared to those observed in HIV- participants. In HIV+ participant groups, levels of p62 were significantly higher after ART than those in ART-naïve participants, regardless of neurocognitive status. When assessing autophagic flux, LC3-II and p62 levels were significantly higher in CQ-treated lysates from ART-naïve, HIV+ participants compared to untreated lysates. This effect of CQ was not observed following ART. Taken together these results suggest that ART alters the ALP regardless of cognitive status. While our analysis of autophagic flux in CD8+ T cell lysates was unable to predict cognitive status, the observed effects of HIV on ALP function, and the additional effect of ART supports further investigation of the ALP as a means of monitoring disease progression.

Title: Dysbiosis in HIV-1 Transgenic Rats: Potential Treatment of HAND through the Gut-Brain-Microbiota Axis

Authors: *M. RODRIGUEZ[1], K. A. MCLAURIN[2], C. F. MACTUTUS[1], R. M. BOOZE[1]; [2]Exptl. Psychology, [1]Univ. of South Carolina, Columbia, SC

Abstract: HIV-1 associated neurocognitive disorders (HAND) have been found to be associated with microbial translocation and dysbiosis. These changes are associated with the progression and severity of HAND symptoms in humans. HIV-1 transgenic (Tg) rats are used to study the neurocognitive deficits associated with HAND but the role the gut-brain-microbiota axis contributes remains unknown. S-equol is a metabolite produced by the gut when ingesting specific phytoestrogens and has been found to be neurorestorative. This study was a 2x2 factorial design where we used 16S rRNA gene sequencing and profiling to determine if there was a difference in microbiome composition between adult HIV-1 Tg rats (n = 21) and F344/N control

rats (n = 21), before and after S-equol treatment. HIV-1 Tg rats contain 7 of the 9 HIV-1 viral proteins (env, tat, rev, vif, vpr, vpu, nef) and are noninfectious due to not having gag and pol proteins. Treatment consisted of S-equol (four 0.5mg pellets) or four sucrose control pellets per animal per day for 70 days. Stool samples were collected before and after treatment, with intestinal samples being collected only after. Alpha diversity analysis between HIV-1 Tg vs. control rats at baseline was approaching significance ($p<0.051$) with beta diversity analysis indicating a clear difference in phylogenetic composition but not abundance ($p<0.001$). At the genus level, baseline differences were found between HIV-1 Tg rats vs. controls with Alloprevotella and Bacteroides being increased in the HIV-1 Tg rats. Weighted UniFrac analysis of phylogenetic differences and taxonomic abundance provided evidence of a significant effect of S-equol in HIV-1 Tg rats ($p<0.007$) and controls ($p<0.047$). After treatment, Alloprevotella was decreased in HIV-1 Tg animals, with a relative abundance closer to controls. The intestinal tissue samples did not display a difference in beta diversity analysis or at the phylum level, but the genus level indicated a larger relative abundance of Fusobacterium in the HIV-1 Tg rats vs. controls. The decrease in Alloprevotella supports the use of S-equol as a treatment for HAND due to Alloprevotella being gram-negative and possessing Lipopolysaccharide (LPS), an inflammatory endotoxin found on the outer membrane of gram-negative bacteria. LPS is an important measure of microbial translocation due to its ability to activate microglia, increasing inflammation and contributing to worsening cognitive deficits associated with HAND. Improving the microbiome and reducing the circulating LPS through S-equol treatment would provide a mechanism by which to treat HAND through the gut-brain-microbiota axis.

Title: Elucidating the role of ephrin-b1 in interferon beta mediated neuroprotection of HIV associated neurocognitive disorder (HAND)

Authors: *J. KOURY[1], H. SINGH[1,2], S. SUTLEY[1], D. FOK[1], B. GELMAN[3], I. ETHELL[1], M. KAUL[1,2];
[1]Biomed. Sci. Grad. Program, Univ. of California Riverside, Riverside, CA; [2]Sanford Burnham Prebys Med. Discovery Inst., La Jolla, CA; [3]Pathology, Univ. of Texas Med. Br., Galveston, TX

Abstract: 37 million people worldwide are diagnosed with Human Immunodeficiency Virus (HIV). Of these 37 million, an estimated 15-55% of people living with HIV develop HIV-associated neurocognitive disorder (HAND). Previous work in ours and other labs identifies a transient increase of interferon beta (IFNβ), an anti-inflammatory and antiviral type 1 interferon, preceding any behavioral or neuropathological signs in the HIVgp120 transgenic mouse and SIV models, suggesting a neuroprotective role for IFNβ in early HIV infection. We have previously shown that exogenous intranasal exposure of HIVgp120tg animals with IFNβ is sufficient to confer neuroprotection. Here, we describe the ability of IFNβ to regulate an important cell surface transmembrane ligand, ephrin-b1, in the CNS. Neuronal ephrin-b1 has been well studied and implicated in neuronal development, recruitment of NMDA receptors and synaptic plasticity. However, the regulation of ephrin-b1 as well as ephrin-b1's role in HIV has not been well characterized. In this study, we identify a significant positive correlation between type 1 interferon master regulator, IRF7, and Ephrin-b1 mRNA in the cortex of HIV+ Patients. In addition, we describe significant inverse correlations between Ephrin-b1 mRNA in the cortex of HIV+ Patients with both neurocognitive domain scores and neuronal gene expression. In a transgenic NeuroHIV mouse *in vivo* model, HIVgp120tg, we show in cortex and hippocampus that abrogating IFNβ signaling decreases RNA expression of ephrin-b1. Conversely, intranasal treatment with IFNβ induces ephrin-b1 protein expression in a cell type specific manner within the hippocampus and partially in the cortex in non-transgenic control animals while paradoxically, IFNβ treatment of HIVgp120tg mice leads to a robust decrease in ephrin-b1. Taken together, this data suggests that IFNβ may be an important regulator of ephrin expression, and that the direction of this regulation is contingent on the presence of a viral component, such as HIVgp120.

Title: High-content analysis and Kinetic Image Cytometry identify toxic and epigenotoxic effects of HIV antiretrovirals on human iPSC-neurons and primary neural precursor cells

Authors: A. S. SMITH[1], S. ANKAM[1], C. FARHY[2], L. FIENGO[2], R. C. B. BASA[1], *K. GORDON[1], A. V. TERSKIKH[2], K. L. JORDAN-SCIUTTO[3], **J. H. PRICE**[1], P. M. MCDONOUGH[1];

Abstract: Despite viral suppression due to combination antiretroviral therapy (cART), HIV-associated neurocognitive disorders (HAND) continue to affect half of people with HIV, suggesting that certain antiretrovirals (ARVs) may contribute to HAND. We examined the effects of nucleoside/nucleotide reverse transcriptase inhibitors tenofovir disproxil fumarate (TDF) and emtricitabine (FTC) and the integrase inhibitors dolutegravir (DTG) and elvitegravir (EVG)) on viability, structure, and function of glutamatergic neurons derived from human induced pluripotent stem cells (hiPSC-neurons), and primary human neural precursor cells (hNPCs), which are responsible for neurogenesis. Using the Microscopic Imaging of Epigenetic Landscapes (MIEL) assay, we found that TDF decreased hNPC viability and changed the distribution of histone modifications that regulate chromatin packing, suggesting that TDF may reduce neuroprogenitor pools important for CNS development and maintenance of cognition in adults. Using automated digital microscopy and image analysis (high content analysis, HCA), we found that DTG, EVG, and TDF decreased hiPSC-neuron viability, neurites, and synapses after seven days of treatment. Analysis of hiPSC-neuron calcium activity using kinetic image cytometry demonstrated that DTG and EVG also decreased the frequency and magnitude of intracellular calcium transients. Longer ARV exposures and simultaneous exposure to multiple ARVs increased the magnitude of these neurotoxic effects. We then tested if co-culturing the hiPSC-neurons with hiPSC microglia prior to treatment with ARVs could yield a protective effect on neuronal health. Inclusion of microglia in the cultures attenuated the toxic effect of DTG and EVG on neuronal calcium activity. We are working to develop co-culture techniques with hiPSC-neurons, astrocytes, and microglia to advance the model for ARV toxicity to resemble the CNS more closely. This study establishes human preclinical assays that can screen potential ARVs for CNS toxicity and develop safer cART regimens and HAND therapeutics.

Title: Role of Divalent Metal Transporter 1 in Morphine-Mediated Upregulation of Neuronal Ferritin Heavy Chain

Authors: *E. IROLLO[1,2], R. BRANDIMARTI[1,2], O. MEUCCI[1,2,3];
[1]Dept. of Pharmacol. & Physiol., [2]Ctr. of Neuroimmunology and CNS Therapeutics, Inst. of Mol. Med. and Infectious Disea, [3]Dept. of Microbiology and Immunol., Drexel Univ. Col. of Med., Philadelphia, PA

Abstract: HIV-associated neurocognitive disorders (HAND) persist in about 50% of people with HIV on antiretroviral therapies, highlighting an important clinical and scientific challenge. HAND symptoms are also worsened by opioids and other abused substances, which may be at least partially due to the ability of these substances to alter synaptic function in brain regions involved in learning and memory and executive function. Indeed, our previous work demonstrated that opioids reduce dendritic spine density in cortical neurons through a unique pathway. We first found that morphine inhibits the dendritic spine promoting action of the CXCL12/CXCR4 chemokine signaling axis by upregulating the iron storage protein ferritin heavy chain (FHC). Further analysis showed that morphine released iron stored in neuronal endolysosomes to the cytoplasm, and this was required to upregulate FHC. Here, we tested if this mechanism involves the divalent metal transporter 1 (DMT1), a well-known iron transporter expressed on endolysosomes. First, we validated antibodies for the different DMT1 isoforms (+/-IRE) in HEK293 cells expressing recombinant DMT1+/-IRE proteins or silenced for DMT1. We then optimized conditions to detect DMT1 isoforms (+/-IRE) in rat cortical neurons and found that the majority of DMT1 was expressed in the cytoplasm. Immunofluorescent staining showed colocalization of DMT1 isoforms and the endolysosomal marker lysosomal-associated membrane protein 1 (LAMP1), suggesting that both DMT1 isoforms are expressed in endolysosomal vesicles. To assess the potential contribution of DMT1 in morphine-mediated upregulation of FHC, we pre-treated neuronal cultures with ebselen, a potent inhibitor of the iron transport of DMT1. Ebselen prevented FHC upregulation in morphine treated cultures, suggesting that DMT1 does play a role in morphine-mediated endolysosomal iron efflux. To further validate the contribution of DMT1, we are currently testing the effect of a specific genetic inhibition through viral-mediated silencing of DMT1 in cortical neurons. Overall, these studies suggest that DMT1 is involved in morphine-mediated regulation of CNS iron metabolism and that therapeutic interventions targeting the brain iron metabolism might be beneficial for individuals affected by neurocognitive disorders.

Title: Glycogen synthase kinase-3 inhibition rescues sex-dependent contextual fear memory deficit in HIV-1 transgenic mice

Authors: *S. MOIDUNNY[1], M. A. BENNEYWORTH[4], D. J. TITUS[4], E. BEUREL[2], U. KOLLI[1], J. MEINTS[4], R. JALODIA[1], S. RAMAKRISHNAN[1], C. M. ATKINS[3], S. ROY[1]; [1]Dept. of Surgery, [2]Dept. of Psychiatry and Behavioral Sciences; Dept. of Biochem. and Mol. Biol., [3]The Miami Project to Cure Paralysis, Dept. of Neurolog. Surgery, Univ. of Miami Miller Sch. of Med., Miami, FL; [4]Dept. of Neurosci., Univ. of Minnesota, Minneapolis, MN

Abstract: Background and Purpose. A significant number of HIV-1 patients on antiretroviral therapy develop HIV-associated neurocognitive disorders (HAND). Recent evidence indicate that biological sex may regulate HAND pathogenesis, but the mechanisms remain unknown. We investigated synaptic mechanisms associated with sex differences in HAND, using the HIV-1-transgenic 26 (Tg26) mouse model. **Experimental approach.** Contextual- and cue-dependent memories of male and female Tg26 mice and littermate wild-type mice were assessed in a fear conditioning paradigm. Hippocampal electrophysiology, immunohistochemistry, western blot, qRT-PCR and ELISA techniques were used to investigate cellular, synaptic and molecular impairments. **Key results.** Cue-dependent memory was unaltered in both male and female Tg26 mice when compared to wild-type mice. Interestingly, male, but not female, Tg26 mice showed deficits in contextual fear memory. Consistently, only male Tg26 mice showed depressed hippocampal basal synaptic transmission and impaired LTP induction in area CA1. These deficits in male Tg26 mice were independent of hippocampal neuronal loss and microglial activation but were associated with increased HIV-LTR mRNA expression, reduced hippocampal synapsin-1 protein, reduced BDNF mRNA and protein, reduced AMPA glutamate receptor (GluA)1 phosphorylation levels and increased glycogen synthase kinase-3 (GSK3) activity. Importantly, selective GSK3 inhibition using 4-Benzyl-2-methyl-1,2,4-thiadiazolidine-3,5-dione increased levels of synapsin-1, BDNF and phosphorylated-GluA1 proteins, restored hippocampal basal synaptic transmission and LTP, and improved contextual fear memory in male Tg26 mice. **Conclusion and Implications.** Sex-dependent impairments in contextual fear memory and synaptic plasticity in Tg26 mice are associated with increased GSK3 activity. This implicates GSK3 inhibition as a potential therapeutic strategy to improve cognition in HIV-1 patients.

Title: Blocking LOX: a Doorway to Neurotoxic Damage in HIV-1 gp120 Associated Brain Injury

Authors: *N. YUAN[1], A. B. SANCHEZ[2], C. DEROSIERES[3], K. MEDDERS[3], M. KAUL[1]; [1]UCR Sch. of Med., Riverside, CA; [2]Sanford Burnham Prebys Med. Discovery Inst., La Jolla, CA; [3]Sanford Burnham Inst. for Med. Res., San Diego, CA

Abstract: Individuals infected with human immunodeficiency virus (HIV)-1 often develop HIV-associated neurocognitive disorders (HAND). Studies in our laboratory indicate that p38 MAPK is essential for the neurotoxic phenotype of HIV gp120-stimulated macrophages and microglia, as well as the induction of neuronal apoptosis triggered by macrophage-derived toxins and proinflammatory molecules. Microarray analyses of human macrophages stimulated with HIV envelope protein gp120 and of brains of transgenic mice expressing the viral gp120 under the control of a modified GFAP promotor in astrocytes (gp120tg mice) suggested the involvement of cysteinyl leukotrienes (cysLTs) in HIV neurotoxicity.
Leukotrienes (LTA_4, LTB_4, LTC_4, LTD_4, and LTE_4) are the product of the 5-lipoxygenase (5-LOX) metabolism of arachidonic acid. CysLTs (LTC_4, LTD_4, and LTE_4) are formed by the addition of cysteine derivatives. Two distinct CysLT receptors exist, CysLTR1 and CysLTR2 (Kanaoka & Austen reported a third CysLTR). CysLTs are most notably researched for their role in the pathophysiology of asthma but their role in the brain is largely unknown.
We have found that cysteinyl leukotrienes (CysLTs) are released by both HIV-1 infected and gp120-stimulated macrophages, and knockdown of p38 MAPK down-regulates cysteinyl leukotriene synthase (LTC4S). Herein, we describe the characterization of both CysLTR1 deficiency and LTC4S deficiency in gp120tg mice by immunofluorescence staining, RNA analysis, analyte detection, and behavioral studies, which suggests a critical role for the CysLT pathway in NeuroHIV.

Title: Neuro-immune interactions after HIV-1 infection in human microglia-containing cerebral organoids

Authors: *A. J. BORELAND[1], H.-C. LIN[3], A. STILLITANO[3], R. XU[2], R. P. HART[2], P. JIANG[2], Z. P. PANG[1], A. B. RABSON[3];

Abstract: While combined antiretroviral therapy (cART) has reduced the incidence and severity of HIV-related AIDS, up to half of HIV-positive patients must still grapple with neurological complications. These complications can eventually escalate into HIV-Associated Neurocognitive Disorder (HAND). There is an urgent need to develop a more representative human model system to study the molecular and cellular mechanisms underlying HIV-related neuropathology. We have developed human microglia-containing cerebral organoids (hmCOs) derived from human pluripotent stem cells (hPSC) to investigate how HIV-1 infection leads to microglial dysregulation, persistent inflammation, and neuronal functional changes. We derived primitive macrophage precursor cells (PMPs) from hPSCs that underwent further microglia differentiation before infecting with replication-competent macrophage-tropic HIV-1. We detected productive infection by detecting p24 in a time-dependent manner as well as changes in inflammatory cytokine/chemokine secretion. RNAseq analysis revealed enrichment of interferon type I signaling pathways. Finally, we incorporated HIV-infected microglial cells into cerebral forebrain organoids. We found that microglia successfully integrate and interact with neurons within hmCOs and assessed viability and mobilization of HIV-1 infected microglial cells. Further analyses will reveal the impact of HIV-1 infection on microglial and neuronal physiology. We anticipate that this platform will help facilitate new insights into pathogenesis and novel therapeutics for neuroAIDS.

Title: Transcutaneous spinal cord stimulation alters excitability between multiple converging segments of the spinal cord

Authors: *T. S. BARSS[1,2,3], B. PARHIZI[1,2,3], V. K. MUSHAHWAR[1,2,3];
[1]Neurosci. and Mental Hlth. Inst., Univ. of Alberta, Edmonton, AB, Canada; [2]Div. of Physical Med. and Rehabilitation, Dept. of Medicine, Univ. of Alberta, Edmonton, AB, Canada; [3]Sensory Motor Adaptive Rehabil. Technol. (SMART) Network, Univ. of Alberta, Edmonton, AB, Canada

Abstract: Transcutaneous spinal cord stimulation (tSCS) has the potential to facilitate improved sensorimotor rehabilitation by non-invasively modulating circuitry of the spinal cord. Currently, little is known about how cervical or lumbar tSCS influences the excitability of spinal and corticospinal networks and whether synergistic effects of multi-segmental tSCS occur between remote segments of the spinal cord. Two studies aimed to determine the extent to which spinal (H-reflex) and corticospinal circuitry (motor evoked potential [MEP]) can be modulated by cervical, lumbar, or combined tSCS. Study participants were seated in a recumbent cycling system. During study 1 (n=13), lower limb H- reflexes were elicited in the soleus muscle, while in study 2 (n=14), upper limb H-reflex and MEP amplitudes were evaluated in the flexor carpi radialis muscle. These were assessed during 2 tasks: 1) Limbs held in a static position; 2) During rhythmic cycling of the arms (study 1) or legs (study 2). In both studies, conditions included 1) No tSCS, 2) tSCS applied to the cervical enlargement, and 3) tSCS applied to the lumbar enlargement. In study 2, tSCS was also simultaneously applied to the cervical and lumbar enlargements. Interestingly, tSCS of the cervical cord with arms static significantly suppressed lumbar cord excitability as indicated by a 22.9% reduction in soleus H-reflexes amplitude, while lumbar tSCS facilitated H-reflex amplitude in the upper limbs by 11.1% and combined cervical and lumbar tSCS increasing the facilitation to 19.6%. A convergence of combined tSCS significantly increased MEP amplitude by 19.7% compared to No tSCS. As hypothesized, soleus H-reflex amplitude was significantly suppressed by 19.2 % during arm cycling relative to arms static (without tSCS) while leg cycling alone suppressed the FCR H-reflex by 13.6%. When combined with either arm or leg cycling, tSCS was unable to alter excitability across both studies indicating that in neurologically intact individuals where interlimb coordination and corticospinal tract are intact, the effect of arm or leg cycling on cervico-lumbar coupling and corticospinal drive was not impacted significantly with the tSCS intensity used. These studies demonstrate that tonic activation of spinal cord networks alters excitability over multiple segments of the spinal

cord while multiple sites of tSCS converge to enhance modulation of spinal reflex and corticospinal pathways. This highlights the potential for engaging cervical and lumbar spinal cord networks through tSCS to enhance the effectiveness of rehabilitation interventions.

Title: Laser-microfabricated, smart polymer intraspinal multielectrodes reduce foreign body responses in mixed glial cell cultures and generate functional responses in the pig spinal cord

Authors: *D. A. ROSZKO[1], C. TSUI[1], S. MIRKIANI[1], N. TYREMAN[2], D. WILSON[2], K. G. TODD[3], V. K. MUSHAHWAR[4];
[1]Neurosci. and Mental Hlth. Inst., [2]Dept. of Med., Univ. of Alberta, Edmonton, AB, Canada; [3]Psychiatry, [4]Dept. of Med., Univ. Alberta, Edmonton, AB, Canada

Abstract: Intraspinal microstimulation (ISMS) is an emerging neural prosthetic approach for restoring standing and walking after spinal cord injury (SCI) by applying electrical stimulation within the spinal cord. Historically, ISMS has been implemented with hair-like microwire electrodes with one active site each (Holinski et al. 2016), or very stiff silicon multielectrodes (MEs) (Pikov et al. 2020) that exacerbate foreign body responses (FBR). This project focused on developing flexible, smart polymer MEs to improve the targeting efficiency and biocompatibility of ISMS implants. Three-channel flexible polymer MEs were fabricated from a polydimethylsiloxane (PDMS) composite substrate, modified with 1.75% w/w dimethylsiloxane-(ethylene oxide) block copolymer (PDMS-PEG BCP) (Gökaltun et al., 2019), and platinum-iridium (Pt/Ir: 80%/20%) foil using a nanosecond laser. Electrochemical parameters were assessed in phosphate-buffered saline (PBS) using electrochemical impedance spectroscopy (EIS) and voltage transients (VT). Glial cell adhesion and reactivity were assessed using immunocytochemistry in mixed mouse glial cell cultures at 7 and 14 days for MEs prepared with unaltered or BCP-modified PDMS substrates. Implant buckling forces were assessed through standard compression tests. In vivo assessments of ME electrochemical properties were performed in 4 domestic pigs and compared to those of 50 µm Pt/Ir microwires commonly used for ISMS. The capacity of the new MEs in producing functional leg movements was also tested.

ME stimulating sites exhibited significantly greater electrochemical impedance values than microwire electrodes in PBS, displayed higher charge injection limits than microwire electrodes in vivo, and were capable of evoking sufficient joint torques and kinematics for producing functional movements. The buckling force of the MEs was significantly lower than the microwire electrodes, demonstrating improved flexibility. MEs with PDMS-PEG surface modifications also showed a marked reduction in glial cell adhesion in vitro compared to unaltered PDMS, suggesting that reduced FBRs may also be seen in chronic in vivo implants. In conclusion, laser-fabricated, smart polymer MEs may be viable alternatives to current ISMS implants in the future.

Title: Robot-assisted investigation of the neural mechanisms underlying arm function

Authors: *B. PARHIZI[1,2], A. DINEROS[3], G. SIVADASAN[3], V. MUSHAHWAR[1,2,4];
[1]Neurosci. and Mental Hlth. Inst., [2]Sensory Motor Adaptive Rehabil. Technol. (SMART) Network, [3]Dept. of Electrical & Computer Engin., [4]Div. of Physical Med. and Rehabilitation, Dept. of Med., Univ. of Alberta, Edmonton, AB, Canada

Abstract: Introduction: Daily activities necessitate engagement of the arms and are not limited to simple isolated reaching movements. Spinal cord injury (SCI) often affects arm function, and complex movements including those that require bimanual manipulation concurrent with cognitive and sensory processing may be more clinically relevant for improving rehabilitation outcomes than current strategies. Nonetheless, the choice of a rehabilitation intervention needs to be based on an understanding of the underlying organizations in the neural correlates of arm movement. The goal of this project was to identify the influence of more complex movements on motor processes associated with the planning and execution of arm movements.**Methods:** The underlying mechanisms of motor control of goal-directed reaching movements were investigated in neurologically intact (NI) study participants. Cortical activity was recorded via electroencephalographic electrodes while the participants performed multiple movements: 1)

unimanual visually-guided reaching (VGR) where they were instructed to move their virtual hand to peripheral targets surrounding a central location (using KINARM exoskeleton); 2) reverse VGR whereby they moved their hand to peripheral targets by moving their arm in the reversed direction to add a cognitive load; 3) uncooperative bimanual VGR in which each arm performed similar center-out reaching movements to peripheral targets simultaneously; 4) cooperative bimanual reaching movements where the participants moved a ball placed on a horizontal bar to peripheral targets through cooperative movement of the two arms, each holding one end of the bar; and 5) reverse VGR versions of the uncooperative and cooperative bimanual movements. Beta band (13-30Hz) cortical activity associated with sensorimotor processes was computed using spectral power for C1, C3, FC1, and FC3 electrodes.**Results:** Uncooperative bimanual reaching movements increase the magnitude of activity during both planning and execution stages in motor and pre-motor areas compared to both unimanual and cooperative bimanual movements. Interestingly, moving in the reverse direction, both in unimanual and bimanual movements, reduces the level of activity in the motor and pre-motor cortex during both planning and execution stages.**Significance:** This project demonstrates, for the first time, the alterations in motor control of goal-directed arm movements with increasing motor and cognitive demands. Cortico-muscular coherence and cortical functional connectivity will be investigated to explore the neural mechanisms associated with different spectral power level across complex tasks.

Med. Ctr., Nashville, TN; [9]Rockefeller Neurosci. Inst., West Virginia Univ., Morgantown, WV

Abstract: Introduction: Epidural spinal cord stimulation was proposed for restoring walking after severe spinal cord injury, and 4 individuals were able to step overground for distances up to 91m using their arms to weight-bear. With better targeting of the locomotor networks residing in the ventral horn of the lumbar enlargement, walking may be improved. These networks were successfully mapped in pre-clinical models; however, their location is unknown in humans. This study developed a procedure for mapping these locomotor networks and evaluated its safety in adult Yucatan pigs. **Methods:** Pigs underwent pre-surgical assessments including walking kinematics and reflex function in the legs. Under anesthesia, clinically-approved microelectrodes (125µm) were inserted into the ventral horn using a stereotactic frame and ultrasound guidance. To facilitate electrode penetration through the pia mater, small cuts were made using an arachnoid knife. The pigs were divided into 2 groups, an experimental and a sham control group. The experimental group received up to 12 electrodes insertions in one side of the spinal cord and the resulting movements induced by microstimulation were documented. The sham control received pial cuts only. Four weeks post-surgery, the kinematics and reflexes were reassessed in all animals and compared to pre-surgical measures. The animals were then euthanized, and their spinal cords extracted for immunohistochemical analysis. **Results:** Post-surgically, the experimental and sham control groups had similar balance and gait deficits over the first 2 weeks. Four weeks post-surgery, reflexes returned to pre-surgical levels and walking kinematics were similar to pre-surgical measures in all but one animal in the experimental group. Immunohistochemical analyses revealed only very few electrode tracks (<10% of all penetrations). Disruption to the dorsal surface of the spinal cord caused by the pial cuts was much more visible and at times extended 1mm into the spinal cord. **Conclusion:** Following an adequate recovery period, the reflexes and kinematics return to baseline despite multiple cord penetrations during the intraoperative procedure. Damage caused by electrode insertions is negligible; however, damage caused by the pial insertions is notable. A less disruptive technique should be developed or smaller diameter microelectrodes with sharper tips that allow for penetration through the pia mater that have safely been used in intraspinal microstimulation, should be utilised. The results suggest that intraoperative insertion of electrodes into the spinal cord is potentially safe for future application in humans to map the locomotor networks.

Title: Intraspinal microstimulation to restore functional walking after complete chronic spinal cord injury

Authors: *P. FARIDI[1], V. K. MUSHAHWAR[2];
[1]Neurosci. and Mental Hlth. Inst. and SMART Network, [2]Dept. of Med. and SMART Network, Univ. of Alberta, Edmonton, AB, Canada

Abstract: The overall goal of this project is to develop a technique to restore over-ground walking in animals with complete spinal cord injury (SCI) using intraspinal microstimulation (ISMS). ISMS entails implanting micro-electrodes into the lumbosacral enlargement of the spinal cord to produce synergistic activations of the legs. To date, ISMS has produced in-place stepping in cats with complete chronic SCI (Saigal et al, 2004), and also long distances of over ground walking in anesthetized cats (Holinski et al, 2016). However, two unanswered questions need to be addressed prior to translating ISMS to humans. 1) Can over-ground walking be achieved with ISMS in cats with chronic SCI in which varying degrees of spasticity and exaggerated reflex responses, commonly seen after SCI in humans, are present? 2) Can the stimulation patterns be automatically predicted for each individual since each injury is different, and each person walks differently from others?To restore functional walking, a biologically-inspired state control strategy was designed and successfully bench-tested for coordinating the activation of neural networks and resulting muscle synergies. The strategy included time-based transitions within different phases of the step cycle, resembling the rhythmic alternations of legs, which then can be modified through pre-defined rules, using feedback from force plates built in a walkway and angular velocities from gyroscopes placed on the hindlimbs of the animal. To answer the second question, reinforcement learning in combination with Pavlovian control, inspired by classical conditioning, are implemented to learn the feedback signals' patterns and produce predictive a walking strategy. This predictive method was implemented previously, for the first time, in cats with incomplete SCI, where feedback signals of the intact limb were used to predict the state of walking for the paralyzed limb, moved through ISMS (Dalrymple et al, 2020).To test the feasibility of the predictive controller for a complete SCI model, a musculoskeletal model of cat hindlimbs was developed in MATLAB which used Newtonian

dynamics and Hill-type muscle properties (Hill et al, 1938). Walking was divided into 4 sub-phases and muscle synergies in each sub-phase were activated with a constant level of motoneuronal excitation, leading to a muscle activation pattern that mimics the activation generated by ISMS. This project is a critical step towards producing personalized bipedal walking. If successful in both simulation and in-vivo testing, the system may change the lives of many people living with SCI, giving them the capability to walk independently.

Engin., Illinois Inst. of Technol., Chicago, IL; [6]Dept. of Surgery, Div. of Neurosurg., Edmonton, AB, Canada

Abstract: Intraspinal microstimulation (ISMS) is a novel technique that directly stimulates locomotor circuits in the ventral horn of the spinal cord using penetrating microelectrodes. While ISMS has demonstrated promising results in restoring standing and walking after spinal cord injury in rats and cats, design modifications are required for large animal models, and eventually humans, due to their higher range of motion. In this study, we demonstrate a strain-relief system for ISMS that can minimize the stresses on the electrodes. Microwires (25 µm Pt-Ir, 80%-20%, insulated with polyimide) forming the leads to each microelectrode were coiled around a tungsten rod (D= 100 µm) using a custom-built coiling device. The coiled microwires (length of coiled region= 4 mm, OD= 160 µm) were then dip-coated with polydimethylsiloxane (PDMS) and cured using a heat gun (100 °C for 10 minutes). The uncoiled ends of 16 leads were then bundled, inserted in a Silastic tube (OD: 500 µm, ID: 30 µm), and coiled around a tungsten rod (D= 200 µm). The tube was then filled with PDMS, unwound, and placed in the oven at 100 °C for 1 hour to cure the PDMS. A PDMS tab (250 µm thick) was incorporated in the Silastic tube using a spin-coater before insertion of the microwires. The tab was used to anchor the ISMS device on the spinal cord. Uniaxial tension and electrochemical impedance spectroscopy (EIS)

tests were performed on the coiled cable containing the 16 microwires to analyze their mechanical and electrical properties. The cable was stretched up to 40% of strain and the effect of elongation on its impedance was evaluated. The system was also tested in vivo in five freshly euthanized domestic pigs to assess the feasibility of anchoring the ISMS system to the spinal cord, dura mater, and spinous process of the L3 vertebra. The elongation force (at 40% of strain) was 701± 12,8 mN (mean ± SD, 6 repeated measurements). The capacitance of the coiled cable at 100 Hz and 1 kHz was calculated to be 0.033±0.0014 nF, and 0.029±0.0002 nF, respectively (mean ± SD, 6 repeated measurements). Applying up to 40% strain on the coiled leads had no significant effect on the impedance, capacitance, and resistance of the wires ($p>0.05$). Pig cadaver experiments confirmed the appropriateness of the size of the coiled microwires and coiled cable in the limited subarachnoid space of the spinal cord. Moreover, the ISMS array was successfully secured to the spinal cord. The increase in extension capability of the ISMS array obtained by incorporating the coiled cable offers more reliability and safety of the electrodes by minimizing the tethering forces on the spinal cord.

Title: Comparative anatomy and functional neurophysiology of the lumbar spinal cord and locomotor networks: implications for spinal cord neuromodulation

Authors: A. TOOSSI[1], D. EVERAERT[2], B. PARHIZI[1], S. MIRKIANI[1], C. O'SULLIVAN[1], S. I. PERLMUTTER[3], ***V. MUSHAHWAR**[2];

Abstract: Electrical spinal cord neuromodulation is an emerging approach for restoring locomotor function after severe spinal cord injury; however, the methods for most effectively

activating the locomotor networks which reside in the lumbar enlargement remain elusive. The goal of this project was to identify the location and functional organization of the locomotor networks across multiple species to provide a systematic understanding of their activation through neuromodulation. Several studies were performed: 1) Immunohistochemistry was used to identify the distribution of cells activated by two spinal cord neuromodulation approaches: epidural spinal cord stimulation (eSCS) and intraspinal microstimulation (ISMS). 2) Electrophysiology was used to map the spinal cord in cats, pigs and non-human primates. 3) MRI was used to develop atlases of the lumbar cord in rats, cats, pigs, non-human primates and humans. Preliminary studies in anesthetized pigs used the activity marker cfos to compare the distribution of neurons activated in the lumbar cord by eSCS and ISMS. Bilateral eSCS and ISMS electrodes were implanted and electrical stimuli were delivered to one side, eliciting small but perceptible movements in the ipsilateral limb. With eSCS, the distribution of activated neurons was concentrated in laminae I-IV with sparse scattering in the rest of the gray matter, while with ISMS, the distribution was concentrated in laminae VI, VII and medial IX. The spinal cords in cats, pigs and non-human primates were mapped to investigate the functional organization of locomotor networks in the ventral horn. Single electrodes were advanced in a 3D grid throughout the lumbar enlargement in cats and non-human primates, and arrays of microwire electrodes were implanted in pigs. For each site, stimulation threshold and the evoked limb kinematics, force and EMG activity in the ipsilateral limb were obtained and used to construct 3D functional maps. The maps were similar between species, with minor differences in the size allocation of various components of the map in non-human primates. The findings suggest that eSCS activates locomotor networks indirectly, likely through reflex pathways, while ISMS activates locomotor-related networks more directly. They also demonstrate that the functional organization of locomotor networks is preserved across mammalian species and is likely to be similar in humans. To facilitate more accurate modeling of the locomotor networks, detailed 3D atlases of the location of the locomotor networks were constructed based on high-resolution MRIs of spinal cords extracted post-mortem from 5 species commonly used in neuromodulation experiments.

Title: Identification of trigeminal sensory neuronal types innervating masseter muscle

Authors: K. A. LINDQUIST;
Pharmacol., Univ. of Texas Hlth. Sci. Ctr. San Antonio, San Antonio, TX

Abstract: Understanding masseter muscle (MM) innervation is critical for themanagement of head and neck disorders and performing masseteric nerve transplantation/transfer. This study identifies and characterizes trigeminal (TG) sensory neuronal groups innervating MM (MM TG neurons), including muscle fibers, masseteric fascia, and tendons. We identified 9 distinct types of MM TG neurons using a combination of patch clamp electrophysiology and immunohistochemistry on TG neurons back-traced from reporter mouse MM. Of these neurons, 24% belonged to nonpeptidergic IB-4+/TRPA1- or IB-+/TRPA1+ groups, while two TRPV1+ small-sized neuronal groups were classified as peptidergic/CGRP+. One small-sized CGRP+ neuronal group had a unique electrophysiological profile and were recorded from Nav1.8- or trkC+ neurons. The remaining CGRP+ neurons were medium-sized, could be divided into Nav1.8-/trkC- and Nav1.8low/trkC+ clusters, and showed large 5HT-induced current. The final two MM TG neuronal groups were trkC+ and had no Nav1.8 and CGRP. MM TG neurons dis not have TRPV1+/CGRP-(somatostatin+), tyrosine hydroxylase+ (C-LTMR), TRPM8+, MrgprA3+ or trkB+ (Aδ-LTMR) groups. We next examine distribution of different afferent fibers in MM. Use of Nav1.8-YFP reporter, and labeling with CGRP, TRPV1, neurofilament heavy chain (NFH) and pgp9.5 antibodies showed that muscle fibers and tendons were exclusively innervated by medium-to-large neurons. These nerves were myelinated, either CGRP+/NFH+ or CGRP-/NFH+ and mainly distributed in tendon and at junctions of deep-middle-superficial parts of MM. Overall, the data presented here demonstrates that MM is innervated by a distinct subset of TG neurons, which have unique characteristics and innervation patterns compared to DRG neurons and fibers.

Title: Multi-unit recording in the parabrachial in rats after whisker pad injection of varicella zoster virus

Authors: *R. HORNUNG[1], P. KINCHINGTON[2], P. KRAMER[1];
[1]Texas A&M Univ. Col. of Dent., Dallas, TX; [2]Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Multi-unit recording in the parabrachial in rats after whisker pad injection of varicella zoster virus**Rebecca S. Hornung, Ph.D.**[1], Paul R. Kinchington, Ph.D.[2], Phillip R. Kramer, Ph.D.[11]Texas A&M University College of Dentistry, Dallas, TX, United States[2]University of Pittsburgh, Department of Ophthalmology, Pittsburgh, Pennsylvania, United States
Background: The parabrachial nucleus (PBN) modulates the affective-motivational component of orofacial pain. The central amygdala (CeA) has inhibitory GABAergic neurons that project to and inhibit the lateral PBN. In a rat model of neuropathic pain, the neuronal activity of the lateral PBN is amplified. Stimulating the CeA-PBN pathway suppresses acute pain, while inhibiting the pathway induces nociceptive behaviors. Our lab utilizes a chronic post-herpetic neuralgia animal model where human varicella zoster virus (VZV) is injected into the whisker pad of the rat. Injection of VZV to the whisker pad results in herpes zoster-associated (HZ; shingles) pain that can last for at least 3 months. In humans, the most common complication of HZ is postherpetic neuralgia (PHN) and PHN is observed more following HZ of the orofacial region. In rodents, VZV-induced pain results in hypersensitivity like PHN in humans. Our long-term goal is to test the hypothesis that inhibiting GABAergic neurons within the CeA that project to the lateral PBN will result in increased neuronal activity and increased affective-motivational behavior in rats. Since the PBN is located deep within the brain, we first had to investigate whether implantation of a microelectrode to the PBN could detect neuronal activity. **Methods**: GAD67 transgenic adult male Long Evans rats were infused with an adeno-associated virus (AAV) containing a Cre-dependent G inhibitory designer receptor exclusively activated by designer drugs (DREADD) to the amygdala. Following infusion, a microelectrode was implanted to the depth of the PBN. Four weeks later, VZV was injected into the left whisker pad. One week later, affective-motivational behavior was tested using a place escape avoidance paradigm (PEAP) and neuronal activity was recorded with a Tucker Davis RZ10x.**Results**: Results indicate neuronal activity of neurons within the PBN of adult male rats in-vivo can be measured. **Conclusion**: Results suggest that modulation of PBN neuronal activity events of adult rats can be measured in-vivo.**Acknowledgements**: This study was funded by NIDCR grant (DE026749) to PRKramer, NIDCR grant (NS064022) to PRKinchington, and NEI core grant (EY08098).

Title: Trigeminal inputs directly relay nociceptive information to rostral ventromedial medulla pain-modulating neurons

Authors: *C. C. DE PRETER[1], M. M. HEINRICHER[2];
[1]Oregon Hlth. & Sci. Univ. Behavioral Neurosci. Grad. Program, Portland, OR; [2]Dept Neurol Surgery, Mail Stop L-472, Oregon Hlth. and Sci. Univ. Dept. of Neurol., Portland, OR

Abstract: The brain regulates nociceptive processing through descending projections from the brainstem to the spinal and trigeminal dorsal horns. These endogenous pain-modulating circuits can amplify or suppress pain-related signals. Under normal conditions, these circuits maintain a balance between facilitation and inhibition of pain, but become dysregulated in chronic pain states. The output of this pain-modulating system, via the rostral ventromedial medulla (RVM), has been extensively studied. Bidirectional pain control from this region is mediated by two, physiologically defined cell classes, "ON-cells" and "OFF-cells," that respectively facilitate and inhibit nociceptive transmission. However, sensory inputs to RVM remain to be fully defined. Indirect inputs from the dorsal horn via the parabrachial complex were recently shown to convey nociceptive information to RVM and contribute to the sensitization of RVM neurons in persistent inflammatory pain. However, there also is anatomical evidence for a direct input from the dorsal horn to RVM. The purpose of this study was to define direct and indirect inputs to RVM from the trigeminal dorsal horn, which relays sensory input from the face and head. Using a combination of single-cell recording in RVM with optogenetic activation of trigeminal inputs expressing channelrhodopsin, light-evoked responses of identified ON- and OFF-cells were recorded in lightly anesthetized male and female Sprague-Dawley rats. Stimulation of the direct trigeminal-to-RVM projection resulted in a significant increase in ON-cell firing rate and a significant decrease of OFF-cell firing rate. NEUTRAL-cells, RVM neurons without a known role in pain modulation, showed no change in activity following activation of this pathway. Conversely, archaerhodopsin-induced inhibition of trigeminal terminals in RVM attenuated the noxious-evoked activity of ON- and OFF-cells. A similar approach revealed an indirect relay of trigeminal information to RVM through the parabrachial complex. These data demonstrate a direct trigeminal relay that conveys nociceptive information to RVM, with a parallel indirect pathway through the parabrachial complex.

Title: Orofacial hyperalgesia (is) associated with selective deletion of trigeminal lemniscal patterning in Prrxl1 mutant mouse

Authors: *G. CATALDO[1], P. FEINSTEIN[2], H. P. ZEIGLER[3], J. C. BRUMBERG[1];
[1]Dept. of Psychology, Queens College, City Univ. of New York, Flushing, NY; [2]Dept. of Biol. Sci., [3]Dept. of Psychology, Hunter College, City Univ. of New York, New York, NY

Abstract: Trigeminal neuropathic pain, a frequently debilitating orofacial pain more prevalent with age and in women, is difficult to manage, resistant to conventional treatment and contributes significantly to a poor quality of life. Prrxl1, a paired homeodomain transcription factor, which is indispensable for the development of patterning in the trigeminal lemniscal pathway is also expressed by primary sensory neurons in dorsal root ganglia and their central targets in the dorsal horn. Prrxl1 deletion disrupts patterning of primary sensory afferent fibers into the spinal dorsal horn and abolishes patterning in the whisker-to-barrel cortex pathway. It has long been known that Prrxl1 deletion is associated with hypoalgesia to body stimulation; we now report that it is also associated with hyperalgesia to stimulation of the orofacial region as well as displaying significantly extended bouts of orofacial grooming. Taken together, these observations suggest a hitherto unreported contribution of Prrxl1 to the organization of orofacial nociception. The rodent trigeminal system has been implicated in a variety of active sensing behaviors, including object recognition, texture discrimination and ingestive behavior. Although absence of patterning is associated with disruption of these behaviors, its involvement in nociception has not been previously reported and the impact of nociception on these behaviors is poorly understood. To elucidate these effects, facial mechanical hyperalgesia was assessed using von Frey monofilaments applied to the mystacial (whisker) pad. Similarly, spinally mediated mechanical as well as thermal nociception was evaluated at the hind paw and tail respectively and compared to trigeminally mediated responses obtained from the face in Prrxl1 KO, Barrelless (BRL, an animal lacking cortical patterning) and wild-type (WT) CD-1 mice. It was found that, Prrxl1 KO mice exhibited hypoalgesia of the hind paws while displaying hyperalgesia of the orofacial region which was significantly attenuated by subcutaneous administration of the anti-inflammatory analgesic Carprofen (5.0 mg/kg). The frequency of orofacial grooming was also determined through 24-hour continuous video monitoring. Prrxl1 mice displayed significantly more grooming bouts and groomed for a longer duration compared to BRL and WT. These results suggest (1) that the disruption of lemniscal patterning in Prrxl1 KO mice is selectively associated with orofacial nociception (2) that these altered behaviors are reflective of a chronic pain condition and (3) that this mutant may be a useful, non-invasive model of orofacial pain.

Title: Responses of trigeminal ganglion neurons to noxious and innocuous stimuli remain unchanged with aging

Authors: O. UDDIN[1], *A. KELLER[1], M. PLANK[1], R. MASRI[2];
[1]Univ. of Maryland Sch. of Med., Baltimore, MD; [2]Dept. of Advanced Oral Sci. and Therapeut., Univ. of Maryland Sch. of Dent., Baltimore, MD

Abstract: With age come changes in sensory function. The incidence of chronic pain increases with age (PMID: 30212442). In humans, pain thresholds increase with age, while pain tolerance is reported to either decrease (PMID: 15876494) or remain unchanged (PMID: 28159611). Of particular concern is that pain in the elderly, particularly among those with dementia, is underreported (PMID 26955380). Because neural activity can provide insight into sensory processing and functional outcomes, one approach to developing pain metrics and understanding mechanisms of pain in aging is to compare responses along the somatosensory pathway, starting with the trigeminal ganglion. We recorded responses from trigeminal ganglion neurons of adult Fischer 344 (F344) rats aged 4-6 months (7 males and 10 females), and aged F344 rats ages 19-25 months (4 male and 10 female rats). We used single-cell, extracellular, urethane-anesthetized recordings to assess trigeminal ganglion neuron responses to both noxious mechanical stimulation and to innocuous, high-frequency whisker deflection. There was no age difference in the magnitude of responses to noxious mechanical stimulation (n= 22 adult neurons, n=24 aged, Mann-Whitney U=255, p=0.85). The fidelity of responses to high-frequency, “pink noise” vibrissa stimulations are highly reproducible in rats (PMID: 15218153). There was no effect of age on the reproducibility of these responses, as quantified by the correlation coefficient between trials (n=19 control male cells, n=13 aged male cells, n=12 control female cells, n=13 aged female cells; $F(1,53)=0.26$, $p=0.61$). However, there was a main effect of sex, with males having higher correlation coefficients between stimulation trials than females ($F(1,53)=17.6$, $p=0.0001$, eta squared=0.25, large effect size), suggesting that responses in males are more reproducible. These data suggest that changes in age-related sensory functions are unlikely related to changes in primary afferents, and might reflect changes in downstream CNS structures.

Title: 5-ht preferentially releases complement peptides c3a from peripheral tissues of women compared to men, leading to the sexual dimorphic increase in trpv1 activities in trigeminal sensory neurons

Authors: *M. TRAM, M. ESKANDER, Q. LI, P. CHANG, N. B. RUPAREL, K. M. HARGREAVES;
Endodontics, Univ. of Texas Hlth. Sci. Ctr. at San Antonio, San Antonio, TX

Abstract: Numerous studies have documented sex and gender differences in pain, but the underlying mechanisms remain unclear. Our group has demonstrated that serotonin (5-HT) sensitizes human dental pulp to capsaicin (CAP)-dependent CGRP release in biopsies from women, but not men (Loyd et al Pain 153:3061). Here, we determine the mechanisms mediating this effect. Methods: Participants provided human third molar dental pulps after standard extraction protocol under IRB approval. Dental pulp superfusion was conducted as previously described (Loyd et al.). Soluble factors were subjected to 2D-DIGE proteomics. Activity of cultured trigeminal (TG) neurons was measured by whole cell patch recording or calcium imaging (Fura2 AM). Data were analyzed by ANOVA. Results: The application of 5-HT to female, but not male, human dental pulp released a soluble factor that sensitized TG neurons to I_{CAP} or CAP-induced [Ca]i. This soluble factor was a protein and not a lipid as the CAP sensitizing effect was destroyed by incubation with proteinase K, but not lipid removal using Clean Ascites. 2D-DIGE identified complement peptide C3a (C3a) as being differentially released from female compared to male superfused dental pulp. The CAP-sensitizing effect of the conditioned media from superfused dental pulp was abolished by incubation with anti-C3a antibody or application of a C3a receptor angatonist (SB290157). The application of C3a peptide to TG neurons triggered significant increases in TG neurons to I_{CAP} or CAP-induced [Ca]i. Finally, the CAP-sensitizing effects of C3a on TG neurons was abolished by pre-treatment with either a PKC inhibitor (bisindolymaleimide) or a SRC inhibitor (A419259). Conclusions: 5-HT preferentially releases C3a from peripheral tissues of women compared to men, leading to the sexual dimorphic increase in TRPV1 activities in trigeminal sensory neurons.

Title: Sex Differences in Stress-Exacerbated Orofacial Pain and Glial Density in Ascending Trigeminal Pain Pathways

Authors: *D. CANTU, A. LOPEZ-RAMIREZ, N. SANTOS, E. RODRIGUEZ, D. AVERITT; Biol., Texas Woman's Univ., Denton, TX

Abstract: Psychological stress influences craniofacial and orofacial pain disorders, many of which disproportionately affect women. Unfortunately, most preclinical studies investigating the effects of stress on orofacial pain are reported in male rodents. It is unclear whether stress exacerbated orofacial pain occurs in females. Probable mechanisms involved in stress exacerbated orofacial pain may implicate corticosterone levels and astrocyte activity. Studies indicate that stress decreases Glial Fibrillary Acid Protein in the brain (GFAP). Other studies have shown that astrocytes increase one day after exposure to Complete Freund's Adjuvant (CFA; inflammatory agent) into the masseter muscle. Moreover, more cortisol is present in women experiencing pain when compared to men. Overall, our study aims to determine whether exposure to sub-chronic stress (the forced swim test; FST) can alter mechanical sensitivity at the inflamed vibrissal pad in male and female rats, correlate exposure to the FST with corticosterone levels, and visualize astrocytes in the brainstem of these rats. We hypothesized that FST evokes greater orofacial pain behaviors in females which correlates to increased blood corticosterone levels and increased astrocyte density in ascending trigeminal pain circuitry. Mechanical sensitivity was recorded in adult Sprague-Dawley male and female rats using the von-Frey method. Rats received one injection of CFA into the right vibrissal pad (RVP). Twenty-four hours later, orofacial allodynia was confirmed. All rats were subjected to either three consecutive days of the FST or sham test. Mechanical allodynia was re-assessed on 1, 4, and 8, and 11 days following the FST or sham paradigms. On day 8, all rats received the trans-synaptic tracer wheat-germ-agglutinin into the RVP. On day 11, mechanical allodynia was re-assessed immediately, followed by perfusion fixation. Baseline blood corticosterone was measured via ELISA and re-assessed following FST. The trigeminal ganglia and brainstem were extracted, sectioned, and analyzed by confocal microscopy. We report that injecting CFA into the RVP evoked significant mechanical allodynia in males and females. Females display greater allodynia one, four, and eight days after FST when compared to males. Our data also indicate that inflamed males exposed to the FST express more GFAP in the brainstem when compared to sham.

Conversely, female brainstem expressed comparable GFAP after FST or sham conditions. Altogether, our data indicate sex differences in the effects of stress on mechanical allodynia in the orofacial region, which may be one contributing mechanism to the prevalence of orofacial pain in women.

Title: Spatial modulation of dark versus bright stimulus responses in the mouse visual system

Authors: *B. WILLIAMS[1], J. DEL ROSARIO[2], T. MUZZU[3], K. PEELMAN[2], S. COLETTA[2], E. K. BICHLER[2], A. SPEED[2], L. MEYER-BAESE[2], A. B. SALEEM[3], B. HAIDER[2]; [1]Biomed. Engin., [2]Georgia Tech. and Emory Univ., Atlanta, GA; [3]Univ. Col. London, London, United Kingdom

Abstract: A fundamental task of the visual system is to respond to both increases and decreases of luminance (ON and OFF responses). OFF responses are stronger, faster, and more salient than ON responses in primary visual cortex (V1) of cats and primates and primates (Yeh et al., 2009; Jin et al., 2011; Xing et al., 2010), but in ferrets and mice ON responses can be stronger, weaker, or balanced in comparison to OFF responses (Smith et al., 2015; Smith and Hausser, 2010; Polack and Contreras, 2012; Jimenez et al., 2018). These discrepancies could arise from differences in species, experimental techniques, or stimulus properties, particularly retinotopic location in the visual field, as has been speculated (Smith et al., 2015); however, the role of retinotopy for ON/OFF dominance has not been systematically tested across multiple scales of neural activity within species during awake vision. Here, we measured OFF versus ON responses across 150° of visual space (spanning both monocular and binocular visual fields) with silicon probe and whole-cell patch-clamp recordings in awake mouse V1 and lateral geniculate nucleus (LGN). We analyzed local field potential (LFP), extracellular spiking, and subthreshold membrane potential responses to brief, spatially localized visual stimuli (flashed bars or squares). For all recordings, we quantified the relative ratio of ON versus OFF responses, facilitating comparisons across recording modalities.We found that OFF responses dominated in the central visual field, whereas ON and OFF responses were more balanced in the periphery. These

findings were broadly consistent across local field potential (LFP), spikes, and subthreshold membrane potential in V1, and were aligned with spatial biases in ON/OFF responses in LGN. Our findings reveal that retinotopy may provide a common organizing principle for spatial modulation of OFF versus ON processing in mammalian visual systems.

Title: Figure-ground representation of horizontal and vertical disparity mechanisms in human visual cortex

Authors: *M. KAESTNER[1], A. M. NORCIA[2];
[2]Dept. of Psychology, [1]Stanford Univ., Stanford, CA

Abstract: Previous work has shown that signals evoked by horizontal and vertical disparities are stronger in the presence of a disparity reference (Norcia et al, 2017). Therefore, both mechanisms could support perceptual figure-ground segmentation that depends on edge discontinuities between two disparity-defined regions. However, only horizontal disparities give rise to vivid percepts of depth. This suggests that reference effects are likely to arise via different cortical mechanisms for the two disparity types. Here, we used fMRI to probe the cortical distribution of responses to horizontal and vertical disparities, particularly in relation to a zero-disparity surround. Participants (N=11) viewed circular dynamic random-dot stereograms that consisted of a central 4-degree disk embedded within a 12-degree annulus. The central region could be segmented from its surround on the basis of one of four disparity types. These were crossed or uncrossed horizontal disparity, and corresponding vertical disparity conditions. Disparity amplitude of the central disk was modulated between +/- 12 and 0 arcmin, at a rate of 2 Hz. In a fifth condition, the central disk was modulated between 0 disparity and binocularly uncorrelated dots. Stimuli were presented in blocks of 12 seconds and were interspersed with a zero-disparity baseline condition consisting of a uniform field of random dots. During scanning, participants monitored centrally placed nonius lines and pressed a button when they noticed a colour change. fMRI scans were pre-processed and aligned to high-resolution, segmented anatomical scans using fmriprep. Response amplitudes were estimated using a standard GLM

approach in voxels restricted to the grey matter. Preliminary results indicate that horizontal disparity conditions (crossed and uncrossed) evoked robust responses in a network of areas that spanned early visual and lateral occipital cortex. Responses to vertical disparity were weaker and clustered in early visual areas, highlighting differences in the cortical representation of the two cues. In some participants, we also measured negative BOLD responses at the edges of the retinotopically-defined central disk representation. This was more pronounced for horizontal disparity, suggesting the presence of a suppressive mechanism that may support image segmentation via higher level form-from-disparity cues.

Title: Contrast versus luminance in retina and visual cortex

Authors: *L. DYBALLA[1], M. HOSEINI[3], M. RUDZITE[5], G. D. FIELD[6], S. W. ZUCKER[2], *M. P. STRYKER[4];
[2]Computer Sci., [1]Yale Univ., New Haven, CT; [4]Ctr. for Integrative Neurosci, Dept Physiol, [3]Univ. California Med. Sch., San Francisco, CA; [6]Dept. of Neurobio., [5]Duke Univ., Durham, NC

Abstract: The traditional view is that visual cortex is concerned with contrast and discounts changes in background luminance as compared with retina. We studied responses of neurons in retina and primary visual cortex (V1) of mouse to stimuli including moving gratings and optic flows built from either dark or light dots or short line segments (Dyballa et al *PNAS* 2018). Stimuli subtending ~60° x 40° were presented for 1.25 sec separated by 0.75 sec mid-gray screens. We asked whether average luminance matters when comparing retinal with cortical responses.
Two interleaved stimulus sets were identical except for the background. In one, the flow stimuli background was the mid-gray of the inter-stimulus interval (equal background, *eqbg*), leading to a change of 9-10% in the space-average luminance. In the other, the space-average luminance of the entire stimulus field was adjusted to a constant (equal luminance, *eqlum*) within 0.5%; i.e., the background was slightly lightened when the dots in the flow were dark, and darkened when the dots were bright.
Most cortical cells appeared to respond similarly to the two stimulus sets, as if stimulus structure

mattered but not the background change, while the responses of most retinal ganglion cells appeared to differ between the two conditions. Machine learning algorithms confirmed this quantitatively. A manifold embedding of neurons to the two stimulus sets was constructed using diffusion maps. In this manifold, the responses of the same cell to *eqlum* and *eqbg* stimuli were significantly closer to one another for V1 rather than for the retina. Geometrically, the median ratio of the distance between the responses of each cell to the two stimulus sets as compared to the distance to the closest cell on the manifold was 3.5 for V1 compared to 12.7 for retina. Topologically, the fraction of cells for which the responses of the same cell to the two stimulus sets were connected in the diffusion map datagraph was 53% for V1 but only 9% for retina; when retina and cortex were co-embedded in the manifold, these fractions were 44% and 6%. While retina and cortex differ on average, it will be intriguing to determine whether particular classes of retinal cells behave more like V1 neurons, and vice versa.

Title: Standardizing methods for analyzing the P100 latency of visually evoked potentials

Authors: *F. M. INGRAM[1], J. C. WAGNER[2], S. A. BEARDSLEY[2,3];
[1]Dept. of Biol. Sci., [2]Dept. of Biomed. Engin., Marquette Univ., Milwaukee, WI; [3]Med. Col. of Wisconsin, Milwaukee, WI

Abstract: Visually evoked potentials (VEPs) represent changes in the brain's electrical activity due to a visual stimulus. VEPs are often measured using electroencephalography (EEG) and can be characterized by the latency of the P100 peak as an indicator for the onset of visual processing in the occipital lobe. VEP P100 latency is widely used for diagnosing damage along the optic tract, such as with optic neuritis, and can provide insight into damage elsewhere in the brain, as with Multiple Sclerosis (MS) patients. However, lack of consensus in the literature has resulted in a failure to create a criterion for classifying latencies. The goal of this study is to establish a standardized method for measuring the P100 latency. In a pilot study, 5 young adults with normal or corrected-to-normal vision (2 males, ages 19-25 years) participated in a 2 Hz pattern reversal checkerboard experiment while 64-channel EEG was recorded. Two different check sizes (1.05° and 1.43°) were examined for monocular and binocular viewing conditions across

200 reversals. After typical EEG preprocessing, channel level analysis of the P100 latency was quantified using two different methods: peak latency and percent area. Peak latency was defined as the time the signal reached maximum amplitude whereas the percent area method used the timepoint where the signal reached 50% of the area under the curve within the P100 onset/offset window. Latencies for both methods were calculated for all conditions using the signals from the left (O1), medial (Oz), and right (O2) EEG occipital channels averaged across reversals. A three-way ANOVA was used to identify differences between method, check size, and eye condition. No significant differences in the P100 latency were found between conditions ($p > 0.05$), but observable trends in the variability of measured latencies were present for check size and analysis method. Increased variability occurred with the larger check size (e.g., right eye variance peak method, large: 98.0 ms^2 vs. small: 14.7 ms^2) and when using the peak latency method of analysis (vs. right eye variance percent area method, large: 11.8 ms^2). Reducing variability in latency calculations is important, especially in populations whose EEG signals may be more susceptible to noise. This percent area method reduces the variability of latency measurements by averaging the effects of noise across the P100 interval. Future work will evaluate the changes in P100 latency with age and for patient populations, such as those with MS. Standardizing VEP latency analysis around a single sensitive and robust method will facilitate comparisons across studies and EEG systems.

Title: Binocular integration as nonlinear mixing: how binocular neurons in primary visual cortex preserve eye-specific information for downstream visual processing

Authors: *E. S. CHENG, F. BARTSCH, D. A. BUTTS;
Dept. of Biol., Univ. of Maryland, College Park, MD

Abstract: The visual cortex integrates the visual information from the two eyes into a single “fused” percept. The straightforward way to combine the information from each eye is to use the relative shift between the two images, known as the binocular disparity, to bring the images into register. Indeed, a fraction of neurons in primary visual cortex (V1) are tuned to specific disparities, and it is commonly thought that such disparity signals are necessary to appropriately

integrate eye-specific information in V1 or downstream areas. Paradoxically, however, a large fraction of neurons in V1 are binocular but have little-to-no sensitivity to disparity. Here, we explore an alternative mode of binocular integration: based on the hypothesis that "binocular untuned" neurons support the preservation of eye-specific information in the form of nonlinear mixtures. We support this hypothesis by analyzing accurate data-driven models that are based on macaque V1 neurons recorded in a previous study. In these models, disparity tuning in V1 arises from linear summations of left- and right-eye information; and conversely, the responses of binocular untuned neurons represent nonlinear mixtures of left and right eye information. We performed population-level simulations of each V1 neuron in a binocular rivalry paradigm with independent images presented to each eye. Using population decoding of these simulated responses, we find that rather than obscuring visual information from each eye, such nonlinear mixtures preserve eye-specific information. Conversely, disparity-tuned neurons - which linearly mix information from the two eyes - were less able to preserve eye-specific information. However, the performance of these disparity-tuned neurons in the decoding paradigm could be "rescued" by modifying the models to replace linear with nonlinear summation of left- and right-eye information, leaving all other aspects of the models the same. Our results demonstrate that a large fraction of V1 neurons preserve eye-specific visual information, even though they are binocular. Furthermore, we suggest that the formatting of eye-specific information in the form of nonlinear mixtures is a feature, not a bug, to support downstream processing that requires eye-specific information: for example, in tasks involving the reconstruction of three-dimensional geometries from the two-dimensional images available to our two eyes.

Title: Amplification of disparity selectivity by spatial convolutions in the primary visual cortex

Authors: *F. BARTSCH[1], S. HENRIKSEN[2,3], J. C. READ[3], B. G. CUMMING[2], D. A. BUTTS[1];

Abstract: Our two eyes see slightly shifted versions of the visual world, which are combined within the brain into a single fused percept. Bringing the two images into register requires knowing the binocular disparity (shift between the images in each eye), and some neurons in primary visual cortex (V1) are exquisitely sensitive to the disparity of binocularly presented stimuli. However, while existing models of binocular integration can explain V1 disparity tuning in the context of simple stimuli such as drifting gratings, it is not clear whether these mechanisms generalize to more natural stimuli. Here, we present a model for V1 processing that accounts for its disparity tuning in the context of complex spatiotemporal visual stimuli. It is based on the canonical mechanism of linear summation of spatiotemporally filtered inputs from each eye - common to most previous models of disparity tuning - but adds a novel mechanism for disparity amplification via spatial convolutions. We use a data-driven modeling framework applied to recordings from V1 neurons in awake macaques, where random bar stimuli aligned to each neuron's receptive field were presented using a haploscope with randomly changing disparity. Unlike previous models of V1 disparity tuning, our model is able to almost completely reproduce the disparity tuning of a wide variety of binocular V1 neurons to complex stimulus patterns: explaining nearly all of the disparity-driven response of V1 neurons that were significantly disparity tuned (mean disparity-R^2 = 88%, n=11, with many neurons almost perfectly explained). Furthermore, because the model concurrently captures each neuron's spatiotemporal feature selectivity, such a model also generalizes to non-disparity-tuned V1 neurons (mean explainable R^2 = 56%, n=50). Furthermore, based on these models fit to data, we derive an understanding of how disparity processing of specialized disparity-tuned neurons is amplified by spatial convolution. Specifically, the spatial convolution allows identical processing to be performed across space, resulting in sensitivity to the correlations present in natural visual input: with disparity typically correlated over large spatial scales (due to the depth structure of the visual scene) and spatiotemporal patterns changing on much finer spatial scales. Convolutional processing thus amplifies the correlated disparity signals across space while averaging out the signals driven by spatiotemporal patterns. In addition to offering an elegant explanation for disparity processing, such a convolutional strategy - observed broadly in V1 neurons - is likely at play in amplifying selectivity to a variety of other visual features.

Title: Functional parcellation of the STS: A comparison of four atlases and six social perception localizers

Authors: *B. C. HACKNEY[1], D. A. STEHR[2], J. A. PYLES[3], E. D. GROSSMAN[1];
[1]Dept. of Cognitive Sci., Univ. of California, Irvine, Irvine, CA; [2]Dept. of Psychological and Brain Sci., Dartmouth Col., Hanover, NH; [3]Ctr. for Human Neurosci., Univ. of Washington, Seattle, WA

Abstract: BACKGROUND: In the human neuroimaging field, there is significant effort to develop brain parcellation algorithms that automatically draw borders between distinct functional regions. The benefits to automated brain parcellation include dimensional reduction and consistent functional mapping across individual participants without conversion to volumetric templates such as MNI. Ideally, parcellations that strongly align with functionally localized regions would eliminate the need for collecting additional localizer scans, reducing burdens on the human participant and standardizing approaches across fMRI studies. The superior temporal sulcus (STS) covers a large expanse of cortex stretching from the anterior temporal lobe to posterior parietal cortex, and is host to numerous cognitive functions in social and cognitive domains (Liebenthal et al., 2014). Currently available atlas schemes, optimized for whole-brain parcellation, yield very different boundary definitions within the STS (Patel et al., 2020). We therefore compared these parcellations on their ability to differentiate core social cognitive tasks that yield complex activation patterns on the human STS. METHOD: We evaluated four publicly available automated parcellation schemes on their efficacy in discriminating the following tasks: biological motion perception, perception of agency from Heider-Simmel type animations, theory of mind as induced by false belief tasks, stationary and dynamic face perception, and audiovisual speech perception. Efficacy of atlas parcellation was evaluated using leave-one-subject-out classification on task labels, with the classifier trained on metrics of homogeneity of activation and functional connectivity within each parcel. RESULTS: All tasks were readily classified for all four atlas parcellations across a variety of homogeneity metrics, evidence that each of the six tasks yield unique multivariate activation patterns apparent even at the parcel level. In particular, the homogeneity of effect sizes within the parcels had robust information that yielded improved classification, even superior to homogeneity of mean effect sizes and within-parcel connectivity. CONCLUSIONS: These findings demonstrate that qualitatively different activation maps from pSTS localizers yield multivariate patterns across atlas parcels that are readily differentiated quantitatively. Further work is required to identify what features promote optimal task-identification and thus have potential to improve the utility of atlases in replacing functional localizers.

Title: Functional connectivity of the pSTS in the action observation network (AON) modulated by attention to action features during action and goal inference, an fMRI experiment

Authors: *X. ZHOU[1], D. A. STEHR[2], J. A. PYLES[3], E. GROSSMAN[1];
[1]Cognitive Sci., Univ. of California Irvine, Irvine, CA; [2]Univ. of California, Irvine, Irvine, CA; [3]Dept. of Psychology, Ctr. for the Neural Basis of Cognition, Carnegie Mellon Univ., Pittsburgh, PA

Abstract: Background. Neural mechanisms of action understanding are associated with the action observation network (AON), which includes the posterior superior temporal sulcus (pSTS), the inferior frontal gyrus (IFG), and bilateral intraparietal lobule (IPL). Whereas the pSTS is linked specifically to perceptual representations of action kinematics, the IPL and IFG are proposed to represent the implied goals and outcomes of the observed action. Theoretical models propose, and empirical findings support the notion, that representations in the IFG modulate and restructure perceptual representations in the pSTS via feedback routed through the IPL. The IFG and IPL, however, are large and functionally heterogeneous brain regions with complex organization. Moreover, there exist multiple pathways by which the IFG may interact with sensory cortical systems during action recognition. The goal of this study is to evaluate the fine-grained organization of parcels functionally connected to the pSTS during action recognition and that are modulated by the attentive state during action observation. Methods. The right pSTS was identified in the native cortical surface of 24 participants using a traditional biological motion localizer. The bilateral IFG, IPL, and an anterior STS region were identified as those parcels that were functionally connected to the right pSTS seed. Functional connectivity was computed on trial-based beta estimates acquired when observers viewed action vignettes (jumping up to reach a high box, crouching down to reach a low box) under two attention instructions: attend to action or attend to goal. Paired t-tests identified those parcels for which functional connectivity was modulated by the attention instruction and functional networks derived from the Yeo et al (2011) 7-network system were assigned. Results. The participant's attentional states modulated pSTS connectivity to the right IFG and anterior right STS, predominantly in the frontal control and default mode networks, such that connectivity was strengthened when participants attended to action as compared to attending to action goals.

These increases in connectivity were decoupled from the univariate response, which was stronger when attending to goal rather than action. There was no attentional modulation on pSTS connectivity to the IPL. Conclusion. Functional connectivity and brain mapping reveal distinct properties of the AON. Attention directed to actions strengthens the connectivity in a right-lateralized system that excludes the IPL. Thus the viewer's attentive state during action observation has the potential to restructure the coupling of nodes within the AON network.

Title: Human intracranial recordings of neural responses to visual dynamics in movies

Authors: *M. NENTWICH[1], M. LESZCZYNSKI[2], B. E. RUSS[3], S. BICKEL[4], N. MARKOWITZ[4], A. D. MEHTA[4], C. E. SCHROEDER[2], L. C. PARRA[1];

Abstract: Our visual experience in daily life is dominated by movement -- movement of objects in the world, movements of the eyes and changing perspective due to head and body movement. Neural processing of such dynamic visual input has been studied in movie watching experiments. Past studies have focused either on visual motion, eye movements or scene cuts. However, these features have not been analyzed in combination, which seems imperative, as they clearly interact. Eye movements are guided by moving objects, and scene cuts elicit saccades. Neural visual processing, in turn, is modulated by saccades. Here we focus on the interaction of these dominant visual dynamics in movies. We explore intracranial recordings (4477 electrodes) from 19 patients who passively watched up to 50 minutes of videos. Intracranial recordings capture neural responses at the rapid time scale of these visual dynamics. They also provide good spatial resolution to identify distinct responses in different brain areas. Linear neural responses were estimated for the local field potentials (LFP) as well as broadband high-frequency amplitude (BHA, 70-150 Hz). Only a few electrodes showed significant responses to mean optical flow, a measure of overall motion in the video. However, we found strong responses to scene cuts and saccades, lasting up to 1000 ms and extending far beyond traditional visual processing areas of the brain. Among saccades, we found stronger responses immediately following scene cuts. In

the parietal, temporal and frontal cortex we found long lasting BHA and LFP responses beyond 1000 ms for saccades after scene cuts, but not spontaneous saccades. In contrast, in the occipital cortex, saccades after scene cuts and spontaneous saccades show similar increases in BHA peaking about 200ms after saccade onset. Among scene cuts, we found stronger responses for those cuts that mark a transition in the narrative of the video. Importantly, higher level cortical areas, the parietal, temporal and frontal lobes, were more selective in responding to these narrative cuts. In contrast, occipital electrodes were not selective for the type of scene cut. The BHA responses were mostly characterized by an increase of neural activity 200ms-800ms following a scene cut, regardless of brain location. Taken together we conclude that novelty in the visual input is the dominant driver of neural activity. Specifically, meaningful semantic content leads to stronger and longer lasting responses that reach higher cortical processing stages.

Title: A week in the life of the human connectome: stable homeostasis and characteristic excursions

Authors: *M. WANG[1,3], M. WARD[4], M. G'SELL[2], M. RICHARDSON[5,4], A. S. GHUMAN[4,1]; [1]Program of Neural Computation, [2]Statistics, Carnegie Mellon Univ., Pittsburgh, PA; [3]Med. Scientist Training Program, [4]Neurolog. Surgery, Univ. of Pittsburgh, Pittsburgh, PA; [5]Neurosurg., Massachusetts Gen. Hosp., Boston, MA

Abstract: During the course of a day, our brains must accomplish a wide range of tasks and demonstrate a remarkable amount of flexibility despite their anatomic stability. How do ecologically valid brain states balance the tension between these demands of flexibility and stability? To answer this question, we explored how the human functional connectome changes using continuous intracranial electroencephalography recordings in six epilepsy patients while

they go about their day: eating, talking with visitors, reading, etc. over the course of a week. By tracking how the coherence between all pairs of the 100-120 electrodes implanted in each patient changes over each five second window during the entire week, we were able to use unsupervised autoregressive methods to identify the prevalent dynamic patterns of connectivity. Two major patterns emerged. First, brain networks had a stable baseline state that the brain would consistently return to after individual subnetworks took excursions of various types throughout the day. This stable state was similar across all our subjects, consisting of elevated lower beta coherence and decreased theta and gamma coherence. Our second finding was that there was a discrete set of probable ways to leave this baseline state. Different sub-networks of the brain were not activated or inactivated randomly to each other: they formed a specific set of patterns of which networks could be activated together over which frequencies. These patterns were well-preserved from day to day: if one network's beta activation were linked to another network's gamma inactivation in one day, the same would generally hold true in other days. Additionally, the length of the excursion (e.g. the autocorrelation of each dynamic pattern) was consistent from day-to-day. These patterns show that after perturbations, the brain's functional networks are pulled to return within a stable baseline dynamic range that is similar from person-to-person, which may represent an optimal homeostatic state for the functional connectome. Excursions from this state occur frequently, presumably to accomplish tasks such as sleep or heightened activity, but the excursions are always marked by a return back to homeostasis. The day to day consistency of the largest excursions from homeostasis may indicate some underlying anatomic or energy limitation that forces departures from homeostasis to follow characteristic trajectories. Taken together, these results suggest a homeostasis-like mechanism by which the functional connectome achieves stability while allowing for neurocognitive flexibility.

Title: A novel experimental paradigm to investigate awareness of action

Authors: *D. S. JIN[1], M. S. KHURANA[2], S. L. AERTS[1], E. SIFF[1], I. FU[2], S. I. KRONEMER[1], K. L. CHRISTISON-LAGAY[3], J. LI[2], A. KUMAR[2], N. C. FREEDMAN[2], G. P. CHANDRASEKARAN[2], S. TINAZ[3], H. BLUMENFELD[3];
[1]Interdepartmental Neurosci. Program, [2]Yale Univ., New Haven, CT; [3]Dept. of Neurol., Yale Univ. Sch. of Med., New Haven, CT

Abstract: Loss of awareness of action is a common phenomenon in which complex, overlearned motor actions are performed but later are not reportable as aware experiences. Although previous research has investigated the generation of volitional actions and the awareness of intention to act, to date there have been no studies which isolate individual actions performed with and without awareness. Here, we developed a novel behavioral paradigm which distinguishes between actions with and without awareness. Our task uses aspects of inattentional blindness to achieve these outcomes and is readily adapted to EEG, pupillometry and other neurophysiological measures. Our experimental paradigm centered around repeated presentations of the classic board game Rush Hour, where a target block is moved to a key location by clearing away blocks which impede the path of movement. Subjects are explicitly tasked with recalling details from a background video constantly playing behind the game to incorporate inattentional blindness. Subjects recount details in a three-minute free-recall period after each ten-minute run. Randomly, subjects may be asked a two-part quiz: 1. A four-option multiple choice question where subjects choose their most recent move, and 2: A sliding scale on which subjects indicate their confidence in their choice. To learn the paradigm, subjects first perform a training day without quizzes. Then, subjects participate in two testing days with the quizzes. Subjects' self-assessed confidence was deemed "high" if it was in the top quartile of slider positions, or "low" if it was in the bottom quartile. Moves where questions were answered correctly with high confidence were rated as "aware". Moves where questions were answered incorrectly with low confidence were rated as "unaware". Our method produced high rates of agreement between answer result and confidence scores. In the top quartile of subject confidence, 93.2% of answers were correct. In the bottom quartile of subject confidence, only 28.7% of answers were correct, close to chance (25%) performance. In addition, our paradigm produced sufficient numbers of "aware" (mean 30.7) and "unaware" (mean 22.9) moves per subject across the two testing days for use with EEG and other neurophysiological measures. In conclusion, our task provides a means of distinguishing discrete actions performed with and without awareness, with high levels of validation and sufficient sample size for analysis. These discrete actions will be useful in determining the spatiotemporal dynamics of pre-action anticipatory voluntary motor signals and post-action perceptual signals in further testing with EEG and neuroimaging methods.

Title: A novel visual perception no-report paradigm reveals early and broad responses from whole brain fMRI and high-density scalp EEG

Authors: *S. KRONEMER[1], T. XIN[1], J. DING[1], M. AKSEN[1], J. RYU[1], J. DING[1], J. PRINCE[1], H. KWON[1], A. KHALAF[1], S. FORMAN[1], M. KHOSLA[1], D. JIN[1], K. WANG[1], K. CHEN[1], C. Abstract: Identifying the core neural mechanisms of consciousness is confounded by post-perceptual processing. The development of so-called no-report paradigms aims to relieve the engagement of cognitive processes that can be confused for perception-linked signals. Recent findings from no-report paradigms suggest late electrophysiology and higher-order association cortices are muted in the absence of overt report. However, these findings are nascent, there are competing results and interpretations in the literature, and little work has been done to investigate the subcortical dynamics in conscious perception. The current investigation utilizes a novel visual, perceptual-threshold report and no-report paradigm where overt report is replaced by machine learning based predictions of stimuli perception determined from eye tracking and pupillometry dynamics. Concurrent fMRI and high-density scalp EEG recordings allow access to both high spatial and temporal resolution dynamics of the healthy, adult brain physiology in processing visual conscious perception. In the overt report condition, there are early (<4s) blood-oxygen-level-dependent (BOLD) responses that distinguish perceived and not perceived stimuli in detection, arousal, and salience (DAS) network sites, including the primary visual cortex, dorsal lateral prefrontal cortex, anterior cingulate cortex, thalamus, and midbrain. At later times (>5s), widespread and sustained BOLD increases in the posterior parietal and prefrontal cortices and decreases in the default mode network (DMN) are found. Scalp EEG responses in the report condition show four prominent event-related potentials: N100, visual awareness negativity (VAN), N2, P2, and P3. Only the N100 is shared between the perceived and not perceived stimuli. In the no-report condition, perceived versus not perceived early BOLD signal dynamics are again found in DAS regions, including midbrain, thalamus, frontal, and parietal cortices. However, late responding BOLD signals found in the report condition are muted or absent, including components of the task-positive network increases and DMN decreases. Scalp EEG responses in the no-report condition isolate the core perception-link ERP to the VAN, while the N100 is present for both perceived and not perceived stimuli and the late ERPs are muted or absent, including the P3. Together these results support an early and broad core network for visual conscious perception independent of report. Future studies should investigate the causal role of these cortical and subcortical regions.

Title: Investigating tactile conscious perception with a threshold task and intracranial EEG

Authors: *S. MAJUMDER[1], N. C. FREEDMAN[1], J. Z. DING[1], M. M. GUSSO[3], K. L. CHRISTISON-LAGAY[4], S. I. KRONEMER[5], D. S. JIN[6], M. KHURANA[1], I. FREEDMAN[5], T. BUI[5], K. WU[2], I. H. BLUMENFELD[4]; [1]Neurol., [2]Neurosurg., Yale Sch. of Med., New Haven, CT; [3]Programa de Pos-Graduacao em Tecnologia em Saude, Pontificia Univiersidade Catolica do Parana, Curitiba, Brazil; [4]Dept. of Neurol., Yale Univ. Sch. of Med., New Haven, CT; [5]Neurol., [6]Yale Univ., New Haven, CT

Abstract: Recent studies have made significant progress towards understanding the spatiotemporal dynamics underlying consciousness. To this end, our lab has combined neural recordings with novel perceptual threshold tasks in visual and auditory domains, in which participants were played threshold-level stimuli and subsequently reported their percepts. These studies showed that while activity in Not Perceived trials is limited to early sensory areas, Perceived trials are characterized by increases in sensory areas and areas critical to detection, a transient pulse from subcortical regions, a wave of activity that spreads to association regions, and a monotonic decrease in the default mode network. To ascertain if this pattern of activity is shared across modalities, a tactile correlate of the tasks was used. A vibration, calibrated to the participant's 50% detection threshold, was delivered via vibrating tactor to one of a participant's non-thumb fingers; 14% of trials contained no vibration. After each trial, participants reported whether they (1) felt the vibration and (2) the location of the vibration; if they felt no vibration, they were instructed to guess randomly. In this study, our participants were patients undergoing intracranial electroencephalography (icEEG) for intractable epilepsy. Behavioral findings indicate that participants (n=5) perceived a vibration in 59.7% (SEM 3.2%) of vibration-present trials; the false positive rate was 9.5% (SEM 5.2%) for blank trials. When participants reported perception of the stimulus, they correctly indicated its location in 79% (SEM 3.2%) of trials; when they reported no perception, finger localization accuracy was 19% (SEM 2.3%; chance is 25%). icEEG recordings were analyzed for power in the high gamma frequency range (40-115 Hz), of its known relationship to local neural activity. In Not Perceived trials, post-stimulus activity was dominated by a spatiotemporally limited increase in gamma power in the somatosensory regions. However, in Perceived trials, the observed increases in gamma power in

somatosensory regions expanded outward to association regions and were accompanied by increases in regions associated with the salience network (such as anterior insula/frontal operculum) and decreases in regions associated with the default mode network (such as medial frontal cortex). These early results are in line with our previous findings in visual and auditory paradigms, indicating that there are shared mechanisms of conscious perception involving a broad network of cortical regions across sensory modalities.

Title: Early neural activity changes associated with visual conscious perception

Authors: *A. KHALAF, S. I. KRONEMER, K. L. CHRISTISON-LAGAY, H. KWON, J. LI, H. BLUMENFELD;
Dept. of Neurol., Yale Univ. Sch. of Med., New Haven, CT

Abstract: The neural mechanisms of visual conscious perception have been investigated for decades. However, the spatiotemporal dynamics associated with the earliest neural responses following consciously perceived stimuli are still poorly understood. Using a dataset of intracranial EEG recordings, the current study aims to investigate the neural activity changes associated with the earliest stages of visual conscious perception. Subjects (N=10) completed a continuous performance task in which individual letters were presented in series and subjects were asked to press a button when they saw a target letter. Broadband gamma power (40-115Hz) dynamics were considered because of their known relationship to populational neural firing. In particular, target trials with button presses and non-target trials without button presses were filtered using a Butterworth band-pass filter to limit the frequency content of the trials to include only frequencies within the broadband gamma frequency range. Broadband gamma power was calculated by squaring the filtered signal amplitude of each trial. Afterwards, within each subject, gamma power time course of each trial was z-score transformed using the mean and standard deviation of the gamma power across all trials of that subject. To identify the statistically significant changes in post-stimulus z-scored gamma power compared to the baseline, we employed a spatiotemporal cluster-based permutation test. We analyzed changes that were common to both target and non-target stimuli as well as differences between targets and non-

targets.
Our results revealed early gamma power increases within 0-100 ms from stimulus onset, regardless of whether the stimulus was a target or a non-target, in bilateral visual processing cortex, medial temporal cortex, frontal eye fields, superior frontal, orbital frontal, inferior frontal, and left temporal/parietal cortex. At later times (>300 ms), increases in broad regions of left frontal, parietal, and temporal cortices were seen specifically for target stimuli suggesting that these regions are possibly a part of the cortical networks involved in responding to target stimuli (the right hand was used for the response). These findings suggest a broadly distributed cortical visual detection network including frontal, parietal, and temporal cortices is engaged within 100 ms after signal transduction from the retina.

Med., New Haven, CT

Abstract: Although recent work has made significant headway in understanding the temporal and spatial dynamics of the neural mechanisms of conscious perception, much of that work has

focused on visual paradigms. To determine whether there are shared mechanisms for perceptual consciousness across sensory modalities, here we investigate the auditory domain. We developed an auditory task, in which target sounds (calibrated to a participant's 50% detection threshold) were embedded in white noise. Participants were subsequently prompted to report if they perceived the sound, and the sound's identity (to validate perception). When participants indicated they did not hear a sound, they were asked to randomly guess on the question about sound identity. This task was completed by patients undergoing intracranial electroencephalography (icEEG) for intractable epilepsy. We found that participants' (n=31) perception rate was 58.0% (2.0 % SEM) when a target was present; false positive rate was 8.5% (1.4% SEM) for blank trials. When participants indicated they heard a target, they correctly identified the sound in 89.2% (1.4% SEM) of trials; sound identification accuracy for unheard trials was 40.2% (2.0% SEM) (chance: 33%). Intracranial recordings from over 2,800 grey matter electrodes representing widespread cortical coverage have been analyzed for power in the high gamma range (40-115 Hz)—a frequency range that reflects local neural activity. We performed a series of cluster-based permutation analyses to identify clusters of significant activity across perceived and not perceived trial conditions. For not perceived trials, we find that significant activity is restricted to early auditory regions (and areas immediately adjacent to the Sylvian fissure); and that this activity appears at ~150 ms and lasts until ~800 ms post stimulus onset. Perceived trials also show activity in early auditory regions, but this is accompanied by activity in the right caudal middle frontal gyrus, and shortly thereafter by activity in non-auditory thalamus. This is followed by a wave of activity that sweeps through the higher auditory association regions and into parietal and frontal cortices, similar to the wave observed in our visual conscious perception paradigm. We also find a decrease below baseline activity in orbital frontal and rostral inferior frontal cortex beginning ~200 ms post stimulus onset, consistent with the 'switch' observed in our visual paradigms. In summary, we found a broad network of cortical and subcortical regions involved in auditory perception that are similar to the networks observed with vision, suggesting shared general mechanisms for conscious perception.

Title: The thalamic awareness potential: subcortical neural mechanisms of visual conscious perception from fMRI and intracranial EEG

Authors: *Q. XIN[1], S. I. KRONEMER[1], J. DING[1], M. AKSEN[1], J. RYU[3], H. KWON[2], J. DING[2], J. S. PRINCE[2], A. KHALAF[2], S. FORMAN[3], M. KHOSLA[1], K. WANG[2], K. CHEN[2], C. HU[2], A. Abstract: Studying the neural mechanisms of consciousness is an important query in modern cognitive neuroscience with broad scientific and clinical implications. Most studies and debate for identifying the core consciousness network have focused on cortical physiology. However, subcortical signals have been largely neglected from consideration as a neural mechanism for transient conscious percepts. In this study, two cohorts were recruited to study the spatial and temporal subcortical signal dynamics linked to visual conscious perception. First, healthy, adult participants were recorded with whole-brain fMRI while completing a report-based visual perceptual-threshold task. Second, a cohort of people with epilepsy that were chronically implanted with depth electrodes targeting the centromedian nucleus of the interlaminar thalamus (Responsive Neurostimulator System, NeuroPace, Inc.) were recruited to complete the same visual perception task while simultaneously recording scalp EEG. Blood-oxygen-level-dependent (BOLD) responses between perceived and not perceived stimuli demonstrate widespread subcortical engagement, including in the midbrain, thalamus, striatum, and cerebellum. At later times, cortical networks were also found specifically responsive to perception, including BOLD increases in task positive and decreases in the default mode networks. These BOLD results are strengthened by the electrophysiological findings from thalamic depth channels that reveal a perception-linked thalamic awareness potential (TAP; peak latency=439±16ms after stimulus onset) that occurs after the cortical scalp event-related potentials N100 (109±5ms) and visual awareness negativity (227±9ms) but precedes the P3 (487±20ms). The transient dynamic of the TAP suggests that the thalamus may have a neuromodulatory role for discrete conscious events and potentially augmenting later cortical activity, for example, those related to the P3. Together, the BOLD and intracranial electrophysiological results support a role of subcortical regions in visual conscious perceptual events. Further work may help elucidate the possible mechanistic role of the TAP and other subcortical potentials by direct electrical stimulation while observing changes in perceptual threshold.

Title: Neural ensemble dynamics and speech encoding in Broca's area

Authors: P. ROUSSEL[1], F. BOCQUELET[1], S. CHABARDÈS[2], ***B. YVERT**[1];
[1]INSERM and Univ. Grenoble Alpes, Gières, France; [2]CHU Grenoble Alpes, Grenoble, France

Abstract: Broca's area is a key region of the cortical speech production and processing network, that has been widely investigated and shown to be activated during overt and covert speech production with functional imaging techniques. However, ensemble activity in Broca's area remains largely unexplored. In particular, the extent to which its dynamics share similarities between overt and covert speech production, and whether and how speech is encoded in this region at the level of a neural population is unknown. Here we addressed these two questions in a patient undergoing awake surgery for the removal of a tumor located below the cortical surface of Broca's area. A 96-channel intracortical Utah array was transiently inserted in Pars Triangularis and single unit activity could be recorded in this region while the patient read aloud or imagined pronouncing short sentences presented on a screen. First, we found that the overall dynamics of the population of recorded neurons was different between overt and covert speech as indicated by different trajectories in a low-dimensional space of neural firing. This was further assessed by the possibility to decode between overt, covert, and silence conditions well above chance level. Then, we further observed strong similarities in the firing patterns of small sets of individual neurons when a same sentence was overtly pronounced twice. Such similarity involved different sets of neurons depending on the sentence. This similarity of spiking for identical sentences was further quantified by computing for each neuron, the Viktor and Purpura distance between spike trains for all pairs of sentences. We found that identical sentences yielded higher spiking similarity than different sentences ($P<0.001$). Furthermore, when considering only different sentences, the spiking similarity was strongest for pairs of sentences with the lowest phonetic distance. Overall, these results indicate that Broca's area gets differently activated between overt and covert speech and that similarity in spiking dynamics occurring in this region may reflect similarity in the phonetic content of overtly produced speech.

Title: Both tactile and visual feedback improve tongue motor ability in pointing the target on palatal surface, but tactile feedback led to stronger retention

Authors: *B. JIANG[1], J. KIM[2], H. PARK[1];
[1]Electrical and Computer Engin., [2]Engin. Technol. & Industrial Distribution, Texas A&M Univ., College station, TX

Abstract: Incomplete tongue motor control is a common yet challenging issue among individuals with neurotraumas and neurological disorders such as spinal cord injury (SCI), stroke, Parkinson's disease, and Alzheimer's disease. Incomplete tongue motor control may lead to serious limitations in accomplishing daily oral activities such as swallowing, speech, and respiration. There are also several tongue-controlled assistive technologies, developed for people with quadriplegia, which requires a lot of training and accurate tongue motor control to operate. To enhance the tongue motor control accuracy and overcome the problems and challenges associated with the incomplete tongue motor control, a few training methods have been developed and employed with multiple sensory modalities including visual, auditory, and tactile feedback. However, the effectiveness of each sensory modality and the combinations of them in tongue motor learning is still in question. The object of this study is to test the effectiveness of the tactile assistance on motor training and compare it with that of the visual assistance. To do so, eight healthy subjects performed the tongue pointing task, in which they were visually instructed to touch the target on the palate by their tongue tip as accurate as possible. Each subject wore a custom-made dental retainer with 12 electrodes distributed over the palatal area. For visual training, an array of LEDs corresponding to the electrode locations was shown on the computer screen. When one electrode was contacted, the corresponding LED would be turned on. The further away from the target, the brighter the color of the LED. For tactile training, a small protrusion was added onto the dental retainer as an indicator of the target, and electrical stimulation with different frequency was provided to the tongue. The further away from the target, the higher the stimulation frequency. A crossover design was selected to increase the statistical power and counterbalance the learning effect. One baseline session and three post-training sessions were conducted during three days. Experimental result showed that both visual and tactile feedback improved tongue motor control ability of pointing the target palatal location, and tactile training provided stronger retention than visual training. These results suggest that current sensory feedback was not enough for tongue pointing task, and therefore additional assistive sensory feedback improved the tongue pointing accuracy. The results also suggest that sensory assistance provided via corticobulbar pathway may contribute to stronger retention than sensory assistance provided via corticospinal pathway.

Title: A gesture-based forward model for speech motor control

Authors: *J. VEILLETTE, H. NUSBAUM;
Univ. of Chicago, Chicago, IL

Abstract: Vocal learning species are able coordinate the activity of hundreds of muscles to produce sound and swiftly correct movement errors despite intrinsic latencies between motor output and auditory feedback. This remarkable ability is thought to be facilitated by the maintenance of a forward model, which makes predictions about the current state of the body's periphery and the sensory consequences of movement to which feedback is compared. In the zebra finch, HVC neurons burst and interneurons are suppressed within milliseconds of critical points in the trajectory of the biophysical parameters that control the vibration of the glottis, which has been interpreted as a strikingly explicit neural implementation of a forward model. The present study demonstrates that gamma band power in the human electroencephalogram linearly tracks extremity in the trajectory of glottal control parameters with near-zero time-lag during the production of fluent speech. Given that humans and zebra finches do not share a common vocal learning ancestor, this finding suggests similar internal models of vocal tract physics have independently evolved in both species - pointing to a general principle of vocal motor control.

Title: Inhibition of ongoing speech production in the frontal cortex

Authors: *L. ZHAO[1], A. B. SILVA[2], E. F. CHANG[1];
[1]Dept. of Neurolog. Surgery, [2]Med. Scientist Training Program, Univ. of California, San Francisco, San Francisco, CA

Abstract: An important capacity for normal speech is the ability to stop ongoing production quickly when required. This ability is crucial for maintaining smooth conversations and deficits in it are often indicative of speech disorders. Previous studies have investigated the neural control for canceling speech and other motor outputs before their onset. However, it is largely unknown how the brain controls speech termination when one has already started speaking. Here we studied this question by directly recording neural activity from the human frontal cortex while participants start and stop their speech following visual cues. We found increased high-gamma activity near the end of the production in the frontal cortex during cued stopping, which was not observed in the self-paced, natural finish of a sentence. Across single trials, a subset of frontal regions was activated according to the time of the stop cue or stop action. Activity in single electrodes and across populations distinguish whether stopping occurred before an entire word was finished. In addition, we ask how the neural process for stopping is related to concurrent articulatory control. We found that stop activity existed in largely separate regions from those in the sensorimotor cortex encoding articulator movements. Interestingly, there is increased functional connectivity between the area with stop activity and the area with articulator encoding during stopping, compared to that before the stop cue. Finally, we found that the area with stimulation-induced speech arrest overlapped with the area showing stop activity, suggesting that speech arrest may be caused by inhibition of speech production, not by disruption of motor activities. Together, these data provide evidence that neural activity in the frontal cortex may act as an inhibitory control signal that underlies the stopping of ongoing speech production.

Title: The Effects of Delayed Auditory Feedback on the Speech Production of Epilepsy and Parkinson's Disease Patients

Authors: *E. JENSEN[1,2,3], M. OZKER[2,3,1], M. POURFAR[2,4], L. PAN[1,2], A. MOGILNER[1,4], A. FLINKER[1,3,2];
[2]Neurol., [1]NYU Sch. of Med., New York, NY; [3]Comprehensive Epilepsy Ctr., New York, NY; [4]Neurosurg., NYU Langone Hlth., New York, NY

Abstract: Hearing one's self is a fundamental part of the ability to speak fluently and without error. The auditory system continuously monitors self-generated vocal sounds in order to detect vocalization errors, which allows for the adjustment of motor actions to achieve the intended vocalization. Meaning that when the auditory feedback becomes disrupted, the vocalization will become altered in order to compensate for this disruption (e.g. speaking loudly when listening to music over headphones). To study this auditory feedback control during speech production, we implemented a delayed auditory feedback (DAF) paradigm, which strongly disrupts speech fluency by causing stutter-like speech, characterized by syllable repetitions, prolonged words and longer pauses. We studied two different patient populations with a pre-existing conditions of Epilepsy (EP) and Parkinson's Disease (PD) who have undergone deep brain stimulation implantation. Subjects were visually presented with 3-syllable words and 8-word sentences in separate sessions. As they read aloud the presented stimuli, their voice was recorded by a microphone and played back to them with 0, 50, 100 or 200 millisecond delays through earphones. In regards to the PD participants, the sessions were completed once with an activated Deep Brain Stimulation (DBS) and once again with the DBS deactivated. We found that in both EP and PD patients the total articulation duration increased significantly with the amount of delay in both the sentence sessions and word sessions. We examined the data gathered during the sentence sessions to determine whether DAF prolonged words or pauses between the words within the sentence. Both subject groups showed a significant increase in pause durations and articulation durations with relation to delay (EP pauses: $F = 14.81$, $p = 0.00202$, EP words: $F = 13.97$, $p = 0.00249$, PD pauses: $F = 8.528$, $p = 0.0266$, PD words: $F = 7.521$, $p = 0.0336$). We found that PD patients prolonged the articulation duration significantly more than the EP patients, but not the pauses between the articulations. Interestingly, the DBS did not have a significant effect on the articulation duration or the pause durations for PD patients. Overall these results suggest that DAF slows down speech both by prolonging articulation duration and pause durations between the words. We showed that PD patients are more susceptible to the effects of the DAF than the EP patients. DBS for PD patients provides minimal contribution to clear and accurate speech production.

Title: Voice power spectra of sustained vowel and fricative phonemic condition

Authors: *J. FORBES, S. DELMAS, Y. CHOI, B. YACOUBI KEYHANI, E. CHRISTOU; Univ. of Florida, gainesville, FL

Abstract: Phonation and articulation are the building blocks of human speech that are carried out by various frequencies for effective communication. Much of the work characterizing the frequency structure of speech focuses on frequencies from 100 to 5000 Hz where much of the phonetic information of speech resides. However, the successful production of human speech requires the interaction of various systems that are largely controlled by lower frequencies, particularly the motor system. To date, the characterization of human speech below 100 Hz remains largely unexplored. Here, we use an experimental paradigm that incorporates simple sustained production of three different vowels (/a/, /i/, /u/) and a voiceless fricative (/ʃ/). The three vowels are the most common vowels across the world's languages and the fricative represents a speech production that does not include phonation with the vocal folds as the source of the sound comes from turbulence within the vocal tract. We hypothesize that each of these speech conditions will exhibit a robust oscillatory structure below 60 Hz likely related to a central drive that extends through multiple systems. Five healthy adults (3 females) sustained a sound at a comfortable pitch and loudness for 5 seconds. They performed 10 trials producing 3 vowels (/a/, /i/, /u/) and a voiceless fricative (/ʃ/) with a rest of 10 seconds between each trial. For each condition, we analyzed the acoustic structure of the sound output by performing a power spectrum and quantified the absolute and relative power below 60 Hz. We found that each phonemic condition exhibited a similar acoustic structure below 60 Hz. Specifically, each condition had distinct peaks at 2-3 Hz, 4-5 Hz, 18-25 Hz, and 35-55 Hz. Moreover, this finding was consistent across all participants for both the absolute and relative power ($p > 0.3$). Whereas these peaks are present in natural and connected speech, they are often considered a result of language structure and arising from the opening and closing of the mandible during syllables. The presence of these common oscillations across different sustained vowels and a voiceless fricative (with no oscillations being generated vocal fold vibration) suggests that these oscillations may be the result of the central drive to the articulatory structure regardless of speech task. The results also provide a foundation for using these simple speech tasks to explore motor control across systems along with the effects of age and impairment.

Title: Distribution analysis of the tongue motion amongst healthy population

Authors: *V. BRATLAND[1], G. SORESINI[1], D. BONDAVALLI[1], J. L. PATTON[2], H. ESMAILBEIGI[1];
[1]Biomed. Engin., Univ. of Illinois at Chicago, Chicago, IL; [2]Sensory Motor Performance Prog, Rehab Inst. Chicago, Chicago, IL

Abstract: Neural injuries affecting the tongue motion could have dire consequences on speech, swallowing, and breathing. Studies have shown that visualization of the tongue motion could assist in diagnosis of motor deficits impacting this organ. However, to date, all available visualization technologies(Imaging, Electropalatography, Electromagnetic Articulography, etc.) are not portable and require a clinical setting. Our team has developed a discreet Bluetooth-enabled intra-oral wearable that recognizes the tongue's contact inside the oral cavity and quantifies its motion. Hence for the first time enabling a user-friendly approach to studying tongue motion. In this preliminary work, we study healthy tongue motion to evaluate the presence of distinctive patterns. Ten healthy individuals were asked to randomly traverse their entire palate with the tip of their tongue (referred to as "free-exploration"), which motivated individuals to express the full tongue's motor capabilities. Distribution analysis of position, velocity, and acceleration for all individuals, both within and between subjects, suggest that healthy individuals exhibit an individualized motion pattern. This pattern is most distinguishable in the position probability distribution. Higher derivatives exhibit similarities amongst individuals, which could be attributed to physiological limitations. The current work represents an important initial step towards our larger goal of better understanding of both healthy and deficit-induced tongue motion characteristics.

Title: The effect of tDCS on learning a simple motor skill: operantly conditioning the soleus H-reflex

Authors: *L. M. MCCANE[1,2], J. R. WOLPAW[1,3], S. E. D'ANDREA[4], A. K. THOMPSON[5]; [1]Natl. Ctr. For Adaptive Neurotechnologies, Albany, NY; [2]Univ. of Rhode Isalnd, Kingston, RI; [3]Sch. of Publ. Health, State Univ. of New York, Albany, NY; [4]Univ. of Rhode Island, Kingston, RI; [5]Dept. of Hlth. Sci. and Research, Col. of Hlth. Professions, Med. Univ. of South Carolina, Charleston, SC

Abstract: Transcranial direct current stimulation (tDCS) can modulate cortical activity. Excitatory tDCS (positive current into the brain) can enhance motor skill acquisition and retention (Brain Cogn 102: 1-12). The responsible mechanisms are not clear. Remarkably, little is known about tDCS's impact on the spinal cord. Spinal reflexes participate in our everyday movements, change throughout life, and can be modified by experience and injury (J Physiol 596(16): 3469-3491). People can change the size of a spinal reflex through operant conditioning (J Neurosci 29(18): 5784-5792). Acquisition of this simple motor skill (a larger or smaller spinal reflex) requires supraspinal drive and demonstrates task dependent adaption (TDA) (J Neurophysiol 87: 645-652). This study asks if excitatory tDCS affects the magnitude or consistency of operantly conditioned decrease in the human soleus H-reflex.
The study is approved by the MUSC IRB. Neurotypical participants receive Active (excitatory, 2mA, 0.06mA/cm^2, 30 min) or Sham tDCS over the contralateral leg region of primary motor cortex (M1) during soleus H-reflex down-conditioning (3 sessions/wk). Soleus H-reflexes are elicited by tibial nerve stimulation at the popliteal fossa (1ms sq cathodal pulse). Participants maintain soleus background activity in a defined range while comfortably standing. During 4 Baseline (BL) sessions, H-reflexes are simply recorded (control reflex trials, 3 blocks of 75 each). During 12 subsequent Conditioning sessions (CSs), participants practice reducing the reflex size from the mean BL value (reflex conditioning trials, 3 blocks of 75). Visual feedback about H-reflex size occurs after each reflex conditioning trial. H-reflex/M-wave recruitment curves and control reflexes (n=20) are collected at the start of each session. A 1-month follow-up (FU) session examines skill retention.
To date, 8 participants (4 women, 5 Active tDCS, Age 22-36) have completed the study. Final conditioned H-reflex sizes (mean of CSs 10-12 as % BL mean) were 58, 67, 90, 99, 215% for Active and 71,115,125% for Sham participants. Average TDAs for CSs 1-4, 5-8, 9-12 were (in % of means of the control trials): +10.9, -4.1, -6.7% and +0.5, +3.6, -6.4%, Active and Sham,

respectively. In 4 Active participants who completed the FU visit, the conditioned reflexes were 16, 57, 98, and 233% and TDA was -2.5, -2.6, -38, and +37%. In 2 Sham participants who completed the FU visit, the conditioned reflexes were 27 and 59% and TDAs were -6.5 and -8.5%. The study is ongoing. The results of this study may improve understanding of tDCS's impact on motor skill acquisition and guide its therapeutic use a neuromodulator.

Title: Operant down-conditioning of the soleus H-reflex in chronic stroke patients with spastic hemiparesis

Authors: *A. K. THOMPSON[1], C. R. GILL[1], W. FENG[3], R. L. SEGAL[2];
[1]Dept. of Hlth. Sci. and Res., [2]Dept of Hlth. Professions, Med. Univ. of South Carolina, Charleston, SC; [3]Dept. of Neurol., Duke Univ. Sch. of Med., Durham, NC

Abstract: Introduction: Through operant conditioning, spinal reflex behaviors can be changed. Previous studies in rats indicate that the sensorimotor cortex and corticospinal tract are essential in producing and maintaining reflex changes induced through conditioning. In individuals with incomplete spinal cord injury (SCI), an operant down-conditioning protocol can decrease the soleus H-reflex size and improve walking (J Neurosci 2013;33:2365-2375; J Physiol 2021;599:2453-2469), suggesting that partially preserved spinal cord can support conditioning-induced plasticity and benefit from it. This study aimed to exam whether down-conditioning can decrease the soleus H-reflex in people with supraspinal injury, cortical or subcortical stroke.Methods: Operant down-conditioning was applied to the soleus H-reflex in 12 participants (37-76 years old, 1.5-11.5 years post-stroke) with spastic hemiparesis due to chronic stroke. Each participant completed 6 baseline and 30 conditioning sessions over 12 weeks. In each baseline

session, 225 control H-reflexes were elicited without any feedback on H-reflex size. In each conditioning session, 225 conditioned H-reflexes were elicited while the participant was asked to decrease H-reflex size and was given visual feedback as to whether the resulting H-reflex was smaller than a criterion value. Before and after conditioning, 10-m walking speed was measured. Results and Discussion: In 6 out of 12 study participants with stroke, H-reflex size decreased significantly over the course of conditioning ($p<0.05$) and their walking speed was significantly increased (+0.14m/s) after conditioning. Their final reflex size (70±18% baseline, mean±SD) was similar to that in people with chronic SCI (69±27%, J Neurosci 2013;33:2365-2375), yet its composition and development differed from that in SCI; it consisted of robust within-session conditioning-task-dependent change (-12%) and slow and limited across-session long-term change (-18%), in contrast to 7% within-session change and -14% long-term change in SCI. In other 6 participants with stroke, H-reflex did not become smaller (final size: 104±8% consisted of -14% within-session change and +18% long-term change) and the walking speed did not change (+0.00m/s). Differences in the extent of within-session task-dependent adaptation, the rate of long-term plasticity development, and the conditioning success rate across populations may reflect a potentially critical role of supraspinal (i.e., cortical) activity in producing the spinal cord long-term plasticity.

Title: Effects of dry needling of the medial gastrocnemius on ankle range of motion and spinal reflexes in people with and without chronic stroke

Authors: *G. SEIF[1], A. PHIPPS[1], M. MCLEOD[1], J. DONNELLY[2], C. FERNANDEZ-DE-LAS-PENAS[3], A. ZULOAGA[1], R. A. MCLAUGHLIN[1], B. DELLENBACH[1], A. THOMPSON[1];
[1]The Med. Univ. of South Carolina, Charleston, SC; [2]Univ. of St. Augustine, Miami, FL; [3]Univ. Rey Juan Carlos Facultad de Ciencias de la Salud, Madrid, Spain

Abstract: Introduction: To define the clinical utility of dry needling (DN), it is essential to understand its neurophysiological impact on CNS pathways involved in sensorimotor function.

Mechanical actions of DN are as follows: DN that targets trigger points (TrP) can restore muscle fiber length by disrupting dysfunctional motor end plates and stretch the shortened sarcomeres. DN stimulates nociceptors. DN can activate serotonergic and noradrenergic systems and influence the impact of sensory inputs in the spinal dorsal horn. DN increases the local muscle blood flow and oxygen saturation. While the understanding of mechanisms of actions continues to improve, to date, how DN affects spinal and supraspinal somatosensory processing is not well understood. Thus, the purpose of this study was to examine neurophysiological effects of DN on spinal reflexes in people with and without stroke.
Methods: Before, 0, 90 min, and 72 hours after a single bout of DN of a TrP in the medial gastrocnemius (MG), the triceps surae (i.e., soleus, MG, and lateral gastrocnemius (LG)) H-reflexes and reciprocal inhibition were examined; and the perceptual threshold (PT) of cutaneous distal tibial nerve (DTN) and superficial peroneal nerve (SP) stimulation were determined. All measurements were made while the participant stood and maintained natural standing posture and soleus muscle activity. Ankle dorsiflexion (DF) range of motion (ROM) was also measured.
Participants: 14 adults ages 22-57 years old without stroke and 11 adults ages 35-70 with clinical spasticity due to stroke. **Results:** In people without stroke, at 72 hours after DN the MG H-reflex amplitude was decreased (-13% from pre DN, p=0.003 by paired t-test); reciprocal inhibition of the soleus was increased (+68%, p=0.019); PT for the DTN stimulation was decreased (-19%, p=0.009); and ankle DF ROM was increased (+4 deg, p=0.003). In people with stroke, the ankle DF ROM was increased at 0 (+4.6 deg, p=0.000), 90 min (+3.1 deg, p=0.024), and 72 hours post (+4.9 deg, p=0.001), while reflex changes were inconsistent across individuals.
Discussion: In persons without stroke, DN produces neurophysiological effects in multiple spinal pathways that are clearly present at 72 hours post. In persons with stroke, DN increases DF ROM; yet the current sample size is not sufficient to elucidate its impact on spinal neurophysiology. To overcome the neurophysiological heterogeneity of people with stroke, further studies are currently underway. Understanding the neurophysiological effects of DN will help clinicians determine optimal DN applications, including the timing of post-DN intervention implementation.

Title: Altered task-dependent modulation of cutaneous reflexes in people with chronic incomplete spinal cord injury

Authors: *A. M. PHIPPS, A. K. THOMPSON;
Dept. of Hlth. Sci. and Research, Col. of Hlth. Professions, Med. Univ. of South Carolina, Charleston, SC

Abstract: In individuals without neurological injuries, cutaneous (CUT) reflexes to non-noxious stimuli are task-dependently modulated (Brain Res. 1993:613:230-238). Currently, CUT reflexes in ambulatory individuals with spinal cord injury (SCI) are not well understood. The purpose of this study was to examine CUT reflexes in the triceps surae during standing and walking in SCI. Eight individuals with chronic incomplete SCI and eleven age-matched controls free from injury participated in this study. CUT reflexes were elicited by stimulating the sural (SR), superficial peroneal (SP), or distal tibial nerve (TN) near the ankle of the clinically more spastic leg in SCI and the left leg in controls. For each nerve stimulation, a 5 x 1-ms pulse train (200 Hz) at ≈ 1.7 x radiating threshold was delivered while the participant stood upright and while they walked at his/her comfortable speed on a treadmill for 4.5-6 minutes. Electromyography was recorded from the triceps surae (soleus (SOL) and medial (MG) and lateral gastrocnemius (LG)) ipsilateral to the stimulation site. Short (50-80 ms post-stimulus, SLR) and medium (80-120 ms, MLR) latency CUT reflexes in the triceps surae were quantified in standing and during the early stance phase of walking and normalized to the maximum M-wave (M-max) elicited by single pulse posterior tibial nerve stimulation during standing.
In the SCI group, following SR stimulation, the SOL SLR showed greater suppression in walking (-0.58% M-max) compared to standing (-0.24%) ($p = 0.022$ by paired t-test). However, in controls, the SLR was different following SP stimulation, showing a reversal from excitation in standing (0.43, 0.14, and 0.05%) to suppression during walking (-0.62, -0.49, and -0.21%) for the SOL ($p = 0.02$), MG ($p = 0.035$), and LG ($p = 0.03$), respectively. SCI did exhibit reflex reversal in the MG MLR following SP stimulation (0.01% standing vs. -0.21% walking, $p = 0.042$). A reversal of the MLR was also seen in the control group following SP stimulation, but in the SOL (0.36% standing vs. -0.83% walking, $p < 0.001$). In controls, following SR stimulation, both the SOL and MG showed greater suppression in walking compared to standing ($p = 0.028$ and $p = 0.014$, respectively).
CUT reflexes are task-dependently modulated in individuals with SCI, exhibiting both magnitude differences (i.e. greater suppression) and reflex reversal. Present, yet altered CUT reflexes in SCI, may serve as unique therapeutic training targets for guiding beneficial plasticity through neuromodulation interventions for rehabilitation in people with SCI.

Title: The effects of speed and weight on the soleus and lateral gastrocnemius muscle activity during walking

Authors: *B. A. POULIOT, A. K. THOMPSON;
Hlth. Sci. and Res., Col. of Hlth. Professions, Med. Univ. of South Carolina, Charleston, SC

Abstract: Introduction: Previous studies have shown differential contribution of Ia, II, and Ib afferents to the stance phase soleus activity in human locomotion (J Physiol 2000;523:817-827; J Neurophysiol 2005;93:167-177). To further our understanding of afferent contribution to locomotor control, here we investigated the soleus and lateral gastrocnemius (LG) H-reflexes and muscle activity at different walking speeds with different weight bearing conditions. Methods: To ensure the robust impact of fixed weight and speed conditions, all participants were young women of similar physical size (27±6 yr, 163±4 cm, 65±9 kg) with no history of neurological or orthopedic injury. Each participant walked on the treadmill at 1.0 and 1.5 m/s with or without an additional 20.4 kg, which was worn as a set of weighted belt and vest, either on the front or back of the body. During each of the six (1.0 and 1.5 m/s speeds x none, front, and back weight conditions) ≈10-minute treadmill walking bouts, the soleus and LG locomotor EMG and H-reflexes, ankle, knee, and hip joint motion, and ground reaction force (GRF) were measured.Results: Overall, speed and weight affected the step cycle duration (≈230 ms difference across conditions) but produced only minor effects on hip and knee joint motion and their peak flexion/extension timings (i.e., all effects remained within 10° or 4% gait cycle range). Speed clearly affected ankle motion; late stance dorsiflexion (DF) was ≈5° less and end stance plantarflexion was ≈10° more and they reached the peak angles 4-5% earlier in gait cycle with 1.5 m/s than 1.0 m/s. Corresponding to the impact of speed on ankle joint motion, the late stance EMG amplitude with 1.5 m/s was nearly 200% of that with 1.0 m/s (178-193% for soleus and 195-214% for LG). The late stance H-reflexes were also larger with 1.5 m/s than with 1.0 m/s but to a lesser extent (+12-30%). Further analyses of mid-late stance ankle joint motion and GRF revealed slower DF (-5°/s) and 2-3x higher rate of force development (RFD) with 1.5 m/s than with 1.0 m/s, suggesting the occurrence of enhanced loading with 1.5 m/s during this phase.

Added weight appeared to enhance DF speed reduction and RFD increase. Discussion: Walking speed has significant impact on plantarflexor activity and ankle joint motion in the mid-late stance phase. Small increases in H-reflex amplitude relative to background EMG, together with robust increases in RFD and reductions in DF, observed during 1.5 m/s walking support a possibility that load-sensitive afferents play a major role in increasing plantarflexor activity in response to increasing gait speed. To better assess the effects of added weight, further analyses are currently underway.

Title: Investigating the role of low level reinforcement reflex loops in insect locomotion

Authors: *C. GOLDSMITH[1], R. D. QUINN[2], N. SZCZECINSKI[1];
[1]Mechanical and Aerospace Engin., West Virginia Univ., Morgantown, WV; [2]Mechanical and Aerospace Engin., Case Western Reserve Univ., Cleveland, OH

Abstract: Insects have been identified as highly capable walkers, but how the insect nervous system controls locomotion is not presently understood. In particular, it is unknown what precise mechanisms exist in the ventral nerve cord (VNC) to control locomotion, and the information passed between this ``lower level" and the ``upper level" areas of the head ganglia to facilitate this control is unclear. In this work, we seek to explore these questions by investigating how systems traditionally described as ``positive feedback" may give rise to stepping in the VNC. We focus on the `reflex reversal' of insect joints between a resistance reflex (RR) and an active reaction (AR) in response to joint flexion, as well as the excitement of populations of descending dorsal median unpaired (desDUM) neurons from limb strain as our primary reflex loops. We discuss the development of a neuromechanical model of the stick insect (*Carausius morosus*) femur-tibia (FTi) and coxa-trochanter (CTr) joint control networks "in-the-loop" with a physical robotic limb. We based our network on mappings of the non-spiking interneuron (NSI) joint control network for FTi joint, extrapolated network connectivity based on known biological responses, and previously developed morphological mechanisms to produce sideways stepping. To determine the mechanisms behind reflex reversal, we selectively inhibited the network's sensory afferents of the femoral chordotonal organ (fCO) and observed the reflexes of the simulated joint to a ramp-and-hold flexion stimulus. We find that inhibiting the network's flexion

position and velocity afferents enacts a reflex reversal in the FTi joint. We also explored the results of the full network sustaining steady locomotion on our test limb. Our findings suggest that the reflex reversal and limb strain reinforcement mechanisms are both necessary but individually insufficient to produce and maintain rhythmic stepping in the limb, which can be initiated or halted by brief, transient descending signals. Removing portions of this feedback loop or creating a large enough disruption can halt stepping independent of the higher-level centers. We conclude by discussing why the nervous system might control joint behavior in this manner, as well as how to apply these findings to generalized nervous system understanding and improved robotic control.

Title: Differential effect of quadriceps muscle and femoral nerve stimulation onto Soleus H-reflex.

Authors: *C. CUADRA[1,2], S. L. WOLF[1], M. A. LYLE[1];
[1]Div. of Physical Therapy, Sch. of Med., Emory Univ., Atlanta, GA; [2]Kinesiolgia, Univ. Andres Bello, Vina del Mar, Chile

Abstract: Intermuscular feedback from proprioceptors (e.g. muscle spindle, Golgi tendon organ [GTO]) has an important role in motor coordination, but the unique action of individual circuits is not well understood. A better understanding would help clarify their functional role during movement and how alterations caused by neuropathology contribute to motor impairments. Traditionally, nerve stimulation has been used to evaluate intermuscular neural effects, but this technique activates sensorimotor axons based on diameter, which biases spindle feedback. We have recently found that quadriceps muscle stimulation evoked twitch contractions result in intermuscular inhibition with minimal excitation of spindle axons compared to nerve stimulation. We can use this approach to study intermuscular feedback in patient populations (e.g., stroke), but our prior study required a steady ~20% max soleus contraction that could be challenging for patients. In this study, we evaluated the influence of intermuscular feedback from quadriceps onto Soleus H-reflex (Sol-HR) generated by pairing stimulation of tibial nerve (TNS) with femoral nerve and quadriceps muscle stimulation (FNS, QMS). We hypothesized that FNS, but not QMS, will generate an increase in Sol-HR when spindle afferent volleys from TNS and

FNS/QS are timed to reach the spinal cord concurrently (excitation periods). We also predicted that inhibition of Sol-HR produced by FNS and QMS will be similar if inhibitory volleys (GTO/Recurrent inhibition) from FNS/QMS are timed to arrive onto Sol motoneurons concurrently with TNS volleys (inhibitory periods).13 participants were seated on a dynamometer with ankle fixed in an ankle immobilizer. Participants targeted 6-10% of their Sol MVIC during H-reflex recruitment and testing trials. Sol-HR size was compared when recorded with TNS only (test reflex, ~40-60% Sol-HR max) and when TNS was paired with either FNS or QMS (conditioned reflex). Test and conditioning stimuli were randomly alternated over ~20 trials for each. FNS and QMS intensities (~1.5 vs ~2x motor threshold) were selected so that knee extension torque was matched between both stimulation conditions. As predicted, FNS resulted in significantly greater excitation (larger Sol-HR) compared to QMS during excitation periods. QMS and FNS produced similar levels of inhibition for each of the inhibitory periods. Our results suggest that muscle twitch contractions may be useful to bias intermuscular inhibitory pathways with reduced influence from spindle feedback. In addition to force dependent GTOs, inhibitory feedback could arise from recurrent inhibitory pathways.

Title: The effect of task complexity on h-reflex gain in children with spastic cerebral palsy

Authors: *B. C. CONNER[1], Z. F. LERNER[2,1];
[1]Col. of Med. - Phoenix, Univ. of Arizona, Phoenix, AZ; [2]Dept of Mechanical Engin., Northern Arizona Univ., Flagstaff, AZ

Abstract: Cerebral palsy (CP) is a pediatric onset movement disorder caused by injury to the developing brain. A common feature in CP is spasticity, which is characterized by exaggerated stretch reflexes that can lead to inefficient movement patterns. Understanding the underlying mechanisms of these exaggerated reflexes may be used to inform present and future interventions. In healthy individuals, it has been observed that the soleus H-reflex gain, a measure of stretch reflex excitability, decreases with increased task complexity. It was

hypothesized that this behavior reflects a supraspinal mechanism for preserving the motor pool for the task at hand. The purpose of this exploratory study was to determine the effect of task complexity on stretch reflex excitability in CP. Six children with CP (12 to 18 years, Gross Motor Function Classification System levels I - III, spastic hemiplegic and diplegic distributions) were recruited for this study. Surface electromyography (EMG) sensors were placed over the soleus of the non-dominant leg of each participant for measuring reflex responses and muscle activity. Stimulating electrodes were placed in the popliteal fossa of the participant's non-dominant leg for stimulation of the posterior tibial nerve. Stimulations were 1 ms square-wave pulses ranging from 1 - 30 mA. Reflex responses were evoked at a low level of stimulation and progressively increased until a visible M-wave was present. Reflex responses were then recorded for participants under two conditions: 1) standing on both legs (less complex condition), and 2) standing on the non-dominant leg (more complex condition). Fifteen reflexes were recorded for each condition where the associated M-waves were within ± 10% of one another to ensure a consistent stimulus strength. Background EMG (bEMG) activity was measured 50 ms before each respective stimulation. H-reflex amplitudes were measured as the peak-to-peak magnitude of the raw EMG signal. H-reflex gain was calculated for each condition as the change in H-reflex amplitude relative to the change in mean bEMG activity within a condition. Four out of six participants had an increase in H-reflex gain (31 ± 23%) with increased task complexity, representing an atypical response of increased stretch reflex excitability. The two participants who had a typical response of decreased H-reflex gain (-21 ± 7%) had undergone a selective dorsal rhizotomy (SDR). These findings offer insight into the effect of CP and SDR procedures on the supraspinal control of stretch reflexes with changes in task complexity, which could have important implications for rehabilitative interventions that seek to modulate these reflex responses.

Title: Stretch reflexes reflect volitional activity from several muscles about a joint during movement

Authors: *Z. VILLAMAR[1,3], D. LUDVIG[1,3], E. J. PERREAULT[1,3,2];
[1]Biomed. Engin., Northwestern Univ., Evanston, IL; [2]Physical Med. and Rehabil., Northwestern Univ., Chicago, IL; [3]Shirley Ryan AbilityLab, Chicago, IL

Abstract: The stretch reflex is a fundamental building block of motor function, modulating its sensitivity across tasks to augment volitional control. Reflex amplitudes increase with the background activity of the stretched muscle, known as gain scaling. Most studies of gain scaling have been performed in simple, isometric tasks without much co-contraction but amplitude modulation also exists during movement and tasks with co-contraction. Recent microneurography work shows that afferent activity from muscle spindles during movement represents the balance of activity within agonist and antagonist muscles acting about a joint. The objective of this study was to determine if the stretch reflex also reflects this balance of activity during movement and if this balance can account for the reported differences in reflex sensitivity between posture and movement.

Data were collected from 18 subjects. Each had their elbow fixed to a rotary motor via a fiberglass cast. We used surface electromyography to record activity from two elbow flexors and extensors during cyclic movements spanning 20 degrees. Subjects also performed isometric contractions at the mean posture of the movement trials; contraction levels spanned the range of activations measured during movement. The motor applied small pseudorandom perturbations during all trials to elicit stretch reflexes. Linear mixed effects models were used to determine how stretch reflex magnitude varied with agonist and antagonist muscle activity during movement compared to during posture.

Reflexes during movement were sensitive to agonist and antagonist background activity, as assessed by comparing models of reflex activity that considered background activity in the homonymous muscle to those that also considered agonists and antagonists. R^2 increased from 0.54 to 0.84 ($p = 0.004$) when all muscles were considered; activity in antagonists reduced reflex amplitude whereas agonists increased amplitude. Gain scaling from agonists was 75% lower in the flexor muscles during movement relative to posture and 89% lower in the extensor muscles (both $p = 0.0001$), indicating the balance of activity contributing to reflex modulation cannot account for all differences between posture and movement. In contrast, there were much smaller task-dependent changes in the effect of antagonist activity on reflex amplitude. Our results show how stretch reflexes at the elbow reflect the state of agonists and antagonists, and how gain scaling for all muscles changes between posture and movement. We identified two distinct mechanisms for modulating reflex sensitivity in the many tasks involving co-contraction and movement.

Title: Effects of early life adversity on stress-induced alcohol consumption and the VTA CRF system

Authors: *J. M. BRETON, K. G. BATH;
Psychiatry, Columbia Univ., New York, NY

Abstract: Experiencing early life adversity (ELA) increases the risk for developing substance use disorders later in life. Emerging evidence suggests that ELA alters reward and stress circuits, providing a potential mechanism underlying vulnerability to addiction. Animal models of ELA, such as the limited bedding and nesting (LBN) paradigm, may provide insights into the neurobiological factors that contribute to risk for drug seeking behavior. To date, there have been mixed findings as to whether LBN protects against or augments later-life drug seeking, with effects differing based on the class of drug, mode of administration, and sex of the subject. An important and less well understood factor that contributes to drug seeking is the state of the animal, including current or recent experience of stress. Indeed, a secondary stressor later in life may augment drug seeking in animals that have previously experienced ELA. However, little is known regarding how ELA might alter stress-induced drug seeking. Here, we tested whether exposure to an acute stress in the form of foot shocks altered ethanol consumption in control and LBN reared mice. Adult male and female mice in both groups underwent several weeks of voluntary ethanol consumption using a two-choice continuous access paradigm. Once stable drinking was established, mice were given a short series of foot shocks. Ethanol preference was temporarily altered after acute stress. Specifically, ethanol preference was reduced in LBN females for several days following the stressor before restabilizing to pre-shock levels. In addition, we assessed the effects of LBN on reward circuitry. We focused on the ventral tegmental area (VTA), a critical node for both stress and reward processing. The corticotropin releasing factor (CRF) system in the VTA has been previously linked with ethanol consumption and with stress-induced reinstatement of drug seeking. Here, we found that LBN increases CRF binding protein expression levels in the VTA, in both male and female mice. Additional work will be required to assess whether these changes in the VTA are functionally related to stress-induced changes in ethanol seeking. Overall, this work provides critical insight into the effects of ELA on stress-related behaviors, their circuits and the overlap between stress and the risk for addiction.

Title: Effects of Maternal Separation on Initial Reward to Alcohol in Mice: Influence of b-endorphin & Sex

Authors: M. R. SCOPANO[1], H. E. JONES[1], ***J. E. GRISEL**[2];
[1]Bucknell, LEWISBURG, PA; [2]Bucknell Univ., Lewisburg, PA

Abstract: Adverse childhood experiences, ACEs, affect 61% of the population and are associated with chronic health problems, mental illness, and substance misuse in adulthood (Center for Disease Control, 2020; Pilowsky et al., 2009). The response to stressful stimuli, such as an ACE, relies upon the opioid peptide β-endorphin which regulates the stress response and has been implicated in the risk for excessive drinking (Nentwig et al., 2019). Clinical research has demonstrated that initial sensitivity to the rewarding effects of alcohol is associated with stress sensitivity and predicts the risk of developing an alcohol use disorder, or alcoholism (e.g., Ray et. al, 2010, 2013). Here, we explore the effects of maternal separation on initial sensitivity to alcohol reward in mice, as measured using a single-exposure conditioned-place preference paradigm (SE-CPP) based on prior research (Grisel et al., 2014). Using female and male wildtype C57BL/6J (B6, n=22) mice and beta-endorphin-deficient mice (B6.129S2-Pomc tm1Low /J; KO, n=20), with sex as a biological variable, rodents were subjected to either maternal separation (MS, n= 3 KO♂**,** 4 KO♀, 7 B6♂, 6 B6♀) or no MS (CTL, n= 5 KO♂**,** 8 KO♀, 1 B6♂, 6 B6♀) for 3hr each day from postnatal days (PND) 5 to 18. They were weaned and group housed in standard conditions at PND-21. On PND-26, subjects were assessed open-field activity (OFA) and conditioned and tested as adolescents or adults using the SE-CPP protocol between PND-28 to -32. The protocol was counterbalanced so each animal received one injection of ethanol and one of saline in either of two distinct contexts on day 1 or day 3 of a five-day conditioned place preference experiment (days 2 & 4 mice were left undisturbed in their home cages) and tested for conditioned bias on day 5 following a saline injection. In adolescent mice, the effect of maternal separation depended on strain and sex. In KO females, maternal separation decreases initial rewarding effects of ethanol; whereas, in B6 females had no effect on initial subjective reward to alcohol. These data suggest that b-endorphin mitigates the effect of maternal separation on alcohol reward during adolescence. These data support the contention that sex differentially impacts vulnerability to effect of stress on alcohol use disorders.

Title: The effects of postnatal maternal ethanol consumption on maternal care and offspring anxiety-related behaviors

Authors: *A. E. HOWARD, C. M. KREITLER, S. L. P. LIPPI;
Angelo State Univ., San Angelo, TX

Abstract: Children of alcoholic parents are at a greater risk of experiencing neglect and/or developing a mental illness later in life (Mosel, 2021). The current research was to assess the effects of ethanol use on maternal care and offspring anxiety-related behaviors using a mouse model. Maternal behavior is a common measurement of neglect in mice. Three C57BL/6J female mice were used to breed in-house and were randomly separated into one of two conditions: control or ethanol administration (EA). This study replicated an intermittent two-bottle choice paradigm, one of water and the second of 10% ethanol solution, to simulate voluntary binge drinking in rodents. The amount of time interacting with one's pups, time spent nest building, and time away from their nest over a 30-minute period was recorded as maternal behavior. After weaning on PND 21, the offspring from each mother were tested using the Open Field Test (OFT), Elevated Zero Maze (EZM), and Forced Swim Test (FST) starting on PND 28 to measure anxiety and depression-like behaviors. An independent sample t-test (ethanol v. control) was run for each of the behavioral tests. A paired-sample t-test was run to compare weights of the dams' drinking bottles to determine how much water and ethanol was drunk. The results found were not in support of the initial hypothesis. The EA mothers drank significantly more water than ethanol throughout the administration period, which may have contributed to the insignificant maternal behavior results and lack of anxiety and depression-like behaviors in the EA offspring. This study showed that limited binge drinking has little effect on offspring anxiety symptoms during adolescence.

Title: Sex differences in resilience induced by chronic, predictable stress in mice

Authors: L. KENNEY[1], *S. SMITH[2];
[1]SUNY Downstate Med. Ctr., NEW YORK, NY; [2]SUNY Downstate Med. Ctr., Brooklyn, NY

Abstract: Most studies investigating stress during adolescence focus on its negative effects, while few explore its benefits during this critical period. Rodent studies mostly utilize males, despite evidence that females have a higher risk of developing mood and anxiety disorders. The goal of this study was to explore the effect of chronic, predictable stress during the pubertal period in both male and female mice on measures of anxiety and depression. Mice were restrained for 2 hours/day over 2 weeks, beginning at the onset of puberty (PND 35 for females and PND 38 for males). They were then tested with the elevated plus maze (EPM) and forced swim test (FST) to assess avoidance behavior and coping strategy, respectively. Restrained female mice were significantly less immobile in the FST compared to controls (R: 37% ± 0.04, C: 56% ± 0.04, $t(26)= 3.6$, $p= 0.001$), suggesting development of resilience to depressive behavior. Interestingly, this effect was not seen in male mice, as restrained and control mice were equally immobile (R: 58% ± 0.12, C: 52.6% ± 0.17, $t(17)= 0.69$, $p=0.50$). Altogether, results indicate that chronic, predictable stress during puberty prevents a depressive phenotype in female mice only.

Abstract: Exposure to early life adversity (ELA) is associated with heightened risk for the development of anhedonia, depression and substance use disorder. Adverse outcomes may reflect ELA-linked impacts on reward pursuit including blunted reward sensitivity, more habitual control of behavior, and steeper delayed discounting. However, the effects of ELA on the development of reward-motivated behavior and their neural underpinnings remain poorly understood. Here, in a probabilistic bandit task, we studied the sensitivity of mice raised under

control or ELA conditions to reward contingencies and rates of adaptation to changing contingencies across reward rich and reward poor environments. Overall, mice adapted their choice patterns when reward contingencies changed and were also sensitive to environmental richness as defined by the frequency of rewards in recent history. Importantly, mice exposed to ELA adapt more slowly when contingencies changed and showed deficits in sensitivity to reward contingencies as a function of environmental richness. Ongoing computational modeling and molecular work will explore the link between behavioral outcomes and striatal dopamine function.

Title: Sex-differences in threat anticipation and related circuitry as a consequence of early life adversity

Authors: *C. DEMAESTRI[1], D. OFRAY[1], M. CRITZ[1], K. G. BATH[2];
[2]Psychiatry, [1]Columbia Univ., New York, NY

Abstract: Experiencing early life adversity (ELA), such as resource scarcity, is associated with increased risk for anxiety disorders, with females having a two-fold greater risk compared to males. A core feature of many anxiety disorders is excessive anticipation of threat. In particular, the startle response is a suitable and translational behavior to study threat anticipation because it is reliably enhanced when threat is cued and it is conserved across species. ELA alters the development of threat circuitry, with excessive recruitment of the central amygdala (CeA) and bed nucleus of the stria terminalis (BNST) as well as altered expression of corticotropin-releasing hormone (Crh). Here, we sought to test for sex- and ELA-specific changes in activation of Crh cells within these regions after mice engage in a task that tests threat responding. The goal is to better understand the neural mechanisms of excessive threat anticipation. We used the limited bedding model of ELA to test its effects on startle response. We found that mice startled to a loud noise when that noise was cued by a conditioned tone, suggesting accurate elevation of vigilance. However, female ELA mice also showed enhanced startle when threat was uncued, suggesting heightened reactivity. We carried out studies assessing immediate early gene activation, Crh cell number and the overlap of these two markers in the BNST and CeA to test

for possible mechanistic underpinnings of this sex disparity in startle response. This work will lay the groundwork for future studies aimed at identifying sex-specific vulnerability to pathology and will contribute to the development of effective treatments that are individualized to the experience and sex of the individual.

Title: Fkbp51 in glutamatergic forebrain neurons mediates beneficial effects of moderate early life adversity on hippocampal structure and function.

Authors: L. VAN DOESELAAR, H. YANG, S. MITRA, J. BORDES, C. ENGELHARDT, B. M. LEA, J. DEUSSING, B. BOULET, M. CZISCH, M. EDER, M. V. SCHMIDT;
Max Planck Inst. of Psychiatry, Muenchen, Germany

Abstract: Exposure to stressors in early in life can be a risk factor for later psychopathologies, but may also enhance stress resilience, dependent on the genetic background and later life conditions of an individual. The chaperone FKBP51 has been implicated in mediating such effects, but the underlying mechanism are still largely unclear. Furthermore, recent research has highlighted the differential responses to stress between sexes. In this study, we addressed the question whether early-life stress exposure can enhance cognitive performance in adulthood and if FKBP51 plays a role in this process. Mice with a conditional deletion of FKBP51 in forebrain glutamatergic neurons ($FKBP51^{Nex}$) or wild-type (WT) litter mates were either subjected to early life stress in the form of limited nesting and bedding material (ELS) or left undisturbed. Cognitive testing in adulthood at 5 - 7 months of age revealed that predominantly in female offspring ELS resulted in an improved cognitive performance specifically under high-stress conditions, and this effect was absent in $FKBP51^{Nex}$ mice. Structural MRI following the behavioral tests revealed genotype or ELS-induced volumetric changes in cortical brain regions or the BNST and cerebellum, respectively. In addition, RNA bulk sequencing revealed interesting differences in expression profiles within the ventral hippocampus of female mice, whereas field potential recordings in CA1 dorsal hippocampal slices of a separate cohort of female $FKBP51^{Nex}$ and WT mice exposed contrasting LTP induction profiles in response to a corticosterone application. Taken together, our results show that moderate exposure to early life adversity can enhance resilience in a sex-dependent manner by improving cognitive performance

under high stress conditions as a result of molecular, functional and structural changes. By further unraveling the structural and molecular pathways responsible for this pro-resilient phenotype, we will gain valuable insights in potential intervention and treatment strategies.

Title: Inhibition of the psychiatric risk factor FKBP51 reverses long-term effects of early life stress on social behavior

Authors: *J. BORDES[1], S. KARAMIHALEV[1], L. MIRANDA[1], M. PÖHLMANN[1], L. BRIX[1], L. VAN DOESELAAR[1], C. ENGELHARDT[1], J. DEUSSING[1], G. WINTER[2], F. HAUSCH[3], B. MÜLLER-MYHSOK[1], A. CHEN[1], M. V. SCHMIDT[1];
[1]Max Planck Inst. of Psychiatry, Munich, Germany; [2]Ludwig-Maximillians-Universität, Munich, Germany; [3]TU of Darmstadt, Darmstadt, Germany

Abstract: Stress-related disorders are drastically increasing the burden on society. In particular depression has been described by the WHO as the leading cause of worldwide disability and affects an estimated 264 million people. However, the classical anti-depressant treatment options rely on a poorly understood mechanism which show an enormous variability in efficacy and high numbers of relapse. Interestingly, human genetic studies observe a profound link between the FKBP5 gene (coding for the FKBP51 protein) and the risk for stress-related disorders. The current study investigates the role of the novel anti-depressant drug target, the FKBP51 inhibitor SAFit2 as a potential novel drug-treatment for stress-related disorders. Mice were exposed to early life stress (ELS) using limited nesting and bedding material and were treated with SAFit2 during the entirety of the stress protocol. Male offspring of stress or control litters with or without treatment were then tested for social behavior during adolescence and adulthood in the social box, an enriched environment allowing continuous tracking of multiple mice over several days. Exposure to ELS significantly affected the hierarchical position of the animals during adolescence and adulthood, with stressed animals being more likely to become subordinate compared to nonstressed mice. Interestingly, this effect was reversed by the treatment with SAFit2 in stressed mice. Moreover, a similar effect was observed on social approaches, in which

stressed animals showed a lower social interest then nonstressed and stressed, SAFit2 treated animals. In conclusion, the current study shows that ELS has a strong effect on social behavior in mice, leading to an alteration in social hierarchy. This effect can be fully rescued by administering the FKBP51 antagonist SAFit2 during the stress exposure. Future experiments include to investigate short-term social behavioral effects using DeepLabCut analysis in a social interaction task and investigating the molecular profile using RNA sequencing in important brain regions for social behavior and stress. The current study underlines the importance of FKBP51 in stress physiology and stress-related disorders. Importantly, the results further encourage the clinical development of FKBP51 inhibitors for the treatment of stress-related disorders.

Abstract: Objective To determine the anxiolytic effect of the compound Gardenin A using unconditioned anxiety tests. **Justification** The drugs used for the treatment of anxiety disorder have severe adverse effects, which has led to the search for new anxiolytic substances. Medicinal plants have presented great potential as a source of new bioactive substances. Gardenin A (GA), extracted from the *Gardenia gummifera* plant, exerts antihyperlipidemic and hepatoprotective effects against non-alcoholic fatty liver disease, in addition to being a vessel-relaxing and antioxidant. GA is an important component of medicinal plants with anxiolytic and antidepressant effects, in the present investigation, this function was evaluated with unconditioned behavioral tests. **Methodology** We used three groups of eight mice each, from the CD1 strain. The mice were administered 100 µL of an oral GA compound, using concentrations of 1, 10, and 25 mg/kg per weight. After one hour of administration of the compound, the mice were subjected to three unconditioned tests (elevated plus maze, light/dark box, open field) to

generate anxiety and so evaluate if the compound decreases it. The results are compared with positive control of clonazepam and saline solution (vehicle). **Results** In the elevated plus maze, mice treated with the three different concentrations of GA showed similar behavior to mice treated with clonazepam, by showing an increase in the number of entries, exploration time, and distance traveled in the open arms. No significant differences were observed concerning the three concentrations tested. In addition, the dwell time and the distance traveled in the closed arms was less, compared to the vehicle. In the light/dark box the mice treated with GA showed a greater number of entries in the illuminated area of the camera, as well as they stayed longer in it. In the open field, mice treated with GA and with clonazepam stayed longer and traveled a greater distance in the central area, compared to the vehicle that stayed longer in the periphery area (safe zone). **Conclusions** The results suggest that GA induces anxiolytic effects in mice subjected to unconditioned anxiety tests, as behaviors similar to clonazepam (anxiolytic agent) were observed.

Title: Effects of bisphenol-a (BPA) exposure on anxiety behaviors necessary for survival

Authors: *K. CARDONA[1,2], C. VELÁZQUEZ[2], K. VEGUILLA[2], A. RIVERA[2];
[1]Anat. and Neurobio., Univ. of Puerto Rico- Med. Sci. Campus, San Juan, PR; [2]Inst. of Neurobio., San Juan, PR

Abstract: Bisphenol-A (BPA) is an anthropogenic stressor mass-produced to assist in the manufacturing of almost all plastics and resins since the 1960s. Plastic pollution has become an increasing concern over the past six decades with BPA production surpassing 7 billion kilograms per year. It is common to encounter BPA in air, dust, food, and water. Heat and changes in pH cause this chemical to leach out of products and spread throughout the environment. Important environmental organizations like EPA, have declared BPA as the third-highest priority environmental hazard. The concentrations of BPA in the environment vary depending on location, its temperature, pH, source, and time of sampling. For example, BPA has been detected

in effluents in the United States at concentrations of 12 µg/L. The current U.S. EPA (Environmental Protection Agency) reference for Lowest Observed Adverse Effect Level (LOAEL) is 50 mg/kg/d, of BPA. Previous studies have shown that at low BPA concentrations, i.e. 2 mg/kg/day, there are some effects on the development of secondary sexual characteristics and neurotoxic effects in the brain and behavior. Specifically, neurologic effects have been noted after early-life exposure to BPA in the rodent brain, producing deficits in social behavior, cognitive impairment, and increases in anxiety and depression-like behavior. All of these deficits compromise the innate ability to face challenges and limits chances for survival. Furthermore, current research has determined a link between BPA-induced epigenetic changes in early childhood, leading to increased DNA methylation of Fkbp5 gene and stress-induced expression, associated to increased sensitivity to stress and the risk of developing PTSD and anxiety behaviors. Despite these potential indicators, there has been no research directly addressing the development of anxiety-like behavior in males in response to BPA exposure at early stages of development. Our preliminary data with adult male mice show a decrease in fear learning when exposed to Bisphenol-A (50ppm). Therefore, ***our hypothesis states that early exposure to BPA increases the likelihood of developing anomalies in stress response correlated to the development of anxiety-like disorders***. Our results showed that expression of fear in adolescent mice is significantly more in Bisphenol-A exposed mice (50ppm) than the control group during extinction learning. These results provide novel evidence for the capacity of common contaminants such as BPA, at physiologically relevant concentrations, to lower the threshold for neurological disorders in response to challenges, specifically learning in adolescent mice.

Title: Evaluation of the anxiolytic effect of a pseudobulb extract of Stanhopea tigrin

Authors: *M. GONZÁLEZ QUEVEDO[1], A. J. ALONSO CASTRO[1], C. ALBA BETANCOURT[2], M. A. DEVEZE ÁLVAREZ[3], D. GASCA MARTÍNEZ[4];
[2]Pharm. department, [1]Univ. de Guanajuato, Guanajuato, Mexico; [3]Univ. de Guanajuato, Guanajauto, Mexico; [4]Neurobio. Inst., Univ. Nacional Autónoma de México, Querétaro, Mexico

Abstract: Objective To determine the anxiolytic effect of Stanhopea tigrina pseudobulb extract using unconditioned anxiety tests.
JustificationAnxiety is a health problem that can become disabling and has increased because of COVID-lock down. The available treatments have adverse side effects, so the search for new

options, particularly from natural sources, becomes necessary. Orchids are used to cure dysentery, cough, insolation, headache, fever and has been attributedanti-inflammatory properties. *Stanhopea tigrina* is an orchid endemic to Mexico. Its flowers were used to treat insolation and weakness. Pseudobulbs are the storage area and source of nutrients of orchids, as they conserve water, carbohydrates and micronutrients, being a fundamental part of these plants. In this work we propose to evaluate the possible anxiolytic properties of this plant structure as an approach to propose an alternative treatment for anxiety.
MethodologyThree concentrations of a pseudobub extract of *Stanhopea tigrina* (10, 50 and 100 mM)were tested in 3 groups of 10 CD1 mice, the extract was orally administered. The results were compared with clonazepam (anxiolytic drug, positive control) and saline solution (vehicle).After one hour of administration of the compound, the mice were placed in 3 different unconditioned tests (elevated plus maze, light/dark box, open field) to evaluate the possible anxiolytic effect of the orchid.
ResultsIn the plus maze, the mice treated with the extract stayed longer and entered many more time the area of the open arms, compared to the vehicle. Similarly, they also explored the closed arms of the labyrinth, without showing significant differences with mice treated with clonazepam. In the light/dark box, the mice treated with the extract showed a number of entries to the illuminated area similar to clonazepam and it seemed dose-dependent.
In the open field the mice traveled a total distance and to the center area similar to clonazepam, being also dose-dependent.
ConclusionsThe results suggest that the pseudobulb extract of *S. tigrina* induces anxiolytic effects in mice evaluated in unconditioned tests.

Title: Anxiolytic-sedative activity of Sargassum fluitans and Sargassum buxifolium: an experimental study

Authors: *S. A. GIL-LÓPEZ[1], M. DÉCIGA-CAMPOS[1], E. HERNÁNDEZ-NUÑEZ[2];
[1]SEPI, Escuela Superior de Medicina, Inst. Politécnico Nacional, Mexico City, Mexico; [2]Dept. de Recursos del Mar, Cinvestav Mérida, Mérida, Mexico

Abstract: Sargasso is constituted by a mixture of macroalgae that are found in the Ocean. Currently, in Mexico, *Sargassum* has been concentrated on the coasts of Yucatán and Quintana Roo. The influx of *Sargassum spp.* into the Mexican Caribbean Sea representing health, economic and environmental problems. This study aimed to characterize the anxiolytic, anticonvulsant, and sedative activity of *Sargassum fluitans* and *Sargassum buxifolium* MeOH extracts. Mice administered with various doses of *Sargassum fluitans* (30-600 mg/kg i.p.), *Sargassum buxifolium* (30-600 mg/kg i.p.), or diazepam (2 mg/kg, i.p.; a positive control) were assessed in ambulatory activity (cylinder of exploration, open-field, and hole-board tests), potentiation of the sodium pentobarbital-induced hypnosis and seizures-induced pentylenetretrazol (PTZ) assays. Results showed that both MeOH extracts gradually decrease the number of explored squares, surveys and perforations explored. Thus, *Sargassum fluitans* and *Sargassum buxifolium* showed a dose-dependent anxiolytic-like effect. In contrast, both species of Sargassum neither modify the sedative-hypnotic activity nor reduce the seizures-induced PTZ. Mass-spectrometry analysis showed that *Sargassum fluitans* extract has 64 compounds and *Sargassum buxifolium* extract 71 compounds. Some of these compounds are related to anxiolytic effects (-(+)-Ascorbic acid 2,6-dihexadecanoate; Phytol; Octadecanoic acid; ς-Tocopherol; Ergostanol; Stigmasterol;dl-à-Tocopherol). The results support further investigation of *Sargassum* as a potential anxiolytic phytomedicinal agent. In addition, it offers the opportunity to continue studying other pharmacological activities of the *Sargassum* related to the central nervous system and their therapeutic use.

Title: Altered functional connectivity during acute global hypoxia using calcium imaging in mice

Authors: *M. BAKKER[1], I. DJEROUROU[2], S. BELANGER[4], F. LESAGE[5], M. P. VANNI[3]; [1]Biomed. Engin., Polytechnique de Montréal, Montréal, QC, Canada; [2]École d'Optométrie, Univ. de Montréal, Montréal, QC, Canada; [3]Univ. de Montréal, Montreal, QC, Canada; [4]Labeo Technologies, Montreal, QC, Canada; [5]Ecole Polytechnique Montreal, Montreal, QC, Canada

Abstract: A lack of oxygen in tissue, or hypoxia, can occur as a result of sleep apnoea, COVID-19 implications, and stroke, among others. Hypoxia is related to a lower cognition, both in

chronic and acute situations. How this decrease in cognition comes into play is still unknown, but might be related to altered functional connectivity of the brain. Resting state connectivity assesses the way the brain is communicating with itself in the absence of stimuli and has been shown to be altered in some diseases, such as schizophrenia, multiple sclerosis or Alzheimer's. Among changes linked to cognition, the amount of connectivity between hemispheres has been frequently used as a biomarker. However, previous studies show contradicting results; some find cognition correlated with increased interhemispheric connectivity while others find the opposite. Most of these studies were done with fMRI, which measures BOLD response and not direct neuronal activity. This may explain the contradictory results, since BOLD measurements in diseases that alter vasculature in the brain might not be a good proxy for neuronal activity. Here, imaging techniques directly measuring the neuronal activity, such as calcium imaging, may help shed light on these questions. In this study, we used calcium and intrinsic optical imaging in mice to investigate changes in connectivity during acute global hypoxia. First, mice were injected (IV) with a virus allowing the expression of GCaMP6 in the dorsal cortex and were implanted with a chronic window. After a recovery period, we imaged the fluctuations of fluorescence and reflectance signals in the cortex during resting state in different settings: normoxia (21%), light hypoxia (12%), mild hypoxia (10%) and severe hypoxia (8%). The fluorescence intensity was corrected from hemodynamic signals and the standard deviation was calculated for each pixel as a proxy of neuronal activity. Then, correlation values between the centroids of cortical functional areas were calculated and used to assess the connectivity of inter- and intrahemispheric networks. During hypoxia, we observed a general decrease in neuronal activity. This decrease was spatially heterogeneous. Furthermore, we found altered interhemispheric and intrahemispheric connectivity. Since this change in connectivity is not measured with hemodynamic proxies, these preliminary results give a more robust substantiation of the idea that interhemispheric connectivity is related to cognitive functioning. Additionally, we shed light on the functional connectivity changes that occur during hypoxia, thereby providing important fundamental knowledge for COVID-19, Alzheimer's, and aging, among others.

Title: Relationships between cerebral metabolic rate of oxygen consumption during task and at rest in older adults

Authors: *D. ABDELKARIM[1], Y. ZHAO[1], M. P. TURNER[1], K. WEST[1], D. SIVAKOLUNDU[2], P. LIU[3], H. LU[3], B. P. RYPMA[1];

Abstract: Brain aging processes are complex, involving many interacting physiological systems. Age-related changes in metabolic processes arise from altered pathways and cellular damage that increase steadily over the lifespan. It is known that the resting cerebral metabolic rate of oxygen consumption ($CMRO_2$) increases with age while $CMRO_2$ during task decreases. In this study, we aimed to compare these divergent processes and their relationships to other processes of brain aging. In groups of younger (20-35) and older (55-70) adults, we used the T2-relaxation under spin tagging (TRUST) technique along with arterial phase contrast-derived cerebral blood flow to estimate resting $CMRO_2$, and we calculated $CMRO_2$ during a simple visual task using a dual-echo sequence and hypercapnia gas challenge. During the visual task, participants viewed a checkerboard flickering at a rate of 2Hz, 4Hz or 8Hz. Volumetric measurements were calculated based on high-resolution anatomical scans. We found that resting $CMRO_2$ differs between age groups. In older adults, there were significant anticorrelations between resting $CMRO_2$ and task-based $CMRO_2$ across flicker frequencies. No such relationships were observed in younger adults. These age-differences were further explored using other physiological data such as atrophy estimates, blood flow, and neural-vascular coupling. These results suggest that aging exerts metabolic demands upon neural processes at rest and contribute to the resources demanded during task performance. Such resource demands would be expected to compromise those hyperemic systems involved in guiding metabolic resources to active parenchyma in older adults.

Title: Resting state fMRI signals contain spectral signatures of local hemodynamic response timing

Authors: *S. M. BAILES, L. D. LEWIS;
Dept. of Biomed. Engin., Boston Univ., Boston, MA

Abstract: While neural activity fluctuates on timescales of milliseconds, the subsequent changes in blood oxygenation measured by fMRI occur over several seconds, referred to as the hemodynamic response function (HRF). Both the shape and timing of the HRF vary substantially across the brain, and proper characterization of these variations is critical for the interpretation of the blood oxygenation level dependent (BOLD) signal obtained from fMRI. Despite this, most current studies do not map local HRF timing due to the limitations of current techniques for estimating vascular delays. We aim to test if the information from the spectrum of resting state fMRI can be used to map vascular delays across the brain. Resting state scans are acquired in most studies and require no task performance from the subject; thus, using information from the resting state signals would provide a simple and effective way of understanding the temporal dynamics of the HRF across the brain. To test whether the spectrum of resting state fMRI signals should contain signatures of HRF timing, we first used HRFs with varying timings to generate simulated BOLD responses. Analysis of the spectra of these simulated BOLD responses showed voxels with faster dynamics exhibited less power in low frequency bands but a shallow decline at higher frequencies with the difference being most prominent <0.2 Hz. Next, we verified this finding in fast fMRI data collected at 7 Tesla. We quantified the phase delay of voxels in the primary visual cortex in response to an oscillating stimulus and identified groups of fast and slow voxels. We found significant differences in features derived from the resting state spectra between fast and slow voxels, quantified by the slope of the spectrum under 0.2 Hz, the mean power under 0.1 Hz, and the exponent of the aperiodic 1/f fit. Lastly, to investigate brain-wide differences in spectral features in a large dataset, we examined a subset of the Human Connectome Project Aging dataset, and calculated the slope of the resting state spectra <0.2 Hz across the brain. We found that deeper brain structures consistently had more shallow slopes compared to cortical structures across all subjects. Taken together, our results demonstrate that temporal properties of the HRF affect the spectral features of spontaneous fMRI signals. We find that this insight enables us to distinguish voxels and regions exhibiting faster or slower hemodynamic responses using only resting state information. This can allow researchers to better understand and predict the temporal properties of the HRF within individuals and large groups on both voxel-wise and regional levels, which is crucial for accurate fMRI analyses.

Title: Chronic Cranial Windows for Long Term Multimodal Neurovascular Imaging in Mice

Authors: K. KILIÇ[1], M. DESJARDINS[2], J. TANG[3], M. THUNEMANN[1], S. SUNIL[1], E. ERDENER[4], D. D. POSTNOV[5], P. DORAN[1], D. A. BOAS[1], A. DEVOR[1];

Abstract: The utilization of multiple imaging modalities in experimental neurosciences enables comprehensive investigation of brain structure and function in mice. Each imaging technology has unique advantages and disadvantages: for example, while ultrasound allows whole-brain imaging of cerebral blood flow, it cannot achieve micrometer resolution. On the other hand, two-photon microscopy yields micrometer resolution but is limited by relatively shallow penetration (in common practice, limited to the upper cortical layers in brain) and a relatively small field of view (usually, <1 mm). Combination of multiple imaging modalities offers measurements of a wide spectrum of neuronal, glial, vascular, and metabolic parameters needed for comprehensive investigation of physiological and pathophysiological mechanisms. Previous studies have described a variety of designs and surgical implantation techniques for chronic cranial windows in mice enabling longitudinal measurements. These window implants allow imaging of awake mice, which is important for investigation of brain function without the confounding effects of anesthesia on the physiology of nervous and cardiovascular systems. Although some of these protocols are very detailed, they usually employ imaging with one modality. With this study we expanded on these previous publications and describe a spectrum of surgical methods in mice suited for multiple imaging modalities, used alone or in combination, including two-photon microscopy, laser speckle contrast imaging, intrinsic optical signal imaging, optical coherence tomography, and functional US. Our optical windows can last for a span of up to 6 months after surgery and can be made MRI-safe for combined optical imaging or optogenetic (OG) stimulation in awake mice undergoing fMRI. We applied the presented procedures to investigate physiological mechanisms as well as animal models of disease (such as stroke). Following these surgical techniques and practices will yield higher experimental success and reproducibility of results and decrease the number of animals needed.

Title: Dietary fat, but not obesity, significantly affects brain reward activity to visual food cues

Authors: *I. GALLAGHER[1], V. L. DARCEY[1], J. A. AVERY[3], J. GUO[1], A. B. COURVILLE[2], W. K. SIMMONS[4], J. E. INGEHOLM[3], A. MARTIN[3], K. D. HALL[1];

Abstract: The neural mechanisms underlying the biological, behavioral, and environmental influences on the development of obesity remain unclear. Functional neuroimaging studies have led to inconsistent results, with some studies suggesting that people with obesity have greater response to visual food cues in brain regions associated with reward processing, whereas others report no significant group differences. The aim of this study was to determine whether people with obesity, compared to those without obesity, have altered brain activity in reward regions in response to visual food cues during an fMRI pleasantness task in a highly controlled, inpatient setting. On the 4th day of a standardized weight maintenance diet (50% of calories from carbohydrate, 35% fat, 15% protein), participants completed fMRI scans, 3 hours after their last meal. The scan included an event-related food pleasantness design with 144 food images, varying from highly processed, high calorie foods to minimally processed/raw low calorie produce. Participants were asked "If given the opportunity right now, how pleasant would it be to eat this food?" and responded on a scale from 1 to 7, with 1 "*neutral*" and 7 "*extremely pleasant*". Neuroimaging preprocessing and group-level analyses (3dttest++) were performed using Analysis of Functional Neuroimaging tools. Predictive BOLD signals were amplitude modulated by participant's pleasantness ratings for each food image. Analyses were conducted using a reward circuit mask for small volume correction. The study enrolled 20 adults with obesity (35.3±7.5 years old; BMI 36.6±4.6 kg/m^2) and 22 adults without obesity (27.7±6.2 years old; BMI 22.5±2.8 kg/m^2). During the fMRI task, though people with obesity rated all foods more pleasant than participants without obesity (4.5±0.5 vs 4.0±-0.8, p=0.016), there were no group differences in brain activity to visual food cues . Given absence of group differences, we found that, among the full, combined sample (n=42), brain regions responsive to subjective pleasantness of visual food cues were similar to our previously published work examining solely the control group without obesity. Exploratory regression analyses using 3-day food records of participants free-living diets suggest that greater percent of calories from fat in participants usual diet is associated with greater left ventral striatal response to highly pleasant visual food cues ($p<0.0001$, $R^2 = 0.25$). In summary, dietary fat may modulate reward-related brain activity to visual food cues, but contrary to our hypothesis, there were no significant differences in brain activity to visual food cues between people with and without obesity.

Title: Neural activity drives macroscopic cerebrospinal fluid flow in the awake human brain

Authors: *S. D. WILLIAMS, N. E. FULTZ, N. TACUGUE, Z. VALDIVIEZO, B. SETZER, L. D. LEWIS;
Boston Univ., Boston, MA

Abstract: The circulation of cerebrospinal fluid (CSF) in the brain facilitates the exchange of waste products with fresh nutrients to maintain brain homeostasis. Given the importance of CSF flow in the clearance of potentially toxic macromolecules, identifying the underlying mechanisms that drive fluid flow could enable modulation of these critical fluid dynamics that support brain health. Several drivers of CSF flow have been identified, including systemic respiratory and cardiac-linked mechanisms. In addition to these mechanisms, recent work in humans has also demonstrated there may be a neural driver of macroscopic CSF flow. Waves of neural activity precede macroscopic CSF flow through the fourth ventricle during non-rapid eye movement sleep. This coupling suggests that in addition to the well-characterized systemic physiological drivers of flow, macroscopic CSF flow may also be driven by neural mechanisms. To test whether the temporal coupling between neural activity and CSF flow reflects a causal relationship, we used sensory stimulation to drive neural activity in the awake human brain and measured corresponding evoked CSF flow. We performed three experiments to test whether neural activity could drive CSF flow, using high-contrast flickering checkerboard visual stimuli to induce widespread neural activity and BOLD responses. First, we collected simultaneous electroencephalography (EEG) and functional magnetic resonance imaging (fMRI) in humans to track the temporal relationship between neural, hemodynamic, and CSF signals. We identified a clear sequence of events: stimulus-locked neural activity recruited waves of global BOLD changes, which alternated with waves of CSF inflow. Next, we replicated our finding that inducing BOLD changes with visual stimuli can evoke CSF flow in a second larger fMRI dataset. Finally, we manipulated the stimuli parameters in a third experiment to test whether stimulus parameters could modulate the amplitude of evoked global cortical and CSF signals. We found that the flicker frequency of the visual stimuli did not significantly alter the amplitude of either the global cortical signal or CSF flow. These results demonstrated that visual stimulation can induce CSF flow, indicating that CSF flow can be driven by neural activity in the

awake human brain. Our findings are consistent with our hypothesis that neural activity drives increases in cerebral blood volume that alternate with compensatory changes in CSF flow. Considering the importance of CSF flow in clearing metabolic waste, future work could investigate whether this neurally-driven flow is associated with significant metabolite clearance in the human brain.

Title: Standardized mapping of sampled sites in the brain involved in energy balance and autonomic control: Developing an a posteriori approach to estimate microdissection accuracy of the rostral ventrolateral medulla

Authors: *S. BALIVADA, G. P. TAPIA, M. J. KENNEY, A. M. KHAN;
Biol. Sci., The Univ. of Texas at El Paso, El Paso, TX

Abstract: Molecular analysis *in situ* is a valuable tool to identify molecular signatures associated with different brain subregions. For this purpose, a region of interest (ROI) is usually identified *a priori* in unstained or partially stained brain sections using reference landmarks. Although this *a priori* approach assists in sampling the ROI, it does not estimate the sampling accuracy. Here, we proposed an *a posteriori* approach to evaluate the sampling accuracy by mapping the sampled sites within an open-access rat brain reference atlas (*Brain Maps 4.0 (BM4.0); Swanson LW, 2018. J. Comp. Neurol. 526, 935*). To test this approach, the rostral ventrolateral medulla (RVLM) (which corresponds primarily to the *paragigantocellular reticular nucleus lateral part (>1840)* in *BM4.0*) was micropunched from 200 µm-thick fresh frozen hindbrain cryosections collected from male young (3 months), middle-aged (12 months), and aged (24 months) F344 rats (*a priori* approach). For the *a priori* approach, Paxinos and Watson's stereotaxic rat brain reference atlas was used to identify the RVLM-containing sections. The ventrolateral curved edge of the sections and spinal trigeminal tract (Sp5) were used as landmarks. After micropunching, sections were stained with a modified cresyl violet staining procedure. Based on the stained sections' cytoarchitecture, associated *BM4.0* atlas levels were identified, and sampled sites were mapped onto atlas level templates (*a posteriori* approach). Although most of the punches landed in the atlas levels containing the RVLM, we observed a systematic sampling

error in all three age groups. Specifically, more rostral sampling was observed in young and middle-aged rat brain sections (BM4.0 atlas levels 56-65), and more caudal sampling was observed in aged rat brain sections (levels 58-67). These results suggest that standardized mapping of the sampled site as an *a posteriori* approach can be used to evaluate the spatial accuracy of ROI dissection. We plan to use these mapped atlas level templates to develop a quantitative estimate for the ROI dissection accuracy and replicate this *a posteriori* approach using laser capture-microdissected brain sections.

Title: Standardized mapping and a high-spatial resolution comparison of the inputs and outputs of the anterior and dorsal regions of the lateral hypothalamic area in the adult male rat using the atlas framework of Brain Maps 4.0

Authors: *A. R. TOCCOLI, D. SOTELO, V. I. NAVARRO, K. NEGISHI, A. M. KHAN; Biol. Sci., The Univ. of Texas at El Paso, El Paso, TX

Abstract: The lateral hypothalamic area (LHA) was long considered to be one large monolithic structure spanning that vast majority of the hypothalamus. However, Swanson (2004; *Brain Maps 3.0*) proposed further provisional subdivisions of this larger structure which were initially based on careful reconsideration of cytoarchitecture. These provisional subdivisions, which are retained in Swanson (2018; *Brain Maps (BM) 4.0*), have since been further tested with the targeted use of tract-tracers to explore if connectional differences between subregions may offer support. These experiments, however, have thus far only covered select subdivisions of the LHA, leaving others untested. We explore the neuroanatomical inputs and outputs of the dorsal (LHAd) and anterior (LHAa) regions of the lateral hypothalamic area (LHA) from *BM4.0* atlas levels 5-41 of the male rat to analyze where these regions differ and overlap in connections. These neuroanatomical connections were made visible with the use of retrograde and anterograde tracers cholera toxin B subunit (CTB) and *Phaseolus vulgaris*-leucoagglutinin (PHA-L) respectively. Inputs and outputs were represented with high-spatial resolution within the atlas templates of *BM4.0* to bring these data into spatial registry with those that have

previously been generated of other LHA subregions which include the juxtaparaventricular (LHAjp), juxtadorsomedial (LHAjd) and suprafornical (LHAs) regions. Thus far these preliminary results seem to demonstrate some variations and overlap in the connectional profiles of the LHAd and LHAa. Although transport of both PHAL and CTB can be seen in various overlapping regions such as the PVT, SUMl, VTA and LH the distributions of these connections within those regions create patterns that are distinct from each other. These regions also show distinctions from previously mapped LHAjp, LHAjd and LHAs subregions. The preliminary results we have observed offer some additional support to the hypothesis that the provisional cytoarchitectural subdivisions of the LHA are connectionally distinct.

Title: Standardized mapping and high-spatial resolution analysis of dorsal and ventral agranular insular area connections with the endbrain (forebrain) in a reference atlas of the rat brain

Authors: *L. P. MONTES, K. NEGISHI, M. QUINTANA, M. GARCIA, A. M. KHAN; Biol. Sci., The Univ. of Texas at El Paso, El Paso, TX

Abstract: The *insular region (Brodmann, 1909)* (INS) (following the nomenclature proposed by Swanson LW (2015). *Neuroanatomical Terminology*, Oxford Univ. Press), plays a role in diverse functions such as interoception, gustation, emotional state recognition/regulation, social decision-making, social interaction, and aversive states. The INS contains *agranular insular areas (Swanson, 2018)* (AI) that include the *dorsal* and *ventral agranular areas (Krettek & Price, 1977)* (AId and AIv, respectively) and a *posterior agranular insular area (Krettek & Price, 1977)* (AIp). Although *endbrain (Kuhlenbeck, 1927)* (EB) regions involved in autonomic, limbic, and cognitive functions are known to be anatomically connected to the INS, AId and AIv connections with EB have not been compared and precisely mapped in a standardized reference atlas. Here, we characterized projections from the AId and AIv to EB subregions in a high-spatial resolution atlas (*Brain Maps 4.0 (BM4.0)*; Swanson, 2018, *J Comp Neurol*). The AId and AIv each received a cocktail of anterograde and retrograde tracers, *Phaseolus vulgaris* leucoagglutinin (PHA-L) and cholera toxin B subunit (CTb), respectively. The AId and AIv injection deposits mapped between *BM4.0* levels 9-13, and 9-12, respectively; with their centers

mapping to levels 10 and 11 (AP= +2.15 to +1.70 mm from bregma (β)) and level 10 (AP= +2.15 mm from β), respectively. PHA-L and CTb labeling were co-visualized by diaminobenzidine (DAB) and nickel-enhanced DAB reactions, respectively, in coronal brain sections. Whereas the AId displayed more projections dorsally in the *prelimbic area (Brodmann, 1909)* (PL) and *secondary somatomotor areas (>1840)* (MOs), projections from the AIv were more abundant ventrally in the PL, *infralimbic area (Rose & Woolsey, 1948)* (ILA), and *orbital region, (Rolando, 1831)* (ORB). Furthermore, the AId projections were distributed in various thalamic subregions and AIv projections mainly in the *mediodorsal thalamic nucleus (>1840)* (MD). Also, the amygdalar region had differences in dorsal and ventral expression except for the *lateral amygdalar nucleus (>1840)*. The *basolateral amygdalar nucleus (>1840)* (BLA) and *central amygdalar nucleus (Johnston, 1923)* (CEA) were heavily targeted by the AId, the AIv deposit resulted in robust PHA-L labeling in the *basomedial amygdalar nucleus (>1840)* (BMA) and *cortical amygdalar complex (Swanson, 2015)* (COX). Further analysis of anatomical connections of INS subregions will contribute to the design of functional experiments to understand its role in different behaviors.

Title: Standardized mapping and high-spatial resolution analysis of rostral and caudal prelimbic cortical connections in the endbrain (forebrain) of the adult male rat

Authors: *K. NEGISHI[1], L. P. MONTES[1], C. OLIVEROS[1], M. S. PONCE[1,2], Y. C. WELLS[1], A. M. KHAN[1];
[1]Biol. Sci., The Univ. of Texas at El Paso, El Paso, TX; [2]Natl. Inst. of Dent. and Craniofacial Res., Bethesda, MD

Abstract: The *prelimbic area (Brodmann, 1909)* (PL) (following the nomenclature proposed by Swanson LW (2015). *Neuroanatomical Terminology*, Oxford Univ. Press) in rodents is a portion of the *cingulate region (Brodmann, 1909)* (CNG; “medial prefrontal cortex”) that is associated with a variety of functions including attention, executive control, and working memory. We have

previously compared connections of rostral and caudal parts of the PL using co-injected anterograde and retrograde tracers (*Phaseolus vulgaris* leucoagglutinin and cholera toxin subunit B, respectively). We used a standardized cytoarchitecture-based strategy that is the basis of a widely used reference atlas (*Brain Maps 4.0 (BM4.0); Swanson, 2018; J Comp Neurol*) to localize and compare histological data. Here, we expand on an earlier showcase of results by showing fully mapped datasets from the rostral pole of the *cerebral cortex (Swanson, 2000)* (CTX) to sections containing its caudal end (approx. +5.20 mm to −7.90 mm from Bregma). Among *cerebral nuclei (Swanson, 2000)* (CNU), pronounced differences were observed in the *accumbens nucleus (Ziehen, 1897-1901)* (ACB). Projections from the caudal PL densely targeted both ACB "shell" and "core" divisions whereas terminals from the rostral PL were restricted to the "core". Outputs to the nearby *olfactory tubercle (Calleja, 1893)* (OT) mainly originated from the caudal PL. The *caudoputamen (Heimer & Wilson, 1975)* (CP) received PL terminals adjacent to the *lateral ventricle (Vesalius, 1543)* (VL), with the rostral PL occupying a slightly more lateral field. The *hypothalamus (Kuhlenbeck, 1927)* (HY) received light projections from the rostral PL whereas the caudal PL innervated several hypothalamic structures, most of which were found in the *lateral hypothalamic area (Nissl, 1913)* (LHA). In the *thalamus (His, 1893)* (TH), PL connections were bidirectional. Rostral and caudal PL connections showed remarkably little spatial overlap despite having similar target structures. Caudal PL was strongly connected to the *mediodorsal thalamic nucleus medial part (>1840)* (MDm) whereas rostral PL mainly connected with its *central part* (MDc). The *paratenial nucleus (>1840)* (PT) connected with the caudal PL in its rostral part, but not its caudal extension, whereas rostral PL primarily connected with its caudal part. Overall, our structural work suggests that functional experiments involving the PL could produce variable effects depending on which rostrocaudal segment is targeted. Further anatomical and functional characterization of these circuits will help to refine their precision targeting and contribute to better division schemes for the rat CNG.

Title: Standardized mapping and high spatial-resolution analysis of the inputs and outputs of the accumbens nucleus "hedonic hotspot" in the male rat using Brain Maps 4.0

Authors: J. GUERRA-RUIZ[1], V. I. NAVARRO[2], K. NEGISHI[1], ***A. M. KHAN**[1];
[1]Biol. Sci., The Univ. of Texas at El Paso, El Paso, TX; [2]Biol. Sci., The Univ. of Texas At El Paso, El Paso, TX

Abstract: The *accumbens nucleus (Ziehen, 1897-1901)* (ACB) (following the nomenclature proposed by Swanson LW (2015). *Neuroanatomical Terminology*, Oxford Univ. Press) is a major nexus of affect-based processing that is heavily connected to various regions which mediate emotional, reward and aversive responses. Some of these major regions have been neuroanatomically linked to the ACB using retrogradely transportable neuronal tracers deposited in various brain regions. Similarly, injections of anterograde tracers have been deposited into the ACB to determine if this region was sending information to other regions involved in affect-based processing. However, these various studies have not yet taken a detailed high spatial-resolution approach to create an atlas representation of the connections to and from this highly studied region. Here we use a combination of *Phaseolus vulgaris-leucoagglutinin* and cholera toxin B subunit to reveal the outputs and inputs, respectively, of the ACB. These connections were represented onto templates of a widely used reference atlas (*Brain Maps 4.0* (*BM4.0*); Swanson, 2018; *J. Comp. Neurol.*) spanning atlas levels 5-41. Preliminary results demonstrate reciprocating inputs and outputs from areas such as the *prelimbic area (Brodmann, 1909)* (PL), *lateral septal nucleus (Cajal, 1909-1911)* (LS), and *innominate substance (Schwalbe, 1881)* (SI). Major regions supplying inputs to the ACB include the *paraventricular thalamic nucleus (>1840)*, *paratenial nucleus (>1840)*, and *basolateral amygdalar nucleus (>1840)*, while major outputs from the ACB were found in the *anterior cingulate area (Brodmann, 1909)* (ACA), *lateral preoptic area (>1840)* (LPO), and *anteroventral preoptic nucleus (Simerly et al., 1984)* (AVP). Of these the regions, those that demonstrated the highest densities of tracer transport were found to be the PL, PVT, PT, BLA, and *subiculum (>1840)* (SUB). Thus far, these preliminary results are in line with previous studies that have placed tracers into other regions and observed transport to the ACB.

Title: A hindbrain dopaminergic neural circuit prevents weight gain by reinforcing food satiation

Authors: *Y. HAN, G. XIA, Y. HE, Y. HE, M. FARIAS, Y. XU, Q. WU;
Baylor Col. of Med., Houston, TX

Abstract: The neural circuitry mechanism that underlies dopaminergic (DA) control of innate feeding behavior is largely uncharacterized. Here, we identified a subpopulation of DA neurons situated in the caudal ventral tegmental area (cVTA) directly innervating DRD1-expressing neurons within the lateral parabrachial nucleus (LPBN). This neural circuit potently suppresses food intake via enhanced satiation response. Notably, this cohort of DA cVTA neurons are activated immediately prior to the cessation of each feeding bout. Acute inhibition of these DA neurons prior to bout termination significantly suppresses satiety and prolongs the consummatory feeding. Activation of post-synaptic DRD1 LPBN neurons inhibits feeding, whereas genetic deletion of Drd1 within the LPBN causes robust increase in food intake and subsequent weight gain. Furthermore, the DRD1 LPBN signaling manifests the central mechanism in methylphenidate-induced hypophagia. In conclusion, our study illuminates a hindbrain DAergic circuit that controls feeding through dynamic regulation in satiety response and meal structure.

Title: Evidence that $GABA_A$ receptors in the lateral septum mediate nocturnal feeding at the onset of the dark phase

Authors: *I. GABRIELLA[1], B. STANLEY[2];
[1]Univ. of California, Riverside, Riverside, CA; [2]Depts of Psychology & Cell Biology/Neuroscience, Univ. California, Riverside, Riverside, CA

Abstract: Approximately 42.4% of US adults were afflicted with obesity from 2017 to 2018, a level which has steadily increased since 2000. Given the negative health impacts, understanding the neural substrates of overeating is a public health priority. Recent studies suggest that the lateral septum (LS) may be involved in eating control mechanisms. Previous research from our lab had shown that LS injections of $GABA_A$ and $GABA_B$ agonists rapidly elicit intense, dose-dependent feeding responses. At the same time, LS pretreatment with antagonists of GABA receptors decreased the elicited feeding. Together, these studies provide converging evidence that stimulation of GABA receptors in the LS can elicit eating. The current project investigated whether GABA receptors in the LS mediate nocturnal feeding at the onset of the dark phase of the light-dark cycle. Groups of adult male rats ($n \geq 11$/group) were microinjected with the $GABA_A$ receptor antagonist picrotoxin (0.1 μg / 0.3 μl), or the $GABA_B$ receptor antagonist, 2-OH saclofen (1.25 μg / 0.3 μl), or the aCSF vehicle (0.3 μl). Injections took place at the onset of the dark phase when rats eat spontaneously. Food and water intake was measured at 1, 2, 4, and 24 hours. Results showed that LS injection of the $GABA_A$ receptor antagonist picrotoxin produced an immediate and prolonged suppression of nocturnal feeding. In contrast, LS injections of the $GABA_B$ receptor antagonist 2-OH saclofen did not significantly reduce nocturnal eating. Water intake was unchanged in either condition, consistent with feeding behavior selective effects. These results suggest that activation of LS $GABA_A$ receptors but not $GABA_B$ receptors may be involved in nocturnal feeding. These findings may inform future research on pharmacological treatments for obesity or eating disorders.

Title: Conditional $RGS2^{MC4R}$ knockout mice show distinct metabolic phenotypes from whole-body RGS2 knockout mice

Authors: *Y. DENG[1], U. SINGH[1], K. SAITO[1], G. DENG[1], J. DICKEY[1], J. L. GROBE[2], H. CUI[1];
[1]Dept. of Neurosci. and Pharmacol., Univ. of Iowa, Iowa City, IA; [2]Dept. of Physiol., Med. Col. of Wisconsin, Milwaukee, WI

Abstract: Obesity has become a major public health concern due to its high risk of developing life-threatening chronic diseases, such as hypertension and diabetes. While extensive evidence indicates that melanocortin-4 receptor (MC4R) and multiple other G protein-coupled receptors (GPCRs) signaling is critical for maintaining energy homeostasis, the intracellular regulatory components of these GPCRs affecting energy balance remain vague. Regulators of G protein signaling (RGS) proteins are key components of GPCR-Gα signaling by acting as GTPase-activating proteins (GAP) to turn off Gα signal transduction. RGS2, a member of the RGS family of proteins, has been implicated in metabolic control as conventional whole-body RGS2 knockout mice exhibit reduced body weight and disrupted adipogenesis. Our *in-situ* hybridization (ISH) analyses revealed that RGS2 is highly expressed in PVN where it co-expresses with MC4R, and that 24h food restriction significantly increased $RGS2^{PVN}$ expression. Based on these observations, we hypothesized that the lean phenotype observed in whole-body RGS2 knockout mice is due to loss of RGS2 in MC4R-expressing cells. Strikingly, however, conditional $RGS2^{MC4R}$ knockout mice showed significantly increased body weight compared to their littermate controls. Further analyses revealed that $RGS2^{MC4R}$ knockout mice have significantly altered body composition, increased body length and elevated fasting blood glucose levels. Interestingly, $RGS2^{MC4R}$ knockout mice did not exhibit disruption in eating behavior, except that males showed a moderately increased caloric intake when fed high-fat diet. Taken together, we found that $RGS2^{MC4R}$ knockout mice exhibit opposing metabolic phenotypes to whole-body RGS2 knockout mice, indicating that the role of RGS2 in energy homeostasis could be either tissue- or cell type-dependent, and that RGS2 might affects the physiology of MC4R-expressing neurons.

Title: A neuronal network encoding food decisions under sensory conflict in Drosophila

Authors: *P. F. SAREEN, L. Y. MCCURDY, M. N. NITABACH;
Cell. & Mol. Physiol., Yale Univ. Sch. of Med., New Haven, CT

Abstract: Animals make everyday decisions about which foods to consume. Frequently such decisions are based on the comparison of subjective value of the available options after resolving

sensory conflict. For example, a hungry fly may choose a high calorie rotten fruit over a low calorie fresh option. Addressing such hierarchical adaptive decision-making has been difficult in human and mammalian models because of their cognitive and neuronal complexity and experimental restraints. To this end, we leveraged *Drosophila* fly gustation that comes equipped with a well described sensory taste system, a simpler yet rich behavioral repertoire, and high experimental tractability to understand the neuronal and molecular mechanisms underlying adaptive decision-making. *Drosophila* live around decomposing food matter and when hungry must balance obtaining essential nutrition with avoiding toxins, pathogens, etc. By virtue of their natural habitat, flies must weigh and integrate conflicting nutritive and harmful value of their food options before consumption. To emulate these naturalistic conditions, we employed a behavioral paradigm in which hungry freely walking flies sample and choose between different ratios of sweet and bittersweet foods. In this setup, we recorded the ingested food choice and the position of the flies on the food source. Concurrently, we manipulated cell-specific neuronal activity using optogenetics and RNAi knockdown while flies actively made decisions.
We found that when given a choice between a low calorie sweet option and a high calorie bittersweet option, hungry flies make trade-offs between the appetitive (sweet) and aversive (bitter) value of the food. In an optogenetic screen, we identified a neural ensemble that encodes adaptive food choice. This ensemble consists of upstream neuropeptidergic and dopaminergic neurons (DANs) that potentially encode and update internal metabolic state and food-related sensory information. Using receptor RNAi knockdown, we confirmed that these upstream inputs are relayed to a converging node in the neural sub-population called the fan-shaped body layer 6 (FBl6). FB is a *Drosophila* central brain region that is thought to be analogous to vertebrate basal ganglia, which is involved in mammalian decision making. Importantly, the dynamic neural activity in FBl6 neurons is context-dependent, changes with a fly's experience and hunger state, and represents the transient choice made by an individual fly.

Title: Sexual differences in rodent hierarchical associative learning and reward-seeking

Authors: *A. L. MAHERAS[1], S. PETERSON[2], J. I. CHAVIRA[2], B. WU[2], R. KEIFLIN[2];
[1]Dept. of Mol. Cell. and Developmental Biol., [2]Dept. of Psychological and Brain Sci., UC Santa Barbara, Santa Barbara, CA

Abstract: Reward learning is generally conceived as the binary association between some environmental stimuli and an ensuing rewarding outcome. However, animals can also engage in complex hierarchical associative learning in which certain stimuli (often contextual stimuli) acquire the ability to modify the predictive status of an ambiguous reward-paired cue (e.g. animals can learn that a cue results in reward if, and only if, it is encountered in a specific context). The behavioral and neurobiological bases of Binary and Hierarchical learning appear to be partially distinct, and alterations in the mechanisms of hierarchical associations have been proposed to contribute to several neuropsychiatric disorders (e.g. substance use disorder [SUD], post-traumatic stress disorder [PTSD]). However, studies into the behavioral and neurobiological basis of hierarchical associative learning have largely focused on male rodents. Here, we compared the learning and performance of male and female rodents in Binary vs. Hierarchical associative learning. Male and female Long Evans rats were trained in four different Pavlovian discrimination tasks. A first group of rats was trained in a context-dependent Pavlovian discrimination task in which the validity of two brief auditory tones (A and B) to signal a common reward was dependent upon the contextual visual background (Cx1 and Cx2, alternating every 2 min). Specifically, cue A was rewarded only in the Cx1, but not in the Cx2, while the opposite was true for cue B (Cx1: A+ / B-; Cx2: A- / B+). A second group was trained in a similar task, except that two distinct outcomes were used for the two rewarded trials (Cx1: A+/ B-; Cx2: A-/ B*). A third group was trained in a simple Pavlovian discrimination task in which one cue reliably signaled reward in both contexts, while the other cue was never paired with reward (Cx1: A+ / B-; Cx2: A+ / B-). Finally, for a fourth group both auditory cues were ambiguous predictors of reward regardless of the context (Cx1: A+- / B+-; Cx2: A+- / B+-). Critically, we observed sex-differences only in the first discrimination task (context-dependent discrimination with a single outcome), in which a majority (~75%) of male rats successfully learned the task, while only a minority (~35%) of females learned the task after 75 daily sessions. Further work will focus on identifying the behavioral and neurobiological mechanisms underlying these observed sex differences.

Title: Investigating the interaction between sex and vendor on the acquisition of goal- and sign-tracking behaviors in male and female rats

Authors: A. TURFE[1], S. R. WESTBROOK[2], S. A. LOPEZ[4], V. SANCHEZ FRANCO[5], *S. B. FLAGEL[2,3];
[2]Michigan Neurosci. Inst., [3]Psychiatry, [1]Univ. of Michigan, Ann Arbor, MI; [4]Oregon Hlth. and Sci. Univ., Portland, OR; [5]Case Western Reserve Univ., Cleveland, OH

Abstract: Cues in the environment become predictors of biologically relevant stimuli through associative learning. However, these cues can not only act as predictors, but also can be attributed with incentive value, gain excessive control over behavior, and lead to maladaptive behaviors characteristic of numerous psychopathologies. Rats that undergo Pavlovian conditioned approach (PavCA) training, in which the presentation of a discrete lever cue (conditioned stimulus, CS) is followed by the delivery of a food reward (unconditioned stimulus, US), will develop a conditioned response directed towards the lever-CS (i.e. sign-trackers), the food cup (i.e. goal-trackers), or vacillate between the two (i.e. intermediate responders). We have previously found that after just one PavCA session, corticosterone (CORT) plasma levels are higher in rats that become sign-trackers relative to those that become goal-trackers. Here, we assessed the effects of systemic CORT on the acquisition of sign- and goal-tracking behaviors in male and female rats, while examining whether vendor may play a role in these effects. Adult rats from either Charles River Laboratories or Taconic were used for these studies and rats from both vendors were run concurrently under identical experimental conditions. Rats underwent 5 sessions of PavCA training with 3 mg/kg CORT or vehicle injections (i.p.) administered 30 minutes prior to each session. The effects of CORT administration on sign-tracking and goal-tracking behaviors were assessed using several outcome measures, including the number of lever-CS vs. food cup contacts, the probability to approach the lever-CS vs. food cup, and the latency to approach the lever-CS vs. the food cup. CORT administration increased sign-tracking behaviors in male rats from Charles River, but not in those from Taconic. This interaction of treatment and vendor was present only in males, as there was not a significant effect of vendor, CORT treatment, or an interaction on the acquisition of sign-tracking or goal-tracking behaviors in female rats. Thus, the effects of systemic CORT administration on PavCA behavior differs between sexes and between rats from different vendors. We speculate that these effects are driven by differences in the distribution of behavioral phenotypes (i.e. sign-trackers vs. goal-trackers) between sexes and vendors. Ongoing studies are assessing whether differences in baseline CORT levels or glucocorticoid receptor expression between sexes and vendors might also contribute to these effects. These findings underscore the importance of reporting sex and vendor in scientific research and including them as critical variables of analysis.

Title: The effects of diet and environment on sucrose reinforcement and spatial learning in rats

Authors: S. WINCHESTER, L. HERRERA, J. PULIDO, F. GOMEZ, A. M. GANCARZ-KAUSCH, *I. C. SUMAYA;
Dept. of Psychology, California State University, Bakersfield, Bakersfield, CA

Abstract: In humans, it is well known that a diet high in fat and sucrose can lead to negative health outcomes including obesity, diabetes, and cardiovascular disease. Less known are the effects of a high fat diet and sucrose on behaviors such as reward-seeking and learning. In the context of brain function, recent data in rodents have shown that both high-fat diets and sucrose can alter dopamine function in the mesolimbic reward circuitry providing clues as to how both may affect behavior. The aim of our research was to investigate the effect of a high-fat diet containing sucrose (Western Diet) on operant responding and spatial learning. Additionally, we were interested in the known positive effects of environmental enrichment on both behaviors. Rodents were fed a Western diet containing sucrose (45% fat and 6% sucrose) or a low-fat diet lacking sucrose (standard chow, 14% fat no sucrose) for 30 days while housed in either enriched or standard housing. After 30 days, rats were tested for operant responding for 10% sucrose solution for 7 days. Daily sessions were 60 min in duration, during which snout pokes to the active alternative resulted in presentation of 100ul of sucrose according to a Fixed Ratio 1 (FR1) schedule of reinforcement, which was increased to an FR5 schedule on Day 3. Rats fed a Western diet earned significantly fewer sucrose rewards than the low-fat no sucrose group. After 7 days of 10% sucrose testing, operant responding for 4 additional concentrations of sucrose (0.1, 0.3, 1.0, 3.0%) were measured in a once daily FR5. Rats fed a Western diet earned significantly more sucrose rewards at 0.1% and 0.3% concentrations compared to their low-fat, no sucrose counterparts. Taken together, these data suggest the Western diet may produce a leftward shift in the concentration response to sucrose solution. Enrichment produced no significant changes in sucrose reinforcement. Following operant testing, rats were then tested for spatial learning (8-arm maze) for 8 days. Rats fed a Western diet significantly committed more errors as compared to their low-fat no sucrose counterparts. However, enrichment ameliorated the negative effects of the Western diet. Overall, the western diet adversely affected both operant and learning behavior as shown by the leftward shift in the concentration response which may

indicate an increased sensitivity to sucrose, and the increased errors in the 8-arm maze. Interestingly, enrichment was able to ameliorate the negative effects of the Western diet in spatial learning but not in reward-seeking. These data may have implication for humans, suggesting a link between chronic early Western diet intake and future reward-seeking and learning.

Dept. of Psychology, Stanford, CA; [7]Dept Pharmacol. and Systems Physiol., Univ. of Cincinnati, Cincinnati, OH

Abstract: Transgenic rat strains are becoming increasingly available and popular for use in neuroscience research. However, the behavioral phenotypes of these transgenic rat strains are often not studied or overlooked in favor of their utility for probing neural mechanisms. Here, we compared the tendency of three transgenic rat strains—glucocorticoid receptor (GR)-CRISPR, tyrosine hydroxylase (TH)-Cre, and Orexin-Cre—to attribute incentive value to a reward-associated cue in a Pavlovian conditioned approach (PavCA) task. All three transgenic strains were bred in-house at the University of Michigan. GR-CRISPR rats have a Sprague Dawley background, while TH-Cre and Orexin-Cre rats have a Long Evans background. Adult rats were exposed to a PavCA task for 5 sessions, during which an illuminated lever (conditioned stimulus,

CS) was extended for 8 seconds before it was retracted, and a food pellet (unconditioned stimulus, US) was delivered into an adjacent food cup. Each session consisted of 25 lever-food (CS-US) pairings. Upon Pavlovian learning, rats developed a conditioned response directed towards the lever-CS (sign-trackers, STs), the food cup-US (goal-trackers, GTs), or they vacillated between the two (intermediate responders, IRs). Rats were classified as STs, GTs, or IRs based on a composite PavCA index that incorporates the numbers of contacts with, the probability to approach, and the latency to approach the lever vs. the food cup during lever presentations. We found that the three transgenic strains differed in their distribution of these behavioral phenotypes. The GR-CRISPR strain is heavily skewed towards STs (87%) with zero GTs to date after 6 litters across F1 and F2 generations. The TH-Cre strain is also skewed towards STs (72%). The Orexin-Cre strain shows a more even distribution between STs (41%), IRs (39%), and GTs (20%), which is similar to what we have observed in outbred rat strains (~33% each). Importantly, these differences in transgenic strains are not due to breeding protocols, as all were bred in-house with similar procedures and precautions to minimize inbreeding. Nor can these findings be explained by background strain, as both TH-Cre and Orexin-Cre rats have a Long Evans background, yet the TH-Cre line is skewed towards STs. These findings demonstrate that we should not assume the distribution of behavioral phenotypes in transgenic rat strains is the same as outbred strains or as other transgenic strains based on genetic background or breeding factors. Further, these findings have significant implications for the use of transgenic rat strains and emphasize the need to determine behavioral phenotypes prior to probing neural mechanisms.

Title: Effects of chemogenetic inhibition of the ventral hippocampus to nucleus accumbens projection on sign- and goal-tracking behavior

Authors: *C. E. MARÍA-RÍOS[1], F. CZESAK[1], C. GROVES[2], P. CAMPUS[3], J. D. MORROW[3];
[1]Neurosci. Grad. Program, [3]Dept. of Psychiatry, [2]Univ. of Michigan, Ann Arbor, MI

Abstract: Reward-associated cues can acquire excessive motivational value, resulting in maladaptive behaviors like those linked to addiction and relapse. Individual differences in Pavlovian conditioned approach (PCA) behavior can be used to detect increased sensitivity to reward cues, an identified risk factor for addiction. "Sign-tracking" rats (ST) reliably approach a reward-associated cue (i.e., lever) and interact with it, while "goal-tracking" rats (GT) direct their conditioned behavior away from the cue and towards the site of impending food reward (i.e., food cup). Compared to GT, ST not only use the cue as a predictor of the reward, but also attribute it with incentive salience, indicating that the cue becomes rewarding in and of itself. Glutamatergic transmission in the nucleus accumbens (NAc) — a critical region of the motive circuit - is necessary for the development of sign-tracking, but it remains unclear which glutamatergic afferents to the NAc play this functional role. The NAc is densely innervated by the ventral hippocampus (vHPC), and past work in our lab showed that lesions of the vHPC attenuate the acquisition of sign-tracking. However, whether this effect is exerted via direct modulation of the NAc is unclear. We explored the hypothesis that the vHPC-NAc projection plays a functional role in determining the ST/GT phenotype. We used an *in vivo* dual-vector approach by injecting Cre recombinase into the NAc and an inhibitory Cre-dependent, Gi-coupled *designer receptor exclusively activated by designer drugs* (*DREADD*) into the vHPC to selectively target the vHPC-NAc projection. After 5 weeks of incubation, rats were subjected to 6 daily sessions of PCA with clozapine-N-oxide (CNO; 3mg/kg, i.p.) or vehicle (6% DMSO, i.p.) on board, followed by a cross-treatment test session. We found that inhibition of the vHPC-NAc projection had no significant effect on the acquisition of sign- and goal-tracking behavior. However, after disinhibition of the vHPC-NAc during the cross-treatment test session, rats classified as ST, showed a significant decrease in sign-tracking compared to their last acquisition session, suggesting that chronic vHPC-NAc inhibition affected their expression/performance of sign-tracking. GT's behavior in the test session remained unaffected. Our data suggests that the vHPC-NAc projection might play a selective role in the performance of sign-tracking behavior in ST. More experiments need to be performed to further dissect this role and shed light on the neurocircuitry responsible for biasing ST/GT behavior.

Title: Using Pavlovian-Instrumental Transfer to Test a Modified Law of Effect

Authors: *H. P. DE GUZMAN, I. ENRIQUEZ, A. P. BLAISDELL;
Psychology, UCLA, Los Angeles, CA

Abstract: During the extinction of a learned response, increases in the variability of the response (e.g., temporal, spatial) have been observed. Edward Thorndike's Law of Effect (LOE), while a popular model of stimulus-response (S-R) learning processes, fails to account for many observations during extinction, such as increased behavioral variability. A modified Law of Effect (MLOE) was recently proposed to expand the explanatory power of the LOE, adding several postulates to the original tenet of the LOE which mimic real world neural processes such as mutual inhibition between excitatory neurons. To test the MLOE, a Pavlovian-Instrumental transfer (PIT) procedure was administered to rats. In Experiment 1, 16 female rats were first administered Pavlovian conditioning; they were presented with a continuously reinforced cue (CRF; 100% probability) and a partially reinforced cue (PRF; 25% probability) on separate trials which were paired with delivery of sucrose pellets. Then, during instrumental training, rats learned to make a lever press response for sucrose pellet delivery. A final PIT test presented each conditioned stimulus (CS) during extinction of instrumental lever pressing. We assessed variability using the coefficient of quartile variance (CQV) for both lever press durations and lever press inter-response times (IRT) during the PIT test. Because each CS had never been present during instrumental training, the MLOE predicts no difference in lever press variability elicited by the Pavlovian cues. We found instead that variability was lower during the CRF cue than the PRF cue in both lever press duration ($t(24) = 2.474$, $p = 0.021$) and IRT ($t(21.937) = 2.446$, $p = 0.023$), which supports the Law of Expect (LOX), that is, as outcome expectancy decreases, behavioral variability increases. Due to the use of pairing a single lever with a single reward during instrumental training, it is unclear whether the transfer effects were due to specific or general PIT, each of which is mediated by different neural mechanisms. The literature suggests this design produces general PIT. Thus, in Experiment 2, we incorporated additional food reward outcomes and paired two out of three of those outcomes with two different levers during instrumental training, theoretically allowing us to observe specific PIT. Results allowed us to discriminate between predictions of MLOE, which accounts for specific PIT in terms of S-R processes, and the LOX, which accounts for general PIT in terms of outcome expectation.

Title: Multi-site electrophysiological recordings reveal synchronic activity in the basal ganglia during sucrose consumption

Authors: *E. CASEY[1], A. KRAVITZ[1,2,3];
[1]Psychiatry, [2]Anesthesiol., [3]Neurosci., Washington Univ. in St. Louis, Saint Louis, MO

Abstract: Obesity is a growing public health concern due to its increasing prevalence and because it is associated with a variety of disabling and fatal health conditions. Though several factors account for the development of obesity, caloric intake above the physiological needs is one of its major causes. Despite animal research has revealed several circuits and cell types that mediate feeding, the actual contribution of each one to the development of obesity is still unclear. Hedonic motivation for highly palatable foods drives humans and animals to overeating, and evidences from humans and animal research indicate that the NAc is a central regulator of hedonic feeding and is also a major site of dysfunction in obesity. Then, with the goal of finding global activity signatures for hedonic feeding that could play a role in the development of obesity, we recorded local field potentials simultaneously in the NAc and its three major inputs (the prefrontal cortex (PFC), the basolateral amygdala (BLA) and the ventral hippocampus (vHip)) while mice received intra-oral infusion of sucrose solutions. A principal component analysis revealed an increase in the power of the low gamma band in the PFC, BLA and NAc, locked to the liquid infusion. Moreover, synchronicity at the low-gamma band between the PFC, NAc and BLA significantly increased during infusions, although this signaling was insensitive to differences in concentration of sucrose. Though this signaling does not seem to reflect the hedonic value of the liquid infused, we evaluated if low gamma synchronic activity can predicts variations in weight gain. Our data suggest that the level of synchronicity between the PFC and the NAc at the low gamma band correlates with the weigh gained after one week of high fat diet. Altogether, our preliminary results points that synchronic oscillatory activity at the low gamma band between the NAc and its inputs is involved in the signaling of food delivery and may predict weight gain.

Title: Chemogenetic manipulations of the globus pallidus externus in frustration: Selective effects during the early stages of reward downshift

Authors: S. GUARINO, *C. W. HAGEN, *M. R. PAPINI;
Texas Christian Univ., Fort Worth, TX

Abstract: The role of the globus pallidus externus (GPe) in the adjustment to reward downshift and open field (OF) activity was studied using designer receptors exclusively activated by designer drugs (DREADDs). Rats exposed to unexpected downshifts of sucrose concentrations exhibit significant suppression of licking response to the downshifted sucrose solution relative to unshifted controls always given access to the same sucrose solution. In the current study, groups of rats received bilateral infusion of the inhibitory hM4D(Gi) or excitatory hM3D(Gq) designer receptors into the GPe. Inhibition of the GPe using the DREADD activator clozapine N-oxide (CNO) to activate the hM4D(Gi) receptors led to reduced licking in early 32-to-2% sucrose downshift sessions, but not in late downshift sessions. By contrast, excitation of the GPe using CNO to activate the hM3D(Gq) receptors led to increased licking in early 12-to-2% downshift sessions, but not in late downshift sessions. These chemogenetic manipulations had no detectable effects on OF activity. Another set of experiments, using the same 32-to-2% sucrose downshift for inhibitory DREADDs and an 8-to-2% sucrose downshift for excitatory DREADDs, replicated the selective effects of neural manipulation in the early downshift sessions, as well as the lack of detectable effects in late downshift sessions and in the OF task. These results are the first to show opposite effects of chemogenetic inhibition vs. excitation of GPe neurons on behavior during a reward downshift event. Furthermore, these effects were observed during the early stages of reward downshift, when the emotional response to reward loss is at its peak, without affecting the late stages of reward downshift, when recovery of consummatory behavior had occurred. These effects occurred in the absence of any evidence of motor alterations after either inhibitory or excitatory DREADD activation in the OF. This research is the first to demonstrate a role of the GPe in frustrative nonreward, encouraging further investigation of potential functions for other basal ganglia structures in frustration.

Title: Cell-type specific responses to associative learning in the primary motor cortex

Authors: *C. LEE[1], E. HARKIN[1], R. NAUD[1,3,2,4], S. X. CHEN[1,3,4];
[1]Dept. of Neurosci., [2]Dept. of Physics, Univ. of Ottawa, Ottawa, ON, Canada; [3]Brain and Mind Res. Inst., Ottawa, ON, Canada; [4]Ctr. for Neural Dynamics, Ottawa, ON, Canada

Abstract: The primary motor cortex (M1) is a critical site for movement initiation and motor learning. Intriguingly, it has been demonstrated that neurons in M1 also show reward-related activity, possibly to facilitate reward-based learning of new movements. However, whether reward-related signals are represented among different cell types in M1, and whether their response properties change after cue-reward conditioning remains unclear. Here, we performed longitudinal *in vivo* two-photon Ca^{2+} imaging to monitor the activity of different neuronal cell types in M1 of adult mice engaged in a classical conditioning task. Our findings reveal that most of the major neuronal cell types in M1 show robust but differential responses to both cue and reward stimuli, and their response properties undergo cell-type specific modifications following associative learning. PV inhibitory neuron responses became more reliable to the cue stimulus, while VIP inhibitory neuron responses became more reliable to the reward stimulus. Pyramidal neurons showed robust responses to novel reward but this diminished following conditioning. Lastly, SOM inhibitory neuron responses emerged and became more reliable to both conditioned cue and reward stimuli after conditioning. These observations suggest that cue- and reward-related signals are represented among different neuronal cell types in M1, and the distinct modifications they undergo during associative learning could be essential in triggering different aspects of local circuit reorganization in M1 during reward-based motor skill learning.

Title: A gradual backward shift of dopamine responses during associative learning

Authors: *R. AMO[1], S. MATIAS[1], A. YAMANAKA[2], K. F. TANAKA[3], N. UCHIDA[1], M. WATABE-UCHIDA[1];

Abstract: Multiple lines of evidence suggest that the phasic activity of midbrain dopamine neurons convey temporal difference (TD) prediction error, a teaching signal developed in reinforcement learning frameworks. A fundamental prediction of this model is that dopamine activity should resemble the dynamics of TD errors during the learning process. However, whether this similarity holds true during learning remains elusive. Specifically, a class of TD learning models using a temporal representation based on sequential activation of neurons (complete serial compound) predicts that the error signal gradually shifts backward in time from reward delivery to a reward-predictive cue. Still, such a shift has not been demonstrated experimentally, putting into question its existence, and the TD explanation of dopamine phasic activity. In this study, we show that a gradual backward shift in peak dopaminergic activity occurs over trials during associative learning. Specifically, to detect a small activity "bump" between cue and reward on a trial-by-trial basis, we used optical methods that integrate signals from a large population of neurons (fiber fluorometry) and across time (i.e. slow measurements using calcium indicator or dopamine sensor). To temporally resolve slow signal modulations, we included a relatively long delay between the cue and the outcome (e.g. 3 sec). As a result, we reliably observed a gradual backward shift of dopamine signal in the ventral striatum (VS) during learning of odor-reward association, especially in naïve mice ($p = 0.16 \times 10^{-4}$, $n = 7$ mice). This shift was also observed in well-trained mice ($p = 0.65 \times 10^{-3}$, $n = 5$ mice). A gradual backward shift of activity was also observed using fiber fluorometry of calcium signals measured from dopamine neuron soma in the ventral tegmental area (VTA). To resolve single neuron activity, we next performed 2-photon calcium imaging in the VTA. We observed a gradual backward shift of activity in single dopamine neurons although the extent and speed of the shift varied across neurons. Our modeling confirms that integrating signals over time using slow measurements can indeed facilitate the detection of such small and time-spread activity. These results establish that, at least in some conditions, a gradual backward shift of dopamine responses, a long-sought link between TD learning and dopamine activity, can be observed during associative learning. These shared dynamics of TD error and dopamine activity provide a critical evidence supporting the TD account of dopamine signals.

Title: Lateral habenula neurons encode step-by-step changes of reward prediction

Authors: *H. LEE[1], O. HIKOSAKA[2];
[2]Lab. Sensorimotor Res., [1]Natl. Eye Inst., Bethesda, MD

Abstract: Changes of prediction play critical role in sequential goal-directed behaviors (e.g., Chess and Go games). In the brain, lateral habenula (LHb) and dopamine neurons have been widely studied to encode value of reward outcome compared with their previous prediction (Matsumoto and Hikosaka, 2009). To reach a reward outcome, we often need appropriate multiple goal-directed behavior step-by-step. However, brain mechanisms have been poorly studied in multiple steps of goal-directed behaviors. Here we hypothesized that LHb play an important role in sequential goal-directed behaviors with encoding step-by-step changes of reward prediction. Therefore, we devised triple-step saccade task consisted of the series of reward-oriented events (environment, action cue, and object), each of which changed reward prediction multiple times before reaching a final outcome of a trial. We found that LHb neurons represent changes of reward prediction, selectively between before and after each event. At each event, LHb activity changed sequentially in multiple contexts according to the strength of reward prediction errors. This finding suggests that LHb can play a critical role to calculate reward prediction error to control action sequence and action skills in multiple steps of sequential goal-directed behaviors.

Title: Dopaminergic control of the explore-exploit tradeoff

Authors: *L. VARGAS, M. V. FUCCILLO;
Univ. of Pennsylvania, Philadelphia, PA

Abstract: In order to effectively make decisions, individuals must use prior experiences to balance choices that have a known positive outcome (exploitation) and choices that sample alternatives to better estimate the comparative value of the current selection (exploration). Altered regulation of these fundamental behavioral states is essential for survival and may underlie executive function defects in neuropsychiatric disorders such as autism, obsessive compulsive disorder, Tourette syndrome and addiction. The dorsal striatum is an important brain region for decision-making and action-selection. Recent literature suggests that dopamine may mediate the explore-exploit tradeoff by modulating activity in striatal direct pathway and indirect pathway neurons. According to this model, exploration would be characterized by increased dopamine, increased activity in direct-pathway neurons, and therefore a greater number of active ensembles representing different potential actions. Alternatively, exploitation would be characterized by reduced dopamine, reduced activity in direct-pathway neurons, and therefore a smaller number of active ensembles. To study how dopamine mediates the balance between exploration and exploitation, we generated a novel 3-alternative choice task for mice. Mice gain access to three nosepoke ports via a touchscreen-activated doorway. Each port has a different probability of reward that is shuffled between blocks of trials. The animals must continually learn the value of the ports by sampling ports and evaluating outcomes. We employed three different classifiers of choice behavior from the literature to define exploration and exploitation: consecutive choice, hidden Markov models, and softmax-based reinforcement learning models. To record in vivo dorsal striatal dopamine signals during task execution, we injected the GRAB-DA sensor in either dorsomedial (DMS) or dorsolateral (DLS) striatum. We found that there was robust modulation of the dopamine signal as mice engaged in the task, particularly in the pre-choice period when mice are standing on the touchscreen. Furthermore, we found these pre-choice signals were differentially modulated depending on whether the current choice was exploring or exploiting. These data will provide important experimental tests of theories implicating dopamine in explore-exploit behaviors and will generate a framework for testing causal contributions of dopamine to decision-making strategies.

Title: Fef neurons signal surprise separately from value

Authors: *M. SHTEYN[1,2], C. R. OLSON[1,2];
[1]Ctr. for the Neural Basis of Cognition, Carnegie Mellon Univ., Pittsburgh, PA; [2]Ctr. for Neurosci., Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Our previous research has demonstrated that neurons in the macaque frontal eye field (FEF)respond to visual cues with a strength that depends both on the value of the reward they predict and onhow surprising the reward is. The effects related to value and surprise might reflect dependence ofneuronal activity on a single latent factor, for example the capture of attention, or might beindependent. The possibility that the signals are independent is supported by the observation in ourprevious studies that the timing of signals related to value and surprise is different. Here, we approachthe issue directly by asking whether, across the neuronal population, signals related to value andsurprise are dissociable. In a task requiring central fixation, macaque monkeys viewed sequences oftwo visual cues followed by the delivery of a reward. The leading image predicted with highprobability ($p = 0.83$) the delivery of either a large or small reward at the end of the trial. The trailingimage indicated with certainty that the ensuing reward would be large or small. The informationconveyed by the trailing image usually confirmed ($p = 0.83$), but occasionally violated ($p = 0.17$), theprediction conveyed by the leading image. Overall, neurons responded more strongly to a trailingimage that violated an expectation set by the leading image than to a trailing image that confirmed anexpectation set by the leading image. Firing was enhanced for outcomes that were both better thanexpected and worse than expected. However, the dynamics of the response depended on whether thesurprise was good or bad. In response to good surprise, FEF neurons enhanced their firing rate in boththe early and sustained components of their visual response. In response to bad surprise, FEF neuronssuppressed their firing rate in the early component of their response, but enhanced their firing rate inthe sustained component of their response. Upon measuring the correlation across neurons between thestrength of the value signal and the strength of the surprise signal, we found that each variableaccounted for only a small fraction of the explainable variance in the other. We conclude that value-related and surprise-related signals in the FEF are dissociable not only with respect to their dynamicsbut also with respect to the populations of neurons carrying them.

Title: Contextual gating of motivationally-relevant stimuli in the mouse nucleus accumbens

Authors: *J. M. GMAZ, M. A. A. VAN DER MEER;
Dartmouth Col., Hanover, NH

Abstract: The nucleus accumbens (NAc) is an important contributor to the motivational control of behavior, acting directly through output pathways involving brainstem motor nuclei ("limbic-motor interface") and indirectly through return projections within cortico-striatal loops. Accordingly, neural activity in the NAc is thought to track fundamentally value-centric quantities such as current or future expected reward, reward prediction errors, the value of work, opportunity cost, and approach vigor. However, in complex, dynamic behavioral tasks, lesions or inactivations of the NAc lead to deficits that are not straightforward to explain from a purely value-centric perspective. In addition, prominent corticolimbic inputs suggest that the NAc has access to non-value signals that would be expected to not only inform its function but help shape its neural activity. This raises the question of if, and how, non-value signals are encoded in NAc, and if found, how such a signal relates to classical value correlates.
To address this issue, we trained 4 mice to perform a biconditional discrimination task using odor cues, in which two different "context" cues determine whether a subsequent "target" cue will be rewarded. Thus, in context O1, O3 but not O4 is rewarded, whereas in context O2, O4 but not O3 is rewarded. We recorded ensembles of NAc neurons and tested whether there is coding of the (reward-independent) context cues at the single cell and population level. We found coding for context cues in 26% of all recorded units, that could not be attributed to differences in the perceived values of the cues.
Next, we sought to determine the relationship between this context signal and classical value coding, using contemporary population analysis tools to test if context coding can be used to inform subsequent value-related processing of target cues. We found that the population level context signal occupied a neural subspace orthogonal to classic value representations, suggesting that both can be read out without interfering with each other. Despite this independence, the context signal could explain a significant proportion of variance in the subsequent value signal in response to a given target cue.
Together, the finding of clear non-value correlates suggests a revision of the value-centric account of NAc neural activity, encouraging future work to explore the precise computational role of these signals. Furthermore, the functional link at the population level between the context signal and value signal supports a circuit-level gating model for how the NAc contributes to behavioral flexibility and provides a novel population level perspective from which to view NAc computations.

Title: Selectivity of pavlovian to instrumental transfer is regulated by dorsal raphe projections to the nucleus accumbens

Authors: D. N. TAPP, C. M. BODNER, Z. PLATOW, E. BOGDANSKI, G. PETRYK, *M. S. MCMURRAY;
Psychology, Miami Univ., Oxford, OH

Abstract: Learning about reward predictive cues and responding for rewards is an adaptive component of motivated behavior. Previously learned reward predictive cues can influence the vigor of ongoing operant responding through a process called pavlovian to instrumental transfer (PIT). For example, a previously learned drug predictive cue can increase the intensity of on ongoing operant response, such as lever pressing, even when the lever does not result in the delivery of a drug reward. This process is fundamentally disrupted during substance use disorders. Thus, identifying the neural systems involved is key to developing effective treatments. The mesocorticolimbic dopamine system plays a critical role in pavlovian cue learning, operant responding, and PIT. The dorsal raphe nucleus (DRN) projects to the mesocorticolimbic system at both the level of the cell bodies in the ventral tegmental area (VTA) and the primary projection site in the nucleus accumbens (NAc). Thus, DRN activity may regulate cue learning and responding by influencing neural activity within the VTA and NAc. Recent work established that activation of projections between the DRN and the VTA is reinforcing and promotes dopamine release into the NAc. However, the role of DRN projections to either the VTA or the NAc in PIT has yet to be established. Here, we utilized an excitatory chemogenetic approach (DREADDs) in a rodent model to determine how DRN projections influence cue learning, operant responding, and PIT. Following recovery from surgery, animals completed ten sessions of pavlovian conditioning, in which three auditory cues predicted the delivery of three unique food rewards. Next, animals completed six sessions of random ratio training, in which each of two levers predicted the delivery of two of the previously paired rewards. Finally, animals were tested for PIT on two separate days using an extinction task where one lever was available and pavlovian cues were played, but no rewards were delivered. Excitation of DRN to NAc projections produced a selective suppression of PIT responses, in which animals were less likely to make lever presses during cues that had never been paired with the operant response. DRN to VTA excitation did not enhance or suppress PIT responses compared to control subjects. These results suggest that selective activation of DRN projections to the NAc may alter the generalizability of reward-predictive cues. Further, these results suggest that the DRN projections to the NAc may warrant further investigation in the context of addiction and impulse control disorders.

Title: One group of dopamine neurons is sensitive to peripheral visual input before saccade

Authors: *G. COSTELLO, O. HIKOSAKA;
Natl. Inst. of Health/NEI, Bethesda, MD

Abstract: Midbrain dopamine (DA) neurons are known to exhibit short-latency phasic activity to conditioned stimuli. The traditional hypothesis suggests that this phasic response signal the reward predictions errors (RPE), but a more recent hypothesis suggests that this response reports the saliency of the stimuli. This study proposes to test both the reward prediction hypothesis and the stimulus salience-based alternative hypothesis of DA function. We recorded 96 DA cells in two monkeys during a broad spectrum of behavioral tasks, including Pavlovian conditioning with appetitive and aversive associations. Consistent with previous findings from our lab the rostral-ventral-medial region (rvmSNc) contains DA neurons that are activated by appetitive conditioned stimuli and are suppressed by aversive conditioned stimuli (Value Cells). Conversely, DA neurons in the caudal-dorsal-lateral region (cdlSNc) are activated by both appetitive and aversive conditioned stimuli (Salience cells). More importantly our analysis of the response of DA neurons to reward-predicting stimuli reveled two distinct timescales. In the salience cells there was an early phasic burst around 90ms which is rapidly followed by a second burst at 140ms. In contrast in the value cells, we found only the second burst of activity at 140ms. More interestingly when the DA activity is aligned on the saccade, in the salience cells the early phasic burst was presaccadic while the late second burst was post saccadic. In the value cells the single burst of activity was post saccadic. We suggest that the early phasic burst represent the stimulus driven saliency component while the second burst after the saccade initiation represent the value based and may code for RPE.

Title: Ventral pallidum projections to the ventral tegmental area encode reward outcome, but not the incentive motivational value of cues

Authors: *D. PALMER, A. SCOTT, M. WEBERG, I. LIN, J. RICHARD;
Neurosci., Univ. of Minnesota, Minneapolis, MN

Abstract: Reward-predictive sensory cues contribute to escalation and reinstatement of maladaptive seeking behavior in addiction. Reward cues exert their influence through dissociable psychological mechanisms, including incentive motivation and conditioned reinforcement. Ventral tegmental area (VTA) dopamine circuits have been implicated in both the motivating and reinforcing effects of cues. The ventral pallidum (VP) is a major input to the VTA and common node among preclinical models of relapse. Previous work demonstrated that VP projections to the VTA are necessary for cue-induced reinstatement of cocaine seeking, yet the associative processes by which these projections (VP→VTA) promote seeking are unclear. Given prior evidence that VP neurons encode the incentive motivational value of cues, we hypothesized that VP→VTA neurons respond to reward-predictive cues and encode the vigor of seeking behavior. To test this hypothesis, we used fiber photometry to measure VP→VTA calcium activity in female Long Evans rats (n=9) during a discriminative stimulus (DS) task. To target VP→VTA specifically, we injected a virus expressing a cre-dependent genetically encoded calcium sensor (GCaMP6f) into the VP and a retrograde virus expressing Cre into the VTA. Optical fibers were implanted over the VP to collect bulk fluorescence signals. Rats were then trained in the DS task, in which one auditory discriminative stimulus (DS) signals availability of 10% sucrose, contingent on rats' port-entry. A neutral stimulus (NS) is also presented which is never associated with reward availability. Contrary to our hypothesis, we did not observe VP→VTA responses to DS cue onset. Moreover, post-DS calcium signal did not predict port entry latency. Instead, we observed robust activity following port-entry on DS trials, during the time of sucrose consumption. These results suggest that VP→VTA encode outcome value of reward but not the incentive motivational value of cues. Our findings suggest that previous effects of VP→VTA manipulations on cue-induced reinstatement may have been due to the contributions of this projection to conditioned reinforcement, not invigoration, by the drug cue.

Title: Investigating ventral pallidal encoding of expected outcome value

Authors: *A. SOOD[1], J. M. RICHARD[2];
[2]Dept. of Neurosci., [1]Univ. of Minnesota, Minneapolis, MN

Abstract: Disruptions in goal-directed decision-making are a core component of several neuropsychiatric conditions, including addiction. Goal-directed behavior relies on accurate mental representations of future outcomes and their expected value. An understanding of the neural mechanisms underlying expected value encoding within the brain reward centers is key for developing effective long term treatments for addiction. The Ventral Pallidum (VP) is a key structure in the basal forebrain that is important for motivation and reward processing and prior work has shown that VP neuronal populations encode the expected outcome value. However, the sensitivity of these representations to a change in the expected outcome value remains poorly understood. Outcome (reward) devaluation, in which the value of the expected outcome is diminished, is a classic test of goal-directed behavior that allows for testing whether the neural representations of expected outcome value change with a change in the value of the expected outcome. In this study, we used in-vivo electrophysiology to record from single units in the VP of adult rats responding to Pavlovian reward cues before and after reward devaluation. Adult rats (n= 5, 3 males, 2 females) were trained with an auditory conditioned stimulus (CS+) that signalled delivery of a 10% sucrose reward and a control cue (CS-) that never predicted reward. We then recorded from the VP of these rats during training and reward devaluation sessions. Reward devaluation was achieved via sensory specific satiety by allowing the animals free access to either sucrose (thereby altering its expected value) or a control substance (maltodextrin). As expected, we found that many VP neurons (65%) were excited by the CS+, and that these neurons were more responsive to the CS+ than the CS-. Additionally, VP responses to the CS+ were reduced after free consumption of sucrose. Interestingly, free access to maltodextrin also reduced VP responses to the CS+, suggesting that these changes in VP responding were not due to the encoding of the sucrose reward specifically. Future experiments will aim to investigate whether VP neurons respond more selectively to other forms of devaluation. Overall, this study will enhance our understanding of expected outcome value encoding within the VP and how that representation changes with a change in the value of the expected outcome.

Title: Retrograde tracing reveals forebrain afferents to the anterior or posterior ventral pallidum in the rat brain

Authors: *R. G. KOLPA[1], K. R. URSTADT[1], K. C. BERRIDGE[2];
[1]Cognitive Sci., Occidental Col., Los Angeles, CA; [2]Psychology, Univ. of Michigan, Ann Arbor, MI

Abstract: The Ventral Pallidum (VP) is a brain structure involved in limbic functions including disgust, hedonia, feeding, and motivation. However, inputs to this region are not well established. Using retrograde tract tracing, we identified potential forebrain afferents to the VP. Tracer solutions of 2% Fluorogold or 0.25% cholera toxin subunit B (CTB) were micro-iontophoretically injected into various locations within or near the anterior or posterior VP, and traced neurons were labeled with tyramide signal amplified immunofluorescence. Labeled neurons were then quantified in various forebrain regions. Anterior VP injections primarily labeled large numbers of neurons in the Accumbens Core, Accumbens Shell, and Caudate Putamen. Meanwhile, posterior VP injections labeled moderate numbers of neurons in the Lateral Septum, Magnocellular Preoptic nucleus, Paraventricular Thalamus, Basomedial Amygdala, insular cortex, nucleus of the horizontal limb of the diagonal band, piriform cortex, and olfactory tubercle. Posterior VP injections also labeled small numbers of neurons in the bed nucleus of the stria terminalis, medial preoptic area, sublenticular extended amygdala, lateral hypothalamus, and paraventricular hypothalamus. Most regions demonstrating labeling are associated with regulation of pleasure, feeding, and/or reward processing, according to past literature. This suggests that these regions may regulate these functions, in part, via the VP.

Title: Interrupting VP activity during acquisition of cue relationships and sign-tracking behavior

Authors: *E. SMEDLEY, K. S. SMITH;
Psychological and Brain Sci., Dartmouth Col., Hanover, NH

Abstract: Appetitive Pavlovian autoshaping, where cues precede a reward delivery, can produce several conditioned responses in animals. Some animals produce a sign-tracking response whereby they come to interact with the cue and the cue attains incentive value beyond its predictive properties (i.e., the cue itself becomes wanted). Previous studies have demonstrated that the ventral pallidum (VP) plays a critical role in the sign-tracking behaviors. Notedly, many autoshaping procedures used single lever cues to predict reward and previous work has described how cues learned in sequence will both gain a sign-tracking response, with a bias toward the first lever in sequence, and are each able to later update and inform the other cue and impact subsequent sign-tracking behavior (Smedley & Smith, 2018a, 2018b). Given the VPs role in sign-tracking, and how neurons in the VP represent the incentive value of sign-tracked cues, we suspected that the VP will be involved in representing many cues in sequence. Further, it would likely have the capability of building associations between serially sign-tracked cues and modifying these relationships if outcomes change (i.e., the cue mediated extinction effect seen when one cue in sequence is extinguished). Here, rats were implanted with bilateral optical fibers, and transduced with either a virus containing archaerhodopsin (eArch3.0) or a control virus (eYFP) in the VP. Preliminary results indicate that inhibition of VP during distal lever delivery does not alter the quantity of sign-tracking behavior. However, animals with VP inhibition during the distal cue were faster to subsequently interact with the proximal lever. Notedly, the differences in latency to respond did not persist into subsequent testing days after lever extinction indicating that this effect may only be present in acquisition. These findings suggest that VP may be modulating the timing and vigor of the sign-tracked behavioral response.

Title: Neuronal mechanisms of novelty seeking

Authors: *T. OGASAWARA[1], F. SOGUKPINAR[3], K. ZHANG[4], Y.-Y. FENG[4], J. PAI[1], A. JEZZINI[1], I. E. MONOSOV[1,3,4,5,2];

Abstract: Humans and other primates interact with the world by observing and exploring visual objects. In particular, they often seek out the opportunities to view novel objects that they have never seen before, even when they have no extrinsic primary reward value. However, despite the importance of novel visual objects in our daily life, we currently lack an understanding of how primate brain circuits control the motivation to seek out novelty. We found that novelty-seeking is regulated by a small understudied subcortical region, the zona incerta (ZI). In a task in which monkeys made eye movements to familiar objects to obtain the opportunity to view novel objects, many ZI neurons were preferentially activated by predictions of future novel objects and displayed burst excitations before gaze shifts to gain access to novel objects. Low intensity electrical stimulation of ZI facilitated gaze shifts, while inactivations of ZI reduced novelty-seeking. Surprisingly, additional experiments showed that this ZI-dependent novelty-seeking behavior is not regulated by canonical neural circuitry for reward prediction. The habenula-dopamine pathway, known to reflect reward predictions, was relatively inactive during novelty-seeking behavior in which novelty had no extrinsic reward value. Instead, high channel-count electrophysiological experiments and anatomical tracing identified a prominent source of control signals for novelty-seeking in the anterior ventral medial temporal cortex (AVMTC), a brain region known to be crucially involved in visual processing and object memory. In addition to their well-known function in signaling the novelty or familiarity of objects in the current environment, AVMTC neurons reflected the predictions of future novel objects, akin to the way neurons in reward-circuitry predict future rewards in order to control reward-seeking. Our data uncover a network of primate brain areas that regulate novelty-seeking. The behavioral and neural distinctions between novelty-seeking and reward-prediction highlight how the brain can accomplish behavioral flexibility, providing a mechanism to explore novel objects.

Abstract: The bed nucleus of the stria terminalis (BNST) plays a valence surveillance role, integrating inputs and regulating Hypothalamo-Pituitary Adrenal responses. BNST is highly heterogenous, sexually dimorphic, and composed of diverse nuclei and cell populations. One subregion, the anterior BNST (aBNST), is populated by GABAergic Corticotropin-Releasing Factor (CRF)- expressing neurons, which are important regulators of avoidance behaviors. However, CRF+ neurons in BNST also project to brain areas involved in reward and motivation behaviors. Here we used both optogenetic and chemogenetic approaches to dissect the importance of aBNST CRF+ neurons in avoidance, reward, and motivation behaviors in both male and female C57BL/6J mice.

Title: Oxytocin decreases expression of sucrose conditioned place preference via mechanisms in the ventral tegmental area

Authors: *M. SUNDAR[1], K.-C. LEONG[2];
[2]Dept. of Psychology, [1]Trinity Univ., San Antonio, TX

Abstract: Understanding the neural processes underlying natural reward-seeking behavior, for rewards such as sugar, has widespread implications. While the reward circuit serves an important

adaptive function for physiological and psychological health, maladaptation of this circuit may be attributed to various disorders including addiction, eating disorders, diabetes, and obesity. Recently, the neuropeptide oxytocin (OXT) has been shown to modulate reward-related behaviors and processes. The present study examined how OXT affects sucrose-seeking behaviors in rodents using the conditioned place preference (CPP) paradigm, which serves to measure reward seeking and the expression of context-reward associations. In Experiment 1, Sprague-Dawley male rats underwent conditioning trials in which they were given sucrose pellets (45 mg) in a distinctive environment or no reward in a separate environment. On test day, rats were injected peripherally with OXT (1 mg/kg; i.p.; n = 7) or saline (n = 7) prior to the CPP test. The systemic administration of OXT attenuated the expression of sucrose CPP. The ventral tegmental area (VTA) is a key structure in the reward circuit, responsible for mediating various reward-related processes for natural and drug rewards, and also shows robust expression of OXT receptors. In Experiment 2, rats underwent the same behavioral paradigm as in Experiment 1. On test day rats received an intra-VTA infusion of OXT (0.5 µg/0.5 µL; n = 6) or saline (0.5 µL; n = 7). Intra-VTA OXT administration resulted in attenuation of sucrose CPP expression, suggesting that the modulatory effect of OXT is mediated by processes within the VTA. These results provide valuable information about oxytocin's mechanisms for reducing addictive behaviors and encourage its potential as a therapeutic for addiction.

Title: Cholinergic transmission in the nucleus accumbens core alters the flexibility of sign-tracking responses

Authors: *E. S. TOWNSEND, K. A. AMAYA, E. B. SMEDLEY, K. S. SMITH; Dartmouth Col., Hanover, NH

Abstract: Reward predictive cues can acquire their own motivational value. The physical manifestation of this motivation is often cue-directed Pavlovian conditioned approach, commonly referred to as sign-tracking. In dynamic environments, sign-tracking behaviors must be flexible enough to change as well, or the animal will risk losing out on rewarding outcomes. Thus, after the introduction of an omission schedule, where deflection of a lever-cue cancels

delivery of the reward, animals flexibly express sign-tracking by morphing their behavior to align with the new cue information (e.g., increases in non-contact behaviors such as sniffing and orienting, and overall avoidance of lever deflection) without changes in cue attraction. However, neural mechanisms underlying this type of flexibility remain unclear. One area of interest is the nucleus accumbens core (NAcC). While its role in governing sign-tracking behavior itself is well known, the modulatory role of a small population of cholinergic interneurons in the NAcC has received little attention. Recently, these cells have been studied with respect to other forms of motivation. Still, it is unknown what role cholinergic transmission plays in the regulation of sign-tracking behavior during the omission condition. Using pharmacological manipulations in rats that actively displayed sign-tracking behavior, nicotinic receptors in the NAcC were inhibited by administering mecamylamine, a nicotinic antagonist, during the first five days of the omission schedule following sign-tracking acquisition. Reduction of nicotinic activity in the NAcC suppressed the rats' ability to flexibly alter their sign-tracking responses during omission in contrast to controls, although nicotinic inhibition did not entirely prevent the rats from eventually compensating for the omission schedule. Behavioral microanalysis suggested that rats with inhibited nicotinic receptor signaling engaged in more food port directed behaviors and displayed delayed changes in cue-directed, non-contact behaviors such as sniffing and orienting relative to controls. Altogether, these results indicate that activity at NAcC nicotinic receptors are important for animals to integrate information into their sign-tracking behavior in a way that aids motivational flexibility.

Title: The complementary GABAergic and Glutamatergic neuron activity in the lateral hypothalamus orchestrates palatability-guided consumption.

Authors: *M. LUNA[1], A. COSS[2], O. X. GUERRERO GUTIERREZ[1], A. GARCIA[3], R. GUTIERREZ[1];
[1]Pharmacol., [2]Electrical Engin., CINVESTAV, Ciudad de Mexico, Mexico; [3]Neuroscience, Cell. Physiol. Inst., UNAM, Ciudad de Mexico, Mexico

Abstract: Obesity has become a major global health concern. One culprit of this epidemic is the overconsumption of sucrose, which due to its high palatability (hedonic value) promotes its intake beyond homeostatic need. The Lateral Hypothalamic Area (LHA) coordinates fundamental behaviors, including sleep-wake cycles, feeding, motivation, stress, and nociception. Optogenetic and chemogenetic approaches have revealed that the GABAergic (LHA^{GABA}) and glutamatergic (LHA^{Glut}) populations participate in consummatory and avoidance behavior, respectively. In our previous work, extracellular recordings on mice revealed that LHA contains a subpopulation of palatability-related neurons; these were optotagged as GABAergic and non-GABAergic (perhaps glutamatergic), and they responded directly and inversely proportional to sucrose's palatability, respectively. Thus, we hypothesized that complementary activation of LHA^{GABA} and silencing of LHA^{Glut} neurons could encode sucrose's palatability. To this aim, we used transgenic mice (Vgat-ires-Cre and Vglut2-ires-Cre) and induced expression GCaMP6m on LHA^{GABA} and LHA^{Glut} neurons. We employed fiber photometry and a Brief Access Taste Test (BATT), giving 4s access to either an empty sipper, water, 3%, or 18% sucrose. The lick rate was used as a descriptor of palatability. We found that LHA^{GABA} neuron activity was directly proportional to the palatability of the tastants, while LHA^{Glut} neuronal activity was inversely related. It is plausible that this antithetical modulatory pattern between LHA^{GABA} and LHA^{Glut} neurons allows palatability-guided consumption. We used $LHA^{Vgat\text{-}ChR2}$, $LHA^{Vgat\text{-}GtACR2}$, $LHA^{Vglut2\text{-}ChR2}$, and $LHA^{Vglut2\text{-}GtACR2}$ mice to test the causal effect of activating (with ChR2) or silencing (with GtACR2) these neurons with real-time place preference and closed-loop two bottle conditioning. We found that activating LHA^{GABA} or silencing LHA^{Glut} neurons made a less preferred side or sucrose bottle more preferred. In contrast, silencing LHA^{GABA} or activating LHA^{Glut} neurons resulted in avoiding the more preferred photostimulated side or bottle. Finally, open-loop experiments with solid foods (Chow, High-Fat Diet (HFD), and sucrose pellet) confirmed that well-fed $LHA^{Vgat\text{-}ChR2}$ and $LHA^{Vglut\text{-}GtACR2}$ mice increased interaction time and consumption of the most palatable food available. Besides, in 20 h fasted $LHA^{Vgat\text{-}GtACR2}$ and $LHA^{Vglut2\text{-}ChR2}$ mice avoided HFD and only consumed it in the unstimulated period. Our findings shed light on the functional difference of these two subpopulations of neurons and how they might complement each other to induce rewarding and aversive behaviors.

Title: Distinct involvement of hypothalamic oxytocin cell populations in juvenile social play behavior

Authors: *S. M. BOWDEN[1], A. M. LUXHOJ[1], A. R. TATONE[1], V. GRINEVICH[2], R. BREDEWOLD[1], A. H. VEENEMA[1];
[1]Michigan State Univ., East Lansing, MI; [2]German Cancer Res. Ctr., Heidelberg, Germany

Abstract: Juvenile social play is a highly motivated and rewarding behavior displayed across a variety of mammalian species, including rats and humans. Deficits in social play are a hallmark symptom in children diagnosed Autism Spectrum Disorder (ASD). Although the oxytocin (OXT) system has been implicated as a potential therapeutic in ASD, little is known about its role in juvenile social play. Here, we determined the involvement of OXT cell populations in the paraventricular nucleus of the hypothalamus (PVN) and supraoptic nucleus (SON) in the modulation of social play behavior in juvenile rats. To achieve this, an excitatory DREADD construct under the control of the OXT promoter was infused into either the PVN or SON of 26-day-old rats. Social play behavior was assessed one week later over two trials, in which either clozapine-*N*-oxide or saline was administered 30-minutes prior to testing in a randomly assigned counterbalanced manner. In a first round of experiments in females, we found that chemogenetic activation of PVN^{OXT} cells selectively increased the duration of social play, while chemogenetic activation of SON^{OXT} cells selectively increased social investigation. Current studies are underway to determine the effects of chemogenetic activation of PVN^{OXT} and SON^{OXT} cells on social play behavior in males. Because ASD disproportionally affects males, we hypothesize to find sex differences in the role of hypothalamic OXT in social play behavior. Together, these experiments demonstrate a differential involvement of PVN^{OXT} cells and SON^{OXT} cells in the modulation of social behavior in juvenile female rats. Future studies will explore the neural circuitry by which PVN^{OXT} cells modulate social play behavior in both sexes. Overall, this research aims to provide insights into the potential sex-specific use of OXT-based therapeutics to alleviate social play deficits in children with ASD.

Title: Sex-specific activation of oxytocin receptor expressing cells within nodes of the social behavior neural network following social investigation

Authors: *K. E. YOEST[1], A. R. BARRETT[2], M. H. HENRY[1], H. A. VELISEK[1], D. ANDERSON[4], A. H. VEENEMA[3];
[1]Psychology, [2]Neurosci., [3]Dept. of Psychology, Michigan State Univ., East Lansing, MI; [4]Univ. Ana G. Mendez, San Juan, PR

Abstract: The social behavior neural network (SBNN) is an interconnected circuit of brain regions that aid in the regulation of a wide variety of social behaviors. Within this network, the neuropeptide oxytocin (OXT) and its corresponding receptor (Oxtr) play a prominent role in which sex differences in the organization of the OXT system have been linked to the sex-specific regulation of social behaviors in adult rats. Sex differences in the OXT system in some nodes of the SBNN are already present early in development, but the functional implications at a young age remain unknown. Here, we determined how activation of Oxtr expressing cells within three nodes of the SBNN differs in juvenile male and female rats following exposure to a social stimulus. Using in situ hybridization, we measured the number of cells expressing Oxtr mRNA as well as fos mRNA (as a marker of neuronal activation) within the bed nucleus of the stria terminalis (BNST), ventromedial hypothalamus (VMH), and medial amygdala (MeA). In the BNST of males, but not females, exposure to a social stimulus increased the proportion of fos positive cells that expressed Oxtr without altering the overall number of cells that were activated, indicating a shift in the population activity of the BNST. Conversely, in the VMH, females have greater expression of both fos positive cells and Oxtr expressing cells that are fos positive than males, suggesting higher overall activity in the VMH of females. Ongoing work seeks to determine whether patterns of Oxtr cell activation within the MeA resemble those seen in the BNST or in the VMH. Together, these results indicate that specific nodes of the SBNN show differential recruitment of Oxtr cells in response to social experience in juvenile rats and provide insight into how OXT may act across SBNN nodes to coordinate age and sex-specific responses to social stimuli.

Title: Structural sex differences in the ventral pallidal vasopressin system are associated with the sex-specific regulation of social play behavior in juvenile rats

Authors: *J. D. A. LEE, C. J. REPPUCCI, E. D. M. HUEZ, S. M. BOWDEN, R. BREDEWOLD, A. H. VEENEMA;
Michigan State Univ., East Lansing, MI

Abstract: Social play is displayed by juveniles of many mammalian species, including rats and humans, and engagement in social play helps develop social competence throughout life. Children diagnosed with autism spectrum disorder, a sex-biased neurodevelopmental disorder, show decreased involvement in social play, thus emphasizing the need to understand the neural mechanisms underlying social play in both sexes. We recently showed that vasopressin (AVP) acting in the lateral septum regulates social play behavior in juvenile rats and AVP acting in the ventral pallidum (VP) regulates sociosexual motivation in adult rats, with AVP modulating both behaviors in a sex-specific manner. However, whether intra-VP AVP signaling is involved in the sex-specific regulation of juvenile social behaviors, such as social play, is unknown. In this study, we first examined the structure of the intra-VP AVP system in juvenile rats and found multiple sex differences, with denser AVP-immunoreactive fibers and vasopressin 1a receptor (V1aR) binding in males compared to females, but a greater number of v1aR+ cells in females compared to males. However, when we examined AVP inputs to the VP originating from the bed nucleus of the stria terminalis (BNST), we found no sex differences in the number of avp+ cells in the BNST or in the proportion of VP-projecting BNST avp+ cells. We are currently determining whether there are sex differences in the recruitment of BNST avp+ cells following exposure to social play. In addition, we are examining whether there are sex differences in AVP inputs to the VP originating from the posterodorsal medial amygdala (MePD) and in the recruitment of MePD avp+ cells following exposure to social play. Next, in order to determine the functional role of intra-VP AVP signaling in regulating social play behavior, we investigated whether exposure to social play altered recruitment of VP v1aR+ cells and determined the causal involvement of intra-VP AVP signaling in the regulation of social play by infusing a specific V1aR antagonist into the VP prior to social play exposure. We found that exposure to social play enhanced recruitment of VP v1aR+ cells in males only. However, V1aR blockade in the VP increased social play duration in males but decreased social play duration in females compared to same sex control groups. Together, these findings demonstrate robust structural sex differences in the VP-AVP system that may underlie the sex-specific regulation of social play behavior by the VP-AVP system. Furthermore, these findings provide insights into the involvement of AVP signaling across a network of brain regions in the sex-specific regulation of social play behavior in juvenile rats.

Title: 5HT2C receptors mediate age- and stress-dependent social interactions

Authors: *A. J. NG, B. H. BRADY, L. K. VINCELETTE, J. P. CHRISTIANSON; Psychology and Neurosci., Boston Col., Chestnut Hill, MA

Abstract: Social interaction allows for the transfer of affective states among community members in a phenomenon referred to as “emotional contagion.” The behaviors and expressions of individuals experiencing pain and fear can evoke anxiety-like states in observers which shape subsequent social interactions. The serotonin 2C receptor (5HT2C) is an important central regulator of anxiety, and we hypothesized that social reactions to stressed individuals may be mediated by 5HT2C receptors systemically and in the insular cortex, an area involved in the approach/avoidance decisions with stressed others. We administered the selective 5HT2C antagonist SB242084 both systemically (10mg/kg*)* and directly into the insula (5μM*)* and found that both treatments prevented the approach and avoidance, respectively, of stressed juvenile (PN30) or stressed adult (PN50) conspecifics in the social affective preference test. Interestingly, direct infusion of the selective 5HT2C agonist CP809101 (5μM) was insufficient to alter social interaction with juvenile or adult conspecifics. On a multielectrode array, bath application of CP809101 augmented glutamatergic synaptic transmission as evidenced by increased field excitatory postsynaptic potentials (fEPSP) peak amplitude in what appears to be a dose dependent manner (data collection is ongoing). We conclude that observation of a stressed other evokes serotonin release and binding at insular 5HT2C receptors which may underlie an empathetic anxiety-like state and shape social decision making.

Title: The role of the basolateral amygdala and its projections to the insula in social investigation of stressed adult rats

Authors: *A. DJERDJAJ[1], A. J. NG[1], N. WORLEY[1], B. CAREY[1], J. P. CHRISTIANSON[2]; [2]Psychology, [1]Boston Col., Chestnut Hill, MA

Abstract: Social vocalizations, chemosignals, and behavioral expressions of one's internal affective state shape the selection of social behavior responses made by others who detect these cues. A network of interconnected brain structures called the social decision making network (SDMN) integrates these stimuli and network output yields social behaviors that are appropriate for a given interaction. Deficits in SDMN connectivity underlie several psychiatric disorders such as schizophrenia and autism so further understanding the function of the SDMN may grant us new insight into aberrant social behaviors. The basolateral amygdala (BLA) and the insular cortex (IC) are reciprocally connected and each contribute to social and emotional behaviors. The BLA is commonly viewed as a valence encoder while the IC mediates approach and avoidance behaviors. Prior work from our lab showed this BLA-IC tract is necessary for social investigation of stressed juveniles (PN30) in a social affective preference (SAP) paradigm in which a test rat is presented with 2 conspecifics, 1 naïve to treatment and 1 stressed via 2 footshocks. Here, we explored the involvement of these BLA projections to the IC in a SAP test with 2 adult conspecifics (PN50). Test rats prefer interaction with the naive adult in this paradigm. Local inhibition of the BLA was achieved via bilateral transduction of AAV-hSyn-hM4D(Gi)-mCherry followed by systemic administration of clozapine-N-oxide (3mg/kg) prior to SAP tests with adult conspecifics. Further, tract-specific inhibition of IC-projecting BLA neurons was achieved via bilateral transduction of AAV-hSyn-hM4D(Gi)-mCherry in the BLA, bilateral cannulation in the IC, and CNO injection (1μM) directly into the IC prior to SAP testing with adult conspecifics. Ongoing investigations include transsynaptic tracing to identify BLA-IC projection patterns and manipulate these specific IC neurons receiving monosynaptic input from the BLA. Additionally, in vivo Ca2+ imaging of both BLA neurons and BLA-IC neurons aims to describe neuronal activity of these general and projection-defined neurons during encounters with naive and stressed conspecifics. The current results expand on previous studies investigating the role of this tract in social affective preference for juvenile conspecifics. Taken together, these studies identify a new tract by which social emotional information is processed within the SDMN.

Title: Neural circuit mechanisms underlying the medial preoptic area-mediated social play behavior in rats

Authors: *C. ZHAO, L. RITERS;
Integrative Biol., Univ. of Wisconsin-Madison, Madison, WI

Abstract: The medial preoptic area (MPOA) is well-known for its role in sexual and maternal reward, but it is also implicated in pair-bond maintenance behavior and centrally involved in non-sexual, affiliative song and reward in birds. Recent studies from our laboratory demonstrate that MPOA is a central nucleus in which opioids act to govern non-sexual affiliative, highly rewarding social play behavior in adolescent rats. However, the neural circuit mechanisms underlying the MPOA-mediated social play behavior remain largely unresolved. The MPOA contains a large cluster of neuronal populations that send direct efferent projections to approximately 20 brain areas. The MPOA to ventral tegmental area (VTA) pathway is involved in motivation and reward associated with sexual and maternal behaviors. We hypothesize that this projection pathway may also mediate social play behavior through a positive and rewarding mechanism. Additionally, the MPOA projects to the periaqueductal gray (PAG), which is well-known for its role in pain and aversive emotional states such as fear and anxiety. Affiliative social interactions are not only rewarding but also reduce negative affective states. We hypothesize that the signal pathway from the MPOA to PAG may promote non-sexual affiliative interactions (i.e., social play) via reducing a negative affective state. To begin to test these hypotheses, we combined retrograde tract tracing with immediate early gene expression and immunofluorescent labeling for mu opioid receptors (MORs) to identify opioid-sensitive projection pathways from the MPOA to VTA and PAG that are activated after performance of social play. Retrograde tracer, Fluoro-Gold (FG), was microinjected into the VTA or PAG. Immediate early gene expression (i.e., Egr1) was assessed and triple immunofluorescent labeling of MOR, Egr1 and FG in the MPOA was performed after social play. We revealed that play animals displayed an increase in neurons double-labeled with Egr1 and FG (i.e., activated projection neurons), and triple-labeled with MOR, Egr1 and FG (i.e., activated MOR projection neurons) in the MPOA when compared to no-play rats. The increased activation of projection neurons that express MORs from MPOA to VTA or PAG after social play suggests that opioids may act through these projection pathways to govern social play. Collectively, this study provides neuroanatomical evidence supporting that projection pathways from the MPOA to VTA and PAG are involved in the modulation of social play by MORs in the MPOA.

Title: Exploring sex-based differences in sign-tracking compulsivity following outcome devaluation

Authors: *E. A. BIEN[1], K. S. SMITH[2];
[1]IND, [2]PBS, Dartmouth Col., Hanover, NH

Abstract: Forming habits to get rewards can be helpful for efficient behavior; however, if those behaviors become compulsive when change is needed, they can be unhealthy. Sign-tracking, in which animals motivationally engage with a reward cue, has proven to be a useful readout for kinds of reward-seeking that can be either inflexible or flexible depending on different conditions. It needs to be determined if sign-tracking behavior itself shows sex differences that match the sex differences that we see in human disorders characterized by maladaptive reward seeking. To determine this, we allowed male and female rats (outbred Long Evans; Charles River) to first develop a sign-tracking response to a reward-predictive cue. Then, we used a conditioned taste aversion-mediated outcome devaluation (OD) procedure to assess how much animals continued to sign-track for a devalued reward. First, we found, surprisingly, that males and females did not differ in sign-tracking levels during acquisition and did not differ in the speed with which they acquired sign-tracking behavior. We also found that female and male rats exposed to LiCl decreased their pellet consumption during the OD task and decreased their sign-tracking behavior after the task compared to their female and male saline control counterparts; again, however, sex was not found to influence these decreases in behavior. Males and females exposed to LiCl showed similar decreases in pellet consumption and decreases in sign-tracking behavior after OD. These results were unexpected given that previous studies in Sprague Dawley rats found that female rats have more stimulus-directed Pavlovian Approach than males and that females are more insensitive to OD (e.g., Hammerslag and Gulley, 2014; Pitchers et al., 2015). In conclusion, our findings with this type of rat strain show that sex does not affect sign-tracking behavior, devaluation of its outcome, or how sign-tracking adjusts to the devalued outcome. This suggests that genetic or other unknown factors can contribute to whether sex plays any role in variations in cue-directed motivation.

Title: The effect of pair-housing on ethanol conditioned place preference in male rats

Authors: *E. LORENZ, H. BALLAS, K.-C. LEONG;
Trinity Univ., San Antonio, TX

Abstract: According to the 2019 National Survey on Drug Use and Health (NSDUH), 14.5 million people above the age of twelve reported suffering from alcohol use disorder (AUD). While social support has been shown to maintain sobriety in individuals, social support may also protect against the development of the addiction. The objective of this study was to understand the relationship between social interaction and alcohol reward processes in male Sprague Dawley rats using an alcohol conditioned place preference model in combination with pair-housing. Pair-housed and single-housed rats received conditioning trials in which ethanol exposure (20% v/v 1.0 mg/kg; orally administered) was paired with a distinctive environment while a separate environment was paired with saline exposure (orally administered). Our results revealed that pair-housed rats displayed diminished alcohol conditioned place preference relative to single-housed rats, as indicated by their time spent in the alcohol-paired context. The neuropeptide oxytocin has previously been established in both drug reward and social interaction, however, the effects of social interaction on drug reward is not fully understood. We also examined the role of oxytocin on mediating the effect of pair-housing on alcohol conditioned place preference through co-administration of an oxytocin receptor antagonist. These results investigate the role of oxytocin in driving the attenuating effect of pair-housing on alcohol reward-related behaviors.

Title: Adolescent voluntary alcohol drinking impairs response inhibition in adulthood and alters cortical-striatal dynamics in male and female rats

Authors: *A. MCCANE[1], B. MOGHADDAM[2];
[2]Behavioral Neurosci., [1]Oregon Hlth. and Sci. Univ., Portland, OR

Abstract: Development of alcohol use disorder (AUD) is strongly associated with initiation of drinking during adolescence. A better understanding of the impact of alcohol exposure on the adolescent brain in the context of motivated behavior is fundamental for understanding the etiology and pathophysiology of AUD. Deficits in response inhibition are a critical feature of AUD and are a clinically relevant endophenotype of the disorder. However, little is known about the functional consequences of adolescent alcohol drinking on response inhibition and related cognitive measures in adulthood. Here, we used a moderate voluntary adolescent drinking model combined with a recently developed Cued Response Inhibition Task (CRIT) that assesses response inhibition, stimulus-response relationships, attentional processes and behavioral flexibility in adolescents or adults. We find adult rats who drank ethanol during adolescence made more (irrelevant) nose pokes during the inter-trial-interval, were quicker to make premature responses, and exhibited reduced response inhibition, relative to sucrose exposed controls. We are currently investigating the mechanistic basis of this observation by recording from single units and local field potential activity in two brain regions implicated in response inhibition, the orbitofrontal cortex (OFC) and dorsal striatum (DS), with power, OFC-DS synchrony, firing rate and spike correlations being computed during all behavioral epochs. Our preliminary analysis of recording data reveals ethanol exposed rats show an enhanced response to reward in the OFC and an augmented response in the DS during premature responding. Because dysfunction of cortico-striatal circuits is a critical feature of AUD, these translational result will enhance our mechanistic understanding of brain changes that occur in these circuits as a consequence of adolescent ethanol exposure.

Title: Anterior insular cortex activity encodes aversion-resistant alcohol consumption

Authors: *P. STARSKI[1], M. MORNINGSTAR[2], S. KATNER[4], R. SANDLER[4], S. WEAN[4], C. C. LAPISH[3], F. W. HOPF[5];
[1]Univ. of Indiana, Indianapolis, IN; [3]Psychology, [2]IUPUI, Indianapolis, IN; [5]Psychiatry, [4]Indiana Univ. Sch. of Med., Indianapolis, IN

Abstract: Compulsive alcohol drinking is a core facet of alcohol use disorder, where alcohol intake persists despite adverse consequences, and a major clinical obstacle to successful treatment. Recent work has shed light on underlying circuit and neurochemical mechanisms in aversion-resistant drinking, but still remain largely undefined. Previously, we have described that the anterior insular cortex, a critical mediator of emotion, motivation, and interoception, plays a significant role in promoting aversion-resistant drinking. Indeed, optogenetic inhibition of the insula-ventral striatum network significantly decreased compulsive alcohol drinking in rat as observed when the aversive stimulus was a bitter-tasting quinine or intermittent footshock. However, these same inhibitions had no effect during alcohol-only drinking, suggesting this insula-related circuit is critical specifically for aversion-resistant drinking. Additionally, heavy human drinkers show similar insula-circuit recruitment when responding for alcohol under threat of shock. Together, these studies indicate that the insula plays a significant role, in both rodent and human, when overcoming conflict (compulsion) to drink alcohol. Here, we hypothesized that alcohol intake paired with aversive challenge will increase firing levels in the anterior insula described by 32-electrode multi-wire electrophysiology implants. Rats were first trained to consume 20% alcohol through an intermittent intake paradigm over 3 months. Quinine, a bitter additive, was given at two concentrations (10 mg/L and 60 mg/L) to assess aversion-resistant, compulsive motivation for alcohol drinking. Animals demonstrating compulsive drinking were implanted with multi-wire recording probes, allowing insula neuron activity to be recorded during alcohol-only and two levels of aversion-resistant drinking. Licking patterns were assessed concurrently with lickometry. Similar to previous findings, rats maintain longer licking bouts during alcohol-only sessions, with shorter bouts during quinine-alcohol drinking. Insular electrophysiological recording has revealed firing data of over 1200 neurons from 13 rats during alcohol-only and moderate (10 mg/L) and high (60 mg/L) quinine challenge in alcohol. Ongoing analyses focus on the comparison of anterior insular neuron firing characteristics between drinking conditions with one main hypothesis being greater insula firing scaling to the level of challenge and amount of consumption.

Title: Chronic ethanol and withdrawal dysregulates glutamatergic function in 'reward' and 'aversion' basolateral amygdala neurons in a circuit- and sex-dependent manner

Authors: M. PRICE, *B. MCCOOL;
Wake Forest Sch. of Med., Winston Salem, NC

Abstract: The basolateral amygdala (BLA) regulates aversion and reward processing during alcohol withdrawal through projections to the bed nucleus of the stria terminalis (BNST) and nucleus accumbens (NAC), respectively. Glutamatergic pyramidal neurons in the BLA receive glutamatergic projections from two distinct input pathways. Midline structures like the medial prefrontal cortex send projections through the *stria terminalis* (ST) whereas lateral cortical areas send projections through the external capsule (EC). Previous studies revealed that chronic intermittent ethanol and withdrawal (CIE/WD) increases glutamate release from ST inputs and increases postsynaptic function at EC-BLA synapses. In this study, we compared neurophysiological changes in CIE/WD-exposed 'reward' and 'aversion' BLA neurons to understand the neurophysiological mechanisms involved in anxiety and alcohol intake in male and female rats. We used retrograde labeling of BLA neurons projecting to the NAC (BLA-NAC) or BNST (BLA-BNST) as representative 'reward' and 'aversion' BLA neurons, respectively. A 2-way ANOVA revealed that CIE/WD increased glutamate release from ST inputs onto BLA-BNST neurons in male and female rats (main effect of CIE/WD $p<0.001$). There were no significant effects in BLA-NAC neurons. In contrast, increased postsynaptic function at EC-BLA synapses is both circuit- and sex-dependent. A 2-way ANOVA showed that CIE/WD increased postsynaptic function at EC synapses with BLA-NAC neurons, independent of sex (main effect of CIE/WD $p<0.01$). In BLA-BNST neurons, there was a main effect of CIE/WD ($p<0.01$) and an interaction effect ($p<0.05$), and post-hoc tests revealed that CIE/WD increased postsynaptic function at EC synapses with BLA-BNST neurons only in females ($p<0.01$). These findings indicate that CIE/WD dysregulates the neurophysiology of 'reward' and 'aversion' BLA neurons through distinct mechanisms, and that female rats are more vulnerable to changes in 'aversion' BLA neurons than males. We then investigated the effects of increased glutamatergic function on BLA neuron excitability in male rats. Using mixed effects analyses, we found that CIE/WD increased the excitability of BLA-NAC (main effect of current $p<0.0001$, interaction effect $p<0.05$) and BLA-BNST neurons (main effect of current $p<0.0001$, interaction effect $p<0.0001$) when only GABAergic transmission was blocked. However, the enhanced excitability was abolished in BLA-NAC and BLA-BNST neurons when both glutamatergic and GABAergic transmission were blocked, supporting the idea that increased glutamatergic function facilitates BLA excitability after CIE/WD.

Title: Chronic ethanol exposure potentiates nucleus basalis magnocellularis (NBM) neurotransmission and facilitates pathological release of glutamate in the BLA during ethanol withdrawal

Authors: *S. SIZER, B. MCCOOL;
Wake Forest Univ., Winston Salem, NC

Abstract: Chronic ethanol exposure potentiates basolateral amygdala (BLA) glutamatergic afferents, driving BLA pyramidal neuron hyperexcitability and the expression of anxiety during withdrawal (WD). The purpose of the present study was to understand the contribution of nucleus basalis magnocellularis (NBM) cholinergic projections to withdrawal-induced alterations in glutamate neurophysiology in the BLA. Following 10 days of chronic intermittent ethanol (CIE) vapor exposure and 24 hours of withdrawal, we completed *ex vivo* whole-cell patch clamp electrophysiology and utilized optogenetics to bidirectionally manipulate NBM terminal activity before recording electrically-evoked paired-pulse ratios (PPRs) as a measure of presynaptic function. Specifically, we compared presynaptic nicotinic acetylcholine receptor (nAChR)-dependent changes in stria terminalis (ST) glutamate PPR between CIE animals and age-matched AIR controls. Optical excitation of NBM terminals significantly increases ST glutamate release probability in AIR animals (one-way repeated-measures ANOVA, $p<0.01$), with no significant effect in CIE animals. Mecamylamine (MEC; non-selective nAChR antagonist) perfusion reverses this effect, illustrating that laser stimulation of NBM cholinergic projections activates presynaptic nAChRs on ST glutamate terminals. In contrast, optical inhibition of NBM terminals attenuates withdrawal-induced increases in ST glutamate release probability in CIE neurons (mixed effects ANOVA, $p<0.05$). In AIR neurons, laser inhibition of NBM terminals show no appreciable effects on ST glutamate PPR (mixed effects ANOVA, $p>0.05$). Laser activation of NBM terminals alone elicits a monosynaptic EPSC that is potentiated following CIE exposure and withdrawal. Together, these data strongly indicate that CIE/WD strengthens NBM neurotransmission and produces tonic activity of nAChRs on ST glutamatergic synapses, resulting in a ‘pathological’ elevation of glutamate release. These findings illustrate that CIE-dependent modifications to NBM neurophysiology may profoundly shift the excitatory/inhibitory balance in the BLA.

Title: Ethanol-induced suppression of GIRK-dependent signaling in the basal amygdala

Authors: *E. MARRON[1], M. E. TIPPS[1], B. HAIDER[2], T. R. ROSE[2], B. N. VO[2], M. C. DEBAKER[3], K. D. WICKMAN[1];
[1]Pharmacol., [2]Grad. Program of Pharmacol., [3]Grad. Program of Neurosci., Univ. of Minnesota, Minneapolis, MN

Abstract: Repeated cycles of ethanol intoxication and withdrawal are thought to induce neuroadaptations in brain regions that regulate mood, goal-directed behavior, and learning, promoting key features of alcohol use disorder (AUD). The GABAB receptor (GABABR) is a critical regulator of the behavioral sensitivity to drugs of abuse and has emerged as a promising therapeutic target for AUD treatment. Our work and others has shown that psychostimulants can suppress GABABR-dependent signaling in key neuron populations in the mesocorticolimbic system, including the ventral tegmental area and the prelimbic cortex. Despite the established involvement of limbic structures in AUD, the potential influence of drug exposure on GABABR-dependent signaling in these brain regions remains unknown. Here, we examined the impact of alcohol exposure on GABABR-dependent signaling in the basolateral amygdala (BLA). Using two distinct ethanol exposure approaches, we found that the somatodendritic inhibitory effect of GABABR activation on principal neurons in the basal (BA) sub-region of the BLA (p=0.0274, n=12-13/group), but not the lateral (LA) (p=0.7144, n=8-10/group), was reduced during withdrawal from ethanol. Experiments using KO animals and pharmacological manipulations showed that this adaptation was mediated by a selective weakening of the G protein-gated inwardly rectifying K+(GIRK/Kir3) channel component of the GABABR-induced response. Similar to other brain regions studied, this GABABR-GIRK response in the BA is driven by heterotetramers of GIRK channels containing both GIRK1 and GIRK2 subunits. Interestingly, although the GIRK3 subunits do not seem to participate in channel formation, the neuroadaptation was absent in GIRK3KO animals (p=0.7529, n=11/group), suggesting a modulatory role of this subunit. We next sought to identify a behavior correlate of this

neuroadaptation by performing a battery of behaviors. Ethanol withdrawal produced robust physical dependence indicated by a handling induced convulsions test (p=0.0001, n=12/group), anxiety-like phenotype in the light/dark box test (p=0.0041,n=12/group), anxiety/compulsive-like phenotype in the marble burying test (male: p=0.0296, n= 6/group; female: p=0.0453, n=6/group) and increased irritability-like behavior in the bottle brush test (male: p=0.0007, n=6/group; female: p=0.0002, n= 6/group). Interestingly, preliminary data obtained from constitutive GIRK3KO animals show GIRK3 subunit ablation prevents these behavioral changes. These results suggest that the behavioral effects induced by ethanol exposure withdrawal might be, at least in part, mediated by GIRK3.

Abstract: Alcohol use disorder (AUD) is a complex neuropsychiatric disorder that combines behavioral, neurobiological, and psychosocial alterations. The development of AUD has been characterized as a three-stage cycle: binge/intoxication, withdrawal/negative affect, and preoccupation/anticipation. Although these stages have been studied in humans and animals, there is still missing knowledge of the neuroadaptative changes happening across the brain during each stage. Knowledge of these changes would possibly help us understand how AUD is established. Preclinical models of AUD are key to model these stages, and in combination with longitudinal in vivo neuroimaging, could provide a better understanding of the neuroadaptative changes in AUD. In this study, we used the Intermittent-Access Ethanol 2-Bottle-Choice Drinking Paradigm in n= 29 (16 female), Wistar rats, starting at a weight of 160 g (∼7weeks old−45 days post-natal corresponding to adolescence). Animals had ad-libitum access to standard

laboratory chow and water. After the baseline MRI scans, 22 rats were assigned to the EtOH group and 7 to the Control group. EtOH group underwent a modified version of the Wise pre-clinical AUD model where, briefly, rats received continuous access to 20% ethanol on a 12-hour reversed light/dark cycle for 45 days. The first acquisition was at baseline, and the second MRI acquisition was after finishing the 20 sessions (45 days, P90) of ethanol intake. We used deformation-based morphometry to create Jacobian maps per subject and time point using a Two Level DBM tool using a Fisher rat atlas template and parcellation, with mixed model GLM, we compared the within-subjects effect of baseline versus 20 sessions of intermittent alcohol. The main alcohol intake (g/Kg/24 h) was 1.90 +-2.08 (mean/ +-sd). For the group x session interaction. We found local volume changes after 20 sessions of voluntary alcohol consumption in rats, thalamus, cerebral cortex showed reduction while Dentate Gyrus and Caudate-Putamen showed an increase. In order to find the brain morphological phenotype associated with alcohol consumption, two classes were created (high consumption / low consumption). Finally, a Bayesian logistic regression model was used to determine the brain morphology associated with alcohol consumption. These changes may arguably be neuroadaptive structural changes related to chronic alcohol use, however, he results are not corrected for multiple comparisons.

Title: Sex, age and beta-endorphin expression interact to alter the effect of alcohol on open field behavior in mice

Authors: *K. LEONARD[1], H. JONES[1], M. WALDRON[2], J. E. GRISEL[2], *E. RHINEHART[1]; [1]Susquehanna Univ., Selinsgrove, PA; [2]Bucknell Univ., Lewisburg, PA

Abstract: Alcohol causes enduring changes in the motivation and reward neurocircuitry, and Alcohol Use Disorder (AUD) affected 19.3 million Americans aged 12+ in 2018. One common denominator of rewarding, potentially addictive substances, including alcohol, is an acute increase in central mesolimbocortical dopaminergic pathway activity concomitant with psychomotor stimulation in behavioral tests, such as the open field test (OFT). Previous research has shown that sex, age, and expression of the opioid peptide, beta-endorphin (BE), affect the behavioral responses to alcohol in tests such as the elevated plus maze and the light-dark box. Therefore, we hypothesized that OFT behavior after a single acute alcohol administration would be dependent upon age, sex and BE expression. To test this hypothesis, we examined the impact

of EtOH treatment (1.5g/kg, n=62 or 1.75g/kg, n=61) on OFT behavior in adult (n=62) and adolescent (n=61), male (n=58) and female (n=65) C57BL/6J mice that either expressed BE (BE +/+, n=53) or lacked BE (BE-/-, n=70). As expected, sex, genotype and EtOH dosage all interacted to influence the amount of time animals spent in the center part of the open field arena ($p<0.05$), an indicator of anxiety-like behaviors in rodents. In addition, age, sex and genotype all independently impacted distance traveled in the center of the arena ($p<0.05$), an indicator of psychomotor stimulation. For example, at 1.75 g/kg EtOH, the adolescent, female, BE+/+ animals traveled a significantly greater distance while in the center of the arena than their male counterparts (12.6 ± 2.5 vs. 18.8 ± 2.1, $p<0.05$), unlike the adolescent, BE -/- animals that showed no sex difference (8.0 ± 2.0 for males vs. 6.2 ± 1.5 for females, n.s.). These data indicate that it is necessary to simultaneously consider a complex array of factors to determine how any one individual experiences the subjective anxiolytic and stimulant effects of alcohol. At the end of the behavioral study animals were sacrificed and brains were perfused with paraformaldehyde and sectioned at 35 microns to be processed immunohistochemically for both tyrosine hydroxylase, a marker for dopaminergic neurons, and c-fos, a protein marker of neuronal activation to allow us to determine if differences in the activation of dopaminergic neurons correlate with any of the observed differences OFT behavior (data in progress). These data will help us better understand how several physiological factors interact to determine the initial subjective experience of alcohol and how that relates to site specific neuronal activation, which may shed light on the mechanisms responsible for differences in individual susceptibility to AUD.

Title: Effects of physical activity and alcohol ingestion on female mouse brain GABA-B receptor concentrations

Authors: *T. J. BUHR[1], C. H. REED[2], E. E. BAUER[1], A. SHOEMAN[1], R. J. VALENTINE[2], P. J. CLARK[1];
[1]Food Sci. and Human Nutr., Iowa State Neurosci. Interdepartmental Grad. Program, Ames, IA; [2]Kinesiology, Iowa State Univ., Ames, IA

Abstract: Alcohol misuse (e.g. binge-drinking) is a risk factor to alcohol dependence and a major contributor to the development of numerous health problems. Evidence suggests that

regularly misusing alcohol can result in adaptations in the metabotropic GABA-B receptor system, which remains a popular pharmacological target to treat alcohol dependence. Moreover, evidence suggests that exercise can cause alterations in brain GABA systems, including GABA-B receptor mediated signaling. Therefore, we investigated the possible interactions between alcohol misuse and chronic mild physical activity on GABA-B receptor protein levels across the brain, as it may have important implications for the treatment of alcohol use disorders. Adult female C57/BL6J mice received 2.5hr access to voluntary running wheels daily or remained sedentary for 35 days. During the last five days following wheel access, the voluntary binge-like drinking paradigm, "drinking in the dark" (DID), was employed, whereby runner and sedentary mice received access to either a 20% ethanol solution or water for a 2-4 hour period in their home cages approximately 3 hours into the dark cycle (i.e. active period). Mice were sampled immediately following DID and the prefrontal cortex, hypothalamus, striatum, cerebellum, hippocampus, brainstem, and remaining cortical areas were rapidly microdissected. GABA-B receptor protein density across brain regions was assessed via western blot. 35 days of moderate physical activity had no effect on amounts of ethanol ingested during DID. Preliminary data indicate that GABA-B receptor 1 levels increase with exercise, but were unaffected by alcohol, in the prefrontal cortex. Possible exercise-increased GABA-B receptor protein densities may hold significance in treatment of not only alcohol use disorders, but also treatment of other substance abuse and stress-related mental health disorders.

Title: A behavioral approach for sex-specific increase in ethanol consumption after repeated stress in mice

Authors: *V. GARCIA-RIVAS, M. THOMAS, Y. S. MINEUR, M. R. PICCIOTTO;
Dept of Psychiatry, Yale Univ., New Haven, CT

Abstract: Recent epidemiological data suggest that, compared to men, women are more likely to drink alcohol to cope with stress and negative affect. This stress-induced drinking is problematic, as it may put women at higher risk for developing alcohol use disorders. Even though the precise neurobiological mechanisms behind this phenomenon remain unknown, there is converging

evidence suggesting that exposure to chronic ethanol dysregulates the neural networks in the basolateral amygdala, which may prime for exacerbated stress responses in a sex-dependent manner, which can be then alleviated by acute ethanol intake. To test this hypothesis, we first developed a behavioral model that captures this female-specific increase in ethanol drinking after repeated stress. Adult male (n=10) and female (n=10) C57BL6J mice were trained to drink ethanol daily in a modified “drinking-in-the-dark” (DID) paradigm, which consisted of introducing two sippers (water and 10% ethanol diluted in water), to their home cage for 2 hours, 3 hours into their dark phase. Once drinking behavior was stabilized after 12 daily sessions, mice were split into control (n=5 per sex) and *"stress"* (n=5 per sex) groups for the remainder of the experiment. On days 13, 14, 20 and 21, *"stress"* mice underwent stress sessions at least 4 hours prior to the corresponding DID for that day. These stress sessions consisted of 1hr exposure to mild foot shocks, applied at semi-random intervals in specialized chambers equipped with an electrified grid. During this time, control mice remained in their home cage undisturbed. An increase in alcohol intake in the *"stress"* female group was observed on the last stress day (day 21), compared to control female mice and male subgroups. Differences in alcohol seeking between female *"stress"* and control mice was also apparent when the same mice were then later trained to seek for an oral 10% ethanol reward using an FR3 operant alcohol self-administration paradigm. This behavioral approach is well suited to be combined with fiber photometry or optogenetics in freely moving mice, to assess how sex-specific neural dynamics in the basolateral amygdala at the intersection between chronic alcohol and repeated stress may put females at risk of maladaptive ethanol drinking.

Abstract: Sex dependent behavioral strategies for compulsion-like alcohol drinking. Thatiane de Oliveira Sergio[1,2], Jacob Kellner[1], David Darevsky[2], Vanessa De Paula Soares Rachetti[3], Andrea F Jones[2], Frederic W Hopf[1,2].[1]Department of Psychiatry, Indiana University School of Medicine, Indianapolis, IN.[2]Department of Neurology, University of California, San Francisco, San Francisco, CA[3] University Federal of Rio Grande do Norte, Natal, BrazilCompulsive alcohol drinking, where intake persists despite adverse consequences, is a central driver of excessive alcohol drinking and major obstacle to treating alcohol use disorder. Hazardous drinking in women has dramatically increased across the last decades, making it critical to understand sex-specific mechanisms driving pathological intake and develop more targeted anti-addiction therapies. Using lickometry, we examined microstructural behavioral changes that can reflect altered motivation, as well as different behavioral strategies, between males and females during conflict-resistant intake of quinine-alcohol (QuiA). Overall, it was widely observed that females drank more under all conditions. Quinine-sensitivity in three different concentrations (10, 60 and 100mg/L) was similar across sexes, however, females showed differences in the bout length for the highest concentrations of quinine. Together, our findings indicate that females and males have different strategies for maintaining alcohol drinking in the face of negative consequences. Knowing these differences can be useful to better understand the drinking problem in females.Supported by R01AA024109.

Title: Emotional modulation of memory: a computational model shows how excessive amygdala input to the hippocampus can lead to overgeneralization of fear-related memories

Authors: *Y. J. JOHN[1], J. WANG[3], D. BULLOCK[2], H. BARBAS[1];
[1]Neural Systems Lab, Dept of Hlth. Sci., [2]Dept. of Psychological and Brain Sci., Boston Univ., Boston, MA; [3]Dept. of Psychological and Brain Sci., Univ. of California at Santa Barbara, San Diego, CA

Abstract: The emotional system of the brain has powerful effects on processing of context and episodic memory. A key pathway in the circuit mediating these effects is the projection from the amygdala to the anterior hippocampus (ventral in rodents). Wang and Barbas (2018) uncovered a

distinctive pattern in the amygdalar projections to hippocampal neurons in primates. The projections from amygdala to the CA3 subfield targeted excitatory pyramidal neurons as well as parvalbumin (PV) and calretinin (CR) inhibitory neurons. Evidence suggests that the inhibitory PV and CR interneurons act on CA3 pyramidal neurons in a manner analogous to their counterparts in cortex: PV provides strong perisomatic inhibition of pyramidal (excitatory) neurons, whereas CR provides disinhibition by inhibiting dendrite-targeting inhibitory interneurons. Amygdalar projections to the CA1 subfield were found to differ from those to CA3 by not targeting PV interneurons. The projections primarily targeted pyramidal neurons and CR interneurons, indicating synergistic excitatory and disinhibitory effects. Given that CA1 is the primary source of hippocampal outputs, understanding the overall effect of the amygdala on hippocampal function requires modeling the combined effects of its inputs to the integrated CA3-CA1 circuit. We therefore developed a computational model of spiking neurons that demonstrates some key functional implications of these projections. Our simulations show that the amygdala-CA3 projection can serve as a potent mechanism for two emotion-guided processes: (1) gating of CA3-dependent mnemonic and contextual processes, and (2) reduction of episodic richness in CA3. A moderate level of amygdala excitation can boost CA3 activity broadly, enabling rich detail to be available for discrimination and associative learning. But abnormally high amygdala activity can suppress “non-emotional” inputs to CA3 from other sources, leading to loss of detail. Our simulations also show that amygdala input to CA1 modulates the transition between a phasic “pattern-match” mode and a tonic “pattern-mismatch” mode vital for new learning. These effects of the amygdala on the anterior hippocampus suggest a mechanistic basis for “sticky” overgeneralization in cases of elevated fear, and, more broadly, for anxiety-related shifts in the processing of context and episodic memory.

Title: Density of parvalbumin, calbindin, and calretinin inhibitory neurons in subgenual cingulate area 25 of the neurotypical human

Authors: M. RAKOCZY, ***M. JOYCE**, B. ZIKOPOULOS, H. BARBAS;
Boston Univ., Boston, MA

Abstract: Brodmann Area 25 (A25) in the posterior ventromedial prefrontal cortex is linked with areas associated with learning, memory, motivation, and reward. Hyperactivity in A25 has been observed in humans with depression. In marmosets, pharmacological overactivation increases anxiety- and anhedonia-like behaviors. Inhibition is a critical component of neuronal circuitry, and disruptions in the equilibrium between inhibition and excitation can lead to pathological changes in brain circuits. The hyperactivity observed in A25 in depression may involve an imbalance between the activity of excitatory and inhibitory neurons. To investigate the inhibitory neuron composition of the neurotypical subgenual cingulate in *post-mortem* human brains, we used immunohistochemistry to label the calcium-binding proteins parvalbumin (PV), calbindin (CB), and calretinin (CR), which label almost all cortical inhibitory neurons and have different functional roles in local inhibition. Here we used stereology, a method of unbiased systematic random volumetric sampling, to estimate the laminar density of PV, CB, and CR neurons in A25 of *post-mortem* neurotypical human brains for comparison with previous data in the rhesus macaque. The primate A25 contains CB positive pyramidal neurons that stain lightly and can be distinguished from darkly labeled CB positive inhibitory neurons. In this study, only the darkly labeled CB neurons were included. We found that CR neurons are denser in A25 than PV and CB. CR neurons are concentrated most densely in superficial layers I-IIIa of A25. Conversely, PV neurons are predominantly found in mid-deep layers III-VI, while CB dark-labeled neurons have a more even distribution among layers, with slightly higher density in mid-superficial layers II and IIIa. These findings are comparable to recently published data in the rhesus macaque. CR and CB neurons in superficial layers are thought to fulfill a disinhibitory or modulatory role, while PV neurons exert a strong inhibitory effect by targeting pyramidal neurons perisomatically. These data provide the basis for future comparison with data from brains with psychiatric disease states, including depression.

Title: Impaired Sleep Spindles in Schizophrenia: Studying Underlying Mechanisms with a Biophysical Neural Model

Authors: N. MATUK, B. ZIKOPOULOS, *A. YAZDANBAKHSH;
Boston Univ., Boston, MA

Abstract: Sleep spindles are brief oscillations present during EEG recordings that can be seen during nonrapid eye movement sleep and are implicated in memory consolidation. Spindles originate within the thalamocortical loop, which consists of the inhibitory thalamic reticular nucleus (TRN), thalamocortical relay, and cortical neurons. The thalamocortical circuity is further subdivided into a matrix and core, the former is implicated in limbic processing and memory consolidation, while the latter is associated with sensory processing. Although the mechanism responsible for generating spindles is understood, their functionality is still largely unknown. Therefore, the full extent of the functional consequences of spindle impairments in schizophrenia are not well understood. In this study, we built a detailed circuit-based, biophysical neural model of the thalamocortical loop, incorporating Boltzmann equations for voltage and neurotransmitter-gated channels, both ionotropic and metabotropic, to address our key question of why sleep spindle frequency and density decrease in schizophrenia. We tested a variety of connectivity changes to replicate patterns of spindles observed in schizophrenia as well as neurotypical individuals. By comparing the reversed engineered circuit that generates schizophrenia-like spindles with functional imaging and electrophysiological data we were able to create a prioritized list of changes within the circuit to further investigate as potential mechanisms responsible for the spindle deficits in schizophrenia. With models of isolated matrix and core thalamocortical loops, our studies focused on reduced TRN inhibition and disruption of reciprocal thalamocortical connectivity, both at the level of the thalamus and the cortex, as potential mechanisms. Incorporating changes in cortical feedback in order to mimic cortical “up” and “down” states was also investigated to understand spindling and bursting in different states. Our model acts as a tool to direct future imaging and electrophysiology experiments to identify the neural mechanisms underlying schizophrenia spindle impairments.

Title: Molecular and synaptic features in thalamic neural circuits of primates

Authors: X. LIU, J. SON, L. TRAVIS, N. ZAMAN, K. SKUBISZ, K. WASIF, S. KONSTANTINIDOU, E. ANGELOPOULOS, J. NGO, H. BARBAS, ***B. ZIKOPOULOS**; Boston Univ., Boston, MA

Abstract: The primate thalamus forms two parallel and distinct thalamocortical (TC) circuits with reciprocal components: the core and matrix, which drive and modulate TC activity. The core TC circuit, prevalent in sensory thalamus, drives activity focally in the middle cortical layers and gets feedback through small modulatory cortical axon terminals from pyramidal neurons in layer 6 (L6). The matrix TC circuit can drive activity in high-order thalamus, through large axon terminals from cortical layer 5 (L5) pyramidal neurons and sends broad thalamic feedback to the superficial cortical layers. The inhibitory thalamic reticular nucleus (TRN) intercepts all TC communication and is situated strategically between the thalamus and cortex. However, little is known about the molecular and synaptic profiles of core and matrix thalamic circuits and their interactions in primates. To begin to address this gap, we used immunostaining, brightfield, fluorescent, confocal, and electron microscopy to systematically examine and quantitatively map key molecular and synaptic features, including markers of excitatory, inhibitory, and calcium-binding proteins in a primarily core thalamic nucleus, the visual lateral geniculate nucleus (LGN), a high-order nucleus, the mediodorsal (MD), and the TRN. We found predominantly core neurons in LGN, while the expression of core and matrix markers was more mixed in MD with more matrix neurons in the medial, limbic MD. The LGN had significantly fewer inhibitory neurons compared to MD, with the lateral, parvicellular MD, containing the highest density of GABAergic interneurons. We also found that core and matrix thalamocortical tracts passing through TRN were organized following a dorsal-ventral gradient, with relatively more matrix tracts dorsally and more core tracts ventrally. Further examination of synaptic profiles in thalamic nuclei at high resolution, showed a majority of excitatory synapses, mainly from the cortex, with variable shapes and sizes, in all nuclei. Moreover, a significant proportion of large inhibitory synapses targeted the soma and proximal segments of TC projection neurons in LGN, MD, and inhibitory TRN neurons. Our results provide support for the anatomical and functional organization of core and matrix TC circuits and highlight the prominent role of local and external inhibition in the primate thalamus, which provides additional flexibility to TC processing.

Title: Pathways linking the Amygdala, Hippocampus, and Subgenual Area 25 in the Primate Nucleus Reuniens

Authors: *L. G. MARSHALL[1], M. P. JOYCE[1], S. BANIK[1], J. WANG[1], J. HOLZ[1], D. XIAO[1], J. G. BUNCE[2], H. BARBAS[1];
[1]Boston Univ., Boston, MA; [2]Northeastern Univ., Boston, MA

Abstract: The primate thalamic Reuniens Nucleus (RE) is the most ventral of the limbic anterior midline nuclei, situated directly above the third ventricle. The RE is distinguished among thalamic nuclei by its bidirectional connections with the hippocampus and medial prefrontal cortex (mPFC). In rats, detailed investigation has demonstrated RE's role in several cognitive functions that require hippocampus-mPFC activity coordination, including spatial working memory, memory consolidation, and strategy shifting. However, in the primate, several foundational questions remain unanswered: What is the chemoarchitecture of RE? Are other limbic structures, such as the amygdala, also connected with RE? To address the chemoarchitecture of the RE, we used immunohistochemistry to label GABA, a marker of inhibitory neurons, and for the calcium-biding proteins parvalbumin (PV), calbindin (CB), and calretinin (CR), all of which label excitatory projection neurons in the thalamus. PV neurons are associated with a core thalamocortical connectional system that terminates in middle layers of cortex. CB and CR are associated with a matrix profile of thalamocortical connections, with terminations in the upper layers 1-3a and layer 6. We found that the RE is primarily populated by CB and CR neurons with sparse PV neurons and processes, classifying it as a matrix-dominant thalamic nucleus. Injections of neural tracers in subgenual cingulate cortical area 25, amygdala, and hippocampus showed robust incoming and outgoing connections with the RE in all three pathways. The hippocampal and posterior area 25 pathways were densest in anterior RE, while the amygdala had a consistent density of connections throughout the anterior to posterior axis of RE. We also used high resolution methods to examine ultrastructural characteristics of incoming connections from the three pathways that form synapses in RE. We observed multiple instances of amygdala axonal boutons forming successive synapses with the same postsynaptic structure. We also observed some hippocampal terminations forming multisynaptic complexes that are comparable to synaptic triads formed by amygdala terminations in the thalamic Mediodorsal Nucleus. In summary, the primate RE shows a specialization by its strong connection with the amygdala. The connections of RE with the hippocampus, area 25, and amygdala positions it to coordinate activity among these regions and is likely an integral node in limbic memory and emotional networks.

Title: Role of hippocampus in reward valuation under uncertainty and for effort

Authors: B. ATTAALLAH, P. PETITET, R. ZAMBELLAS, S. IRANI, S. MANOHAR, *M. HUSAIN;
Univ. of Oxford, Oxford, United Kingdom

Abstract: The hippocampus plays an important role in many functions including memory and spatial cognition. Converging evidence from animal and human studies indicates that it might also play an important role in motivation and value-based decision making. This contribution, however, is under-investigated and yet to be established.
Here, we assessed people with focal hippocampal damage (N=19) as a result of autoimmune limbic encephalitis. We investigated how they make value-based decisions in two contexts using two behavioural paradigms. In the first task, participants made decisions in the context of uncertainty. In a passive form of this paradigm, they decided simply whether to accept or reject potential rewards in exchange for tolerating uncertainty. In an active search form, they could gather information, which came at a cost, to reduce uncertainty prior to committing to their decisions. In the second paradigm, participants made decisions in the context of effort, accepting/rejecting decisions based on whether the reward on offer was worth the effort assigned to it.
The results showed that people with hippocampal damage, in comparison to healthy controls, have reduced sensitivity to changes in reward when evaluated against uncertainty, but not effort. While maintaining intact sensitivity to uncertainty, the influence of changes in reward (in the passive task) and information cost (in the active task) was blunted in hippocampal patients. Moreover, this reduced sensitivity to changes in reward was more pronounced in patients with more severe hippocampal atrophy. In contrast, performance of hippocampal patients on the effort task was intact.
These results suggest a context-dependent role of the hippocampus in reward processing and valuation, which might represent an important step forward in understanding hippocampal contributions to value-based decision making and motivated behaviour in general.

Title: Visualizing neurons in the reward circuit based on their co-projections

Authors: *A. LUZ-RICCA, W. LERCHNER, J. SCHEIDT, K. E. DASH, M. A. ELDRIDGE, B. J. RICHMOND;
NIMH/NIH, Bethesda, MD

Abstract: The orbital frontal cortex (OFC) and rostromedial caudate (rmCD) are brain regions considered important for reward value processing and decision-making. The OFC is thought to be involved mainly in reward value assessment, whereas the rmCD is thought to play a role in reward expectation and action selection. To identify neurons that project from other areas to both of these regions, we injected retrograde viruses expressing red and green fluorescent reporters into the OFC and rmCD, respectively. After injection of the viral vectors, histological analysis showed a population of neurons in many regions co-expressing both fluorescent reporters, indicating that these neurons co-project to the OFC and rmCD. These neurons were located within higher order visual areas (TE and V4) but were also identified in brain areas involved with processing spatial and emotional salience, such as the amygdala, rhinal cortex, and insula. Perhaps surprisingly, in the hemisphere contralateral to the injection site, these same regions had a larger than expected percentage of co-projecting neurons relative to neurons projecting to either OFC or rmCD alone. For example, in the amygdala of the ipsilateral hemisphere, approximately 20% of the neurons projecting to OFC also projected to rmCD, but from the contralateral amygdala nearly all OFC-projecting neurons also projected to rmCD. We are further characterizing the population of co-projecting neurons, which presumably carries identical signals to two brain regions thought to underlie reward evaluation and may play a role in the normalization of sensory information.

Title: A role for projection neurons from monkey's rhinal cortex to rostromedial caudate in stimulus-reward associations

Authors: *W. WANG[1], M. A. ELDRIDGE[1], N. MIYAZAKI[1], J. E. PEARL[1], W. LERCHNER[1], T. SETOGAWA[2], J. N. TURCHI[1], B. LI[1], B. J. RICHMOND[1];
[1]Lab. of Neuropsychology, NIMH, Bethesda, MD; [2]Univ. of Tsukuba, Tsukuba, Japan

Abstract: Primates, including old-world monkeys, learn stimulus-reward associations seemingly without effort. We previously showed that rhinal cortex has a causal role in associating value with visual stimuli, with monkeys without a rhinal cortex being less sensitive to previously learned stimulus-reward associations and learning new associations between visual cues and reward schedule states slowly, if at all. Rorstromedial caudate (rmCD) also plays a causal role in stimulus-reward associations. When rmCD is inactivated chemogenetically, monkeys show a deficit in evaluating the size of the upcoming reward signaled by visual cues. There is a known connection between deep layers of the rhinal cortex projecting to rmCD. Here, we interrupted this connection by combining a unilateral rhinal cortex lesion with contralateral expression of an hM_4Di DREADD via a retrograde lentivirus (FugE) injected into rmCD. The monkey was trained to perform a task with four visual cues, which signaled the upcoming reward of one, two, four or eight drops of water, respectively. A new set of cues was used each day. Without chemogenetic inactivation, the monkey learned quickly to accept only the two larger sizes of reward and refuse the smaller rewards. However, when all neurons projecting to rmCD were silenced by systemically injected DCZ, the monkey needed significantly more trials to learn the stimulus-reward mapping. The monkey's decision time also increased. To manipulate projection neurons from rhinal cortex to rmCD selectively, on some days, microinjections (3ul x 4 sites, [100nM]) of DCZ were made into perirhinal cortex. The microinjections led to a small but significant deficit in the stimulus-reward mapping. Thus, our results show that projection neurons from rhinal cortex to rmCD are causally involved in the learning of visual stimulus-reward associations.

Title: A possible role for divisive normalization in the primate value-reward circuit

Authors: *W. LERCHNER[1], J. SCHEIDT[3], A. LUZ-RICCA[3], K. E. DASH[2], M. A. ELDRIDGE[4], B. J. RICHMOND[5];
[2]NIMH, [1]NIH, Bethesda, MD; [3]NIMH/NIH, Bethesda, MD; [4]Lab. of Neuropsychology, [5]NIMH, Bethesda, MD

Abstract: Signals for reward value are distributed widely throughout the brain and are thought to be important for evaluating sensory stimuli when faced with behavioral choices. One mechanism for normalizing the value of sensory information is divisive normalization. In the early visual system normalization of luminance is achieved through feedback inhibition of multifurcating complex cells onto simple cells. At the other end of the decision-making hierarchy, there is evidence for divisive normalization in human and old-world monkey choice behaviors. Here we present evidence for the existence of a widespread neuron population that could be part of a substrate for normalizing the value of sensory signals by co-projecting to the orbital prefrontal cortex (OFC) and the rostromedial caudate (rmCD) from both hemispheres. OFC and rmCD are considered key structures for evaluating and updating reward signals. We identified this co-projecting neuron population in two monkeys by unilaterally injecting a retrograde lentivirus expressing a fluorescent protein with one color into OFC and a retrograde lentivirus expressing another color into rmCD. Clusters of individual neurons that expressed both colors, and thus projected to both regions, were found throughout the temporal lobe and other cortical regions responsible for processing visual and emotionally relevant information, including insular cortex and the dorsomedial thalamus. The highest percentages of co-projecting neurons relative to neurons only projecting to one of the two regions were found in areas of the basal and medial amygdala rich in dopamine innervation, the parahippocampus (TF) and the temporal parietal occipital area (TPO). In the same regions in the contralateral hemisphere, co-projecting neurons were found in smaller numbers but with a much higher percentage of co-projecting neurons compared to populations only projecting to the OFC or rmCD individually. Any signal responsible for normalization of value-reward association would need to be collected from sensory processing regions of both hemispheres, making this neuron population a prime candidate for sending identical value information to OFC and rmCD, which could be used to feed back a signal for adjusting gains in sensory processing areas.

Title: Irrational choice via curvilinear value geometry in ventromedial prefrontal neurons

Authors: K. JUREWICZ[1], B. J. SLEEZER[2], P. MEHTA[2], B. Y. HAYDEN[3], ***B. EBITZ**[1]; [1]Univ. de Montréal, Montréal, QC; [2]Univ. of Minnesota, Minneapolis, MN; [3]Univ. of Minnesota Twin Cities, Minneapolis, MN

Abstract: Many patterns of irrational choice can be explained by algorithmic or computational bounds. Other patterns defy psychological explanation, but could still be due to bounds on hardware: perhaps there are constraints on the brains' ability to faithfully represent the value of choice options. Here, we used methods recently developed to study the geometry of neural representations to determine (1) whether there are limits on the accuracy of the neural representation of value and (2) what impact these limits could have on rational decision-making. We trained two rhesus monkeys to perform a value-based decision-making task while we recorded in the ventromedial prefrontal cortex (vmPFC, area 14), a prefrontal region implicated in economic decision-making. The monkeys repeatedly chose from random sets of sequentially-presented options, which offered different volume of juice. We used neural state-space analyses to probe the geometry of the vmPFC population response to these offers.
Offer value representations were predictably arranged in vmPFC, but also nonlinearly: offer values traced a curved path through neuron-dimensional space. Because decoding from a curvilinear manifold becomes increasingly warped as the range of encoded items increases, the curvature predicted a specific violation of rational choice theory: that terrible offers—offers that were never chosen—should systematical affect the preference for better offers because they increased the range of offers. Indeed, monkeys were much more likely to confuse good options when an irrelevant offer was worse (and the range was bigger), compared to when an irrelevant offer was better (and the offers should have been harder to discriminate, not easier).
Theoretical work often assumes that values are linearly represented within the brain a geometry and a linear geometry is likely critical for generating rational economic decisions. However, we found that (1) value is represented nonlinearly in at least one economic decision-making region, and (2) that behavior is irrational in exactly the way we expect from this curvilinear geometry. We conclude that curvature in the value-coding manifold may be another important cause of irrational decision-making.

Title: Ca^{2+}/calmodulin-dependent protein kinase ll alpha expression in hippocampus after moderate and intense inhibitory avoidance training

Authors: *T. A. MARIN-JUAREZ[1], C. X. RUIZ-LOPEZ[1], A. C. MEDINA[1], P. C. BELLO-MEDINA[2], G. L. QUIRARTE[1], R. A. PRADO-ALCALA[1];

Abstract: Typical amnestic treatments are ineffective when administered to subjects trained in aversively-motivated tasks using relatively high foot-shock intensities. This effect has been found when treatments that disrupt neuronal activity are administered to different regions of the brain, including the hippocampus. However, the molecular mechanisms induced by intense training are unknown. Changes in the expression of several proteins have been associated with the consolidation process. Ca^{2+}/calmodulin-dependent protein kinase II alpha (CaMKIIα) is a protein that has been implicated in learning and memory and is a key essential mediator of synaptic plasticity. We analyzed mean fluorescence intensity (MFI) of phosphorylated CaMKIIα (p-CaMKIIα) and CaMKIIα in the hippocampus (CA1, CA3, and dentate gyrus (DG)) after moderate and intense training. Rats were trained in an inhibitory avoidance (IA) task using different intensities of foot-shock (1.0 or 3.0 mA). We also studied three controls groups: a cage group (rats that were not trained), a 0.0 mA group (rats "trained" in the task, but the foot-shock was not delivered), and a shock-only group (rats that were placed in the shock compartment and received a non-contingent 3.0 mA foot-shock). The rats from each group were sacrificed 2 or 24 h after training for immunohistochemical p-CaMKIIα/CaMKIIα protein detection. At 24h after training we found a significant high MFI ratio of p-CaMKIIα/CaMKIIα in CA3, but not in CA1 and DG, in the 1.0 and 3.0 mA groups compared with the cage control group. These results suggest that synaptic plastic changes, mediated by CaMKIIα, in this region may be required for the formation of memory of moderate and intense aversive learning. On the other hand, the fact there were no significant differences in the ratio of p-CaMKIIα/CaMKIIα expression 2 h after training, or in the other regions analyzed here, does not rule out the possibility that these regions are involved in memory formation of the IA task under both training conditions, and that there may be differential expression times depending on the regions, due to a different temporary processing of information derived from training. We thank N. Serafín, B. Osorio, E. N. Hernández, S. Méndez, A. González, and O. González for technical assistance. Supported by PAPIIT IN203918.

Title: Expression of phosphorylated CREB in striatal glial cells after moderate and intense training

Authors: *A. C. MEDINA[1], G. R. TORRES[1], J. G. TECKANI[1], P. C. BELLO-MEDINA[2], G. L. QUIRARTE[1], R. A. PRADO-ALCALÁ[1];

Abstract: Many studies indicate that phosphorylation of cAMP response element-binding (pCREB) is related to memory consolidation, participating in genomic neuronal activity, but little is known about the involvement of glial pCREB activity in memory processes. It is known that intense training of inhibitory avoidance (IA) generates both a memory trace which is highly resistant to extinction and a protective effect against treatments that, when administered to the striatum, produce amnesia under moderate training conditions. The objective of this study was to investigate whether moderate and intense IA training would induce changes in the ratio of pCREB-positive glial nuclei in the striatum during memory consolidation. To this end independent groups of rats were trained using different foot-shock intensities (0.0, 1.0, or 3.0 mA); an additional group was kept in the bioterium and another group only received the highest electric foot-shock (3.0 mA) without being trained in the task. The brains were extracted one hour later for immunohistochemical detection of pCREB. There were no significant differences among the groups either in the dorsal or in the ventral regions. When comparing the dorsal vs. the ventral region a higher overall proportion of pCREB-positive in glial nuclei was observed in the ventral region. These findings indicate that the transcription pathway modulated by pCREB of the striatal glial cells does not participate in the consolidation of memory of intense and moderate IA training. Title: Creb phosphorylation in striatal neurons after moderate and intense inhibitory avoidance training

Authors: *P. C. BELLO-MEDINA[1], E. V. ALONSO-LORENZO[2], A. C. MEDINA[2], G. L. QUIRARTE[2], R. A. PRADO-ALCALÁ[2];
[1]Dept. de Neurobiología del Desarrollo y Neurofisiología, Inst. de Neurobiología, UNAM Campus Juriquilla, Querétaro, Mexico; [2]Dept. de Neurobiología Conductual y Cognitiva, Inst. de Neurobiología, UNAM Campus Juriquilla, Querétaro, Mexico

Abstract: Intense training of inhibitory avoidance (IA) is brought about by increasing the foot-shook during training, which produces a strong and persistent memory that is highly resistant to extinction. Intense training protects memory consolidation against the amnestic effects of pharmacological treatments in the striatum (STR). The phosphorylation status of the cyclic AMP (cAMP)-responsive element-binding protein (CREB) is an indicator of its transcriptional activity and gene expression in memory consolidation of moderate IA training. To explore if the same happens after intense training, three groups of adult male Wistar rats were trained in IA using different intensities of foot-shock (0.0, 1.0, and 3.0 mA); two control groups were studied: one that received the higher foot-shock (3.0 mA; SO) without training, and a naïve group (Naï). These rats were sacrificed 1 h after training for immunohistochemical detection of phospho-CREB ser133 (pCREB) in the dorsal and ventral STR. The results showed an increased pCREB ratio in trained (0.0, 1.0, and 3.0 mA) and SO groups vs. the Naï group in ventral but not in the dorsal STR. In addition, the pCREB ratio showed lateralization; the right hemisphere showed a generalized increase pCREB ratio in all groups in comparison with the Naï group, while the left hemisphere showed a higher pCREB ratio in the moderate (1.0 mA) group in comparison to the other groups. A higher pCREB ratio was not found in the intense training (3.0 mA) group. The lateralization effect observed in this study is consistent with an increase in dopamine levels and D2 dopaminergic receptors in the left STR and these changes have been related to sensitivity to rewarding brain stimulation in the preferred direction of rotation, arm of a T-maze, or lever choice tasks. The increase in pCREB neurons ratio in the left STR after moderate IA training suggests that memory consolidation of moderate training induces CREB phosphorylation that

produces gene transcription related to synaptic plasticity; however, memory formation of the intense training does not activate CREB-dependent genomic mechanisms. We thank Norma Serafín, Bernardino Osorio, Nydia Hernández, Alejandra Castilla, and Ramón Martínez for technical assistence. This study was supported by PAPIIT IN203918.

Title: Modulation of memory maintenance by calcineurin

Authors: *S. E. REYES-GARCÍA[1], M. L. ESCOBAR[2];
[1]UNAM, Facultad de Psicología, Mexico City, Mexico; [2]UNAM, Fac Psicologia, Mexico City, Mexico

Abstract: Learning can be defined as the process by which an organism acquires information, while memory refers to the process of retaining that information. The latter can be divided into acquisition, consolidation, recall, and extinction phases. Nowadays, it is widely accepted that memory extinction involves the formation of a new associative memory that inhibits a previously conditioned association. Nevertheless, the cellular and molecular mechanisms that underlie these processes are still unclear. In this regard, a body of evidence suggests that the protein phosphatase calcineurin (CaN) is involved in the extinction and maintenance of some behavioral tasks. Indeed, our previous studies showed that conditioned taste aversion (CTA) extinction increases the CaN expression in the insular cortex (IC) while CaN inhibition prevents metaplastic changes produced by the extinction of CTA. CTA is a well-established learning and memory paradigm in which an animal associates a novel taste with nausea. Meanwhile, the IC is a region of the brain that lies in the temporal neocortex and is known for its role in processing aversively motivated learning tasks, like CTA. The aim of the present study was to evaluate the participation of CaN in the CTA extinction. To do so, we infused bilaterally in the IC of adult male Wistar rats, the calcineurin-specific inhibitor FK506, 30 minutes before the second extinction session. Our results show that infusion of FK506 elicits an impairment of CTA extinction. CaN inhibition slows down the extinction of CTA, thus revealing that this phosphatase plays an important role in extinction learning, and therefore in the maintenance of CTA.

Title: Physiological role of dopamine D3 receptors in hippocampal synaptic plasticity and memory

Authors: *M. TROPEA[1], W. GULISANO[1], A. ROMANO[1], F. GIANNINO[1], G. LEGGIO[1], D. PUZZO[1,2];
[1]Univ. of Catania, Catania, Italy; [2]Oasi Res. Inst. - IRCCS, Troina, Italy

Abstract: Dopamine D3 receptors (D3-Rs) are involved in several functions such as reward, social behavior, and movement control. Indeed, D3Rs have been proposed as a therapeutical target for drug abuse, schizophrenia, and Parkinson's disease. More recently, some studies have evidenced the involvement of D3-Rs in cognition, demonstrating that activation of D3-Rs impairs attention, working memory and episodic memory, whereas their inhibition exerts a pro-cognitive effect. However, the function of D3-Rs in physiological mechanisms underlying synaptic plasticity and memory at hippocampal level has not been thoroughly investigated. Here, we examined the role of D3-Rs in hippocampal long-term potentiation (LTP) and memory in mice. For this purpose, we first performed extracellular electrophysiological recordings at CA3-CA1 synapses of hippocampal slices treated with a D3-Rs inhibitor. Then, we investigated the effect of D3-Rs inhibition on recognition memory studied by Novel Object Recognition test on wild-type mice treated with a D3-Rs inhibitor and on D3 knock out (D3-KO) mice. We found that perfusion of hippocampal slices with a D3-Rs antagonist was able to convert early-LTP evoked by a weak tetanic stimulation into late-LTP. These effects were dependent upon protein kinase A (PKA) since a concomitant treatment with a PKA inhibitor prevented the D3-Rs inhibitor to enhance plasticity. Behavioral experiments confirmed that the pharmacological blockage or genetic deletion of D3-Rs had a cognitive enhancing effect. In fact, wild type mice treated with a D3-Rs inhibitor showed a switch from short-term into long-term memory. A similar effect was found in D3-KO animals. The analyses of discrimination index indicated that D3-KO mice were able to form long-term memory when receiving a weak stimulus compared with vehicle-treated animals that showed natural forgetting. In conclusion, our findings suggest that D3-Rs plays a role in synaptic plasticity and memory and that the improvement of memory elicited by D3-Rs antagonists can be useful to treat disease characterized by cognitive dysfunction.

Title: Memory consolidation and extinction after administration of cort:bsa in the inactivated dorsomedial striatum

Authors: *M. MARTÍNEZ-DEGOLLADO[1], A. C. MEDINA[1], P. C. BELLO-MEDINA[2], G. L. QUIRARTE[1], R. A. PRADO-ALCALÁ[1];
[1]Dept. de Neurobiología Conductual y Cognitiva, Inst. de Neurobiología, UNAM, [2]Dept. de Neurobiología del Desarrollo y Neurofisiología, Inst. de Neurobiología, UNAM, Univ. Nacional Autonoma de Mexico, Querétaro, Mexico

Abstract: The consolidation process, necessary for the establishment of long-term memory, is time-dependent and supposedly requires the synthesis of proteins; some events or treatments may interfere with this process generating amnesia. We have shown that infusion of tetrodotoxin (TTX) into the dorsal striatum produces a marked impairment of consolidation of inhibitory avoidance (IA) learning and that intense training counteracts this effect. In the behavioral paradigm of IA, it has been observed that when the intensity of the aversive stimulus is increased, corticosterone (CORT) levels in blood increase after training. It has also been shown that the administration of CORT in the striatum after learning facilitates memory consolidation. It is not known, however, if in addition to a genomic action CORT exerts this facilitation by binding to neuronal membrane receptors. Therefore, it is of great relevance to determine whether activation of membrane glucocorticoid receptors by conjugated CORT (CORT:BSA) prevents the amnesic effect of intra-striatal TTX. To this end, we studied male rats bilaterally implanted with cannulae in the dorsomedial striatum (DMS), and then trained in the IA task with different foot-shock intensities (0.0, 0.5, 1.0, or 3.0 mA). Different groups received all combinations of the following treatments: vehicle (VEH) or TTX 30 min prior to training, and VEH or CORT:BSA immediately after training. Retention latency was recorded every 24 h for seven sessions to observe the processes of memory consolidation and extinction. We found that at 0.5 mA VEH-CORT:BSA treatment facilitated memory consolidation and produced a higher resistance to extinction compared to its control (VEH-VEH). At 1.0 mA, the TTX-VEH group showed amnesia and the VEH-CORT group had a higher resistance to extinction than the VEH-

VEH group, and memory consolidation was facilitated in the TTX-CORT:BSA group. Finally, at 3.0 mA, the TTX-VEH group was not amnestic, and in the VEH-CORT:BSA and TTX-CORT:BSA groups the extinction process was accelerated. In conclusion, we demonstrated that the administration of CORT:BSA in the DMS simulates the conditions of high intensity training; these results provided the first experimental evidence of a non-genomic mechanism involved in the protective effect of memory caused by intense training. We thank Norma Serafín, Martín García, Bernardino Osorio, Alejandra Castilla, Nuri Aranda, and Omar González for technical assistance. Supported by PAPIIT IN203918 and CONACYT 473131.

Title: Blockade of striatal protein kinase c activity with chelerythrine induces deterioration of memory consolidation

Authors: *I. G. MONTIEL[1], A. C. MEDINA[1], P. C. BELLO-MEDINA[2], G. L. QUIRARTE[1], R. A. PRADO-ALCALA[1];
[1]Dept. de Neurobiología Conductual y Cognitiva, Inst. de Neurobiología, UNAM Campus Juriquilla, Querétaro, Mexico; [2]Dept. de Neurobiología del Desarrollo y Neurofisiología, Inst. de Neurobiología, UNAM Campus Juriquilla, Querétaro, Mexico

Abstract: The protein kinase C (PKC) family is involved in several signaling cascades associated with different types of memory and it is suggested that its inhibition could impair memory consolidation. We decided to use a chelerythrine (CHEL), a drug that blocks all isoforms of PKC, to determine if PKC activity of dorsomedial striatum (DMS) is involved in memory consolidation of inhibitory avoidance training. In the first experiment, CHEL (3.84, 7.68 or 15.36 µg/0.5µL) was infused twenty minutes before inhibitory avoidance (IA) training using a 1.0 mA foot-shock. We found that inhibition of PKC interferes with memory in a dose-dependent manner. In the second experiment, we evaluated if CHEL would impede the formation of a short-term memory (STM). Two groups of rats were injected either CHEL or VEH 20 min before IA training and 30 min later we tested them in a STM test. We found no differences between groups and no detriment in STM. Because in the previous experiments CHEL was administered 20 min before training and retention latency was measured 48 h

afterwards, it might be argued that the amnesic effect observed was due to a state-dependent effect and not to disturbance of memory consolidation process. To evaluate this issue, in the third experiment, independent groups of rats were injected with CHEL or VEH twice: 20 min before training and 20 min before retention test. Lack of state-dependency memory was evident because CHEL produced a significant retention impairment as compared with its respective control group. We conclude that PKC in DMS participates in memory consolidation of inhibitory avoidance training probably using different molecular pathways. We thank the technical support of Bernardino Osorio, Norma Serafín, Martín García, Alejandra Castilla, Nuri Aranda and Ramón Martínez. Supported by PAPIIT IN203918.

Title: Sex differences in type I interferon modulation of learning and memory

Authors: *C. K. POSILLICO, N. C. TRONSON;
Univ. of Michigan, Ann Arbor, MI

Abstract: The neuroimmune system is necessary to carry out normal neural and cognitive functions including learning and memory, and neuroimmune activation during illness impairs these processes. There are known sex differences in the neuroimmune response to various pathogens, but whether biological sex plays a critical role in how neuroimmune activation affects learning and memory processes is unknown. Here, we investigated the interaction of neuroimmune activation and hippocampal-dependent memory mechanisms in both male and female C57Bl/6 mice using intracerebroventricular administration of a synthetic viral mimic, polyinosinic:polycytidylic acid (poly I:C), and context fear conditioning. First, poly I:C treatment induced significant cytokine responses in the hippocampus of both sexes. Males had a greater magnitude of response than females for IL-1α, IL-1β, IL-6, IL-10, IFNα, TNFα, CCL2, and CXCL10. Additionally, while both males and females showed increased expression of type I interferon β, only males showed increased type I interferon α. Next, we found that poly I:C treatment four hours prior to training in context fear conditioning resulted in significant deficits in freezing responses in both males and females when tested three days later. Pre-training poly I:C appeared to blunt training-induced cFos in the dorsal hippocampus of males, but it had no

effect on cFos levels in females. Thus, the same memory deficit in both males and females may be due to different and sex-specific mechanisms in the hippocampus. Next, we tested whether the sex difference in the type I interferon responses to poly I:C contributed to the sex difference in hippocampal mechanisms underlying memory deficits. We blocked type I interferon receptors (IFNAR) two hours prior to poly I:C treatment, followed by context fear conditioning four hours post-poly I:C. We found that IFNAR inhibition significantly rescued the poly I:C-induced deficit in males, but not females. This suggests that type I interferons play a more important role in modulating learning in males compared with females, and type I interferon signaling is a potential target for understanding sex differences in biological mechanisms of memory impairment induced by neuroimmune activation. Given that there are sex differences in the prevalence of debilitating memory disorders such as Alzheimer's disease and Post-Traumatic Stress disorder that present with neuroimmune dysfunction, it is important to identify sex-specific mechanisms of memory deficits that may lead to more effective treatments.

Title: Age and sex differences in the impacts of ibuprofen on cognitive functions

Authors: *K. R. MAGNUSSON, E. P. SACKINGER, J. RAUENHORST, M. FRISCHMAN, I. A. ABOU-SEADA;
Oregon State Univ., Corvallis, OR

Abstract: Epidemiological studies suggest that non-steroidal anti-inflammatory drugs reduce risk of Alzheimer's disease, but interventional studies find little benefit or negative outcomes. Our previous study showed a trend for impairment of long-term memory in aged male mice fed a low over-the-counter dose of ibuprofen (375 ppm in chow; 2.2 pills/day human equivalent). Ibuprofen also altered N-Methyl-D-aspartate (NMDA) receptor subunit expression in both young and older male mice. In the present study we examined dose response effects of ibuprofen on cognitive functions across aging in male mice and between sexes in young mice. Male and female 2-month-olds and 23-24-month old male (N=6-7) C57BL/6 mice were randomly assigned to 3 groups receiving 0, 375, or 1000 ppm ibuprofen in NIH-31M chow for 8 weeks. After 6 weeks of feeding, the Morris water maze was used to assess long-term, short-term (delayed match to place task (DMP)), and associative (cued control) memory and cognitive flexibility

(reversal trials). At the highest dose of ibuprofen, older males showed significantly poorer long-term memory, as compared to 0 ppm ibuprofen (p=.047), and there was a trend for young males to perform worse than young females at the same dose (p=.067). The young males fed 1000 ppm ibuprofen showed less perseveration for the old platform in reversal probe trials than the other doses. There were Sex (p=.029) and Age (p=021) interactions with Dose in the young only or male only analyses, respectfully, in the DMP task. The young males showed improved performance across both naïve and delayed trials when fed 375 (p =.007) or 1000 (p=.024) ppm ibuprofen, as compared to 0 ppm, suggesting that executive functions, such as search efficiency and flexibility were more improved than short-term memory. Performance in the DMP task was similar across doses for the young females and older males and all groups showed improvement in the delay trials, compared to the naïve trials. These results suggest that a high over-the-counter dose of ibuprofen (5.8 pills/day human equivalent) could impair long-term memory in older males, which could exacerbate cognitive aging and Alzheimer's disease symptoms. Ibuprofen improved cognitive flexibility and other executive functions in young males, but had little effect on young females.

Title: Delivery of DNA Constructs Using Different Sized Surface Modified PAMAM Dendrimer Nanomolecules

Authors: *B. SRINAGESHWAR[1,2,3], N. SINGH[1,2], E. L. CRESPO[3], G. L. DUNBAR[1,2,4,9], D. SWANSON[5], A. SHARMA[5], U. HOCHGESCHWENDER[6,3], J. ROSSIGNOL[7,8,2];

Abstract: The overall goal of the study is to assess the feasibility of surface modified polyamidoamine (PAMAM) dendrimer nanomolecules as a generic non-invasive molecular tool delivery platform to the brain. Dendrimers are highly branched nanomolecules that can be used to deliver drugs and biomolecules to different types of cells, including neurons, *in vitro* and *in vivo*. They are organic macromolecules with clinically favorable features such as cellular degradation, serum resistance and efficient excretion. We developed unique PAMAM dendrimers that have significantly reduced toxicity while maintaining efficient cell entry, and that have a cystamine core cleavable within cells, thereby releasing its cargo. In previous studies in HEK293 cells we achieved efficient expression of plasmid DNA using cystamine core (cys) dendrimers of generation 4 (G4) with a hydroxyl/amine ratio of 90/10, G4-cys-90/10. We systematically investigated the contribution of various parameters of dendrimer composition on transfection efficiency in primary rat neurons, using plasmid DNA expressing the fluorescent reporter EYFP under control of the ubiquitous CAG promoter. We complexed the reporter plasmid with lower generations of PAMAM dendrimers such as G1 and G2 at different ratios. While the G1 and G2 dendrimers were able to deliver the plasmid efficiently, expression was not maintained for more than a few days. We next modified the surface of the G4 PAMAM dendrimers used for forming complexes with the reporter plasmid by varying the composition of hydroxyl and amine groups (cysG4-90/10, -70/30, -50/50). We discovered that G4-70/30 dendrimers are more efficient in transforming primary neurons than G4-90/10 dendrimers, whereas G4-50/50 are toxic to neurons. Lastly, we heat-activated the G4-70/30 dendrimers at different time points prior to forming complexes with the reporter plasmid. Heat-activation for 24 hours of G4-70/30 dendrimers significantly improves transformation efficacy in neurons. Currently ongoing dendrimer modifications are aimed at increasing cargo size and biodistribution in vivo to lead to a widely useful generic non-invasive molecular tool delivery platform for the brain. Such a delivery platform would ultimately be compatible with applications in humans.

Title: The Equalizer Expression System Enables Uniform Protein Expression Levels in Transiently Transfected Cells

Authors: *S. YANG[1,4], J. YANG[7], J. LEE[5], M. LAND[2], O. A. IGOSHIN[6], F. ST-PIERRE[3]; [2]Dept. of Neurosci., [3]Neurosci., [1]Baylor Col. of Med., Houston, TX; [4]Chem. and Biomolecular Engin., [5]Systems, Synthetic, and Physical Biol. Program, [6]Dept. of Bioengineering, Rice Univ., Houston, TX; [7]Dept. of Biol. Engin., MIT, Cambridge, MA

Abstract: The functional study of natural proteins and the expression of biosensors and actuators generally relies on the expression of these transgenes from plasmids. However, transient plasmid transfections in mammalian cells produce a wide variation of plasmid copy numbers among cells, and consequently cause high expression heterogeneity. This cell-to-cell variability can result in some cells overexpressing at unphysiological or even toxic levels while others producing too low expression levels for detection or functional significance. Here, we report plasmid-based synthetic circuits - Equalizers - that compensate plasmid copy number variation at the single-cell level, thereby producing uniform gene expression in transiently transfected cells. Equalizers combine negative feedback and incoherent feedforward circuitries, enabling them to operate over a wide range of plasmid copy numbers. We demonstrate that Equalizers produce as low cell-to-cell variation as chromosomally integrated genes. We also present our ongoing attempts to produce Equalizer variants that achieve distinct expression levels. Finally, we demonstrate that episome-encoded Equalizers enable the rapid generation of extrachromosomal cell lines with stable and uniform expression for over two months. Overall, Equalizers are simple and versatile devices for homogenous gene expression and should facilitate the study of proteins, cells, and neuronal networks.

Abstract: *In vivo* imaging of model organisms is heavily reliant on fluorescent proteins with high brightness. Here we describe a practical method for rapid optimization of fluorescent proteins via directed molecular evolution in mammalian cells. We employed this approach to enhance intracellular brightness of a set of the spectrally diverse fluorescent proteins. The developed proteins demonstrated high performance for fluorescent labeling of neurons in culture and *in vivo* in model organisms such as *C.elegans, Drosophila* fruit flies, and zebrafish. The described method has great potential to be adopted by protein engineers due to its simplicity and convenience. We also believe that the new enhanced FPs will find wide application for *in vivo* imaging of small model organisms.

Title: Modulation of Mesolimbic Dopamine Transmission Through Selective Stimulation of Locus Coeruleus Noradrenergic Neurons.

Authors: *R. YATES, R. BHIMANI, J. PARK;
Univ. At Buffalo, Buffalo, NY

Abstract: The central catecholamines, dopamine (DA) and norepinephrine (NE), are involved in many physiological processes and behaviors ranging from fear and anxiety to learning and reward. Recent studies have suggested these processes may not be independent, as NE neurons in the locus coeruleus (LC), the primary source of NE in the brain, synapse with DA neurons in the ventral tegmental area (VTA), the major source of DA in the mesolimbic DA system. Increasing electrophysiological and pharmacological evidence has indicated a net excitatory effect of LC-NE on VTA-DA neurons via pre- and post-synaptic α-adrenergic receptors in the VTA. However, little is known about how mesolimbic DA transmission and DA-dependent behaviors are modulated directly by LC-NE through VTA-DA neurons. To better understand these anatomical and neurochemical processes, a combinatorial adeno-associated virus (AAV) approach was used to selectively target LC-NE neurons to express either a light-sensitive channelrhodopsin-2 (ChR2) or an excitatory Designer Receptor Exclusively Activated by Designer Drugs (DREADDs). Through immunohistochemistry, we showed selective expression of LC-NE terminals in the VTA. Furthermore, our data suggests that optical stimulation of these terminals in the VTA modulates DA transmission in the nucleus accumbens (NAc) of awake rats without any significant behavioral changes. Excitatory DREADD activation of LC-NE also increased electrically evoked DA release in the NAc in anesthetized rats. These fundamental studies will provide new insights to the understudied roles of direct and indirect noradrenergic modulation of dopaminergic functions using cutting edge methods (optogenetics and chemogenetics), which will delineate how NE contributes to DA-dependent learning and behaviors.

Title: Ablating choroid plexus epithelial cells in adult mouse brain: A new tool to approach CSF disorders.

Authors: *A. M. BEDOLLA[1], E. IWASAWA[2], A. TARANOV[1], E. FUGATE[2], D. LINDQUIST[2], F. TURCATO[1], J. WANG[1], J. GOTO[2], Y. LUO[1];

Abstract: Cerebrospinal fluid (CSF) has multiple facets for maintaining a healthy brain. It plays a homeostatic role, regulating the distribution of substances across the parenchyma and clearing waste, and a protective role, acting as a shock absorber in the case of mechanical injury. Abnormal CSF volume is associated with developmental brain disorders, such as pediatric hydrocephalus and autism. Choroid plexus (CP) atrophy has also been described in adults with executive dysfunction. Contrary to its potential essential roles, the CP-CSF system has remained an under-explored field in neuroscience due to limitations in the number of available tools to precisely modulate development and function. Therefore, the development and characterization of robust models that allow us to manipulate CSF will have a significant impact on understanding the role of CSF in health and diseases. While exploring microglia ablation models, we unexpectedly discovered a robust tool that can break new ground for studies of the CP-CSF system in the mouse brain. Our preliminary data demonstrate that the transgenic animal with a floxed-diphtheria toxin receptor in the ROSA26 allele (iDTR) express sufficient level of DTR exclusively in the CP epithelial cells in the absence of Cre, which induces a significant loss of CSF and shrinkage of ventricular space upon diphtheria toxin (Dtx) administration. The loss of CSF and shrinkage of ventricular space are further validated by both 3D-fluid sensitive magnetic resonance imaging and histological analysis. Furthermore, TUNEL staining demonstrated specific CP epithelial cell apoptosis upon Dtx treatment in iDTR mice but not wt controls. Upon further investigation, using immunohistochemistry and a battery of behavioral assays, our data suggests disrupted CSF production and circulation leads to progressive neuroinflammation in the adult mouse brain supporting the important role of CSF in maintaining the homeostasis of the brain. We are currently evaluating the behavioral outcome of this novel CSF ablation mouse model.

Introduction: Malformations of cortical development (MCD), including focal cortical dysplasia (FCD), can cause epilepsy and are often associated with refractory seizures [1]. Chromosomal structural variants have been described in patients with neurodevelopmental disorders, including intellectual disability, autism, schizophrenia, and some types of epilepsy [2-4]. We aim to investigate the presence of copy number variations (CNVs) in patients with epilepsy due to FCD.

Materials and Methods: We examined samples obtained from 30 patients with FCD. We used the Microarray CytoScanHD Affymetrix to interrogate the CNVs, which were identified using the *Chromosome Analysis Suite (ChAS)* from Affymetrix. We compared the CNVs identified in patients with control databases (BIPMed and aDGV) and databases with information about diseases and syndromes, such as OMIM, Decipher, ClinGen. Also, we used the Franklin® platform to assist in the CNV classification. **Results:** We identified six putatively pathogenic variants in five patients (16.6%). Three were losses classified as 'likely pathogenic.' The first was present in one patient at chromosome chr1p12-p11.2, involving the *NOTCH2* gene. The second was present in a single patient at chr18q21.1, involving the *SMAD2* gene. The third ‘likely pathogenic’ CNV was identified in two patients, at chr22q13.3, involving the *MLC1* gene. In addition, we found one large loss, classified as ‘pathogenic” in two patients, at chr16p13.3, and involving 13 genes, including *TSC2*.

Discussion/Conclusion: We identified CNVs with a potential role in FCD in over 16% of patients with FCD. Noteworthy, we found two patients with the same large deletion involving the *TSC2* gene. Given the frequency of putatively pathogenic CNVs found in patients with FCD, we suggest investigating these types of variants as part of the clinical workup for patients with FCD.

Title: Investigating the burden of chromosomal structural variants in Latin American patients with developmental and epileptic encephalopathies

Authors: *H. T. MORAES[1], H. URQUIA-OSORIO[1], M. MONTENEGRO[1], A. COAN[1], M. T. MEDINA[2], R. CARABALLO[3], A. REIS[4], C. THIEL[4], S. UEBE[4], I. LOPES-CENDES[1]; [1]State Univ. of Campinas, Campinas, Brazil; [2]Natl. Autonomous Univ. of Honduras, Tegucigalpa, Honduras; [3]Hosp. JP Garrahan, Buenos Aires, Argentina; [4]Friedrich-Alexander Univ. Erlangen-Nürnberg, Erlangen, Germany

Abstract: Developmental and epileptic encephalopathies (DEEs) are a heterogeneous group of early-onset epilepsies characterized by different types of seizures associated with a high risk of global developmental delay and cognitive dysfunction. Rare copy number variations (CNVs) are known causes of the DEEs; however, information in the Latin-American population is lacking. We performed whole-exome sequencing (WES, *SureSelectXT Human All Exons V6* and *Illumina Hiseq 4000/NovaSeq 6000*) in 236 patients and chromosomal microarray analysis (CMA, *Genome-Wide Human SNP Array 6.0*) in 241 patients. From the WES data, the CNVs were called using Exome Depth 1.1.15 and were prioritized using a list of 127 genes already related to the DEEs. For the CMA data, the CNVs and the regions of homozygosity (ROH) were analyzed using the Genotyping Console Software 4.2 and BRLMM-P+ algorithm and were visualized in Chromosome Analysis Suite software 4.2. CNVs and ROH were filtered based on size, number of markers, coverage, and frequency and were classified according to criteria proposed by the American College of Medical Genetics and Genomics (ACMG). In the WES dataset, we found 11 potentially pathogenic CNVs in 11 patients (4.7%). Two of these CNVs were observed only in the WES data. In the CMA dataset, we observed 13 potentially pathogenic CNVs in 16 patients (6.6%). Eight of these CNVs were found only in the CMA data. More frequently affected chromosomes were 15 and 16, with 5 and 4 CNVs, respectively. We observed ten deletions, three duplications, one triplication, and one patient with a deletion and a duplication, both classified as pathogenic. In addition, we found large ROH in 13 patients, three of whom presented evidence of consanguinity, loss of heterozygosity in more than 5% of the genome. These regions are important targets in the search for homozygous variants responsible for autosomal recessive diseases and should be analyzed further. In conclusion, we found that rare CNVs are a significant cause of DEEs in Latin-American patients and should be investigated in the clinical setting. In addition, we found that the use of CMA combined with WES increased the chances of identifying pathogenic CNVs in these patients. Furthermore, the analysis of ROH may help identify additional causal genetic variants in patients with DEEs.

Title: The structural brain network of anorexia nervosa: results from analysis of a large, multi-study, harmonized dataset

Authors: *E. LLOYD[1,2], K. FOERDE[1,2], A. MURATORE[1,2], N. AW[1,2], D. SEMANEK[1,2], J. STEINGLASS[1,2], J. POSNER[1,2];
[1]New York State Psychiatric Inst., New York, NY; [2]Dept. of Psychiatry, Columbia Univ. Irving Med. Ctr., New York, NY

Abstract: Purpose: Anorexia nervosa (AN) is characterized by persistent restrictive eating behavior, and marked fear of eating/weight-gain, despite the maintenance of a seriously low weight. Altered connectivity within structural brain networks may affect communication between diffuse brain regions, leading to abnormal cognition and behavior. Here we analyzed differences in whole-brain white matter connectivity between individuals with AN and healthy controls (HC), in a large sample. **Methods:** Diffusion-weighted MRI data acquired from females with AN (N = 147) and female HC (N = 109), aged 12-40 years, were combined across five independent studies. Probabilistic fiber tracking was completed, and full cortex connectomes describing streamline counts between 84 brain regions generated. Connectome data were harmonized, to remove scanner effects. The network-based statistic (NBS) approach tested the presence of subnetworks differing in connection strength between groups. Graph theoretical measures indicating communication/integration ability (strength and efficiency) were calculated for the 84 brain regions, and compared between groups using multiple linear regression. Associations between network and graph theory variables that differed between groups, and body mass index (BMI), were explored amongst individuals with AN using multiple linear

regression. All statistical models included age, motion, and study as covariates. **Results:** NBS outcomes indicated patients with AN, relative to HC, had reduced connectivity in a subcortical network including hippocampus, parahippocampal gyrus, thalamus, amygdala, and caudate, regions ($p < 0.05$, FWE cluster-wise corrected). NBS outcomes also indicated greater connectivity within a frontal cortical network including orbitofrontal, inferior frontal, and frontal pole, regions, among AN patients relative to HC ($p < 0.05$, FWE cluster-wise corrected). Greater connectivity within the subcortical component was related to higher BMI, while greater cortical component connectivity was related to lower BMI, in the AN group ($p < 0.05$, uncorrected). Graph theory analyses indicated greater efficiency of the left lateral orbitofrontal cortex, and reduced strength of the left hippocampus and parahippocampal gyrus, amongst AN patients relative to HC ($p < 0.05$, permutation corrected). Graph measures were not associated with BMI in the AN group. **Discussion:** Structural network differences suggesting an altered balance between cortical and subcortical connectivity are present in AN. Subnetwork connectivity is related to BMI amongst AN patients, further supporting the relevance of the structural connectome to AN.

Title: Got integrity? Conventional white matter structural descriptors found to be impacted by fiber orientation dispersion across the brain.

Authors: *E. J. RIZOR[1], N. M. DUNDON[2], M. HAYES[2], S. T. GRAFTON[2];
[1]Dynamical Neurosci., Univ. of California, Santa Barbara, Santa Barbara, CA; [2]Psychological & Brain Sci., Univ. of California Santa Barbara, Santa Barbara, CA

Abstract: Fractional anisotropy (FA), a measure commonly used to quantify white matter (WM) structural integrity, is known to be sensitive to fiber orientation dispersion. Diffusion-based q-space trajectory encoding (QTE) imaging allows for the estimation of parameters that describe diffusion tensor size, shape, and orientation (Topgaard, 2017). Independent estimations can be derived for microscopic FA (μFA) and an orientation parameter (OP) that models the degree of fiber dispersion in a voxel. The conventional DTI measure FA can be mathematically derived from these two parameters (Lasič et al., 2014). By fixing μFA or OP to 1, we can estimate their

relative contributions to FA's presumed measure of microstructure. To investigate how these contributions vary regionally across the WM, QTE images were obtained from 28 young, healthy adults (ages 18-29, 13F/15M). We hypothesized that variation of FA across the WM would be dominated by regional variation of OP, and that regions of the brain known to contain crossing fibers would be sites of increased OP domination. For each participant, images representing the percent relative difference (PRD) between FA and FA when OP is fixed to 1 (FAvFA_max_OP) and the PRD between FA and FA when μFA is fixed to 1 (FAvFA_max_μFA) were calculated. Across the WM, FAvFA_max_OP was 38.37% across all participants. In contrast, WM FAvFA_max_μFA across all participants was 6.16%. With Bayesian hierarchical modeling, hyper-distributions were generated for both PRD parameters across the deep WM and for individual parcellations as defined by the JHU ICBM WM atlas. K-means clustering analysis of these hyper-distributions revealed that regions are clustered mainly based on variation in FAvFA_max_OP. Regions in one grouping (lower FAvFA_max_OP) include the corpus callosum, the cerebellar and cerebral peduncles, and the anterior and posterior limbs of the internal capsule. Regions present in another grouping (greater FAvFA_max_OP) include the superior longitudinal fasciculus and the corona radiata. These results align with previous mappings of number of fiber orientations per voxel, where regions with greater FAvFA_max_OP are labeled as having an elevated fiber orientation count compared to others (Jeurissen et al., 2012). In conclusion, regional variation of WM FA, a descriptor of tissue integrity, is four-fold more likely to be explained by local heterogeneity of fiber orientations than by the underlying microscopic diffusion anisotropy. Conventional diffusion tensor imaging (DTI) may yield results that do not adequately reflect the underlying microstructure independent of fiber orientation.

Title: Partial connectomes of adult-born granule cell dendritic integration

Authors: *A. SOROKINA[1,2], V. SAMPATHKUMAR[1,2], X. VALENCIA[1], N. B. KASTHURI[1,2];
[1]Neurobio., Univ. of Chicago, Chicago, IL; [2]Biol. Sci. Div., Argonne Natl. Lab., Lemont, IL

Abstract: The hippocampal dentate gyrus is one of few places in the mammalian brain that undergoes adult neurogenesis. While adult-born granule cells functionally integrate into the

existing circuit, the exact mechanism for how this integration occurs remains unknown. Here we used a combination of low-resolution serial electron microscopy for dendritic morphology, with targeted high-resolution serial electron microscopy for annotating synapses. We first traced the dendritic arbors of granule cells from the hilus to the outer molecular layer and classified them as adult-born, neonatal-born, or embryonic-born, based on distinct morphological characteristics. We find that synapses onto adult-born granule cell dendrites differ from synapses on neonatal or embryonic-born granule cells. Adult-born neurons were much more likely to be innervated by axonal boutons making more than one synapse, multisynaptic boutons (MSBs), than embryonic or neonatal-born granule cells. Using MSBs as a proxy for synaptic competition, our data suggests that younger cells compete with older cells for synapses in the molecular layer, supporting previous literature. Further, we find that this competition may take place on an age gradient, with older cells competing for synapses less than younger cells. We conclude that large volume electron microscopy can provide previously unknown details about how adult-born neurons integrate in the hippocampus.

Title: Setting the stage for chemogenetic manipulations of whole brain resting state functional connectivity in nonhuman primates

Authors: *A. K. CUSHNIE, J. ZIMMERMANN, S. R. HEILBRONNER;
Dept. of Neurosci., Univ. of Minnesota, Twin Cities, Minneapolis, MN

Abstract: Designer Receptors Exclusively Activated by Designer Drugs (DREADDs) are modified G-Protein Coupled Receptors that can be targeted to select neuronal populations. Once expressed, pharmacological activation of DREADDs with a chemogenetic ligand allows for transient, remote and reversible manipulation of cells expressing the receptors. Clozapine-N-Oxide (CNO) is commonly used to activate DREADDs, however, CNO demonstrates poor brain permeability; requiring large doses to be administered and is metabolized into clozapine. Nonetheless, recent studies have shown that low dose clozapine (CLZ) and novel ligand

Deschloroclozapine (DCZ) have a higher affinity for DREADDS with minimal off-target binding.
The utilization of DREADDs in nonhuman primates (NHP), though limited in comparison to studies using rodents, allows for the causal perturbation of targeted cells, in a model species that has great homology to humans. The objective of many of these studies is to understand the function of the targeted cells/circuit, and the role they play in healthy brain functioning. Functional Magnetic Resonance Imaging (fMRI) is a non-invasive neuroimaging approach that measures fluctuation in hemodynamic signals locally and across the whole brain. fMRI has identified altered functional connectivity in many neurological and psychiatric disorders.
The aim of this study was to lay the groundwork for combining DREADDs manipulation with resting state fMRI in NHP. To this end, we first determined the infection and transport patterns of common AAV serotypes in macaques (see Cushnie et al., 2020). Next, we evaluated the effects of chemogenetic ligands on resting state functional connectivity (rs-fc) prior to DREADDs transduction in NHP, which has previously not been determined. Accordingly, macaques underwent a series of resting state fMRI scans at 10.5 Tesla. Animals were sedated, then administered intramuscularly varying doses of CLZ or DCZ (up to 0.2mg/kg) acutely before the start of each scan. Region to Region and Independent Component Analysis were used to characterize whole brain functional connectivity following administration of the ligands.
This proof of principle study revealed local and whole brain functional connectivity patterns prior to DREADDS expression, setting the stage for more detailed network interrogation using chemogenetic manipulations and rs-fMRI in NHPs.

Title: Alterations in intrinsic functional networks in squirrel monkey brains produced by lesions of thalamus VPL nucleus revealed using independent component analysis of resting state fMRI

Authors: A. SENGUPTA[1], A. MISHRA[1], P.-F. YANG[1], Z. YANG[2], F. WANG[1], J. L. REED[1], L. CHEN[1], *J. C. GORE[1];

Abstract: Inter-regional correlations in resting state fluctuations of MRI signals (rsfMRI) are interpreted as indicators of functional connectivity (FC) between brain regions. Resting state functional connectivity (rsFC) has been widely used to identify and characterize functional circuits in both human and animal brains. However, the effects of deprivation of subcortical drives on rsFC and how changes in rsFC patterns are related to behavioral changes remain largely unknown. The goals of this study are to (1) quantify how interruption of thalamic inputs to cortex affect whole brain rsFC networks and (2) evaluate how changes in rsFC are related to behavioral deficits. We selectively deprived thalamic inputs to cortex by targeted lesions of the thalamus VPL nucleus and used Independent Component Analysis (ICA) to derive rsFC networks. Studies were performed on 10 healthy and (to date) one thalamus VPL lesioned monkeys at 9.4T under light anesthesia. All fMRI images were co-registered to the squirrel monkey VALIDATE atlas in order to perform group level analyses. After standard fMRI signal pre-processing steps (motion and physiological noise corrections, bandpass filtering), group spatial ICA was performed on gray matter only by temporal concatenation of all the data using GIFT software. Visual identification of the spatial locations of components revealed coherent BOLD signal fluctuations in regions and networks similar to those reported previously for non-human primates, including the visual and sensorimotor regions. A unilateral lesion was produced at the digit representation in thalamic VPL nucleus in one monkey brain using an electrode. RsfMRI data were acquired longitudinally at 1-, 3- and 10-weeks post lesion. Estimates of the correlations between different IC time series revealed significant changes in network patterns and inter-reginal connectivity strengths at different stages of recovery. Power Spectra of the IC time series also altered over time. More lesioned animals are being studied to understand how targeted lesions in the thalamus modulate specific networks in monkey brain and how these network changes predict hand sensorimotor behavioral impairments and recovery. The results from this study will provide valuable information about how synchronized BOLD signal fluctuations in cortex are driven, and confirmation of the interpretation of networks derived from rsfMRI.

Title: Identification of region-specific alterations in white matter microstructure and connectivity with atlas-based multilevel brain analyses in a piglet model of chronic hypoxia

Authors: *J. LI[1], C.-H. HSU[3], V. LAM[1], T. MAEDA[1], C. LEONETTI[1], G. R. STINNETT[1], K. KOBAYASHI[1], A. AGARONYAN[3], K. HAMILTON[1], K. LYDIC[1], G. TAYLOR[1], S. LIN[3], J. D. ASIS-CRUZ[1], N. SARIC[2], A. V. FARIA[4], P. C. WANG[3], T.-W. TU[3], S. MORI[4], N. ISHIBASHI[1];

Abstract: Diffusion tensor imaging (DTI)-based brain atlases allow automatic parcellation for all brain regions including white matter (WM), facilitating inter-subject and inter-group quantitative whole brain analysis. Use of piglet brains in pediatric brain research offers various advantages due to its similarities with human pediatric brains. We created 3D piglet brain atlases with 133 cerebral structures, including 24 subcortical and 36 cortical gray matter, and 26 deep and 36 superficial white matter (SWM) regions using high-resolution DT images. Impacts of development and chronic hypoxia to WM were investigated, respectively, using multi-shell diffusion images with DTI atlas-based multilevel brain analyses, including volume, voxel-by-voxel based analysis for DTI and neurite orientation dispersion and density imaging (NODDI), structure connectomics and histological analyses. Differences in region- and tract type-dependent WM developmental changes were demonstrated with imaging and histology. Chronic hypoxia induced global brain volume reduction and WM microstructure alterations, with prefrontal-striatum connections disturbances. Following hypoxia, persistent SWM injury, with particular vulnerability in prefrontal WM, were evidenced by voxel-based analysis. Persistent demyelination and its potential association with histone modification of oligodendrocytes caused by chronic hypoxia were detected in dorsal prefrontal cortex-WM by histological analyses. Introducing DTI atlas-based multilevel diffusion imaging approach to piglet models achieves an unbiased comprehensive whole brain evaluation, with a wealth of clinical/pathological bidirectionally exchangeable information, providing a new insight into complex human brain development and a wide range of neurodevelopmental disorders.

Title: Serial section electron tomography for whole-brain mammalian connectomics

Authors: A. T. KUAN[1], S. PHAN[2], M. KIM[1], M. H. ELLISMAN[2], ***W.-C. A. LEE**[3];
[1]Harvard Med. Sch., Boston, MA; [2]UCSD, La Jolla, CA; [3]BCH / Harvard Med. Sch., Boston, MA

Abstract: Recent advances in high-throughput electron microscopy (EM) have made it possible to image brain volumes as large as 1 mm^3 with sufficient resolution to comprehensively resolve synaptic connectivity between neurons. These approaches have produced unprecedented connectomic datasets of complete insect nervous systems and distinct microcircuits in the mouse brain. However, scaling connectomic imaging to whole-brain mouse volumes (~500 mm^3) faces critical scaling and sample preparation challenges. Here, we present a large-scale EM imaging approach that boosts effective imaging rates and circumvents the need for ultra-thin sectioning. Using intermediate voltage tomography, we show semi-thick brain sections (~1 μm) can be rapidly reconstructed at synapse resolution from a moderate number of projections (~20), and that successive sections can be stitched together to form large contiguous volumes. Furthermore, we show that the same samples can be imaged at even higher resolution using scanning transmission EM (STEM) tomography to resolve smaller structures such as gap junctions. We present a proof-of-principle volume reconstruction from the cerebellum and propose integrating electron tomography with tape-based sample handling as an end-to-end imaging solution for whole-brain mouse connectomics.

Abstract: Orbitofrontal cortex supports economic decision making and learning through its intricate micro-circuitry. Pyramidal neurons in layer 5 constitute the main output of cortex and project outside of the cortico-thalamic system to distribute information to specialized subcortical structures, but a blueprint for the different output pathways is lacking. Here, we used a combination of viral tracing, single-cell resolution projection mapping, and RNA sequencing to comprehensively map descending outputs in rat orbitofrontal cortex - the preferred model organism to investigate complex choice behavior. At a single neuron resolution, we characterize the connectivity of ~60,000 neurons and demonstrate that most neurons project to a single subcortical target, representing a dedicated line. These connectivity-defined projection neurons preferentially reside in L5a and in intermediate sublayers of L5b, and express unique sets of genes, including transcription factors and surface receptors. Taken together, this multi-modal evidence reveals that subcortical projection neurons in orbitofrontal cortex represent genetically distinct neuronal cell types that might have distinct roles as specialized output channels.

Title: Interrogating the functional logic of Drosophila brain circuits at single-synapse scale

Authors: *M. TURKCAN, Y. ZHOU, A. A. LAZAR;
Dept. of Electrical Engin., Columbia Univ., New York, NY

Abstract: The current paradigm of computational studies of neural circuit function largely focuses on characterizing neuron connectivity. A widely-used approach is to model neurons as nodes in a graph and their connections as edges. However, this neglects the myriad of differing functions that synapses may achieve. Based upon the visualization and analysis of the Hemibrain connectome/synaptome dataset of the fruit fly brain, we propose a new computing paradigm for discovering the functional logic of fly brain circuits that shifts the modeling emphasis from communicating neurons to the interactions between blocks of synapses.
Underlying the computing paradigm introduced here, there are two building blocks: the synaptic computing complex (SCC) and the synaptic processing unit (SPU). The SCC models an axon terminal, the synapses and neuromodulatory inputs impinging on the axon terminal, and the synapse lying across active zones of the axon terminal and postsynaptic densities. SCCs can be found throughout the fly brain. The ubiquitousness of SCCs suggests that in addition to the processing in the postsynaptic neurons, computation heavily takes place in the presynaptic terminals. The SPU models a synapse-rich volume such as a glomerulus in the antennal lobe (AL) and a compartment in the mushroom body (MB). An SPU consists of SCCs as atomic building blocks and defines the computation in the SPU. The compositions of SPUs take the form of communicating neurons interpreted here as wires that connect SPUs, governing the I/O of a local processing unit (LPU) modeling a neuropil [1].
To explore the functional logic of neural circuits, we model SCCs in the AL and MB at three levels of abstraction. The first level corresponds to the ground truth synaptome of the Hemibrain dataset, where each individual axon terminal interacts with a different set of input synapses. At the second level, all the inputs onto an axon are grouped to interact with all the axon terminals of the neuron. At the third level, we group all the inputs onto the axons of neurons of the same cell

type. We provide circuit diagrams and a FlyBrainLab library to automatically map these three levels and compositions of SPUs into executable circuits by leveraging the Hemibrain dataset [2]. We quantitatively characterize the role of SCCs in shaping the response of the circuit. The I/Os of the three levels are then compared to identify the appropriate level for modeling the functional logic of each neuropil.

Abstract: Due to advances in automated image acquisition and analysis, whole-brain connectomes with many thousands of neurons are finally on the horizon. The Drosophila community is still awaiting an adult whole-brain connectome. Despite advances in automated segmentation of EM volumes, generation of connectomes still requires human proofreading of automated reconstructions, which requires many person-years of effort, due to the huge volumes

of data involved. We created FlyWire, an online community for proofreading neural circuits in a full adult fly brain, and will discuss how its novel computational and social structures are organized to scale up to whole-brain connectomics. FlyWire is based on a previously released EM dataset (FAFB, Zheng et al., 2018), and we segmented the neurons in this dataset with high accuracy, reducing the time needed for proofreading. We also introduce a new data framework, a spatially-chunked supervoxel graph, that enables collaborative editing of neurons, making it possible to simultaneously distribute proofreading to individuals located anywhere in the world. Information in the edit history is programmatically accessible for a variety of uses such as estimating proofreading accuracy and facilitating collaboration. An open community is also accelerating scientific discovery via information sharing. We will present our progress towards generation of a fully proofread adult whole-brain connectome and demonstrate how FlyWire enables brain-wide circuit analysis.

Title: Toolkit for Oscillatory Real-time Tracking and Estimation (TORTE)

Authors: *M. SCHATZA, E. B. BLACKWOOD, S. NAGRALE, A. WIDGE;
Univ. of Minnesota Twin Cities, Minneapolis, MN

Abstract: Closing the loop between brain activity and behavior is one of the most active areas of development in neuroscience. There is particular interest in developing closed-loop control of neural oscillations. Many studies report correlations between oscillations and functional processes. Oscillation-informed closed-loop experiments might determine whether these relationships are causal and would provide important mechanistic insights which may lead to new therapeutic tools. These closed-loop perturbations require accurate estimates of oscillatory phase and amplitude, which are challenging to compute in real time. We developed an easy to implement, fast and accurate Toolkit for Oscillatory Real-time Tracking and Estimation (TORTE). TORTE operates with the open-source Open Ephys GUI (OEGUI) system, making it immediately compatible with a wide range of acquisition systems and experimental preparations. TORTE efficiently extracts oscillatory phase and amplitude from a target signal and includes a variety of options to trigger closed-loop perturbations. Implementing these tools into existing experiments is easy and adds minimal latency to existing protocols. Most labs use in-house lab-specific approaches, limiting replication and extension of their experiments by other groups. Accuracy of the extracted analytic signal and accuracy of oscillation-informed perturbations with TORTE match presented results by these groups. However, TORTE provides access to these tools in a flexible, easy to use toolkit without requiring proprietary software. We hope that the availability of a high-quality, open-source, and broadly applicable toolkit will increase the number of labs able to perform oscillatory closed-loop experiments, and will improve the replicability of protocols and data across labs.

Title: Frequency-dependent behavioral effects of mid-striatum deep brain stimulation on cognitive flexibility

Authors: *D. C. COOPER[1], A. E. REIMER[2], A. S. WIDGE[1];
[1]Psychiatry, Univ. of Minnesota, Minneapolis, MN; [2]Psychology, Federal Univ. of São Carlos, São Paulo, Brazil

Abstract: High-frequency deep brain stimulation (HF-DBS, >100 Hz) has emerged as a safe and effective treatment option for motor disorders and, more recently, has shown promising results in

treatment-resistant neuropsychiatric disorders. Stimulation frequency, among other factors such as stimulation site, seems to strongly influence the motor symptoms of Parkinson's Disease. Recently, we showed that HF-DBS applied to ventral capsule/ventral striatum in patients with major depressive and/or obsessive-compulsive disorder results in improved cognitive flexibility; however, the effects of low-frequency deep brain stimulation (LF-DBS, <100 Hz) on cognitive flexibility have yet to be examined. Here, we compared the effects of LF- and HF-DBS applied to the mid-striatum of rats submitted to an operant set-shifting paradigm. Long-Evans rats (n=12) underwent bilateral mid-striatum electrode implantation followed by subsequent training. The set-shifting task consisted of daily alternate sham or stimulation treatments. Chronic biphasic stimulation (300 μA, 0.1 ms pulse width, at 130 or 20 Hz) was delivered continuously one hour prior to and while set-shifting. HF-DBS significantly reduced reaction time (β=-0.057, z=-3.01, p=0.003) without affecting total errors (p>0.05). Conversely, LF-DBS did not affect RT (p>0.05) but significantly increased total errors (β=0.193, z=2.19, p=0.029). Our study shows that frequency is an important parameter in accessing the effects of mid-striatum DBS on cognitive flexibility.

Title: Behavioral Effects of Mid-Striatum Deep Brain Stimulation Reflect Cognitive Flexibility, Not Impulsivity

Authors: *A. J. WALD[1], A. E. REIMER[2], A. ALPERS[3], D. COOPER[1], E. HOSKINS[1], K. SINGH[1], K. WARNER[1], A. S. WIDGE[1];
[1]Univ. of Minnesota - Twin Cities, Minneapolis, MN; [2]Federal Univ. of Sao Carlos, SP, Brazil; [3]Western Washington Univ., Bellingham, WA

Abstract: Abstract Deep brain stimulation (DBS) has emerged as a safe and effective treatment option for motor disorders and, more recently, has shown promising results in treatment-resistant neuropsychiatric disorders. Recently, we showed that DBS applied to patients with major depressive and/or obsessive compulsive disorder results in improved cognitive flexibility. We replicated this in rodents, where DBS of the mid striatum significantly reduced reaction time in a

Set-Shifting task ($z= -3.01$, $p = 0.003$) without affecting total errors ($p > 0.05$), however, the mechanism behind this improvement has yet to be determined. We needed to decipher whether or not the improvement seen in this previous study reflected an increase in cognitive flexibility, or an increase in impulsive behavior. An increase in cognitive flexibility would give back a patient's ability to live their lives without the tendancy toward risky behavior which may come with an increase in impulsivity.To do so, we submitted Long-Evans rats to a 5 Choice serial reaction time (5CSRTT) paradigm. This task is designed to measure impulsive-like behavior which is one potential explanation for the improvement seen in the set-shifting task. Rats were trained on the task and then underwent bilateral electrode implantation targeting the mid-striatum. All animals performed the 5 choice task daily, with sham and active stimulation given on alternating days. For the stimulation treatment, biphasic stimulation (300 µA, 0.1 ms pulse width, at 130 Hz) was delivered continuously, one hour prior to and during the 5 choice task. This stimulation did not result in a significant change in number of premature responses ($z = 1.29$, $p = 0.198$) or number of correct responses ($z = -0.223$, $p = 0.824$). Our study suggests that the effect of stimulation to the mid-striatum reflects a true increase in cognitive flexibility, and cannot be explained by an increase in impulsive responding.

Abstract: The ability to discriminate between threatening and non-threatening environmental cues and execute an appropriate behavioral response is crucial for survival and for maintaining a healthy balance between avoidance and reward seeking. However, little is known about the neural circuits that underlie this decision making. The basolateral nucleus of the amygdala (BLA), infralimbic (IL) and prelimbic (PL) medial prefrontal cortices have been implicated in

reward-seeking and fear-related responses, and often have altered outputs in psychiatric disorders like anxiety and Post Traumatic Stress Disorder (PTSD). Little is known about the circuit-level connectivity between these regions that coordinates appropriate behavioral responses. Platform mediated avoidance (PMA) is a behavioral paradigm that resembles real life avoidance scenarios and captures approach-avoidance conflict behavior, which is critical for its application to clinical avoidance. In this paradigm, rats learn to avoid a tone-signaled footshock by stepping onto a platform, with the cost of avoidance being the loss of access to food.
This study aims to explore interactions between the medial pre-frontal cortex (mPFC) and amygdala in behaving animals during the PMA task. Adult Long-Evans rats (n=6) between 5 and 7 months of age received electrode bundles or tetrode implants in the IL and PL of the mPFC and BLA regions after training in the PMA task. Following 20 days of high conflict training, 3 of 6 trained rats spent more time in the platform zone (exhibiting more avoidance like behavior), one rat spent more time in the reward zone (exhibiting more reward seeking behavior) and two rats timed appropriately to balance reward seeking and avoidance of the foot shock.
We will analyze the correlation between the oscillatory synchrony in theta frequency band (4-8Hz) between IL to BLA, and PL to BLA, and behavioral responses such as time spent in different zones (platform zone, reward zone and out of platform zone) or bar press rates during PMA high conflict performances. This study is an exploratory study that may provide a neurobehavioral correlation during motivated decision making. The outcome of this study could allow us to find specific targets that are altered in anxiety disorders like PTSD and serve as a basis to develop stimulation-based therapeutic interventions for these disorders in humans.

Title: Alteration of state dependent brain connectivity using a closed loop stimulation method in a fear regulation circuit

Authors: *R. YOUNK, D. J. TITUS, S. NAGRALE, K. DRAHOS, M.-C. LO, A. WIDGE; Univ. of Minnesota, Twin Cities, Minneapolis, MN

Abstract: Information flow in brain networks may depend on the oscillatory synchrony of local field potential (LFP) between regions. For fear-related disorders, the connection between the medial prefrontal cortex (mPFC) and basolateral amygdala (BLA) is particularly important. Theta-band (4-8 Hz) PFC-BLA LFP synchrony correlates with the ability to learn and recall safety memories, but acute stressors alter the oscillatory synchrony between these regions. Manipulating that synchrony may thus require strategies that adapt to changes in the circuit biology. We sought to assess an adaptive stimulation method to alter PFC-BLA connectivity based on stimulation locked to the theta oscillation. Electrodes with 8 recording channels and one stimulating channel were implanted into infralimbic cortex (IL, the rodent homologue of mPFC) and BLA of Long-Evans rats. Rats underwent 16 phase-locked stimulation sessions. Single electrical pulses (90 μs and 100 μA) were delivered to BLA when IL phase was at 0, 90, 180, or 270° at theta band for a total of 4 sessions per phase. Each session consisted of pre recordings and evoked response potential (ERP) measurements (50 biphasic pulses, 90 μs and 100 μA pulse width, delivered to either IL or BLA), followed by 30 minutes of phase-locked stimulation, and 60 minutes of post recordings with ERP measurements every 15 minutes. Rats then underwent a three-day tone-shock and extinction paradigm with habituation/conditioning, extinction, and recall phases. After the recall phase, rats underwent 16 phase-locked stimulation sessions as previously described. We measured stimulation induced LFP connectivity changes for targeted phase and pre/post conditioning. Prior to conditioning, we expect that 180-degree phase-locked stimulation will be most effective in increasing LFP synchrony and enhancing synaptic connectivity in the IL-to-BLA direction. Since phase-locked stimulation is concordant with the brain's natural rhythm, we also expect stimulation to continue to induce LFP synchrony post fear conditioning, although it is unknown which phase will be optimal. In summary, we have proposed a phase-locked electrical stimulation technique to alter brain oscillatory synchrony pre and post tone-shock conditioning and are exploring that technique's state dependence relative to emotionally valenced learning (shock conditioning). If we can identify methods for manipulating IL-BLA connectivity that are viable even after acute stressors, these may lead more effective therapies for treatment-resistant varieties of psychiatric disorders.

Title: Deep brain stimulation modulates oscillatory dynamics in cognitive control in treatment-resistant depression

Authors: *A. ALLAWALA[1], S. VARTANY[2], J. ADKINSON[5], H. RITZ[3], R. MATHURA[5], D. OSWALT[7], K. BIJANKI[5], A. SHENHAV[4], W. GOODMAN[6], N. POURATIAN[8], D. A. BORTON[1], S. A. SHETH[5];

Abstract: Major Depressive Disorder (MDD) is one of the most common mental disorders in the US and the leading source of disability worldwide. Cognitive control has been shown to be impaired in depression, manifesting as rumination, negative automatic thoughts, and biases. Deep brain stimulation (DBS) has shown promise for treating treatment-resistant depression (TRD) and enhancing cognitive control, but the implicated cognitive control neurophysiological network and how it is modulated by DBS remains unclear. Here we report the outcome from a parametric cognitive control task performed in subjects with TRD (N=2) and refractory epilepsy (N=6) in an in-patient hospital setting with continuous intracranial electrophysiological monitoring. Both TRD and Epilepsy Cohorts were implanted with temporary sEEG electrodes across regions, including the dorsolateral prefrontal cortex (dlPFC), dorsal anterior cingulate cortex (dACC) and medial orbitofrontal cortex (mOFC). The TRD Cohort was also implanted with DBS leads in the ventral capsule/ventral striatum (VC/VS) and the subcallosal cingulate (SCC). In the task, a cloud of colored dots moving left or right is presented on a computer screen. Subjects were asked to indicate the color of the dots(relevant feature) by pressing a left or right button, while ignoring the motion direction(distracting feature).The congruence of motion direction and the required response side was varied on a continuous scale, allowing for parametric control of conflict level for each trial. The task was performed pre-, post-, and during DBS in TRD participants. Across both cohorts, sEEG recordings from dlPFC, dACC, and mOFC showed that activity in the theta (4-7 Hz) and high gamma (80-150 Hz) bands were parametrically modulated with task conflict. Stimulation at 130 Hz in the VC/VS and SCC improved task accuracy (42% increase overall for the first participant) and reduced reaction time (300 ms decrease overall for the second participant). An increase in theta power across contacts in the PFC and ACC in the first participant was observed during DBS alongside differences in spatial distribution of contacts exhibiting theta band power from pre to post-DBS states. Epilepsy participants showed comparable reaction times (1100 ms overall ±161 ms SEM) and accuracy (80% overall ±8%SEM) to pre-DBS TRD participant task performance. Further work will compare changes in spectral power between both Cohorts as a function of conflict, as well as during DBS for the second TRD participant. These recordings, coupled with causal manipulation will help shed light on the neurophysiology of controlled decision-making and possible mechanisms of therapeutic action of DBS.

Title: Orientation and amplitude of directional deep brain stimulation impact evoked potentials at sensorimotor cortex

Authors: *C. PASCHALL[1], L. LEVINSON[1], S. SUN[2], J. G. OJEMANN[3], A. KO[4], J. A. HERRON[5];

Abstract: Directional Deep Brain Stimulation (dDBS) uses radially segmented electrodes to direct current to a targeted volume of neural tissue with more precision than traditional DBS. Stimulation of subcortical targets using the cylindrical electrodes of traditional DBS has been shown to evoke potentials in contralateral sensorimotor cortex which modulate with the amplitude of depth stimulation. Our study characterizes the effect of stimulation orientation in directional DBS on both contralateral and ipsilateral cortical evoked potentials. To do this, neural data were collected intraoperatively from patients undergoing Boston Scientific Vericise dDBS implantation to treat Parkinson's Disease (n=6) and Essential Tremor (n=2). The Vericise probe offers a 1-3-3-1 configuration of cylindrical (1) and radially segmented (3) electrodes. Single, constant current, biphasic stimulation pulses of 200us per phase were delivered for 2 minutes at a rate of 2Hz, yielding 240 pulses with approximately 500ms of post-stimulation evoked potential recording, across each multipolar configuration of the six radially segmented electrodes. Both quadripolar and bipolar electrode configurations at four stimulation amplitudes of 2,3,4 and 5mA were explored. An example quadripolar configuration is one in which vertically aligned electrodes 2 and 5 serve as the positive pole and electrodes 3 and 6 the negative pole, while an example bipolar configuration would be between electrodes 2 and 5. The vertically-aligned quadripolar stimulation pair approach limits depth stimulation to 3 distinct orientation combinations: 2/5 and 3/6, 2/5 and 4/7, and 3/6 and 4/7, while the bipolar configurations offer 15 potential (6-choose-2) combinations. To evaluation evoked potentials, windowed root mean square (rms), peak-to-trough magnitude and latency, and high-gamma band power metrics were implemented, and the distributions compared in a multi-way ANOVA to evaluate the variance in

each EP metric attributable to stimulation orientation, magnitude, and the interaction of orientation and magnitude. Our analysis reveals that evoked potential (EP) rms magnitude and high-gamma power modulate with stimulation orientation and magnitude. Using alignment of preoperative MRI and intraoperative CT, EPs were shown to be most pronounced and modulated in cortical electrodes associated with the primary sensorimotor cortices. Intraoperative EPs may predict the clinical efficacy of directional stimulation and may guide the selection of dDBS therapeutic parameters.

Title: Differential Effects of Nucleus Accumbens Deep Brain Stimulation on Cocaine Reinstatement in Female and Male Rats

Authors: *S. T. MANKAME, S. J. WOROBEY, S. E. SWINFORD-JACKSON, R. C. PIERCE;
Dept. of Psychiatry, Robert Wood Johnson Med. School, Rutgers Univ., Piscataway, NJ

Abstract: There are currently no FDA approved treatments to reduce cocaine craving and relapse. Recent basic and clinical studies have shown that deep brain stimulation (DBS) in limbic regions of the brain involved in drug craving, particularly the nucleus accumbens, can reduce drug seeking behavior. Previous work from our laboratory and others indicated that DBS of the nucleus accumbens shell attenuated cocaine reinstatement in male rodents. Female subjects have not yet been assessed in experiments of this sort, which is a significant oversight since it is becoming increasingly evident that biological sex is an important variable to consider when it comes to drug seeking behavior. A growing body of evidence indicates that female rodents are more susceptible to the reinforcing effects of cocaine and therefore more vulnerable to relapse during the estrus phase. Here, we sought to determine the effect of nucleus accumbens shell DBS on drug seeking behavior in female rats, and whether this effect is dependent on estrous cycle phase. Female rats were allowed to lever press for i.v. cocaine two hours daily for 21 days under a fixed ratio 1-5 schedule. Responding on the active lever resulted in an infusion of cocaine while the inactive lever presses had no consequences. Rats then underwent extinction where responses on the active lever produced infusions of saline. Daily extinction sessions continued

until lever pressing fell below 20% of responding under cocaine. Prior to any reinstatement sessions, the rats were divided into two groups to either be tested in the estrus or the non-estrus phases; each group received both DBS and sham stimulation during two counterbalanced reinstatement sessions. Cocaine seeking behavior was reinstated with an intraperitoneal injection of cocaine (10 mg/kg). Prior to the priming injection of cocaine, the nucleus accumbens shell was electrically stimulated with either 0 µA or 150 µA delivered at 160 Hz throughout the two-hour test session under extinction conditions. Preliminary data suggest that, contrary to the attenuation of cocaine seeking in male rats, DBS of the nucleus accumbens shell does not attenuate and may even enhance cocaine seeking behavior in female rats. Ongoing behavioral experiments will further clarify the potential role of the estrous cycle in the effect of DBS on cocaine seeking in female rats. Our initial results indicate clear sex differences in the effects of DBS on cocaine priming-induced reinstatement of drug seeking in rats.

Title: Detection of deep brain activities via cortical magnetoencephalography of deep brain stimulation

Authors: *J. BORE;
Cleveland Clin. Fndn., Elyria, OH

Abstract: Deep brain stimulation (DBS) of the subthalamic nucleus (STN) is a well-established treatment approach for patients with Parkinson's disease (PD). The success of DBS is highly dependent on delivering the appropriate dose of stimulation at the best location within the target region. The STN is subdivided into different sub-territories (motor, associative, and limbic), each with different connections and specific functions. The most effective contacts to ameliorate PD symptoms segregate to the dorso-lateral, sensorimotor aspect of the STN, whereas current spread to the limbic and associative sub-segments may be linked to the affective and cognitive side-effects. Methods: In this study we stimulated different sub-regions of the STN and evaluated the

cortical effects using magnetoencephalography (MEG)-derived source imaging in PD patients. In particular, we performed source localization to characterize the neural sources of activity within the brain of a PD patient, and the effects of subthalamic nucleus (STN) DBS on these sources. Results: Our findings from DBS of distinct regions of STN support the segregated model of the basal ganglia (BG), which describes the anatomical separation of sensorimotor, limbic, and associative sub-regions. In particular, activation of the directional DBS contacts in the of sensorimotor area of the STN reveal sources in the motor cortex, while activation of the DBS contacts in the associative regions localized neural sources in the frontal brain areas. Conclusion: These findings show the capabilities of MEG to detect and differentiate cortical activities during DBS. Significance: DBS lead diameter and electrode recording configurations can affect the post-implant interpretation of oscillatory features. Such insights will be important for extrapolating results from intraoperative and externalized LFP recordings.

Title: Manipulation of local GABAergic interneurons disrupts prefrontal cortex dependent behaviors

Authors: *A. OROZCO, E. HU, S. DUBE, A. CABALLERO, K. Y. TSENG;
Anat. and Cell Biol., Univ. of Illinois At Chicago, Col. of Med., Chicago, IL

Abstract: A variety of complex functions such as working memory, learning, and emotional regulation are largely dependent on intact prefrontal cortex (PFC) function which is determined by a careful balance of excitation and inhibition. This balance is set by the activity of excitatory pyramidal neurons and inhibitory GABAergic interneurons. Previously published data indicate that post-synaptic blockade of GABA transmission in the PFC disrupts many PFC-dependent behaviors. However, within the PFC, it remains unclear how interactions between local GABAergic interneurons and pyramidal cells ultimately affect PFC function to elicit biologically relevant behaviors. To address this, GABAergic activity in the PFC was manipulated in adult rats using designer receptors exclusively activated by designer drugs (DREADD) to either stimulate (Gs) or inhibit (Gi) local GABAergic interneurons in the adult PFC. Assessment of PFC functionality was determined through a two-day trace fear conditioning and extinction paradigm,

in which the extinction phase is strongly dependent on PFC activity. The Gs and Gi DREADDs were activated by clozapine N-oxide (CNO) 20 minutes before the extinction phase to determine whether it is altered by excitation or inhibition of prefrontal GABAergic interneurons. Our results revealed that rats who received the Gs DREADD treatment had a decreased rate of extinction compared to rats who received Gi DREADD treatments. In other words, Gs DREADD treated rats displayed more extensive prefrontal deficits. These results suggest that in normal animals, increasing GABAergic activity is disruptive to PFC function, and thus could have potentially detrimental effects throughout other areas of the brain modulated by the PFC.

Title: Kappa Opioid receptor control of prefrontal cortex circuitry

Authors: *H. E. YARUR, S. M. CASELLO, H. WANG, S. MALDONADO, Q. WANG, H. A. TEJEDA;
Unit on Neuromodulation and Synaptic Integration, Natl. Inst. of Mental Hlth., Bethesda, MD

Abstract: The prefrontal cortex (PFC) is a key brain area implicated in the processing and regulation of fear memories, which are due to an exposure to a stressful stimulus. In stressful/aversive situations opioidergic neurotransmission is increased in a variety of limbic nuclei. Yet, the underlying neurobiological principles of opioidergic neurotransmission during aversive experiences are still unknown. Kappa opioid receptor (KOR) is component of the opioid system which controls pain, reward and addictive behaviors. This system is composed of three receptor subtypes, of which KOR activation by endogenous DYN or exogenous agonists induces negative effects in humans and animals. KORs are expressed in brain areas implicated in aversive learning in both humans and rodents, such as the PFC. DYN is highly expressed in the prefrontal cortex of humans and rodents. We hypothesize that PFC DYN/KOR system activity regulates processing of aversive information by modulating PFC circuitry. Unpublished work from our laboratory has demonstrated that DYN is expressed in both excitatory and a subset of

inhibitory neurons in the PFC. However, there is a critical knowledge gap in our understanding of the role of the endogenous DYN/KOR systems in regulating prefrontal cortical circuits. To this end we performed RNA scope, whole cell patch clamp recordings and tracing experiments in transgenic mice to disentangle the role of KOR in the control of PFC circuitry. Our results demonstrate that the PFC is innervated by several KOR-expressing inputs, including the basolateral amygdala (BLA) paraventricular nucleus of the thalamus (PVT), and claustrum. a. KOR expression in PFC neurons is primarily localized to excitatory neurons in deeper layers, with extremely sparse expression in inhibitory interneurons. KOR-expressing synapses within the PFC are inhibited by dynorphin via KORs. Importantly, KORs do not regulate all PFC afferents as ventral hippocampal inputs are insensitive to dynorphin regulation and do not express KORs. Our results suggest that KORs exert control over PFC circuitry by regulating afferent drive in a pathway-specific manner. This study increases our understanding of the neuronal mechanisms that underlay psychopathologies wherein processing of aversive experiences is dysregulated, like in anxiety and mood disorders, and provide a novel therapeutic for their treatment.

Title: Divergent roles of the medial PFC and the mediodorsal thalamus in alcohol-related behaviors

Authors: *J. A. RINKER[1], J. KNAPP[1], R. D. CANNADY[3], S. N. ROBERTS[1], H. C. BECKER[2], J. J. WOODWARD[1], P. J. MULHOLLAND[1];
[1]Neurosci., [2]Psychiatry, Med. Univ. of South Carolina, Charleston, SC; [3]Biol., NC A&T State Univ., Greensboro, NC

Abstract: Alcohol use disorder (AUD) is a chronic and relapsing condition characterized by uncontrolled, excessive alcohol consumption. Adaptations in medial prefrontal cortical (mPFC) networks produced by chronic alcohol exposure can enhance incentive salience of cues associated with alcohol and diminish engagement in behaviors related to alternative rewards.

There is a substantial gap in our understanding of the mechanisms and neurocircuitry underlying this cortically driven inflexible behavior. The mediodorsal thalamus (MD) is a higher-order thalamic nucleus that is reciprocally connected to the mPFC, and acts as hub for integration of cortical and subcortical signaling. The MD plays a critical role in adaptive goal-directed choice behavior and higher-order cognitive flexibility, making it perfectly situated to play a central role in mediating cortical deficits in AUD, and yet has gone largely unexplored in the context of alcohol-related behaviors. These experiments used a combination of alcohol drinking and dependence models coupled with ex vivo slice electrophysiology, immunolabeling, and in vivo calcium imaging to study activated cortical and thalamic neurons. As well, use of the newly developed Targeted Recombination in Active Populations (TRAP) mouse line (FosTRAP) that allows tamoxifen-inducible Cre expression of tdTomato in *Fos*-expressing cells in a temporally controlled manner with slice electrophysiology allowed identification of functional adaptations in alcohol-activated neuronal ensembles. Chronic intermittent ethanol (CIE) induced different patterns of cFos activation during acute withdrawal in the mPFC and the MD, as well as different CIE-induced changes in evoked-firing. While both regions showed increases in tdTomato+ cells in the mPFC, as well as the MD thalamus, patch-clamp electrophysiological recordings demonstrated that tdTomato+ in mPFC layer II/III, which receives dense innervation from the MD, fired more evoked action potentials than adjacent non-activated neurons. And finally, the mPFC and the MD show divergent patterns of calcium-dependent neural activity during active and voluntary alcohol consumption. Findings from these studies using cutting-edge technology in mice identified stable and specific subsets of neural populations in cortical and thalamic circuits that are activated by alcohol drinking and dependence. The functional assessment revealed neural mechanisms and functional signatures underlying ethanol-induced plasticity that may drive heavy drinking and loss of reward-based flexible behaviors in individuals with AUD.
